JA, Breuer J, Edwards S, Kellam P, Pillay D, Towers GJ.	Infection and Immunity, University College London, London, United Kingdom. e.gray@ucl.ac.uk	or related retroviruses in a London HIV-1-positive patient cohort.	23;6(3):e18096.	gammaretrovirus, XMRV (Xenotropic murine leukaemia virus-related virus), in chronic fatigue syndrome and prostate cancer, though whether as causative agent or opportunistic infection is unclear. It has also been suggested that the virus can be found circulating amongst the general population. The discovery has been controversial, with conflicting results from attempts to reproduce the original studies. METHODOLOGY/PRINCIPAL FINDINGS: We extracted peripheral blood DNA from a cohort of 540 HIV-1-positive patients (approximately 20% of whom have never been on anti-retroviral treatment) and determined the presence of XMRV and related viruses using TaqMan PCR. While we were able to amplify as few as 5 copies of positive control DNA, we did not find any positive samples in the patient cohort. CONCLUSIONS/SIGNIFICANCE: In view of these negative findings in this highly susceptible group, we conclude that it is unlikely that XMRV or related viruses are circulating at a significant level, if at all, in HIV-1-positive patients in London or in the general population.
Güthlin C, Anton A, Kruse J, Walach H.	1Johann Wolfgang Goethe University, Frankfurt/Main, Germany.	Subjective concepts of chronically ill patients using distant healing.	Qual Health Res. 2012 Mar;22(3):320-31. Epub 2011 Sep 14.	Distant healing procedures consist of benevolent intentions, often taking the form of prayers for a patient. Despite inconclusive evidence regarding distant healing, prayers are a widespread health-related technique. We studied subjective concepts of distant healing in 17 patients suffering from chronic fatigue syndrome and multiple chemical sensitivity who were given distant healing during a randomized controlled trial. We applied reconstructive interview analysis when analyzing the results. The overall theme was the tension between mainstream medicine and the immaterial healing procedure. Several components highlighted this tension: (a) patterns of legitimizing the use of distant healing, (b) distant healing and the social setting, (c) integrating distant healing into their belief system, and (d) reconstruction of effects by means of hindsight. The interviews showed that patients felt the need to legitimize having tried distant healing. They had to bear the full ambiguity of biomedicine being in competition with distant healing, though also experiencing distant healing as giving support.
Haba-Rubio J, de Seigneux S, Heinzer R.	Centre d'investigation et de recherche sur le sommeil, CHU Vaudois (CHUV), BH 06-204, 1011 Lausanne, Suisse.	[Sleep disorders in chronic renal failure.] [Article in French]	Nephrol Ther. 2011 Sep 29. [Epub ahead of print]	Sleep disorders are common in patients with chronic renal failure (CRF), especially in those receiving hemodialysis. Sleep-related complaints in this patient population may include insomnia, daytime sleepiness or fatigue and depression. In addition to causing impairment of daytime function and quality of life, sleep apnea may also increase the cardiovascular morbidity and mortality, especially in dialysis patients. In CRF patients, an increased prevalence of sleep apnea, restless legs syndrome and periodic limb movement during sleep has been reported. Epidemiology, pathophysiology and treatment of sleep disorders in CRF and dialysis patients are still unclear and require further research. Copyright © 2011 Association Société de néphrologie. Haldorsen K, Bjelland I, Bolstad	Broegelmann Research	A five-year prospective study of	Arthritis Res Ther. 2011 Oct	ABSTRACT: INTRODUCTION: Fatigue is prevalent in primary Sjögren's syndrome (pSS), and contributes to the considerably reduced health related quality of life in this

Al, Jonsson R, Brun JG.	Laboratory, The Gade Institute, Laboratory Bldg,, Haukeland University Hospital, N-5021 Bergen, Norway. karstein.haldorsen@uib.no.	fatigue in primary Sjögren's syndrome.	13;13(5):R167. [Epub ahead of print]	disease. The symptom is included in proposed disease activity and outcome measures for pSS. Several studies indicate that there is an inflammatory component of fatigue in pSS and other chronic inflammatory rheumatic diseases. The purpose of this study was to investigate fatigue change in pSS in a longitudinal study, and explore whether any clinical or laboratory variables at baseline, including serum cytokines, were associated with a change in fatigue scores over time. METHODS: A clinical and laboratory investigation of 141 patients fulfilling the American-European consensus criteria of pSS was undertaken in the period May 2004 to April 2005. Median time since diagnosis was 5.5 years. Examinations included the fatigue questionnaires: fatigue severity scale (FSS), fatigue visual analogue scale (VAS), functional assessment of chronic illness therapy - fatigue (FACIT-F) and medical outcome study short form-36 (SF-36) vitality, which were repeated in a follow-up investigation in January and February 2010. RESULTS: A total of 122 patients (87%) responded at both time-points. Thirty-five percent of patients experienced a clinically significant FSS increase. On the group level, fatigue measures did not change except that there was a slight deterioration in SF-36 vitality score. High serum anti-Sjögren's syndrome A antigen (anti-SSA) showed weak associations with high baseline fatigue, and patients with increasing fatigue had lower baseline unstimulated whole salivary volume. Weak associations between increasing fatigue and serum immunoglobulin G (IgG), and the pro-inflammatory cytokine interleukin-17 (IL-17), were observed. Baseline sicca symptoms correlated with higher fatigue both at baseline and with increasing fatigue over time. Linear regression analysis did not identify any predictive ability of clinical or laboratory measures on fatigue change over time. CONCLUSIONS: Fatigue remained mainly unchanged over time. Using multivariate models did not reveal any clinical or laboratory predictors of fatigue change over time.
Hamaguchi M, Kawahito Y, Takeda N, Kato T, Kojima T.	Inflammation and Immunology, Graduate School of Medical Science, Kyoto Prefectural University of Medicine, 465, Kajii-cho, Kawaramachi-Hirokoji, Kamigyo-ku, Kyoto 602-8566, Japan. seele@koto.kpu-m.ac.jp	Characteristics of chronic fatigue syndrome in a Japanese community population : chronic fatigue syndrome in Japan.	Clin Rheumatol. 2011 Jul;30(7):895-906. Epub 2011 Feb 8.	This study seeks to estimate the prevalence of chronic fatigue syndrome (CFS) and assess the characteristics of CFS in a community population in Japan using laboratory tests and questionnaires for lifestyle, fatigue states, and depression states. The design of this study is a cross-sectional observational study. The setting of this study is a medical health checkup program in a general hospital. This study was conducted with 1,430 Japanese (867 men and 563 women), 20 to 78 years of age. We classified participants who complained of fatigue according to the case definition of CFS proposed by the Centers for Disease Control and Prevention in the USA in 1994. Alcohol, caffeine, catechin and total polyphenol consumption, smoking status, sleep duration, and physical activity were evaluated using questionnaires. The prevalence of CFS was 1.0% (95% CI 0.5-1.6%) of a community population in Japan. Although various lifestyle factors of the participants with CFS were similar to those without chronic fatigue, average sleep duration was significantly shorter among the participants with CFS (5.5 ± 0.8 h) compared to those without chronic fatigue (6.3 ± 0.9 h, $P < 0.001$). Proportion at subjects having average sleep duration of less than 6 h was 64.3%

				among the participants with CFS in contrast to only 15.0% in those without chronic fatigue (P < 0.001). Among the eight case-defining symptoms, "Unrefreshing sleep" had high sensitivity and high specificity for screening CFS in Japanese population (92.9% and 87.8%, respectively). The average sleep duration was notably shorter in Japanese suffering from CFS. Further longitudinal study is needed to evaluate the possibility of extreme short sleep duration as a major cause of CFS in Japan.
Hambrook D, Oldershaw A, Rimes K, Schmidt U, Tchanturia K, Treasure J, Richards S, Chalder T.	Division of Psychological Medicine and Psychiatry, Section of Eating Disorders, King's College London, Institute of Psychiatry, UK.	Emotional expression, self-silencing, and distress tolerance in anorexia nervosa and chronic fatigue syndrome.	Br J Clin Psychol. 2011 Sep;50(3):310-25. doi: 10.1348/014466510X519215. Epub 2011 Mar 8.	OBJECTIVES. Difficulties in processing emotional states are implicated in the aetiology and maintenance of diverse health conditions, including anorexia nervosa (AN) and chronic fatigue syndrome (CFS). This study sought to explore distress tolerance, self-silencing, and beliefs regarding the experience and expression of emotions in individuals diagnosed with AN and CFS. These conditions were chosen for this study because their clinical presentation is characterized by physical symptoms, yet cognitive behavioural models suggest that emotional processing difficulties contribute to the aetiology and maintenance of both. DESIGN. A between-subjects cross-sectional design was employed. METHODS. Forty people with AN, 45 with CFS, and 48 healthy controls (HCs) completed the Distress Tolerance Scale (DTS), Silencing the Self Scale (STSS), Beliefs about Emotions Scale (BES), and measures of clinical symptomatology. RESULTS. Initial group comparisons found that both AN and CFS participants scored higher than HCs on a subscale measuring difficulties in distress tolerance. AN and CFS participants were also more likely to judge themselves by external standards, endorse statements reflecting a tendency to put the needs of others before themselves, and present an outwardly socially compliant image of themselves whilst feeling hostile within. Relative to HCs, AN participants reported more maladaptive beliefs regarding the experience of having negative thoughts and feelings and revealing these emotions to others, with CFS participants showing a non-significant trend in the same direction. After controlling for differences in age, anxiety, and depression the only significant difference to remain was that observed for the STSS care as self-sacrifice subscale. More maladaptive beliefs about the experience and expression of emotions were associated with greater degree of eating disorder symptomatology in the AN group. CONCLUSIONS. Differences in emotional processing are present in AN and CFS compared to HCs, with some disorder-specific variation, and may be associated with greater clinical symptomatology. These findings support current explanatory models of both AN and CFS, and suggest that emotional processing should be addressed in the assessment and treatment of individuals with these illnesses. ©2010 The British Psychological Society.
Hareide L, Finset A, Wyller VB.	Akershus Universitetssykehus, Seksjon Klosteret, Alexander	Chronic fatigue syndrome: a qualitative investigation of young patient's	Disabil Rehabil. 2011;33(23-24):2255-63. Epub 2011 Apr 7.	PURPOSE: The aim of this pilot study was to explore illness beliefs and coping strategies among adolescent patients with chronic fatigue syndrome/myalgic encephalomyelitis (CFS/ME), applying a qualitative methodology. Recent studies have explored the illness beliefs and coping strategies of adult patients with CFS/ME as possible contributing factors to the disease aetiology. These studies have mainly used

	Kiellands Gate 11, 2000 Lillestrøm, Lillestrøm, Norway. livehareide@hotmail.com	beliefs and coping strategies.		quantitative methods, finding that patients often explain their illness as being due to physical causes, deny psychological causes and make use of passive and avoidant coping strategies. METHOD: Semi-structured, in-depth interviews were conducted with nine adolescent patients with CFS/ME, thematic analysis was adapted to the material and the results were interpreted in light of theories of attribution and coping. RESULTS: The qualitative method allowed for more complex and nuanced accounts of illness experience. The findings showed that the adolescents differ from what has previously been reported, applying more varied and flexible illness attributions and coping mechanisms than expected. CONCLUSIONS: The heterogeneity suggested in the results has implications. We suggest three perspectives should be taken into account, both for further research and in clinical practice: (1) individual differences; (2) a developmental perspective and (3) interactive relational focus.

Haywood KL, Staniszewska S, Chapman S.	Royal College of Nursing Research Institute, School of Health and Social Studies, University of Warwick, Coventry CV4 7AL, UK. k.l.haywood@warwick.ac.uk	Quality and acceptability of patient-reported outcome measures used in chronic fatigue syndrome/myalgic encephalomyelitis (CFS/ME): a systematic review.	Qual Life Res. 2012 Feb;21(1):35-52. Epub 2011 May 18.	PURPOSE: To review the quality and acceptability of condition-specific, domain-specific and generic multi-item patient-reported outcome measures (PROMs) used in the assessment of adults with chronic fatigue syndrome/myalgic encephalomyelitis (CFS/ME). METHODS: Systematic literature searches were made to identify PROMs. Quality and acceptability was assessed against an appraisal framework, which captured evidence of both the thoroughness and results of evaluations: evidence of measurement (reliability, validity, responsiveness, interpretability, data quality/precision) and practical properties (feasibility, patient acceptability), and the extent of active patient involvement was sought. RESULTS: A total of 11 CFS/ME-specific, 55 domain-specific and 11 generic measures were reviewed. With the exception of the generic SF-36, all measures had mostly limited evidence of measurement and/or practical properties. Patient involvement was poorly reported and often cursory. CONCLUSIONS: The quality and acceptability of reviewed PROMs is limited, and recommendations for patient-reported assessment are difficult.

				Significant methodological and quality issues in PROM development/evaluation were identified by the appraisal framework, which must be addressed in future research. Clear discrepancies exist between what is measured in research and how patients define their experience of CFS/ME. Future PROM development/evaluation must seek to involve patients more collaboratively to measure outcomes of importance using relevant and credible methods of assessment.
Heins MJ, Knoop H, Lobbestael J, Bleijenberg G.	Expert Centre for Chronic Fatigue, Radboud University Nijmegen Medical Centre, The Netherlands. m.heins@nkcv.umcn.nl	Childhood maltreatment and the response to cognitive behavior therapy for chronic fatigue syndrome.	J Psychosom Res. 2011 Dec;71(6):404-10. Epub 2011 Jun 30.	OBJECTIVE: To examine the relationship between a history of childhood maltreatment and the treatment response to cognitive behavior therapy for chronic fatigue syndrome (CFS). METHODS: A cohort study in a tertiary care clinic with a referred sample of 216 adult patients meeting the Centers for Disease Control and Prevention criteria for CFS, and starting cognitive behavior therapy. Main outcome measures changes between pre- and post therapy in fatigue (Checklist Individual Strength fatigue subscale), disabilities (Sickness Impact Profile total score), physical functioning (short form 36 health survey subscale) and psychological distress (Symptom checklist 90 total score). RESULTS: At baseline, patients with a history of childhood maltreatment had significantly more limitations and a higher level of psychological distress, but were not more severely fatigued. Change scores on the outcome measures after cognitive behavior therapy did not differ significantly between patients with or without a history of childhood maltreatment, or between the different types of childhood maltreatment. However, patients with a history of childhood maltreatment still experienced more limitations and a higher level of psychological distress after CBT. CONCLUSIONS: A history of childhood maltreatment was not related to the treatment response of cognitive behavior therapy for CFS. In patients with a history of childhood maltreatment CFS symptoms can be treated with CBT just as well as those without. 2011 Elsevier Inc. All rights reserved.
Hlavaty LE, Brown MM, Jason LA.	Center for Community Research, DePaul University, Chicago, IL 60614, USA. leahlavaty@gmail.com	The effect of homework compliance on treatment outcomes for participants with myalgic encephalomyelitis/chronic fatigue syndrome.	Rehabil Psychol. 2011 Aug;56(3):212-8.	PURPOSE: This study examined the relationship between level of treatment engagement through completion of homework on treatment outcomes within nonpharmacological interventions for participants with ME/CFS. METHOD: A sample of 82 participants with ME/CFS was randomly assigned to one of four nonpharmacological interventions. Each intervention involved 13 sessions over the course of 6 months. Change scores were computed for self-report measures taken at baseline and 12-month follow-up. Homework compliance was calculated as the percentage of completed assignments across the total number of sessions and grouped into three categories: minimum (0-25%), moderate (25.1-75%), or maximum (75.1-100%). RESULTS: Findings revealed that after controlling for treatment condition, those who completed a maximum amount of homework had greater improvement on a number of self-report outcome measures involving role, social, and mental health functioning. There were no differential improvements in physical and fatigue functioning based on level of homework compliance. IMPLICATIONS: Findings from this study suggest homework compliance can have a positive influence on some

				aspects of physical, social, and mental health functioning in participants with ME/CFS. It should be emphasized that these interventions do not cure this illness. The lack of significant changes in physical functioning and fatigue levels suggests a need for more multidisciplinary treatment approaches that can elicit improvement in these areas.
Hoeck AD, Pall ML.	ad.hoeck@t-online.de	Will vitamin D supplementation ameliorate diseases characterized by chronic inflammation and fatigue?	Med Hypotheses. 2011 Feb;76(2):208-13. Epub 2010 Oct 25.	Chronic NF-κB activation has been supposed as a key event in chronic fatigue syndrome (CFS) and many other better-defined pro-inflammatory diseases. Knowledge about the impact of deficiency vitamin D on chronic NF-κB activation could open a new disease approach. Whereas NF-κB activation leads at first to a pro-inflammatory immune response, later on a vitamin D-dependent anti-inflammatory response ensues. Binding of the active vitamin D metabolite 1,25(OH)(2)D(3) to vitamin D receptor (VDR) yields a transcription factor which represses NF-κB activation, and additionally modulates and down-regulates adaptive, but enhances innate immune responses, and improves redox balance, thus counterbalancing inflammation on multiple levels. However, this built-in late counterbalance against inflammation works only when stores of calcium and 25(OH)D(3) are abundant. Therefore a connection between lowered vitamin D-metabolism and persistent NF-κB activation, augmented nitrosative-oxidative stress, redox imbalance, chronic inflammation, and concomitant fatigue can be postulated. In order to confirm this hypothesis, randomized controlled clinical studies about the clinical effects of supplementation of calcium and vitamin D(3) would be necessary in diseases characterized by persistent NF-κB activation and chronic inflammation and fatigue. Hohn O, Bannert N.	Center for HIV and Retrovirology, Robert Koch Institute, Berlin, Germany. HohnO@rki.de	Origin of XMRV and its demise as a human pathogen associated with chronic fatigue syndrome.	Viruses. 2011 Aug;3(8):1312-9. Epub 2011 Jul 27.	Retroviruses are well known pathogens of mammals, birds and fish. Their potential to induce cancer in chickens was already described almost 100 years ago and murine retroviruses have been a subject of study for 50 years. The first human retroviruses, HTLV and HIV, were discovered more than 30 years ago, surprising researchers and physicians by the profound differences in the diseases they cause. HTLV-1 is able to induce, after decades of infection, lymphomas/leukemia or neuroimmune disorders whereas untreated HIV infection leads almost inevitably to AIDS. The recently described XMRV (xenotropic murine leukemia virus-related virus) appeared to possess many of the features known for HTLV and was regarded by some to be the third human retrovirus. However, recent publications by Knox et al. and Paprotka et al. have shed new light on this gammaretrovirus. Knox and colleagues clearly demonstrate that XMRV is absent in patients belonging to a chronic fatigue syndrome cohort who had previously been reported to be XMRV-positive. This supports the growing suspicion that laboratory contamination was responsible for the postulated link between XMRV and the disease. Furthermore, Paprotka et al's identification of XMRV's origin and the phylogenetic analysis of known XMRV sequences are further nails in the coffin to the notion that XMRV is a clinically relevant infectious human retrovirus.

Holgate ST, Komaroff AL, Mangan D, Wessely S.	University of Southampton, Infection, Inflammation and Immunity Division, School of Medicine, Southampton General Hospital, Tremona Road, Southampton, SO16 6YD, UK. sth@soton.ac.uk	Chronic fatigue syndrome: understanding a complex illness.	Nat Rev Neurosci. 2011 Jul 27;12(9):539-44. doi: 10.1038/nrn3087.	Chronic fatigue syndrome (CFS) is a debilitating illness that affects many people. It has been marred by controversy, from initial scepticism in the medical community about the existence of the condition itself to continuing disagreements--mainly between some patient advocacy groups on one side, and researchers and physicians on the other--about the name for the illness, its aetiology, its pathophysiology and the effectiveness of the few currently available treatments. The role of the CNS in the disease is central in many of these discussions. Nature Reviews Neuroscience asked four scientists involved in CFS research about their views on the condition, its causes and the future of research aimed at improving our understanding of this chronic illness.
Hollingsworth KG, Hodgson T, Macgowan GA, Blamire AM, Newton JL.	From Newcastle Magnetic Resonance Centre, Institute of Cellular Medicine, Newcastle University, NE4 5PL Department of Cardiology, Freeman Hospital, Newcastle upon Tyne, NE7 7DN and Institute of Genetic Medicine, Newcastle University, NE1 3BZ Institute for Ageing and Health, Newcastle University, NE4 5PL; Newcastle upon Tyne, UK.	Impaired cardiac function in chronic fatigue syndrome measured using magnetic resonance cardiac tagging.	J Intern Med. 2011 Jul 27. doi: 10.1111/j.1365-2796.2011.02429.x. [Epub ahead of print]	Abstract. Hollingsworth KG, Hodgson T, MacGowan GA, Blamire AM, Newton JL (Institute of Cellular Medicine, Campus for Ageing and Vitality; Institute of Genetic Medicine; and Institute for Ageing and Health, Campus for Ageing and Vitality; Newcastle University, Newcastle, UK). Impaired cardiac function in chronic fatigue syndrome measured using magnetic resonance cardiac tagging. J Intern Med 2011; 10.1111/j.1365-2796.2011.02429.x. Objectives. Impaired cardiac function has been confirmed in patients with chronic fatigue syndrome (CFS). Magnetic resonance cardiac tagging is a novel technique that assesses myocardial wall function in vivo. We hypothesized that patients with CFS may have impaired development and release of myocardial torsion and strain. Methods. Cardiac morphology and function were assessed using magnetic resonance imaging and cardiac tagging methodology in 12 CFS patients (Fukuda) and 10 matched controls. Results. Compared to controls, the CFS group had substantially reduced left ventricular mass (reduced by 23%), end-diastolic volume (30%), stroke volume (29%) and cardiac output (25%). Residual torsion at 150% of the end-systolic time was found to be significantly higher in the patients with CFS (5.3 ± 1.6°) compared to the control group (1.7 ± 0.7°, P = 0.0001). End-diastolic volume index correlated negatively with both torsion-to-endocardial-strain ratio (TSR) (r = -0.65, P = 0.02) and the residual torsion at 150% end-systolic time (r = -0.76, P = 0.004), so decreased end-diastolic volume is associated with raised TSR and torsion persisting longer into diastole. Reduced end-diastolic volume index also correlated significantly with increased radial thickening (r = -0.65, P = 0.03) and impaired diastolic function represented by the ratio of early to late ventricular filling velocity (E/A ratio, r = 0.71, P = 0.009) and early filling percentage (r = 0.73, P = 0.008). Conclusion. Patients with CFS have markedly reduced cardiac mass and blood pool volumes, particularly end-diastolic volume: this results in significant impairments in stroke volume and cardiac output compared to controls. The CFS group appeared to have a delay in the release of

				torsion. © 2011 The Association for the Publication of the Journal of Internal Medicine.
Houghton CA, Steels EL, Fassett RG, Coombes JS.	School of Human Movement Studies, University of Queensland, St Lucia, Qld 4067, Australia. christine.houghton@uqconnect.edu.au	Effects of a gliadin-combined plant superoxide dismutase extract on self-perceived fatigue in women aged 50-65 years.	Phytomedicine. 2011 Apr 15;18(6):521-6. Epub 2010 Nov 1.	Fatigue syndromes exist on a continuum of severity from mild and transient to the disabling chronic fatigue syndrome, with oxidative stress linked to its pathogenesis. A thermolabile gliadin-combined plant superoxide dismutase (SOD) extract has shown potential in clinical trials as a therapeutic antioxidant. This study investigated the effects of 12 weeks of 500 mg/day of a SOD/gliadin supplement on fatigue. Thirty-eight women aged 50-65 years with self-perceived fatigue entered this randomized, double-blind, placebo-controlled trial. The primary outcome measure was general fatigue determined by the Multidimensional Fatigue Inventory (MFI). Secondary outcome measures included other measures of fatigue from the MFI and blood measures of oxidative stress, antioxidant status and hormones. There were no significant (P>0.05) differences between, or within groups, for decreases in general fatigue (active=1.6%, placebo=4.1%). There were no within or between group differences (P>0.05) in other measures of fatigue (physical fatigue, reduced activity, reduced motivation, mental fatigue and total fatigue score). In regard to the biochemical measures, there were non-significant (P>0.05) differences in increases in plasma SOD activity (active=7.1%, placebo=12.2%), plasma GPx activity (active=2.4%, placebo=0.7%), red blood cell GPx activity (active=9.8%, placebo=4.4%). Markers of oxidative stress were decreased but there were no differences (P>0.05) within or between groups; malondialdehyde (active=4.1%, placebo=1.6%), F-2 isoprostanes (active=14.7%, placebo=22.4%). There was a trend (P=0.08) for a decrease in cortisol in the active group (24.6%), however this was not significantly different from the decrease in the placebo participants (4.1%). DHEA differences were not significant (P<0.05) and declined 1.3% in the active group and 14.4% in the placebo group. In summary, the thermolabile SOD/gliadin supplement had no significant effect on self-perceived fatigue, antioxidants, oxidative stress or hormones in women aged 50-65 years. Hsu ES.	Department of Anesthesiology, David Geffen School of Medicine at UCLA, Los Angeles, CA, USA. ehsu@mednet.ucla.edu	Acute and chronic pain management in fibromyalgia: updates on pharmacotherapy.	Am J Ther. 2011 Nov;18(6):487-509.	Fibromyalgia (FM) is a mysterious pain syndrome with progressive and widespread pain, explicit areas of tender points, stiffness, sleep disturbance, fatigue, and psychological distress without any obvious disease. FM is commonly perceived as a condition of central pain and sensory augmentation. There are documented functional abnormalities in pain and sensory processing in FM. Central sensitization and lack of descending analgesic activity are the 2 leading mechanisms that have been demonstrated by advance in both basic and clinical research. The pathogenesis of FM may also be attributed to the genetic polymorphisms involving serotoninergic, dopaminergic, and catecholaminergic systems. Any psychiatric disorders and psychosocial influences in FM may also affect the severity of pain. The various external stimuli or trigger such as infection, trauma, and stress may all contribute to proceed to presentation of FM. The recent launches of 3 US Food and Drug

				Administration-approved pharmacotherapy for FM namely pregabalin, duloxetine, and milnacipran have certainly raised the profile of optimal chronic pain management. However, appropriate evaluation and efficacious management of acute pain has not been as well publicized as chronic pain in FM. Acute pain or flare up caused by any trauma or surgery certainly may present a real challenge for patients with FM and their health care providers. Pre-emptive analgesia and pro-active treatment may offer the momentum for acute pain control based on model of central sensitization and pain in FM. This review article on FM appraises the modern practice of multimodal therapy focus on both acute and chronic pain management. Meanwhile, the evolving nonpharmacological approach is summarized and stressed as an essential component of integrated care in FM.
Huang Y, Liu YH.	Department of Orthodontics, School of Stomatology, Tongji University, Shanghai, China.	Effects of phytoestrogens on genioglossus contractile properties in ovariectomized rats exposed to chronic intermittent hypoxia may be independent of their estrogenicity.	Eur J Oral Sci. 2011 Apr;119(2):128-35. doi: 10.1111/j.1600-0722.2011.00815.x.	Chronic intermittent hypoxia (CIH) is a frequent feature of obstructive sleep apnea/hypopnea syndrome (OSAHS), and it may alter upper airway muscle endurance. We have previously reported the positive effects of estrogen on genioglossus fatigue resistance in rats. Our present study was designed to evaluate the effects of two phytoestrogens - genistein and coumestrol - on genioglossus contractile function and estrogen receptor (ER) expression in female rats exposed to CIH. Eight-wk-old female rats were ovariectomized and exposed to CIH for 5 wk. Genistein and coumestrol, respectively, were administered by intraperitoneal injection, at a dose of 2.5 mg kg(-1) d(-1), during the last 4 d of exposure to CIH. The contractile properties of the genioglossus were measured. Real-time RT-PCR and western blotting were performed to determine the expression of ERs in the genioglossus. Phytoestrogens were found to significantly increase genioglossus fatigue resistance, the effect of genistein being more powerful than that of coumestrol. However, higher levels of ER mRNA and protein were detected in the coumestrol group than in the genistein group. We conclude that phytoestrogens, especially genistein, could improve the endurance of the genioglossus muscle in ovariectomized rats exposed to CIH, and this effect is, in part, not related to its estrogenic action. © 2011 Eur J Oral Sci.
Hunter M.		Chronic fatigue syndrome could be costing UK economy pound 100m a year, study says.	BMJ. 2011 Sep 19;343:d5905. doi: 10.1136/bmj.d5905.	
Hurley BF, Hanson ED, Sheaff AK.	Department of Kinesiology, School of Public Health, University of Maryland, College Park,	Strength training as a countermeasure to aging muscle and chronic disease.	Sports Med. 2011 Apr 1;41(4):289-306. doi: 10.2165/11585920-000000000-00000.	Strength training (ST) has long been considered a promising intervention for reversing the loss of muscle function and the deterioration of muscle structure associated with advanced age but, until recently, the evidence was insufficient to support its role in the prevention or treatment of disease. In recent decades, there has been a long list of quality reviews examining the effects of ST on functional abilities and a few on risk factors for specific diseases, but none have provided a comprehensive assessment of

	Maryland 20742, USA. benhur@umd.edu			ST as an intervention for a broad range of diseases. This review provides an overview of research addressing the effectiveness of ST as an intervention for the prevention or treatment of the adverse consequences of (i) aging muscle; (ii) the metabolic syndrome (MetS) and its components, i.e. insulin resistance, abdominal obesity, hyperlipidaemia and hypertension; (iii) fibromyalgia; (iv) rheumatoid arthritis; and (v) Alzheimer's disease. Collectively, these studies indicate that ST may serve as an effective countermeasure to some of the adverse consequences of the MetS, fibromyalgia and rheumatoid arthritis. Evidence in support of the hypothesis that ST reduces insulin resistance or improves insulin action comes both from indirect biomarkers, such as glycosylated haemoglobin (HbA(1c)), and insulin responses to oral glucose tolerance tests, as well as from more direct procedures such as hyperglycaemic and hyperinsulinaemic-euglycaemic clamp techniques. The evidence for the use of ST as a countermeasure of abdominal obesity is less convincing. Although some reports show statistically significant reductions in visceral fat, it is unclear if the magnitude of these changes are physiologically meaningful and if they are independent of dietary influences. The efficacy of ST as an intervention for reducing dyslipidaemia is at best inconsistent, particularly when compared with other pharmacological and non-pharmacological interventions, such as aerobic exercise training. However, there is more consistent evidence for the effectiveness of ST in reducing triglyceride levels. This finding could have clinical significance, given that elevated triglyceride is one of the five criterion measures for the diagnosis of the MetS. Small to moderate reductions in resting and exercise blood pressure have been reported with some indication that this effect may be genotype dependent. ST improves or reverses some of the adverse effects of fibromyalgia and rheumatoid arthritis, particularly pain, inflammation, muscle weakness and fatigue. Investigations are needed to determine how these effects compare with those elicited from aerobic exercise training and/or standard treatments. There is no evidence that ST can reverse any of the major biological or behavioural outcomes of Alzheimer's disease, but there is evidence that the prevalence of this disease is inversely associated with muscle mass and strength. Some indicators of cognitive function may also improve with ST. Thus, ST is an effective countermeasure for some of the adverse effects experienced by patients of many chronic diseases, as discussed in this review.
Hurum H, Sulheim D, Thaulow E, Wyller VB.	Oslo University Hospital, Norway.	Elevated nocturnal blood pressure and heart rate in adolescent chronic fatigue syndrome.	Acta Paediatr. 2011 Feb;100(2):289-92. doi: 10.1111/j.1651-2227.2010.02073.x. Epub 2010 Nov 17.	AIM: To compare ambulatory recordings of heart rate (HR) and blood pressure in adolescents with chronic fatigue syndrome (CFS) and healthy controls. We hypothesized both HR and blood pressure to be elevated among CFS patients. METHODS: Forty-four CFS patients aged 12-18 years were recruited from our paediatric outpatient clinic. The controls were 52 healthy adolescents having similar distribution of age and gender. 24-h ambulatory blood pressure and HR were recorded using a validated, portable oscillometric device. RESULTS: At night (sleep),

				HR, mean arterial blood pressure and diastolic blood pressure were significantly higher in CFS patients as compared with controls ($p < 0.01$). During daytime, HR was significantly higher among CFS patients ($p < 0.05$), whereas blood pressures were equal among the two groups. CONCLUSIONS: The findings support previous experimental evidence of sympathetic predominance of cardiovascular control in adolescent CFS patients. Also, the findings prompt increased focus on cardiovascular risk assessment and suggest a possible target for therapeutic intervention. © 2010 The Author(s)/Acta Paediatrica © 2010 Foundation Acta Paediatrica.
Hussain SA, Al-Khalifa II, Jasim NA, Gorial FI.	Department of Pharmacology and Toxicology, College of Pharmacy, University of Baghdad, Baghdad, Iraq. saad_alzaidi@yahoo.com	Adjuvant use of melatonin for treatment of fibromyalgia.	J Pineal Res. 2011 Apr;50(3):267-71. doi: 10.1111/j.1600-079X.2010.00836.x. Epub 2010 Dec 16.	Fibromyalgia syndrome (FMS) is a chronic musculoskeletal disorder characterized by generalized muscular pain accompanied by fatigue and tenderness at specific anatomic sites called tender points. Although preliminary evidence indicates that melatonin may be effective in treating the pain associated with FMS, no definitive evidence supports this claim. This study was designed to evaluate the significance of using different doses of melatonin, alone or in combination with fluoxetine for the management of FMS. A double-blind, placebo-controlled clinical study was performed on 101 patients (95 women and 6 men) who fulfilled the criteria of the American College of Rheumatology (ACR) of FMS. The patients were randomized into four groups: group A (24 patients) treated with 20 mg/day fluoxetine alone; group B (27 patients) treated with melatonin 5 mg alone; group C (27 patients) treated with 20 mg fluoxetine plus 3 mg melatonin; group D (23 patients) treated with 20 mg fluoxetine plus 5 mg melatonin. Both drugs were given once daily in the morning and night time, respectively, for 8 wk. Each patient was clinically evaluated through direct interview with the patients using the Fibromyalgia Impact Questionnaire (FIQ) at zero time and after 8 wk. Using melatonin (3 mg or 5 mg/day) in combination with 20 mg/day fluoxetine resulted in significant reduction in both total and different components of FIQ score compared to the pretreatment values. In conclusion, administration of melatonin, alone or in a combination with fluoxetine, was effective in the treatment of patients with FMS. © 2010 The Authors. Iqbal R, Mughal MS, Arshad N, Arshad M.	Zoology Department, G. C. University, Lahore, 54000, Pakistan.	Pathophysiology and antioxidant status of patients with fibromyalgia.	Rheumatol Int. 2011 Feb;31(2):149-52. Epub 2010 Apr 8.	Fibromyalgia syndrome (FMS) is characterized by systemic pain of unknown etiology and is often accompanied by various psychological symptoms. Research on different parameters in fibromyalgia (FM) indicates that multifactors are involved in its pathophysiology; such as genetic factors, substance P, serotonin, hypothalamic pituitary adrenal axis (HPA), muscles metabolic dysfunction, reactive oxygen species (ROS) and reactive nitrogen species (RNS). Oxidative stress has also been implicated in the pathophysiology of FM; therefore, supplementation with antioxidants may be important in modulation of the effects of ROS in patients with FM.
Israeli E, Pardo A.	The Chaim Zabludowicz Center for	The sick building syndrome as a part of the autoimmune	Mod Rheumatol. 2011 Jun;21(3):235-9. Epub 2010 Dec 29.	Sick building syndrome (SBS) is a term coined for a set of clinically recognizable symptoms and ailments without a clear cause reported by occupants of a building. In the 1990s the term "functional somatic syndromes" was applied to several

	Autoimmune Diseases, Chaim Sheba Medical Center, 52621 Tel-Hashomer, Israel. eitanister@gmail.com	(auto-inflammatory) syndrome induced by adjuvants.		syndromes, including SBS, multiple chemical sensitivity, repetition stress injury, the side effects of silicone breast implants, the Gulf War syndrome (GWS), chronic fatigue syndrome, the irritable bowel syndrome, and fibromyalgia. Recently, Shoenfeld and Agmon-Levin suggested that four conditions--siliconosis, macrophagic myofascitis, the GWS, and post-vaccination phenomena--which share clinical and pathogenic resemblances, may be included under a common syndrome entitled the "autoimmune (auto-inflammatory) syndrome induced by adjuvants". Comparison of the clinical manifestations, symptoms, and signs of the four conditions described by Shoenfeld and Agmon-Levin with those described for SBS shows that nine out of ten main symptoms are present in all 5 conditions. Shoenfeld and Agmon-Levin further propose several major and minor criteria, which, although requiring further validation, may aid in the diagnosis of this newly defined syndrome. We propose here that SBS may also be included as a part of "Shoenfeld's syndrome".
Itoh Y, Shigemori T, Igarashi T, Fukunaga Y.	Department of Pediatrics, Nippon Medical School, Sendagi, Bukyo City, Tokyo, Japan.	Fibromyalgia and chronic fatigue syndrome in children.	Pediatr Int. 2011 Nov 24. doi: 10.1111/j.1442-200X.2011.03514.x. [Epub ahead of print]	Background: Fibromyalgia (FM) is characterized by widespread persistent pain and the presence of multiple discrete tender points. Chronic fatigue syndrome (CFS) is a syndrome characterized by debilitating fatigue associated with a variable number of non-specific complaints. Because neither condition had necessarily been recognized in children until recently, those patients have been treated as having school refusal without being diagnosed as having either syndrome. There is a considerable overlap of clinical symptoms between these two syndromes. It is therefore controversial as to whether these syndromes have the same pathogenesis or not. The aim of the present study was to clarify the relationship between these syndromes in children. Methods: Fifteen patients with FM and 21 patients with CFS were investigated both clinically and immunologically. Immunological assessments included thorough analysis of autoantibodies using several techniques. Results: Anti-nuclear antibody titers were higher and the prevalence of anti-Sa antibody was far more frequent in CFS patients than in FM patients. Conclusion: CFS and FM are different from each other at least in childhood, from an immunological aspect, although some patients could have both conditions. © 2011 The Authors. Jacobson E.	Department of Global Health and Social Medicine, Harvard Medical School, Boston, MA, USA. eric_jacobson@hms.harvard.edu	Structural integration, an alternative method of manual therapy and sensorimotor education.	J Altern Complement Med. 2011 Oct;17(10):891-9. Epub 2011 Oct 12.	OBJECTIVES: The objectives of this report are to review the clinical practice of Structural Integration (SI), an alternative method of soft-tissue manipulation and sensorimotor education, and to summarize the evidence to date for mechanism and clinical efficacy. METHODS: The author's personal knowledge of SI literature, theory, and practice was supplemented by a database search, consultation with other senior SI practitioners, and examination of published bibliographies and websites that archive SI literature. RESULTS: SI purports to improve biomechanical functioning as a whole by progressively approximating specific ideals of posture and movement, rather than to treat particular symptoms. Hypothesized mechanisms at the level of local tissue change include increases in soft-tissue pliability, release of adhesions

				between adjacent soft-tissue structures, and increased interstitial fluid flow with consequently improved clearance of nociceptive potentiators. Hypothesized mechanisms for more global changes include improved biomechanical organization leading to reductions in mechanical stress and nociceptive irritation, a perception of improved biomechanical efficiency and coordination that generalizes to the self, and improvements in sensory processing and vagal tone. Emotional catharsis is also thought to contribute to psychologic changes. Limited preliminary evidence exists for improvements in neuromotor coordination, sensory processing, self-concept and vagal tone, and for reductions in state anxiety. Preliminary, small sample clinical studies with cerebral palsy, chronic musculoskeletal pain, impaired balance, and chronic fatigue syndrome have reported improvements in gait, pain and range-of-motion, impaired balance, functional status, and well-being. Adverse events are thought to be mild and transient, although survey data are not available. Contraindications are thought to be the same as for massage. CONCLUSIONS: Evidence for clinical effectiveness and hypothesized mechanisms is severely limited by small sample sizes and absence of control arms. In view of the rapidly increasing availability of SI and its use for treatment of musculoskeletal pain and dysfunction, more adequate research in warranted.
Jammes Y, Steinberg JG, Delliaux S.	UMR MD2 P2COE, Faculty of Medicine, Aix-Marseille University and Clinical Respiratory Physiology and Exercise Testing Laboratory, Thorax Pole, National Assistance - Hospitals in Marseille, Marseille, France.	Chronic fatigue syndrome: acute infection and history of physical activity affect resting levels and response to exercise of plasma oxidant/antioxidant status and heat shock proteins.	J Intern Med. 2011 Nov 24. doi: 10.1111/j.1365-2796.2011.02488.x. [Epub ahead of print]	Abstract. Jammes Y, Steinberg JG, Delliaux S (Aix-Marseille University, Marseille, France). Chronic fatigue syndrome: acute infection and history of physical activity affect resting levels and response to exercise of plasma oxidant/antioxidant status and heat shock proteins. J Intern Med 2012; doi: 10.1111/j.1365-2796.2011.02488.x. Objectives. A history of high-level physical activity and/or acute infection might constitute stress factors affecting the plasma oxidant-antioxidant status and levels of heat shock proteins (HSPs) in patients with chronic fatigue syndrome (CFS). Design. This case-control study compared data from 43 CFS patients to results from a matched control group of 23 healthy sedentary subjects. Setting and subjects. Five patients had no relevant previous history (group I). Eighteen had practised high-level sport (group II), and severe acute infection had been diagnosed in nine patients (group III). A combination of sport practice and infection was noted in 11 patients (group IV). Interventions. After examination at rest, all subjects performed a maximal cycling exercise test. Plasma levels of two markers of oxidative stress [thiobarbituric acid reactive substances (TBARS) and reduced ascorbic acid (RAA)] and both HSP27 and HSP70 were measured. Results. At rest, compared with the control group, the TBARS level was higher in groups II, III and IV patients, and the RAA level was lower in groups III and IV. In addition, HSP70 levels were significantly lower in all CFS groups, compared with controls, but negative correlations were found between resting HSP27 and HSP70 levels and the history of physical activity. After exercise, the peak level of TBARS significantly increased in groups II, III and IV, and the variations in HSP27 and HSP70 were attenuated or suppressed, with the greatest effects in groups

				III and IV. Conclusion. The presence of stress factors in the history of CFS patients is associated with severe oxidative stress and the suppression of protective HSP27 and HSP70 responses to exercise. © 2011 The Association for the Publication of the Journal of Internal Medicine.
Jason L, Sorenson M, Sebally K, Alkazemi D, Lerch A, Porter N, Kubow S.	Department of Psychology, DePaul University, Chicago, IL 60614, United States.	Increased HDAC in association with decreased plasma cortisol in older adults with chronic fatigue syndrome.	Brain Behav Immun. 2011 Nov;25(8):1544-7. Epub 2011 Apr 28.	Hypocortisolism is a frequent finding in individuals with chronic fatigue syndrome (CFS) with other research findings implying potential dysregulation of glucocorticoid signaling. Glucocorticoid signaling is under the influence of several pathways, several of which are of interest in the study of CFS. Oxidative stress and decreased antioxidant capacity are known to disrupt the hypothalamic-pituitary-adrenal (HPA) axis (Epel et al., 2004) and the presence of histone deacetylases (HDAC) could also impact glucocorticoid signaling. The intent of this pilot study was to investigate the relationship among oxidative stress elements, select HDAC's (2/3) and glucocorticoid receptor signaling in an elderly sample with CFS. Findings suggest increased histone deacetylase activity, lower total antioxidant power, in the context of decreased plasma cortisol and increased plasma dehydroepiandrosterone concomitant with decreased expression of the encoding gene for the glucocorticoid receptor. These findings support the presence of HPA axis dysregulation in elderly individuals with CFS. Copyright © 2011 Elsevier Inc. All rights reserved.
Jason L, Brown M, Evans M, Anderson V, Lerch A, Brown A, Hunnell J, Porter N.	Center for Community Research, DePaul University, Chicago, IL 60614, USA. ljason@depaul.edu	Measuring substantial reductions in functioning in patients with chronic fatigue syndrome.	Disabil Rehabil. 2011;33(7):589-98. Epub 2010 Jul 9.	PURPOSE: All the major current case definitions for chronic fatigue syndrome (CFS) specify substantial reductions in previous levels of occupational, educational, social, or personal activities to meet criteria. Difficulties have been encountered in operationalizing 'substantial reductions.' For example, the Medical Outcomes Study Short Form-36 Health Survey (SF-36) has been used to determine whether individuals met the CFS disability criterion. However, previous methods of using the SF-36 have been prone to including people without substantial reductions in key areas of physical functioning when diagnosing CFS. This study sought to empirically identify the most appropriate SF-36 subscales for measuring substantial reductions in patients with CFS. METHOD: The SF-36 was administered to two samples of patients with CFS: one recruited from tertiary care and the other a community-based sample; as well as a non-fatigued control group. Receiver operating characteristics were used to determine the optimal cutoff scores for identifying patients with CFS. RESULTS: The SF-36 Role-Emotional subscale had the worst sensitivity and specificity, whereas the Vitality, Role-Physical, and Social Functioning subscales had the best sensitivity and specificity. CONCLUSION: Based on the evidence from this study, the potential criteria for defining substantial reductions in functioning and diagnosing CFS is provided. © 2011 Informa UK, Ltd.
Jason LA, Skendrovic B, Furst J, Brown A, Weng A, Bronikowski C.	DePaul University, USA. Ljason@depaul.edu	Data mining: comparing the empiric CFS to the Canadian ME/CFS	J Clin Psychol. 2012 Jan;68(1):41-9. doi: 10.1002/jclp.20827. Epub 2011 Aug 5.	This article contrasts two case definitions for myalgic encephalomyelitis/chronic fatigue syndrome (ME/CFS). We compared the empiric CFS case definition (Reeves et al., 2005) and the Canadian ME/CFS clinical case definition (Carruthers et al., 2003) with a sample of individuals with CFS versus those without. Data mining with decision

		case definition.		trees was used to identify the best items to identify patients with CFS. Data mining is a statistical technique that was used to help determine which of the survey questions were most effective for accurately classifying cases. The empiric criteria identified about 79% of patients with CFS and the Canadian criteria identified 87% of patients. Items identified by the Canadian criteria had more construct validity. The implications of these findings are discussed. © 2011 Wiley Periodicals, Inc.
Jason LA, Evans M, Brown M, Porter N, Brown A, Hunnell J, Anderson V, Lerch A.	DePaul University.	Fatigue Scales and Chronic Fatigue Syndrome: Issues of Sensitivity and Specificity.	Disabil Stud Q. 2011 Winter;31(1). pii: 1375.	Few studies have explored issues of sensitivity and specificity for using the fatigue construct to identify patients meeting chronic fatigue syndrome (CFS) criteria. In this article, we examine the sensitivity and specificity of several fatigue scales that have attempted to define severe fatigue within CFS. Using Receiver Operating Characteristic (ROC) curve analysis, we found most scales and sub-scales had either significant specificity and/or sensitivity problems. However, the post-exertional subscale of the ME/CFS Fatigue Types Questionnaire (Jason, Jessen, et al., 2009) was the most promising in terms of specificity and sensitivity. Among the more traditional fatigue scales, Krupp, LaRocca, Muir-Nash, and Steinberg's (1989) Fatigue Severity Scale had the best ability to differentiate CFS from healthy controls. Selecting questions, scales and cut off points to measure fatigue must be done with extreme care in order to successfully identify CFS cases.
Jason LA, Sorenson M, Porter N, Belkairous N.	DePaul University, Center for Community Research. Fullerton Ave., Chicago, USA.	An Etiological Model for Myalgic Encephalomyelitis/Chronic Fatigue Syndrome.	Neurosci Med. 2011 Mar 1;2(1):14-27.	Kindling might represent a heuristic model for understanding the etiology of Myalgic Encephalomyelitis/chronic fatigue syndrome (ME/CFS). Kindling occurs when an organism is exposed repeatedly to an initially sub-threshold stimulus resulting in hypersensitivity and spontaneous seizure-like activity. Among patients with ME/CFS, chronically repeated low-intensity stimulation due to an infectious illness might cause kindling of the limbic-hypothalamic-pituitary axis. Kindling might also occur by high-intensity stimulation (e.g., brain trauma) of the limbic-hypothalamic-pituitary axis. Once this system is charged or kindled, it can sustain a high level of arousal with little or no external stimulus and eventually this could lead to hypocortisolism. Seizure activity may spread to adjacent structures of the limbic-hypothalamic-pituitary axis in the brain, which might be responsible for the varied symptoms that occur among patients with ME/CFS. In addition, kindling may also be responsible for high levels of oxidative stress, which has been found in patients with ME/CFS.
Jason LA, Porter N, Hunnell J, Brown A, Rademaker A, Richman JA.	DePaul University. Ljason@depaul.edu	A natural history study of chronic fatigue syndrome.	Rehabil Psychol. 2011 Feb;56(1):32-42.	OBJECTIVE: There is a need for natural history chronic fatigue syndrome (CFS) studies from random, community-based, multi-ethnic populations. DESIGN: The present study examined the course of CFS from Wave 1 to Wave 2, which spanned over a ten year period of time, and, assessed whether socio-environmental and symptomatology factors were associated with CFS status over the ten year period. RESULTS: There was relative stability over time on critical measures of disability, fatigue, support, optimism and coping over time. One cardinal symptoms of CFS, post-exertional malaise, best differentiated the CFS group from the others. By Wave 2, of the original group of 32 individuals diagnosed with CFS, 4 had died, and 24 were found and

				agreed to be re-evaluated, and of this group, 16 continued to have CFS, 5 developed exclusionary illnesses, 2 were classified as Idiopathic chronic fatigue, and one had remitted. CONCLUSIONS: The current study found that over time in a community-based sample, unbiased by help seeking behavior the CFS group remained rather ill with a variety of different conditions over time. Jason LA, Brown AA, Clyne E, Bartgis L, Evans M, Brown M.		Contrasting Case Definitions for Chronic Fatigue Syndrome, Myalgic Encephalomyelitis/Chronic Fatigue Syndrome and Myalgic Encephalomyelitis.	Eval Health Prof. 2011 Dec 7. [Epub ahead of print]	This article uses data from patients recruited using the 1994 case definition of chronic fatigue syndrome (CFS) to contrast those meeting criteria for the Myalgic Encephalomyelitis/chronic fatigue syndrome (ME/CFS) Canadian case definition with those that did not meet these criteria. The study also contrasts those meeting criteria for Myalgic Encephalomyelitis (ME) based on criteria from Ramsay and other theorists with those that did not meet the ME criteria. The ME/CFS case definition criteria identified a subset of patients with more functional impairments and physical, mental, and cognitive problems than the subset not meeting these criteria. The ME subset had more functional impairments, and more severe physical and cognitive symptoms than the subset not meeting ME criteria. When applied to a population meeting the 1994 CFS case definition, both ME/CFS and ME criteria appear to select a more severe subset of patients.
Jason LA.	DePaul University, Chicago, IL, USA, ljason@depaul.edu.	Small Wins Matter in Advocacy Movements: Giving Voice to Patients.	Am J Community Psychol. 2011 Aug 20. [Epub ahead of print]	In this article, the various players are delineated in a story of a contested illness and patient advocacy, played out within the corridors of federal power. It is suggested that the mistreatment and negative attitudes that health care providers and others have towards those with chronic fatigue syndrome (CFS) is possibly due to the social construction of this illness as being a "Yuppie flu" disease. Institutional factors are identified that created these norms and attributions, as well as the multiple stakeholders and constituent groups invested in exerting pressure on policy makers to effect systemic change. This article also provides examples of how the field of Community Psychology, which is fundamentally committed to/based on listening to and giving voice to patients, is broadly relevant to patient activism communities. This approach focused, over time, on epidemiological studies, the name, the case definition, and ultimately the change in CFS leadership at the Centers for Disease Control and Prevention. Keys to this "small wins" approach were coalition building, use of "oppositional experts" (professionals in the scientific community who support patient advocacy goals) to challenge federal research, and taking advantage of developing events/shifts in power. Ultimately, this approach can result in significant scientific and policy gains, and changes in medical and public perception of an illness.
Jason LA, Porter N, Hunnell J, Rademaker A, Richman JA.	DePaul University, USA. Ljason@depaul.edu	CFS prevalence and risk factors over time.	J Health Psychol. 2011 Apr;16(3):445-56. Epub 2011 Jan 11.	The present natural history study examined the course of CFS from 1995-97 (Wave 1) to approximately 10 years later (Wave 2) from a random, community-based, multi-ethnic population. The rate of CFS remained approximately the same over the period of time from Wave 1 to Wave 2, although a high level of mortality was found (18% of those with medical or psychiatric exclusions group, 12.5% for the CFS group). Physical measures of disability and fatigue, along with measures of specific somatic symptoms,

				better differentiate individuals who later are diagnosed with CFS than more psychosocial measures such as stress and coping.
Jerome KR, Diem K, Huang ML, Selke S, Corey L, Buchwald D.	Department of Laboratory Medicine, University of Washington, Seattle, WA 98105, USA. kjerome@fhcrc.org	Xenotropic murine leukemia virus-related virus in monozygotic twins discordant for chronic fatigue syndrome.	Diagn Microbiol Infect Dis. 2011 Sep;71(1):66-71. Epub 2011 Jul 26.	A recent report suggested an association between xenotropic murine leukemia virus-related virus (XMRV) and chronic fatigue syndrome (CFS). If confirmed, this would suggest that antiretroviral therapy might benefit patients suffering from CFS. We validated a set of assays for XMRV and evaluated the prevalence of XMRV in a cohort of monozygotic twins discordant for CFS. Stored peripheral blood mononuclear cell (PBMC) samples were tested with 3 separate polymerase chain reaction (PCR) assays (one of which was nested) for XMRV DNA, and serum/plasma was tested for XMRV RNA by reverse transcription (RT)-PCR. None of the PBMC samples from the twins with CFS or their unaffected co-twins was positive for XMRV, by any of the assays. One plasma sample, from an unaffected co-twin, was reproducibly positive by RT-PCR. However, serum from the same day was negative, as was a follow-up plasma sample obtained 2 days after the positive specimen. These data do not support an association of XMRV with CFS. Jones DE, Hollingsworth KG, Jakovljevic DG, Fattakhova G, Pairman J, Blamire AM, Trenell MI, Newton JL.	Institute of Cellular Medicine Newcastle, Newcastle University, Newcastle, UK.	Loss of capacity to recover from acidosis on repeat exercise in chronic fatigue syndrome: a case-control study.	Eur J Clin Invest. 2012 Feb;42(2):186-94. doi: 10.1111/j.1365-2362.2011.02567.x. Epub 2011 Jul 12.	BACKGROUND: Chronic fatigue syndrome (CFS) patients frequently describe difficulties with repeat exercise. Here, we explore muscle bioenergetic function in response to three bouts of exercise. METHODS: A total of 18 CFS (CDC 1994) patients and 12 sedentary controls underwent assessment of maximal voluntary contraction (MVC), repeat exercise with magnetic resonance spectroscopy and cardio-respiratory fitness test to determine anaerobic threshold. RESULT: Chronic fatigue syndrome patients undertaking MVC fell into two distinct groups: 8 (45%) showed normal PCr depletion in response to exercise at 35% of MVC (PCr depletion >33%; lower 95% CI for controls); 10 CFS patients had low PCr depletion (generating abnormally low MVC values). The CFS whole group exhibited significantly reduced anaerobic threshold, heart rate, VO(2) , VO(2) peak and peak work compared to controls. Resting muscle pH was similar in controls and both CFS patient groups. However, the CFS group achieving normal PCr depletion values showed increased intramuscular acidosis compared to controls after similar work after each of the three exercise periods with no apparent reduction in acidosis with repeat exercise of the type reported in normal subjects. This CFS group also exhibited significant prolongation (almost 4-fold) of the time taken for pH to recover to baseline. CONCLUSION: When exercising to comparable levels to normal controls, CFS patients exhibit profound abnormality in bioenergetic function and response to it. Although exercise intervention is the logical treatment for patients showing acidosis, any trial must exclude subjects who do not initiate exercise as they will not benefit. This potentially explains previous mixed results in CFS exercise trials. © 2011 The Authors. Jones DE, Gray J,	UK NIHR	Fatigue severity	J Intern Med. 2011	OBJECTIVES: to examine fatigue variability over time in chronic fatigue syndrome

Frith J, Newton JL.	Biomedical Centre in Ageing, Institute of Cellular Medicine, Institute for Ageing and Health, Newcastle University, Newcastle, UK.	remains stable over time and independently associated with orthostatic symptoms in chronic fatigue syndrome: a longitudinal study.	Feb;269(2):182-8. doi: 10.1111/j.1365-2796.2010.02306.x. Epub 2010 Nov 14.	(CFS) and the effect of other symptoms on its predictability. DESIGN: longitudinal cohort study of patients with CFS (Fukuda criteria). SETTING: specialist CFS clinical service. SUBJECTS: phase 1: 100 patients who participated in a study of CFS symptoms in 2005 were revisited in 2009. Phase 2: 25 patients completed fatigue diaries to address intra- and inter-day variability in perceived fatigue. MAIN OUTCOME MEASURES: phase 1: subjects completed fatigue impact scale (FIS), Epworth sleepiness scale (ESS), orthostatic grading scale (OGS) and hospital anxiety and depression scale (HADS). Changes in variables represented the differences between 2005 and 2009. Phase 2: subjects rated fatigue on a scale of 0 (no fatigue) to 10 (severe fatigue) four times a day for 5 weeks. RESULTS: symptom assessment tools were available in both 2005 and 2009 for 74% of patients. FIS and HADS depression (HAD-D) and anxiety (HAD-A) scores significantly improved during follow-up whereas ESS and OGS remained stable. FIS improved in 29/74 (39%) subjects, and by ≥ 10 points in 19 (26%). FIS worsened by ≥ 10 points in 33/74 (45%) subjects. On multivariate analysis, independent predictors of current fatigue (FIS in 2009) were FIS in 2005, HAD-D in 2009, OGS in 2009 and change in HAD-A. Reported fatigue was stable from week to week and from day to day. Patients reported higher fatigue in the morning (mean ± SD; 6.4 ± 2), becoming significantly lower at lunchtime (6.2 ± 2; $P < 0.05$) and increasing again to 7 ± 2 at bedtime. CONCLUSIONS: current fatigue is independently associated with current autonomic symptom burden, current depression and change in anxiety during follow-up. These findings have implications for targeted symptom management in CFS.
Juel J, Markvardsen LH, Jakobsen J.	Neurologisk Afdeling F, Aarhus Universitetshospital, Aarhus Sygehus, Denmark. jju@studmed.au.dk	[Haemolytic anaemia as a complication to intravenous infusion of human immunoglobulin]. [Article in Danish]	Ugeskr Laeger. 2011 Aug 15;173(33):1963-4.	A 85-year-old female treated for chronic inflammatory demyelinating polyradiculoneuropathy had three episodes of anaemia one week following treatment with large doses (2g/kg body weight) of immunoglobulin (Ig). At the final episode, she presented with haemolytic anaemia with fatigue, jaundice and loss of appetite. During the next two months anaemia was recognized in two additional cases. Subsequently, a series of twelve conseuntively studied IVIg treated patients showed a significant decrease of haemoglobin of 0.80 mmol/l 8-15 days after infusion. Haemolytic anaemia is a severe side effect that seems to be more frequent than previously recognized. It may possibly be prevented by the use of lyophilized Ig-preparations with low isohaemagglutinin titers or by slower Ig infusion rates.

Kallet RH.	Department of Anesthesia, University of	Patient-ventilator interaction during acute lung injury, and	Respir Care. 2011 Feb;56(2):181-9.	Since the early 1970s there has been an ongoing debate regarding the wisdom of promoting unassisted spontaneous breathing throughout the course of critical illness in patients with severe respiratory failure. The basis of this debate has focused on the

	California, San Francisco, CA, USA. rkallet@sfghsom.ucsf.edu	the role of spontaneous breathing: part 1: respiratory muscle function during critical illness.		clinical relevance of opposite problems. Historically, the term "disuse atrophy" has described a situation wherein sustained inactivity of the respiratory muscles (ie, passive ventilation) results in deconditioning and weakness. More recently it has been referred to as "ventilator-induced diaphragmatic dysfunction." In contrast, "use atrophy" describes a situation where chronic high-tension inspiratory work causes structural damage to the diaphragm and weakness. Both laboratory and clinical studies demonstrated that relatively brief periods of complete respiratory muscle inactivity, as well as intense muscle loading, result in acute inflammation, loss of muscle mass, and weakness. Yet in critical illness other factors also affect respiratory muscle function, including prolonged use of neuromuscular blocking agents, administration of corticosteroids, and sepsis. This makes the attribution of acquired respiratory muscle weakness and ventilator-dependence to either ventilator-induced diaphragmatic dysfunction or loaded breathing extremely difficult. Regardless, the clinical implications of this research strongly suggest that passive mechanical ventilation should be avoided whenever possible. However, promotion of unassisted spontaneous breathing in the acute phase of critical illness also may carry a substantial risk of respiratory muscle injury and weakness. Use of mechanical ventilation modes in a manner that induces spontaneous breathing effort, while simultaneously reducing the work load on the respiratory muscles, is probably sufficient to minimize both problems.
Kang DE, Lee MC, Das Gupta J, Klein EA, Silverman RH.	Glickman Urological and Kidney Institute, Cleveland Clinic, 9500 Euclid Avenue, Cleveland, OH 44195, USA.	XMRV Discovery and Prostate Cancer-Related Research.	Adv Virol. 2011;2011:432837. Epub 2011 Jun 21.	Xenotropic murine leukemia virus-related virus (XMRV) was first reported in 2006 in a study of human prostate cancer patients with genetic variants of the antiviral enzyme, RNase L. Subsequent investigations in North America, Europe, Asia, and Africa have either observed or failed to detect XMRV in patients (prostate cancer, chronic fatigue syndrome-myalgic encephalomyelitis (CFS-ME), and immunosuppressed with respiratory tract infections) or normal, healthy, control individuals. The principal confounding factors are the near ubiquitous presence of mouse-derived reagents, antibodies and cells, and often XMRV itself, in laboratories. XMRV infects and replicates well in many human cell lines, but especially in certain prostate cancer cell lines. XMRV also traffics to prostate in a nonhuman primate model of infection. Here, we will review the discovery of XMRV and then focus on prostate cancer-related research involving this intriguing virus.

Zoology, University of Oxford, South Parks Road, Oxford OX13PS, United Kingdom.	of murine leukemia virus sequences from longitudinally sampled chronic fatigue syndrome patients suggests PCR contamination rather than viral evolution.	Oct;85(20):10909-13. Epub 2011 Aug 17.	from human prostate cancer and chronic fatigue syndrome (CFS) patient samples. Other studies failed to replicate these findings and suggested PCR contamination with a prostate cancer cell line, 22Rv1, as a likely source. MLV-like sequences have also been detected in CFS patients in longitudinal samples 15 years apart. Here, we tested whether sequence data from these samples are consistent with viral evolution. Our phylogenetic analyses strongly reject a model of within-patient evolution and demonstrate that the sequences from the first and second time points represent distinct endogenous murine retroviruses, suggesting contamination.
Kawatani J, Mizuno K, Shiraishi S, Takao M, Joudoi T, Fukuda S, Watanabe Y, Tomoda A.	Department of Child Development, Faculty of Life Sciences, Kumamoto University, Kumamoto, Japan.	Cognitive dysfunction and mental fatigue in childhood chronic fatigue syndrome--a 6-month follow-up study.	Brain Dev. 2011 Nov;33(10):832-41. Epub 2011 May 6.	OBJECTIVES: Cognitive function was investigated in patients with childhood type chronic fatigue syndrome (CCFS) using the modified advanced trail making test (mATMT). METHODS: mATMT was performed on 19 patients with CCFS and 25 healthy controls of comparable age and sex. The effectiveness of combined treatment with cognitive behavioral therapy (CBT) and pharmacotherapy and its relationship to cognitive function was investigated by evaluation of Chalder's fatigue scale and behavior state before and after treatment for 6 consecutive months. RESULTS: All three tasks (motor skill, selective and alternative attention, and spatial working memory) of the mATMT, especially the difference in reaction time of the alternative attention task, could discriminate CCFS patients from control subjects with 70.5% accuracy (P=0.007). CCFS patients showed significantly lower alternative attention and Chalder's fatigue score before treatment (P=0.037 and 0.002, respectively). A significant improvement in performance status scores was found during the 6 months follow-up period with combined treatment with CBT and medication (P<0.001). Improvement of their cognitive symptoms was significantly correlated with improvement of alternative attention (r=0.653, P=0.002). CONCLUSIONS: Higher-order level cognitive dysfunction affects CCFS pathogenesis. Alternative attention performance evaluated by the mATMT may be used to monitor improvement in patients with CCFS. Combined treatment with CBT and medication may be effective to improve poor attention characteristics associated with CCFS.
Kearney MF, Lee K, Bagni RK, Wiegand A, Spindler J, Maldarelli F, Pinto PA, Linehan WM, Vocke CD, Delviks-Frankenberry KA, Devere White RW, Del Prete GQ, Mellors JW, Lifson	HIV Drug Resistance Program, National Cancer Institute at Frederick, Frederick, MD 21702-1201, USA.	Nucleic Acid, Antibody, and Virus Culture Methods to Detect Xenotropic MLV-Related Virus in Human Blood Samples.	Adv Virol. 2011;2011:272193. Epub 2011 Nov 17.	The MLV-related retrovirus, XMRV, was recently identified and reported to be associated with both prostate cancer and chronic fatigue syndrome. At the National Cancer Institute-Frederick, MD (NCI-Frederick), we developed highly sensitive methods to detect XMRV nucleic acids, antibodies, and replication competent virus. Analysis of XMRV-spiked samples and/or specimens from two pigtail macaques experimentally inoculated with 22Rv1 cell-derived XMRV confirmed the ability of the assays used to detect XMRV RNA and DNA, and culture isolatable virus when present, along with XMRV reactive antibody responses. Using these assays, we did not detect evidence of XMRV in blood samples (N = 134) or prostate specimens (N = 19) from two independent cohorts of patients with prostate cancer. Previous studies detected

JD, Kewalramani VN, Pathak VK, Coffin JM, Le Grice SF.				XMRV in prostate tissues. In the present study, we primarily investigated the levels of XMRV in blood plasma samples collected from patients with prostate cancer. These results demonstrate that while XMRV-related assays developed at the NCI-Frederick can readily measure XMRV nucleic acids, antibodies, and replication competent virus, no evidence of XMRV was found in the blood of patients with prostate cancer.
Kempke S, Luyten P, Van Houdenhove B, Goossens L, Bekaert P, Van Wambeke P.	Department of Psychology, University of Leuven, Tiensestraat 102, 3000 Leuven, Belgium. stefan.kempke@psy.kuleuven.be	Self-esteem mediates the relationship between maladaptive perfectionism and depression in chronic fatigue syndrome.	Clin Rheumatol. 2011 Dec;30(12):1543-8. Epub 2011 May 17.	Patients with chronic fatigue syndrome (CFS) often experience depression which may negatively affect prognosis and treatment outcome. Research has shown that depression in CFS is associated with maladaptive or self-critical perfectionism. However, currently, little is known about factors that may explain this relationship, but studies in nonclinical samples suggest that low self-esteem may be an important mediator of this relationship. The present study therefore examined whether self-esteem mediated the cross-sectional association between maladaptive perfectionism and severity of depression in 192 patients meeting Centres for Disease Control and Prevention criteria for CFS. Patients completed self-report measures of maladaptive perfectionism, self-esteem, depression, and fatigue. Regression analyses and more direct tests of indirect effects (i.e., the Sobel test and bootstrapping) were used to test for mediation. Congruent with expectations, we found that self-esteem fully mediated the relationship between maladaptive perfectionism and depression in CFS. Findings from this study suggest that self-esteem may explain the link between maladaptive perfectionism and depression in CFS, which may have important implications for the treatment and prevention of depression in these patients.
Kempke S, Van Houdenhove B, Luyten P, Goossens L, Bekaert P, Van Wambeke P.	Department of Psychology, University of Leuven, Leuven, Belgium. stefan.kempke@psy.kuleuven.be	Unraveling the role of perfectionism in chronic fatigue syndrome: is there a distinction between adaptive and maladaptive perfectionism?	Psychiatry Res. 2011 Apr 30;186(2-3):373-7. Epub 2010 Oct 18.	In the current study, we investigated whether the distinction between adaptive (i.e. high personal standards) and maladaptive (i.e. concern over mistakes and doubt about actions) perfectionism that has been found in the literature, is also valid in patients with chronic fatigue syndrome (CFS). We hypothesized that maladaptive, but not adaptive, perfectionism would be significantly and positively related to severity of fatigue and depression in CFS. We examined this hypothesis in a sample of 192 CFS patients using structural equation modelling (SEM). Although the two perfectionism dimensions were related to each other, results supported a model in which only maladaptive perfectionism was positively related to severity of fatigue and depression. Further, we found that depression fully mediated the effect of maladaptive perfectionism on fatigue. The results suggest that adaptive and maladaptive perfectionism are two distinct, albeit related, dimensions in CFS. Findings of this study have important implications for theory and treatment of CFS, particularly for cognitive-behavioral treatment. Copyright © 2010 Elsevier Ireland Ltd. All rights reserved.
Kenyon JC, Lever AM.	Department of Medicine, University of Cambridge,	XMRV, prostate cancer and chronic fatigue syndrome.	Br Med Bull. 2011;98:61-74. Epub 2011 May 6.	BACKGROUND: A new retrovirus, xenotropic murine leukaemia virus-related virus (XMRV), was identified in 2006 and an association was claimed between it and a genetic polymorphism predisposing to cancer of the prostate. In 2009 the same virus was identified in a cohort of patients with chronic fatigue syndrome (CFS). In 2010 a

	Addenbrooke's hospital, Cambridge, UK.			second related virus was identified in a separate group of CFS patients. A series of studies from disparate geographical areas have failed to substantiate this work. Most recently several papers have suggested that the detection of these viruses was explained by laboratory contamination. SOURCES OF DATA: All papers including the wording XMRV were abstracted from the NIH library of medicine database and included in the analysis. AREAS OF AGREEMENT: XMRV is a newly described retrovirus whose nucleic acid has been identified in samples from patients with both prostate cancer and CFS. AREAS OF CONTROVERSY: Opinions differ as to whether the detected nucleic acid indicates infection with this virus in this disease or whether laboratory contamination of samples accounts for its presence. GROWING POINTS: An increasing number of papers now refute the association of XMRV with human disease in humans although there is some evidence of serological reactivity to the virus. While it is unlikely that XMRV is a major cause of either prostate cancer or CFS, it can infect human cells and might yet have a role in human disease. AREAS TIMELY FOR DEVELOPING RESEARCH: Further studies to either prove or disprove the disease association of the virus are ongoing.

Kim JW, Lee JO, Han SW, Oh DY, Im SA, Kim TY, Bang YJ.	Department of Internal Medicine, Seoul National University Hospital, Seoul National University College of Medicine, Seoul, Korea.	Clinical outcomes of sorafenib treatment in patients with metastatic hepatocellular carcinoma who had been previously treated with fluoropyrimidine plus platinum-based chemotherapy.	Am J Clin Oncol. 2011 Apr;34(2):125-9.	OBJECTIVES: There has been no report on sorafenib therapy in patients with metastatic hepatocellular carcinoma (HCC) who had been treated with systemic chemotherapy. The objectives of this analysis were to investigate efficacy and safety of sorafenib in these patients and to elucidate risk factors associated with clinical outcomes. METHODS: We analyzed patients with metastatic HCC who were treated with sorafenib after failure of fluoropyrimidine plus platinum-based chemotherapy between April 2007 and December 2008. RESULTS: Twenty-four patients (male, 79.2%) were included. Median age was 53 years. Chronic hepatitis B was the predominant cause of HCC (79.2%), followed by chronic hepatitis C (4.2%) and alcohol (4.2%). Twenty patients (83.3%) were Child-Pugh A and 4 patients (16.7%) were Child-Pugh B. Median follow-up duration was 11.1 months. No objective response was observed. Fourteen patients (58.3%) had stable disease. The disease control rate was 58.3%. Median progression-free survival was 2.3 months (95% confidence interval, 0.5-4.1) and overall survival was 7.1 months (95% confidence

				interval, 3.5-10.7). Grade 3 neutropenia was observed in 1.4% and grade 3 anemia in 1.4%. Grade 3 or 4 nonhematologic toxicities were hand-foot syndrome (16.7%), skin rash (8.3%), diarrhea (4.2%), headache (4.2%), and fatigue (4.2%). Four patients (16.7%) discontinued the therapy because of toxicities. CONCLUSIONS: Sorafenib had modest efficacy and tolerable toxicity in patients with metastatic HCC who had received fluoropyrimidine plus platinum-based chemotherapy.

Kindt S, Van Oudenhove L, Mispelon L, Caenepeel P, Arts J, Tack J.	Center for Gastroenterological Research, Department of Pathophysiology, University Hospital Gasthuisberg,	Longitudinal and cross-sectional factors associated with long-term clinical course in functional dyspepsia: a 5-year follow-up study.	Am J Gastroenterol. 2011 Feb;106(2):340-8. Epub 2010 Oct 26.	OBJECTIVES: Functional dyspepsia (FD) is a heterogeneous disorder with different pathophysiological mechanisms underlying the symptom pattern, but little is known about its clinical course. The aims of this study were to study the long-term evolution of symptoms in a clinical FD population and to identify factors associated with outcome. METHODS: FD patients who previously underwent gastric function testing and filled out a dyspepsia symptom score (DSS) were contacted. At follow-up, patients indicated whether symptoms had worsened, remained unchanged, improved, or disappeared. Anxiety and depression, DSS, chronic fatigue symptoms, irritable bowel

	University of Leuven, Leuven, Belgium.			syndrome (IBS) comorbidity, and FD-specific quality of life (QoL) were assessed using mailed questionnaires. Bivariate associations between different patient characteristics and DSS and QoL at follow-up were tested; multiple linear regression was used to identify factors associated with the outcomes, both longitudinally and cross-sectionally. RESULTS: Data were obtained from 253 patients (84.9% of the eligible and consenting population (n=298) and 53.2% of the original population (n=476)). The mean duration of follow-up was 68±2 months. Disappeared, improved, unchanged, and worsened symptoms were reported by 17.4, 38.3, 30.8, and 13.4% of the patients, respectively. Correlations between dyspepsia symptoms at initial visit and follow-up were small to moderate in magnitude. DSS at initial visit and trait anxiety were longitudinally associated with DSS at follow-up, with a trend found for weight loss; depression, chronic fatigue, and IBS at follow-up were cross-sectionally associated with DSS. Trait anxiety, weight loss, and DSS at initial visit were independently associated with QoL at follow-up; depression as well as DSS and chronic fatigue at follow-up were cross-sectionally associated. CONCLUSIONS: About half of FD patients reported disappeared or improved symptoms after a mean follow-up of 5 years. Although stability of symptom levels is low to moderate, DSS at initial visit, trait anxiety, and initial weight loss are more strongly associated with outcome than gastric sensorimotor function.
Kishi A, Natelson BH, Togo F, Struzik ZR, Rapoport DM, Yamamoto Y.	Educational Physiology Laboratory, Graduate School of Education, The University of Tokyo, Tokyo, Japan.	Sleep-stage dynamics in patients with chronic fatigue syndrome with or without fibromyalgia.	Sleep. 2011 Nov 1;34(11):1551-60.	STUDY OBJECTIVES: Chronic fatigue syndrome (CFS) and fibromyalgia (FM) are medically unexplained conditions that often have overlapping symptoms, including sleep-related complaints. However, differences between the 2 conditions have been reported, and we hypothesized that dynamic aspects of sleep would be different in the 2 groups of patients. PARTICIPANTS: Subjects were 26 healthy control subjects, 14 patients with CFS but without FM (CFS alone), and 12 patients with CFS and FM (CFS+FM)-all women. MEASUREMENTS AND RESULTS: We studied transition probabilities and rates between sleep stages (waking, rapid eye movement [REM] sleep, stage 1 [S1], stage 2 [S2], and slow-wave sleep [SWS]) and duration distributions of each sleep stage. We found that the probability of transition from REM sleep to waking was significantly greater in subjects with CFS alone than in control subjects, which may be the specific sleep problem for people with CFS alone. Probabilities of (a) transitions from waking, REM sleep, and S1 to S2 and (b) those from SWS to waking and S1 were significantly greater in subjects with CFS+FM than in control subjects; in addition, rates of these transitions were also significantly increased in subjects with CFS+FM. Result (a) might indicate increased sleep pressure in subjects with CFS+FM whereas result (b) may be the specific sleep problem of subjects with CFS+FM. We also found that shorter durations of S2 sleep are specific to patients with CFS+FM, not to CFS alone. CONCLUSIONS: These results suggest that CFS and FM may be different illnesses associated with different problems of sleep regulation.

Knox K, Carrigan D, Simmons G, Teque F, Zhou Y, Hackett J Jr, Qiu X, Luk KC, Schochetman G, Knox A, Kogelnik AM, Levy JA.	Wisconsin Viral Research Group, Milwaukee, WI 53226, USA.	No evidence of murine-like gammaretroviruses in CFS patients previously identified as XMRV-infected.	Science. 2011 Jul 1;333(6038):94-7. Epub 2011 May 31. Comment in Nat Rev Urol. 2011 Aug;8(8):409.	Members of the gammaretroviruses--such as murine leukemia viruses (MLVs), most notably XMRV [xenotropic murine leukemia virus (X-MLV)-related virus--have been reported to be present in the blood of patients with chronic fatigue syndrome (CFS). We evaluated blood samples from 61 patients with CFS from a single clinical practice, 43 of whom had previously been identified as XMRV-positive. Our analysis included polymerase chain reaction and reverse transcription polymerase chain reaction procedures for detection of viral nucleic acids and assays for detection of infectious virus and virus-specific antibodies. We found no evidence of XMRV or other MLVs in these blood samples. In addition, we found that these gammaretroviruses were strongly (X-MLV) or partially (XMRV) susceptible to inactivation by sera from CFS patients and healthy controls, which suggested that establishment of a successful MLV infection in humans would be unlikely. Consistent with previous reports, we detected MLV sequences in commercial laboratory reagents. Our results indicate that previous evidence linking XMRV and MLVs to CFS is likely attributable to laboratory contamination.
Knudsen AK, Henderson M, Harvey SB, Chalder T.	Research Section of Mental Health Epidemiology, Department of Health Promotion and Development, Faculty of Psychology, University of Bergen, Christiesgt. 13, N-5020 Bergen, Norway. Ann.Knudsen@psych.uib.no	Long-term sickness absence among patients with chronic fatigue syndrome.	Br J Psychiatry. 2011 Nov;199(5):430-1. Epub 2011 Sep 8.	Chronic fatigue syndrome is associated with high levels of occupational disability. Consecutive out-patients at a chronic fatigue syndrome treatment service were studied for associations between occupational status, symptom severity and cognitive and behavioural responses to symptoms. All patients had high symptom levels; however, those on long-term sickness absence had significantly more physical fatigue ($\beta = 0.098$, $P<0.05$) and worse sleep ($\beta = 0.075$, $P<0.05$). Patients with long-term sickness absence also demonstrated more embarrassment avoidance cognitions ($\beta = 0.086$, $P<0.05$) and avoidance resting behavioural responses ($\beta = 0.078$, $P<0.05$). Identifying and addressing avoidance behaviours and cognitions regarding embarrassment in interventions may enhance the chances of individuals returning to work.
Knudsen AK, Omenås AN, Harvey SB, Løvvik CM, Lervik LV,	Department of Health Promotion and Development,	Chronic fatigue syndrome in the media: a content analysis of	JRSM Short Rep. 2011 May;2(5):42. Epub 2011 May 25.	OBJECTIVES: Although cognitive behavioural therapy and graded exercise treatment are recognized evidence-based treatments for chronic fatigue syndrome/myalgic encephalomyelitis (ME), their use is still considered controversial by some patient groups. This debate has been reflected in the media, where many patients gather

Mykletun A.	Faculty of Psychology, University of Bergen , Bergen , Norway.	newspaper articles.		health information. The aim of this study was to examine how treatment for chronic fatigue syndrome/ME is described in the newspaper media. DESIGN: Content analysis of newspaper articles. SETTING: The digitalized media archive Atekst was used to identify Norwegian newspaper articles where chronic fatigue syndrome/ME was mentioned. PARTICIPANTS: Norwegian newspaper articles published over a 20-month period, from 1 January 2008 to 31 August 2009. MAIN OUTCOME MEASURES: Statements regarding efficiency of various types of treatment for chronic fatigue syndrome/ME and the related source of the treatment advice. Statements were categorized as being either positive or negative towards evidence-based or alternative treatment. RESULTS: One hundred and twenty-two statements regarding treatment of chronic fatigue syndrome/ME were identified among 123 newspaper articles. The most frequent statements were positive statements towards alternative treatment Lightning Process (26.2%), negative statements towards evidence-based treatments (22.1%), and positive statements towards other alternative treatment interventions (22.1%). Only 14.8% of the statements were positive towards evidence-based treatment. Case-subjects were the most frequently cited sources, accounting for 35.2% of the statements, followed by physicians and the Norwegian ME association. CONCLUSIONS: Statements regarding treatment for chronic fatigue syndrome/ME in newspapers are mainly pro-alternative treatment and against evidence-based treatment. The media has great potential to influence individual choices. The unbalanced reporting of treatment options for chronic fatigue syndrome/ME in the media is potentially harmful.
Komaroff AL, Cho TA.	Division of General Medicine, Department of Medicine, Brigham and Women's Hospital, Boston, Massachusetts 02115, USA. Komaroff@hms.harvard.edu	Role of infection and neurologic dysfunction in chronic fatigue syndrome.	Semin Neurol. 2011 Jul;31(3):325-37. doi: http://dx.doi.org/10.1055/s-0031-1287654. Epub 2011 Sep 30.	Chronic fatiguing illnesses following well-documented infections and acute "infectious-like" illnesses of uncertain cause have been reported for many decades. Chronic fatigue syndrome (CFS) was first formally defined in 1988. There is considerable evidence that CFS is associated with abnormalities of the central and autonomic nervous systems. There also is evidence linking several infectious agents with CFS, although no agent has been proven to be a cause of the illness. Most of the infectious agents that have been linked to CFS are able to produce a persistent, often life-long, infection and thus are a constant incitement to the immune system. Most also have been shown to be neuropathogens. The evidence is consistent with the hypothesis that CFS, in some cases, can be triggered and perpetuated by several chronic infections that directly or indirectly affect the nervous system, and that symptoms are a reflection of the immune response to the infection. © Thieme Medical Publishers.
Korenromp IH, Heijnen CJ, Vogels OJ, van den Bosch JM, Grutters JC.	Department of Pulmonology, St. Antonius Hospital Nieuwegein; , University	Characterization of chronic fatigue in patients with sarcoidosis in clinical remission.	Chest. 2011 Aug;140(2):441-7. Epub 2011 Feb 17.	BACKGROUND: Patients with sarcoidosis frequently complain of fatigue, even when sarcoidosis has come into clinical remission. The primary aim of this study was to assess the severity of fatigue in patients with sarcoidosis in clinical remission and to characterize it according to the international criteria for chronic fatigue syndrome (CFS). Furthermore, we evaluated whether fatigue is associated with depression and

	Medical Center Utrecht, Utrecht, The Netherlands.			anxiety, health status, and patient-reported sleep quality, and we recorded physical activity levels and muscle strength as objective assessments of fatigue. METHODS: Data on 75 patients with sarcoidosis in clinical remission were obtained by questionnaires (Checklist Individual Strength [CIS], Symptom Checklist-90, Beck Depression Inventory for primary care, Medical Outcomes Study 36-Item Short-Form Health Survey), standardized interview (CFS criteria), sleep diary, accelerometer, and muscle strength tests. RESULTS: Fatigue severity mean score in patients with sarcoidosis in clinical remission was high (CIS fatigue severity 30.5 ± 15.5), and criteria for CFS were met in 47% of fatigued participants. Median time since diagnosis was 9 years. Fatigue was associated with depression (P = .01), anxiety (P = .013), and reduced health status (P < .001). Scores on sleep quality were normal. Physical activity levels were reduced in fatigued participants. Muscle strength, particularly handgrip (P = .006) and quadriceps strength (P < .001), was significantly associated with fatigue. CONCLUSIONS: Fatigue in patients with sarcoidosis in clinical remission is a frequent symptom and can be characterized as a severe and long-lasting problem, symptomatically similar to CFS. Psychologic distress and reduced health status are associated with fatigue. Interestingly, we observed significantly reduced physical activity and muscle weakness in fatigued patients.
Kreijkamp-Kaspers S, Brenu EW, Marshall S, Staines D, Van Driel ML.	Academic General Practice, Faculty of Health Sciences & Medicine, Bond University, Gold Coast, Queensland. skreijka@bond.edu.au	Treating chronic fatigue syndrome - a study into the scientific evidence for pharmacological treatments.	Aust Fam Physician. 2011 Nov;40(11):907-12.	BACKGROUND: Chronic fatigue syndrome, or myalgic encephalomyelitis (CFS), is a severe disabling condition. Patients with CFS usually trial many different medicines, both conventional and complementary. An overview of the pharmacological treatments used by CFS patients and the available evidence underpinning the use of these treatments would be of great value to both patients and their healthcare providers. METHODS: Ninety-four CFS patients recruited into an Australian study investigating immunological biomarkers filled out a questionnaire assessing the medicines they were taking. Evidence from randomised clinical trials was sought in biomedical databases. RESULTS: The 94 CFS patients used 474 different medicines and supplements. The most commonly used medicines were antidepressants, analgesics, sedatives, and B vitamins. We identified 20 randomised controlled trials studying these medicines in CFS patients. DISCUSSION: While conventional and complementary medicines are widely used by CFS patients, the evidence for effectiveness in CFS is very limited.
Kumar A, Garg R, Gaur V, Kumar P.	Department of Pharmacology, University Institute of Pharmaceutical Sciences, Panjab University, Chandigarh-160	Nitric oxide modulation in protective role of antidepressants against chronic fatigue syndrome in mice.	Indian J Pharmacol. 2011 May;43(3):324-9.	BACKGROUND AND OBJECTIVE: The present study was designed to elucidate the possible nitric oxide (NO) mechanism in the protective effect of antidepressants using mice model of chronic fatigue syndrome (CFS). MATERIALS AND METHODS: Male albino laca mice were forced to swim for each 6 min session for 7 days and immobility period was measured on every alternate day (1(st), 3(rd), 5(th), 7(th)). After 7 days various behavioral tests (locomotor, mirror chamber, and plus maze tests for anxiety) were performed and biochemical estimations (lipid peroxidation, nitrite levels, GSH (reduced glutathione), and catalase activity) in mice brain were performed. Animals

	014, India.			were pretreated with citalopram (5 and 10 mg/kg) and imipramine (10 and 20 mg/kg) daily for 7 days. RESULTS: The present study showed that continued forced swimming for 7 days caused chronic fatigue-induced anxiety-like behavior as assessed in mirror chamber, plus maze tests, and impairment in locomotor activity followed by oxidative damage (as evidenced by increased lipid peroxidation, nitrite levels, depleted reduced glutathione, and catalase activity) in animals. Seven days pretreatment with citalopram (5 and 10 mg/kg) and imipramine (10 and 20 mg/kg) significantly improved behavioral and biochemical alterations. Further, L-nitro-arginine methyl ester (L-NAME,5 mg/kg) and methylene blue (MB, 10 mg/kg) pretreatment with citalopram (5 mg/kg) or imipramine (10 mg/kg) potentiated their protective effect. However, l-arginine (100 mg/kg) pretreatment with citalopram (5 mg/kg) or imipramine (10 mg/kg) reversed their protective effect as compared with their effect per se ($P < 0.05$). CONCLUSION: The present study suggests that protective effect of citalopram and imipramine might be due to its NO modulation against chronic fatigue induced behavioral and biochemical alterations.

Larbcharoensub N, Boonsakan P, Aroonroch R, Rochanawutanon M, Nitiyanant P, Phongkitkarun S, Poonvutikul S, Watchararanan	Department of Pathology, Faculty of Medicine Ramathibodi Hospital, Mahidol University, Bangkok,	Adrenal histoplasmosis: a case series and review of the literature.	Southeast Asian J Trop Med Public Health. 2011 Jul;42(4):920-5.	Adrenal histoplasmosis is an uncommon mycotic disease typically caused by Histoplasma capsulatum. The objective was to determine the clinicopathological findings in adrenal histoplasmosis. Pathological records were searched from the database at the Department of Pathology, Faculty of Medicine Ramathibodi Hospital, Mahidol University from 1993 to 2008 for cases of adrenal histoplasmosis. The keywords were "histoplasmosis" and "adrenal gland". Adrenal histoplasmosis was diagnosed by histopathology and Gomori-Grocott methenamine silver staining. Histoplasma capsulatum was confirmed by tissue culture and/or serology. The

SP, Ngarmukos C.	Thailand. Noppadol_l@hotmail.com			authors report seven cases of adrenal histoplasmosis in immunocompetent patients. The mean age at diagnosis was 67 years. All patients presented as chronic fatigue syndrome. The onset of symptoms ranged from one to three months. Addison's disease was found in adrenal histoplasmosis in one case (14.3%). The computed tomography revealed adrenal nodules measuring 1.2 to 7.8 cm in diameter. The histopathology showed granulomatous inflammation with caseous necrosis. Culture of adrenal tissue from two patients revealed Histoplasma capsulatum. Serum Histoplasma antibodies were positive in four cases. A cure was accomplished in 6 out of 7 cases (85.7%). The patients were followed up for 2.5 to 16.5 years.
Larun L, Malterud K.	Research Unit for General Practice, Uni Research, Bergen, Norway. lillebeth.larun@kunnskapssenteret.no	Finding the right balance of physical activity: a focus group study about experiences among patients with chronic fatigue syndrome.	Patient Educ Couns. 2011 May;83(2):222-6. Epub 2010 Jun 26.	OBJECTIVE: To explore contexts of experiences of physical activity perceived as beneficial or harmful for CFS patients. METHODS: A qualitative study with empirical data from two focus groups with purposive sampling. Mean age was 50, two of ten participants were male, and social demographics varied. Participants were invited to share stories of good as well as bad experiences concerning physical activity. Data were analysed with systematic text condensation. RESULTS: Participants were not averse to physical activity, but specific preconditions would determine how the activity was perceived. Physical activity was experienced as helpful and enjoyable, especially related to leisure activities where flexible and individual adaptation was feasible. Non-customized activity may precipitate set-backs giving patients the impression of losing control and being betrayed by their bodies. Strategies to review energy usage in daily life could adjust expectations, diminish stress load and assist in approaching a more appropriate priority and balance. CONCLUSION: Self-management, body awareness and physical activity of choice combined with facilitation and advice from health care professionals is essential to achieve a positive outcome. PRACTICE IMPLICATIONS: Exercise programmes should be adapted, paced, and self-managed in accordance with personal preferences and activity levels to be beneficial and empowering for CFS patients. Larun L, Malterud K.	Allmennmedisinsk forskningsenhet i Bergen, Uni helse, Kalfarveien 31, Bergen. ela@nokc.no	[Exercise therapy for patients with chronic fatigue syndrome]. [Article in Norwegian]	Tidsskr Nor Laegeforen. 2011 Feb 4;131(3):231-6. Comment in Tidsskr Nor Laegeforen. 2011 May 6;131(8):803.	BACKGROUND: Post-exertional fatigue is the main symptom of chronic fatigue syndrome. Evidence-based guidelines recommend cognitive behavioral therapy and graded exercise therapy. In this article, we present a systematic review of outcome studies and discuss procedures for individualized exercise therapy for patients with chronic fatigue syndrome. MATERIAL AND METHODS: The effect of exercise treatment for these patients was assessed through a meta-analysis of randomized controlled trials which were identified through a systematic literature review. Effect size was calculated for fatigue, pain and health-related quality of life and the GRADE system was used to estimate the documentation level (quality of the evidence and strength of the recommendations). RESULTS: Seven outcome studies were included in the meta-analysis. They demonstrated that exercise therapy seems to reduce fatigue, but the results were inconclusive for pain and health-related quality of life. The

				documentation level is moderate to low and further research can modify the results in positive or negative directions. We found no indications of adverse effects of individualized exercise programs which were adapted to the patients' functional level and included adequate follow-up. INTERPRETATION: In light of general knowledge about positive health effects of exercise therapy and empirically based hypotheses about disease mechanisms in chronic fatigue syndrome, we conclude that further research has a high probability of confirming recommendations on individualized exercise therapy to these patients.
Lee SS, Kim SH, Nah SS, Lee JH, Lee YA, Hong SJ, Kim HS, Lee HS, Kim HA, Joung CI, Choe JY, Kim SK.	Department of Internal Medicine, Chonnam National University Medical School, Gwangju, Republic of Korea.	Smoking habits influence pain and functional and psychiatric features in fibromyalgia.	Joint Bone Spine. 2011 May;78(3):259-65. Epub 2010 Sep 20.	OBJECTIVE: Numerous epidemiologic data have shown that smoking may play a role in the disease manifestations or severity of chronic musculoskeletal pain. The authors of the present study investigated the effect of smoking on clinical features such as pain, fatigue, functional impairment, and psychiatric features in the Korean population with fibromyalgia syndrome (FMS). METHODS: A total of 336 patients with FMS were consecutively enrolled from 10 medical centers which participated in the Korean national fibromyalgia survey. Smoking was divided into current smokers and non-smokers. Instruments of FMS assessment included tender points, Fibromyalgia Impact questionnaire (FIQ), 36-item Medical Outcomes Study Short-Form Health Survey (SF-36), Brief Fatigue Inventory (BFI), Brief Depression Inventory (BDI), State-Trait Anxiety Inventory (STAI)-1 and STAI-2, and social family support and social friend support. Statistical analyses included Chi-square test, Fisher's exact test, Mann-Whitney U test, and multivariate logistic regression analysis. RESULTS: Thirty-three patients (9.8%) out of 336 participants were current smokers. The number of tender points (P=0.037), BFI (P=0.026), general health of SF-36 (P=0.028), BDI (P=0.014), syncope (P=0.024), and reflex sympathetic dystrophy (P=0.003) showing significance between current smokers and non-smokers were not associated with smoking habits after adjustment. The significance of the number of tender points (P=0.009), scores of total tender points (P=0.032), BDI (P=0.038), general weakness (P=0.047), and reflex sympathetic dystrophy (P=0.011) was observed between randomized non-smokers (n=55) and smokers (n=33). In addition, the number of tender points (P=0.027, OR=1.379) was associated with smoking status after adjustment. The analysis between randomized non-smokers (n=45) and smokers (n=22) in female FMS patients showed that BDI in FMS was associated with smoking status (P=0.023, OR=1.077) after logistic regression analysis. CONCLUSIONS: This study revealed that smoking habits may, in part, influence pain or functional and psychiatric features in FMS patients. The impact of smoking on clinical features in FMS should be assessed in a larger study population. Copyright © 2010 Société française de rhumatologie. Published by Elsevier SAS. All rights reserved.
Leone SS, Wessely S, Huibers MJ, Knottnerus JA,	Department of Epidemiology, Maastricht	Two sides of the same coin? On the history and	Psychol Health. 2011 Apr;26(4):449-64. Epub 2010 Apr 29.	BACKGROUND: Burnout and chronic fatigue syndrome (CFS) are two fatigue syndromes which have developed largely independently from each other, yet whose similarities in symptoms can be a source of confusion. We aim to explore the

Kant I.	University, Maastricht, The Netherlands. Stephanie.Leone @epid.unimaas.nl	phenomenology of chronic fatigue and burnout.		phenomenology of burnout and CFS in a historical context as this may provide some insight into the links and relationship between these conditions. METHOD: A narrative review based on literature in the fields of history, social science and medicine. RESULTS: The origins of CFS lie within medicine, whereas burnout developed in a psychological setting. As well as symptoms, burnout and CFS also share similar themes such as an overload process triggering illness onset, the need for restoration of depleted energy, external causal attributions and the characteristics of people suffering from these illnesses. However, these themes are expressed in either psychological or medical terms according to the historical background. CONCLUSION: Despite their similarities, there have been few direct comparisons of the two concepts. Culture, illness perceptions and accountability are important issues in both conditions and could contribute to their differences. Comparing burnout and CFS within one sample frame, thus looking beyond the psychology/medicine divide, could be a useful first step towards understanding their relationship.
Li B, Mahan CM, Kang HK, Eisen SA, Engel CC.	Institute for Clinical Research, Inc., Washington DC, USA.	Longitudinal health study of US 1991 Gulf War veterans: changes in health status at 10-year follow-up.	Am J Epidemiol. 2011 Oct 1;174(7):761-8. Epub 2011 Jul 27.	The authors assessed changes in the health status of US 1991 Gulf War-era veterans from a 1995 baseline survey to a 2005 follow-up survey, using repeated measurement data from 5,469 deployed Gulf War veterans and 3,353 nondeployed Gulf War-era veterans who participated in both surveys. Prevalence differences in health status between the 2 surveys were estimated for adverse health indices and chronic diseases for each veteran group. Persistence risk ratios and incidence risk ratios were calculated after adjustment for demographic and military service characteristics through Mantel-Haenszel stratified analysis. At 10-year follow-up, deployed veterans were more likely to report persistent poor health, as measured by the health indices (functional impairment, limitation of activities, repeated clinic visits, recurrent hospitalizations, perception of health as fair or poor, chronic fatigue syndrome-like illness, and posttraumatic stress disorder), than nondeployed veterans. Additionally, deployed veterans were more likely to experience new onset of adverse health (as measured by the indices) and certain chronic diseases than were nondeployed veterans. During the 10-year period from 1995 to 2005, the health of deployed veterans worsened in comparison with nondeployed veterans because of a higher rate of new onset of various health outcomes and greater persistence of previously reported adverse health on the indices.
Li N, Qiu MY, Hao JR, Zhang QM, Wang SH, Liang F, Yin Y, Luan J, Ge GZ, Qin T, Li BQ.	Wangjing Hospital, China Academy of Chinese Medical Sciences, Beijing 100102, China.	[Randomized controlled trail on moxibustion for maintenance hemodialysis patients in deficiency syndrome]. [Article in Chinese]	Zhongguo Zhen Jiu. 2011 Jan;31(1):15-8.	OBJECTIVE: To explore the effective therapy for maintenance hemodialysis patients in dificiency syndrome in end-stage renal disease. METHODS: Ninety-seven cases were divided into an observation group (51 cases) and a control group (46 cases) randomly, and routine western medicine was used in both of them. On this base, moxibustion was used in Zusanli (ST 36) and Sanyinjiao (SP 6) in paper-tube-moxibustion equipment in the observation group. Evaluate the therapeutic effect on symptoms by comparing the symptom scores in two groups before and after treatment. RESULTS: All the symptom scores in the observation group were improved after treatment, and

				the differences were significant (all P < 0.05). Among all symptoms, the most improved ones included lassitude and fatigue, short breath and aversion to talk, poor appetite, soreness and softness of waist and knees, aversion to cold, cold extremities and so on. In the aspect of therapeutic effect on symptoms, the total effective rate in observation group (64.7%, 33/51) was higher than that in control group (23.9%, 11/46), and the difference was significant (P < 0.05). CONCLUSION: Moxibustion can improve the clinical symptoms of maintenance hemodialysis patients in end-stage renal disease, and can generate some therapeutic effect to the dificiency syndrome of this disease.
Light AR, Bateman L, Jo D, Hughen RW, Vanhaitsma TA, White AT, Light KC.	Department of Anesthesiology The Brain Institute Department of Neurobiology and Anatomy Department of Exercise and Sport Science, University of Utah, Salt Lake City, UT 84132, USA. alan.light@hsc.utah.edu	Gene expression alterations at baseline and following moderate exercise in patients with Chronic Fatigue Syndrome and Fibromyalgia Syndrome.	J Intern Med. 2012 Jan;271(1):64-81. doi: 10.1111/j.1365-2796.2011.02405.x. Epub 2011 Jul 13.	OBJECTIVES: To determine mRNA expression differences in genes involved in signalling and modulating sensory fatigue, and muscle pain in patients with chronic fatigue syndrome (CFS) and fibromyalgia syndrome (FM) at baseline, and following moderate exercise. DESIGN: Forty-eight patients with CFS only, or CFS with comorbid FM, 18 patients with FM that did not meet criteria for CFS, and 49 healthy controls underwent moderate exercise (25 min at 70% maximum age-predicted heart rate). Visual-analogue measures of fatigue and pain were taken before, during and after exercise. Blood samples were taken before and 0.5, 8, 24 and 48 h after exercise. Leucocytes were immediately isolated from blood, number coded for blind processing and analyses and flash frozen. Using real-time, quantitative PCR, the amount of mRNA for 13 genes (relative to control genes) involved in sensory, adrenergic and immune functions was compared between groups at baseline and following exercise. Changes in amounts of mRNA were correlated with behavioural measures and functional clinical assessments. RESULTS: No gene expression changes occurred following exercise in controls. In 71% of patients with CFS, moderate exercise increased most sensory and adrenergic receptor's and one cytokine gene's transcription for 48 h. These postexercise increases correlated with behavioural measures of fatigue and pain. In contrast, for the other 29% of patients with CFS, adrenergic α-2A receptor's transcription was decreased at all time-points after exercise; other genes were not altered. History of orthostatic intolerance was significantly more common in the α-2A decrease subgroup. FM-only patients showed no postexercise alterations in gene expression, but their pre-exercise baseline mRNA for two sensory ion channels and one cytokine were significantly higher than controls. CONCLUSIONS: At least two subgroups of patients with CFS can be identified by gene expression changes following exercise. The larger subgroup showed increases in mRNA for sensory and adrenergic receptors and a cytokine. The smaller subgroup contained most of the patients with CFS with orthostatic intolerance, showed no postexercise increases in any gene and was defined by decreases in mRNA for α-2A. FM-only patients can be identified by baseline increases in three genes. Postexercise increases for four genes meet published criteria as an objective biomarker for CFS and could be useful in guiding treatment selection for different subgroups. © 2011 The

Light KC, White AT, Tadler S, Iacob E, Light AR.	Departments of Anesthesiology, Neurobiology and Anatomy, and Exercise and Sport Science, The University of Utah, Salt Lake City, UT 84132, USA.	Genetics and Gene Expression Involving Stress and Distress Pathways in Fibromyalgia with and without Comorbid Chronic Fatigue Syndrome.	Pain Res Treat. 2012;2012:427869. Epub 2011 Sep 29.	In complex multisymptom disorders like fibromyalgia syndrome (FMS) and chronic fatigue syndrome (CFS) that are defined primarily by subjective symptoms, genetic and gene expression profiles can provide very useful objective information. This paper summarizes research on genes that may be linked to increased susceptibility in developing and maintaining these disorders, and research on resting and stressor-evoked changes in leukocyte gene expression, highlighting physiological pathways linked to stress and distress. These include the adrenergic nervous system, the hypothalamic-pituitary-adrenal axis and serotonergic pathways, and exercise responsive metabolite-detecting ion channels. The findings to date provide some support for both inherited susceptibility and/or physiological dysregulation in all three systems, particularly for catechol-O-methyl transferase (COMT) genes, the glucocorticoid and the related mineralocorticoid receptors (NR3C1, NR3C2), and the purinergic 2X4 (P2X4) ion channel involved as a sensory receptor for muscle pain and fatigue and also in upregulation of spinal microglia in chronic pain models. Methodological concerns for future research, including potential influences of comorbid clinical depression and antidepressants and other medications, on gene expression are also addressed.

Chronic Viral Diseases Branch, Mail Stop A-15, Centers for Disease Control and Prevention, 1600 Clifton Road NE, Atlanta, GA 30333, USA. dwe3@cdc.gov.	The economic impact of chronic fatigue syndrome in Georgia: direct and indirect costs.	Cost Eff Resour Alloc. 2011 Jan 21;9(1):1.	BACKGROUND: Chronic fatigue syndrome (CFS) is a debilitating chronic illness affecting at least 4 million people in the United States. Understanding its cost improves decisions regarding resource allocation that may be directed towards treatment and cure, and guides the evaluation of clinical and community interventions designed to reduce the burden of disease. METHODS: This research estimated direct and indirect costs of CFS and the impact on educational attainment using a population-based, case-control study between September 2004 and July 2005, Georgia, USA. Participants completed a clinical evaluation to confirm CFS, identify other illnesses, and report on socioeconomic factors. We estimated the effect of CFS on direct medical costs (inpatient hospitalizations, provider visits, prescription medication spending, other medical supplies and services) and loss in productivity (employment and earnings) with a stratified sample (n = 500) from metropolitan, urban, and rural Georgia. We adjusted medical costs and earnings for confounders (age, sex, race/ethnicity, education, and geographic strata) using econometric models and weighted estimates to reflect response-rate adjusted sampling rates. RESULTS: Individuals with CFS had mean annual direct medical costs of $5,683. After adjusting

				for confounding factors, CFS accounted for $3,286 of these costs (p < 0.01), which were driven by increased provider visits and prescription medication use. Nearly one-quarter of these expenses were paid directly out-of pocket by those with CFS. Individuals with CFS reported mean annual household income of $23,076. After adjustment, CFS accounted for $8,554 annually in lost household earnings (p < 0.01). Lower educational attainment accounted for 19% of the reduction in earnings associated with CFS. CONCLUSIONS: Study results indicate that chronic fatigue syndrome may lead to substantial increases in healthcare costs and decreases in individual earnings. Studies have estimated up to 2.5% of non-elderly adults may suffer from CFS. In Georgia, a state with roughly 5.5 million people age 18-59, illness could account for $452 million in total healthcare expenditures and $1.2 billion of lost productivity.

Lack of infection with XMRV or other MLV-related viruses in blood, post-mortem brains and paternal gametes of autistic individuals.	PLoS One. 2011 Feb 23;6(2):e16609.	BACKGROUND: Autistic spectrum disorder (ASD) is characterized by impaired language, communication and social skills, as well as by repetitive and stereotypic patterns of behavior. Many autistic subjects display a dysregulation of the immune system which is compatible with an unresolved viral infection with prenatal onset, potentially due to vertical viral transmission. Recently, the xenotropic murine leukemia virus-related virus (XMRV) has been implicated in chronic fatigue syndrome (CFS) and in prostate cancer by several, though not all studies. METHODOLOGY/PRINCIPAL FINDINGS: We assessed whether XMRV or other murine leukemia virus (MLV)-related viruses are involved in autistic disorder. Using nested PCR targeted to gag genomic sequences, we screened DNA samples from: (i) peripheral blood of 102 ASD patients and 97 controls, (ii) post-mortem brain samples of 20 ASD patients and 17 sex- and age-matched controls, (iii) semen samples of 11 fathers of ASD children, 25 infertile individuals and 7 fertile controls. No XMRV gag DNA sequences were detected, whereas peripheral blood samples of 3/97 (3.1%) controls were positive for MLV. CONCLUSIONS| SIGNIFICANCE: No MLV-related virus was detected in blood, brain, and semen samples of ASD patients or fathers. Hence infection with XMRV or other MLV-related viruses is unlikely to contribute to autism pathogenesis.
Liu KP, Fang M, Dai	Department of	[A study of median	Zhong Xi Yi Jie He Xue	OBJECTIVE: To study the changes in median frequency (MF) from a surface

DC, Jiang SY, Zuo YZ.	Tuina, Shanghai University of Traditional Chinese Medicine, Shanghai, China. yaotuzheng@126.com	frequencies of skeletal muscle undergoing Tuina intervention in patients with chronic fatigue syndrome]. [Article in Chinese]	Bao. 2011 Oct;9(10):1083-7.	electromyogram of skeletal muscles and functional assessment of chronic illness therapy (FACIT) figure scale scores for patients with chronic fatigue syndrome (CFS) before and after Tuina treatment. METHODS: A controlled clinical trial was adopted. Thirty-two patients suffering from CFS were enrolled according to the inclusion criteria from outpatient department of Shanghai Yueyang Hospital of Integrated Chinese and Western Medicine in China; thirty normal people whose gender, age, height and body mass were concordant with the CFS patients were selected as the normal group. Surface electromyography was used to detect the median frequency (MF) of biceps, quadriceps, and waist and back muscle before and after a 20-day course of treatment. CFS patients also were asked to fill out the figure scale of FACIT to evaluate the degree of fatigue. RESULTS: There was no significant difference in surface electromyography MF of myoelectric signal of biceps and quadriceps between CFS and normal person; however, the waist and back muscle MF of the normal person was significantly lower than that of the CFS patients. Before and after treatment, there were no obvious changes in the MF of myoelectric signals of all muscles. Tuina significantly decreased the scale score of FACIT. CONCLUSION: Tuina can improve the symptom of patients with CFS.
Liu Y, Zhang HG, Li XH.	Institute of Materia Medica and Department of Pharmaceutics, College of Pharmacy, Third Military Medical University, Chongqing, 400038, PR China.	A Chinese herbal decoction, Danggui Buxue Tang, improves chronic fatigue syndrome induced by food restriction and forced swimming in rats.	Phytother Res. 2011 Dec;25(12):1825-32. doi: 10.1002/ptr.3499. Epub 2011 Apr 15.	Danggui Buxue Tang (DBT), a Chinese medicinal decoction that contains Radix Angelicae sinensis (Danggui) and Radix Astragali (Huangqi) at a ratio of 1:5, is used commonly for treating women's ailments. The present study explored the effects of this preparation on chronic fatigue syndrome (CFS). Rats were subjected to a combination of food restriction and forced swimming to induce CFS, and rats were gavaged once daily with either 12 or 24 g/kg DBT for 28 days. Body weights, T-cell subset counts, (3) H-TdR incorporation measurements and mRNA levels of IL-1β, TNF-α, NF-κB, p38MAPK and JNK were determined on days 14 and 28. The swimming endurance capacity was measured on day 28. Rats that received DBT exhibited increased body weight and endurance capacity, corrected T cell subsets counts, increased (3) H-TdR incorporation and decreased mRNA levels of IL-1β, TNF-α, NF-κB, p38MAPK and JNK compared with rats that did not receive DBT. The results indicate that DBT can ameliorate CFS through immune modulation and may act to normalize cytokines and their related signaling pathways. Copyright © 2011 John Wiley & Sons, Ltd.

Virginia St. Reno, NV 89557-0552, USA. vclombardi@wpinstitute.org	Xenotropic murine leukemia virus-related virus-associated chronic fatigue syndrome reveals a distinct inflammatory signature.	In Vivo. 2011 May-Jun;25(3):307-14.	BACKGROUND: The recent identification of xenotropic murine leukemia virus-related virus (XMRV) in the blood of patients with chronic fatigue syndrome (CFS) establishes that a retrovirus may play a role in the pathology in this disease. Knowledge of the immune response might lead to a better understanding of the role XMRV plays in this syndrome. Our objective was to investigate the cytokine and chemokine response in XMRV-associated CFS. MATERIALS AND METHODS: Using Luminex multi-analyte profiling technology, we measured cytokine and chemokine values in the plasma of XMRV-infected CFS patients and compared these data to those of healthy controls. Analysis was performed using the Gene Expression Pattern Analysis Suite and the Random Forest tree classification algorithm. RESULTS: This study identifies a signature of 10 cytokines and chemokines which correctly identifies XMRV/CFS patients with 93% specificity and 96% sensitivity. CONCLUSION: These data show, for the first time, an immunological pattern associated with XMRV/CFS.
Lommel K, Bamford J, Jhavari M, Martin C, Crofford L.	Division of Rheumatology and College of Public Health, Department of Psychiatry, University of Kentucky, Lexington, KY 40509, USA. karen.lommel@uky.edu	A pilot study: pain, fatigue and stress in maternal relatives of adolescent female psychiatric inpatients assessed for juvenile primary fibromyalgia syndrome.	Int J Adolesc Med Health. 2011;23(1):59-63.	BACKGROUND: This study was designed to assess the presence of pain and impaired functioning in the maternal relatives of adolescent females in an inpatient adolescent psychiatric population. We compared the relatives of adolescents who met the criteria for juvenile primary fibromyalgia syndrome (JPFS) to relatives of adolescents who did not meet the criteria for JPFS. METHODS: A total of 55 biological maternal relatives of adolescent females admitted to a psychiatric unit were recruited to participate in the study. Participants completed four self-administered questionnaires: Multidimensional Fatigue Inventory, Fibromyalgia Impact Questionnaire, Medical Outcomes Survey (SF36v2), and the EPIFUND Health Survey. RESULTS: The maternal relatives of adolescents who met the criteria for JPFS did not score higher than the maternal relatives of adolescents who did not meet the criteria for JPFS. However, all maternal relatives consistently scored higher on self-reported measures of pain, impaired functioning, fatigue, and fibromyalgia symptoms than the average patient diagnosed with fibromyalgia or a chronic pain syndrome. CONCLUSION: Mood disorders and pain disorders share genetic risk factors and vulnerability. Future research is needed to further delineate other factors impacting the maternal caregivers' functioning. These could include stress associated with an adolescent child with psychiatric issues severe enough to warrant hospitalization.
Lopez C, Antoni M, Penedo F, Weiss D, Cruess S, Segotas MC, Helder L, Siegel S, Klimas N, Fletcher MA.	University of Miami, Miami, FL, USA.	A pilot study of cognitive behavioral stress management effects on stress, quality of life, and symptoms in persons	J Psychosom Res. 2011 Apr;70(4):328-34. Epub 2011 Jan 15.	OBJECTIVE: The present pilot study was designed to test the effects of a 12-week group-based cognitive behavioral stress management (CBSM) intervention on stress, quality of life, and symptoms in chronic fatigue syndrome (CFS). We hypothesized that participants randomized to CBSM would report improvements in perceived stress, mood, quality of life, and CFS symptomatology from pre- to postintervention compared to those receiving a psychoeducational (PE) seminar control. METHOD: We

		with chronic fatigue syndrome.		recruited 69 persons with a bona fide diagnosis of CFS and randomized 44 to CBSM and 25 to PE. Participants completed the Perceived Stress Scale (PSS), Profile of Mood States (POMS), Quality of Life Inventory (QOLI), and a Centers for Disease Control (CDC)-based CFS symptom checklist pre- and postintervention. RESULTS: Repeated measures analysis of variance revealed a significant Group×Time interaction for PSS, POMS-total mood disturbance (TMD), and QOLI scores, such that participants in CBSM evidenced greater improvements than those in PE. Participants in CBSM also reported decreases in severity of CFS symptoms vs. those in PE. CONCLUSIONS: Results suggest that CBSM is beneficial for managing distress, improving quality of life, and alleviating CFS symptom severity. Copyright © 2011 Elsevier Inc. All rights reserved.
Luyten P, Kempke S, Van Wambeke P, Claes S, Blatt SJ, Van Houdenhove B.	Department of Psychology at the University of Leuven, in Leuven, Belgium. Patrick.Luyten@psy.kuleuven.be	Self-critical perfectionism, stress generation, and stress sensitivity in patients with chronic fatigue syndrome: relationship with severity of depression.	Psychiatry. 2011 Spring;74(1):21-30.	Chronic Fatigue Syndrome (CFS) is a highly disabling disorder that is part of a broader spectrum of chronic pain and fatigue disorders. Although the etiology and pathogenesis of CFS largely remain unclear, there is increasing evidence that CFS shares important pathophysiological disturbances with mood disorders in terms of disturbances in the stress response and the stress system. From a psycho-dynamic perspective, self-critical perfectionism and related personality factors are hypothesized to explain in part impairments of the stress response in both depression and CFS. Yet, although there is ample evidence that high levels of self-critical perfectionism are associated with stress generation and increased stress sensitivity in depression, evidence supporting this hypothesis in CFS is currently lacking. This study therefore set out to investigate the relationship between self-critical perfectionism, the active generation of stress, stress sensitivity, and levels of depression in a sample of 57 patients diagnosed with CFS using an ecological momentary assessment approach. Results showed, congruent with theoretical assumptions, that self-critical perfectionism was associated with the generation of daily hassles, which in turn predicted higher levels of depression. Moreover, multilevel analyses showed that self-critical perfectionism was related to increased stress sensitivity in CFS patients over a 14-day period, and that increased stress sensitivity in turn was related to increased levels of depression. The implications of these findings for future research and particularly for the development of psychodynamic treatment approaches of CFS and related conditions are discussed.
Maes M, Mihaylova I, Kubera M, Ringel K.	Maes Clinics @ TRIA, Bangkok, Thailand. dr.michaelmaes@hotmail.com	Activation of cell-mediated immunity in depression: association with inflammation, melancholia, clinical staging and the fatigue and somatic	Prog Neuropsychopharmacol Biol Psychiatry. 2012 Jan 10;36(1):169-75. Epub 2011 Sep 16.	BACKGROUND: Depression is characterized by activation of cell-mediated immunity (CMI), including increased neopterin levels, and increased pro-inflammatory cytokines (PICs), such as interleukin-1 (IL-1) and tumor necrosis factor-α (TNFα). These PICs may induce depressive, melancholic and chronic fatigue (CF) symptoms. METHODS: We examined serum neopterin and plasma PIC levels in depressive subgroups in relation to the depressive subtypes and the melancholic and CF symptoms of depression. Participants were 85 patients with depression and in 26 normal controls. Severity of depression was assessed with the Hamilton Depression Rating Scale (HDRS) and

		symptom cluster of depression.		severity of CF with the Fibromyalgia and Chronic Fatigue Syndrome (FF) Rating Scale. RESULTS: Serum neopterin was significantly higher in depressed patients and in particular in those with melancholia. There were positive correlations between serum neopterin, the plasma PICs and the number of previous depressive episodes. Neopterin and TNFα were associated with melancholia, while both PICs were associated with CF. Melancholia-group membership was predicted by the HDRS and neopterin, and CF group membership by age, the FF score and serum TNFα. DISCUSSION: Depression and melancholia are accompanied by CMI activation, suggesting that neopterin plays a role in their pathophysiology, e.g. through activation of oxidative and nitrosative stress and apoptosis pathways. The intertwined CMI and inflammatory responses are potentially associated with the onset of depression and with the melancholic and CF symptoms of depression. Exposure to previous depressive episodes may magnify the size of CMI and PIC responses, possibly increasing the likelihood of new depressive episodes. CMI activation and inflammation may contribute to the staging or recurrence of depression. Copyright © 2011 Elsevier Inc. All rights reserved.
Maes M, Twisk FN, Kubera M, Ringel K.	Maes Clinics @ TRIA, Bangkok, Thailand.	Evidence for inflammation and activation of cell-mediated immunity in Myalgic Encephalomyelitis/Chronic Fatigue Syndrome (ME/CFS): Increased interleukin-1, tumor necrosis factor-α, PMN-elastase, lysozyme and neopterin.	J Affect Disord. 2011 Oct 3. [Epub ahead of print]	BACKGROUND: There is evidence that inflammatory pathways and cell-mediated immunity (CMI) play an important role in the pathophysiology of Myalgic Encephalomyelitis/Chronic Fatigue Syndrome (ME/CFS). Activation of inflammatory and CMI pathways, including increased levels of cytokines, is known to induce fatigue and somatic symptoms. Given the broad spectrum inflammatory state in ME/CFS, the aim of this study was to examine whether inflammatory and CMI biomarkers are increased in individuals with ME/CFS. METHODS: In this study we therefore measured plasma interleukin-(IL)1, tumor necrosis factor (TNF)α, and PMN-elastase, and serum neopterin and lysozyme in 107 patients with ME/CFS, 37 patients with chronic fatigue (CF), and 20 normal controls. The severity of ME/CFS was measured with the Fibromyalgia and Chronic Fatigue Syndrome (FF) Rating Scale. RESULTS: Serum IL-1, TNFα, neopterin and lysozyme are significantly higher in patients with ME/CFS than in controls and CF patients. Plasma PMN-elastase is significantly higher in patients with ME/CFS than in controls and CF patients and higher in the latter than in controls. Increased IL-1 and TNFα are significantly correlated with fatigue, sadness, autonomic symptoms, and a flu-like malaise; neopterin is correlated with fatigue, autonomic symptoms, and a flu-like malaise; and increased PMN-elastase is correlated with concentration difficulties, failing memory and a subjective experience of infection. CONCLUSIONS: The findings show that ME/CFS is characterized by low-grade inflammation and activation of CMI. The results suggest that characteristic symptoms of ME/CFS, such as fatigue, autonomic symptoms and a flu-like malaise, may be caused by inflammatory mediators, e.g. IL-1 and TNFα. Maes M, Twisk FN,	Maes Clinics @	Increased IgA	J Affect Disord. 2011	BACKGROUND: Myalgic Encephalomyelitis/Chronic Fatigue Syndrome (ME/CFS) is

Kubera M, Ringel K, Leunis JC, Geffard M.	TRIA, Bangkok, Thailand.	responses to the LPS of commensal bacteria is associated with inflammation and activation of cell-mediated immunity in chronic fatigue syndrome.	Oct 1. [Epub ahead of print]	accompanied by a) systemic IgA/IgM responses against the lipopolysaccharides (LPS) of commensal bacteria; b) inflammation, e.g. increased plasma interleukin-(IL)1 and tumor necrosis factor (TNF)α; and c) activation of cell-mediated immunity (CMI), as demonstrated by increased neopterin. METHODS: To study the relationships between the IgA/IgM responses to the LPS of microbiota, inflammation, CMI and the symptoms of ME/CFS we measured the IgA/IgM responses to the LPS of 6 different enterobacteria, serum IL-1, TNFα, neopterin, and elastase in 128 patients with ME/CFS and chronic fatigue (CF). Severity of symptoms was assessed by the Fibromyalgia and Chronic Fatigue Syndrome (FF) Rating Scale. RESULTS: Serum IL-1, TNFα, neopterin and elastase are significantly higher in patients with ME/CFS than in CF patients. There are significant and positive associations between the IgA responses to LPS and serum IL-1, TNFα, neopterin and elastase. Patients with an abnormally high IgA response show increased serum IL-1, TNFα and neopterin levels, and higher ratings on irritable bowel syndrome (IBS) than subjects with a normal IgA response. Serum IL-1, TNFα and neopterin are significantly related to fatigue, a flu-like malaise, autonomic symptoms, neurocognitive disorders, sadness and irritability. CONCLUSIONS: The findings show that increased IgA responses to commensal bacteria in ME/CFS are associated with inflammation and CMI activation, which are associated with symptom severity. It is concluded that increased translocation of commensal bacteria may be responsible for the disease activity in some ME/CFS patients. Copyright © 2011 Elsevier B.V. All rights reserved.
Maes M, Ringel K, Kubera M, Berk M, Rybakowski J.	Maes Clinics @ TRIA, Bangkok, Thailand.	Increased autoimmune activity against 5-HT: A key component of depression that is associated with inflammation and activation of cell-mediated immunity, and with severity and staging of depression.	J Affect Disord. 2011 Dec 12. [Epub ahead of print]	BACKGROUND: Depression is characterized by inflammation and cell-mediated immune (CMI) activation and autoimmune reactions directed against a multitude of self-epitopes. There is evidence that the inflammatory response in depression causes dysfunctions in the metabolism of 5-HT, e.g. lowering the 5-HT precursor tryptophan, and upregulating 5-HT receptor mRNA. This study has been undertaken to examine autoimmune activity directed against 5-HT in relation to CMI activation and inflammation. METHODS: 5-HT antibodies were examined in major depressed patients (n=109) versus normal controls (n=35) in relation to serum neopterin and lysozyme, and plasma pro-inflammatory cytokines (PIC), i.e. interleukin-1 (IL-1) and tumor necrosis factor-α (TNFα). Severity of depression was assessed with the Hamilton Depression Rating Scale (HDRS) and severity of fatigue and somatic symptoms with the Fibromyalgia and Chronic Fatigue Syndrome (FF) Rating Scale. RESULTS: The incidence of anti-5-HT antibody activity was significantly higher in depressed patients (54.1%), and in particular in those with melancholia (82.9%), than in controls (5.7%). Patients with positive 5-HT antibodies showed increased serum neopterin and lysozyme, and plasma TNFα and IL-1; higher scores on the HDRS and FF scales, and more somatic symptoms, including malaise and neurocognitive dysfunctions. There was a significant association between autoimmune activity to 5-HT and the number of previous depressive episodes. DISCUSSION: The autoimmune

				reactions directed against 5-HT might play a role in the pathophysiology of depression and the onset of severe depression. The strong association between autoimmune activity against 5-HT and inflammation/CMI activation is explained by multiple, reciprocal pathways between these factors. Exposure to previous depressive episodes increases the incidence of autoimmune activity directed against 5-HT, which in turn may increase the likelihood to develop new depressive episodes. These findings suggest that sensitization (kindling) and staging of depression are in part based on progressive autoimmune responses. Copyright © 2011 Elsevier B.V. All rights reserved.
Maes M, Mihaylova I, Kubera M, Leunis JC, Geffard M.	Maes Clinics @ TRIA, Bangkok, Thailand. dr.michaelmaes@hotmail.com	IgM-mediated autoimmune responses directed against multiple neoepitopes in depression: new pathways that underpin the inflammatory and neuroprogressive pathophysiology.	J Affect Disord. 2011 Dec;135(1-3):414-8. Epub 2011 Sep 17.	BACKGROUND: There is evidence that depression is accompanied by oxidative and nitrosative stress (O&NS), as indicated by increased free radical levels, lipid peroxidation, and lowered antioxidant levels. The aims of the present study are to examine whether depression is accompanied by autoimmune responses directed against a) neoepitopes that are formed following O&NS damage; and b) the major anchorage molecules, i.e. palmitic and myristic acids and S-farnesyl-L-cysteine. METHODS: We examined serum IgM antibodies to the conjugated fatty acids, palmitic and myristic acids; acetylcholine; S-farnesyl-L-cysteine; and NO-modified adducts in 26 depressed patients and 17 normal controls. Severity of depression was measured with the Hamilton Depression Rating Scale and severity of fatigue and somatic (F&S) symptoms with the Fibromyalgia and Chronic Fatigue Syndrome (FF) Rating Scale. RESULTS: The prevalences and mean values for the serum IgM levels directed against conjugated palmitic and myristic acids, acetylcholine, S-farnesyl-L-cysteine; and the conjugated NO adducts, NO-tyrosine, NO-phenylalanine, NO-aspartate, NO-histidine, and NO-creatine were significantly higher in depressed patients than in normal controls. The autoimmune responses were significantly related to FF symptoms, such as fatigue and a flu-like malaise, whereas the indicants of nitrosative stress were related to gastro-intestinal and autonomic symptoms. DISCUSSION: Depression is characterized by IgM-related autoimmune responses directed against a) neoepitopes that are normally not detected by the immune system but that due to damage by O&NS have become immunogenic; and b) anchorage epitopes, i.e. palmitic and myristic acids, and S-farnesyl-L-cysteine. These autoimmune responses play a role in the inflammatory and O&NS pathophysiology of depression and may mediate the cellular dysfunctions that contribute to neuroprogression, e.g. aberrations in signal transduction, cellular differentiation and apoptosis. Maes M.	Maes Clinics @ TRIA, 998 Rimklongsamsen Road, Bangkok 10310, Thailand.	An intriguing and hitherto unexplained co-occurrence: Depression and chronic fatigue	Prog Neuropsychopharmacol Biol Psychiatry. 2011 Apr 29;35(3):784-94. Epub 2010 Jul 4.	There is a significant 'comorbidity' between depression and myalgic encephalomyelitis/chronic fatigue syndrome (ME/CFS). Depressive symptoms frequently occur during the course of ME/CFS. Fatigue and somatic symptoms (F&S), like pain, muscle tension, and a flu-like malaise, are key components of depression. At the same time, depression and ME/CFS show major clinical differences, which allow

	dr.michaelmaes@hotmail.com	syndrome are manifestations of shared inflammatory, oxidative and nitrosative (IO&NS) pathways.		to discriminate them with a 100% accuracy. This paper aims to review the shared pathways that underpin both disorders and the pathways that discriminate them. Numerous studies have shown that depression and ME/CFS are characterized by shared aberrations in inflammatory, oxidative and nitrosative (IO&NS) pathways, like systemic inflammation and its long-term sequels, including O&NS-induced damage to fatty acids, proteins and DNA; dysfunctional mitochondria; lowered antioxidant levels, like zinc and coenzyme Q10; autoimmune responses to neoepitopes formed by O&NS; lowered omega-3 polyunsaturated fatty acid levels; and increased translocation of gram-negative bacteria. Some IO&NS-related pathways, like the induction of indoleamine 2-3-dioxygenase, neurodegeneration and decreased neurogenesis, are more specific to depression, whereas other pathways, like the 2'-5' oligoadenylate synthetase/RNase L pathway, are specific to ME/CFS. Most current animal models of depression, e.g. those induced by cytokines, are not reminiscent of human depression but reflect a mixture of depressive and F&S symptoms. The latter symptoms, sometimes called sickness behavior, differ from depression and ME/CFS because the former is a (sub)acute response to infection-induced pro-inflammatory cytokines that aims to enhance recovery, whereas the latter are characterized by long-term sequels in multiple IO&NS pathways. Depression and ME/CFS are not 'comorbid' disorders, but should be regarded as 'co-associated disorders' that are clinical manifestations of shared pathways. Copyright © 2010 Elsevier Inc. Maes M, Kubera M, Uytterhoeven M, Vrydags N, Bosmans E.	Maes Clinics@TRIA, Bangkok, Thailand. dr.michaelmaes@hotmail.com	Increased plasma peroxides as a marker of oxidative stress in myalgic encephalomyelitis/chronic fatigue syndrome (ME/CFS).	Med Sci Monit. 2011 Apr;17(4):SC11-5.	BACKGROUND: There is evidence that myalgic encephalomyelitis/chronic fatigue syndrome (ME/CFS) is characterized by activation of immune, inflammatory, oxidative and nitrosative stress (IO&NS) pathways. The present study was carried out in order to examine whether ME/CFS is accompanied by increased levels of plasma peroxides and serum oxidized LDL (oxLDL) antibodies, two biomarkers of oxidative stress. MATERIAL/METHODS: Blood was collected from 56 patients with ME/CFS and 37 normal volunteers. Severity of ME/CFS was measured using the Fibromyalgia and Chronic Fatigue Syndrome (FF) Rating Scale. RESULTS: Plasma peroxide concentrations were significantly higher in patients with ME/CFS than in normal controls. There was a trend towards significantly higher serum oxLDL antibodies in ME/CFS than in controls. Both biomarkers contributed significantly in discriminating between patients with ME/CFS and normal controls. Plasma peroxide and serum oxLDL antibody levels were both significantly related to one of the FF symptoms. CONCLUSIONS: The results show that ME/CFS is characterized by increased oxidative stress.
Maes M, Mihaylova I, Kubera M, Uytterhoeven M, Vrydags N,	Piyavate Hospital, Bangkok, Thailand, Thailand. dr.michaelmaes@	Lower whole blood glutathione peroxidase (GPX) activity in depression, but not	Neuro Endocrinol Lett. 2011;32(2):133-40.	BAKGROUND: Major depression and myalgic encephalomyelitis / chronic fatigue syndrome (ME/CFS) are two disorders accompanied by an upregulation of the inflammatory and oxidative and nitrosative (IO&NS) pathways and a decreased antioxidant status. Moreover, depression is accompanied by disorders in inflammatory and neuroprogressive (IN-PRO) pathways.METHODS: This study

Bosmans E.	hotmail.com	in myalgic encephalomyelitis / chronic fatigue syndrome: another pathway that may be associated with coronary artery disease and neuroprogression in depression.		examines whole blood glutathione peroxidase (GPX) in depression and in ME/CFS; GPX is an enzyme that reduces hydroperoxides by oxidizing glutathione and consequently protects the cells from oxidative damage. Blood was sampled in 39 patients with depression, 40 patients with ME/CFS and 24 normal volunteers. Whole blood was analysed for GPX activity using the Ransel assay (Randox). Severity of illness was measured by means of the Hamilton Depression Rating Scale (HDRS) and the Fibromyalgia and Chronic Fatigue Syndrome Rating Scale (FF scale). RESULTS: We found that whole blood GPX activity was significantly (p=0.001) lower in depressed patients than in normal controls and that there were no significant differences between ME/CFS and controls. In depression and ME/CFS, there were significant and inverse relationships between GPX activity and the FF items, depressed mood and autonomic symptoms. In depression, there were significant and negative correlations between whole blood GPX and the HDRS score and autonomic symptoms. DISCUSSION: The results show that lowered whole blood GPX activity contributes to the lowered antioxidant status in depression. Since GPX activity is a predictor of neuroprogression and coronary artery disease (CAD), lowered GPX activity in depression contributes to the IN-PRO pathways and the comorbidity between depression and CAD. Our results suggest that patients with depression would benefit from Ebselen or a supplementation with glutathione, N-Acetyl-l-Cysteine and selenium.
Maes M, Kubera M, Obuchowiczwa E, Goehler L, Brzeszcz J.	Maes Clinics @ TRIA, Bangkok, Thailand, Thailand.	Depression's multiple comorbidities explained by (neuro)inflammatory and oxidative & nitrosative stress pathways.	Neuro Endocrinol Lett. 2011;32(1):7-24.	There is now evidence that depression, as characterized by melancholic symptoms, anxiety, and fatigue and somatic (F&S) symptoms, is the clinical expression of peripheral cell-mediated activation, inflammation and induction of oxidative and nitrosative stress (IO&NS) pathways and of central microglial activation, decreased neurogenesis and increased apoptosis. This review gives an explanation for the multiple "co-morbidities" between depression and a large variety of a) brain disorders related to neurodegeneration, e.g. Alzheimer's, Parkinson's and Huntington's disease, multiple sclerosis and stroke; b) medical disorders, such as cardiovascular disorder, chronic fatigue syndrome, chronic obstructive pulmonary disease, rheumatoid arthritis, psoriasis, systemic lupus erythematosus, inflammatory bowel disease, irritable bowel syndrome, leaky gut, diabetes type 1 and 2, obesity and the metabolic syndrome, and HIV infection; and c) conditions, such as hemodialysis, interferon-α-based immunotherapy, the postnatal period and psychosocial stressors. The common denominator of all those disorders/conditions is the presence of microglial activation and/or activation of peripheral IO&NS pathways. There is evidence that shared peripheral and / or central IO&NS pathways underpin the pathophysiology of depression and the previously mentioned disorders and that activation of these IO&NS pathways contributes to shared risk. The IO&NS pathways function as a smoke sensor that detect threats in the peripheral and central parts of the body and signal these threats as melancholic, anxiety, and fatigue and somatic (F&S) symptoms. The

				presence of concomitant depression is strongly associated with a lower quality of life and increased morbidity and mortality in medical disorders. This may be explained since depression contributes to increased (neuro)inflammatory burden and may therefore drive the inflammatory and degenerative progression. It is concluded that the activation of peripheral and / or central IO&NS pathways may explain the co-occurrence of depression with the above disorders. This shows that depression belongs to the spectrum of inflammatory and degenerative disorders.

Xenotropic murine leukaemia virus-related virus is not found in peripheral blood cells from treatment-naive human immunodeficiency virus-positive patients.	Clin Microbiol Infect. 2012 Feb;18(2):184-8. doi: 10.1111/j.1469-0691.2011.03580.x. Epub 2011 Jun 14.	Clin Microbiol Infect 2012; 18: 184-188 ABSTRACT: The human pathogen xenotropic murine leukaemia virus-related virus (XMRV) has been tentatively associated with prostate cancer and chronic fatigue syndrome. Unfortunately, subsequent studies failed to identify the virus in various clinical settings. To determine whether XMRV circulates in humans and the relationship with its host, we searched for the virus in 124 human immunodeficiency virus-infected patients who might have been exposed to XMRV, might be prone to infection as a result of progressive immunodeficiency, and had not yet been treated with antiretroviral drugs. Using nested PCR and single-step TaqMan real-time PCR, both designed on the XMRV gag gene, we could not find any positive samples. These findings add to the growing amount of scepticism regarding XMRV. © 2011 The Authors. Mahdi AA, Fatima G, Das SK, Verma NS.	Department of Biochemistry, C.S.M. Medical University U.P, Lucknow, 226 003, India. mahdiaa@rediffm	Abnormality of circadian rhythm of serum melatonin and other biochemical parameters in fibromyalgia syndrome.	Indian J Biochem Biophys. 2011 Apr;48(2):82-7.	Fibromyalgia syndrome (FMS) is a complex chronic condition causing widespread pain and variety of other symptoms. It produces pain in the soft tissues located around joints throughout the body. FMS has unknown etiology and its pathophysiology is not fully understood. However, abnormality in circadian rhythm of hormonal profiles and cytokines has been observed in this disorder. Moreover, there are reports of deficiency of serotonin, melatonin, cortisol and cytokines in FMS patients, which are fully regulated by circadian rhythm. Melatonin, the primary hormone of the pineal

	ail.com			gland regulates the body's circadian rhythm and normally its levels begin to rise in the mid-to-late evening, remain high for most of the night, and then decrease in the early morning. FMS patients have lower melatonin secretion during the hours of darkness than the healthy subjects. This may contribute to impaired sleep at night, fatigue during the day and changed pain perception. Studies have shown blunting of normal diurnal cortisol rhythm, with elevated evening serum cortisol level in patients with FMS. Thus, due to perturbed level of cortisol secretion several symptoms of FMS may occur. Moreover, disturbed cytokine levels have also been reported in FMS patients. Therefore, circadian rhythm can be an important factor in the pathophysiology, diagnosis and treatment of FMS. This article explores the circadian pattern of abnormalities in FMS patients, as this may help in better understanding the role of variation in symptoms of FMS and its possible relationship with circadian variations of melatonin, cortisol, cytokines and serotonin levels.
Maher-Edwards L, Fernie BA, Murphy G, Nikcevic AV, Spada MM.	Fatigue Service, Royal Free Hospital, London, UK.	Metacognitive Factors in Chronic Fatigue Syndrome.	Clin Psychol Psychother. 2011 May 12. doi: 10.1002/cpp.757. [Epub ahead of print]	Chronic fatigue syndrome (CFS), which is characterized by fatigue and flu-like symptoms that are not alleviated by rest, is a poorly understood condition and an often controversial diagnosis. Earlier research has indicated that general metacognitions are associated with the severity of symptoms in patients with CFS. In the current study, we aimed to determine whether specific metacognitive factors are implicated in CFS. Using the metacognitive profiling interview template we investigated the following: (1) whether patients held positive or negative metacognitions about conceptual processes; (2) what their goals with respect to engaging in these processes were; and (3) what indicated that it was appropriate to stop. We also examined attention focus when experiencing CFS symptoms, and its advantages and disadvantages. Results showed that patients endorsed positive and negative metacognitions pertaining to conceptual processes. The goals of engaging in these processes were to identify the cause of, and devise strategies to cope with, symptoms. Patients were either unable to identify a stop signal for conceptual processing or identified an improvement in fatigue-related symptoms as representing the stop signal. Finally, patients reported that their attention focus when experiencing symptoms included distraction and monitoring of symptoms. Advantages to these strategies included symptom management, whereas disadvantages included an escalation of negative affect. The present findings provide preliminary evidence that specific metacognitive factors may be involved in CFS. Copyright © 2011 John Wiley & Sons, Ltd. KEY PRACTITIONER MESSAGE: Metacognitive profiling that may aid assessment and conceptualisation of psychological distress in CFS. Copyright © 2011 John Wiley & Sons, Ltd.
Maher-Edwards L, Fernie BA, Murphy G, Wells A, Spada MM.	Fatigue Service, Royal Free Hospital, London, UK.	Metacognitions and negative emotions as predictors of symptom severity in	J Psychosom Res. 2011 Apr;70(4):311-7. Epub 2010 Nov 18.	OBJECTIVE: Chronic fatigue syndrome (CFS) describes a condition that is primarily characterized by fatigue and flu-like symptoms that are not alleviated by rest. This study investigated the relationship among metacognitions, negative emotions, and symptom severity in CFS. METHODS: A total of 96 patients who had received a

		chronic fatigue syndrome.		diagnosis of CFS according to the Oxford Criteria completed a battery of self-report measures that consisted of the Depression Anxiety Stress Scales, the 30-Item Metacognitions Questionnaire, the Chalder Fatigue Questionnaire (CFQ), and the RAND 36-Item Short-Form Health Survey-Physical Functioning. RESULTS: Correlation analyses showed that negative emotions and metacognitions were positively correlated with measures of symptom severity and that metacognitions were a better predictor of symptom severity than anxiety and depression. Hierarchical regression analyses indicated that (1) lack of cognitive confidence predicted both mental and physical factors of the CFQ and physical functioning independently of negative emotions and (2) beliefs about the need to control thoughts predicted the mental factor of the CFQ independently of negative emotions and lack of cognitive confidence. CONCLUSION: The data support the potential application of the metacognitive model of psychological disorder to understanding CFS. Copyright © 2011 Elsevier Inc. All rights reserved.
Makarova N, Zhao C, Zhang Y, Bhosle S, Suppiah S, Rhea JM, Kozyr N, Arnold RS, Ly H, Molinaro RJ, Parslow TG, Hunter E, Liotta D, Petros J, Blackwell JL.	Emory Vaccine Center, Emory University, Atlanta, Georgia, United States of America.	Antibody responses against xenotropic murine leukemia virus-related virus envelope in a murine model.	PLoS One. 2011 Apr 6;6(4):e18272. Erratum in PLoS One. 2011;6(5). doi:10.1371/annotation/913fdc1e-877e-4c70-ac20-761d2d72400d.	BACKGROUND: Xenotropic murine leukemia virus-related virus (XMRV) was recently discovered to be the first human gammaretrovirus that is associated with chronic fatigue syndrome and prostate cancer (PC). Although a mechanism for XMRV carcinogenesis is yet to be established, this virus belongs to the family of gammaretroviruses well known for their ability to induce cancer in the infected hosts. Since its original identification XMRV has been detected in several independent investigations; however, at this time significant controversy remains regarding reports of XMRV detection/prevalence in other cohorts and cell type/tissue distribution. The potential risk of human infection, coupled with the lack of knowledge about the basic biology of XMRV, warrants further research, including investigation of adaptive immune responses. To study immunogenicity in vivo, we vaccinated mice with a combination of recombinant vectors expressing codon-optimized sequences of XMRV gag and env genes and virus-like particles (VLP) that had the size and morphology of live infectious XMRV. RESULTS: Immunization elicited Env-specific binding and neutralizing antibodies (NAb) against XMRV in mice. The peak titers for ELISA-binding antibodies and NAb were 1:1024 and 1:464, respectively; however, high ELISA-binding and NAb titers were not sustained and persisted for less than three weeks after immunizations. CONCLUSIONS: Vaccine-induced XMRV Env antibody titers were transiently high, but their duration was short. The relatively rapid diminution in antibody levels may in part explain the differing prevalences reported for XMRV in various prostate cancer and chronic fatigue syndrome cohorts. The low level of immunogenicity observed in the present study may be characteristic of a natural XMRV infection in humans.

Mariman A, Vogelaers D, Hanoulle I, Delesie L, Tobback E, Pevernagie D.		Validation of the three-factor model of the PSQI in a large sample of chronic fatigue syndrome (CFS) patients.	J Psychosom Res. 2012 Feb;72(2):111-3. Epub 2011 Dec 22.	OBJECTIVE: To evaluate whether a 3-factor model of the Pittsburgh Sleep Quality Index (PSQI) scale would fit the constellation of sleep disturbances in patients with a diagnosis of chronic fatigue syndrome (CFS). METHODS: Consecutive CFS patients filled out the PSQI. Scores from this self-report questionnaire were examined with exploratory and confirmatory factor analysis (CFA). RESULTS: 413 CFS patients were included for analysis in this study. CFA showed that the 7 PSQI component scores clustered into the 3 factors reported by Cole et al. (2006), i.e. Sleep Efficiency, Perceived Sleep Quality and Daily Disturbances. In contrast with the single-factor and all 2-factor models, all factor loadings were significant, and all goodness-of-fit values were acceptable. CONCLUSION: In CFS, the PSQI operates as a 3-factor scoring model as initially seen in healthy and depressed older adults. The separation into 3 discrete factors suggests the limited usefulness of the global PSQI as a single factor for the assessment of subjective sleep quality, as also evidenced by a low Cronbach's alpha (0.64) in this patient sample. Markeljević J, Sarac H, Rados M.	University of Zagreb, School of Medicine, Zagreb University Hospital Centre, Department of Internal Medicine, Zagreb, Croatia. Jasenka-markeljevic@gmail.com	Tremor, seizures and psychosis as presenting symptoms in a patient with chronic lyme neuroborreliosis (LNB).	Coll Antropol. 2011 Jan;35 Suppl 1:313-8.	Lyme borreliosis is a multisystem disorder caused by Borrelia burgdorferi (Bb). Neurological symptoms such as lymphocytic meningoradiculoneuritis (Bannwart's syndrome), cranial neuritis (II,III,IV,V,VI), encephalitis, transverse myelitis are found in about 10% of cases during the second phase of the disease. In the chronic stage, many months or years after the initial infection, other neurologic complications may occur, such as encephalomyelitis, epileptic crises, cognitive impairment, peripheral neuropathy and psychiatric disturbances such as depression, anxiety, panicc attacks, catatonia, psychosis etc. Some patient continue to experience symptoms of fatigue, insomnia or psychiatric disorder in the post borrelia syndrome. We describe here a patient with a triad of unusual symptoms in chronic LNB including tremor, seizures and psychosis. Standardized medical interview, neurologic examination, neuroimaging, serum and CSF serology as well as EEG and EMNG evaluation were performed. The patient was treated with intravenous ceftriaxone and doxycycline and responded with rapid clinical and functional improvement.Newertheless, he suffered from multiple systemic and neurologic sequelas that influenced his daily activities in post treatment period. Emphasis is placed on the atypical onset and evolution, the difficulties encountered in formulating diagnosis, early treatment and the uncertainties concerning the sequelae after treatment. In patients with non-specific long lasting symptoms in the absence of overt clinical signs suggesting CNS

				involvement, routine treatment with i.v. ceftriaxone is not to be encouraged.
Marshall R, Paul L, Wood L.	Nursing & Health Care, Faculty of Medicine, University of Glasgow, Glasgow, Scotland, UK. r.marshall@clinmed.gla.ac.uk	The search for pain relief in people with chronic fatigue syndrome: a descriptive study.	Physiother Theory Pract. 2011 Jul;27(5):373-83. Epub 2010 Nov 1.	The purpose of this study was to investigate the use and perceived benefit of complimentary and alternative medicine (CAM) and physiotherapy treatments tried by people with chronic fatigue syndrome (CFS) to ease painful symptoms. This study used a descriptive, cross-sectional design. People with CFS who experienced pain were recruited to this study. Participants were asked during a semistructured interview about the treatments they had tried to relieve their pain. Each interview was conducted in the home of the participant. Fifty participants were recruited, of which, 10 participants were severely disabled by CFS. Eighteen participants were trying different forms of CAM treatment for pain relief at the time of assessment. Three participants were currently receiving physiotherapy. Throughout the duration of their illness 45 participants reported trying 19 different CAM treatments in the search for pain relief. Acupuncture was reported to provide the most pain relief (n=16). Twenty-seven participants reported a total of 16 different interventions prescribed by their physiotherapist. The results of this study suggest some physiotherapy and CAM treatments may help people manage painful CFS symptoms. Future research should be directed to evaluating the effectiveness of interventions such as acupuncture or gentle soft tissue therapies to reduce pain in people with CFS.
Masquelier E, Scaillet N, Luminet O, Desmet A, Grisart J.	Centre de Référence Multidisciplinaire de la Douleur Chronique UCL Mont-Godinne, Belgique. etienne.masquelier@uclouvain.be	[What's about overactive lifestyle in fibromyalgia and chronic fatigue syndrome]. [Article in French]	Rev Med Suisse. 2011 Jun 29;7(301):1421-2, 1424-5.	Fibromyalgia and chronic fatigue syndrome are clinical conditions different but they share common components, particularly multifactorial aetiology. High level of action proneness and "overactive" lifestyle can be considered as predisposing risk factors and perpetuating factors for these somatic functional syndromes. For the clinicians managing complex situations, only a holistic, circular and biopsychosocial approach could restore a new equilibrium (allostasis) with strategies of coping with chronic pain and planification of activities.
McCarberg BH.		Clinical Overview of Fibromyalgia.	Am J Ther. 2011 Feb 15. [Epub ahead of print]	Fibromyalgia (FM) is a complex disorder that affects up to 5% of the general population worldwide, more frequently in women than in men. In addition to chronic widespread pain, patients with FM usually experience other characteristic symptoms, including fatigue, disturbed sleep, stiffness, reduced functioning, dyscognition, and depressed mood. Many patients also have comorbid conditions such as depression, irritable bowel syndrome, temporomandibular disorder, or migraine. Although the etiology of FM remains unclear, evidence suggests that biologic, genetic, and environmental factors are involved. The variability of symptoms and the frequency of comorbidities among patients with FM make this a difficult disorder to diagnose. Diagnosis may be further complicated by the stigmatization of this disorder among treatment providers, the health insurance industry, and the general population. Treating chronic pain disorders such as FM can be time consuming and costly, and other issues such as polypharmacy, treatment adherence, and access to treatment

				often need to be addressed. The aim of this article is to provide physicians with a general overview of FM, including a brief review of the pathophysiology that explains the biologic and genetic bases of this disorder. Also included is a synopsis of new diagnostic criteria and other useful diagnostic tools and a discussion of various treatment challenges and strategies.
McDermott C, Lynch J, Leydon GM.	Primary Medical Care Research Department, University of Southampton, Southampton, UK. crm20@soton.ac.uk	Patients' hopes and expectations of a specialist chronic fatigue syndrome/ME service: a qualitative study.	Fam Pract. 2011 Oct;28(5):572-8. Epub 2011 May 9.	BACKGROUND: The 2007 National Institute for Health and Clinical Excellence guidelines on Chronic Fatigue Syndrome/Myalgic Encephalomyelitis (CFS/ME) recommend early management of the condition. Investment by the Department of Health has expanded the number of specialist U.K. CFS/ME services but there has been little research on what patients hope or expect from referral. METHODS: A qualitative study exploring hopes and expectations of patients newly referred to a CFS/ME Service in the South of England. Interviews with 20 patients were analysed using the constant comparative method. RESULTS: Participants hoped referral to a specialist service would clarify diagnosis, give guidance and support, assist in understanding the complexity of the illness and provide hope for the future. While many participants valued the support of their GP, all viewed referral as offering a level of specialist expertise beyond that available in primary care. Many participants expressed high levels of uncertainty about the nature of CFS/ME. While participants hoped that the service would be able to provide information and guidance, many expressed the view that more information earlier in their illness would make the waiting period less stressful and make it possible for them to do more to help themselves. CONCLUSIONS: GP referral to a specialist service appeared to be highly valued by the participants in this study. The levels of uncertainty expressed by many patients about the nature of CFS/ME raises the issue of the role of information on CFS/ME during the early stages of the illness and suggests a need for more reassurance and positive advice during the waiting period.

McMahon L, Murray C, Simpson J.	Tees Time to Talk IAPT Service , Middlesbrough , UK.	The potential benefits of applying a narrative analytic approach for understanding the experience of fibromyalgia: a review.	Disabil Rehabil. 2011 Nov 11. [Epub ahead of print]	Purpose: People with fibromyalgia (FM), a medically unexplained illness, habitually experience widespread pain and fatigue. While some qualitative research has aimed to understand the experiences of people with FM, studies from a specific narrative perspective are particularly lacking. This review argues that future research could be significantly enhanced by studies which analyse the narratives of people with FM. Method: This argument is made through reference to an examination of the extant qualitative literature on the experience of FM and theories and narrative studies on chronic illnesses and identity. Results: The empirical literature is reviewed from a narrative perspective; this assumes that the stories people tell reveal much about their identities and social worlds. As such, it is proposed that narrative analysis is

				particularly well suited for exploring issues of self and culture and for appreciating how meanings evolve over time. Further, it is also argued that consideration of these issues is particularly relevant for understanding the experience of FM given the enigmatic nature of the syndrome and its chronic course. Conclusions: The review concludes by emphasizing that narrative analysis is a valuable method which offers the potential for uncovering novel insights about the illness experience for these individuals. [Box: see text].
Meeus M, Ickmans K, De Clerck LS, Moorkens G, Hans G, Grosemans S, Nijs J.	Department of Human Physiology, Faculty of Physical Education and Physiotherapy, Vrije Universiteit Brussel, Building L-Mfys, Pleinlaan 2, 1050 Brussels, Belgium. Mira.Meeus@vub.ac.be	Serotonergic descending inhibition in chronic pain: design, preliminary results and early cessation of a randomized controlled trial.	In Vivo. 2011 Nov-Dec;25(6):1019-25.	AIM: We examined whether activation of serotonergic descending pathways improves pain inhibition during exercise in patients with chronic fatigue syndrome (CFS) and comorbid fibromyalgia (FM) in comparison with rheumatoid arthritis (RA) and sedentary, healthy controls in a double-blind randomized controlled trial with cross-over design. PATIENTS AND METHODS: Three female CFS/FM patients, one female RA patient and two healthy women were randomly allocated to the experimental group (2 ml of citalopram intravenously) or the placebo group (2 ml of 0.9% NaCl intravenously). Participants performed a submaximal exercise protocol, preceded and followed by an assessment of endogenous pain inhibition. Seven days later, groups were crossed over. RESULTS: Significant side-effects were observed in all, but one participant immediately after intravenous administration of citalopram. One CFS/FM patient withdrew because of severe post-exertional malaise. CONCLUSION: It was decided that proceeding with the study would be unethical. No conclusion could be made regarding pain inhibition during exercise in CFS/FM compared to RA and controls.
Meeus M, van Eupen I, van Baarle E, De Boeck V, Luyckx A, Kos D, Nijs J.	Division of Musculoskeletal Physiotherapy, Department of Health Sciences, Artesis University College Antwerp, Belgium.	Symptom fluctuations and daily physical activity in patients with chronic fatigue syndrome: a case-control study.	Arch Phys Med Rehabil. 2011 Nov;92(11):1820-6.	OBJECTIVES: To compare the activity pattern of patients with chronic fatigue syndrome (CFS) with healthy sedentary subjects and examine the relationship between the different parameters of performed activity (registered by an accelerometer device) and symptom severity and fluctuation (registered by questionnaires) in patients with CFS. DESIGN: Case-control study. Participants were asked to wear an accelerometer device on the nondominant hand for 6 consecutive days. Every morning, afternoon, and evening patients scored the intensity of their pain, fatigue, and concentration difficulties on a visual analog scale. SETTING: Patients were recruited from a specialized chronic fatigue clinic in the university hospital, where all subjects were invited for 2 appointments (for questionnaire and accelerometer adjustments). In between, activity data were collected in the subject's normal home environment. PARTICIPANTS: Female patients (n=67) with CFS and female age-matched healthy sedentary controls. INTERVENTIONS: Not applicable. MAIN OUTCOME MEASURES: Accelerometry (average activity counts, peak activity counts, ratio peak/average, minutes spent per activity category) and symptom severity (intensity of pain, fatigue, and concentration difficulties). RESULTS: Patients with CFS were less active, spent more time sedentary, and less time lightly active (P<.05). The course of the activity level during the registration period (P

				interaction>.05), peak activity, and the staggering of activities (ratio peak/average) on 1 day were not different between groups (P>.05). Negative correlations (-.242 varying to -.307) were observed for sedentary activity and the ratio with symptom severity and variation on the same and the next day. Light, moderate, and vigorous, as well as the average activity and the peak activity, were positively correlated (.242 varying to .421) with symptom severity and variation. CONCLUSIONS: The more patients with CFS are sedentary and the better activity is dispersed, the fewer symptoms and variations they experience on the same and next day. Inversely, more symptoms and variability is experienced when patients were more active that day or the previous day. The direction of these relations cannot be determined in a cross-sectional study and requires further study. Copyright © 2011 American Congress of Rehabilitation Medicine. Published by Elsevier Inc. Meeus M, Van Eupen I, Willems J, Kos D, Nijs J.	Division of Musculoskeletal Physiotherapy, Department of Health Sciences, Artesis University College Antwerp (AHA), Antwerp, Belgium.	Is the International Physical Activity Questionnaire-short form (IPAQ-SF) valid for assessing physical activity in Chronic Fatigue Syndrome?	Disabil Rehabil. 2011;33(1):9-16. Epub 2010 May 6.	PURPOSE: To evaluate the criterion validity and internal consistency of the International Physical Activity Questionnaire-short form (IPAQ-sf) in Chronic Fatigue Syndrome (CFS) patients. METHOD: Fifty-six CFS patients completed the IPAQ-sf after they wore a tri-axial accelerometer and filled out activity diaries during 1 week. Spearman rank correlation coefficients and Cronbach's Alpha were calculated. RESULTS: The IPAQ-sf correlated significantly with the energy expenditure and Metabolic Equivalents (METs) minutes spent moderately to vigorously active following the activity diary and accelerometer. These correlation coefficients were however low (r varying between 0.282 and 0.426) and rather irrelevant, since CFS patients hardly reach moderate or vigorous activity levels. Internal consistency between the three subitems used for the total score of the IPAQ-sf was 0.337. CONCLUSION: The observed associations between the IPAQ-sf data and the data obtained from the accelerometer (gold standard) and the diaries were too low to be in support of the use of the IPAQ-sf in patients with CFS. The IPAQ-sf does not seem an appropriate tool to assess physical activity in CFS patients. Further study is required to seek for a valid, practical and affordable tool.
Mendoza R, Vaughan AE, Miller AD.	Human Biology Division, Fred Hutchinson Cancer Research Center, 1100 Fairview Ave. N., Seattle, WA 98109-1024, USA.	The left half of the XMRV retrovirus is present in an endogenous retrovirus of NIH/3T3 Swiss mouse cells.	J Virol. 2011 Sep;85(17):9247-8. Epub 2011 Jun 22.	Xenotropic murine leukemia virus-related virus (XMRV) is a gammaretrovirus found in association with human prostate cancer and chronic fatigue syndrome, although these associations are controversial. XMRV shows at most 94% identity to known mouse retroviruses. Here we used XMRV-specific PCR to search for a more closely related source of XMRV in mice. While we could not find a complete copy, we did find a 3,600-bp region of XMRV in an endogenous retrovirus present in NIH/3T3 cells. These results show that XMRV has clear ancestors in mice and highlight another possible source of contamination in PCR assays for XMRV.
Menéndez-Arias L.	Consejo Superior de Investigaciones Científicas and	Evidence and controversies on the role of XMRV in prostate cancer and	Rev Med Virol. 2011 Jan;21(1):3-17. doi: 10.1002/rmv.673. Epub 2010 Nov 26.	The recent discovery of xenotropic murine leukaemia virus-related virus (XMRV) in prostate cancer tissues and in the blood of individuals suffering from chronic fatigue syndrome has attracted considerable interest. However, the relevance and significance of XMRV to human disease remain unclear, since the association has not

	Universidad Autónoma de Madrid, Madrid, Spain. lmenendez@cbm.uam.es	chronic fatigue syndrome.		been confirmed in other studies. XMRV is the first gammaretrovirus to be found in humans. XMRV and murine leukaemia viruses share similar structures and genomic organisation. Human restriction factors such as APOBEC3 or tetherin inhibit XMRV replication. Although XMRV induces low rates of transformation in cell culture, it might be able to induce cancer by low-frequency insertional activation of oncogenes or through the generation of highly active transforming viruses. A preference for regulatory regions of transcriptional active genes has been observed after a genomic-wide analysis of XMRV integration sites. Genes related to carcinogenesis and androgen signalling have been identified in the vicinity of integration sites. The XMRV genome contains a glucocorticoid responsive element, and androgens could modulate viral replication in the prostate. Evidence supporting the involvement of XMRV in chronic fatigue syndrome is still very weak, and needs further confirmation and validation. Currently approved anti-retroviral drugs such as zidovudine, tenofovir and raltegravir are efficient inhibitors of XMRV replication in vitro. These drugs might be useful to treat XMRV infection in humans. The identification of XMRV has potentially serious health implications for the implementation of novel techniques including gene therapy or xenotransplantation, while raising concerns on the need for screening donated blood to prevent transmission through transfusion. Mets MA, Ketzer S, Blom C, van Gerven MH, van Willigenburg GM, Olivier B, Verster JC.	Division of Pharmacology, Utrecht Institute for Pharmaceutical Sciences, Utrecht University, P.O. Box 80082, 3508 TB, Utrecht, The Netherlands.	Positive effects of Red Bull® Energy Drink on driving performance during prolonged driving.	Psychopharmacology (Berl). 2011 Apr;214(3):737-45. Epub 2010 Nov 10.	BACKGROUND: The purpose of this study was to examine if Red Bull® Energy Drink can counteract sleepiness and driving impairment during prolonged driving. METHODS: Twenty-four healthy volunteers participated in this double-blind placebo-controlled crossover study. After 2 h of highway driving in the STISIM driving simulator, subjects had a 15-min break and consumed Red Bull® Energy Drink (250 ml) or placebo (Red Bull® Energy Drink without the functional ingredients: caffeine, taurine, glucuronolactone, B vitamins (niacin, pantothenic acid, B6, B12), and inositol) before driving for two additional hours. A third condition comprised 4 h of uninterrupted driving. Primary parameter was the standard deviation of lateral position (SDLP), i.e., the weaving of the car. Secondary parameters included SD speed, subjective driving quality, sleepiness, and mental effort to perform the test. RESULTS: No significant differences were observed during the first 2 h of driving. Red Bull® Energy Drink significantly improved driving relative to placebo: SDLP was significantly reduced during the 3rd ($p < 0.046$) and 4th hour of driving ($p < 0.011$). Red Bull® Energy Drink significantly reduced the standard deviation of speed ($p < 0.004$), improved subjective driving quality ($p < 0.0001$), and reduced mental effort to perform the test ($p < 0.024$) during the 3rd hour of driving. Subjective sleepiness was significantly decreased during both the 3rd and 4th hour of driving after Red Bull® Energy Drink ($p < 0.001$ and $p < 0.009$, respectively). Relative to uninterrupted driving, Red Bull® Energy Drink significantly improved each parameter. CONCLUSION: Red Bull® Energy Drink significantly improves driving performance and reduces driver

				sleepiness during prolonged highway driving.
Mi Z, Lu Y, Zhang S, An X, Wang X, Chen B, Wang Q, Tong Y.	Beijing Institute of Microbiology and Epidemiology and Affiliated Hospital, Academy of Military Medical Sciences, Beijing, China. zhiqiangmi@yahoo.com.cn	Absence of xenotropic murine leukemia virus-related virus in blood donors in China.	Transfusion. 2012 Feb;52(2):326-31. doi: 10.1111/j.1537-2995.2011.03267.x. Epub 2011 Aug 19.	BACKGROUND: Xenotropic murine leukemia virus-related virus (XMRV) is a novel human gammaretrovirus that was first identified in patients with prostate cancer in 2006. Subsequent studies have shown that XMRV is also detected in patients with chronic fatigue syndrome (CFS) and even in some healthy controls and blood donors. However, some conflicting findings have been reported by different laboratories or in different regions. The association of XMRV with human diseases and the prevalence of XMRV in different populations needs to be further determined. STUDY DESIGN AND METHODS: XMRV was screened in 391 blood samples from healthy blood donors in China. Nested reverse transcription-polymerase chain reaction (PCR) was used to amplify gag and env genes of XMRV from total RNA of peripheral blood mononuclear cells (PBMNCs) and plasma, respectively. Quantitative PCR was performed to detect XMRV env gene in genomic DNA of PBMNCs. To enhance the detection sensitivity, plasma was added into LNCaP cells to amplify XMRV in the plasma samples. RESULTS: No XMRV was found in the 391 blood donors in China or in the LNCaP cells inoculated with plasma from the blood donors. CONCLUSION: Both PCR and virus isolation in highly permissive LNCaP cells failed to detect XMRV in 391 Chinese blood donors, indicating that XMRV infection might not be present in blood donors in China. © 2012 American Association of Blood Banks.
Minetto MA, Lanfranco F, Botter A, Motta G, Mengozzi G, Giordano R, Picu A, Ghigo E, Arvat E.	Division of Endocrinology, Diabetology and Metabolism, Department of Internal Medicine, Molinette Hospital, University of Turin, C.so Dogliotti 14, 10126 Turin, Italy. marco.minetto@unito.it	Do muscle fiber conduction slowing and decreased levels of circulating muscle proteins represent sensitive markers of steroid myopathy? A pilot study in Cushing's disease.	Eur J Endocrinol. 2011 Jun;164(6):985-93. Epub 2011 Mar 14.	OBJECTIVE: Glucocorticoids are known to decrease protein synthesis and conduction velocity of muscle fibers. However, the degree of impairment of muscle protein synthesis and conduction slowing in patients with Cushing's disease remains poorly characterized. Our objective was to investigate whether and to what extent chronic endogenous hypercortisolism could decrease the circulating levels of muscle proteins and modify myoelectric indexes of sarcolemmal excitability and fatigability. DESIGN: A total of ten patients with Cushing's disease and 30 healthy controls matched for age, sex, and body mass index were compared. METHODS: Blood sampling and electrophysiological tests on vastus lateralis, vastus medialis, and tibialis anterior muscles were performed. RESULTS: Serum creatine kinase (CK) and plasma myoglobin were significantly lower in patients with respect to controls ($P<0.001$ and $P<0.05$ respectively): the mean relative difference between patients and controls was 48.9% for CK and 21.4% for myoglobin. Muscle fiber conduction velocity (MFCV) and myoelectric manifestations of fatigue were significantly decreased in all muscles of the patients with respect to controls. The mean relative difference in MFCV between patients and controls was 26.0% for vastus lateralis, 22.9% for vastus medialis, and 11.6% for tibialis anterior. These differences contrasted with the paucity of signs suggestive of myopathy that were obtained by needle electromyography in the patients. CONCLUSIONS: Slowing of muscle fiber conduction and decreased levels of circulating muscle proteins are sensitive markers of impaired muscle function, which are suitable for use in combination with clinical assessment and standard

				electrodiagnostic tests for accurate identification and follow-up of myopathic patients.
Missen A, Hollingworth W, Eaton N, Crawley E.	School of Social and Community Medicine, University of Bristol School of Health and Social Care, University of West of England, Bristol, UK.	The financial and psychological impacts on mothers of children with chronic fatigue syndrome (CFS/ME).	Child Care Health Dev. 2011 Sep 1. doi: 10.1111/j.1365-2214.2011.01298.x. [Epub ahead of print]	Background Paediatric chronic fatigue syndrome or myalgic encephalopathy (CFS/ME) is relatively common and children can be severely affected attending little or no school for extended periods. There are no studies quantifying the financial impact of having a child with CFS/ME and there is little information of the impact on parental mood. Methods Forty mothers of children with CFS/ME from a regional specialist CFS/ME service completed inventories to assess their psychological well-being (Hospital Anxiety and Depression Scale, General Health Questionnaire-12) loss of earnings and increased expenditure. In addition, eight mothers took part in a semi-structured qualitative interview. Results Most parents of children with CFS/ME experience loss of monthly income (mean =£247) and increase in monthly expenditure (mean =£206). Twenty-eight (72%) mothers were above the cut-off for the General Health Questionnaire-12 compared with 20% in the healthy population (95% CI 55, 85, P < 0.001) suggesting they probably have a mental health problem. This may be explained by the qualitative interviews where mothers described five areas contributing to poor parental health: lack of understanding from others; marital tension; concern about their child's distress; concern about the impact on siblings and emotional distress causing physical symptoms. Conclusions The majority of families of children with CFS/ME experience decreased income and increased expenditure with a marked impact on maternal psychological health. Clinicians need to be aware of this to provide appropriate support to families who care for children with CFS/ME. © 2011 Blackwell Publishing Ltd.

Miwa K, Fujita M.		Is small heart syndrome a "heart" disease or low output syndrome?	Int J Cardiol. 2011 Jan 7;146(1):95-6. Epub 2010 Nov 12.	
Miwa K, Fujita M.	Department of Internal Medicine, Miwa	Small heart with low cardiac output for orthostatic	Clin Cardiol. 2011 Dec;34(12):782-6. doi: 10.1002/clc.20962.	BACKGROUND: The etiology of chronic fatigue syndrome (CFS) is unknown. Orthostatic intolerance (OI) is common in CFS patients. Recently, small heart with low cardiac output has been postulated to be related to the genesis of both CFS and OI.

	Naika Clinic, Toyama, Japan. info@miwa-naika.com	intolerance in patients with chronic fatigue syndrome.	Epub 2011 Nov 28.	HYPOTHESIS: Small heart is associated with OI in patients with CFS. METHODS: Study CFS patients were divided into groups of 26 (57%) CFSOI(+) and 20 (43%) CFSOI(-) according to the presence or absence of OI. In addition, 11 OI patients and 27 age- and sex-matched control subjects were studied. Left ventricular (LV) dimensions and function were determined echocardiographically. RESULTS: The mean values of cardiothoracic ratio, systemic systolic and diastolic pressures, LV end-diastolic dimension, LV end-systolic dimension, stroke volume index, cardiac index, and LV mass index were all significantly smaller in CFSOI(+) patients than in CFSOI(-) patients and healthy controls, and also in OI patients than in controls. A smaller LV end-diastolic dimension (<40 mm) was significantly (P<0.05) more prevalently noted in CFSOI(+) (54%) and OI (45%) than in CFSOI(-) (5%) and controls (4%). A lower cardiac index (<2 L/min/mm(2)) was more prevalent in CFSOI(+) (65%) than in CFSOI(-) (5%, P<0.01), OI (27%), and controls (11%, P<0.01). CONCLUSIONS: A small size of LV with low cardiac output was noted in OI, and its degree was more pronounced in CFSOI(+). A small heart appears to be related to the genesis of OI and CFS via both cerebral and systemic hypoperfusion. CFSOI(+) seems to constitute a well-defined and predominant subgroup of CFS. © 2011 Wiley Periodicals, Inc.
Moldofsky H, Patcai J.	Sleep Disorders Clinic of the Centre for Sleep and Chronobiology, 340 College St,, Suite 580, Toronto, ON M5T 3A9, Canada. h.moldofsky@utoronto.ca	Chronic widespread musculoskeletal pain, fatigue, depression and disordered sleep in chronic post-SARS syndrome; a case-controlled study.	BMC Neurol. 2011 Mar 24;11:37.	BACKGROUND: The long term adverse effects of Severe Acute Respiratory Syndrome (SARS), a viral disease, are poorly understood. METHODS: Sleep physiology, somatic and mood symptoms of 22 Toronto subjects, 21 of whom were healthcare workers, (19 females, 3 males, mean age 46.29 yrs.+/- 11.02) who remained unable to return to their former occupation (mean 19.8 months, range: 13 to 36 months following SARS) were compared to 7 healthy female subjects. Because of their clinical similarities to patients with fibromyalgia syndrome (FMS) these post-SARS subjects were similarly compared to 21 drug free female patients, (mean age 42.4 +/- 11.8 yrs.) who fulfilled criteria for fibromyalgia. RESULTS: Chronic post-SARS is characterized by persistent fatigue, diffuse myalgia, weakness, depression, and nonrestorative sleep with associated REM-related apneas/hypopneas, an elevated sleep EEG cyclical alternating pattern, and alpha EEG sleep anomaly. Post- SARS patients had symptoms of pre and post-sleep fatigue and post sleep sleepiness that were similar to the symptoms of patients with FMS, and similar to symptoms of patients with chronic fatigue syndrome. Both post-SARS and FMS groups had sleep instability as indicated by the high sleep EEG cyclical alternating pattern rate. The post-SARS group had a lower rating of the alpha EEG sleep anomaly as compared to the FMS patients. The post-SARS group also reported less pre-sleep and post-sleep musculoskeletal pain symptoms. CONCLUSIONS: The clinical and sleep features of chronic post-SARS form a syndrome of chronic fatigue, pain, weakness, depression and sleep disturbance, which overlaps with the clinical and sleep features of FMS and chronic fatigue syndrome.
Morell-Dubois S,	Service de	[Complaints, needs	Rev Med Interne. 2011	PURPOSE: Systemic sclerosis (ScS) is very heterogeneous in its clinical presentation

Condette-Wojtasik G, Clerson P, Berezné A, Launay D, Lambert M, Maillard-Lefebvre H, Hatron PY, Hachulla E.	Médecine Interne, Centre de Référence des Maladies Auto-immunes et des Maladies Systémiques Rares, Sclérodermie Systémique, Hôpital Huriez, CHRU de Lille, rue Michel-Polonovski, 59037 Lille cedex, France. sandrine.morell@wanadoo.fr	of patients with systemic sclerosis: a better understanding for a better care]. [Article in French]	Sep;32(9):537-43. Epub 2011 Mar 9.	and its therapeutic care is not codified. A better knowledge of the patients' needs and complaints could improve the patient educational strategies and their global care. METHODS: A self-administered questionnaire aimed to the ScS patient was developed by subspecialty physicians and nurses involved in patient education. It was a cross-sectional study that also included several validated scales: the health control locus scale, the Mactar, HAD and sHAQ scales. RESULTS: One hundred and eight patients (91 women; 18 limited ScS, 71 limited cutaneous ScS, 19 diffuse ScS) filled in the questionnaires. Fatigue was the main complaint in all types of ScS, independently of the ScS type. The aesthetic discomfort mentioned by the patients suffering from cutaneous sclerosis or from telangectasia was important and reached 52±33mm on a 100-mm visual scale. It was more common in the patients presenting a diffuse form of the illness but the difference did not reach a statistical significance (P=0.06). Twenty-seven percent of the patients said they were very or extremely worried because of the degradation of their physical appearance. The functional discomfort linked to the cutaneous sclerosis was rated 50±32mm on a 100-mm visual scale. The intensity of the pain, the importance of the functional discomfort linked to the sclerosis and the intensity of the dyspnea were correlated to the sHAQ (P<0.001). Patients having more frequent recurrent digital ulcers had higher sHAQ scores (P=0.04). The repercussions on the professional life were linked to fatigue first, to the Raynaud's syndrome and to arthralgia. The repercussions on the personal life were mainly linked to the fatigue, the pain and the dyspnea. The patients' compliance was good. CONCLUSION: Fatigue, pain, dyspnea and discomfort linked to sclerosis are major chronic symptoms of the patients with ScS. Identifying the needs and complaints of the patients with ScS should help to improve their care by implementation of an educational program. Morelli V.	Department of Family and Community Medicine, Meharry Medical College, 1005 Dr. D.B. Todd Jr. Boulevard, Nashville, TN 37208, USA. vmorelli@mmc.edu	Fatigue and chronic fatigue in the elderly: definitions, diagnoses, and treatments.	Clin Geriatr Med. 2011 Nov;27(4):673-86.	Because fatigue is so prevalent in the elderly population, it is important that physicians be well versed in the evaluation and management of this complaint. This article discusses the clinical manifestations and predisposing factors for the three major categories of fatigue: recent, prolonged, and chronic. The CDC classification of chronic fatigue syndrome is included. Patient dissatisfaction with the care for their fatigue is a common problem. Several pharmaceutical treatment methods are presented. Non-pharmacologic options, such as use of vitamins, exercise, behavior modification,and diet are also discussed.
Moriya J, Chen R, Yamakawa J,	Department of General	Resveratrol improves hippocampal atrophy	Biol Pharm Bull. 2011 Mar;34(3):354-9.	Neuroimaging evidence showed structural and/or functional abnormalities existing in the central nervous system, especially the hippocampus, in chronic fatigue syndrome

Sasaki K, Ishigaki Y, Takahashi T.	Medicine, Kanazawa Medical University, Ishikawa 920–0293, Japan.	in chronic fatigue mice by enhancing neurogenesis and inhibiting apoptosis of granular cells.		(CFS) patients. However, its pathophysiologic mechanisms are unclear in part due to the lack of an applicable animal model. We established a chronic fatigue murine model by six repeated injections of Brucella abortus antigen to mice, which was manifested as reduced daily running activity and hippocampal atrophy. Thereafter, resveratrol, a polyphenolic activator of sirtuin 1, was used for treatment in this model. Daily running activity was increased by more than 20%, and the hippocampus was enlarged after 4-week resveratrol therapy. Furthermore, resveratrol inhibited neuronal apoptosis and expression of hippocampal acetylated p53 in the fatigue mice. Resveratrol also improved neurogenesis and expression of brain-derived neurotrophic factor mRNA in the hippocampus. We concluded that repeated injection of B. abortus antigen could induce hypoactivity and hippocampal atrophy in mice. Resveratrol may be effective for improving fatigue symptoms and enlarging the atrophic hippocampus by repressing apoptosis and promoting neurogenesis.
Morrissey RP, Czer L, Shah PK.	Cedars-Sinai Heart Institute, Cedars-Sinai Medical Center, Los Angeles, CA 90048, USA.	Chronic heart failure: current evidence, challenges to therapy, and future directions.	Am J Cardiovasc Drugs. 2011 Jun 1;11(3):153-71. doi: 10.2165/11592090-000000000-00000.	Heart failure (HF) is a complex syndrome characterized by the inability of the heart to maintain a normal cardiac output without elevated intracardiac filling pressures, resulting in signs of pulmonary and peripheral edema and symptoms of dyspnea and fatigue. Central to the management of HF is a multifaceted pharmacological intervention to abate the harmful counter-regulatory effects of neurohormonal activation and avid salt and water retention. Whereas up to 40 years ago HF was managed with diuretics and leaf of digitalis, the cornerstones of therapy for HF patients with systolic dysfunction now include ACE inhibitors or angiotensin II type 1 receptor antagonists (angiotensin receptor blockers), β-adrenoceptor antagonists (β-blockers), and aldosterone antagonists, which have significantly improved survival. However, with the increasing number of beneficial therapies, there are challenges to implementing all of them. Specific cardiomyopathies also merit specific considerations with respect to treatment, and - unfortunately - there is no therapy for HF with preserved left ventricular ejection fraction that has been shown to improve survival. Although mortality has improved in HF, the biggest challenge to treatment lies in addressing the morbidity of this disease, which is now the most common reason for hospital admission in our aged population. As such, there are many therapies that may serve to improve the quality of life of HF patients. Future HF treatment regimens may include direct cellular therapy via hormone and cytokine signaling or cardiac regeneration through growth factors or cell therapy.
Moss-Morris R, Spence MJ, Hou R.	School of Psychology, University of Southampton, Highfield, Southampton, UK.	The pathway from glandular fever to chronic fatigue syndrome: can the cognitive behavioural model provide the map?	Psychol Med. 2011 May;41(5):1099-107. Epub 2010 Jul 21.	BACKGROUND: The cognitive behavioural model of chronic fatigue syndrome (CFS) suggests that the illness is caused through reciprocal interactions between physiology, cognition, emotion and behaviour. The purpose of this study was to investigate whether the psychological factors operationalized in this model could predict the onset of CFS following an acute episode of infectious mononucleosis commonly known as glandular fever (GF). METHOD: A total of 246 patients with GF were recruited into this prospective cohort study. Standardized self-report measures of

	remm@soton.ac.uk			perceived stress, perfectionism, somatization, mood, illness beliefs and behaviour were completed at the time of their acute illness. Follow-up questionnaires determined the incidence of new-onset chronic fatigue (CF) at 3 months and CFS at 6 months post-infection. RESULTS: Of the participants, 9.4% met the criteria for CF at 3 months and 7.8% met the criteria for CFS at 6 months. Logistic regression revealed that factors proposed to predispose people to CFS including anxiety, depression, somatization and perfectionism were associated with new-onset CFS. Negative illness beliefs including perceiving GF to be a serious, distressing condition, that will last a long time and is uncontrollable, and responding to symptoms in an all-or-nothing behavioural pattern were also significant predictors. All-or-nothing behaviour was the most significant predictor of CFS at 6 months. Perceived stress and consistently limiting activity at the time of GF were not significantly associated with CFS. CONCLUSIONS: The findings from this study provide support for the cognitive behavioural model and a good basis for developing prevention and early intervention strategies for CFS.
Mount DL, Johnson DM, Rego MI, Schofield K, Amponsah A, Graham LF.	Wake Forest University School of Medicine, Winston-Salem, NC 27157, USA. Dmount@wfubmc.edu	Preliminary findings exploring the social determinants of Black males' lay health perspectives.	Am J Mens Health. 2012 Jan;6(1):71-9. Epub 2011 Nov 21.	The unequal discussion of Black males' health is a pressing social problem. This study addressed Black males' lay perspectives regarding their health, illness, and mortality, with attention to the determinants of men's health, prevention, lifestyle, and opportunities for health promotion using an exploratory/qualitative research methodology. Participants were 68 Black males aged 15 to 68 years, with an average age of 44 years (SD = 14.5). The narratives represented a complex interplay of biopsychosocial factors, ranging from intrapersonal attitudes, interpersonal experiences to discussions about community and public policy injustices. Five prominent themes emerged: (a) lack of chronic disease awareness, (b) fatalism, (c) fear and anxiety of academic-medical settings, (d) hyperactive masculinity fatigue, and (e) the gay-straight divide. The term Tired Black Male Health syndrome was coined in the forum. Implications of these findings are discussed in the context of culturally relevant strategies for improving Black male community health engagement.
Nacul LC, Lacerda EM, Campion P, Pheby D, Drachler Mde L, Leite JC, Poland F, Howe A, Fayyaz S, Molokhia M.	Department of Nutrition and Public Health Interventions Research, London School of Hygiene and Tropical Medicine, Keppel Street, London, WC1E 7HT, UK. luis.nacul@lshtm.	The functional status and well being of people with myalgic encephalomyelitis/chronic fatigue syndrome and their carers.	BMC Public Health. 2011 May 27;11:402.	BACKGROUND: Diagnosis of myalgic encephalomyelitis/chronic fatigue syndrome or ME/CFS is largely based on clinical history, and exclusion of identifiable causes of chronic fatigue. Characterization of cases and the impact of interventions have been limited due to clinical heterogeneity and a lack of reliable biomarkers for diagnosis and outcome measures. People with ME/CFS (PWME) often report high levels of disability, which are difficult to measure objectively. The well being of family members and those who care for PWME are also likely to be affected. This study aimed to investigate the functional status and well being of PWME and their lay carers, and to compare them with people with other chronic conditions. METHODS: We used a cross sectional design to study 170 people aged between 18 and 64 years with well characterized ME/CFS, and 44 carers, using SF-36 v2™. Mean physical and

	ac.uk			mental domains scores (scales and component summaries) were calculated and compared internally and externally with reference standards for the general population and for population groups with 10 chronic diseases. RESULTS: SF-36 scores in PWME were significantly reduced, especially within the physical domain (mean norm-based Physical Component Summary (PCS) score = 26.8), but also within the mental domain (mean norm-based score for Mental Component Summary (MCS) = 34.1). The lowest and highest scale scores were for "Role-Physical" (mean = 25.4) and "Mental Health" (mean = 36.7) respectively. All scores were in general lower than those for the general population and diseased-specific norms for other diseases. Carers of those with ME/CFS tended to have low scores in relation to population norms, particularly within the mental domain (mean = 45.4). CONCLUSIONS: ME/CFS is disabling and has a greater impact on functional status and well being than other chronic diseases such as cancer. The emotional burden of ME/CFS is felt by lay carers as well as by people with ME/CFS. We suggest the use of generic instruments such as SF-36, in combination of other objective outcome measurements, to describe patients and assess treatments.
Nacul LC, Lacerda EM, Pheby D, Campion P, Molokhia M, Fayyaz S, Leite JC, Poland F, Howe A, Drachler ML.	Department of Nutrition and Public Health Interventions Research, London School of Hygiene and Tropical Medicine, Keppel Street, London, WC1E 7HT, UK. Luis.Nacul@lshtm.ac.uk	Prevalence of myalgic encephalomyelitis/chronic fatigue syndrome (ME/CFS) in three regions of England: a repeated cross-sectional study in primary care.	BMC Med. 2011 Jul 28;9:91.	BACKGROUND: Myalgic encephalomyelitis/chronic fatigue syndrome (ME/CFS) or chronic fatigue syndrome (CFS) has been used to name a range of chronic conditions characterized by extreme fatigue and other disabling symptoms. Attempts to estimate the burden of disease have been limited by selection bias, and by lack of diagnostic biomarkers and of agreed reproducible case definitions. We estimated the prevalence and incidence of ME/CFS in three regions in England, and discussed the implications of frequency statistics and the use of different case definitions for health and social care planning and for research. METHODS: We compared the clinical presentation, prevalence and incidence of ME/CFS based on a sample of 143,000 individuals aged 18 to 64 years, covered by primary care services in three regions of England. Case ascertainment involved: 1) electronic search for chronic fatigue cases; 2) direct questioning of general practitioners (GPs) on cases not previously identified by the search; and 3) clinical review of identified cases according to CDC-1994, Canadian and Epidemiological Case (ECD) Definitions. This enabled the identification of cases with high validity. RESULTS: The estimated minimum prevalence rate of ME/CFS was 0.2% for cases meeting any of the study case definitions, 0.19% for the CDC-1994 definition, 0.11% for the Canadian definition and 0.03% for the ECD. The overall estimated minimal yearly incidence was 0.015%. The highest rates were found in London and the lowest in East Yorkshire. All but one of the cases conforming to the Canadian criteria also met the CDC-1994 criteria, however presented higher prevalence and severity of symptoms. CONCLUSIONS: ME/CFS is not uncommon in England and represents a significant burden to patients and society. The number of people with chronic fatigue who do not meet specific criteria for ME/CFS is higher still. Both groups have high levels of need for service provision, including health and

				social care. We suggest combining the use of both the CDC-1994 and Canadian criteria for ascertainment of ME/CFS cases, alongside careful clinical phenotyping of study participants. This combination if used systematically will enable international comparisons, minimization of bias, and the identification and investigation of distinct sub-groups of patients with possibly distinct aetiologies and pathophysiologies, standing a better chance of translation into effective specific treatments.
Nas K, Cevik R, Batum S, Sarac AJ, Acar S, Kalkanli S.	Departments of Physical Medicine and Rehabilitation, School of Medicine, Dicle University, Diyarbakir, Turkey. knas@dicle.edu.tr	Immunologic and psychosocial status in chronic fatigue syndrome.	Bratisl Lek Listy. 2011;112(4):208-12.	OBJECTIVE: The aim of the study was to investigate the immunologic functions and psychosocial status in patients with chronic fatigue syndrome (CFS). METHODS: Twenty-five patients with CFS diagnosed by the international CFS definition criteria and 20 age- and gender-matched healthy controls were recruited. Depression was assessed by Beck Depression Inventory (BDI) and health status was assessed by Nottingham Health Profile (NHP). Monoclonal antibodies (MAbs) were measured to identify the following NK cell subsets: CD3, CD4, CD8 and CD56 and cytokine measurements were performed for IL2r, IL6 and IL8 in both patients and control subjects. RESULTS: The BDI and NHP scores of CFS group were found to be significantly higher than in the control group. The absolute numbers of CD56 cell were also significantly decreased in the patients with CFS compared with the healthy controls. There were no other significant differences of NK cell activity (CD3, CD4 and CD8) and there were significant differences in IL6 and IL2r levels between patients and controls. There were significant correlations between serum IL-6 level and sleep, social isolation and physical ability NHP subscores, and betweenCD56 NK cell activity and emotional reaction NHP sub score in CFS patients. CONCLUSION: Significantly higher ratios of psychological and physical disturbances were found in patients with CFS. Decreased CD56 NK cell activity and increased IL2r levels seem to be important immunopathologic changes in CFS. IL-6 and CD 56 NK cell activity may play an important role in sleep, physical, social, and physicological manifestations of CFS (Tab. 3, Fig. 1, Ref. 36). Full Text in free PDF www.bmj.sk.
Nater UM, Maloney E, Heim C, Reeves WC.	National Center for Emerging and Zoonotic Infectious Diseases, Centers for Disease Control & Prevention, Atlanta, GA, USA.	Cumulative life stress in chronic fatigue syndrome.	Psychiatry Res. 2011 Sep 30;189(2):318-20. Epub 2011 Aug 15.	We studied the impact of cumulative life stress on CFS in a population-based study. We found that exposure to stressors was significantly more common in persons with CFS compared to NF controls; those with CFS reported experiencing significantly higher levels of psychological distress. Also, post-traumatic stress disorder was significantly more common in people with CFS. These results not only corroborate findings from other studies but, importantly, extend those by: a) measuring a comprehensive spectrum of stress variables, b) for the first time presenting data on stress in a population-based study, thus minimizing the effects of recruitment bias, and c) diagnosing CFS by means of standardized, validated scales, thus allowing replication and extension of our findings. Stress may be an important factor in the pathophysiology of CFS. Consequently, future studies should provide a more detailed understanding of the processes that lead from stress to CFS using longitudinal designs. Published by Elsevier Ireland Ltd.

Neu D, Kajosch H, Peigneux P, Verbanck P, Linkowski P, Le Bon O.	Brugmann University Hospital, Sleep Laboratory and Unit for Chronobiology U78, Department of Psychiatry, Université Libre de Bruxelles (U.L.B), Brussels, Belgium. daniel.neu@chu-brugmann.be	Cognitive impairment in fatigue and sleepiness associated conditions.	Psychiatry Res. 2011 Aug 30;189(1):128-34. Epub 2010 Dec 31.	Although relating to very different concepts, sleepiness and fatigue are often confounded. However, both fatigue-associated conditions such as the chronic fatigue syndrome (CFS) and sleepiness-associated conditions such as the sleep apnea-hypopnea syndrome (SAHS) are associated with cognitive impairment with impaired attention, concentration and memory performances. Fifteen pure CFS patients, without primary sleep disorders or clinically relevant sleepiness, were compared to 15 untreated SAHS patients, without clinically relevant fatigue, and to 16 healthy controls of similar age. The auditory verbal learning test (AVLT), digit span, digit symbol and finger tapping test (FTT) were used as cognitive and behavioural measures. In addition we assessed daytime EEG spectral power and P300 evoked potentials. With exception for the digit span, all tests showed lower performances in patient groups. Recall on the AVLT did not differ between the two patient groups, but the digit and symbol spans showed more severe impairment in SAHS patients. Psychomotor performance on the FTT presented with slower hit rates in SAHS than in CFS. EEG theta power was highest in CFS patients. P300 latencies and amplitudes did not differ between groups. Fatigue- and sleepiness-associated conditions can both present with significant and objective impairment of cognitive functioning and behavioural motor performance. In our sample cognitive impairment and psychomotor performance were worse when associated to sleepiness in SAHS than with fatigue in CFS. Copyright © 2010 Elsevier Ltd. All rights reserved.

Newton JL, Pairman J, Hallsworth K, Moore S, Plötz T, Trenell MI.	UK National Institute for Health Research Biomedical Research Centre in Ageing & Age-related Disease, Institute for Ageing and Health, Newcastle University,	Physical activity intensity but not sedentary activity is reduced in chronic fatigue syndrome and is associated with autonomic regulation.	QJM. 2011 Aug;104(8):681-7. Epub 2011 Mar 7.	BACKGROUND: Chronic fatigue syndrome (CFS) is a common debilitating condition associated with reduced function and impaired quality of life. The cause is unknown and treatments limited. Studies confirm that CFS is associated with impaired autonomic regulation and impaired muscle function. AIM: Define the relationship between sedentary behaviour, physical activity and autonomic regulation in people with CFS. DESIGN: Cohort study. METHODS: Physical activity was assessed objectively in 107 CFS patients (Fukuda) and age, sex and body mass index (BMI)-matched sedentary controls (n= 107). Fatigue severity was determined using the Fatigue Impact Scale in all participants and heart rate variability performed in the CFS group. RESULTS: The CFS group had levels and patterns of sedentary behaviour similar to non-fatigue controls ($P > 0.05$). Seventy-nine percent of the CFS group did not achieve

	Newcastle, UK. j.l.newton@ncl.ac.uk			the WHO recommended 10,000 steps per day. Active energy expenditure [time >3 METs (metabolic equivalents)] was reduced in CFS when compared with controls (P < 0.0001). Physical activity duration was inversely associated with resting heart rate (P = 0.04; r(2) = 0.03), with reduced activity significantly associating with reduced heart rate variability in CFS. There were no relationships between fatigue severity and any parameter of activity. Thirty-seven percent of the CFS group were overweight (BMI 25-29.9) and 20% obese (BMI ≥ 30). CONCLUSION: Low levels of physical activity reported in CFS represent a significant and potentially modifiable perpetuating factor in CFS and are not attributable to high levels of sedentary activity, rather a decrease in physical activity intensity. The reduction in physical activity can in part be explained by autonomic dysfunction but not fatigue severity.
Neyro JL, Franco R, Rodríguez E, Carrero A, Palacios S.	Servicio de Ginecologia y Obstetricia, Universidad del Pais Vasco, EHU-UPV, Hospital Universitario de Cruces, Baracaldo. jlneyro@sego.es	[Fibromyalgia and menopause. Association or coincidence?]. [Article in Spanish]	Ginecol Obstet Mex. 2011 Sep;79(9):572-8.	Fibromyalgia constitutes today, in the western world, an important problem of health that affects fundamentally in women from 45 years. The studies on the influence of the hormones on the symptomatology of the patients with fibromyalgia have not managed to establish a link of causal union between the hormonal climacteric decline and the development of the painful syndrome. Nevertheless, there are studies that relate the pain, the anxiety and the depression to the level of sexual steroids. It is our aim to check these associations. We will have to expect to the development of the intracrinology and, possibly, to know more the relationship between sexual steroids and neurotransmitters to be able to know the exact relation between fibromyalgia and menopause.
Nijhof SL, Maijer K, Bleijenberg G, Uiterwaal CS, Kimpen JL, van de Putte EM.	Department of Pediatrics, Wilhelmina Children's Hospital, University Medical Center Utrecht, Netherlands. s.l.nijhof@umcutrecht.nl	Adolescent chronic fatigue syndrome: prevalence, incidence, and morbidity.	Pediatrics. 2011 May;127(5):e1169-75. Epub 2011 Apr 18.	OBJECTIVE: To determine nationwide general practitioner (GP)-diagnosed prevalence and pediatrician-diagnosed incidence rates of adolescent chronic fatigue syndrome (CFS), and to assess CFS morbidity. DESIGN AND SETTING: We collected data from a cross-sectional national sample among GPs and prospective registration of new patients with CFS in all pediatric hospital departments in the Netherlands. PATIENTS AND METHODS: Study participants were adolescents aged 10 to 18 years. A representative sample of GPs completed questionnaires on the prevalence of CFS in their adolescent patients. Pediatric hospital departments prospectively reported new cases of CFS in adolescent patients. For every new reported case, a questionnaire was sent to the reporting pediatrician and the reported patient to assess CFS morbidity. Prevalence was estimated through the data from GP questionnaires and incidence was estimated on the basis of cases newly reported by pediatricians from January to December 2008. RESULTS: Prevalence was calculated as 111 per 100 000 adolescents and incidence as 12 per 100 000 adolescents per year. Of newly reported patients with CFS, 91% scored at or above cutoff points for severe fatigue and 93% at or above the cutoff points for physical impairment. Forty-five percent of patients with CFS reported >50% school absence during the previous 6 months. CONCLUSIONS: Clinically diagnosed incidence and prevalence rates show that adolescent CFS is uncommon compared with chronic fatigue. The primary adverse impact of CFS is

				extreme disability associated with considerable school absence.
Nijhof SL, Bleijenberg G, Uiterwaal CS, Kimpen JL, van de Putte EM.	Department of Pediatrics, Wilhelmina Children's Hospital, University Medical Centre Utrecht, The Netherlands. s.l.nijhof@umcutrecht.nl	Fatigue In Teenagers on the interNET--the FITNET Trial. A randomized clinical trial of web-based cognitive behavioural therapy for adolescents with chronic fatigue syndrome: study protocol. [ISRCTN59878666].	BMC Neurol. 2011 Feb 19;11:23.	BACKGROUND: Chronic Fatigue Syndrome (CFS) is increasingly recognized as a cause of disability and inactivity in adolescents in the Netherlands. CFS is characterized by unexplained fatigue lasting more than 6 months. Cognitive Behavioural Therapy (CBT) has proven to be effective. However, CBT availability for adolescents with CFS is limited and requires special therapeutic skills not always readily available. An alternative to the face-to-face CBT is FITNET, a web-based therapeutic program designed specifically for adolescents diagnosed with CFS, and their parents. This new CBT approach appeals to the modern youth, who grow up with internet as their main source of information. A web-based program offers the opportunity to lower thresholds for the acceptance and realization of healthcare. This treatment can be activated at any chosen time. The communication between patient and therapist can elapse asynchronously. If effective, this web-based program would greatly increase the therapeutic accessibility. METHODS/DESIGN: A randomized clinical trial is currently conducted. One-hundred-forty adolescents aged 12-18 years diagnosed with CFS will be recruited and randomized to one of two groups: FITNET or usual care. After 6 months, the usual care group will have access to the FITNET program. Outcomes will be assessed at baseline, post intervention, and at 6 months follow-up. Primary outcome measures are school presence, fatigue severity, and physical functioning. DISCUSSION: The FITNET study is the first randomized clinical trial which evaluates the effect of web-based CBT versus usual care in adolescents with CFS. The intervention is based on a theoretical existing model of CBT for patients with CFS. The results of this study will provide information about the possibility and efficacy of web-based CBT for adolescents with CFS and will reveal predictors of efficacy. TRIAL REGISTRATION: ISRCTN: ISRCTN59878666 and ClinicalTrials.gov: NCT00893438.
Nijs J, Meeus M, Van Oosterwijck J, Ickmans K, Moorkens G, Hans G, De Clerck LS.	Department of Human Physiology, Vrije Universiteit Brussel (VUB), Brussels, Belgium. Jo.Nijs@vub.ac.be	In the mind or in the brain? Scientific evidence for central sensitisation in chronic fatigue syndrome.	Eur J Clin Invest. 2012 Feb;42(2):203-12. doi: 10.1111/j.1365-2362.2011.02575.x. Epub 2011 Jul 27.	BACKGROUND: Central sensitisation entails several top-down and bottom-up mechanisms, all contributing to the hyperresponsiveness of the central nervous system to a variety of inputs. In the late nineties, it was first hypothesised that chronic fatigue syndrome (CFS) is characterised by hypersensitivity of the central nervous system (i.e. central sensitisation). Since then, several studies have examined central sensitisation in patients with CFS. This study provides an overview of such studies. MATERIALS AND METHODS: Narrative review. RESULTS: Various studies showed generalised hyperalgesia in CFS for a variety of sensory stimuli, including electrical stimulation, mechanical pressure, heat and histamine. Various tissues are affected by generalised hyperalgesia: the skin, muscle tissue and the lungs. Generalised hyperalgesia in CFS is augmented, rather than decreased, following various types of stressors like exercise and noxious heat pain. Endogenous inhibition is not activated in response to exercise and activation of diffuse noxious inhibitory controls following noxious heat application to the skin is delayed. CONCLUSIONS: The observation of central sensitisation in CFS is in line with our current understanding of CFS. The

				presence of central sensitisation in CFS corroborates with the presence of several psychological influences on the illness, the presence of infectious agents and immune dysfunctions and the dysfunctional hypothalamus-pituitary-adrenal axis as seen in these severely debilitated patients. © 2011 The Authors. European Journal of Clinical Investigation © 2011 Stichting European Society for Clinical Investigation Journal Foundation.
Nijs J, Paul van Wilgen C, Van Oosterwijck J, van Ittersum M, Meeus M.	Department of Human Physiology, Faculty of Physical Education & Physiotherapy, Vrije Universiteit Brussel, Belgium. Jo.Nijs@vub.ac.be	How to explain central sensitization to patients with 'unexplained' chronic musculoskeletal pain: practice guidelines.	Man Ther. 2011 Oct;16(5):413-8. Epub 2011 May 31.	Central sensitization provides an evidence-based explanation for many cases of 'unexplained' chronic musculoskeletal pain. Prior to commencing rehabilitation in such cases, it is crucial to change maladaptive illness perceptions, to alter maladaptive pain cognitions and to reconceptualise pain. This can be accomplished by patient education about central sensitization and its role in chronic pain, a strategy known as pain physiology education. Pain physiology education is indicated when: 1) the clinical picture is characterized and dominated by central sensitization; and 2) maladaptive illness perceptions are present. Both are prerequisites for commencing pain physiology education. Face-to-face sessions of pain physiology education, in conjunction with written educational material, are effective for changing pain cognitions and improving health status in patients with various chronic musculoskeletal pain disorders. These include patients with chronic low back pain, chronic whiplash, fibromyalgia and chronic fatigue syndrome. After biopsychosocial assessment pain physiology education comprises of a first face-to-face session explaining basic pain physiology and contrasting acute nociception versus chronic pain (Session 1). Written information about pain physiology should be provided as homework in between session 1 and 2. The second session can be used to correct misunderstandings, and to facilitate the transition from knowledge to adaptive pain coping during daily life. Pain physiology education is a continuous process initiated during the educational sessions and continued within both the active treatment and during the longer term rehabilitation program. Nijs J, Meeus M, Van Oosterwijck J, Roussel N, De Kooning M, Ickmans K, Matic M.	Artesis University College Antwerp, Antwerp, Belgium. Jo.Nijs@vub.ac.be	Treatment of central sensitization in patients with 'unexplained' chronic pain: what options do we have?	Expert Opin Pharmacother. 2011 May;12(7):1087-98. Epub 2011 Jan 22.	INTRODUCTION: Central sensitization accounts for chronic 'unexplained' pain in a wide variety of disorders, including chronic whiplash-associated disorders, temporomandibular disorders, chronic low back pain, osteoarthritis, fibromyalgia, chronic fatigue syndrome and chronic tension-type headache among others. Given the increasing evidence supporting the clinical significance of central sensitization in those with unexplained chronic pain, the awareness is growing that central sensitization should be a treatment target in these patients. AREAS COVERED: This article provides an overview of the treatment options available for desensitizing the CNS in patients with chronic pain due to central sensitization. It focuses on those strategies that specifically target pathophysiological mechanisms known to be involved in central sensitization. In addition, pharmacological options, rehabilitation and neurotechnology options are discussed. EXPERT OPINION: Acetaminophen,

				serotonin-reuptake inhibitor drugs, selective and balanced serototin and norepinephrine-reuptake inhibitor drugs, the serotonin precursor tryptophan, opioids, N-methyl-d-aspartate (NMDA)-receptor antagonists, calcium-channel alpha(2)delta (a2δ) ligands, transcranial magnetic stimulation, transcutaneous electric nerve stimulation (TENS), manual therapy and stress management each target central pain processing mechanisms in animals that - theoretically - desensitize the CNS in humans. To provide a comprehensive treatment for 'unexplained' chronic pain disorders characterized by central sensitization, it is advocated to combine the best evidence available with treatment modalities known to target central sensitization. © 2011 Informa UK, Ltd
Nijs J, Aelbrecht S, Meeus M, Van Oosterwijck J, Zinzen E, Clarys P.	Department of Human Physiology, Faculty of Physical Education & Physiotherapy, Vrije Universiteit Brussel, Belgium. jo.nijs@vub.ac.be	Tired of being inactive: a systematic literature review of physical activity, physiological exercise capacity and muscle strength in patients with chronic fatigue syndrome.	Disabil Rehabil. 2011;33(17-18):1493-500. Epub 2010 Dec 20.	A systematic review was undertaken to examine whether patients with chronic fatigue syndrome (CFS) differ from healthy sedentary controls in physiological exercise capacity, physical activity level and muscle strength. From the available literature, it can be concluded that patients with CFS perform less physical activity during daily life, and have less peak isometric muscle strength compared to healthy sedentary control subjects. Conflicting data in relation to physiological exercise capacity of patients with CFS have been reported, but the weighted available evidence points towards a reduced physiological exercise capacity in CFS. Future studies should use a wash-out period for medication use, blinded assessments, a priori power calculation and a sedentary control group comparable for age, gender, body weight, body length and current physical activity level.
Nugraha B, Karst M, Engeli S, Gutenbrunner C.	Department of Rehabilitation Medicine, Hannover Medical School, Carl-Neuberg-Str. 1, Hannover, Germany, Nugraha.Boya@mh-hannover.de.	Brain-derived neurotrophic factor and exercise in fibromyalgia syndrome patients: a mini review.	Rheumatol Int. 2011 Dec 31. [Epub ahead of print]	Fibromyalgia syndrome (FMS) is a common chronic pain condition characterized by chronic widespread pain and decreased pain threshold, with hyperalgesia and allodynia. Associated signs include fatigue, morning stiffness, non-restorative sleep, mood disturbance, depression, irritable bowel syndrome, and headache. In addition to the administration of drugs, psychological therapies treatment of FMS mainly consists of physical therapies. Although the precise pathogenesis of FMS remains elucidated, modern understanding conceptualizes FMS as central sensitization as a consequence of altered endogenous pain- and stress-response system and continuous nociceptive input. Altered brain-derived neurotrophic factor (BDNF) levels in FMS suggest that BDNF-well known for its effects on neuronal plasticity-is involved in this sensitization process. Exercise leads to changes in serum BDNF levels, too. This association highlights the importance of exercise in FMS and other chronic pain conditions.
Núñez M, Fernández-Solà J, Nuñez E, Fernández-Huerta JM, Godás-Sieso T, Gomez-Gil E.	Rheumatology Service, Functional Readaptation Unit, Hospital Clinic, Barcelona,	Health-related quality of life in patients with chronic fatigue syndrome: group cognitive behavioural therapy	Clin Rheumatol. 2011 Mar;30(3):381-9. Epub 2011 Jan 15.	Chronic fatigue syndrome (CFS) produces physical and neurocognitive disability that significantly affects health-related quality of life (HRQL). Multidisciplinary treatment combining graded exercise therapy (GET) cognitive behavioural therapy (CBT) and pharmacological treatment has shown only short-term improvements. To compare the effects on HRQL of (1) multidisciplinary treatment combining CBT, GET, and pharmacological treatment, and (2) usual treatment (exercise counselling and

	Spain. mnunez@clinic.ub.es	and graded exercise versus usual treatment. A randomised controlled trial with 1 year of follow-up.		pharmacological treatment) at 12 months of follow-up. Prospective, randomized controlled trial with a follow-up of 12 months after the end of treatment. Patients consecutively diagnosed with CFS (Fukuda criteria) were randomly assigned to intervention (n = 60) or usual treatment (n = 60) groups. HRQL was assessed at baseline and 12 months by the Medical Outcomes Study Short-Form questionnaire (SF-36). Secondary outcomes included functional capacity for activities of daily living measured by the Stanford Health Assessment Questionnaire (HAQ) and comorbidities. At baseline, the two groups were similar, except for lower SF-36 emotional role scores in the intervention group. At 12 months, the intervention did not improve HRQL scores, with worse SF-36 physical function and bodily pain scores in the intervention group. Multidisciplinary treatment was not superior to usual treatment at 12 months in terms of HRQL. The possible benefits of GET as part of multidisciplinary treatment for CFS should be assessed on an individual patient basis.
Oakes B, Qiu X, Levine S, Hackett J Jr, Huber BT.	Pathology Department, Tufts University School of Medicine, 150 Harrison Avenue, Boston, MA 02111, USA.	Failure to Detect XMRV-Specific Antibodies in the Plasma of CFS Patients Using Highly Sensitive Chemiluminescence Immunoassays.	Adv Virol. 2011;2011:854540. Epub 2011 Jul 27.	In 2009, Lombardi et al. reported their startling finding that the gammaretrovirus xenotropic murine leukemia virus-related retrovirus (XMRV) is present in 67% of blood samples of patients suffering from chronic fatigue syndrome (CFS), as opposed to only 3.7% of samples from healthy individuals. However, we and others could not confirm these results, using a nested PCR assay. An alternative to this highly sensitive, but contamination-prone, technique is to measure the serological response to XMRV. Thus, we tested the plasma samples from our cohorts of CFS patients and healthy controls for the presence of XMRV-specific antibodies. Using two novel chemiluminescence immunoassays (CMIAs), we show that none of our samples have any XMRV-reactive antibodies. Taken together with our previous findings, we conclude that XMRV is not present in any human individual tested by us, regardless of CFS or healthy control.
Okifuji A, Bradshaw DH, Donaldson GW, Turk DC.	Pain Research and Management Center, Department of Anesthesiology, University of Utah, 615 Arapeen Drive, Salt Lake City, UT 84108, USA. Akiko.okifuji@hsc.utah.edu	Sequential analyses of daily symptoms in women with fibromyalgia syndrome.	J Pain. 2011 Jan;12(1):84-93. Epub 2010 Jul 1. Erratum in J Pain. 2011 Apr;12(4):509.	Fibromyalgia syndrome (FMS) is a chronic musculoskeletal pain disorder characterized by generalized pain, chronic fatigue, sleep disturbance, and a range of other symptoms having no definitive pathology. Consequently, patient evaluations rely on self-report. Ecological Momentary Assessment (EMA) allows frequent real-time collection of self-report measures, removing recall bias and increasing external validity. We studied 81 females with FMS aged 18 to 42 years. Participants carried EMA devices (Palm Pilot M100) programmed to request ratings to 8 FMS symptoms/conditions 3 times daily for 30 days. Completeness of response rates varied across participants and over time. Controlling for immediately previous fatigue (ie, fatigue rating from the immediately preceding rating), unit increases in immediately previous pain and immediately previous emotional distress predicted 9 and 7% increases, respectively, in current fatigue. Controlling for immediately previous emotional distress, a unit increase in immediately previous pain predicted 7% increase in current emotional distress. Controlled for immediately previous pain, a unit increase in immediately previous fatigue predicted a 7% increase in current pain,

				enhanced by prior diurnal effects; immediately previous emotional distress was not significant. Collectively these results suggest an asymmetry in which emotional stress and pain may increase fatigue, fatigue but not emotional distress may increase pain, and pain but not fatigue may increase emotional distress. Despite small effects and person-to-person variability, these findings suggest that longitudinal data collection by EMA may reveal sequential or causal explanatory patterns with important clinical implications. PERSPECTIVE: Understanding how multiple symptoms covary in FMS is essential for optimal treatment planning. Our results show small but significant temporal relations among pain, fatigue, and emotional distress. Our results also provide support for the use of EMA as a viable data collection method that allows longitudinal, real-time assessment of multiple FMS symptoms. Copyright © 2011 American Pain Society. Oldershaw A, Hambrook D, Rimes KA, Tchanturia K, Treasure J, Richards S, Schmidt U, Chalder T.	Section of Eating Disorders, Division of Psychological Medicine and Psychiatry, Institute of Psychiatry, King's College London, London, UK. anna.oldershaw@kcl.ac.uk	Emotion recognition and emotional theory of mind in chronic fatigue syndrome.	Psychol Health. 2011 Aug;26(8):989-1005. Epub 2011 May 23.	BACKGROUND: Difficulties with social function have been reported in chronic fatigue syndrome (CFS), but underpinning factors are unknown. Emotion recognition, theory of mind (inference of another's mental state) and 'emotional' theory of mind (eToM) (inference of another's emotional state) are important social abilities, facilitating understanding of others. This study examined emotion recognition and eToM in CFS patients and their relationship to self-reported social function. METHODS: CFS patients (n = 45) and healthy controls (HCs; n = 50) completed tasks assessing emotion recognition, basic or advanced eToM (for self and other) and a self-report measure of social function. RESULTS: CFS participants were poorer than HCs at recognising emotion states in the faces of others and at inferring their own emotions. Lower scores on these tasks were associated with poorer self-reported daily and social function. CFS patients demonstrated good eToM and performance on these tasks did not relate to the level of social function. CONCLUSIONS: CFS patients do not have poor eToM, nor does eToM appear to be associated with social functioning in CFS. However, this group of patients experience difficulties in emotion recognition and inferring emotions in themselves and this may impact upon social function.

Olivadoti MD, Weinberg JB, Toth LA, Opp MR.	Neuroscience Graduate Program, University of Michigan, USA.	Sleep and fatigue in mice infected with murine gammaherpesvirus 68.	Brain Behav Immun. 2011 May;25(4):696-705. Epub 2011 Jan 24.	Fatigue, a common symptom of many acute and chronic medical conditions, reduces both quality of life and workplace productivity and can be disabling. However, the pathophysiologic mechanisms that underlie fatigue can be difficult to study in human populations due to the patient heterogeneity, the variety of underlying causes and potential triggering events, and an inability to collect samples that may be essential to elucidation of mechanisms (e.g., brain). Although the etiology of chronic fatigue syndrome (CFS) remains elusive, some studies have implicated viral infections, including Epstein-Barr virus (EBV), a human gammaherpesvirus, as a potential factor

				in the pathogenesis of CFS. Murine gammaherpesvirus 68 (γHV68) is a mouse pathogen that shares many similarities with human γHVs, including EBV. In this study, we use γHV68-infected C57BL/6J mice as a model system for studying the impact of chronic viral infection on sleep-wake behavior, activity patterns, and body temperature profiles. Our data show that γHV68 alters sleep, activity, and temperature in a manner suggestive of fatigue. In mice infected with the highest dose used in this study (40,000plaque forming units), food intake, body weight, wheel running, body temperature, and sleep were normal until approximately 7days after infection. These parameters were significantly altered during days 7 through 11, returned to baseline levels at day 12 after infection, and remained within the normal range for the remainder of the 30-day period after inoculation. At that time, both infected and uninfected mice were injected with lipopolysaccharide (LPS), and their responses monitored. Uninfected mice given LPS developed a modest and transient febrile response during the initial light phase (hours 12 through 24) after injection. In contrast, infected mice developed changes in core body temperatures that persisted for at least 5days. Infected mice showed an initial hypothermia that lasted for approximately 12h, followed by a modest fever that persisted for several hours. For the remainder of the 5-day recording period, they showed mild hypothermia during the dark phase. Running wheel activity of infected mice was reduced for at least 5days after injection of LPS, but for only 12h in uninfected mice. Collectively, these observations indicate that (1) physiologic and behavioral processes in mice are altered and recover during an early phase of infection, and (2) mice with latent γHV68 infection have an exacerbated response to challenge with LPS. These findings indicate that laboratory mice with γHV68 infections may provide a useful model for the study of fatigue and other physiologic and behavioral perturbations that may occur during acute and chronic infection with gammaherpesviruses. Onlamoon N, Das Gupta J, Sharma P, Rogers K, Suppiah S, Rhea J, Molinaro RJ, Gaughan C, Dong B, Klein EA, Qiu X, Devare S, Schochetman G, Hackett J Jr, Silverman RH, Villinger F.	Department of Pathology and Laboratory Medicine, Emory University School of Medicine, Atlanta, Georgia, USA.	Infection, viral dissemination, and antibody responses of rhesus macaques exposed to the human gammaretrovirus XMRV.	J Virol. 2011 May;85(9):4547-57. Epub 2011 Feb 16.	Xenotropic murine leukemia-related virus (XMRV) was identified in association with human prostate cancer and chronic fatigue syndrome. To examine the infection potential, kinetics, and tissue distribution of XMRV in an animal model, we inoculated five macaques with XMRV intravenously. XMRV established a persistent, chronic disseminated infection, with low transient viremia and provirus in blood lymphocytes during acute infection. Although undetectable in blood after about a month, XMRV viremia was reactivated at 9 months, confirming the chronicity of the infection. Furthermore, XMRV Gag was detected in tissues throughout, with wide dissemination throughout the period of monitoring. Surprisingly, XMRV infection showed organ-specific cell tropism, infecting CD4 T cells in lymphoid organs including the gastrointestinal lamina propria, alveolar macrophages in lung, and epithelial/interstitial cells in other organs, including the reproductive tract. Of note, in spite of the intravenous inoculation, extensive XMRV replication was noted in

				prostate during acute but not chronic infection even though infected cells were still detectable by fluorescence in situ hybridization (FISH) in prostate at 5 and 9 months postinfection. Marked lymphocyte activation occurred immediately postinfection, but antigen-specific cellular responses were undetectable. Antibody responses were elicited and boosted upon reexposure, but titers decreased rapidly, suggesting low antigen stimulation over time. Our findings establish a nonhuman primate model to study XMRV replication/dissemination, transmission, pathogenesis, immune responses, and potential future therapies.
Op De Beeck K, Vermeersch P, Verschueren P, Westhovens R, Mariën G, Blockmans D, Bossuyt X.	Experimental Laboratory Immunology, Department of Medical Diagnostic Sciences, Catholic University Leuven, Belgium.	Detection of antinuclear antibodies by indirect immunofluorescence and by solid phase assay.	Autoimmun Rev. 2011 Oct;10(12):801-8. Epub 2011 Jun 30.	Testing for antinuclear antibodies is useful for the diagnosis of systemic rheumatic diseases. Solid phase assays are increasingly replacing indirect immunofluorescence for detection of antinuclear antibodies. In the most recent generation of solid phase assays, manufacturers attempt to improve the performance of the assays by adding extra antigens. Solid phase assay (EliA CTD Screen, Phadia, in which antibodies to 17 antigens are detected) was compared to indirect immunofluorescence for the detection of antinuclear antibodies in diagnostic samples of 236 patients with autoimmune connective tissue diseases, in 149 healthy blood donors, 139 patients with chronic fatigue syndrome, and 134 diseased controls. The sensitivity of EliA CTD Screen for systemic lupus erythematosus, systemic sclerosis, primary Sjögren's syndrome, mixed connective tissue disease, and inflammatory myopathy was 74%, 72%, 89%, 100%, and 39%, respectively. The reactivity in blood donors, in patients with chronic fatigue syndrome, and in diseased controls was <4%. Likelihood ratios increased with increasing antibody concentrations. Generally, a positive test result by EliA CTD Screen had a higher likelihood ratio for systemic rheumatic disease than a positive test result by indirect immunofluorescence. A negative test result by indirect immunofluorescence, however, had a lower likelihood ratio than a negative test result by EliA CTD Screen, indicating that the negative predictive value was higher for indirect immunofluorescence than for EliA CTD screen. Ortega F, Zorzanelli R.	Instituto de Medicina Social, Universidade do Estado do Rio de Janeiro, Rio de Janeiro, RJ, Brazil. fjortega2@gmail.com	[Neuroimaging and the case of chronic fatigue syndrome]. [Article in Portuguese]	Cien Saude Colet. 2011 Apr;16(4):2123-32.	This article analyzes the use of neuroimaging in research into chronic fatigue syndrome. It reviews some works published in the 1990 s and investigates a specific aspect of these studies, namely the search for a cerebral abnormality, in the form of an altered activation pattern, which could provide a pattern for diagnosis and treatment of the disease. The understanding of chronic fatigue syndrome as a disease reduced to some cerebral findings is analyzed, arguing in favor of a broader vision of this disease that includes psychosocial elements of the patient's life as opposed to entirely somatic explanations.
Papadopoulos AS, Cleare AJ.	Department of Psychological Medicine, Institute of	Hypothalamic-pituitary-adrenal axis dysfunction in chronic fatigue	Nat Rev Endocrinol. 2011 Sep 27;8(1):22-32. doi: 10.1038/nrendo.2011.	The weight of current evidence supports the presence of the following factors related to hypothalamic-pituitary-adrenal (HPA) axis dysfunction in patients with chronic fatigue syndrome (CFS): mild hypocortisolism; attenuated diurnal variation of cortisol; enhanced negative feedback to the HPA axis; and blunted HPA axis responsiveness.

	Psychiatry, Box P074, 103 Denmark Hill, London SE5 8AZ, UK.	syndrome.	153.	Furthermore, HPA axis changes seem clinically relevant, as they are associated with worse symptoms and/or disability and with poorer outcomes to standard treatments for CFS. Regarding etiology, women with CFS are more likely to have reduced cortisol levels. Studies published in the past 8 years provide further support for a multifactorial model in which several factors interact to moderate HPA axis changes. In particular, low activity levels, depression and early-life stress appear to reduce cortisol levels, whereas the use of psychotropic medication can increase cortisol. Addressing these factors-for example, with cognitive behavioral therapy-can increase cortisol levels and is probably the first-line approach for correcting HPA axis dysfunction at present, as steroid replacement is not recommended. Given what is now a fairly consistent pattern of findings for the type of HPA axis changes found in CFS, we recommend that future work focuses on improving our understanding of the cause and relevance of these observed changes.
Paprotka T, Delviks-Frankenberry KA, Cingöz O, Martinez A, Kung HJ, Tepper CG, Hu WS, Fivash MJ Jr, Coffin JM, Pathak VK.	Viral Mutation Section, HIV Drug Resistance Program, National Cancer Institute at Frederick, Frederick, MD 21702, USA.	Recombinant origin of the retrovirus XMRV.	Science. 2011 Jul 1;333(6038):97-101. Epub 2011 May 31. Comment in Nat Rev Urol. 2011 Aug;8(8):409.	The retrovirus XMRV (xenotropic murine leukemia virus-related virus) has been detected in human prostate tumors and in blood samples from patients with chronic fatigue syndrome, but these findings have not been replicated. We hypothesized that an understanding of when and how XMRV first arose might help explain the discrepant results. We studied human prostate cancer cell lines CWR22Rv1 and CWR-R1, which produce XMRV virtually identical to the viruses recently found in patient samples, as well as their progenitor human prostate tumor xenograft (CWR22) that had been passaged in mice. We detected XMRV infection in the two cell lines and in the later passage xenografts, but not in the early passages. In particular, we found that the host mice contained two proviruses, PreXMRV-1 and PreXMRV-2, which share 99.92% identity with XMRV over >3.2-kilobase stretches of their genomes. We conclude that XMRV was not present in the original CWR22 tumor but was generated by recombination of two proviruses during tumor passaging in mice. The probability that an identical recombinant was generated independently is negligible (~10(-12)); our results suggest that the association of XMRV with human disease is due to contamination of human samples with virus originating from this recombination event.
Pardini M, Guida S, Primavera A, Krueger F, Cocito L, Gialloreti LE.	Department of Neurosciences, Ophthalmology and Genetics, University of Genoa, Genoa, Italy. matteo.pardini@gmail.com	Amisulpride vs. fluoxetine treatment of chronic fatigue syndrome: a pilot study.	Eur Neuropsychopharmacol. 2011 Mar;21(3):282-6. Epub 2010 Nov 26.	Different pharmacologic agents have been evaluated in the treatment of Chronic Fatigue Syndrome (CFS), albeit with moderate efficacy. Among the compounds thought to present with potential to be efficacious in CFS patients stands out low-dose amisulpride, a substituted benzamide that has been shown to be an useful treatment for conditions which exhibit some overlap with CFS such as dysthymia and somatoform disorders. We thus recruited forty non-depressed CFS patients that were randomized to receive either amisulpride 25mg bid, or fluoxetine 20mg uid; all subjects were un-blinded to the treatment regimen. At the time of enrollment in the study and after twelve weeks of treatment, enrolled subjects completed the Krupp Fatigue Severity Scale, the Hospital Anxiety and Depression Scale and a visual analog

				scale focused on pain and bodily discomfort. Moreover, all subjects were evaluated by a clinician, blinded to the treatment regimen, using the Clinical Global Impression Severity Scale. Our data revealed a significant improvement both in self-report, and observer-based measures for the amisulpride-treated, but not for the fluoxetine-treated patients. Amisulpride-treated subjects also presented with a significant reduction of somatic complaints, while the amisulpride effect on anxiety and mood levels was not significant. Both drugs were equally well tolerated. Summing up, we showed a positive symptomatic effect of amisulpride, compared to SSRI treatment, in a group of non-depressed CSF patients on self-report and on observer-based measures of fatigue and somatic complaints. If confirmed by larger, blinded studies, amisulpride thus could represent an effective approach to this difficult-to-treat condition. Copyright © 2010 Elsevier B.V. and ECNP. All rights reserved.
Pasi A, Bozzini S, Carlo-Stella N, Martinetti M, Bombardieri S, De Silvestri A, Salvaneschi L, Cuccia M.	HLA Laboratory, Immunohaematology and Transfusion Center, Pavia, Italy.	Excess of activating killer cell immunoglobulin-like receptors and lack of HLA-Bw4 ligands: a two-edged weapon in chronic fatigue syndrome.	Mol Med Report. 2011 May-Jun;4(3):535-40. doi: 10.3892/mmr.2011.447. Epub 2011 Mar 4.	Chronic fatigue syndrome (CFS) is an inflammatory disease of unknown aetiology. Researchers have proposed infectious, neurological and immunological causes of this syndrome. Recently, the xenotropic murine leukemia virus-related virus was detected in 67% of patients with CFS in a US study. This observation is in agreement with one ascertained aspect of the disease: a decreased efficiency in NK cell lytic activity in CFS patients. Here, we analyzed the genomic polymorphism of killer cell immunoglobulin-like receptors (KIRs) and their HLA class I cognate ligands in patients with certified CFS. An excess of KIR3DS1 was found in CFS patients with respect to controls, as well as an increased frequency of the genotype missing KIR2DS5. Forty-four CFS patients and 50 controls also underwent genomic typing for the HLA-ligands. In the patients, a great proportion of KIR3DL1 and KIR3DS1 receptors were found to be missing their HLA-Bw4Ile80 binding motif. We hypothesize that an excess of KIR3DS1, combined with an excess of ligand-free KIR3DL1 and KIR3DS1 receptors, may hamper the clearance of a pathogen via NK cells, thus favouring the chronicity of the infection.
Passeri E, Villa C, Couette M, Itti E, Brugieres P, Cesaro P, Gherardi RK, Bachoud-Levi AC, Authier FJ.	Paris Est-Creteil University & Henri-Mondor University Hospital (APHP): Reference Center for Neuromuscular Diseases Garches-Necker-Mondor-Hendaye, Creteil, F-94010, France.	Long-term follow-up of cognitive dysfunction in patients with aluminum hydroxide-induced macrophagic myofasciitis (MMF).	J Inorg Biochem. 2011 Nov;105(11):1457-63. Epub 2011 Aug 22.	Macrophagic myofasciitis (MMF) is characterized by specific muscle lesions assessing long-term persistence of aluminum hydroxide within macrophages at the site of previous immunization. Affected patients are middle-aged adults, mainly presenting with diffuse arthromyalgias, chronic fatigue, and cognitive dysfunction. Representative features of MMF-associated cognitive dysfunction (MACD) include (i) dysexecutive syndrome; (i) visual memory; (iii) left ear extinction at dichotic listening test. In present study we retrospectively evaluated the progression of MACD in 30 MMF patients. Most patients fulfilled criteria for non-amnestic/dysexecutive mild cognitive impairment, even if some cognitive deficits seemed unusually severe. MACD remained stable over time, although dysexecutive syndrome tended to worsen. Long-term follow-up of a subset of patients with 3 or 4 consecutive neuropsychological evaluations confirmed the stability of MACD with time, despite marked fluctuations. Dagenais P, Lehoux P.	London. vibe.pedersen@kcl.ac.uk	synthesis of data to inform health policy.	Health Care. 2011 Jul;27(3):238-46. doi: 10.1017/S0266462311000213. Epub 2011 Jul 8.	qualitative data with systematic reviews of quantitative and qualitative studies, demonstrated by a study of the psychosocial needs of chronic fatigue syndrome (CFS) sufferers in Québec. METHODS: A systematic literature review was performed across various databases for English and French language studies, on the psychosocial aspects of CFS. Qualitative, quantitative, and mixed method studies published between January 1994 and July 2008 were included. Unpublished literature and reference lists of included studies were also searched. Themes identified in the literature were used to guide semi-structured interviews with seventeen CFS-sufferers, mostly recruited from a large specialist practice in Montreal. Interviews were transcribed verbatim and validated by a research assistant. Transcripts were coded using the identified themes. New codes were created when new issues arose. All themes were subsequently synthesized into overall categories using a constant comparative method. RESULTS: The literature search yielded thirty-one papers: twenty-eight primary studies and three systematic reviews. Twelve themes were identified and synthesized into four overall problem categories, such as "Lack of professional recognition." Interviews confirmed findings from the literature, but also revealed unidentified needs specific to CFS-sufferers in Québec. Policy recommendations were provided to address these needs. CONCLUSIONS: Multi-Source Synthesis provides a systematic method for synthesizing data from original studies with literature findings, thereby broadening the knowledge base and the local relevance of decisions concerning specific patient populations.
Peters S, Wearden A, Morriss R, Dowrick CF, Lovell K, Brooks J, Cahill G, Chew-Graham C.	School of Psychological Sciences, University of Manchester, Manchester, UK. Sarah.peters@manchester.ac.uk.	Challenges of nurse delivery of psychological interventions for long-term conditions in primary care: a qualitative exploration of the case of chronic fatigue syndrome/myalgic encephalitis.	Implement Sci. 2011 Dec 22;6(1):132.	ABSTRACT:BACKGROUND: The evidence base for a range of psychosocial and behavioural interventions in managing and supporting patients with long-term conditions (LTCs) is now well-established. With increasing numbers of such patients being managed in primary care, and a shortage of specialists in psychology and behavioural management to deliver interventions, therapeutic interventions are increasingly being delivered by general nurses with limited training in psychological interventions. It is unknown what issues this raises for the nurses or their patients. The purpose of the study was to examine the challenges faced by non-specialist nurses when delivering psychological interventions for an LTC (chronic fatigue syndrome/myalgic encephalomyelitis [CFS/ME]) within a primary care setting. METHODS: A qualitative study nested within a randomised controlled trial [ISRCTN 74156610] explored the experiences and acceptability of two different psychological interventions (pragmatic rehabilitation and supportive listening) from the perspectives of nurses, their supervisors, and patients. Semi structured in-depth interviews were conducted with three nurse therapists, three supervisors, and 46 patients. An iterative approach was used to develop conceptual categories from the dataset. RESULTS: Analyses identified four sets of challenges that were common to both interventions: (i) being a novice therapist, (ii) engaging patients in the therapeutic model, (iii) dealing with emotions, and (iv) the complexity of primary care.

				Each challenge had the potential to cause tension between therapist and patient. A number of strategies were developed by participants to manage the tensions. CONCLUSIONS: Tensions existed for nurses when attempting to deliver psychological interventions for patients with CFS/ME in this primary care trial. Such tensions should be addressed before implementing psychological interventions within routine clinical practice. Similar tensions may be found for other LTCs. Our findings have implications for developing therapeutic alliances and highlight the need for regular supervision.
Petrov D, Marchalik D, Sosin M, Bal A.	UMDNJ/Robert Wood Johnson Medical School, New Brunswick, NJ, USA.	Factors affecting duration of chronic fatigue syndrome in pediatric patients.	Indian J Pediatr. 2012 Jan;79(1):52-5. Epub 2011 May 27.	OBJECTIVE: To determine factors affecting duration of chronic fatigue syndrome (CFS) in pediatric patients. METHODS: This Retrospective cohort consisted of patients with CFS at the regional referral infectious disease clinic for evaluation of fatigue in children and adolescents. Demographic, clinical, and laboratory data were analyzed to identify the impact on duration and severity of pediatric CFS. RESULTS: A total number of 53 predominantly white (98.1%) patients with CFS, aged 9-18 years, were included in the study. Other than fatigue, headaches and sleep disturbance were the most common symptoms of pediatric CFS. Seropositive status for Borrelia burgdorferi (B. burgdorferi) and Epstein-Barr virus (EBV) was identified in 66% of the patients with the diagnosis of CFS by CDC criteria. No association was found between the CFS symptoms, gender, or age at diagnosis and duration of fatigue symptoms. Duration of CFS was associated with high Body-Mass Index (BMI) in a regression model after adjustment for patient's age, gender, and seropositive status for B. burgdorferi and/or EBV (0.34 ± 0.15, $P < 0.04$). CONCLUSIONS: BMI is significantly associated with prolonged duration of CFS.
Pfeffer G, Sirrs S, Wade NK, Mezei MM.	Division of Neurology, University of British Columbia, Vancouver.	Multisystem disorder in late-onset chronic progressive external ophthalmoplegia.	Can J Neurol Sci. 2011 Jan;38(1):119-23.	INTRODUCTION: Chronic progressive external ophthalmoplegia (CPEO) is a mitochondrial syndrome on a disease spectrum with Kearns-Sayre syndrome (KSS). Clinical presentation is variable and our experience suggested that phenotypic differences exist in CPEO with onset after age 20. METHODS: This descriptive study is a retrospective chart review of 40 patients with late-onset CPEO. Clinical features, laboratory and neurophysiology results were reviewed. RESULTS: Multisystem dysfunction was very common in this series. Gastrointestinal dysfunction was more common than expected (60%) as was migraine headache (40%). Clinical characteristics on the KSS disease spectrum were uncommon in this series with only 2.5% having pigmentary retinopathy, 5% with cardiac conduction abnormality, and 22.5% having endocrinopathy (most often thyroid dysfunction rather than diabetes). Neurophysiology abnormalities included length-dependent axonal polyneuropathy in 44% (sometimes subclinical) and myopathic EMG changes in 26%. Exposure to sources of acquired mitochondrial toxicity including cigarette use and hepatitis C infection were more common than expected in this series. DISCUSSION: Phenotype was different in this late-onset series compared with previous reports in CPEO patients. In this series of late-onset patients, multi-organ dysfunction was more common than previously reported in CPEO, and some classical mitochondrial manifestations, such as

				pigmentary retinopathy were rare. We suggest that acquired mitochondrial toxicity may have a role in the pathogenesis of adult-onset CPEO.
Phillips K, Clauw DJ.	University of Michigan, Ann Arbor, MI, United States. kphill@med.umich.edu	Central pain mechanisms in chronic pain states--maybe it is all in their head.	Best Pract Res Clin Rheumatol. 2011 Apr;25(2):141-54.	Mechanisms underlying chronic pain differ from those underlying acute pain. In chronic pain states, central nervous system (CNS) factors appear to play particularly prominent roles. In the absence of anatomical causes of persistent pain, medical sub-specialities have historically applied wide-ranging labels (e.g., fibromyalgia (FM), irritable bowel syndrome, interstitial cystitis and somatisation) for what now is emerging as a single common set of CNS processes. The hallmark of these 'centrally driven' pain conditions is a diffuse hyperalgesic state identifiable using experimental sensory testing, and corroborated by functional neuroimaging. The characteristic symptoms of these central pain conditions include multifocal pain, fatigue, insomnia, memory difficulties and a higher rate of co-morbid mood disorders. In contrast to acute and peripheral pain states that are responsive to non-steroidal anti-inflammatory drugs (NSAIDs) and opioids, central pain conditions respond best to CNS neuromodulating agents, such as serotonin-norepinephrine reuptake inhibitors (SNRIs) and anticonvulsants. Pihur V, Datta S, Datta S.		Meta analysis of Chronic Fatigue Syndrome through integration of clinical, gene expression, SNP and proteomic data.	Bioinformation. 2011 Apr 22;6(3):120-4.	We start by constructing gene-gene association networks based on about 300 genes whose expression values vary between the groups of CFS patients (plus control). Connected components (modules) from these networks are further inspected for their predictive ability for symptom severity, genotypes of two single nucleotide polymorphisms (SNP) known to be associated with symptom severity, and intensity of the ten most discriminative protein features. We use two different network construction methods and choose the common genes identified in both for added validation. Our analysis identified eleven genes which may play important roles in certain aspects of CFS or related symptoms. In particular, the gene WASF3 (aka WAVE3) possibly regulates brain cytokines involved in the mechanism of fatigue through the p38 MAPK regulatory pathway.
Pinquart M, Shen Y.	Department of Psychology, Philipps University, D-35032 Marburg, Germany. pinquart@staff.uni-marburg.de	Behavior problems in children and adolescents with chronic physical illness: a meta-analysis.	J Pediatr Psychol. 2011 Oct;36(9):1003-16. Epub 2011 Aug 1.	OBJECTIVE: To examine the risk of emotional and behavioral problems among children with a chronic physical illness. METHODS: Random-effects meta-analysis was computed to integrate the results of 569 studies that used the Child Behavior Checklist, Youth Self Report, and the Teacher Report Form. RESULTS: Young people with a chronic physical illness have higher levels of internalizing (g = .47 standard mean difference), externalizing (g = .22) and total behavior problems (g = .42) than healthy peers. The largest differences were found in parental ratings and the weakest differences in adolescent self-ratings. Strongest elevations of internalizing problems were found for chronic fatigue syndrome and strongest elevations of externalizing problems were observed for epilepsy and migraine/tension-type headache. Effects also varied by country and, in part, by age, gender, year of publication, and study design. CONCLUSIONS: The results call for regular screens for psychological distress and referrals for mental health services, when needed.

Pinquart M, Shen Y.	Department of Psychology, Philipps University, D-35032 Marburg, Germany. pinquart@staff.uni-marburg.de	Depressive symptoms in children and adolescents with chronic physical illness: an updated meta-analysis.	J Pediatr Psychol. 2011 May;36(4):375-84. Epub 2010 Nov 18.	OBJECTIVE: To integrate results of available studies that compared levels of depressive symptoms of children and adolescents with chronic physical illness to healthy peers or test norms. METHODS: Random-effects meta-analysis was computed with 340 studies and 450 subsamples. RESULTS: Children and adolescents with chronic illness have, on average, higher levels of depressive symptoms than their healthy peers (d = .19 SD units). Differences are strongest for chronic fatigue syndrome (d = .94), fibromyalgia (d = .59), cleft lip and palate (d = .54), migraine/tension head ache (d = .51), and epilepsy (d = .39). Larger effect sizes were found in studies with higher proportion of girls, with a healthy control group, from developing countries, published before 1990, and that used parent rating or clinician ratings rather than child ratings. CONCLUSIONS: Pediatricians and others working with children with chronic illnesses should screen children with chronic physical illness for symptoms of psychological distress and make appropriate referrals for mental health services, when needed.
Pinquart M, Shen Y.	Philipps University, Department of Psychology, Marburg, Germany. pinquart@staff.uni-marburg.de	Anxiety in children and adolescents with chronic physical illnesses: a meta-analysis.	Acta Paediatr. 2011 Aug;100(8):1069-76. doi: 10.1111/j.1651-2227.2011.02223.x. Epub 2011 Mar 15. Comment in Acta Paediatr. 2011 Aug;100(8):1066-8.	To compare levels of anxiety of children with chronic illness with healthy peers and population norms. Meta-analysis integrated results from 332 studies. Children with chronic illness had elevated levels of anxiety (d=0.18 standard deviation units). Strongest elevations were found for chronic fatigue syndrome, migraine/tension headache, sensory impairment and epilepsy. Paediatricians should screen for anxiety symptoms in children at risk and offer interventions, if needed. © 2011 The Author(s)/Acta Paediatrica © 2011 Foundation Acta Paediatrica.
Pizzutelli S.	Pediatric Allergology, Frosinone General Hospital, Frosinone, Italy. sipizzut@tin.it	Systemic nickel hypersensitivity and diet: myth or reality?	Eur Ann Allergy Clin Immunol. 2011 Feb;43(1):5-18.	Nickel is a very common metal contained in many everyday objects and is the leading cause of ACD (Allergic Contact Dermatitis). Nickel is present in most of the constituents of a normal diet, but some food groups are usually considered to be richer. However, the nickel content of specific food can vary widely, depending on many factors. Thus, the daily intake of nickel is also highly variable both among different populations and in a single individual, in different seasons and even in different days. Measuring precisely the daily intake of nickel from food and drinks is extremely difficult, if not impossible. The relationship between ACD and contact with nickel is undisputed and widely confirmed in literature. The situation is different for systemic nickel allergy syndrome (SNAS). The SNAS can have cutaneous signs and symptoms (Systemic Contact Dermatitis or SCD) or extracutaneous signs and symptoms (gastrointestinal, respiratory, neurological, etc.).The occurrence of SCD as a systemic reaction to the nickel normally assumed in the daily diet is very controversial. A rigorous demonstration of the relationship between SCD and nickel is extremely difficult. In particular, further and larger studies are needed to assess the reality and the prevalence of nickel urticaria. With respect to nickel-related gastrointestinal symptoms, as well as chronic fatigue syndrome, fibromyalgia, headache, recurring cold sores and recurrent infections in general, the data available

				in literature are not conclusive and the studies lack the support of clear, first-hand evidence. With respect to respiratory disorders, the role of food nickel and the effectiveness of a dietary treatment have been assumed but not proven. In fact, the usefullness of a therapeutic low-nickel diet is controversial: rare, if not exceptional, and limited to very sporadic cases of SCD. Additionally, the quantitative and qualitative composition of a low-nickel diet presents few certainties and many uncertainties. The low-nickel diets suggested in literature are highly variable, both in the extension of the restrictions and in their details--and the differences are not marginal. CONCLUSION: an evaluation of the data presented by medical literature about SNAS and its relationship with oral nickel does not allow to draw final conclusions. In the absence of genuine certainty we can only conclude that further and broader studies, more rigorously conducted, are needed.
Poppe C, Crombez G, Hanoulle I, Vogelaers D, Petrovic M.	Department of General Internal Medicine, Ghent University Hospital, De Pintelaan 185, 9000, Ghent, Belgium, Carine.Poppe@ugent.be.	Mental quality of life in chronic fatigue is associated with an accommodative coping style and neuroticism: a path analysis.	Qual Life Res. 2011 Oct 29. [Epub ahead of print]	PURPOSE: An accommodative coping style (e.g. acceptance) is related to a better mental health-related quality of life (MHQL) in patients with chronic fatigue syndrome (CFS). We want to explore whether neuroticism is predictive for this coping style and MHQL. Secondly we want to explore the relation between acceptance and physical health-related quality of life (PHQL) and expect that illness-related variables such as fatigue severity and duration are related to PHQL. METHOD: In this cross-sectional study, 117 patients with chronic fatigue syndrome from an outpatient internal medicine clinic completed self-report questionnaires on quality of life (SF-36), acceptance (ICQ), personality traits (NEO-FFI) and fatigue severity (CIS). RESULTS: Regression analyses showed that neuroticism and acceptance are predictors of MHQL (38% of the variance was explained). The path analysis showed that acceptance mediates between neuroticism and MHQL and that PHQL is related to MHQL. PHQL is related to fatigue severity and duration, but not to neuroticism and acceptance. CONCLUSION: Stimulating an 'accepting accommodative coping style' within the treatment for CFS is important in improving mental quality of life. Our results suggest that neuroticism may be negatively related to acceptance and MHQL. This findings support the idea that a psychological diagnostic workout with special attention to personality traits in relation to their coping style is recommended in order to choose the most appropriate therapeutic approach in this population.
Pukhal'skiĭ AL, Shmarina GV, Aleshkin VA.		[Regulatory T-cells: modern approaches to optimization of their numbers]. [Article in Russian]	Vestn Ross Akad Med Nauk. 2011;(8):24-33.	Regulatory T-cells (Tregs) are important components of the complex adaptive system of the body responsive to environmental challenges. Tregs ensure peripheral tolerance and play an important role in control of inflammatory reactions. Several subsets of Tregs have been described. Naturally occurring CD4+CD25+ Tregs are recognized as a major subset of immune cells responsible for peripheral immune self-tolerance. Another subtype of Tregs is inducible. Such Tregs are generated in the periphery and realize their suppressive potential largely in the form of anti-inflammatory activity. The latter plays an important role in cooperation of three principal anti-inflammatory mechanisms that developed in the course of evolution:

				macrophages possessed of suppressive activity, Tregs, and stress hormones. Normally, all the three mechanisms of inflammation control are in equilibrium. However, the balance may be disturbed with ageing due to repeated episodes of stress and HPA axis activation. As a result, secretion of stress hormones coupled to antigen overload leads to Treg accumulation. In the course of time activation of the HPA axis is replaced by its inhibition manifested both as a decrease of the baseline cortisol level and a reduction of stress-induced cortisol response. Cortisol present in blood at low concentrations is no longer capable of controlling inflammation and Tregs become a principal mechanism of anti-inflammatory machinery. Superfluous Treg accumulation results in the development of functional somatic syndromes, such as chronic fatigue syndrome, and (in some patients) in the growth of tumours resulting from the suppression of anticancer immunity. On the other hand, the lack of adequate antigen loading in the childhood may delay Treg maturation. Allergy and asthma manifestations may be a consequence of such Treg insufficiency. Thus, both excess and deficiency of Tregs may be at the bottom of morbid conditions. The advances in modern pharmacology open up opportunities for developing new methods to control the Treg level.
Puri BK, Jakeman PM, Agour M, Gunatilake KD, Fernando KA, Gurusinghe AI, Treasaden IH, Waldman AD, Gishen P.	Department of Imaging, Hammersmith Hospital, London, UK.	Regional grey and white matter volumetric changes in myalgic encephalomyelitis (chronic fatigue syndrome): a voxel-based morphometry 3-T MRI study.	Br J Radiol. 2011 Nov 29. [Epub ahead of print]	Objective: It is not established whether myalgic encephalomyelitis/chronic fatigue syndrome (CFS) is associated with structural brain changes. The aim of this study was to investigate this by conducting the largest voxel-based morphometry study to date in CFS.Methods: High-resolution structural 3-T cerebral MRI scanning was carried out in 26 CFS patients and 26 age- and gender-matched healthy volunteers. Voxel-wise generalised linear modelling was applied to the processed MR data using permutation-based non-parametric testing, forming clusters at t > 2.3 and testing clusters for significance at p < 0.05, corrected for multiple comparisons across space.Results: Significant voxels (p < 0.05, corrected for multiple comparisons) depicting reduced grey matter volume in the CFS group were noted in the occipital lobes (right and left occipital poles; left lateral occipital cortex, superior division; and left supracalcrine cortex), the right angular gyrus and the posterior division of the left parahippocampal gyrus. Significant voxels (p < 0.05, corrected for multiple comparisons) depicting reduced white matter volume in the CFS group were also noted in the left occipital lobe.Conclusion: These data support the hypothesis that significant neuroanatomical changes occur in CFS, and are consistent with the complaint of impaired memory that is common in this illness; they also suggest that subtle abnormalities in visual processing, and discrepancies between intended actions and consequent movements, may occur in CFS.
Puri BK, Gunatilake KD, Fernando KA,	Imaging Department, Hammersmith	Increased tenderness in the left third intercostal space in	J Int Med Res. 2011;39(1):212-4.	A clinical sign has not thus far been associated with myalgic encephalo myelitis (ME). The present study involved systematic clinical examination that included inspection, palpation, percussion and auscultation of the thorax of 42 ME patients and 20 age-

Gurusinghe AI, Agour M, Treasaden IH.	Hospital, Du Cane Road, London W12 0HS, UK. basant.puri@imperial.ac.uk	adult patients with myalgic encephalomyelitis: a controlled study.		matched healthy controls while sitting. Left lateral third intercostal space tenderness was noted in 34 (81%) of the patients and in none of the controls, a difference that was highly statistically significant. This finding may be related to changes in lymphatic function and to the descending course of the thoracic duct. Further studies, preferably blinded and combined with appropriate imaging, are required.
Qiu X, Swanson P, Tang N, Leckie GW, Devare SG, Schochetman G, Hackett J Jr.	Infectious Diseases R&D, Abbott Diagnostics, Abbott Park, Illinois 60064, USA. xiaoxing.qiu@abbott.com	Seroprevalence of xenotropic murine leukemia virus-related virus in normal and retrovirus-infected blood donors.	Transfusion. 2012 Feb;52(2):307-16. doi: 10.1111/j.1537-2995.2011.03395.x. Epub 2011 Oct 24.	BACKGROUND: Xenotropic murine leukemia virus-related virus (XMRV) has been reported in patients with prostate cancer and chronic fatigue syndrome. Although results have been conflicting, the potential of XMRV as an infectious human retrovirus has raised concerns about transfusion safety. To address this issue, normal and retrovirus-infected blood donors were screened for evidence of XMRV infection. STUDY DESIGN AND METHODS: Plasma from 1000 US, 100 human immunodeficiency virus Type 1-infected Cameroonian, and 642 human T-lymphotropic virus Type I (HTLV-I)-infected or uninfected Japanese blood donors as well as 311 sexually transmitted disease diagnostic specimens were screened for antibodies to XMRV gp70 and p15E using chemiluminescent immunoassays (CMIAs). CMIA-reactive samples were evaluated by p30 CMIA, Western blot, and real-time reverse transcriptase polymerase chain reaction. RESULTS: XMRV seroreactivity was low (0%-0.6%) with the exception of the HTLV-I-infected donors (4.9%). Antibody was detected against only a single XMRV protein (p15E or gp70); none of the seroreactive samples had detectable XMRV pol or env sequences. The elevated seroreactivity in HTLV-I-infected donors was due to an increased p15E seroreactive rate (4.1%). Inspection of XMRV and HTLV sequences revealed a high level of conservation within the immunodominant region (IDR) of the transmembrane protein. In some cases, HTLV IDR peptide competitively reduced the XMRV p15E signal. CONCLUSIONS: Based on the low prevalence of seroreactivity, detection of antibody to only a single XMRV protein and the absence of XMRV sequences, this study finds no compelling evidence of XMRV in normal or retrovirus-infected blood donors. The increased p15E seroreactivity observed in HTLV infection is likely due to cross-reactive antibodies. © 2012 American Association of Blood Banks.
Racciatti D, Gorgoretti V, Sepede G, Gambi F, Pizzigallo E.	Clinic of Infectious Diseases, Department of Medicine and Aging, G. d'Annunzio University, Chieti, Italy. racciatt@unich.it	An Italian study on health-related quality of life and fatigue in patients with chronic fatigue syndrome and patients with chronic HCV virus infection: similarities and differences.	Int J Immunopathol Pharmacol. 2011 Jul-Sep;24(3):673-81.	Severe fatigue and a significantly reduced health-related quality of life (HRQoL) have been described in patients with chronic fatigue syndrome (CFS) in comparison with patients affected by chronic hepatitis C (CHC) and other chronic medical conditions. We examined 39 CFS and 49 CHC patients to explore whether fatigue and a poor HRQoL represent a greater medical and social problem in CFS than in CHC. The severity of fatigue and the HRQoL were assessed using the Fatigue Impact Scale (FIS) and the Health Status Questionnaire Short Form-36 (SF-36), respectively. The statistical analysis showed both a higher score of fatigue and a lower HRQoL in CFS than in CHC patients. Furthermore, in CHC patients the FIS evaluation showed a significantly reduced score of the psychosocial domain in comparison with the other domains. Multivariate linear regression analysis revealed female gender as the most

				important positive variable in chronic hepatitis C patients for total score of FIS. In conclusion, CFS was associated with a severe and disabling fatigue and an impaired HRQOL. In particular, both fatigue and all aspects of HRQOL perceived by CFS patients were significantly impaired compared to CHC patients. Consequently, management of fatigue should be considered a priority in order to improve HRQOL in CFS patients. In CHC patients the impact of fatigue on HRQoL was less significant than in CFS patients, even though the FIS evaluation showed a significant impairment of the psychosocial domain.
Rahman K, Burton A, Galbraith S, Lloyd A, Vollmer-Conna U.	School of Psychiatry, University of NSW, Sydney, Australia.	Sleep-wake behavior in chronic fatigue syndrome.	Sleep. 2011 May 1;34(5):671-8.	STUDY OBJECTIVES: Disturbances of the internal biological clock manifest as fatigue, poor concentration, and sleep disturbances-symptoms reminiscent of chronic fatigue syndrome (CFS) and suggestive of a role for circadian rhythm disturbance in CFS. We examined circadian patterns of activity, sleep, and cortisol secretion in patients with CFS. DESIGN: Case-control study, 5-day behavioral observation. SETTING: Natural setting/home environment PARTICIPANTS: 15 patients with CFS and 15 healthy subjects of similar age, sex, body mass index (BMI), and activity levels. INTERVENTIONS: N/A MEASUREMENTS: Self-report questionnaires were used to obtain medical history and demographic information and to assess health behaviors, somatic and psychological symptoms, and sleep quality. An actiwatch accelerometer recorded activity and sleep patterns over 5 days with concurrent activity and symptom logs. Diurnal salivary cortisol secretion was measured. Additionally, overnight heart rate monitoring and pain sensitivity assessment was undertaken. RESULTS: Ratings of symptoms, disability, sleep disturbance, and pain sensitivity were greater in patients with CFS. No between-group differences were found in the pattern or amount of sleep, activity, or cortisol secretion. Afternoon activity levels significantly increased evening fatigue in patients but not control subjects. Low nocturnal heart rate variability was identified as a biological correlate of unrefreshing sleep. CONCLUSIONS: We found no evidence of circadian rhythm disturbance in CFS. However, the role of autonomic activity in the experience of unrefreshing sleep warrants further assessment. The activity symptom-relationship modelled here is of clinical significance in the approach to activity and symptom management in the treatment of CFS.
Ravindran MK, Zheng Y, Timbol C, Merck SJ, Baraniuk JN.	Division of Rheumatology, Immunology and Allergy, Georgetown University, 3800 Reservoir Road NW, Washington, DC 20007-2197,	Migraine headaches in chronic fatigue syndrome (CFS): comparison of two prospective cross-sectional studies.	BMC Neurol. 2011 Mar 5;11:30.	BACKGROUND: Headaches are more frequent in Chronic Fatigue Syndrome (CFS) than healthy control (HC) subjects. The 2004 International Headache Society (IHS) criteria were used to define CFS headache phenotypes. METHODS: Subjects in Cohort 1 (HC = 368; CFS = 203) completed questionnaires about many diverse symptoms by giving nominal (yes/no) answers. Cohort 2 (HC = 21; CFS = 67) had more focused evaluations. They scored symptom severities on 0 to 4 anchored ordinal scales, and had structured headache evaluations. All subjects had history and physical examinations; assessments for exclusion criteria; questionnaires about CFS related symptoms (0 to 4 scale), Multidimensional Fatigue Inventory (MFI) and Medical

	USA.			Outcome Survey Short Form 36 (MOS SF-36). RESULTS: Demographics, trends for the number of diffuse "functional" symptoms present, and severity of CFS case designation criteria symptoms were equivalent between CFS subjects in Cohorts 1 and 2. HC had significantly fewer symptoms, lower MFI and higher SF-36 domain scores than CFS in both cohorts. Migraine headaches were found in 84%, and tension-type headaches in 81% of Cohort 2 CFS. This compared to 5% and 45%, respectively, in HC. The CFS group had migraine without aura (60%; MO; CFS+MO), with aura (24%; CFS+MA), tension headaches only (12%), or no headaches (4%). Co-morbid tension and migraine headaches were found in 67% of CFS. CFS+MA had higher severity scores than CFS+MO for the sum of scores for poor memory, dizziness, balance, and numbness ("Neuro-construct", p = 0.002) and perceived heart rhythm disturbances, palpitations and noncardiac chest pain ("Cardio-construct"; p = 0.045, t-tests after Bonferroni corrections). CFS+MO subjects had lower pressure-induced pain thresholds (2.36 kg [1.95-2.78; 95% C.I.] n = 40) and a higher prevalence of fibromyalgia (47%; 1990 criteria) compared to HC (5.23 kg [3.95-6.52] n = 20; and 0%, respectively). Sumatriptan was beneficial for 13 out of 14 newly diagnosed CFS migraine subjects. CONCLUSIONS: CFS subjects had higher prevalences of MO and MA than HC, suggesting that mechanisms of migraine pathogenesis such as central sensitization may contribute to CFS pathophysiology. CLINICAL TRIAL REGISTRATION: Georgetown University IRB # 2006-481
Reeves RR, Panguluri RL.	G.V. (Sonny) Montgomery VA Medical Center, (11M), 1500 E. Woodrow Wilson Drive, Jackson, MS 29216, USA. roy.reeves@va.gov	Neuropsychiatric complications of traumatic brain injury.	J Psychosoc Nurs Ment Health Serv. 2011 Mar;49(3):42-50. doi: 10.3928/02793695-20110201-03. Epub 2011 Feb 16.	Traumatic brain injury (TBI) may be defined as any extracranial mechanical force to the brain that results in any period of loss of consciousness, any loss of memory for events immediately before or after the event, or any alteration in mental status at the time of the event. The major causes are automobile accidents, falls, sporting injuries, and assaults. Many soldiers returning from combat in Afghanistan and Iraq have also experienced TBI. This article provides an overview of the neuropsychiatric complications of TBI, including impairment of consciousness, posttraumatic amnesia, cognitive disorders and dementia, posttraumatic epilepsy, aphasia, depression, mania, psychosis, anxiety disorders, personality changes, aggression, behavioral dyscontrol, fatigue/apathy, and increased risk of suicide. Discussion will focus primarily on issues affecting mental health clinicians. Because mental health providers are more involved in care of chronic issues related to TBI, these issues will be discussed in more detail, although acute neuropsychiatric complications of TBI will be briefly explained. Copyright 2011, SLACK Incorporated.
Reid S, Chalder T, Cleare A, Hotopf M, Wessely S.	Imperial College, St Mary's Hospital, London, UK.	Chronic fatigue syndrome.	Clin Evid (Online). 2011 May 26;2011. pii: 1101.	INTRODUCTION: Chronic fatigue syndrome (CFS) affects between 0.006% and 3% of the population depending on the criteria of definition used, with women being at higher risk than men. METHODS AND OUTCOMES: We conducted a systematic review and aimed to answer the following clinical question: What are the effects of treatments for chronic fatigue syndrome? We searched: Medline, Embase, The Cochrane Library, and other important databases up to March 2010 (Clinical Evidence

				reviews are updated periodically; please check our website for the most up-to-date version of this review). We included harms alerts from relevant organisations such as the US Food and Drug Administration (FDA) and the UK Medicines and Healthcare products Regulatory Agency (MHRA). RESULTS: We found 46 systematic reviews, RCTs, or observational studies that met our inclusion criteria. We performed a GRADE evaluation of the quality of evidence for interventions. CONCLUSIONS: In this systematic review we present information relating to the effectiveness and safety of the following interventions: antidepressants, cognitive behavioural therapy (CBT), corticosteroids, dietary supplements, evening primrose oil, galantamine, graded exercise therapy, homeopathy, immunotherapy, intramuscular magnesium, oral nicotinamide adenine dinucleotide, and prolonged rest.
Reuter SE, Evans AM.	From the School of Pharmacy & Medical Sciences, University of South Australia, Adelaide, SA, Australia. stephanie.reuter@unisa.edu.au	Long-chain acylcarnitine deficiency in patients with chronic fatigue syndrome. Potential involvement of altered carnitine palmitoyltransferase-I activity.	J Intern Med. 2011 Jul;270(1):76-84. doi: 10.1111/j.1365-2796.2010.02341.x. Epub 2011 Jan 19.	OBJECTIVE: The underlying aetiology of chronic fatigue syndrome is currently unknown; however, in the light of carnitine's critical role in mitochondrial energy production, it has been suggested that chronic fatigue syndrome may be associated with altered carnitine homeostasis. This study was conducted to comparatively examine full endogenous carnitine profiles in patients with chronic fatigue syndrome and healthy controls. DESIGN: A cross-sectional, observational study. SETTING AND SUBJECTS: Forty-four patients with chronic fatigue syndrome and 49 age- and gender-matched healthy controls were recruited from the community and studied at the School of Pharmacy & Medical Sciences, University of South Australia. MAIN OUTCOME MEASURES: All participants completed a fatigue severity scale questionnaire and had a single fasting blood sample collected which was analysed for l-carnitine and 35 individual acylcarnitine concentrations in plasma by LC-MS/MS. RESULTS: Patients with chronic fatigue syndrome exhibited significantly altered concentrations of C8:1, C12DC, C14, C16:1, C18, C18:1, C18:2 and C18:1-OH acylcarnitines; of particular note, oleyl-L-carnitine (C18:1) and linoleyl-L-carnitine (C18:2) were, on average, 30-40% lower in patients than controls ($P < 0.0001$). Significant correlations between acylcarnitine concentrations and clinical symptomology were also demonstrated. CONCLUSIONS: It is proposed that this disturbance in carnitine homeostasis is reflective of a reduction in carnitine palmitoyltransferase-I (CPT-I) activity, possibly a result of the accumulation of omega-6 fatty acids previously observed in this patient population. It is hypothesized that the administration of omega-3 fatty acids in combination with l-carnitine would increase CPT-I activity and improve chronic fatigue syndrome symptomology. © 2011 The Association for the Publication of the Journal of Internal Medicine.
Revicki DA, Rentz AM, Luo MP, Wong RL.	Outcomes Research, United BioSource Corporation, Bethesda, MD,	Psychometric characteristics of the short form 36 health survey and functional assessment of	Health Qual Life Outcomes. 2011 May 22;9:36.	BACKGROUND: We evaluated the psychometric characteristics of the Short Form 36 (SF-36) Health Survey and the Functional Assessment of Chronic Illness Therapy (FACIT)-Fatigue subscale in patients with ankylosing spondylitis (AS). METHODS: We analyzed clinical and patient-reported outcome (PRO) data collected during 12-week, double-blind, placebo-controlled periods of two randomized controlled trials

	USA. dennis.revicki@unitedbiosource.com	chronic illness Therapy-Fatigue subscale for patients with ankylosing spondylitis.		comparing adalimumab and placebo for the treatment of active AS. The Bath Ankylosing Spondylitis Disease Activity Index, Bath Ankylosing Spondylitis Functional Index, and other clinical measures were collected during the clinical trial. We evaluated internal consistency/reliability, construct validity, and responsiveness to change for the SF-36 and FACIT-Fatigue. RESULTS: The SF-36 (Cronbach alpha, 0.74-0.92) and FACIT-Fatigue (Cronbach alpha, 0.82-0.86) both had good internal consistency/reliability. At baseline, SF-36 and FACIT-Fatigue scores correlated significantly with Ankylosing Spondylitis Quality of Life scores ($r = -0.36$ to -0.66 and $r = -0.70$, respectively; all $p < 0.0001$). SF-36 scores varied by indicators of clinical severity, with greater impairment observed for more severe degrees of clinical activity (all $p < 0.0001$). FACIT-Fatigue scores correlated significantly with SF-36 scores ($r = 0.42$ to 0.74; all $p < 0.0001$) and varied by clinical severity ($p < 0.05$ to $p < 0.0001$). CONCLUSIONS: The SF-36 is a reliable, valid, and responsive measure of health-related quality of life and the FACIT-Fatigue is a brief and psychometrically sound measure of the effects of fatigue on patients with AS. These PROs may be useful in evaluating effectiveness of new treatments for AS.
Reyes Del Paso GA, Pulgar A, Duschek S, Garrido S.	Department of Psychology, University of Jaén, Jaen, Spain.	Cognitive impairment in fibromyalgia syndrome: The impact of cardiovascular regulation, pain, emotional disorders and medication.	Eur J Pain. 2011 Dec 19. doi: 10.1002/j.1532-2149.2011.00032.x. [Epub ahead of print]	This study investigated cognitive performance in fibromyalgia syndrome (FMS) and its association with cardiovascular and clinical parameters. Thirty-five patients with FMS and 29 matched healthy controls completed a neuropsychological test measuring attention and arithmetic processing. As possible factors underlying the expected cognitive impairment, clinical pain intensity, co-morbid depression and anxiety disorders, sleep complaints, medication use, as well as blood pressure parameters were investigated. The patients' test performance was substantially reduced, particularly in terms of lower speed of cognitive processing and restricted improvement of performance in the course of the task. While the extent of depression, anxiety, fatigue and sleep complaints was unrelated to test performance, better performance was observed in patients showing lower pain ratings and those using opiate medication. The data corroborate the presence of substantial cognitive impairment in FMS. While the experience of chronic pain is crucial in mediating the deficits, co-morbid depression, anxiety, fatigue and sleep complaints play only a subordinate role. In the control group, but not in the patients, blood pressure was inversely associated with mental performance. This finding is in line with the well known cognitive impairment in hypertension. The lack of this association in FMS confirms previous research showing aberrances in the interaction between blood pressure and central nervous function in the affected patients. © 2011 European Federation of International Association for the Study of Pain Chapters.
Rimes KA, Wingrove J.	University of Bath, Department of Psychology, Claverton Down,	Mindfulness-Based Cognitive Therapy for People with Chronic Fatigue Syndrome	Clin Psychol Psychother. 2011 Oct 9. doi: 10.1002/cpp.793.	Cognitive behaviour therapy (CBT) is an effective treatment for chronic fatigue syndrome (CFS; sometimes known as myalgic encephalomyelitis). However, only a minority of patients fully recover after CBT; thus, methods for improving treatment outcomes are required. This pilot study concerned a mindfulness-based cognitive

	Bath, UK. K.A.Rimes@bath.ac.uk.	Still Experiencing Excessive Fatigue after Cognitive Behaviour Therapy: A Pilot Randomized Study.	[Epub ahead of print]	therapy (MBCT) intervention adapted for people with CFS who were still experiencing excessive fatigue after CBT. The study aimed to investigate the acceptability of this new intervention and the feasibility of conducting a larger-scale randomized trial in the future. Preliminary efficacy analyses were also undertaken. Participants were randomly allocated to MBCT or waiting list. Sixteen MBCT participants and 19 waiting-list participants completed the study, with the intervention being delivered in two separate groups. Acceptability, engagement and participant-rated helpfulness of the intervention were high. Analysis of covariance controlling for pre-treatment scores indicated that, at post-treatment, MBCT participants reported lower levels of fatigue (the primary clinical outcome) than the waiting-list group. Similarly, there were significant group differences in fatigue at 2-month follow-up, and when the MBCT group was followed up to 6 months post-treatment, these improvements were maintained. The MBCT group also had superior outcomes on measures of impairment, depressed mood, catastrophic thinking about fatigue, all-or-nothing behavioural responses, unhelpful beliefs about emotions, mindfulness and self-compassion. In conclusion, MBCT is a promising and acceptable additional intervention for people still experiencing excessive fatigue after CBT for CFS, which should be investigated in a larger randomized controlled trial. Copyright © 2011 John Wiley & Sons, Ltd. KEY PRACTITIONER MESSAGE: Only about 30% of people with chronic fatigue syndrome (CFS) recover after cognitive behaviour therapy (CBT); thus, methods for improving treatment outcomes are needed. This is the first pilot randomized study to demonstrate that a mindfulness-based intervention was associated with reduced fatigue and other benefits for people with CFS who were still experiencing excessive fatigue after a course of CBT. Levels of acceptability, engagement in the intervention and rated helpfulness were high. A larger-scale randomized controlled trial is required. Copyright © 2011 John Wiley & Sons, Ltd.
Robinson MJ, Erlwein O, McClure MO.	Section of Infectious Diseases, Jefferiss Research Trust Laboratories, Imperial College London, St Mary's Campus, London, W2 1PG, UK.	Xenotropic murine leukaemia virus-related virus (XMRV) does not cause chronic fatigue.	Trends Microbiol. 2011 Nov;19(11):525-9. Epub 2011 Oct 4.	The xenotropic murine leukaemia virus-related virus (XMRV), a gammaretrovirus, was discovered in prostate cancer tumours by Virochip technology in 2006. It was subsequently detected in chronic fatigue patients in 2009. The association between XMRV and chronic fatigue has proved to be controversial. No study has confirmed these findings and many have refuted them. Here, we present the evidence for our contention that XMRV is not a human pathogen. Copyright © 2011 Elsevier Ltd. Robinson MJ, Tuke PW, Erlwein O, Tettmar KI, Kaye S, Naresh KN, Patel A, Walker MM,	Section of Infectious Diseases, Jefferiss Research Trust Laboratories,	No Evidence of XMRV or MuLV Sequences in Prostate Cancer, Diffuse Large B-Cell Lymphoma, or the	Adv Virol. 2011;2011:782353. Epub 2011 Jun 9.	Xenotropic murine leukaemia virus-related virus (XMRV) is a recently described retrovirus which has been claimed to infect humans and cause associated pathology. Initially identified in the US in patients with prostate cancer and subsequently in patients with chronic fatigue syndrome, doubt now exists that XMRV is a human pathogen. We studied the prevalence of genetic sequences of XMRV and related

Kimura T, Gopalakrishnan G, Tedder RS, McClure MO.	Imperial College London, St Mary's Campus, London W2 1PG, UK.	UK Blood Donor Population.		MuLV sequences in human prostate cancer, from B cell lymphoma patients and from UK blood donors. Nucleic acid was extracted from fresh prostate tissue biopsies, formalin-fixed paraffin-embedded (FFPE) prostate tissue and FFPE B-cell lymphoma. The presence of XMRV-specific LTR or MuLV generic gag-like sequences was investigated by nested PCR. To control for mouse DNA contamination, a PCR that detected intracisternal A-type particle (IAP) sequences was included. In addition, DNA and RNA were extracted from whole blood taken from UK blood donors and screened for XMRV sequences by real-time PCR. XMRV or MuLV-like sequences were not amplified from tissue samples. Occasionally MuLV gag and XMRV-LTR sequences were amplified from Indian prostate cancer samples, but were always detected in conjunction with contaminating murine genomic DNA. We found no evidence of XMRV or MuLV infection in the UK blood donors.
Rosenblum H, Shoenfeld Y, Amital H.	Department of Medicine B, Sheba Medical Center, Sackler Faculty of Medicine, Tel Aviv University, Ramat Aviv, Tel-Hashomer 52621, Israel.	The common immunogenic etiology of chronic fatigue syndrome: from infections to vaccines via adjuvants to the ASIA syndrome.	Infect Dis Clin North Am. 2011 Dec;25(4):851-63. Epub 2011 Sep 9.	Chronic fatigue syndrome (CFS) is characterized by unexplained fatigue that lasts for at least 6 months with a constellation of other symptoms. Most cases start suddenly, and are usually accompanied by a flu-like illness. It is a symptom-based diagnosis of exclusion, the pathogenesis of which is unknown. Studies have examined and hypothesized about the possible biomedical and epidemiologic characteristics of the disease, including genetic predisposition, infections, endocrine abnormalities, and immune dysfunction and psychological and psychosocial factors. Recently, the AISA (autoimmune/inflammatory syndrome induced by adjuvants) syndrome was recognized, indicating the possible contribution of adjuvants and vaccines to the development of autoimmunity. Ruiz E, Alegre J, García Quintana AM, Aliste L, Blázquez A, Fernández de Sevilla T.	Servicio de Medicina Interna, Unidad de Urgencias, Hospital General Universitario Vall d'Hebron, Barcelona, España. evruiz@vhebron.net	[Chronic fatigue syndrome: study of a consecutive series of 824 cases assessed in two specialized units]. [Article in Spanish]	Rev Clin Esp. 2011 Sep;211(8):385-90. Epub 2011 Jul 27. Comment in Rev Clin Esp. 2011 Sep;211(8):407-9.	BACKGROUND AND OBJECTIVE: The chronic fatigue syndrome (CFS) is a disabling disorder. Few studies are available in our area on the prevalence and characteristics of CFS. Therefore, we carried out a study of a consecutive series of 824 cases diagnosed in two specialized units. PATIENTS AND METHODS: We evaluated all of the CFS patients seen from January 2008 to June 2010. We analyzed social and demographic data, employment status, time of clinical evolution, trigger factors and onset, Fukuda and Canadian criteria, associated comorbidities and treatment. RESULTS: A total of 824 patients were included, 748 (91%) woman, mean age 48±9 years. Average age of onset of symptoms was 35±11 years, time to diagnosis 108±88 month. A precipitating factor was identified in 481 (58%) patients, the onset was gradual in 517 (63%) and 515 (62.5%) were not employed. The most outstanding diagnostic criteria of Fukuda were prolonged generalized fatigue after exercise, sleep disturbance and impairments in concentration and short-term memory. The different groups of symptoms defined by the Canadian consensus showed that CFS is a homogeneous entity. Accompanying comorbidity phenomena were anxiety 691 (83%), sicca syndrome 678 (82%), fibromyalgia 450 (55%). A total of 63% of patients (520) received pharmacological treatment. CONCLUSIONS: CFS is an illness that preferentially affects young women and results in employment absenteeism. The

				most relevant clinical features were prolonged generalized fatigue after exercise, neurocognitive impairment and sleep disturbance. In the evaluation of the patient, it is very important to apply the Canadian criteria and to assess comorbidity. Copyright © 2011 Elsevier España, S.L. All rights reserved.

Sachdeva AK, Kuhad A, Chopra K.	University Institute of Pharmaceutical Sciences, UGC Centre of Advanced Study, Panjab University, Chandigarh, India.	Epigallocatechin gallate ameliorates behavioral and biochemical deficits in rat model of load-induced chronic fatigue syndrome.	Brain Res Bull. 2011 Oct 10;86(3-4):165-72. Epub 2011 Jul 28.	Chronic fatigue syndrome is a heterogeneous disorder with unknown pathogenesis and etiology, characterized by tiredness, difficulty in concentration and memory, and concomitant skeletal and muscular pain, thus affecting both mental and physical domains. The pathogenesis of chronic fatigue syndrome is multifactorial and involves increased oxido-nitrosative stress along with generation of pro-inflammatory cytokines such as TNF-α. In the present study chronic fatigue was produced in rats by plunging a load of 10 ± 2% body weight and subjecting them to forced swim inside a rectangular jar daily for 28 days. Endurance capacity and post-swim fatigue were assessed on 1st, 7th, 14th, 21st and 28th days. EGCG was administered daily by oral gavage 30 min before forced swim session. On the 29th day, after assessment of various behavioral parameters, blood was collected through tail vein, and animals were sacrificed to harvest the brains, spleens and thymus. Chronic fatigue group exhibited significant behavioral alterations along with enhanced oxido-nitrosative stress and serum TNF-α level as compared to naive group. Chronic treatment with EGCG restored all the behavioral and biochemical alterations associated with chronic fatigue syndrome. The present study signifies the therapeutic potential of EGCG for the treatment of chronic fatigue syndrome. Copyright © 2011 Elsevier Inc. All rights reserved.
Sakakibara S, Sakakibara K, Tosato G.	Laboratory of Cellular Oncology, Center for Cancer Research, National Cancer Institute, National Institutes of Health, Building 37, Room 4134, Bethesda, MD 20892-1907, USA. sakakibs@mail.ni	NF-kappaB activation stimulates transcription and replication of retrovirus XMRV in human B-lineage and prostate carcinoma cells.	J Virol. 2011 Apr;85(7):3179-86. Epub 2011 Jan 26.	Xenotropic murine leukemia virus-related virus (XMRV) is a gammaretrovirus linked to prostate carcinoma and chronic fatigue syndrome. Here we report that NF-κB activation can markedly increase XMRV production. The inflammatory cytokine tumor necrosis factor alpha (TNF-α), which activates NF-κB, significantly augmented viral Gag protein production in XMRV-infected cells. Reporter assays showed that TNF-α and Epstein-Barr virus (EBV) latent membrane protein 1 (LMP1), an intrinsic NF-κB activator, increased long terminal repeat (LTR)-dependent XMRV transcription. We identified two NF-κB binding sites (designated κB-1 and κB-2) in the LTR U3 region of XMRV and demonstrated that both sites bind to the NF-κB component p65/RelA. Mutation of the κB-1 site, but not the κB-2 site, impaired responsiveness to TNF-α and LMP1 in reporter assays. A mutant XMRV with a mutation at the κB-1 site replicated significantly less efficiently than the wild-type XMRV in the prostate carcinoma LNCaP,

	h.gov			DU145, and PC-3 cell lines, HEK293 cells, the EBV-immortalized cell line IB4, and the Burkitt's lymphoma cell line BJAB. These results demonstrate that TNF-α and EBV LMP1 enhance XMRV replication in prostate carcinoma and B-lineage cells through the κB-1 site in the XMRV LTR, suggesting that inflammation, EBV infection, and other conditions leading to NF-κB activation may promote XMRV spread in humans.
Sakuma T, Hué S, Squillace KA, Tonne JM, Blackburn PR, Ohmine S, Thatava T, Towers GJ, Ikeda Y.	Department of Molecular Medicine, Mayo Clinic, Rochester, MN 55905, USA.	No evidence of XMRV in prostate cancer cohorts in the Midwestern United States.	Retrovirology. 2011 Mar 29;8:23.	BACKGROUND: Xenotropic murine leukemia virus (MLV)-related virus (XMRV) was initially identified in prostate cancer (PCa) tissue, particularly in the prostatic stromal fibroblasts, of patients homozygous for the RNASEL R462Q mutation. A subsequent study reported XMRV antigens in malignant prostatic epithelium and association of XMRV infection with PCa, especially higher-grade tumors, independently of the RNASEL polymorphism. Further studies showed high prevalence of XMRV or related MLV sequences in chronic fatigue syndrome patients (CFS), while others found no, or low, prevalence of XMRV in a variety of diseases including PCa or CFS. Thus, the etiological link between XMRV and human disease remains elusive. To address the association between XMRV infection and PCa, we have tested prostate tissues and human sera for the presence of viral DNA, viral antigens and anti-XMRV antibodies. RESULTS: Real-time PCR analysis of 110 PCa (Gleason scores >4) and 40 benign and normal prostate tissues identified six positive samples (5 PCa and 1 non-PCa). No statistical link was observed between the presence of proviral DNA and PCa, PCa grades, and the RNASEL R462Q mutation. The amplified viral sequences were distantly related to XMRV, but nearly identical to endogenous MLV sequences in mice. The PCR positive samples were also positive for mouse mitochondrial DNA by nested PCR, suggesting contamination of the samples with mouse DNA. Immuno-histochemistry (IHC) with an anti-XMRV antibody, but not an anti-MLV antibody that recognizes XMRV, sporadically identified antigen-positive cells in prostatic epithelium, irrespectively of the status of viral DNA detection. No serum (159 PCa and 201 age-matched controls) showed strong neutralization of XMRV infection at 1:10 dilution. CONCLUSION: The lack of XMRV sequences or strong anti-XMRV neutralizing antibodies indicates no or very low prevalence of XMRV in our cohorts. We conclude that real-time PCR- and IHC-positive samples were due to laboratory contamination and non-specific immune reactions, respectively.
Santamarina-Perez P, Eiroa-Orosa FJ, Freniche V, Moreno-Mayos A, Alegre J, Saez N, Jacas C.	Hospital Universitari Vall d'Hebron, Barcelona, Spain. psantamarina@vhebron.net	Length of illness does not predict cognitive dysfunction in chronic fatigue syndrome.	Appl Neuropsychol. 2011 Jul;18(3):216-22.	Neuropsychological studies have shown cognitive impairment in chronic fatigue syndrome (CFS), particularly in information-processing speed. The aim of this study was to examine the evolution of cognitive impairment in CFS. The evolution is one of the most disabling aspects of the CFS, and it has received little attention in the literature. Fifty-six women with CFS were assessed with neuropsychological tests. Patients were divided into three groups based on the duration of the disease. There were no differences between groups in terms of cognitive function. The cognitive impairment in CFS was not found to be more severe with longer disease duration. These data suggest that there is no progressive cognitive impairment in patients with

				CFS. Therefore, the cognitive deficits in CFS should be treated with cognitive rehabilitation programs focused on improving emotional distress associated to the illness and on promoting functional abilities.
Santamarina-Pérez P, Freniche V, Eiroa-Orosa FJ, Llobet G, Sáez N, Alegre J, Jacas C.	Servicio de Psiquiatría, Hospital Universitario Vall d'Hebron, Universitat Autònoma de Barcelona, España. psantamarina@vhebron.net	[The role of depression in cognitive impairment in patients with chronic fatigue syndrome]. [Article in Spanish]	Med Clin (Barc). 2011 Mar 12;136(6):239-43. Epub 2010 Dec 9. Comment in Med Clin (Barc). 2011 Nov 12;137(12):572; author reply 572-3.	BACKGROUND AND OBJECTIVE: To analyze the role of depression in cognitive deficits of patients with chronic fatigue syndrome (CFS). PATIENTS AND METHODS: 57 women with CFS were assessed by neuropsychological tests that included measures of attention: CalCap, Mental control of the WMS-III, PASAT, forward and backward digits (WAIS-III), symbol digit modalities test (SDMT); executive functions: Stroop Test, Trail Making Test (TMT A y B), FAS, Tower of London; memory: Auditory-Verbal Learning Test (AVL), Rey Complex Figure (RCF), and psychomotor skills: Grooved Pegboard. The raw scores on the tests were adjusted according to normative data and transformed to T scores. The sample was divided into two groups based on the presence or absence of depression, assessed by clinical interview and administration of the Hospital Anxiety and Depression Scale (HADS). This study compared neuropsychological test scores between the two groups. RESULTS: CFS patients showed cognitive deficit in attention and executive functions, regardless of the presence of depression. There were no significant differences between the two CFS groups. CONCLUSIONS: The cognitive impairments in patients with CFS are not secondary to the presence of depression. These results should be taken into account in the implementation of therapeutic programs in these patients. Copyright © 2010 Elsevier España, S.L. All rights reserved.
Sato E, Yoshikawa R, Miyazawa T.	Laboratory of Signal Transduction, Department of Cell Biology, Institute for Virus Research, Kyoto University.	Quantitative Assays for Xenotropic Murine Leukemia Virus-Related Virus.	J Vet Med Sci. 2011 Sep 30. [Epub ahead of print]	Xenotropic murine leukemia virus-related virus (XMRV), a novel gammaretrovirus in humans, was found in patients with prostate cancer (PC) and chronic fatigue syndrome (CFS). However, there has been controversy whether XMRV is directly associated with human diseases. In this study, we developed a LacZ marker rescue assay using human embryonic kidney 293T cells and a focus assay using a feline fibroblastic sarcoma-positive leukemia-negative QN10S cells. XMRV induced prominent foci in QN10S cells and the viral titer determined by the focus assay was as high as that by the LacZ marker rescue assay. Because the focus assay is simple and sensitive, it will be useful for monitoring infectious XMRVs in CFS and PC patients and virological studies for XMRV.
Satterfield BC, Garcia RA, Jia H, Tang S, Zheng H, Switzer WM.	Cooperative Diagnostics, LLC, Greenwood, SC 29646, USA. brent@codiagnostics.com	Serologic and PCR testing of persons with chronic fatigue syndrome in the United States shows no association with xenotropic or polytropic murine leukemia virus-	Retrovirology. 2011 Feb 22;8:12.	In 2009, a newly discovered human retrovirus, xenotropic murine leukemia virus (MuLV)-related virus (XMRV), was reported by Lombardi et al. in 67% of persons from the US with chronic fatigue syndrome (CFS) by PCR detection of gag sequences. Although six subsequent studies have been negative for XMRV, CFS was defined more broadly using only the CDC or Oxford criteria and samples from the US were limited in geographic diversity, both potentially reducing the chances of identifying XMRV positive CFS cases. A seventh study recently found polytropic MuLV sequences, but not XMRV, in a high proportion of persons with CFS. Here we tested blood specimens from 45 CFS cases and 42 persons without CFS from over 20 states in the United

		related viruses.		States for both XMRV and MuLV. The CFS patients all had a minimum of 6 months of post-exertional malaise and a high degree of disability, the same key symptoms described in the Lombardi et al. study. Using highly sensitive and generic DNA and RNA PCR tests, and a new Western blot assay employing purified whole XMRV as antigen, we found no evidence of XMRV or MuLV in all 45 CFS cases and in the 42 persons without CFS. Our findings, together with previous negative reports, do not suggest an association of XMRV or MuLV in the majority of CFS cases.

Schmidt S, Grossman P, Schwarzer B, Jena S, Naumann J, Walach H.	Department of Environmental Health Sciences, University Medical Center, Freiburg, Germany. stefan.schmidt@uniklinik-freiburg.de	Treating fibromyalgia with mindfulness-based stress reduction: results from a 3-armed randomized controlled trial.	Pain. 2011 Feb;152(2):361-9. Epub 2010 Dec 13.	Mindfulness-based stress reduction (MBSR) is a structured 8-week group program teaching mindfulness meditation and mindful yoga exercises. MBSR aims to help participants develop nonjudgmental awareness of moment-to-moment experience. Fibromyalgia is a clinical syndrome with chronic pain, fatigue, and insomnia as major symptoms. Efficacy of MBSR for enhanced well-being of fibromyalgia patients was investigated in a 3-armed trial, which was a follow-up to an earlier quasi-randomized investigation. A total of 177 female patients were randomized to one of the following: (1) MBSR, (2) an active control procedure controlling for nonspecific effects of MBSR, or (3) a wait list. The major outcome was health-related quality of life (HRQoL) 2 months post-treatment. Secondary outcomes were disorder-specific quality of life, depression, pain, anxiety, somatic complaints, and a proposed index of mindfulness. Of the patients, 82% completed the study. There were no significant differences between groups on primary outcome, but patients overall improved in HRQoL at short-term follow-up (P=0.004). Post hoc analyses showed that only MBSR manifested a significant pre-to-post-intervention improvement in HRQoL (P=0.02). Furthermore, multivariate analysis of secondary measures indicated modest benefits for MBSR patients. MBSR yielded significant pre-to-post-intervention improvements in 6 of 8 secondary outcome variables, the active control in 3, and the wait list in 2. In conclusion, primary outcome analyses did not support the efficacy of MBSR in fibromyalgia, although patients in the MBSR arm appeared to benefit most. Effect sizes were small compared to the earlier, quasi-randomized investigation. Several methodological aspects are discussed, e.g., patient burden, treatment preference and motivation, that may provide explanations for differences. In a 3-armed randomized controlled trial in female patients suffering from fibromyalgia, patients benefited modestly from a mindfulness-based stress reduction intervention.
Schneider S, Stone AA, Schwartz JE,	Department of Psychiatry &	Peak and end effects in patients' daily	J Pain. 2011 Feb;12(2):228-35.	Clinical research often relies on retrospective recall of symptom levels, but the information contained in these ratings is not well understood. The "peak-and-end

Broderick JE.	Behavioral Science, Stony Brook University, Stony Brook, New York 11794-8790, USA. Stefan.Schneider@sunysb.edu	recall of pain and fatigue: a within-subjects analysis.		rule" suggests that the most intense (peak) and final (end) moments of an experience disproportionately influence retrospective judgments, which may bias self-reports of somatic symptoms. This study examined the extent to which peak and end symptom levels systematically affect patients' day-to-day recall of pain and fatigue. Rheumatology patients (N = 97) completed 5 to 6 momentary ratings of pain and fatigue per day as well as a daily recall rating of these symptoms for 28 consecutive days. For pain, peak and end momentary ratings predicted daily recall of average pain beyond the actual average of momentary ratings. This effect was small, yet was confirmed in both between-person and within-person (repeated measures) analyses. For fatigue, neither peak nor end momentary symptoms significantly contributed to daily recall. Of note, the evidence for peak- and end-effects in recall of pain and fatigue varied significantly between individual patients. These findings suggest that peak- and end-effects create a small bias in recall reports of pain, but not fatigue. However, there are considerable individual differences in susceptibility to peak and end heuristics. PERSPECTIVE: The peak-end cognitive heuristic could bias end-of-day recall of pain and fatigue. An effect was shown for pain, but not for fatigue. The effects were small and were unlikely to substantially bias end-of-day assessments. Individuals were shown to differ in the degree that the heuristic was associated with recall. Copyright © 2011 American Pain Society. Published by Elsevier Inc. All rights reserved.
Schreurs KM, Veehof MM, Passade L, Vollenbroek-Hutten MM.	University of Twente, Enschede, The Netherlands. k.m.g.schreurs@utwente.nl	Cognitive behavioural treatment for chronic fatigue syndrome in a rehabilitation setting: effectiveness and predictors of outcome.	Behav Res Ther. 2011 Dec;49(12):908-13. Epub 2011 Sep 28.	Cognitive behavioural therapy (CBT) was combined with graded exercise therapy (GET) for patients with chronic fatigue syndrome (CFS) in an uncontrolled implementation study of an inpatient multidisciplinary group therapy. During the intake procedure, 160 CFS patients completed a questionnaire on fatigue related measurements, physical impairment, depression, somatic and psychological attributions, somatic focus, and sense of control over symptoms. Pre-treatment physical activity level was measured with an actometer. At baseline, post-treatment and 6-month follow-up individual strength, subjective fatigue and physical impairment, were reassessed. Large effect sizes were found on subjective fatigue (1.2 post-treatment; 1.2 follow-up) and physical impairment (-.9 post-treatment; -.9 follow-up), Clinically significant improvement was found in 33.8% of the participants at post-treatment and 30.6% at follow-up. Individual strength at post-treatment was predicted by level of physical activity before treatment, and by sense of control over symptoms and physical activity at follow-up. Clinically significant improvement in subjective fatigue was predicted by not receiving a disablement insurance benefit, shorter duration of fatigue, higher sense of control over symptoms and, at follow-up by more pre-treatment physical activity. In conclusion, the intervention was effective for CFS patients. Cognitive behavioural factors that perpetuate fatigue symptoms are also predictors of treatment outcome. Schrier M, Amital D, Arnson Y, Rubinow A, Altaman A, Nissenabaum B, Amital H.	Department of Medicine 'B', Sheba Medical Center, 52621, Tel-Hashomer, Ramat-Gan, Israel.	Association of fibromyalgia characteristics in patients with non-metastatic breast cancer and the protective role of resilience.	Rheumatol Int. 2011 Sep 8. [Epub ahead of print]	Cancer patients often complain about weakness, fatigue, and pain. The aim of this study was to assess the features of the fibromyalgia syndrome (FMS) characteristics in patients with non-metastatic breast cancer. The study group included 40 women whose age ranged from 40 to 70 years with Stages 0-3 breast cancer. The control group included 40 healthy women matched by age. A diagnosis of FMS was established based on medical history, physical examination, and the Fibromyalgia Impact Questionnaire (FIQ). Pain measures and functional factors were evaluated by the Brief Pain Inventory and the Sheehan Questionnaire. Resilience was assessed by Antanovsky's Sense of Coherence Questionnaire. Psychiatric disturbances were tested by the MINI Questionnaire and Hamilton questionnaires for depression and anxiety. The prevalence of chronic pain was higher in the study group. Statistically significant differences were also found between the group regarding pain, fatigue, and functional measures. The prevalence of depressive or anxious mood, measured by the Hamilton questionnaires, was strongly related to FMS characteristics reflected by FIQ scores (r = 0.79 between FIQ and the Hamilton Depression Index and r = 0.75 between FIQ and the Hamilton Anxiety Scale). The sense of coherence measure for these patients demonstrated an inverse correlation with pain, fatigue, and functional capability. Women with breast cancer tend to develop chronic widespread pain syndromes more often than do healthy women.
Schutzer SE, Angel TE, Liu T, Schepmoes AA, Clauss TR, Adkins JN, Camp DG, Holland BK, Bergquist J, Coyle PK, Smith RD, Fallon BA, Natelson BH.	Department of Medicine, University of Medicine and Dentistry of New Jersey-New Jersey Medical School, Newark, New Jersey, United States of America. schutzer@umdnj.edu	Distinct cerebrospinal fluid proteomes differentiate post-treatment lyme disease from chronic fatigue syndrome.	PLoS One. 2011 Feb 23;6(2):e17287.	BACKGROUND: Neurologic Post Treatment Lyme disease (nPTLS) and Chronic Fatigue (CFS) are syndromes of unknown etiology. They share features of fatigue and cognitive dysfunction, making it difficult to differentiate them. Unresolved is whether nPTLS is a subset of CFS. METHODS AND PRINCIPAL FINDINGS: Pooled cerebrospinal fluid (CSF) samples from nPTLS patients, CFS patients, and healthy volunteers were comprehensively analyzed using high-resolution mass spectrometry (MS), coupled with immunoaffinity depletion methods to reduce protein-masking by abundant proteins. Individual patient and healthy control CSF samples were analyzed directly employing a MS-based label-free quantitative proteomics approach. We found that both groups, and individuals within the groups, could be distinguished from each other and normals based on their specific CSF proteins ($p<0.01$). CFS ($n=43$) had 2,783 non-redundant proteins, nPTLS ($n=25$) contained 2,768 proteins, and healthy normals had 2,630 proteins. Preliminary pathway analysis demonstrated that the data could be useful for hypothesis generation on the pathogenetic mechanisms underlying these two related syndromes. CONCLUSIONS: nPTLS and CFS have distinguishing CSF protein complements. Each condition has a number of CSF proteins that can be useful in providing candidates for future validation studies and insights on the respective mechanisms of pathogenesis. Distinguishing nPTLS and CFS permits more focused study of each condition, and can lead to novel diagnostics and therapeutic interventions.

Ann Neurol. 2011 Apr;69(4):A9-A10.	retrovirus, xenotropic murine leukemia-related virus (XMRV), in blood; other studies could not replicate this finding. A useful next step would be to examine cerebrospinal fluid, because in some patients CFS is thought to be a brain disorder. Finding a microbe in the central nervous system would have greater significance than in blood because of the integrity of the blood-brain barrier. We examined cerebrospinal fluid from 43 CFS patients using polymerase chain reaction techniques, but did not find XMRV or multiple other common viruses, suggesting that exploration of other causes or pathogenetic mechanisms is warranted. Selin LK, Wlodarczyk MF, Kraft AR, Nie S, Kenney LL, Puzone R, Celada F.	Department of Pathology, University of Massachusetts Medical School, Worcester, MA 01655, USA. liisa.selin@umassmed.edu	Heterologous immunity: immunopathology, autoimmunity and protection during viral infections.	Autoimmunity. 2011 Jun;44(4):328-47. Epub 2011 Jan 20.	Heterologous immunity is a common phenomenon present in all infections. Most of the time it is beneficial, mediating protective immunity, but in some individuals that have the wrong crossreactive response it leads to a cascade of events that result in severe immunopathology. Infections have been associated with autoimmune diseases such as diabetes, multiple sclerosis and lupus erythematosis, but also with unusual autoimmune like pathologies where the immune system appears dysregulated, such as, sarcoidosis, colitis, panniculitis, bronchiolitis obliterans, infectious mononucleosis and even chronic fatigue syndrome. Here we review the evidence that to better understand these autoreactive pathologies it requires an evaluation of how T cells are regulated and evolve during sequential infections with different pathogens under the influence of heterologous immunity.
Selmi C, Mix E, Zettl UK.	Division of Rheumatology, Allergy, and Clinical Immunology, University of California, Davis, United States; Autoimmunity and Metabolism Unit, Department of Medicine, IRCCS Istituto Clinico Humanitas, Rozzano, Italy.	A clear look at the neuroimmunology of multiple sclerosis and beyond.	Autoimmun Rev. 2012 Jan;11(3):159-62. Epub 2011 May 23.	The term neuroimmunology was first coined to refer to a generic involvement of the immune system in the pathogenesis of neurological diseases, particularly of the central nervous system. Since then, the neuroimmunology spectrum has steadily grown and currently spans from classical autoimmune diseases of the central and peripheral nervous systems to previously unsuspected conditions such as autism spectrum disorders or chronic fatigue syndrome. Multiple sclerosis remains the predominant entity in terms of research efforts and social pressure as well as a good model of organ-specific autoimmune disease with limited therapeutic options. While the fast-pace genome-wide association studies reported a number of genes to be significantly associated with multiple sclerosis, these currently explain only a minor part of disease susceptibility. Further, clinicians are continuously challenged with the clinical classifications of immune-mediated or autoimmune central and peripheral conditions and with other pragmatic questions such as the roles of vaccination and physical therapy. For these reasons the present collection of Autoimmunity Reviews is timely as it will address these major issues related to neuroimmunology. Copyright © 2011 Elsevier B.V. All rights reserved.
Senel K, Baygutalp F, Baykal T, Erdal A, Ugur M.	Department of Physical Medicine and	Melatonin levels in premenopausal women with	Rheumatol Int. 2011 Dec 23. [Epub ahead of print]	The fibromyalgia syndrome (FMS) is a chronic, widespread pain disorder of unknown etiology. 	Rehabilitation, Atatürk University Medical Faculty, Erzurum, Turkey, kazimsenel@gmail.com.	fibromyalgia syndrome.		to the development of FMS. The role of melatonin in FMS is unclear. Some studies describe a lower nocturnal peak and a decreased secretion of melatonin in women with FMS when compared with healthy matched controls. The aim of the present study was to determine the possible role of melatonin in FMS patients. We examined the characteristics and levels of melatonin in 25 consecutive premenopausal women with FMS. Serum blood samples were collected from 25 patients and 20 the age and gender matched healthy controls. Melatonin levels were measured by enzyme-linked immunosorbent assay. Then, the results were compared with those from healthy subjects. Serum melatonin levels of FMS patients were not statistically different from those of controls ($P > 0.05$). No association was observed between melatonin levels of patients with FMS and disease duration, sleep disturbances, fatigue, and pain scores. Our results demonstrate that melatonin levels were similar in patients with FMS and healthy controls. Further studies are needed to determine the possible role of melatonin.
Sepede G, Racciatti D, Gorgoretti V, Nacci M, Pizzigallo E, Onofrj M, Di Giannantonio M, Niolu C, Salerno RM, Gambi F.	Department of Neuroscience and Imaging, University of Chieti, Italy. g.sepede@unich.it	Psychophysical distress and alexithymic traits in Chronic Fatigue Syndrome with and without comorbid depression.	Int J Immunopathol Pharmacol. 2011 Oct-Dec;24(4):1017-25.	Patients with Chronic Fatigue Syndrome (CFS) often report a comorbid depressive disorder. Comorbid depression may negatively influence the long-term outcome of CFS therefore it must be correctly diagnosed and treated. The aim of the present study is to provide a clinical and psychometric assessment of CFS patients with and without depressive features. A comparative analysis between 57 CFS subjects (CDC, 1994), 17 of whom with a comorbid depression, and 55 matched healthy volunteers was assessed to evaluate the presence of any psychophysical distress and alexithymic traits, by means of Symptom Checklist-90-R (SCL-90R) and Toronto Alexithymia Scale (TAS-20). The severity of fatigue was also assessed in all CFS patients using the Fatigue Impact Scale (FIS). With regard to psychiatric comorbidity, the SCL-90R scores showed higher levels of somatic complaints in CFS patients than in healthy subjects, whereas augmented depressive and obsessive-compulsive symptoms were observed only in the depressed CFS subgroup. When comparing the TAS-20 scores, we observed a selective impairment in the capacity to identify feelings and emotions, as measured by the Difficulty in Identifying Feelings subscale (DIF), non-depressed CFS patients showing an intermediate score between depressed CFS and healthy controls. Finally, in terms of FIS scores, a statistical trend versus a higher fatigue severity in depressed CFS patients, with respect to non-depressed ones, was observed. In conclusion, comorbid depression in CFS significantly increased the level of psychophysical distress and the severity of alexithymic traits. These findings suggest an urgent need to address and treat depressive disorders in the clinical care of CFS cases, to improve social functioning and quality of life in such patients.
Setty MK, Devadas K, Ragupathy V, Ravichandran V, Tang S, Wood O,	Center for Biologics Evaluation and Research, Food	XMRV: usage of receptors and potential co-receptors.	Virol J. 2011 Sep 6;8:423.	BACKGROUND: XMRV is a gammaretrovirus first identified in prostate tissues of Prostate Cancer (PC) patients and later in the blood cells of patients with Chronic Fatigue Syndrome (CFS). Although XMRV is thought to use XPR1 for cell entry, it infects A549 cells that do not express XPR1, suggesting usage of other receptors or

Gaddam DS, Lee S, Hewlett IK.	and Drug Administration, Bethesda, MD 20892, USA. indira.hewlett@fda.hhs.gov			co-receptors. METHODS: To study the usage of different receptors and co- receptors that could play a role in XMRV infection of lymphoid cells and GHOST (GFP- Human osteosarcoma) cells expressing CD4 along with different chemokine receptors including CCR1, CCR2, etc., were infected with XMRV. Culture supernatants and cells were tested for XMRV replication using real time quantitative PCR. RESULTS: Infection and replication of XMRV was seen in a variety of GHOST cells, LNCaP, DU145, A549 and Caski cell lines. The levels of XMRV replication varied in different cell lines showing differential replication in different cell lines. However, replication in A549 which lacks XPR1 expression was relatively higher than DU145 but lower than, LNCaP. XMRV replication varied in GHOST cell lines expressing CD4 and each of the co-receptors CCR1-CCR8 and bob. There was significant replication of XMRV in CCR3 and Bonzo although it is much lower when compared to DU145, A549 and LNCaP. CONCLUSION: XMRV replication was observed in GHOST cells that express CD4 and each of the chemokine receptors ranging from CCR1- CCR8 and BOB suggesting that infectivity in hematopoietic cells could be mediated by use of these receptors.

Shin CH, Bateman L, Schlaberg R, Bunker AM, Leonard CJ, Hughen RW, Light AR, Light KC, Singh IR.	Department of Pathology, University of Utah, 15 North Medical Drive East, Suite 2100, Salt Lake City, UT 84112, USA.	Absence of XMRV retrovirus and other murine leukemia virus-related viruses in patients with chronic fatigue syndrome.	339. J Virol. 2011 Jul;85(14):7195-202. Epub 2011 May 4.	Chronic fatigue syndrome (CFS) is a multisystem disorder characterized by prolonged and severe fatigue that is not relieved by rest. Attempts to treat CFS have been largely ineffective primarily because the etiology of the disorder is unknown. Recently, CFS has been associated with xenotropic murine leukemia virus-related virus (XMRV) as well as other murine leukemia virus (MLV)-related viruses, though not all studies have found these associations. We collected blood samples from 100 CFS patients and 200 self-reported healthy volunteers from the same geographical area. We analyzed these in a blind manner using molecular, serological, and viral replication assays. We also analyzed samples from patients in the original study that reported XMRV in CFS patients. We did not find XMRV or related MLVs either as viral sequences or infectious viruses, nor did we find antibodies to these viruses in any of the patient samples, including those from the original study. We show that at least some of the discrepancy with previous studies is due to the presence of trace amounts of mouse DNA in the Taq polymerase enzymes used in these previous studies. Our findings do not support an association between CFS and MLV-related viruses, including XMRV, and the off-label use of antiretrovirals for the treatment of CFS does not seem justified at present.

Developing thyroid disorders is associated with poor prognosis factors in patient with stable chronic heart failure.	Int J Cardiol. 2011 Mar 3;147(2):e24-5. Epub 2009 Feb 8.	We sought to assess the developing of thyroid disorders in forty eight patients with chronic stable heart failure and without thyroid abnormalities during six months follow-up. Thyroid function disorders were observed in 27.1% of the subjects: sick euthyroid syndrome (12.5%), subclinical hypothyroidism (10.4%) and overt hypothyroidism (6.2%). Subjects with higher thyroid stimulating hormone (TSH) levels at the end of the study had more hospitalizations. The developing of altered thyroid profile was related to lower hemoglobin levels, smaller phase angle with bioelectrical impedance method and more fatigue perception by the patients. This abnormal thyroid function behavior on stable chronic heart failure and was observed as part of the disease progress and was associated to worse prognosis factors as lower phase angle and anemia. Silvério R, Laviano A, Rossi Fanelli F, Seelaender M.		l-carnitine and cancer cachexia: Clinical and experimental aspects.	J Cachexia Sarcopenia Muscle. 2011 Mar;2(1):37-44. Epub 2011 Jan 26.	Cancer cachexia is a multifaceted syndrome characterized, among many symptoms, by extensive muscle wasting. Chronic systemic inflammation, partly triggered and sustained by cytokines, as well as increased oxidative stress contributes to the pathogenesis of this complex metabolic disorder. l-carnitine plays a central role in the metabolism of fatty acids and shows important antioxidant and anti-inflammatory properties. Systemic carnitine depletion has been described in several diseases, and it is characterized by fatigue, muscle weakness, and decreased tolerance to metabolic stress. In cachectic cancer patients, low serum carnitine levels have been reported, and this change has been suggested to play an important contributory role in the development of cachexia. Based on these data, carnitine supplementation has been tested in preliminary studies concerning human cachexia, resulting in improved fatigue and quality of life. We present here a review of clinical and experimental evidence regarding the use of carnitine supplementation in the management of cancer cachexia.

Collaborators: Glynn S, Holmberg	Blood Systems Research Institute and University of California, San Francisco, San Francisco, CA 94118, USA.	Failure to confirm XMRV/MLVs in the blood of patients with chronic fatigue syndrome: a multi-laboratory study.	Science. 2011 Nov 11;334(6057):814-7. Epub 2011 Sep 22.	Murine leukemia viruses (MLVs), including xenotropic-MLV-related virus (XMRV), have been controversially linked to chronic fatigue syndrome (CFS). To explore this issue in greater depth, we compiled coded replicate samples of blood from 15 subjects previously reported to be XMRV/MLV-positive (14 with CFS) and from 15 healthy donors previously determined to be negative for the viruses. These samples were distributed in a blinded fashion to nine laboratories, which performed assays designed to detect XMRV/MLV nucleic acid, virus replication, and antibody. Only two laboratories reported evidence of XMRV/MLVs; however, replicate sample results showed disagreement, and reactivity was similar among CFS subjects and negative controls. These results indicate that current assays do not reproducibly detect XMRV/MLV in blood samples and that blood donor screening is not warranted.

Slatten LA, David Carson K, Carson PP.	Department of Management, University of Louisiana at Lafayette, USA. las3678@louisiana.edu	Compassion fatigue and burnout: what managers should know.	Health Care Manag (Frederick). 2011 Oct;30(4):325-33. doi: 10.1097/HCM.0b013e31823511f7.	Most health care employees experience and are bolstered by compassion satisfaction as they deal with patients in need. However, the more empathetic a health care provider is, the more likely he or she will experience compassion fatigue. Compassion fatigue is a negative syndrome that occurs when dealing with the traumatic experiences of patients, and examples of symptoms include intrusive thoughts, sleeping problems, and depression. Compassion fatigue is different from burnout. Compassion fatigue is a rapidly occurring disorder for primary health care workers who work with suffering patients, whereas burnout, a larger construct, is a slowly progressing disorder for employees who typically are working in burdensome organizational environments. Managers can mitigate problems associated with compassion fatigue with a number of interventions including patient reassignments, formal mentoring programs, employee training, and a compassionate organizational culture. With burnout, health care managers will want to focus primarily on chronic organizational problems.
Smith AK, Fang H, Whistler T, Unger ER, Rajeevan MS.	Division of High-Consequence Pathogens and Pathology, Centers for Disease Control and Prevention, Atlanta, GA	Convergent genomic studies identify association of GRIK2 and NPAS2 with chronic fatigue syndrome.	Neuropsychobiology. 2011;64(4):183-94. Epub 2011 Sep 9.	BACKGROUND: There is no consistent evidence of specific gene(s) or molecular pathways that contribute to the pathogenesis, therapeutic intervention or diagnosis of chronic fatigue syndrome (CFS). While multiple studies support a role for genetic variation in CFS, genome-wide efforts to identify associated loci remain unexplored. We employed a novel convergent functional genomics approach that incorporates the findings from single-nucleotide polymorphism (SNP) and mRNA expression studies to identify associations between CFS and novel candidate genes for further investigation. METHODS: We evaluated 116,204 SNPs in 40 CFS and 40 nonfatigued control subjects

	30333, USA.			along with mRNA expression of 20,160 genes in a subset of these subjects (35 CFS subjects and 27 controls) derived from a population-based study. RESULTS: Sixty-five SNPs were nominally associated with CFS (p<0.001), and 165 genes were differentially expressed (≥4-fold; p≤0.05) in peripheral blood mononuclear cells of CFS subjects. Two genes, glutamate receptor, ionotropic, kinase 2 (GRIK2) and neuronal PAS domain protein 2 (NPAS2), were identified by both SNP and gene expression analyses. Subjects with the G allele of rs2247215 (GRIK2) were more likely to have CFS (p=0.0005), and CFS subjects showed decreased GRIK2 expression (10-fold; p=0.015). Subjects with the T allele of rs356653 (NPAS2) were more likely to have CFS (p=0.0007), and NPAS2 expression was increased (10-fold; p=0.027) in those with CFS. CONCLUSION: Using an integrated genomic strategy, this study suggests a possible role for genes involved in glutamatergic neurotransmission and circadian rhythm in CFS and supports further study of novel candidate genes in independent populations of CFS subjects. Smith HS, Harris R, Clauw D.	Albany Medical College, Department of Anesthesiology, Albany, NY 12208, USA. smithh@mail.amc.edu	Fibromyalgia: an afferent processing disorder leading to a complex pain generalized syndrome.	Pain Physician. 2011 Mar-Apr;14(2):E217-45.	Fibromyalgia is a condition which appears to involve disordered central afferent processing. The major symptoms of fibromyalgia include multifocal pain, fatigue, sleep disturbances, and cognitive or memory problems. Other symptoms may include psychological distress, impaired functioning, and sexual dysfunction. The pathophysiology of fibromyalgia remains uncertain but is believed to be largely central in nature. In 1990 the American College of Rheumatology (ACR) published diagnostic research criteria for fibromyalgia. The criteria included a history of chronic and widespread pain and the presence of 11 or more out of 18 tender points. Pain was considered chronic widespread when all of the following are present: pain in the left side of the body; pain in the right side of the body; pain above the waist; pain below the waist. In addition, axial skeletal pain must be present and the duration of pain must be more than 3 months. A tender point is considered positive when pain can be elicited by pressures of 4 kg/cm2 or less. For tender points to be considered positive, the patient must perceive the palpation as painful; tenderness to palpation is not sufficient. However, over the next 20 years it became increasingly appreciated that the focus on tender points was not justified. In 2010 a similar group of investigators performed a multicenter study of 829 previously diagnosed fibromyalgia patients and controls using physician physical and interview examinations, including a widespread pain index (WPI), a measure of the number of painful body regions. Random forest and recursive partitioning analyses were used to guide the development of a case definition of fibromyalgia, to develop new preliminary ACR diagnostic criteria, and to construct a symptom severity (SS) scale. The most important diagnostic variables were WPI and categorical scales for cognitive symptoms, un-refreshed sleep, fatigue, and number of somatic symptoms. The categorical scales were summed to create an SS scale. The investigators combined the SS scale and the WPI to recommend a new case definition of fibromyalgia: (WPI > or =

				7 AND SS > or = 5). Although there is no known cure for fibromyalgia, multidisciplinary team efforts using combined treatment approaches, including patient education, aerobic exercise, cognitive behavioral therapy, and pharmacologic therapies (serotonin norepinephrine reuptake inhibitors [e.g., duloxetine, milnacipran] and alpha 2-delta receptor ligands [e.g., pregabalin]) might improve symptoms as well as function in patients with fibromyalgia.
Smits B, van den Heuvel L, Knoop H, Küsters B, Janssen A, Borm G, Bleijenberg G, Rodenburg R, van Engelen B.	Neuromuscular Center Nijmegen, Department of Neurology, Radboud University Nijmegen Medical Center, Nijmegen, The Netherlands. b.smits@neuro.umcn.nl	Mitochondrial enzymes discriminate between mitochondrial disorders and chronic fatigue syndrome.	Mitochondrion. 2011 Sep;11(5):735-8. Epub 2011 Jun 2.	We studied the extent of mitochondrial involvement in chronic fatigue syndrome (CFS) and investigated whether measurement of mitochondrial respiratory chain complex (RCC) activities discriminates between CFS and mitochondrial disorders. Mitochondrial content was decreased in CFS compared to healthy controls, whereas RCC activities corrected for mitochondrial content were not. Conversely, mitochondrial content did not discriminate between CFS and two groups of mitochondrial disorders, whereas ATP production rate and complex I, III and IV activity did, all with higher activities in CFS. We conclude that the ATP production rate and RCC activities can reliably discriminate between mitochondrial disorders and CFS.
Smolensky MH, Di Milia L, Ohayon MM, Philip P.	The University of Texas-Houston Health Sciences Center, United States. msmolensky@austin.rr.com	Sleep disorders, medical conditions, and road accident risk.	Accid Anal Prev. 2011 Mar;43(2):533-48.	Sleep disorders and various common acute and chronic medical conditions directly or indirectly affect the quality and quantity of one's sleep or otherwise cause excessive daytime fatigue. This article reviews the potential contribution of several prevalent medical conditions - allergic rhinitis, asthma, chronic obstructive pulmonary disease, rheumatoid arthritis/osteoarthritis - and chronic fatigue syndrome and clinical sleep disorders - insomnia, obstructive sleep apnea, narcolepsy, periodic limb movement of sleep, and restless legs syndrome - to the risk for drowsy-driving road crashes. It also explores the literature on the cost-benefit of preventive interventions, using obstructive sleep apnea as an example. Although numerous investigations have addressed the impact of sleep and medical disorders on quality of life, few have specifically addressed their potential deleterious effect on driving performance and road incidents. Moreover, since past studies have focused on the survivors of driver crashes, they may be biased. Representative population-based prospective multidisciplinary studies are urgently required to clarify the role of the fatigue associated with common ailments and medications on traffic crash risk of both commercial and non-commercial drivers and to comprehensively assess the cost-effectiveness of intervention strategies.
Sommerfeldt L, Portilla H, Jacobsen L, Gjerstad J, Wyller VB.	Oslo University Hospital, Norway.	Polymorphisms of adrenergic cardiovascular control genes are associated with	Acta Paediatr. 2011 Feb;100(2):293-8. doi: 10.1111/j.1651-2227.2010.02072.x. Epub 2010 Nov 18.	AIM: To explore the frequency of polymorphisms in adrenergic cardiovascular control genes in adolescent with chronic fatigue syndrome (CFS) and the relation of such polymorphisms to cardiovascular variables. METHODS: DNA from 53 patients with CFS, 12-18 years old, was analysed for five single nucleotide polymorphisms (SNPs) in the genes catechol-O-methyltransferase (COMT), the β_2 -adrenergic receptor (two

		adolescent chronic fatigue syndrome.		SNPs), the β_1 -adrenergic receptor and the α_2(a) -adrenergic receptor. Frequencies were compared to a reference population constructed from the National Center for Biotechnology Information (NCBI) database, and associations between frequencies and autonomic cardiovascular responses during a 20° head-up tilt-test were explored. RESULTS: For the COMT SNP Rs4680, patients with CFS had a higher frequency of the AA genotype and a lower frequency of the G containing genotypes (AG and GG), when compared to the reference sample (p = 0.046). Also, the AA genotype was associated with a smaller increase in LF/HF ratio (low-frequency:high-frequency heart rate variability ratio, an index of cardiac sympathovagal balance) during head-up tilt when compared to the AG/GG genotypes. For the β_2 -adrenergic receptor SNP Rs1042714, patients with CFS had a lower frequency of the GG genotype and a higher frequency of the genotypes containing C (CG and CC) (p = 0.044). CONCLUSIONS: CFS might be related to polymorphisms of COMT and the β_2 -adrenergic receptor. More details of the molecular mechanisms remain to be investigated. © 2010 The Author(s)/Acta Paediatrica © 2010 Foundation Acta Paediatrica.

HIV Drug Resistance Program, National Cancer Institute, Frederick, MD 21702-1201, USA.	Prevalence of XMRV Nucleic Acid and Antibody in HIV-1-Infected Men and in Men at Risk for HIV-1 Infection.	Adv Virol. 2011;2011:268214. Epub 2011 Nov 21.	Xenotropic MLV-Related Virus (XMRV) was recently reported to be associated with prostate cancer and chronic fatigue syndrome (CFS). Infection was also reported in 3.7% of healthy individuals. These highly reported frequencies of infection prompted concerns about the possibility of a new, widespread retroviral epidemic. The Multicenter AIDS Cohort Study (MACS) provides an opportunity to assess the prevalence of XMRV infection and its association with HIV-1 infection among men who have sex with men. Reliable detection of XMRV infection requires the application of multiple diagnostic methods, including detection of human antibodies to XMRV and detection of XMRV nucleic acid. We, therefore, tested 332 patient plasma and PBMC samples obtained from recent visits in a subset of patients in the MACS cohort for XMRV antibodies using Abbott prototype ARCHITECT chemiluminescent immunoassays (CMIAs) and for XMRV RNA and proviral DNA using a XMRV single-copy qPCR assay (X-SCA). Although 9 of 332 (2.7%) samples showed low positive reactivity against a single antigen in the CMIA, none of these samples or matched controls were positive for plasma XMRV RNA or PBMC XMRV DNA by X-SCA. Thus, we found no evidence of XMRV infection among men in the MACS regardless of HIV-1 serostatus.
Sprott H.	Rheumaklinik und Institut für Physikalische Medizin,	[Is fibromyalgia a viral disease?]. [Article in German]	Z Rheumatol. 2011 Oct;70(8):637-8.	Are viruses responsible for the pain in patients with fibromyalgia? Are viruses the trigger for rheumatoid arthritis? Is chronic fatigue syndrome a viral disease? There are many open questions with few or controversial answers. According to the current state of knowledge on the origin of the pain in fibromyalgia the varied symptomatic of

	UniversitätsSpital Zürich, Gloriastr. 25, CH-8091, Zürich, Schweiz. haiko.sprott@usz.ch			fibromyalgia is triggered by peripheral as well as central mechanisms. Despite the broad spectrum of symptoms the disease is a specific entity which is mainly treated with dual reuptake inhibitors, anticonvulsives, tramadol, selective serotonin reuptake inhibitors, gamma-hydroxybutyrate and dopamine agonists in individually selected combinations.
Steffen I, Tyrrell DL, Stein E, Montalvo L, Lee TH, Zhou Y, Lu K, Switzer WM, Tang S, Jia H, Hockman D, Santer DM, Logan M, Landi A, Law J, Houghton M, Simmons G.	Blood Systems Research Institute, San Francisco, California, United States of America.	No evidence for XMRV nucleic acids, infectious virus or anti-XMRV antibodies in Canadian patients with chronic fatigue syndrome.	PLoS One. 2011;6(11):e27870. Epub 2011 Nov 17.	The gammaretroviruses xenotropic murine leukemia virus (MLV)-related virus (XMRV) and MLV have been reported to be more prevalent in plasma and peripheral blood mononuclear cells of chronic fatigue syndrome (CFS) patients than in healthy controls. Here, we report the complex analysis of whole blood and plasma samples from 58 CFS patients and 57 controls from Canada for the presence of XMRV/MLV nucleic acids, infectious virus, and XMRV/MLV-specific antibodies. Multiple techniques were employed, including nested and qRT-PCR, cell culture, and immunoblotting. We found no evidence of XMRV or MLV in humans and conclude that CFS is not associated with these gammaretroviruses.
Stewart JM, Medow MS, Messer ZR, Baugham IL, Terilli C, Ocon AJ.	1New York Medical College.	Postural Neurocognitive and Neuronal Activated Cerebral Blood Flow Deficits in Young Chronic Fatigue Syndrome Patients with Postural Tachycardia Syndrome.	Am J Physiol Heart Circ Physiol. 2011 Dec 16. [Epub ahead of print]	Neurocognition is impaired in Chronic Fatigue Syndrome (CFS). We propose that impairment relates to postural cerebral hemodynamics. 25 CFS and 20 control subjects underwent incremental upright tilt at 0°, 15°, 30°, 45°, 60°, and 75° with continuous measurement of arterial blood pressure and cerebral blood flow velocity (CBFv). We used an N-back task with N ranging from 0 to 4 (increased N= increased task difficulty) to test working memory and information processing. We measured N-back outcomes by the number of correct answers and by reaction time. We measured CBFv, critical closing pressure (CCP), and CBFv altered by neuronal activity (activated CBFv) during each N and every tilt angle using transcranial Doppler ultrasound. N-Back outcome in controls decreased with N but was independent of tilt angle. N-Back outcome in CFS decreased with N but deteriorated as orthostasis progressed. Absolute mean CBFv was slightly less than control in CFS at each angle. Activated CBFv in controls was independent of tilt angle and increased with N. In contrast, activated CBFv averaged 0 in CFS, decreased with angle and was less than control. CCP was increased in CFS suggesting increased vasomotor tone and decreased metabolic control of CBFv. CCP did not change with orthostasis in CFS, but decreased monotonically in control subjects, consistent with vasodilation as compensation for the orthostatic reduction of cerebral perfusion pressure. Increasing orthostatic stress impairs neurocognition in CFS. CBFv activation, normally tightly linked to cognitive neuronal activity, is unrelated to cognitive performance in CFS; increased CCP and vasomotor tone may indicate uncoupling of the neurovascular unit during orthostasis.
Stieler K, Schindler S, Schlomm T, Hohn O, Bannert	Institute for Medical Microbiology and	No detection of XMRV in blood samples and tissue	PLoS One. 2011;6(10):e25592. Epub 2011 Oct 12.	BACKGROUND: We recently published the rare detection of xenotropic murine leukemia virus-related virus (XMRV) (1/105) in prostate cancer (PCA) tissue of patients in Northern Europe by PCR. The controversial discussion about the virus

N, Simon R, Minner S, Schindler M, Fischer N.	Virology, University Medical Center Hamburg-Eppendorf, Hamburg, Germany.	sections from prostate cancer patients in Northern Europe.		being detected in PCA tissue, blood samples from patients suffering from chronic fatigue syndrome (CFS), as well as from a significant number of healthy controls prompted us to deepen our studies about detection of XMRV infection applying different detection methods (PCR, cocultivation and immunohistochemistry [IHC]). METHODOLOGY/PRINCIPAL FINDINGS: Peripheral blood mononuclear cells (PBMCs) from 92 PCA and 7 healthy controls were isolated, PHA activated and cocultivated with LNCaP cells for up to 8 weeks. Supernatant of these cells was applied to a reporter cell line, DERSE-iGFP. Furthermore, the PBMCs and cocultivated LNCaP cells were tested for the presence of XMRV by PCR as well as Western Blot analysis. While all PCR amplifications and Western Blot analyses were negative for signs of XMRV infection, DERSE-iGFP cells displayed isolated GFP positive cells in three cases. In all three cases XMRV presence could not be confirmed by PCR technology. In addition, we performed XMRV specific IHC on PCA tissue sections. Whole tissue sections (n = 20), as well as tissue microarrays (TMA) including 50 benign prostate hyperplasia (BPH), 50 low grade and 50 high grade PCA sections and TMAs including breast cancer, colon cancer and normal tissues were stained with two XMRV specific antisera. XMRV protein expression was not detected in any cancer sections included. One BPH tissue displayed XMRV specific protein expression in random isolated basal cells. CONCLUSION: We were unable to conclusively detect XMRV in the blood from PCA patients or from healthy controls and there is no conclusive evidence of XMRV protein expression in PCA, breast cancer and colon cancer tissue sections tested by IHC staining.

Sullivan PF, Allander T, Lysholm F, Goh S, Persson B, Jacks A,	Department of Genetics, University of North Carolina at	An unbiased metagenomic search for infectious agents using monozygotic	BMC Microbiol. 2011 Jan 2;11:2.	BACKGROUND: Chronic fatigue syndrome is an idiopathic syndrome widely suspected of having an infectious or immune etiology. We applied an unbiased metagenomic approach to try to identify known or novel infectious agents in the serum of 45 cases with chronic fatigue syndrome or idiopathic chronic fatigue. Controls were the

Evengård B, Pedersen NL, Andersson B.	Chapel Hill, Chapel Hill, NC, USA. pfsulliv@med.unc.edu	twins discordant for chronic fatigue.		unaffected monozygotic co-twins of cases, and serum samples were obtained at the same place and time. RESULTS: No novel DNA or RNA viral signatures were confidently identified. Four affected twins and no unaffected twins evidenced viremia with GB virus C (8.9% vs. 0%, p = 0.019), and one affected twin had previously undetected hepatitis C viremia. An excess of GB virus C viremia in cases with chronic fatigue requires confirmation. CONCLUSIONS: Current, impairing chronic fatigue was not robustly associated with viremia detectable in serum.

Laboratory Branch, Division of HIV/AIDS Prevention, National Center for HIV/AIDS, Viral Hepatitis, STD, and TB Prevention, Centers for Disease Control and Prevention, Atlanta, Georgia, USA. bswitzer@cdc.gov	No evidence of murine leukemia virus-related viruses in live attenuated human vaccines.	PLoS One. 2011;6(12):e29223. Epub 2011 Dec 22.	BACKGROUND: The association of xenotropic murine leukemia virus (MLV)-related virus (XMRV) in prostate cancer and chronic fatigue syndrome reported in previous studies remains controversial as these results have been questioned by recent data. Nonetheless, concerns have been raised regarding contamination of human vaccines as a possible source of introduction of XMRV and MLV into human populations. To address this possibility, we tested eight live attenuated human vaccines using generic PCR for XMRV and MLV sequences. Viral metagenomics using deep sequencing was also done to identify the possibility of other adventitious agents. RESULTS: All eight live attenuated vaccines, including Japanese encephalitis virus (JEV) (SA-14-14-2), varicella (Varivax), measles, mumps, and rubella (MMR-II), measles (Attenuvax), rubella (Meruvax-II), rotavirus (Rotateq and Rotarix), and yellow fever virus were negative for XMRV and highly related MLV sequences. However, residual hamster DNA, but not RNA, containing novel endogenous gammaretrovirus sequences was detected in the JEV vaccine using PCR. Metagenomics analysis did not detect any adventitious viral sequences of public health concern. Intracisternal A particle sequences closest to those present in Syrian hamsters and not mice were also detected in the JEV SA-14-14-2 vaccine. Combined, these results are consistent with the production of the JEV vaccine in Syrian hamster cells. CONCLUSIONS: We found no evidence of XMRV and MLV in eight live attenuated human vaccines further supporting the safety of these vaccines. Our findings suggest that vaccines are an unlikely source of XMRV and MLV exposure in humans and are consistent with the mounting evidence on the absence of these viruses in humans.
Szu-Ting Fu T, Koutstaal W, Poon L, Cleare AJ.	Institute of Biomedical Sciences, Academia Sinica, 6F, No. 16, Alley	Confidence judgment in depression and dysphoria: The depressive realism vs. negativity	J Behav Ther Exp Psychiatry. 2012 Jun;43(2):699-704. Epub 2011 Oct 5.	BACKGROUND AND OBJECTIVES: According to the negativity hypothesis, depressed individuals are over-pessimistic due to negative self-concepts. In contrast, depressive realism suggests that depressed persons are realistic compared to their nondepressed controls. However, evidence supporting depressive realism predominantly comes from judgment comparisons between controls and nonclinical dysphoric samples

	10, Lane 437, Pa-The Rd Sec 2, Taipei 10552, Taiwan.	hypotheses.		when the controls showed overconfident bias. This study aimed to test the validity of the two accounts in clinical depression and dysphoria. METHODS: Sixty-eight participants, including healthy controls (n = 32), patients with DSM-IV major depression (n = 20), and dysphoric participants with CDC-defined chronic fatigue syndrome (n = 16) performed an adjective recognition task and reported their item-by-item confidence judgments and post-test performance estimate (PTPE). RESULTS: Compared to realistic PTPE made by the controls, patients with major depression showed significant underconfidence. The PTPE of the dysphoric participants was relatively accurate. Both the depressed and dysphoric participants displayed less item-by-item overconfidence as opposed to significant item-by-item overconfidence shown by the controls. LIMITATIONS: The judgment-accuracy patterns of the three groups need to be replicated with larger samples using non-memory task domains. CONCLUSION: The present study confirms depressive realism in dysphoric individuals. However, toward a more severe depressive emotional state, the findings did not support depressive realism but are in line with the prediction of the negativity hypothesis. It is not possible to determine the validity of the two hypotheses when the controls are overconfident. Dissociation between item-by-item and retrospective confidence judgments is discussed. Tak LM, Cleare AJ, Ormel J, Manoharan A, Kok IC, Wessely S, Rosmalen JG.	Interdisciplinary Center for Psychiatric Epidemiology, University Medical Center Groningen, University of Groningen, Groningen, The Netherlands.	Meta-analysis and meta-regression of hypothalamic-pituitary-adrenal axis activity in functional somatic disorders.	Biol Psychol. 2011 May;87(2):183-94. Epub 2011 Feb 18.	Dysfunction of the hypothalamic-pituitary-adrenal (HPA) axis is the most investigated biological risk marker in functional somatic disorders (FSDs), such as chronic fatigue syndrome (CFS), fibromyalgia (FM), and irritable bowel syndrome (IBS). Our aim was to assess whether there is an association between basal hypocortisolism and FSD and to identify potential moderators of this association. Meta-analysis on 85 studies revealed that although basal cortisol levels were generally lower in FSD subjects compared to controls, this association did not reach statistical significance (SMD -0.07, 95% CI -0.17 to 0.04, p=0.241). However, when the three FSD were assessed separately, statistically significant basal hypocortisolism was observed in CFS subjects compared to controls (SMD -0.14, 95% CI -0.28 to 0.00, p=0.047), but not in FM or IBS. When all potential moderators were entered into a meta-regression analysis, only type of FSD and female gender were significant independent predictors of basal hypocortisolism. In conclusion, we did not find evidence to consider all three main FSD as hypocortisolemic disorders, as significant reduction in basal cortisol compared to healthy controls was only found in CFS and in females with FM, but not in IBS. Tang N, Frank A, Leckie G, Hackett J Jr, Simmons G, Busch M, Abravaya K.	Abbott Molecular Inc., Des Plaines, IL 60018, USA. ning.tang@abbott.com	Development of sensitive single-round pol or env RT-PCR assays to screen for XMRV in multiple sample types.	J Virol Methods. 2012 Jan;179(1):127-34. Epub 2011 Oct 25.	The potential association between xenotropic murine leukemia virus-related virus (XMRV) and prostate cancer and chronic fatigue syndrome (CFS) has been much debated. To help resolve the potential role of XMRV in human disease, it is critical to develop sensitive and accurate reverse transcriptase (RT)-PCR assays to screen for the virus. Single-round RT-PCR assays were developed on the automated m2000™ system for detection of the pol or env regions of XMRV in whole blood, plasma, urine

				cell pellets and urogenital swab samples. Assay performance was assessed by testing two blinded panels, one comprised of whole blood and the other of plasma spiked with serial dilutions of XMRV-infected tissue culture cells and supernatant, respectively, prepared by the Blood XMRV Scientific Research Working Group (SRWG). For both whole blood and plasma panel testing, the assays showed excellent specificity and sensitivity as compared to the other tests included in the SRWG phase I study. Analytical specificity of the assays was also evaluated. Neither pol nor env PCR assays detected a panel of potential cross-reactive microorganisms, although some cross-reaction was observed with mouse genomic DNA. Screening of 196 normal human blood donor plasma, 214 HIV-1 seropositive plasma, 20 formalin-fixed paraffin-embedded (FFPE) prostate cancer specimens, 4 FFPE benign prostate specimens, 400 urine pellets from prostate cancer patients, 166 urine pellets from non-prostate cancer patients, and 135 cervical swab specimens, detected no samples as unequivocally XMRV positive. Tang S, Zhao J, Viswanath R, Nyambi PN, Redd AD, Dastyar A, Spacek LA, Quinn TC, Wang X, Wood O, Gaddam D, Devadas K, Hewlett IK.	Laboratory of Molecular Virology, Center for Biologics Evaluation and Research, Food and Drug Administration, Bethesda, Maryland 20892, USA. shixing.tang@fda.hhs.gov	Absence of detectable xenotropic murine leukemia virus-related virus in plasma or peripheral blood mononuclear cells of human immunodeficiency virus Type 1-infected blood donors or individuals in Africa.	Transfusion. 2011 Mar;51(3):463-8. doi: 10.1111/j.1537-2995.2010.02932.x. Epub 2010 Nov 15.	BACKGROUND: Since the identification of xenotropic murine leukemia virus-related virus (XMRV) in prostate cancer patients in 2006 and in chronic fatigue syndrome patients in 2009, conflicting findings have been reported regarding its etiologic role in human diseases and prevalence in general populations. In this study, we screened both plasma and peripheral blood mononuclear cells (PBMNCs) collected in Africa from blood donors and human immunodeficiency virus Type 1 (HIV-1)-infected individuals to gain evidence of XMRV infection in this geographic region. STUDY DESIGN AND METHODS: A total of 199 plasma samples, 19 PBMNC samples, and 50 culture supernatants from PBMNCs of blood donors from Cameroon found to be infected with HIV-1 and HIV-1 patients from Uganda were screened for XMRV infection using a sensitive nested polymerase chain reaction (PCR) or reverse transcription (RT)-PCR assay. RESULTS: Using highly sensitive nested PCR or RT-PCR and real-time PCR assays capable of detecting at least 10 copies of XMRV plasmid DNA per reaction, none of the 268 samples tested were found to be XMRV DNA or RNA positive. CONCLUSIONS: Our results failed to demonstrate the presence of XMRV infection in African blood donors or individuals infected with HIV-1. More studies are needed to understand the prevalence, epidemiology, and geographic distribution of XMRV infection worldwide. © 2010 American Association of Blood Banks.
Tang S, Hewlett IK.	Laboratory of Molecular Virology, CBER, Food and Drug Administration, Bethesda, MD 20892, USA.	Testing strategies for detection of xenotropic murine leukemia virus-related virus infection.	Adv Virol. 2011;2011:281425. Epub 2011 Jul 28.	Xenotropic murine leukemia virus-related virus (XMRV) is a newly identified gamma retrovirus and may be associated with prostate cancer- (PC) and chronic fatigue syndrome (CFS). Since its identification in 2006 and detection of polytropic murine lenkemia virus (MLV)-like sequences in CFS patients in 2010, several test methods including nucleic acid testing methods and serological assays have been developed for detection of XMRV and/or MLV-like sequences. However, these research assays have not yet been validated and evaluated due to the lack of well-characterized reference materials. Mouse DNA contamination should be carefully checked when testing

				human specimens in order to avoid false-positive detection of XMRV or MLV-like sequences.
Tang S, Zhao J, Haleyur Giri Setty MK, Devadas K, Gaddam D, Viswanath R, Wood O, Zhang P, Hewlett IK.	Lab of Molecular Virology, Center for Biologics Evaluation and Research, Food and Drug Administration, Bethesda, Maryland, United States of America. tangshixing@hotmail.com	Absence of detectable XMRV and other MLV-related viruses in healthy blood donors in the United States.	PLoS One. 2011;6(11):e27391. Epub 2011 Nov 14.	BACKGROUND: Preliminary studies in chronic fatigue syndrome (CFS) patients and XMRV infected animals demonstrated plasma viremia and infection of blood cells with XMRV, indicating the potential risk for transfusion transmission. XMRV and MLV-related virus gene sequences have also been detected in 4-6% of healthy individuals including blood donors in the U.S. These results imply that millions of persons in the U.S. may be carrying the nucleic acid sequences of XMRV and/or MLV-related viruses, which is a serious public health and blood safety concern. METHODOLOGY/PRINCIPAL FINDINGS: To gain evidence of XMRV or MLV-related virus infection in the U.S. blood donors, 110 plasma samples and 71 PBMC samples from blood donors at the NIH blood bank were screened for XMRV and MLV-related virus infection. We employed highly sensitive assays, including nested PCR and real-time PCR, as well as co-culture of plasma with highly sensitive indicator DERSE cells. Using these assays, none of the samples were positive for XMRV or MLV-related virus. CONCLUSIONS/SIGNIFICANCE: Our results are consistent with those from several other studies, and demonstrate the absence of XMRV or MLV-related viruses in the U.S. blood donors that we studied.
Tarello W.	Avian & Exotic Division, Pet Connection Veterinary Clinic, P.O. Box 450288, Dubai, UAE.	Etiologic agents and diseases found associated with clinical aspergillosis in falcons.	Int J Microbiol. 2011;2011:176963. Epub 2011 Jun 7.	The aim of this study was to describe parasitological, microbiological, and pathological findings associated with the isolation of Aspergillus species in 94 clinically diseased captive falcons from Dubai. Concomitant agents and/or diseases were identified in 64 cases, causing either single (n = 36) or multiple coinfections (n = 28). Diagnoses found more often in association with aspergillosis were chronic fatigue and immune dysfunction syndrome (CFIDS) (n = 29), Caryospora sp. (n = 16), Serratospiculum seurati infestation (n = 14), cestodiasis (n = 6), bumblefoot (n = 5), trematodosis due to Strigea falconispalumbi (n = 5), trichomoniasis (n = 4), Babesia shortti (n = 4), Mannheimia (Pastorella) haemolytica (n = 4), interstitial hepatitis (n = 4), Escherichia coli (n = 3), and Clostridium perfringens enterotoxemia (n = 2). Compared with a control group of 2000 diseased falcons without evidence of aspergillosis, the prevalence of Babesia shortti, CFIDS, Mannheimia (Pastorella) haemolytica, Escherichia coli, and falcon herpes virus infection was conspicuously higher in association with aspergillosis. These entities may be considered suitable candidates as predisposing factors for the mycosis.
ter Wolbeek M, van Doornen LJ, Kavelaars A, Tersteeg-Kamperman MD, Heijnen CJ.	Laboratory of Neuroimmunology and Developmental Origins of Disease, University Medical Center	Fatigue, depressive symptoms, and anxiety from adolescence up to young adulthood: a longitudinal study.	Brain Behav Immun. 2011 Aug;25(6):1249-55. Epub 2011 Apr 28.	Fatigue is a common complaint among adolescents. We investigated the course of fatigue in females during the transition from adolescence to young adulthood and examined psychological, immunological, and life style risk factors for development of fatigue and chronic fatigue syndrome (CFS)-related symptoms. Six hundred and thirty-three healthy females (age 14.63±1.37 years) filled out questionnaires measuring fatigue severity, depressive symptoms, anxiety, chronic fatigue syndrome (CFS)-related symptoms, sleep features, and life style characteristics at baseline and 4½ years thereafter. Of 64 participants LPS- and CD2CD28-induced cytokine data at

	Utrecht, Office KC 03.068.0, P.O. Box 85090, 3508 AB Utrecht, The Netherlands.			baseline were available. The best predictor of fatigue in young adulthood was previous fatigue severity. In participants who were non-fatigued during adolescence and who experienced a notable increase in fatigue, fatigue development was preceded by emotional problems and CFS-related complaints during adolescence. Increases as well as decreases in fatigue severity were accompanied by respectively increase and decrease in depressive symptoms and anxiety, suggesting that these symptoms cluster and co-vary over time. Higher interferon (IFN)-γ, higher IFN-γ/interleukin (IL)-4 ratio, lower tumor necrosis factor-α and lower IL-10 at baseline were related to fatigue severity at follow up. The rise in total number of CFS-related symptoms at follow up was predicted by anxiety and decreased physical activity during adolescence. Sleep and substance use were associated with fatigue severity and anxiety and depression. In conclusion, vulnerability to develop fatigue and associated symptoms in young adulthood can to a certain extent be identified already years before the manifestation of complaints. Tsang BK, Macdonell R.	Department of Neurology, Austin Hospital, Melbourne,	Multiple sclerosis-diagnosis, management and prognosis.	Aust Fam Physician. 2011 Dec;40(12):948-55.	BACKGROUND: Multiple sclerosis is the most common chronic disabling disease of the central nervous system in young adults. OBJECTIVE: This article summarises the diagnosis, management and prognosis of multiple sclerosis. DISCUSSION: Multiple sclerosis usually starts with an acute episode of neurological disturbance, termed a

	Victoria, Australia. bktsang@optusnet.com.au			'clinically isolated syndrome', followed by an illness phase punctuated by relapses and remissions which may transition after 10 years to a phase of progressive accumulation of disability without relapses. Fifteen to 20% of patients will have a progressive course from the onset. There is significant interpatient variability in prognosis. The main diagnostic criteria are clinical, supported by investigations including magnetic resonance imaging and lumbar puncture and evoked potentials. First line disease modifying agents for relapsing remitting multiple sclerosis include interferon-ß and glatiramer. First line treatment for relapses is usually intravenous methylprednisolone for 3 days. Troublesome symptoms may include spasticity, parasthesias, tremor, erectile dysfunction, depression and anxiety, fatigue and pain. After excluding differential diagnoses, symptomatic management includes pharmacological agents, allied health consultation and continence strategies. Although pregnancy reduces disease activity, there is a higher risk of relapse in the postpartum period.

Tucker P, Haig-Ferguson A, Eaton N, Crawley E.	Royal National Hospital for Rheumatic Diseases, Bath, UK.	What to do about attention and memory problems in children with CFS/ME: a neuropsychological approach.	Clin Child Psychol Psychiatry. 2011 Apr;16(2):215-23.	Our recent research has shown that children with chronic fatigue syndrome/myalgic encephalomyopathy (CFS/ME) describe problems with focused attention, sustained attention, recall and stress. Neuropsychological testing demonstrated lower scores for sustained attention, switching attention, divided attention, auditory learning and immediate recall compared to normative data. This paper describes what is currently known about memory and attention problems in children with CFS/ME and suggests a variety of strategies that could be used to overcome these difficulties.
Tuke PW, Tettmar KI, Tamuri A, Stoye JP, Tedder RS.	Transfusion Microbiology Research and Development, National Transfusion Microbiology Laboratories, National Health Service Blood and Transplant, Colindale, London, United Kingdom. philip.tuke@hpa.	PCR master mixes harbour murine DNA sequences. Caveat emptor!	PLoS One. 2011;6(5):e19953. Epub 2011 May 25.	BACKGROUND: XMRV is the most recently described retrovirus to be found in Man, firstly in patients with prostate cancer (PC) and secondly in 67% of patients with chronic fatigue syndrome (CFS) and 3.7% of controls. Both disease associations remain contentious. Indeed, a recent publication has concluded that "XMRV is unlikely to be a human pathogen". Subsequently related but different polytropic MLV (pMLV) sequences were also reported from the blood of 86.5% of patients with CFS. and 6.8% of controls. Consequently we decided to investigate blood donors for evidence of XMRV/pMLV. METHODOLOGY/PRINCIPAL FINDINGS: Testing of cDNA prepared from the whole blood of 80 random blood donors, generated gag PCR signals from two samples (7C and 9C). These had previously tested negative for XMRV by two other PCR based techniques. To test whether the PCR mix was the source of these sequences 88 replicates of water were amplified using Invitrogen Platinum Taq (IPT) and Applied Biosystems Taq Gold LD (ABTG). Four gag sequences (2D, 3F, 7H, 12C) were generated with the IPT, a further sequence (12D) by ABTG re-amplification of an IPT first round product. Sequence comparisons revealed remarkable similarities

	org.uk			between these sequences, endogeous MLVs and the pMLV sequences reported in patients with CFS. CONCLUSIONS/SIGNIFICANCE: Methodologies for the detection of viruses highly homologous to endogenous murine viruses require special caution as the very reagents used in the detection process can be a source of contamination and at a level where it is not immediately apparent. It is suggested that such contamination is likely to explain the apparent presence of pMLV in CFS.

Tófoli LF, Andrade LH, Fortes S.	Medical School/Post-Graduate Program in Family Health, Universidade Federal do Ceará (UFC), Sobral, CE, Brasil. tofoli@ufc.br	Somatization in Latin America: a review of the classification of somatoform disorders, functional syndromes and medically unexplained symptoms. [Article in English, Portuguese]	Rev Bras Psiquiatr. 2011 May;33 Suppl 1:S59-80.	OBJECTIVE: medically unexplained symptoms are common and associated with mental illness in various contexts. Previous studies show that Latin American populations are prone to somatization. Given the reformulation of the International Classification of Diseases towards its 11th edition the peculiarities of the population from this region of the world shall be taken into consideration. The objective of this study is to provide information on somatization in Latin American populations to help the decision making about medically unexplained symptoms diagnostic categories in the 11th edition of the International Classification of Diseases. METHOD: Extensive review of the academic production from 1995 to 2011 on somatization in populations of Latin American origin. RESULTS: The analysis of 106 studies included in this review was divided into 15 categories: systematic reviews, conceptual reviews, prevalence, primary care, depression and anxiety, risk factors, violence, organic conditions, relationship with health care, ethnicity, culture-bound syndromes, chronic fatigue syndrome, fibromyalgia, body dysmorphic disorder, and conversion and dissociation. CONCLUSION: The Latin American studies confirm the difficulty in defining medically unexplained symptoms categories. The supposed "somatizing trace" of Latin cultures may be linked more to cultural and linguistic expression than to an ethnic nature, and these peculiarities must be on the agenda for the new classification of these phenomena in the Classification of Diseases-11th edition.
Umapathi T, Yuki N.	Department of Neurology, National Neuroscience Institute, Singapore. umapathi@nni.com.sg	Pain in Guillain-Barré syndrome.	Expert Rev Neurother. 2011 Mar;11(3):335-9. Comment on Neurology. 2010 Oct 19;75(16):1439-47.	Evaluation of: Ruts L, Drenthen J, Jongen JL et al. Pain in Guillain-Barré syndrome: a long-term follow-up study. Neurology 75, 1439-1447 (2010). Pain has been recognized as an important symptom of Guillain-Barré syndrome (GBS). The article under review prospectively studied the phenomenon of pain in a cohort of 156 GBS patients for a period of 1 year. It confirmed that pain of significant intensity is relatively common in all subtypes of GBS. It may start before the onset of other symptoms. It correlates with sensory loss, severity of the GBS at its nadir and the presence of diarrhea. In the recovery/chronic stages it correlates with weakness, disability and fatigue. Up to a third of patients have pain at 1 year.

Van Den Eede F, Moorkens G, Hulstijn W, Maas Y, Schrijvers D, Stevens SR, Cosyns P, Claes SJ, Sabbe BG.	Department of Psychiatry, Antwerp University Hospital, Antwerp, Belgium. filip.van.den.eede@uza.be	Psychomotor function and response inhibition in chronic fatigue syndrome.	Psychiatry Res. 2011 Apr 30;186(2-3):367-72. Epub 2010 Aug 24.	Most research points to cognitive slowing in chronic fatigue syndrome (CFS), although there have been negative reports. The present study is one of few that examines fine motor processing and the inhibition of automatic responses in a well-characterised CFS population. A total of 35 female CFS patients without current major depression and 25 female controls performed two computerised figure-copying tasks. The cognitive and fine motor processing of visual-spatial information was measured by recording reaction time (RT) and movement time (MT), respectively. The inhibition of automatic responses was assessed by introducing 'conflicting patterns' (i.e., patterns that were difficult to draw from the preferred left to right). A multivariate general linear model was adopted for the statistical analysis of the movement recordings. As a result, CFS was significantly associated with longer RT and MT in the pooled and in the task-specific analyses. However, there was no interaction between disease status and conflicting character of the patterns. In conclusion, these performance data on the figure-copying tasks provide confirmatory evidence for psychomotor slowing in CFS, but not for a disturbed inhibition of automatic responses. Computerised figure-copying tasks may be promising tools for use in neurobiological research and clinical trials in CFS.
van der Kuyl AC, Cornelissen M, Berkhout B.	Laboratory of Experimental Virology, Department of Medical Microbiology, Center for Infection and Immunity Amsterdam, Academic Medical Center, University of Amsterdam Amsterdam, Netherlands.	Of Mice and Men: On the Origin of XMRV.	Front Microbiol. 2010;1:147. Epub 2011 Jan 17.	The novel human retrovirus xenotropic murine leukemia virus-related virus (XMRV) is arguably the most controversial virus of this moment. After its original discovery in prostate cancer tissue from North American patients, it was subsequently detected in individuals with chronic fatigue syndrome from the same continent. However, most other research groups, mainly from Europe, reported negative results. The positive results could possibly be attributed to contamination with mouse products in a number of cases, as XMRV is nearly identical in nucleotide sequence to endogenous retroviruses in the mouse genome. But the detection of integrated XMRV proviruses in prostate cancer tissue proves it to be a genuine virus that replicates in human cells, leaving the question: how did XMRV enter the human population? We will discuss two possible routes: either via direct virus transmission from mouse to human, as repeatedly seen for, e.g., Hantaviruses, or via the use of mouse-related products by humans, including vaccines. We hypothesize that mouse cells or human cell lines used for vaccine production could have been contaminated with a replicating variant of the XMRV precursors encoded by the mouse genome.

S.M.vanGeelen@	Self-investigation in adolescent chronic fatigue syndrome: narrative changes and health improvement.	Patient Educ Couns. 2011 May;83(2):227-33. Epub 2010 Jun 25.	OBJECTIVE: A small-scale intervention study into narrative self-investigation in adolescent chronic fatigue syndrome (CFS). METHOD: The self-confrontation method (SCM) is an instrument to assess and change personal life stories. Forty-two adolescents diagnosed with CFS were included and randomly assigned to either 6 or 12 sessions with the SCM. Twenty-five healthy adolescents were assigned to 6 sessions. Outcome was measured directly after the self-investigation procedure at 4 months. Follow-up measurements were made 10 months later. The Checklist Individual Strength and the Child Health Questionnaire were used to measure

	umcutrecht.nl			changes in fatigue, physical and psychosocial functioning. RESULTS: Self-investigation resulted in significant changes in participants' narratives. Moreover, after self-investigation there was a significant improvement in fatigue, physical and psychosocial functioning for the adolescents with CFS. The patients who completed 12 sessions improved most. At follow-up, the positive effects were maintained. CONCLUSION: Self-investigation enables a move beyond the symptoms of CFS in an individualized, patient centered way. Narrative transformation seems to contribute to improved physical and psychosocial outcome in adolescent CFS. PRACTICE IMPLICATIONS: The SCM allows adolescents to discover (for themselves) factors that might cause or perpetuate their fatigue. The results suggest that self-investigation is a useful instrument in the management of adolescent CFS. Copyright © 2010 Elsevier Ireland Ltd. All rights reserved.

Department of Human Physiology, Faculty of Physical Education & Physiotherapy, Vrije Universiteit Brussel, Brussels, Belgium.	Pain neurophysiology education improves cognitions, pain thresholds, and movement performance in people with chronic whiplash: a pilot study.	J Rehabil Res Dev. 2011;48(1):43-58.	Chronic whiplash is a debilitating condition characterized by increased sensitivity to painful stimuli, maladaptive illness beliefs, inappropriate attitudes, and movement dysfunctions. Previous work in people with chronic low back pain and chronic fatigue syndrome indicates that pain neurophysiology education is able to improve illness beliefs and attitudes as well as movement performance. This single-case study (A-B-C design) with six patients with chronic whiplash associated disorders (WAD) was aimed at examining whether education about the neurophysiology of pain is accompanied by changes in symptoms, daily functioning, pain beliefs, and behavior. Periods A and C represented assessment periods, while period B consisted of the intervention (pain neurophysiology education). Results showed a significant decrease in kinesiophobia (Tampa Scale for Kinesiophobia), the passive coping strategy of resting (Pain Coping Inventory), self-rated disability (Neck Disability Index), and photophobia (WAD

				Symptom List). At the same time, significantly increased pain pressure thresholds and improved pain-free movement performance (visual analog scale on Neck Extension Test and Brachial Plexus Provocation Test) were established. Although the current results need to be verified in a randomized, controlled trial, they suggest that education about the physiology of pain is able to increase pain thresholds and improve pain behavior and pain-free movement performance in patients with chronic WAD.
Van Oudenhove L, Vandenberghe J, Vos R, Holvoet L, Tack J.	Department of Pathophysiology, Translational Research Center for Gastrointestinal Disorders (TARGID), University of Leuven, Leuven, Belgium. lukas.vanoudenhove@med.kuleuven.be	Factors associated with co-morbid irritable bowel syndrome and chronic fatigue-like symptoms in functional dyspepsia.	Neurogastroenterol Motil. 2011 Jun;23(6):524-e202. doi: 10.1111/j.1365-2982.2010.01667.x. Epub 2011 Jan 24.	BACKGROUND: It is unclear which factors explain the high co-morbidity between functional dyspepsia (FD) and other functional somatic syndromes. The aim of this study is to investigate the association between gastric sensorimotor function, psychosocial factors and 'somatization' on the one hand, and co-morbid irritable bowel syndrome (IBS) and chronic fatigue (CF)-like symptoms on the other, in FD. METHODS: In 259 tertiary care FD patients, we studied gastric sensorimotor function with barostat (sensitivity, accommodation). We measured psychosocial factors (abuse history, alexithymia, trait anxiety, depression, panic disorder) and 'somatization' using self-report questionnaires, and presence of IBS and CF-like symptoms. Hierarchical multiple logistic regression was used to determine which of these factors were independently associated with co-morbid IBS and CF-like symptoms, including testing of potential mediator effects. KEY RESULTS: Co-morbid IBS or CF-like symptoms respectively were found in 142 (56.8%) and 102 (39.4%) patients; both co-morbidities were not significantly associated (P=0.27). Gastric accommodation (β=0.003, P=0.04) and 'somatization' (β=0.17, P= 0.0003) were independent risk factors for IBS (c=0.74, P<0.0001); the effect of adult abuse (β=0.72, P=0.20) was mediated by 'somatization'. Depression (β=0.16, P=0.008) and 'somatization' (β=0.18, P=0.004) were overlapping risk factors for CF-like symptoms (c=0.83, P<0.0001); the effects of alexithymia and lifetime abuse were mediated by depression and 'somatization', respectively. CONCLUSIONS & INFERENCES: 'Somatization' is a common risk factor for co-morbid IBS and CF-like symptoms in FD and mediates the effect of abuse. Gastric sensorimotor function and depression are specific risk factors for co-morbid IBS and CF-like symptoms, respectively. © 2011 Blackwell Publishing Ltd.

Xpr1 is an atypical G-protein-coupled receptor that mediates xenotropic and polytropic murine retrovirus neurotoxicity.	J Virol. 2012 Feb;86(3):1661-9. Epub 2011 Nov 16.	Xenotropic murine leukemia virus-related virus (XMRV) was first identified in human prostate cancer tissue and was later found in a high percentage of humans with chronic fatigue syndrome (CFS). While exploring potential disease mechanisms, we found that XMRV infection induced apoptosis in SY5Y human neuroblastoma cells, suggesting a mechanism for the neuromuscular pathology seen in CFS. Several lines of evidence show that the cell entry receptor for XMRV, Xpr1, mediates this effect, and chemical cross-linking studies show that Xpr1 is associated with the Gβ subunit of the G-protein heterotrimer. The activation of adenylate cyclase rescued the cells from XMRV toxicity, indicating that toxicity resulted from reduced G-protein-mediated cyclic AMP (cAMP) signaling. Some proteins with similarity to Xpr1 are

				involved in phosphate uptake into cells, but we found no role of Xpr1 in phosphate uptake or its regulation. Our results indicate that Xpr1 is a novel, atypical G-protein-coupled receptor (GPCR) and that xenotropic or polytropic retrovirus binding can disrupt the cAMP-mediated signaling function of Xpr1, leading to the apoptosis of infected cells. We show that this pathway is also responsible for the classic toxicity of the polytropic mink cell focus-forming (MCF) retrovirus in mink cells. Although it now seems clear that the detection of XMRV in humans was the result of sample contamination with a recombinant mouse virus, our findings may have relevance to neurologic disease induced by MCF retroviruses in mice.
Verhoeven WM, Egger JI, Kuijpers HJ.	Vincent van Gogh Institute for Psychiatry, Centre of Excellence for Neuropsychiatry, Venray, The Netherlands. wverhoeven@vvgi.nl.	Manganese and acute paranoid psychosis: a case report.	J Med Case Reports. 2011 Apr 12;5:146.	INTRODUCTION: Manganese regulates many enzymes and is essential for normal development and body function. Chronic manganese intoxication has an insidious and progressive course and usually starts with complaints of headache, fatigue, sleep disturbances, irritability and emotional instability. Later, several organ systems may be affected and, due to neurotoxicity, an atypical parkinsonian syndrome may emerge. With regard to neuropsychiatry, an array of symptoms may develop up to 30 years after intoxication, of which gait and speech abnormalities, cognitive and motor slowing, mood changes and hallucinations are the most common. Psychotic phenomena are rarely reported. CASE PRESENTATION: We describe the case of a 49-year-old Caucasian man working as a welder who was referred to our facility for evaluation of acute paranoid psychotic behavior. Our patient's medical history made no mention of any somatic complaints or psychiatric symptoms, and he had been involved in a professional career as a metalworker. On magnetic resonance imaging scanning of his brain, a bilateral hyperdensity of the globus pallidus, suggestive for manganese intoxication, was found. His manganese serum level was 52 to 97 nmol/L (range: 7 to 20 nmol/L). A diagnosis of organic psychotic disorder due to manganese overexposure was made. His psychotic symptoms disappeared within two weeks of treatment with low-dose risperidone. At three months later, serum manganese was decreased to slightly elevated levels and the magnetic resonance imaging T1 signal intensity was reduced. No signs of Parkinsonism were found and a definite diagnosis of manganese-induced apathy syndrome was made. CONCLUSION: Although neuropsychiatric and neurological symptoms caused by (chronic) manganese exposure have been reported frequently in the past, in the present day the disorder is rarely diagnosed. In this report we stress that manganese intoxication can still occur, in our case in a confined-space welder, and may present clinically with a paranoid psychotic state that necessitates a rapid diagnostic procedure in order to avoid the permanent structural brain damage that may occur with chronic exposure.
Vierck CJ.	Department of Neuroscience and Comprehensive Center for Pain	A mechanism-based approach to prevention of and therapy for	Pain Res Treat. 2012;2012:951354. Epub 2011 Oct 2.	Fibromyalgia syndrome (FMS) is characterized by pain referred to deep tissues. Diagnosis and treatment of FMS are complicated by a variable coexistence with regional pain, fatigue, sleep disruption, difficulty with mentation, and depression. The widespread, deep pain of FMS can be a consequence of chronic psychological stress

	Research, Colleges of Medicine and Dentistry, University of Florida, P.O. Box 100444, 1600 S.W. Archer Road, Gainesville, FL 32610, USA.	fibromyalgia.		with autonomic dysregulation. Stress acts centrally to facilitate pain and acts peripherally, via sympathetic vasoconstriction, to establish painful muscular ischemia. FMS pain, with or without a coexistent regional pain condition, is stressful, setting up a vicious circle of reciprocal interaction. Also, stress interacts reciprocally with systems of control over depression, mentation, and sleep, establishing FMS as a multiple-system disorder. Thus, stress and the ischemic pain it generates are fundamental to the multiple disorders of FMS, and a therapeutic procedure that attenuates stress and peripheral vasoconstriction should be highly beneficial for FMS. Physical exercise has been shown to counteract peripheral vasoconstriction and to attenuate stress, depression, and fatigue and improve mentation and sleep quality. Thus, exercise can interrupt the reciprocal interactions between psychological stress and each of the multiple-system disorders of FMS. The large literature supporting these conclusions indicates that exercise should be considered strongly as a first-line approach to FMS therapy.

Vural A, Agacdiken A, Celikyurt U, Culha M, Kahraman G, Kozdag G, Ural D.	Department of Cardiology, Kocaeli University Medical Faculty, Kocaeli, Turkey.	Effect of cardiac resynchronization therapy on libido and erectile dysfunction.	Clin Cardiol. 2011 Jul;34(7):437-41. doi: 10.1002/clc.20918. Epub 2011 Jun 2.	BACKGROUND: Chronic heart failure (HF) is a common, complex clinical syndrome characterized by dyspnea, fatigue and exercise intolerance. HF patients experience decreased libido and erectile dysfunction (ED). The effects of cardiac resynchronization therapy (CRT) on libido and erectile function have not been previously evaluated. We aimed to investigate the effects of CRT on libido and ED. HYPOTHESIS: Cardiac resynchronization therapy improves libido and ED. METHODS: Thirty-one male patients with advanced HF, scheduled for implantation of a CRT device, were included in the study. Left ventricular systolic function, New York Heart Association (NYHA) class, libido, and ED were assessed before and 6 months after CRT. Libido and ED were evaluated with the Aging Male Symptoms (AMS) rating scale and internationally validated Sexual Health Inventory for Men (SHIM) questionnaire, respectively. RESULTS: At the 6-month follow-up, the mean NYHA class improved from 3.4 ± 0.5 to 2.1 ± 0.6 (P<0.001). On echocardiographic examination, an improvement in left ventricular ejection fraction (LVEF) from 18 ± 5% to 32 ± 6% was detected (P<0.001). A significant increase in mean SHIM score and a significant decrease in mean AMS were noted. Changes in SHIM and AMS scores were correlated positively with the increase in LVEF (r = 0.47, P = 0.007 and r = - 0.36, P = 0.04, respectively). Similarly, SHIM scores were correlated negatively (r = - 0.57, P = 0.001) and AMS scores were correlated positively (r = 0.73, P = 0.0001) with the improvement in NYHA class. CONCLUSIONS: CRT results in a significant improvement in libido and erectile function in patients with congestive HF. This improvement is related to the improvements in the LVEF and functional capacity. . © 2011 Wiley Periodicals, Inc.
Wainberg MA, Jeang KT.	McGill University AIDS Centre, Jewish General Hospital, Montreal, Quebec, Canada.	XMRV as a human pathogen?	Cell Host Microbe. 2011 Apr 21;9(4):260-2.	Xenotropic murine leukemia virus-related virus (XMRV) has been proposed to be associated with prostate cancer and chronic fatigue syndrome (CFS). This proposition has been controversial because many investigators have failed to replicate the reported associations. Here, we explore whether XMRV is an authentic human pathogen in the light of recent findings that indicate otherwise. Copyright © 2011 Elsevier Inc. All rights reserved.
Warren JW, Wesselmann U, Morozov V, Langenberg PW.	Department of Medicine, University of Maryland School of Medicine, Baltimore, Maryland 21201, USA. jwarren@medicine.umaryland.edu	Numbers and types of nonbladder syndromes as risk factors for interstitial cystitis/painful bladder syndrome.	Urology. 2011 Feb;77(2):313-9. Comment in Urology. 2011 Feb;77(2):319; author reply 320.	OBJECTIVES: To examine the interaction of types and numbers of antecedent nonbladder syndromes (NBSs) to seek clues to the pathogenesis of interstitial cystitis/painful bladder syndrome (IC/PBS). Numerous case series have shown IC/PBS to be associated with several syndromes that do not include bladder symptoms. In a previously reported case-control study, we confirmed these findings and found that such nonbladder syndromes often preceded the onset of IC/PBS. METHODS: Incident female IC/PBS cases (n = 312) and matched controls were compared for 11 antecedent NBSs. The odds ratios (ORs) for IC/PBS according to the number of antecedent NBSs per person were calculated. From this model, each NBS was serially removed, and the calculations for the ORs were repeated using the remaining 10 NBSs. We assessed the types of NBSs included in each subgroup formed by the

				number of NBSs. RESULTS: The ORs for IC/PBS increased with the increasing number of antecedent NBSs. The types of NBSs were interchangeable in calculating these ORs. The distribution of the types of NBSs was skewed, with allergy overrepresented in those with few NBSs, and the classic functional somatic syndromes of fibromyalgia, chronic fatigue syndrome, and irritable bowel syndrome overrepresented in those with many NBSs. CONCLUSIONS: Two main hypotheses were generated. One was that the incidence of a NBS initiated a process that contributed to the emergence of other NBSs and IC/PBS. The second was that each NBS and IC/PBS was a manifestation of a common, shared pathogenesis. It is likely that a well-designed prospective study will be necessary to distinguish between these 2 hypotheses. Copyright © 2011 Elsevier Inc. All rights reserved.
Waugh EM, Jarrett RF, Shield L, Montgomery D, Dean RT, Mitchell A, Greaves MF, Gallagher A.	LRF Virus Centre, MRC and University of Glasgow Centre for Virus Research, Institute of Infection, Immunity and Inflammation, College of Medical, Veterinary and Life Sciences, University of Glasgow, Glasgow, United Kingdom.	The retrovirus XMRV is not directly involved in the pathogenesis of common types of lymphoid malignancy.	Cancer Epidemiol Biomarkers Prev. 2011 Oct;20(10):2232-6. Epub 2011 Aug 22.	BACKGROUND: A novel retrovirus, xenotropic murine leukemia virus-related virus (XMRV), has been detected in prostate cancer samples and in peripheral blood mononuclear cells (PBMC) from patients with chronic fatigue syndrome. In addition, the virus has been identified in PBMCs from healthy controls. These data suggest that XMRV is circulating in the human population. XMRV is closely related to murine leukemia viruses, which cause lymphoid malignancies in mice. The aim of this study was to determine whether XMRV is directly associated with common forms of human lymphoma or leukemia. METHODS: DNA samples from 368 patients with lymphoid malignancies and 139 patients with benign lymphadenopathy or other malignant disease were screened for XMRV, using three specific and sensitive quantitative PCR assays. RESULTS: XMRV was not detected in any sample using any of the three assays. CONCLUSIONS: The data suggest that this virus is not directly involved in the pathogenesis of common types of lymphoid malignancy and that XMRV is not a prevalent blood borne infection, at least in the United Kingdom. IMPACT: There is no evidence that XMRV is associated with lymphoid malignancies, and further studies should resolve inconsistencies in results of studies examining XMRV prevalence. ©2011 AACR
Webb CM, Collin SM, Deave T, Haig-Ferguson A, Spatz A, Crawley E.	St George's University of London, Cranmer Terrace, London, UK.	What stops children with a chronic illness accessing health care: a mixed methods study in children with Chronic Fatigue Syndrome/Myalgic Encephalomyelitis (CFS/ME).	BMC Health Serv Res. 2011 Nov 11;11:308.	BACKGROUND: Paediatric Chronic Fatigue Syndrome/Myalgic Encephalomyelitis (CFS/ME) is relatively common and disabling with a mean time out of school of more than one academic year. NICE guidelines recommend referral to specialist services immediately if severely affected, within 3 months if moderately affected and within 6 months if mildly affected. However, the median time-to-assessment by a specialist service in the UK is 18 months. This study used a mixed-methods approach to examine factors associated with time taken to access specialist services. METHODS: Time-to-assessment was analysed as a continuous "survival-time" variable in Cox regression models using data from self-completed assessment forms for children attending a regional specialist CFS/ME service between January 2006 and December 2009. Semi-structured interviews about barriers experienced in accessing healthcare

				for their child were conducted with nine parents of children aged < 17 years (8 individual and one parent couple). Interviews were digitally recorded and analysed using "thematic analysis". RESULTS: 405 children were assessed between 2006 and 2009 and information on school attendance was available on 388. Only 1/125 with severe CFS/ME and 49/263 (19%) with mild to moderate CFS/ME were seen within NICE recommended timeframe. Increased fatigue was associated with shorter time to assessment (HR = 1.15; 95% CI 1.03, 1.29 per unit increase in Chalder fatigue score; P = 0.01). Time-to-assessment was not associated with disability, mood, age or gender. Parents described difficulties accessing specialist services because of their own as well as their GP's and Paediatrician's lack of knowledge. They experienced negative attitudes and beliefs towards the child's condition when they consulted GPs, Paediatricians and Child Psychiatrists. Parents struggled to communicate an invisible illness that their child and not themselves were experiencing. CONCLUSIONS: GPs, Child Psychiatrists and Paediatricians need more knowledge about CFS/ME and the appropriate referral pathways to ensure timeliness in referral to specialist services.
Wensaas KA, Langeland N, Hanevik K, Mørch K, Eide GE, Rortveit G.	Department of Public Health and Primary Health Care, University of Bergen, Bergen, Norway. knut-arne.wensaas@uni.no	Irritable bowel syndrome and chronic fatigue 3 years after acute giardiasis: historic cohort study.	Gut. 2012 Feb;61(2):214-9. Epub 2011 Sep 12.	BACKGROUND: Giardia lamblia is a common cause of gastroenteritis worldwide, but there is limited knowledge about the long-term complications. OBJECTIVE: To estimate the relative risk of irritable bowel syndrome (IBS) and chronic fatigue 3 years after acute giardiasis. DESIGN: Controlled historic cohort study with 3 years' follow-up. Data collected by mailed questionnaire. SETTING: Waterborne outbreak of giardiasis in the city of Bergen, Norway. PARTICIPANTS: 817 patients exposed to Giardia lamblia infection verified by detection of cysts in stool samples and 1128 matched controls. MAIN OUTCOME MEASURES: IBS and chronic fatigue. RESULTS: The prevalence of IBS in the exposed group was 46.1%, compared with 14.0% in the control group, and the adjusted RR=3.4 (95% CI 2.9 to 3.8). Chronic fatigue was reported by 46.1% of the exposed group and 12.0% of the controls, the adjusted RR was 4.0 (95% CI 3.5 to 4.5). IBS and chronic fatigue were associated and the RR for the exposed group of having a combination of the two outcomes was 6.8 (95% CI 5.3 to 8.5). The RR was also increased for having just one of the two syndromes, 1.8 for IBS (95% CI 1.4 to 2.3) and 2.2 for chronic fatigue (95% CI 1.7 to 2.8). CONCLUSIONS: Infection with Giardia lamblia in a non-endemic area was associated with a high prevalence of IBS and chronic fatigue 3 years after acute illness, and the risk was significantly higher than in the control group. This shows that the potential consequences of giardiasis are more serious than previously known. Further studies are needed, especially in areas where giardiasis is endemic.
White AT, Light AR, Hughen RW, Vanhaitsma TA, Light KC.	Department of Anesthesiology, University of Utah, 30 N 1900 E, Room 3C444,	Differences in metabolite-detecting, adrenergic, and immune gene	Psychosom Med. 2012 Jan;74(1):46-54. Epub 2011 Dec 30.	OBJECTIVE: Chronic fatigue syndrome (CFS) and multiple sclerosis (MS) are characterized by debilitating fatigue, yet evaluation of this symptom is subjective. We examined metabolite-detecting, adrenergic, and immune gene expression (messenger ribonucleic acid [mRNA]) in patients with CFS (n = 22) versus patients with MS (n = 20) versus healthy controls (n = 23) and determined their relationship to fatigue and pain

	Salt Lake City, UT 84132-2501, USA.	expression after moderate exercise in patients with chronic fatigue syndrome, patients with multiple sclerosis, and healthy controls.		before and after exercise. METHODS: Blood samples and fatigue and pain ratings were obtained at baseline and 0.5, 8, 24, and 48 hours after sustained moderate exercise. Leukocyte mRNA of four metabolite-detecting receptors (acid-sensing ion channel 3, purinergic type 2X4 and 2X5 receptors, and transient receptor potential vanilloid type 1) and four adrenergic (α-2a, β-1, and β-2 receptors and catechol-O-methyltransferase) and five immune markers (CD14, toll-like receptor 4 [TLR4], interleukin [IL] 6, IL-10, and lymphotoxin α) was examined using quantitative polymerase chain reaction. RESULTS: Patients with CFS had greater postexercise increases in fatigue and pain (10-29 points above baseline, $p < .001$) and greater mRNA increases in purinergic type 2X4 receptor, transient receptor potential vanilloid type 1, CD14, and all adrenergic receptors than controls (mean ± standard error = 1.3 ± 0.14- to 3.4 ± 0.90-fold increase above baseline, $p = .04$-$.005$). Patients with CFS with comorbid fibromyalgia ($n = 18$) also showed greater increases in acid-sensing ion channel 3 and purinergic type 2X5 receptors ($p < .05$). Patients with MS had greater postexercise increases than controls in β-1 and β-2 adrenergic receptor expressions (1.4 ± 0.27- and 1.3 ± 0.06-fold increases, respectively, $p = .02$ and $p < .001$) and greater decreases in TLR4 ($p = .02$). In MS, IL-10 and TLR4 decreases correlated with higher fatigue scores. CONCLUSIONS: Postexercise mRNA increases in metabolite-detecting receptors were unique to patients with CFS, whereas both patients with MS and patients with CFS showed abnormal increases in adrenergic receptors. Among patients with MS, greater fatigue was correlated with blunted immune marker expression.

Lancet. 2011 Mar 5;377(9768):823-36. Epub 2011 Feb 18. Comment in Lancet. 2011 Mar 5;377(9768):786-8. Lancet. 2011 May 28;377(9780):1808. Lancet. 2011 May 28;377(9780):1833; author reply 1834-5. Lancet. 2011 May 28;377(9780):1831; author reply 1834-5. Lancet. 2011 May 28;377(9780):1831; author reply 1834-5. Lancet. 2011 May	BACKGROUND: Trial findings show cognitive behaviour therapy (CBT) and graded exercise therapy (GET) can be effective treatments for chronic fatigue syndrome, but patients' organisations have reported that these treatments can be harmful and favour pacing and specialist health care. We aimed to assess effectiveness and safety of all four treatments. METHODS: In our parallel-group randomised trial, patients meeting Oxford criteria for chronic fatigue syndrome were recruited from six secondary-care clinics in the UK and randomly allocated by computer-generated sequence to receive specialist medical care (SMC) alone or with adaptive pacing therapy (APT), CBT, or GET. Primary outcomes were fatigue (measured by Chalder fatigue questionnaire score) and physical function (measured by short form-36 subscale score) up to 52 weeks after randomisation, and safety was assessed primarily by recording all serious adverse events, including serious adverse reactions to trial treatments. Primary outcomes were rated by participants, who were necessarily unmasked to treatment assignment; the statistician was masked to treatment assignment for the analysis of primary outcomes. We used longitudinal regression models to compare SMC alone with other treatments, APT with CBT, and APT with GET. The final analysis included all participants for whom we had data for primary outcomes. This trial is registered at http://isrctn.org, number

Butler J, Doherty P, Law S, Llewelyn M, Sensky T, Aylward M, Spencer P, Clark C, Stansfeld S, Wearden A, Dieppe P, Fletcher A, Feinmann C, Akagi H, Miller A, Spickett G, Bowman B, Fleetwood D.			28;377(9780):1831-2. Lancet. 2011 May 28;377(9780):1834; author reply 1834-5. Lancet. 2011 May 28;377(9780):1833-4; author reply 1834-5. Lancet. 2011 May 28;377(9780):1832; author reply 1834-5. Lancet. 2011 May 28;377(9780):1832-3; author reply 1834-5.	ISRCTN54285094. FINDINGS: We recruited 641 eligible patients, of whom 160 were assigned to the APT group, 161 to the CBT group, 160 to the GET group, and 160 to the SMC-alone group. Compared with SMC alone, mean fatigue scores at 52 weeks were 3·4 (95% CI 1·8 to 5·0) points lower for CBT (p = 0·0001) and 3·2 (1·7 to 4·8) points lower for GET (p = 0·0003), but did not differ for APT (0·7 [-0·9 to 2·3] points lower; p = 0·38). Compared with SMC alone, mean physical function scores were 7·1 (2·0 to 12·1) points higher for CBT (p = 0·0068) and 9·4 (4·4 to 14·4) points higher for GET (p = 0·0005), but did not differ for APT (3·4 [-1·6 to 8·4] points lower; p=0·18). Compared with APT, CBT and GET were associated with less fatigue (CBT p = 0·0027; GET p = 0·0059) and better physical function (CBT p=0·0002; GET p<0·0001). Subgroup analysis of 427 participants meeting international criteria for chronic fatigue syndrome and 329 participants meeting London criteria for myalgic encephalomyelitis yielded equivalent results. Serious adverse reactions were recorded in two (1%) of 159 participants in the APT group, three (2%) of 161 in the CBT group, two (1%) of 160 in the GET group, and two (1%) of 160 in the SMC-alone group. INTERPRETATION: CBT and GET can safely be added to SMC to moderately improve outcomes for chronic fatigue syndrome, but APT is not an effective addition. Wiborg JF, Knoop H, Prins JB, Bleijenberg G.	Expert Centre for Chronic Fatigue, Radboud University Nijmegen Medical Centre, the Netherlands. j.wiborg@nkcv.umcn.nl	Does a decrease in avoidance behavior and focusing on fatigue mediate the effect of cognitive behavior therapy for chronic fatigue syndrome?	J Psychosom Res. 2011 Apr;70(4):306-10. Epub 2011 Feb 12.	OBJECTIVE: Cognitive behavior therapy (CBT) leads to a significant reduction in fatigue severity and impairment in patients with chronic fatigue syndrome (CFS). The purpose of the present study was to determine whether the effect of CBT for CFS on fatigue and impairment is mediated by a decrease in avoidance behavior and focusing on fatigue. METHODS: For this purpose, we reanalyzed a randomized controlled trial which was previously conducted to test the efficacy of CBT for CFS. Two hundred nineteen patients completed assessment prior and subsequent to treatment or a control group period. RESULTS: Mediation analysis revealed that a decrease in focusing on fatigue mediated the effect of CBT for CFS on fatigue and impairment. Avoidance of activity and avoidance of aversive stimuli were not significantly changed by treatment and were therefore excluded from mediation analysis. CONCLUSION: A decrease in the focus on fatigue seems to contribute to the treatment effect of CBT for CFS. Copyright © 2011 Elsevier Inc. All rights reserved.
Williams AM, Kitchen P, Eby J.	Department of Geography and Earth Sciences, McMaster University, Hamilton, Ontario, Canada.	Alternative health care consultations in Ontario, Canada: A geographic and socio-demographic analysis.	BMC Complement Altern Med. 2011 Jun 22;11:47.	BACKGROUND: An important but understudied component of Canada's health system is alternative care. The objective of this paper is to examine the geographic and socio-demographic characteristics of alternative care consultation in Ontario, Canada's largest province. METHODS: Data is drawn from the Canadian Community Health Survey (CCHS Cycle 3.1, 2005) for people aged 18 or over (n = 32,598) who had a consultation with an alternative health care provider. Four groups of consultations are examined: (1) all consultations (2) massage therapy (3) acupuncture, and (4)

				homeopath/naturopath. Descriptive statistics, mapping and logistic regression modeling are employed to analyze the data and to compare modalities of alternative health care use. RESULTS: In 2005, more than 1.2 million adults aged 18 or over consulted an alternative health care provider, representing about 13% of the total population of Ontario. The analysis revealed a varied geographic pattern of consultations across the province. Consultations were fairly even across the urban to rural continuum and rural residents were just as likely to consult a provider as their urban counterparts. From a health perspective, people with a chronic condition, lower health status and self-perceived unmet health care needs were more likely to see an alternative health provider. Women with chronic conditions such as fibromyalgia, high blood pressure, chronic fatigue syndrome and chemical sensitivities were more likely to see an alternative provider if they felt their health care needs were not being met. CONCLUSIONS: The analysis revealed that geography is not a factor in determining alternative health care consultations in Ontario. By contrast, there is a strong association between these consultations and socio-demographic characteristics particularly age, sex, education, health and self-perceived unmet health care needs. The results underscore the importance of women's health needs as related to alternative care use. The paper concludes that there is a need for more place-specific research that explores the reasons why people use specific types of alternative health care as tied to socio-economic status, health, place of residence, and knowledge of these treatments.
Williams DK, Galvin TA, Ma H, Khan AS.	Laboratory of Retroviruses, Division of Viral Products, Center for Biologics Evaluation and Research, U.S. Food and Drug Administration, 8800 Rockville Pike, Bethesda, MD 20892, USA.	Investigation of xenotropic murine leukemia virus-related virus (XMRV) in human and other cell lines.	Biologicals. 2011 Nov;39(6):378-83. Epub 2011 Oct 12.	Xenotropic murine leukemia virus-related virus (XMRV) was discovered in human prostate tumors and later in some chronic fatigue syndrome (CFS) patients. However, subsequent studies have identified various sources of potential contamination with XMRV and other murine leukemia virus (MLV)-related sequences in test samples. Biological and nucleotide sequence analysis indicates that XMRV is distinct from known xenotropic MLVs and has a broad host range and cell tropism including human cells. Therefore, it is prudent to minimize the risk of human exposure to infection by evaluating XMRV contamination in cell lines handled in laboratory research and particularly those used in the manufacture of biological products. Nested DNA PCR assays were optimized for investigating XMRV gag and env sequences in various cell lines, which included MRC-5, Vero, HEK-293, MDCK, HeLa, and A549, that may be used in the development of some vaccines and other cell lines broadly used in research. The sensitivity of the DNA PCR assays was <10 copies in approximately 1.8 x 10(5) cells equivalent of human DNA. The results indicated the absence of XMRV in the cell lines tested; although in some cases DNA fragments identified as cellular sequences were seen following the first round of PCR amplification with the env primer pair. Wolff D, Gerritzen A.	Medical Laboratory Bremen, Bremen, Germany. dietmar.wolff@mlhb.de	Presence of murine leukemia virus (MLV)-related virus gene sequences in a commercial RT-PCR reagent.	Clin Lab. 2011;57(7-8):631-4.	BACKGROUND: The recent identification of murine leukemia virus (MLV)-related viruses in patients with chronic fatigue syndrome (CFS) has aroused much interest, not least among sufferers. However, other studies failed to detect these viruses in CFS patients. METHODS: We wanted to establish a MLV-related virus real-time PCR for routine diagnostics. RESULTS: Our study identified false positive MLV-related virus results due to a contamination of Superscript III Platinum One-Step Quantitative RT-PCR System (Invitrogen). CONCLUSIONS: This observation may be helpful to elucidate discrepant results for the detection of MLV-related virus like xenotropic MLV-related virus (XMRV) in recently published studies.
Wyller VB, Barbieri R, Saul JP.	Department of Pediatrics, Rikshospitalet University Hospital, 0027, Oslo, Norway. brwylle@online.no	Blood pressure variability and closed-loop baroreflex assessment in adolescent chronic fatigue syndrome during supine rest and orthostatic stress.	Eur J Appl Physiol. 2011 Mar;111(3):497-507. Epub 2010 Oct 2.	Hemodynamic abnormalities have been documented in the chronic fatigue syndrome (CFS), indicating functional disturbances of the autonomic nervous system responsible for cardiovascular regulation. The aim of this study was to explore blood pressure variability and closed-loop baroreflex function at rest and during mild orthostatic stress in adolescents with CFS. We included a consecutive sample of 14 adolescents 12-18 years old with CFS diagnosed according to a thorough and standardized set of investigations and 56 healthy control subjects of equal sex and age distribution. Heart rate and blood pressure were recorded continuously and non-invasively during supine rest and during lower body negative pressure (LBNP) of -20 mmHg to simulate mild orthostatic stress. Indices of blood pressure variability and baroreflex function (α-gain) were computed from monovariate and bivariate spectra in the low-frequency (LF) band (0.04-0.15 Hz) and the high-frequency (HF) band (0.15-0.50 Hz), using an autoregressive algorithm. Variability of systolic blood pressure in the HF range was lower among CFS patients as compared to controls both at rest and during LBNP. During LBNP, compared to controls, α-gain HF decreased more, and α-gain LF and the ratio of α-gain LF/α-gain HF increased more in CFS patients, all suggesting greater shift from parasympathetic to sympathetic baroreflex control. CFS in adolescents is characterized by reduced systolic blood pressure variability and a sympathetic predominance of baroreflex heart rate control during orthostatic stress. These findings may have implications for the pathophysiology of CFS in adolescents.

Yuan JP, Peng J, Yin K, Wang JH.	Guangdong Provincial Key Laboratory of Marine Resources and Coastal Engineering, School of Marine Sciences, Sun Yat-Sen University, Guangzhou, PR China. yuanjp@mail.sysu.edu.cn	Potential health-promoting effects of astaxanthin: a high-value carotenoid mostly from microalgae.	Mol Nutr Food Res. 2011 Jan;55(1):150-65. doi: 10.1002/mnfr.201000414. Epub 2010 Nov 18.	The ketocarotenoid astaxanthin can be found in the microalgae Haematococcus pluvialis, Chlorella zofingiensis, and Chlorococcum sp., and the red yeast Phaffia rhodozyma. The microalga H. pluvialis has the highest capacity to accumulate astaxanthin up to 4-5% of cell dry weight. Astaxanthin has been attributed with extraordinary potential for protecting the organism against a wide range of diseases, and has considerable potential and promising applications in human health. Numerous studies have shown that astaxanthin has potential health-promoting effects in the prevention and treatment of various diseases, such as cancers, chronic inflammatory diseases, metabolic syndrome, diabetes, diabetic nephropathy, cardiovascular diseases, gastrointestinal diseases, liver diseases, neurodegenerative diseases, eye diseases, skin diseases, exercise-induced fatigue, male infertility, and $HgCl_2$-induced acute renal failure. In this article, the currently available scientific literature regarding the most significant activities of astaxanthin is reviewed. Copyright © 2011 WILEY-VCH Verlag GmbH & Co. KGaA, Weinheim.
Yunus MB.	Section of Rheumatology, Department of Medicine, University of Illinois College of Medicine at Peoria, One Illini Drive, Peoria, IL 61605, USA.	The prevalence of fibromyalgia in other chronic pain conditions.	Pain Res Treat. 2012;2012:584573. Epub 2011 Nov 17.	Central sensitivity syndromes (CSS) include fibromyalgia syndrome (FMS), irritable bowel syndrome, temporomandibular disorder, restless legs syndrome, chronic fatigue syndrome, and other similar chronic painful conditions that are based on central sensitization (CS). CSS are mutually associated. In this paper, prevalence of FMS among other members of CSS has been described. An important recent recognition is an increased prevalence of FMS in other chronic pain conditions with structural pathology, for example, rheumatoid arthritis, systemic lupus, ankylosing spondylitis, osteoarthritis, diabetes mellitus, and inflammatory bowel disease. Diagnosis and proper management of FMS among these diseases are of crucial importance so that unwarranted use of such medications as corticosteroids can be avoided, since FMS often occurs when RA or SLE is relatively mild.
Zadrazil J.	III. interní nefrologická, revmatologická a endokrinologcá klinika Lékaiské fakulty UP a FN Olomouc.	[Aetiology and a clinical picture of chronic renal failure]. [Article in Czech]	Vnitr Lek. 2011 Jul-Aug;57(7-8):607-13.	The term chronic renal failure (CRF) usually means the final stage of chronic kidney disease (CKD) with a decline in glomerular filtration rate (GF) below 0.25 mL/s. CRF is a world-wide serious health and economic issue with an increasing incidence and prevalence. CRF patients are, in comparison to other patients, hospitalized more often and for longer and, despite improvements in care, their quality of life is usually low and morbidity and mortality high. We present an overview of the most important CKD risk factors and the diseases most likely to result in CRF. Diabetic nephropathy,

	josef.zadrazil@fnol.cz			followed by various forms ofischemic renal disease and primary and secondary glomerulopathy, chronic tubulointerstitial nephritis and autosomal dominant polycystic kidney disease are the leading causes of CRF. We provide a brief overview of other disease states that may result in renal failure. Clinical manifestations of CRF are discussed, mainly cardiovascular, gastrointestinal, haematological and neurological symptoms. Breathlessness is a consequence of hypervolaemia, metabolic acidosis and anaemia. The disease often presents with symptoms, such as headache and visual disturbances, resulting from arterial hypertension. Gastrointestinal symptoms and fatigue, usually caused by anaemia, are frequent. Platelet dysfunction is manifested as an increased bleeding time. Paradoxically, apart form tendency to abnormal bleeding, CRF also tends to be associated with thromboembolic complications. Patients may experience itching, bone, joint and muscle aches, are more prone to infections. They may suffer from insomnia, concentration disorders and apathy. The signs of peripheral mixed sensory-motor neuropathy include paraesthesia, paresis and restless leg syndrome. However, renal failure may also be oligosymptomatic or asymptomatic. Cardiovascular complications are the most frequent cause of morbidity and mortality of CRF patients.
Zeller L, Abu-Shakra M, Weitzman D, Buskila D.	Department of Medicine F, Soroka Medical Center and Faculty of Health Sciences, Ben-Gurion University of the Negev, Beer Sheva, Israel.	The effect of exercise cessation on non-articular tenderness measures and quality of life in well-trained athletes.	Isr Med Assoc J. 2011 Jan;13(1):44-7.	BACKGROUND: The term chronic multi-symptom illness (CMI) refers to a spectrum of pain disorders, such as fibromyalgia and chronic fatigue syndrome, that are characterized by unexplained chronic pain, fatigue, and cognitive and mood complaints OBJECTIVES: To examine the hypothesis that exercise cessation is associated with symptoms similar to CMI in well-trained amateur athletes. METHODS: The study, conducted in running and triathlon clubs in Israel, involved 26 asymptomatic healthy athletes who regularly exercise 6.75 +/- 3.65 hours a week. All athletes were instructed to refrain from physical activity for 7 days. All underwent a complete physical exam, rheumatological assessment including non-articular tenderness threshold (using dolorimeter) and tender points. In addition they completed the SF-36 quality of life questionnaire. Assessments were conducted before exercise cessation and 7 days later. RESULTS: Seven days after sports deprivation all subjects were significantly more tender by all tender measures ($P < 0.001$) (dolorimeter thresholds and tender point count). There was also a significant reduction in the scores for physical role function ($P < 0.001$), emotional role function ($P < 0.001$) and summary subscales of the SF-36 questionnaire after exercise cessation. CONCLUSIONS: Exercise deprivation is associated with change in non-articular tenderness threshold and reduction in quality of life scores. This may be associated with the development of chronic multi-symptom illness.
Zhang HY, Liu ZD, Hu CJ, Wang DX, Zhang YB, Li YZ.	Department of Rheumatology and Clinical Immunology,	Up-regulation of TGF-β1 mRNA expression in peripheral blood mononuclear cells of	J Formos Med Assoc. 2011 Nov;110(11):701-4. Epub 2011 Oct 22.	BACKGROUND/PURPOSE: It has been shown that the abnormality in immune cells in chronic fatigue syndrome (CFS) patients is closely associated with the participation of TGF-β. In order to study the relationship between TGF-β1 and CFS, we investigated the mRNA levels of TGF-β1 in peripheral blood mononuclear cells (PBMCs) in patients

	Peking Union Medical College Hospital, Chinese Academy of Medical Science, No. 1 Shuaifuyuan, Beijing, China.	patients with chronic fatigue syndrome.		with CFS. METHODS: Fluorescent quantitative real time reverse-transcription polymerase chain reaction (FQ-RT-PCR) was performed to test TGF-β1 mRNA expression in PBMCs in 63 cases of CFS, 50 cases of disease controls, and 50 cases of healthy controls. RESULTS: The mean value of TGF-β1 mRNA expression in CFS patients was ΔΔCt=1.17±0.58, which was significantly higher than the disease controls (ΔΔCt=0.07±1.08, df=111, $p < 0.01$) and the healthy controls (ΔΔCt=0.00±1.63, df=111, $p < 0.01$). No significant difference was detected between disease and healthy controls ($p > 0.05$). CONCLUSION: The expression of TGF-β1 in PBMCs is significantly elevated in patients with CFS. It might be correlated to the pathogenesis of the disease. Copyright © 2011. Published by Elsevier B.V.
Zhang ZZ, Guo BF, Feng Z, Zhang L, Zhao XJ.	Department of Epidemiology, Michigan State University, East Lansing, MI 48224, USA.	Is XMRV a causal virus for prostate cancer?	Asian J Androl. 2011 Sep;13(5):698-701. doi: 10.1038/aja.2011.32. Epub 2011 Jul 18.	The potential association between xenotropic murine leukaemia virus-related gammaretrovirus (XMRV) and prostate cancer (PCa) has been documented since 2006. It is important for furthering our understanding of the biological mechanisms of PCa to ascertain whether this association is causal. To summarize the available information on the epidemiological and laboratory findings of the association, we conducted a literature search of the PubMed electronic database (from March 2006 to February 2011) to identify relevant published studies that examined the association between XMRV and PCa. Although several studies showed the positive association between XMRV and PCa, more recent studies did not support this conclusion. The positive findings might be due to contamination of human samples. Further studies are needed to clarify this association.
Zheng H, Jia H, Shankar A, Heneine W, Switzer WM.	Laboratory Branch, Division of HIV/AIDS Prevention, National Center for HIV/AIDS, Viral Hepatitis, STD, and TB Prevention, Centers for Disease Control and Prevention, Atlanta, Georgia, United States of America.	Detection of murine leukemia virus or mouse DNA in commercial RT-PCR reagents and human DNAs.	PLoS One. 2011;6(12):e29050. Epub 2011 Dec 20.	The xenotropic murine leukemia virus (MLV)-related viruses (XMRV) have been reported in persons with prostate cancer, chronic fatigue syndrome, and less frequently in blood donors. Polytropic MLVs have also been described in persons with CFS and blood donors. However, many studies have failed to confirm these findings, raising the possibility of contamination as a source of the positive results. One PCR reagent, Platinum Taq polymerase (pol) has been reported to contain mouse DNA that produces false-positive MLV PCR results. We report here the finding of a large number of PCR reagents that have low levels of MLV sequences. We found that recombinant reverse-transcriptase (RT) enzymes from six companies derived from either MLV or avian myeloblastosis virus contained MLV pol DNA sequences but not gag or mouse DNA sequences. Sequence and phylogenetic analysis showed high relatedness to Moloney MLV, suggesting residual contamination with an RT-containing plasmid. In addition, we identified contamination with mouse DNA and a variety of MLV sequences in commercially available human DNAs from leukocytes, brain tissues, and cell lines. These results identify new sources of MLV contamination and highlight the importance of careful pre-screening of commercial specimens and diagnostic reagents to avoid false-positive MLV PCR results.
Şimşek I.	Medicine Faculty, Department of	Irritable bowel syndrome and other	J Clin Gastroenterol. 2011 Aug;45	Irritable bowel syndrome is one of several highly prevalent functional gastrointestinal disorders (FGID) displaying symptoms of gastrointestinal dysmotility and visceral

	Gastroenterology, Dokuz Eylul University, Izmir, Turkey. ilkay.simsek@deu.edu.tr	functional gastrointestinal disorders.	Suppl:S86-8.	hypersensitivity. Substantial overlap of symptoms and comorbidities occur not only between irritable bowel syndrome and other FGID but also with gastrointestinal disorders that are not related to motility (eg, celiac disease and lactose intolerance) and to somatic conditions (eg, fibromyalgia and chronic fatigue syndrome). Pathogenic mechanisms common among FGIDs may include alternations in intestinal and colonic microflora. Evidence is also emerging of an interplay between gut immune cells/activity and alternations in motility, secretion, and sensation. The role of cytokine activity and inflammation is important in this regard. As recommended by Rome III, diagnostic testing should be guided by the patient's age, primary symptom characteristics, and other clinical and laboratory features. The high prevalence of coexisting conditions suggests the need to routinely assess patients for related disorders. Treatment should be based on an individualized evaluation, explanation, and reassurance.

Ablin JN, Odes L, Neumann L, Buskila D.	Institute of Rheumatology and Internal Medicine 6, Tel Aviv Sourasky Medical Center, Tel Aviv, Israel. ajacob@post.tau.ac.il	The Hebrew version of the FibroFatigue scale: validation of a questionnaire for assessment of fibromyalgia and chronic fatigue syndrome.	Rheumatol Int. 2010 Jul;30(9):1173-6. Epub 2009 Sep 25.	The objective of this study is to validate a translated Hebrew version of the FibroFatigue Scale (FFS). The Hebrew version of the FFS was administered to 100 patients fulfilling ACR criteria for classification of FM together with the validated Hebrew version of the Fibromyalgia Impact Questionnaire (FIQ), the validated Hebrew version of the Short Form-36 (SF-36) and a Visual Analogue Scale (VAS) measurement of pain, anxiety, depression, morning stiffness and global well being. Test-retest reliability was assessed using Spearman correlations. Internal consistency was evaluated with Cronbach's alpha of reliability. Construct validity of the FFS was evaluated by correlations among the FFS, the FIQ and the subscales of the SF-36. Mean duration of symptoms was 10.7 years, and mean age of participants was 53.5 years. Test-retest reliability was between 0.46 and 0.85 for the various FFS items. Internal consistency was 0.89 for the overall FFS. Significant correlations were obtained between the FFS items and the SF-36. These results support the reliability and validity of the data obtained with the Hebrew version of the FSS for detecting and measuring symptom severity in Hebrew speaking patients with FM.

Alegre J, Rosés JM, Javierre C, Ruiz-Baqués A, Segundo MJ, de Sevilla TF.	Servicio de Medicina Interna, Hospital Vall d'Hebrón, Barcelona, España.	[Nicotinamide adenine dinucleotide (NADH) in patients with chronic fatigue syndrome]. [Article in Spanish]	Rev Clin Esp. 2010 Jun;210(6):284-8. Epub 2010 May 5.	BACKGROUND: Nicotinamide adenine dinucleotide (NADH) may be depleted in chronic fatigue syndrome (SFC). The purpose of the study was to evaluate the efficacy of supplementation with NADH in these patients. MATERIAL AND METHODS: A double blind, placebo controlled, 3 month long clinical trial was conducted. The patients were randomized to oral NADH oral 20mg or placebo during the first two months. The intensity of the fatigue, functional performance, mood state, functional impact of the fatigue, quality of life, sleep quality, exercise capacity and functional reserve as well as the investigator's and patient's opinion on the efficacy of the intervention prior to and at 30, 60 and 90 days of the onset of the treatment were evaluated. A stress test was performed in the baseline visit and at 60 days (last day of the double blind treatment). RESULTS: A total of 86 patients, 77 of whom completed the study (mean age, 47 years, 72 women) were enrolled. No significant differences were found in most of the variable studied at the end of the study. Administration of NADH was associated to a decrease in anxiety condition of -1.0 points ($p<0.05$) and of -0.2 points (p=NS) in the placebo assigned group. Maximum heart rate after the stress test decreased a mean of -8.1l/min ($p<0.05$) in the NADH group and increased by +1.7l/min in the placebo group (p=0.73). No differences were found in the perception of efficacy with NADH and placebo, by the investigator and patients. CONCLUSIONS: Administration of oral NADH was associated to a decrease in anxiety and maximum heart rate, after a stress test in patients with CFS. On the contrary, this treatment did not modify other clinical variables and the global functional performance.

Bakker RJ, van de Putte EM, Kuis W, Sinnema G.	Department of Pediatrics, Antonius Ziekenhuis, Sneek, The Netherlands.	Effects of an educational video film in fatigued children and adolescents: a randomised controlled trial.	Arch Dis Child. 2010 Sep 22. [Epub ahead of print]	Background In many cases standard management for chronic fatigue syndrome (CFS) in children and adolescents is ineffective. Objective To evaluate the efficacy of a video film intervention in preventing the development of persistent fatigue and significant school absence in fatigued children and adolescents. Design Randomised controlled trial. Participants 91 patients with fatigue; 50 were randomly assigned to receive the intervention (video film plus usual care) and 41 to usual care only. Intervention A video film on CFS and coping behaviour. Main outcome measures Self-reported fatigue severity, physical activity, motivation, concentration and school absence. Results 79 patients had complete data at 12 months (42 in the video film and 37 in the usual care group). Mean fatigue severity and school absenteeism scores did not differ significantly, but in the intervention group the score for reduced motivation was higher (difference 2.9 (CI 0.1 to 5.7), p=0.038). 18% more patients in the intervention compared to the usual care group also had persistent fatigue with significant school absence. The odds of developing persistent fatigue and of missing >50% of school classes was 3.3 times higher in the intervention than in the usual care group (OR 3.3 (CI 1.0 to 11.3), p=0.046). Conclusion This particular video film intervention plus usual care in children and adolescents with unexplained fatigue did not prevent an unfavourable outcome and possibly had an adverse effect in that it reduced motivation and increased the incidence of persistent fatigue with significant school absence. The use of this particular film is not recommended.
Bannert N.		Is a novel human retrovirus associated with prostate cancer and chronic fatigue syndrome?	Future Microbiol. 2010 May;5(5):689-91.	
Baraniuk JN, Zheng Y.	Division of Rheumatology, Immunology and Allergy, Georgetown	Relationships among rhinitis, fibromyalgia, and chronic fatigue.	Allergy Asthma Proc. 2010 May-Jun;31(3):169-78.	New information about the pathophysiology of idiopathic nonallergic rhinopathy indicates a high prevalence in chronic fatigue syndrome (CFS). This article shows the relevance of CFS and allied disorders to allergy practice. CFS has significant overlap with systemic hyperalgesia (fibromyalgia), autonomic dysfunction (irritable bowel syndrome and migraine headaches), sensory hypersensitivity (dyspnea; congestion; rhinorrhea; and appreciation of visceral nociception in the esophagus,

	University, PHC Building, 3800 Reservoir Road, NW, Washington, DC 20007-2197, USA. baraniuj@georgetown.edu			gastrointestinal tract, bladder, and other organs), and central nervous system maladaptations (central sensitization) recorded by functional magnetic resonance imaging (fMRI). Neurological dysfunction may account for the overlap of CFS with idiopathic nonallergic rhinopathy. Scientific advances are in fMRI, nociceptive sensor expression, and, potentially, infection with xenotropic murine leukemia-related virus provide additional insights to novel pathophysiological mechanisms of the "functional" complaints of these patients that are mistakenly interpreted as allergic syndromes. As allergists, we must accept the clinical challenges posed by these complex patients and provide proper diagnoses, assurance, and optimum care even though current treatment algorithms are lacking.
Baraniuk JN.	Georgetown University, 3800 Reservoir Road NW, Washington, DC 20007-2197, USA. baraniuj@georgetown.edu	Xenotropic murine leukemia virus-related virus in chronic fatigue syndrome and prostate cancer.	Curr Allergy Asthma Rep. 2010 May;10(3):210-4.	Xenotropic murine leukemia virus-related virus (XMRV) is a gamma retrovirus that has been associated with chronic fatigue syndrome (CFS) and prostate cancer. The search for viral causes of these syndromes was reignited by the finding that RNase L activity was low in hereditary prostate cancer and some CFS patients. The six strains of XMRV that have been sequenced have greater than 99% identity, indicating a new human infection rather than laboratory contamination. DNA, RNA, and proteins from XMRV have been detected in 50% to 67% of CFS patients and in about 3.7% of healthy controls. XMRV infections could be transmitted to permissive cell lines from CFS plasma, suggesting the potential for communicable and blood-borne spread of the virus and potentially CFS. This troubling concept is currently under intense evaluation. The most important steps now are to independently confirm the initial findings; develop reliable assays of biomarkers; and to move on to investigations of XMRV pathophysiology and treatment in CFS, prostate cancer, and potentially other virus-related syndromes, if they exist.
Barnes E, Flanagan P, Brown A, Robinson N, Brown H, McClure M, Oxenius A, Collier J, Weber J, Günthard HF, Hirschel B, Fidler S, Phillips R, Frater J.	Nuffield Department of Clinical Medicine, Peter Medawar Building for Pathogen Research, Oxford University, and Oxford NIHR Biomedical Research Centre, Oxford, United Kingdom.	Failure to detect xenotropic murine leukemia virus-related virus in blood of individuals at high risk of blood-borne viral infections.	J Infect Dis. 2010 Nov 15;202(10):1482-5. Epub 2010 Oct 11. Comment in: J Infect Dis. 2010 Nov 15;202(10):1463-6.	A xenotropic murine leukemia virus-related virus (XMRV) has recently been reported in association with prostate cancer and chronic fatigue syndrome, with a prevalence of up to 3.7% in the healthy population. We looked for XMRV in 230 patients with human immunodeficiency virus type 1 or hepatitis C infection. XMRV was undetectable in plasma or peripheral blood mononuclear cells by polymerase chain reaction targeting XMRV gag or env. T cell responses to XMRV Gag were undetectable in peripheral blood mononuclear cells by ex vivo gamma interferon enzyme-linked immunospot assay. In our cohorts, XMRV was not enriched in patients with blood-borne or sexually transmitted infections from the United Kingdom and Western Europe.
Basseri B, Yamini D, Chee G, Enayati PD, Tran T, Poordad F.	Hepatology Section, Division of Gastroenterology, Cedars-Sinai Medical Center, Los Angeles, CA, USA.	Comorbidities associated with the increasing burden of hepatitis C infection.	Liver Int. 2010 Aug;30(7):1012-8. Epub 2010 Apr 8.	BACKGROUND: Hepatitis C virus (HCV) infection is implicated in an increasing number of liver transplantations, hospitalizations and healthcare costs. AIMS: We present an updated assessment of comorbidities associated with HCV in comparison to the general US population. METHODS: Cross-sectional retrospective review of data from 800 patients with HCV evaluated between January 1998 and November 2007. Patient data were prospectively collected using a standardized questionnaire completed at the first encounter and was compared with general US epidemiological data. Odds ratios and 95% confidence intervals (CI) are reported. RESULTS: HCV conferred a 44% (CI 1.16-1.78) and 25%

				(CI 1.01-1.54) increased risk of diabetes (12.5 vs. 7.3-8.4%; P=0.001) and obesity (23.9 vs. 19.8-33.1%; P=0.041), respectively, compared with the US population. Human immunodeficiency virus (HIV) (5.3 vs. 0.3%; P<0.001) and end-stage renal disease (ESRD) (4.5 vs. 0.2%; P<0.001) were 16- and 13-fold more prevalent in HCV. Interestingly, HCV bestowed 90% decreased odds (CI 0.09-0.15) for hyperlipidaemia (12.3 vs. 53.2-56.1%; P<0.001). The HCV population had a higher prevalence of significant alcohol consumption (41.5 vs. 4.7%; P<0.001), current smoking (57.7 vs. 18.8-20.8%; P<0.001), drug use (46.8 vs. 14.6-15.6%; P<0.001), incarceration (6.6 vs. 2.7%; P<0.001) and tattoos (20.3 vs. 14%; P=0.011), as well as chronic fatigue (44.6 vs. 11.3-19%; P<0.001) and depression (29.3 vs. 5.0-10.3%; P<0.001). CONCLUSION: HCV poses an increasing healthcare burden associated with increased prevalence of diabetes, obesity, HIV, ESRD, maladaptive lifestyle habits and poor quality of life. Practitioners should be cognizant of these trends in order to appropriately manage these comorbidities.
Beever R.	Department of Family Medicine, University of British Columbia, British Columbia, Canada. Richard.beever@northernhealth.ca	The effects of repeated thermal therapy on quality of life in patients with type II diabetes mellitus.	J Altern Complement Med. 2010 Jun;16(6):677-81.	OBJECTIVES: Decreased quality of life in diabetes is associated with poor health outcomes. Far-infrared sauna treatments improve the quality of life for those with chronic pain, chronic fatigue syndrome, depression, and congestive heart failure. The objective of this study is to determine whether far-infrared saunas have a beneficial effect on quality of life in those with type II diabetes. DESIGN: This was a sequential, longitudinal, interrupted time series design study. SETTING/LOCATION: The setting was Fraser Lake BC, a rural village in central British Columbia, Canada. SUBJECTS: All patients of the Fraser Lake Community Health Center with type II diabetes were invited to participate in this study. INTERVENTIONS: The study consisted of 20-minute, 3 times weekly infrared sauna sessions, over a period of 3 months. OUTCOME MEASURES: To assess quality of life, subjects completed the 36-item Short-form Health Survey Version 2 (SF-36v2) questionnaire as well as "Zero-to-Ten" Visual Analogue Scales. Baseline study parameters were measured within 1 week prior to commencing sauna sessions. Postintervention measurements were collected between 1 and 3 days after the last sauna session. RESULTS: Physical health, general health, and social functioning indices of the SF-36v2 improved. Visual Analogue Scales for stress and fatigue improved. CONCLUSIONS: Far-infrared sauna use maybe associated with improved quality of life in people with type II diabetes mellitus. Uptake of infrared saunas use is greater than the uptake of other lifestyle interventions.
Biswal B, Kunwar P, Natelson BH.	Departments of Radiology, UMDNJ-New Jersey Medical School, Newark NJ, United States.	Cerebral blood flow is reduced in chronic fatigue syndrome as assessed by arterial spin labeling.	J Neurol Sci. 2010 Dec 15. [Epub ahead of print]	BACKGROUND: Chronic fatigue syndrome is diagnosed by a set of clinical criteria and therefore is probably heterogeneous. Earlier reports tested the hypothesis that the syndrome had a neurological substrate by doing studies of cerebral blood flow (CBF) but with discrepant results. One possible reason for the discrepancy was that relative CBF was assessed. We found reduced CBF in an earlier study of absolute CBF using xenon-CT. The purpose of this study was to use a second method of assessing CBF and to look within the study group for heterogeneity of responses. METHOD: Eleven CFS patients and 10 age matched healthy controls underwent neuroimaging using arterial spin labeling to determine their regional and global absolute CBF. A template was constructed based on the control data, and individual patient montages were compared on a case by case basis to determine if differences in regions of interest occurred. RESULTS: The patients as a group had significantly lower global CBF than the controls. The reduction in CBF occurred across nearly every region assessed. Nine of the 11 patients showed these reductions compared to the average control data, while two patients

				showed actual increases relative to the controls. CONCLUSION: The data extend our earlier observation that CFS patients as a group have broad decreases in CBF compared to healthy controls. However, as expected, the effect was not homogeneous in that 2 of the 11 patients studied showed actual increases in CBF relative to controls.
Bjerregaard P, Nallapaneni H, Gussak I.	Division of Cardiology, VA Medical Center and Washington University in St. Louis, St. Louis, MO 63106, USA. preben.bjerregaard@va.gov	Short QT interval in clinical practice.	J Electrocardiol. 2010 Sep-Oct;43(5):390-5. Epub 2010 Jul 27.	The last ten years have seen a growing interest in clinical scenarios, where a short QT interval may play a role, especially because of an increased risk of sudden cardiac death in some situations. One such entity is Short QT Syndrome, which has emerged as a rare, but very malignant disease, in particular when the QT interval is very short. A short QT interval has also been noticed in some patients with other arrhythmic syndromes such as Idiopathic Ventricular Fibrillation, Brugade Syndrome and Early Repolarization Syndrome, but the role of a short QT interval in these settings is so far not known. Hypercalcemia often leads to shortening of the QT interval, but there are no data in humans to suggest an increased risk of sudden cardiac death in this setting. In addition, a shorter-than-usual QT interval has been reported in patients with Chronic Fatigue Syndrome and in response to atropine, catecholamine and Hyperthermia. When a short QT interval is encountered in daily clinical practice, these various scenarios needs to be considered, but it is still not possible to come up with clear guidelines for how to work up and risk stratify such individuals. Genetic testing is only useful in very few and the value of an electrophysiologic study, Holter monitoring or stress testing to assess QT adaptation to heart rate and T wave morphology analysis may all be helpful, but not well-established, tests in this setting.
Boneva RS, Maloney EM, Lin JM, Jones JF, Wieser F, Nater UM, Heim CM, Reeves WC.	1 Centers for Disease Control and Prevention , Atlanta, Georgia .	Gynecological History in Chronic Fatigue Syndrome: A Population-Based Case-Control Study.	J Womens Health (Larchmt). 2010 Nov 20. [Epub ahead of print]	Abstract Background: Chronic fatigue syndrome (CFS) affects disproportionately more women than men, and the condition is more common at perimenopause. We examined gynecological history events as risk factors for CFS. Methods: In a case-control study from a randomly selected population sample from Wichita, Kansas, 36 women with CFS and 48 nonfatigued controls, of similar age, race, and body mass index (BMI), answered a structured gynecological history questionnaire. Results: CFS cases and controls had the same mean age (51 years) and age at menarche (12 years). Overall, a greater proportion of women with CFS than controls reported pelvic pain unrelated to menstruation (22.2% vs. 1.7%, p = 0.004), endometriosis (36.1% vs. 16.7, %, p = 0.046), and periods of amenorrhea (53.9 % vs. 46.2%, p = 0.06). Compared to controls, women in the CFS group had a higher mean number of pregnancies (2.8 vs 2.0, p = 0.05) and gynecological surgeries (1.8 vs. 1.1, p = 0.05). Similar proportions of the CFS (69.4%) and control (72.9%) groups were menopausal. Although menopausal women in the CFS and control groups had similar mean age (55.5 and 55.8, respectively), menopause occurred about 4.4 years earlier in the CFS group (41.7 years vs. 46.1 years, respectively, p = 0.11). Among menopausal women, 76% of the CFS group reported hysterectomy vs. 54.6% of controls (p = 0.09), and 56% of women with CFS reported oophorectomy vs. 34.3% of controls (p = 0.11). Conclusions: The higher prevalence of gynecological conditions and gynecological surgeries in women with CFS highlights the importance of evaluating gynecological health in these patients and the need for more research to clarify the chronologic and the pathophysiological relationships between these conditions and CFS.
Brenu EW, Staines DR, Baskurt OK,	Faculty of Health Science and	Immune and hemorheological	J Transl Med. 2010 Jan 11;8:1.	BACKGROUND: Chronic Fatigue Syndrome (CFS) is a multifactorial disorder that affects various physiological systems including immune and neurological systems. The immune system has been

Ashton KJ, Ramos SB, Christy RM, Marshall-Gradisnik SM.	Medicine, Population Health and Neuroimmunology Unit, Bond University, Robina, Queensland, Australia. ebrenu@student.bond.edu.au	changes in chronic fatigue syndrome.		substantially examined in CFS with equivocal results, however, little is known about the role of neutrophils and natural killer (NK) phenotypes in the pathomechanism of this disorder. Additionally the role of erythrocyte rheological characteristics in CFS has not been fully expounded. The objective of this present study was to determine deficiencies in lymphocyte function and erythrocyte rheology in CFS patients. METHODS: Flow cytometric measurements were performed for neutrophil function, lymphocyte numbers, NK phenotypes (CD56(dim)CD16(+) and CD56(bright)CD16(-)) and NK cytotoxic activity. Erythrocyte aggregation, deformability and fibrinogen levels were also assessed. RESULTS: CFS patients (n = 10) had significant decreases in neutrophil respiratory burst, NK cytotoxic activity and CD56(bright)CD16(-) NK phenotypes in comparison to healthy controls (n = 10). However, hemorheological characteristic, aggregation, deformability, fibrinogen, lymphocyte numbers and CD56(dim)CD16(+) NK cells were similar between the two groups. CONCLUSION: These results indicate immune dysfunction as potential contributors to the mechanism of CFS, as indicated by decreases in neutrophil respiratory burst, NK cell activity and NK phenotypes. Thus, immune cell function and phenotypes may be important diagnostic markers for CFS. The absence of rheological changes may indicate no abnormalities in erythrocytes of CFS patients.
Brimmer DJ, Fridinger F, Lin JM, Reeves WC.	Division of Viral and Rickettsial Diseases, Centers for Disease Control and Prevention, Atlanta, GA, USA. dyv4@cdc.gov	U.S. healthcare providers' knowledge, attitudes, beliefs, and perceptions concerning Chronic Fatigue Syndrome.	BMC Fam Pract. 2010 Apr 21;11:28.	BACKGROUND: Chronic fatigue syndrome (CFS) is a debilitating illness with particular difficulties for healthcare providers because there are no diagnostic signs or laboratory tests and because management aims to merely improve symptoms. Further complicating management, healthcare providers' awareness concerning CFS has not been rigorously assessed. The present study aimed to ascertain United States (U.S.) healthcare providers' awareness of CFS and to assess their knowledge, attitudes, and beliefs (KAB) related to diagnosis and management of the illness. This information forms the foundation for developing CFS educational strategies. METHODS: We combined convenience and probability samples to measure CFS KAB among healthcare providers. In the convenience sample, 1,255 healthcare providers (81% response rate) from 13 professional conferences completed a 12-item form. Descriptive statistics were reported for 9 KAB item responses and chi-square tests were performed for examining their association with giving a diagnosis of CFS. We used principal component analysis to construct multidimensional subscales and perform a general linear model to examine factors associated with subscales. The probability sample involved data on 15 CFS-specific questions from 2006 and 2007 DocStyles web-based panel surveys collected from 2,750 physicians (average response rate 55%). We calculated descriptive and chi-square statistics. The significance was set at two-tailed with the alpha level of 0.05. RESULTS: Healthcare providers in both samples were aware of CFS and exhibited a high level of knowledge. Overall, 96% of respondents in the DocStyles (probability) sample had heard about CFS. Healthcare providers in the conference (convenience) sample demonstrated good KAB scores; physicians' scores were highest on KAB scales and lowest in perception. Nurses' scores were lowest in knowledge. More than 40% of physicians reported ever giving a CFS diagnosis and in the DocStyles (probability) sample more than 80% of physicians correctly identified CFS symptoms. Physicians reported professional journals, the Internet, and continuing education programs as the top 3 sources from which they obtain CFS information. CONCLUSIONS: Findings from these combined samples fill a gap in the evidence-base of U.S. healthcare providers' and knowledge, attitudes, and beliefs concerning CFS. Importantly, respondents

				in both samples expressed similar knowledge, attitudes, beliefs and perceptions. Awareness was high and negative attitudes were low. The primary areas for future education should address diagnosis and management of CFS and should be delivered through those venues providers indicated they primarily use. Data from this study provide a benchmark for evaluation the success of these future efforts.
Brkic S, Tomic S, Maric D, Novakov Mikic A, Turkulov V.	Clinic for Infectious Diseases, Clinical Center Vojvodina, Novi Sad, Serbia. tomkis@eunet.rs	Lipid peroxidation is elevated in female patients with chronic fatigue syndrome.	Med Sci Monit. 2010 Nov 30;16(12):CR628-32.	BACKGROUND: Chronic fatigue syndrome is a debilitating disease of unclear cause and pathogenesis. It affects mostly women from lower socioeconomic classes. There is mounting evidence that oxidative stress, specifically lipid peroxidation (LPO) contributes to the disease process. We investigated levels of LPO and its possible consequences for these patients. MATERIAL/METHODS: Forty women aged 15-45 years who fulfilled the 1994 Centers for Disease Control's diagnostic criteria for chronic fatigue syndrome (CFS) with no comorbidities were recruited and were age matched to a control group of 40 healthy women. Levels of total cholesterol (TC), triglycerides (TG), LDL cholesterol (LDLc), HDL cholesterol (HDLc), and malondialdehyde (MDA) levels were measured. RESULTS: Although initial statistical analyses showed no differences between groups (P=.345), when subdivided according to the level of MDA, a difference was found in the subgroup of high-level MDA (P=.034). There was a negative correlation between HDLc and MDA levels (r=0.3; P=.046), a positive correlation between TG and MDA levels (r=0.4; P=.006), and lower levels of HDL cholesterol in the CFS group (P=.036). CONCLUSIONS: High levels of MDA, positively correlated with TG and lower HDL levels, might be indicative of proatherogenic events in female CFS patients, a group not otherwise considered a risk for atherosclerosis.
Broderick G, Fuite J, Kreitz A, Vernon SD, Klimas N, Fletcher MA.	Division of Pulmonary Medicine, Department of Medicine, University of Alberta, College Plaza, 8215 112 Street NW, Edmonton, Alberta, Canada. gordon.broderick @ualberta.ca	A formal analysis of cytokine networks in chronic fatigue syndrome.	Brain Behav Immun. 2010 Oct;24(7):1209-17. Epub 2010 May 4. Comment in: Brain Behav Immun. 2010 Oct;24(7):1218; author reply 1219.	Chronic Fatigue Syndrome (CFS) is a complex illness affecting 4 million Americans for which no characteristic lesion has been identified. Instead of searching for a deficiency in any single marker, we propose that CFS is associated with a profound imbalance in the regulation of immune function forcing a departure from standard pre-programmed responses. To identify these imbalances we apply network analysis to the co-expression of 16 cytokines in CFS subjects and healthy controls. Concentrations of IL-1a, 1b, 2, 4, 5, 6, 8, 10, 12, 13, 15, 17 and 23, IFN-γ, lymphotoxin-α (LT-α) and TNF-α were measured in the plasma of 40 female CFS and 59 case-matched controls. Cytokine co-expression networks were constructed from the pair-wise mutual information (MI) patterns found within each subject group. These networks differed in topology significantly more than expected by chance with the CFS network being more hub-like in design. Analysis of local modularity isolated statistically distinct cytokine communities recognizable as pre-programmed immune functional components. These showed highly attenuated Th1 and Th17 immune responses in CFS. High Th2 marker expression but weak interaction patterns pointed to an established Th2 inflammatory milieu. Similarly, altered associations in CFS provided indirect evidence of diminished NK cell responsiveness to IL-12 and LT-α stimulus. These observations are consistent with several processes active in latent viral infection and would not have been uncovered by assessing marker expression alone. Furthermore this analysis identifies key sub-networks such as IL-2:IFN-γ:TNF-α that might be targeted in restoring normal immune function.
Brown M, Khorana N, Jason LA.	DePaul University.	The role of changes in activity as a function of	J Clin Psychol. 2010 Oct 25. [Epub ahead of print]	Nonpharmacological interventions for myalgic encephalomyelitis/chronic fatigue syndrome (ME/CFS) often emphasize gradual increases in activity to promote improvement in physical functioning and fatigue. The energy envelope theory may provide a framework for understanding the relationship

		perceived available and expended energy in nonpharmacological treatment outcomes for ME/CFS.		between changes in activity level and outcomes for patients with ME/CFS. This study examined the relationship between energy envelope and changes in activity after nonpharmacological interventions in a sample of 44 adults with ME/CFS. Results showed that those who were within their energy envelope before treatment showed more improvement in physical functioning and fatigue compared with those outside of their energy envelope. These findings suggest that an assessment of perceived available and expended energy could help guide the development of individualized nonpharmacological interventions for people with ME/CFS. © 2010 Wiley Periodicals, Inc. J Clin Psychol 00:1-8, 2010.
Brown MM, Brown AA, Jason LA.	Center for Community Research, DePaul University, Chicago, IL 60614, USA. mbrown59@depaul.edu	Illness duration and coping style in chronic fatigue syndrome.	Psychol Rep. 2010 Apr;106(2):383-93.	A sample of patients with chronic fatigue syndrome was recruited to assess coping strategies and illness duration. It was hypothesized that adaptive coping strategies would be higher among those with longer illness duration. Those in the longer illness duration group reported higher use of active coping, positive reframing, planning, and acceptance, and lower use of behavioral disengagement than those in the shorter illness duration group. No significant differences were found between the two illness duration groups for physical impairment or symptom severity, but the long duration group revealed a lower percentage of participants who were working than the short duration group. These findings suggest that individuals with longer or shorter duration of the illness have differences in coping styles but not differences in physical impairment or symptom severity.
Burton AR, Rahman K, Kadota Y, Lloyd A, Vollmer-Conna U.	School of Psychiatry, University of NSW, Sydney, Australia.	Reduced heart rate variability predicts poor sleep quality in a case-control study of chronic fatigue syndrome.	Exp Brain Res. 2010 Jul;204(1):71-8. Epub 2010 May 26.	Parasympathetic function is important in the induction and maintenance of sleep. We examined whether nocturnal vagal modulation of heart rate is related to the poor sleep quality commonly reported in chronic fatigue syndrome (CFS). Heart rate (HR, as R-R intervals) was continuously monitored during sleep in 20 patients with CFS and 20 matched control subjects. Questionnaires assessed demographic information, symptoms, functional impairment, and subjective sleep quality. CFS was associated with more sleep problems in general and poorer subjective sleep quality on the study night (all $p < 0.003$), and reports of repeated awakening during the night were 7 times more likely compared to healthy subjects ($p = 0.017$). Time and frequency-domain parameters of HR variability during sleep were significantly lower in patients with CFS (all $p < 0.006$). Multiple regression analyses revealed that heart rate variability (HRV) parameters were the best predictors of subjective sleep measures. This study identified significant reductions in vagal modulation of heart rate during sleep in CFS. Low HRV strongly predicted sleep quality-suggesting a pervasive state of nocturnal sympathetic hypervigilance in CFS.
Bürgel B, Friesland M, Koch A, Manns MP, Wedemeyer H, Weissenborn K, Schulz-Schaeffer WJ, Pietschmann T, Steinmann E, Ciesek S.	Division of Experimental Virology, TWINCORE, Centre for Experimental and Clinical Infection Research; a joint venture between the Medical School	Hepatitis C virus enters human peripheral neuroblastoma cells - evidence for extra-hepatic cells sustaining hepatitis C virus penetration.	J Viral Hepat. 2010 Jun 23. [Epub ahead of print]	Summary. Patients with chronic hepatitis C virus (HCV) infection show an increased incidence of nervous system disorders such as chronic fatigue syndrome, depression and cognitive dysfunction. It is unclear whether this is because of HCV replication in the brain and in peripheral neuronal cells or to more indirect effects of HCV infection on the central or peripheral nervous system. The aim of this study was to investigate whether cells originating from these tissues are permissive for HCV cell entry, RNA replication and virus assembly. Among eight cell lines analysed, the human peripheral neuroblastoma cell line SKNMC expressed all HCV entry factors and was efficiently infected with HCV pseudoparticles (HCVpp) independent of the HCV genotype. All remaining cell types including human neuroblastoma and glioblastoma cell lines and microglial cells lacked expression of at least one host factor essential for HCV entry. When transfected with HCV luciferase reporter virus RNA, inoculated

	Hannover (MHH) and the Helmholtz Centre for Infection Research (HZI), Hannover, Germany.			with HCV reporter viruses or challenged with high-titre cell culture-derived HCV, none of these cells supported detectable HCV RNA replication. Thus, in conclusion, this comprehensive screening did not reveal evidence directly strengthening the notion that HCV enters and replicates in the central nervous system. However, productive viral entry into the peripheral neuroblastoma cell line SKNMC indicates that HCV may penetrate into certain nonhepatic cell types which may serve as viral reservoirs and could modulate viral pathogenesis.
Cameron B, Flamand L, Juwana H, Middeldorp J, Naing Z, Rawlinson W, Ablashi D, Lloyd A.	Center for Infection and Inflammation Research, School of Medical Sciences, University of New South Wales, Sydney, New South Wales, Australia. b.cameron@unsw.edu.au	Serological and virological investigation of the role of the herpesviruses EBV, CMV and HHV-6 in post-infective fatigue syndrome.	J Med Virol. 2010 Oct;82(10):1684-8.	Multiple previous studies have sought evidence for ongoing, active infection with, or reactivation of, Herpesviruses in patients with chronic fatigue syndrome (CFS), with conflicting results. This study aimed to clarify this by studying 20 patients enrolled in a well-characterized model of the onset and evolution of CFS, the prospective cohort of the Dubbo Infection Outcomes Study (DIOS). The patients selected for examination included five CFS patients with primary Epstein-Barr virus (EBV) infection; five CFS patients with acute viral infection not caused by EBV; and 10 matched controls with prompt resolution of primary EBV infection. Serum samples from three timepoints were assayed using a comprehensive range of serological assays for EBV, HHV-6, and CMV. Viral genomes were assessed using quantitative PCR assays. All patients were seropositive for HHV-6, and 10 were seropositive for CMV at infection baseline (five patients and five controls). Low titer CMV IgM antibodies were found at infection baseline in two of these cases and three control patients. HHV-6 IgG antibody titers were highest at infection baseline but did not differ between the CFS cases and the control patients. There were increases in EBV IgG VCA p18, EBNA-1 IgG, and EA IgG titers over time, but these did not differ between CFS cases and control patients. EBV and HHV6 DNA levels were at control levels in a minority of samples, and CMV was undetectable in all samples. These data do not support the hypothesis of ongoing or reactivated EBV, HHV-6, or CMV infection in the pathogenesis of CFS.

Cella M, Chalder T.	Institute of Psychiatry, King's College London, London, United Kingdom. matteo.cella@kcl.ac.uk	Measuring fatigue in clinical and community settings.	J Psychosom Res. 2010 Jul;69(1):17-22. Epub 2009 Dec 11.	OBJECTIVE: The Chalder Fatigue Scale (CFQ) is a widely used instrument to assess fatigue in both clinical and nonclinical settings. Psychometric properties of the scale and discriminative abilities were examined. METHODS: A total of 361 patients with CFS and 1615 individuals in the community were assessed with the CFQ. Principal component analysis (PCA) was used to explore the structure of the scale. Receiver-operating characteristic curve (ROC) was used to investigate the discriminative properties. RESULTS: Two components, physical and mental fatigue, were identified in the CFS patient group and in the general population samples. Area under the curve for ROC was .91. The fatigue scale effectively discriminates, at high scores, between CFS patients and the general population. CONCLUSION: Physical and mental fatigue are clearly separable components of fatigue. The CFQ can discriminate reliably between clinical and nonclinical conditions.
Chalder T, Deary V, Husain K, Walwyn R.	Department of Psychological Medicine and Psychiatry, King's College London, Weston Education Centre, London, UK. trudie.chalder@kcl.ac.uk	Family-focused cognitive behaviour therapy versus psycho-education for chronic fatigue syndrome in 11- to 18-year-olds: a randomized controlled treatment trial.	Psychol Med. 2010 Aug;40(8):1269-79. Epub 2009 Nov 6.	BACKGROUND: Only one previous randomized controlled trial (RCT) has examined the efficacy of cognitive behaviour therapy (CBT) for chronic fatigue syndrome (CFS) in children. The aim of this study was to compare family-focused CBT with psycho-education for CFS in adolescents. METHOD: Sixty-three 11- to 18-year-olds (43 girls, 20 boys) with CFS were randomly assigned to either family-focused CBT or psycho-education delivered over 6 months. School attendance was the main outcome, which was assessed at the end of treatment and at 3, 6 and 12 months follow-up. RESULTS: At the main outcome point (the 6-month follow-up) both groups had improved similarly. However, although those who received family-focused CBT were attending school for longer than those who received psycho-education, at discharge from treatment and at 3 months follow-up, they improved less quickly across the follow-up period. CONCLUSIONS: Adolescents with CFS get back to school more quickly after family-focused CBT. This is important as they are at a crucial stage of their development. However, the finding that psycho-education was as effective as family-focused CBT at 6 and 12 months follow-up has important implications for health service delivery.
Chastin SF, Granat MH.	Glasgow Caledonian University, School of Health and Social Care, Cowcaddens Road, Glasgow G4 0BA, Scotland, UK. Sebastien.Chastin@gcal.ac.uk	Methods for objective measure, quantification and analysis of sedentary behaviour and inactivity.	Gait Posture. 2010 Jan;31(1):82-6. Epub 2009 Oct 24.	The purpose of this study was to develop and test a generic technique to robustly quantify the pattern of sedentary behaviour from objective records. The technique was applied to four groups of subjects: a healthy group with an active occupation (N=54), a healthy group with a sedentary occupation (N=53), a group of subjects with chronic low back pain (N=5) and a group of subjects with chronic fatigue syndrome (N=14). This study presents the first evidence that bouts of sedentary activity are power law distributed. Results showed that there was no significant difference in total sedentary time between the groups, however, the patterns of accumulation of sedentary time were significantly different for the groups. Sedentary groups accumulated their total sedentary time from a small number of longer sedentary bouts. Active groups tended to break their sedentary time into a greater number of shorter bouts. This suggests that the power law exponent alpha and the GINI index G, used to describe the pattern of accumulation of sedentary time, could be used to evaluate and quantify sedentary behaviour.
Chelimsky G,	Department of	A comparison of	Gastroenterol Res	Cyclic vomiting syndrome (CVS) shares many features with migraine headache, including auras,

Madan S, Alshekhlee A, Heller E, McNeeley K, Chelimsky T.	Pediatrics, University Hospitals of Cleveland, Cleveland, OH 44106, USA. gisela.chelimsky@uhhospitals.org	dysautonomias comorbid with cyclic vomiting syndrome and with migraine.	Pract. 2009;2009:701019. Epub 2010 Jan 6.	photophobia, and antimigrainous treatment response being traditionally viewed as a migraine variant. Aims. To determine whether CVS is associated with the same disorders as migraine headache, and compare these associations to those in healthy control subjects.METHODS: Cross-sectional study of patients utilizing the ODYSA instrument, evaluating the probability of 12 functional/autonomic diagnoses, CVS, migraine, orthostatic intolerance (OI), reflex syncope, interstitial cystitis, Raynaud's syndrome, complex regional pain syndrome (CRPS), irritable bowel syndrome, functional dyspepsia, functional abdominal pain, fibromyalgia, and chronic fatigue syndrome. Control subjects were age-matched gender-matched friends. Patients had to fulfill criteria for CVS or migraine, while control subjects could not. RESULTS: 103 subjects were studied, 21 with CVS, 46 with migraine and 36 healthy controls. CVS and migraine did not differ in the relative frequencies of fibromyalgia, OI, syncope, and functional dyspepsia. However, CVS patients did demonstrate a significantly elevated frequency of CRPS. CONCLUSIONS: Although CVS and migraine clearly share many of the same comorbidities, they do differ in one important association, suggesting that they may not be identical in pathophysiology. Since OI is common in CVS, treatment strategies could also target this abnormality.
Chen XH, Li LQ, Zhang W, Yang J, Dai YS, Xu DH, Tang CZ.	Department of Acupuncture and Moxibustion, The First Affiliated Hospital of Guangzhou University of TCM, Guangzhou 510405, China. dr_xinghua@yahoo.com.cn	[Randomized controlled study on acupuncture treatment for chronic fatigue syndrome]. [Article in Chinese]	Zhongguo Zhen Jiu. 2010 Jul;30(7):533-6.	OBJECTIVE: To observe the therapeutic effect of acpuncture treatment for chronic fatigue syndrome (CFS). METHODS: Nighty cases of CFS were randomly divided into an observation group and a control group, 45 cases in each group. The observation group was treated with acupunture at Renying (ST 9), Fengfu (GV 16), Baihui (GV 20); the control group was treated with 250 mL 5% Glucose injectio combined with 20 mL Shenmai injectio. Fatigue Scale (FS) was used to compare the scores between the two groups after treatment. RESULTS: The total scores in the observation group were 9.37 +/- 2.33 and 5.41 +/- 1.96 before and after treatment respectively, and in the control group, they were 9.08 +/- 2.27 and 7.34 +/- 2.03 respectively. FS brainwork integral, physical fatigue integral, and total integral all decreased after treatment in two groups (all $P < 0.001$), and it decreased much more obviously in the observation group ($P < 0.05$, $P < 0.01$). CONCLUSION: Both of the acpuncture treatment and Shenmai injectio are able to decrease fatigue scale score, improve the fatigue symptoms of CFS patients, and the effect of acupucture treatment is obviously superior to that of Shenmai injectio.
Cheng CS, Zhu YH, Liang FR, Wu X, Jin SG, Wu FP.	Acupuncture and Massage College, Chengdu University of TCM, Chengdu 610075, China. ccstcm@163.com	[Effect of electroacupuncture at Shenshu (BL 23) and Zusanli (ST 36) on the event-related potentials of chronic fatigue syndrome]. [Article in Chinese]	Zhongguo Zhen Jiu. 2010 Apr;30(4):309-12.	OBJECTIVE: To observe the effective mechanism of electroacupuncture for chronic fatigue syndrome (CFS). METHODS: The dynamic detection of chronobiology was used to test the event-related potentials in 20 healthy subjects and 20 CFS patients. P3a and P3b latencies at 4 equidistant time points (8:00, 14:00, 20:00, 2:00) within 24 hours were collected and analyzed. RESULTS: (1) Latency of P3a in CFS group was obviously prolonged at 14:00 compared to health group with statistical significance ($P < 0.05$), latency of P3b was decreased at 14:00 after electroacupuncture treatment with statistical significance compared to that of pre-treatment ($P < 0.01$). (2) There were obviously circadian rhythm in latency of P3a and P3b in health group ($P < 0.05$), which were not seen in CFS group ($P > 0.05$); the circadian rhythm latency of P3b restored after treatment ($P < 0.05$). (3) The latency acrophase of P3a and P3b pre-treatment obviously shifted backward compared to that of healthy subjects ($P < 0.05$), shifted forward after electroacupuncture treatment ($P < 0.05$). CONCLUSION: The event-related potential circadian rhythms are lost in CFS patients. Electroacupuncture at Shenshu (BL 23) and Zusanli (ST 36) can regulate the circadian rhythm of P3a

				and P3b latency and improve the cognition of the patients in daytime.
Chew-Graham C, Dowrick C, Wearden A, Richardson V, Peters S.	Primary Care Research Group, School of Community-Based Medicine, University of Manchester, Manchester, UK.	Making the diagnosis of Chronic Fatigue Syndrome/Myalgic Encephalitis in primary care: a qualitative study.	BMC Fam Pract. 2010 Feb 23;11:16.	BACKGROUND: NICE guidelines emphasise the role of the primary care team in the management of patients with Chronic Fatigue Syndrome/Myalgic Encephalitis (CFS/ME). A key stage in effective management is making an accurate early diagnosis, supported by appropriate referral. METHODS: A nested qualitative study within a multi-centre randomised controlled trial which aimed to explore GPs' views on their role in making the diagnosis of CFS/ME and subsequent management of patients in primary care. Semi-structured interviews with 22 GPs. Interviews were transcribed verbatim and an iterative approach used to develop themes from the dataset. RESULTS: GPs described difficulties in defining CFS/ME and suggested that their role in making a diagnosis was to exclude physical causes for the patient's symptoms, but they reported little confidence in positively attributing the label of CFS/ME to a patient and their symptoms. GPs suggested that the label of CFS/ME could be potentially harmful for the patient. The role of referral to secondary care was debated and GPs struggled defining their own role in management of this group of patients. CONCLUSIONS: Until GPs feel comfortable making the diagnosis of CFS/ME and facilitating initial management, and have appropriate services to refer patients to, there will continue to be delays in confirming the diagnosis and patients presenting in primary care with fatigue may not receive appropriate care. TRIAL REGISTRATION: ISRCTN 74156610.
Chia J, Chia A, Voeller M, Lee T, Chang R.	EV Med Research, Torrance, California, USA. evmed@sbcglobal.net	Acute enterovirus infection followed by myalgic encephalomyelitis/ chronic fatigue syndrome (ME/CFS) and viral persistence.	J Clin Pathol. 2010 Feb;63(2):165-8. Epub 2009 Oct 14.	AIMS: Enteroviruses are well-known causes of acute respiratory and/or gastrointestinal infections and non-specific flu-like illness. Although enterovirus protein, RNA and non-cytopathic viruses have been demonstrated in the stomach biopsies of patients with myalgia encephalomyelitis/chronic fatigue syndrome (ME/CFS), causality for chronic diseases is difficult to establish without having well-documented cases of acute enterovirus infections. The aim of this study was to link acute enteroviral infection to viral persistence in patients with ME/CFS. METHOD: Patients admitted to the hospital with acute febrile illnesses were screened for enteroviral infections. Acutely infected patients were followed longitudinally, and those who developed symptoms of ME/CFS underwent oesophagogastroduodenoscopy and biopsies of the antrum to document viral persistence by immunoperoxidase staining for viral protein and viral RNA assay. RESULTS: Three representative patients with different manifestations of acute enterovirus infections progressed to have chronic symptoms of ME/CFS. Persistent viral infection was demonstrated in the antrum years later. CONCLUSION: After acute infections, enteroviruses can persist in patients resulting in manifestation of ME/CFS. Chronic enterovirus infection in an immunocompetent host may be an example of a stalemate between attenuated, intracellular viruses and an ineffective immune response.
Christley Y, Duffy T, Martin CR.	Lecturer, Research and International Project Manager, Chair in Mental Health, School of Health, Nursing and Midwifery, University of the	A review of the definitional criteria for chronic fatigue syndrome.	J Eval Clin Pract. 2010 Oct 4. doi: 10.1111/j.1365-2753.2010.01512.x. [Epub ahead of print]	Rationale, aims and objectives The research community has for more than three decades tried to unravel the diagnostic mystery that is Chronic Fatigue Syndrome (CFS). This has resulted in considerable amounts of time and money being invested in attempts aimed at establishing the aetiology and pathogenesis of CFS. All of this investment has produced evidence of an interesting variety of endocrine, immune, infectious, muscular and neurological abnormalities in CFS; however, the cause remains elusive. The absence of a known causative agent or diagnostic test for CFS has resulted in the development of a number of CFS case definitions. As such, the main objectives of this paper are to provide a critical review of the similarities and differences between the varying

	West of Scotland, Ayr Campus, UK.			approaches to CFS case definition. The conflicts and controversies that have emerged as a result of the differing definitional criterion for CFS are highlighted and the potential impact on future research is identified. Methods, results and conclusions This paper presents a critical review of the most frequently used case definitions in CFS. There are currently five case definitions of CFS; however, the most prominent and widely used of these definitions is the 1994 Centre for Disease Control and Prevention Case Definitions. However, the pre-eminence of this definition over the others has never been substantiated and it has been widely criticized for its lack of specificity. Furthermore, none of the above case definitions have produced evidence to demonstrate their accuracy or precision at defining cases of CFS. A summary description of the symptom profile included in each of the case definitions is provided. The inconsistencies that have emerged in CFS research as a consequence of differing approaches to case definition are also highlighted and discussed.
Ciccone DS, Chandler HK, Natelson BH.	Department of Psychiatry, University of Medicine and Dentistry of New Jersey, New Jersey Medical School, Newark, NJ 07103, USA. cicconds@umdnj.edu	Illness trajectories in the chronic fatigue syndrome: a longitudinal study of improvers versus non-improvers.	J Nerv Ment Dis. 2010 Jul;198(7):486-93.	The natural progression of chronic fatigue syndrome (CFS) in adults is not well established. The aims of this longitudinal study were to (a) compare CFS Improvers and Non-Improvers; (b) determine whether an initial diagnosis of fibromyalgia (FM) was associated with CFS nonimprovement; and (c) determine whether this effect could be explained by the presence of nonspecific physical symptoms. Consecutive referrals to a tertiary clinic that satisfied case criteria for CFS were invited to enroll in a longitudinal study. After an initial on-site physical examination and psychiatric interview, a total of 94 female care-seekers completed biannual telephone surveys, including the Short Form-36 physical functioning (PF) scale, over a period of 2(1/2) years. There were very few differences between Improvers and Non-Improvers at baseline but at final assessment Improvers had less disability, less fatigue, lower levels of pain, fewer symptoms of depressed mood, and fewer nonspecific physical complaints. Participants with FM at baseline were 3.23 times ($p < 0.05$) more likely to become Non-Improvers than those without FM. Participants identified initially as Somatizers were 3.33 times ($p < 0.05$) more likely to become Non-Improvers. Patients with CFS who bear the added burden of FM are at greater risk of a negative outcome than patients with CFS alone. This effect could not be explained by the presence of multiple, nonspecific symptoms.
Clauson KA, Zeng-Treitler Q, Kandula S.	Department of Pharmacy Practice, Nova Southeastern University, College of Pharmacy, Palm Beach Gardens, FL 33410, USA. clauson@nova.edu	Readability of patient and health care professional targeted dietary supplement leaflets used for diabetes and chronic fatigue syndrome.	J Altern Complement Med. 2010 Jan;16(1):119-24.	OBJECTIVES: The purpose of this study was to assess readability of patient and health care professional targeted dietary supplement (DS) leaflets used for diabetes mellitus (DM) and chronic fatigue syndrome (CFS) with a novel measurement tool and Flesch-Kincaid Grade Level (FKGL). METHODS: Patient and professional leaflets for DS used to treat DM and CFS from the Natural Medicines Comprehensive Database (NMCD) and Natural Standard (NS) databases were evaluated. Leaflets were analyzed using FKGL and the author-developed health information readability analyzer (HIReA). HIReA integrates lexical, semantic, syntactic, cohesion, and style features and yields values of -1 (very hard) to 1 (very easy). RESULTS: Patient-targeted leaflets substantially exceeded the consensus readability level (6th grade) as assessed by both FKGL (grade 13.0767) and HIReA (-0.2360). Professional leaflets were similarly more difficult to read as scored by HIReA (-0.7065) and FKGL (grade 14.7429). Most and least difficult-to-read sections in patient leaflets (NS/NMCD) were Related Terms (-0.8863)/Other Names (-0.8146), and Safety Concerns (0.0821)/Scientific Evidence (0.0629), respectively. Overall, leaflets in NS (-0.5721) were more difficult to read than those in NMCD (-0.3704). These differences appeared to be less pronounced when FKGL was used to assess

				the readability, indicating its lack of preciseness. CONCLUSIONS: Readability for patient targeted DS leaflets is far more difficult than recommended levels. HIReA is a more precise method to measure readability than FKGL. The disparity between targeted levels of readability and measured levels may contribute to a lack of understanding by patients, with a resulting negative impact on adherence and outcomes.
Clauw DJ.	Chronic Pain and Fatigue Research Center, The University of Michigan, 24 Frank Lloyd Wright Drive, Ann Arbor, MI 48106, USA. dclauw@umich.edu	Perspectives on fatigue from the study of chronic fatigue syndrome and related conditions.	PM R. 2010 May;2(5):414-30.	Fatigue is a symptom whose causes are protean and whose phenotype includes physical, mood, and behavioral components. Chronic fatigue syndrome (CFS) is an illness that has strong biological underpinnings and no definite etiology. Diagnostic criteria established by the Centers for Disease Control and Prevention have helped classify CFS as an overlap of mood, behavioral, and biological components. These include the presence of fatigue for more than 6 months associated with a diminution of functional activity and somatic symptoms, and pain not attributable to a specific diagnosis or disease. Four of the following criteria need to be present: sore throat, impaired memory or cognition, unrefreshing sleep, postexertional fatigue, tender glands, aching stiff muscles, joint pain, and headaches. Many researchers have observed that CFS shares features in common with other somatic syndromes, including irritable bowel syndrome, fibromyalgia, and temporomandibular joint dysfunction. Correlations between inflammation and infection, augmented sensory processing, abnormalities of neurotransmitters, nerve growth factors, low levels of serotonin and norepinephrine, abnormalities of homeostasis of the stress system, and autonomic dysfunction may be hallmarks of CFS. The relative contributions of each of these abnormalities to the profound fatigue associated with CFS need to be explored further to better evaluate and treat the syndrome.
Cockshell SJ, Mathias JL.	School of Psychology, The University of Adelaide, Adelaide, South Australia, Australia.	Cognitive functioning in chronic fatigue syndrome: a meta-analysis.	Psychol Med. 2010 Aug;40(8):1253-67. Epub 2010 Jan 5. Comment in: Psychol Med. 2010 Jul;40(7):1230-1.	BACKGROUND: Cognitive problems are commonly reported in persons with chronic fatigue syndrome (CFS) and are one of the most disabling symptoms of this condition. A number of cognitive deficits have been identified, although the findings are inconsistent and hindered by methodological differences. The current study therefore conducted a meta-analysis of research examining cognitive functioning in persons with CFS in order to identify the pattern and magnitude of any deficits that are associated with this condition. METHOD: A comprehensive search of the PubMed and PsycINFO databases for studies that examined cognitive functioning in CFS between 1988 and 2008 identified 50 eligible studies. Weighted Cohen's d effect sizes, 95% confidence intervals and fail-safe Ns were calculated for each cognitive score. RESULTS: Evidence of cognitive deficits in persons with CFS was found primarily in the domains of attention, memory and reaction time. Deficits were not apparent on tests of fine motor speed, vocabulary, reasoning and global functioning. CONCLUSIONS: Persons with CFS demonstrate moderate to large impairments in simple and complex information processing speed and in tasks requiring working memory over a sustained period of time.
Comiskey C, Larkan F.	School of Nursing and Midwifery, Trinity College Dublin, 24 D'Olier St, Dublin 2, Ireland. Catherine.comiske	A national cross-sectional survey of diagnosed sufferers of myalgic encephalomyelitis/ chronic fatigue	Ir J Med Sci. 2010 Dec;179(4):501-5. Epub 2010 Sep 26.	BACKGROUND: The diagnosis and treatment of myalgic encephalomyelitis/chronic fatigue syndrome (ME/CFS) is subject to debate. AIMS: To measure the time to diagnosis and services accessed. METHOD: A national cross-sectional study. A profile and service utilisation questionnaire, information on the pathways to diagnosis, the WHOQoL Brief and a listing of priorities of the needs of participants were used. Individuals were invited to participate if they had a medical diagnosis of ME/CFS. RESULTS: A total of 211 surveys were returned. Prior to diagnosis sufferers accessed on average 4.5 services after their initial consultation. The mean time to diagnosis was 3.7 years but time ranged from 0 to 34

	y@tcd.ie	syndrome: pathways to diagnosis, changes in quality of life and service priorities.		years. Quality of life deteriorated post-onset. The priority for future service provision was increased understanding and diagnosis of ME/CFS by the medical profession. CONCLUSION: In order to alleviate the burden on the sufferer there is a greater need for education on this condition.
Costigan A, Elliott C, McDonald C, Newton JL.	NIHR Biomedical Research Centre in Ageing-Cardiovascular Theme, Newcastle University, Newcastle, UK.	Orthostatic symptoms predict functional capacity in chronic fatigue syndrome: implications for management.	QJM. 2010 Aug;103(8):589-95. Epub 2010 Jun 9.	OBJECTIVES: To establish the relationship between the functional impairment experienced by Chronic fatigue syndrome (CFS) patients and the symptoms frequently experienced by those with CFS; specifically cognitive impairment, fatigue and orthostatic symptoms. DESIGN: Cross sectional questionnaire survey. SETTING: Specialist CFS Clinical Service. SUBJECTS: Ninety-nine Fukuda diagnosed CFS and 64-matched controls. MAIN OUTCOME MEASURES: Symptom and functional assessment tools completed and returned by post included; PROMIS HAQ (Patient-Reported Outcomes Measurement Information System, Health Assessment Questionnaire), CFQ (Cognitive Failures Questionnaire), FIS (Fatigue Impact Scale) and OGS (Orthostatic Grading Scale) assessment tools. RESULTS: CFS patients experience greater functional impairment than controls [mean (95% CI) PROMIS HAQ scores CFS 36 (31-42) vs. controls 6 (2-10); P < 0.0001], especially in the functional domains of activities and reach. Poorer functional ability impairment is significantly associated with greater cognitive impairment (P = 0.0002, r = 0.4), fatigue (P < 0.0001, r = 0.5) and orthostatic symptoms (P < 0.0001, r = 0.6). However, only orthostatic symptoms (OGS) independently associated with functional impairment (beta = 0.4, P = 0.01). CONCLUSION: Treatment of orthostatic symptoms in CFS has the potential to improve functional capacity and so improve quality of life.
Courgnaud V, Battini JL, Sitbon M, Mason AL.	Institut de Génétique Moléculaire de Montpellier, Centre National de la Recherche Scientifique, Universite Montpellier, France.	Mouse retroviruses and chronic fatigue syndrome: Does X (or P) mark the spot?	Proc Natl Acad Sci U S A. 2010 Sep 7;107(36):15666-7. Epub 2010 Aug 23. Creavin ST, Dunn KM, Mallen CD, Nijrolder I, van der Windt DA.	Arthritis Research Campaign National Primary Care Centre, Keele University, Staffordshire ST5 5BG, United Kingdom. samcreavin@gmail	Co-occurrence and associations of pain and fatigue in a community sample of Dutch adults.	Eur J Pain. 2010 Mar;14(3):327-34. Epub 2009 Jun 18.	Widespread pain and chronic fatigue are common in the general population. Previous research has demonstrated co-occurrence of syndromes that are associated with pain and fatigue (fibromyalgia and chronic fatigue syndrome), but there is limited existing data on the co-occurrence of these symptoms in general. This study investigates the co-occurrence of pain and fatigue, and characterises people with these symptoms individually, and in combination. A postal questionnaire was sent to a random sample of 4741 community dwelling Dutch adults registered with five general practices. There were 2447 participants (adjusted response=53.5%). Persistent fatigue was reported by 60% of the 451 subjects with chronic widespread pain. Chronic widespread pain was reported by 33% of the 809 responders with persistent fatigue. Anxiety and depression were more common in subjects who

	.com			reported both symptoms than those who reported either one or neither. Participants who had chronic disease, high body mass index, low activity levels or did not perceive ability to influence health had higher adjusted odds of reporting both symptoms (but not one alone) than subjects not having these characteristics. Pain and fatigue occur more often than would be expected by chance and there are a number of reasons for this. Clinicians should be aware that co-occurrence of the symptoms is common, especially in people who have high BMI or chronic disease, and that people with both symptoms are often anxious or depressed. Further work should address longitudinal associations of pain and fatigue.
Creti L, Libman E, Baltzan M, Rizzo D, Bailes S, Fichten CS.	Department of Psychiatry, SMBD Jewish General Hospital, 4333 Cote Ste Catherine Road, B-28, Montreal, Quebec, H3T 1E4, Canada. laura.creti@mail.mcgill.ca	Impaired sleep in chronic fatigue syndrome: how is it best measured?	J Health Psychol. 2010 May;15(4):596-607.	The goal was to examine comparative efficacy of polysomnography, actigraphy, and self-report in evaluating the sleep/wake experience of individuals with chronic fatigue syndrome (CFS). Sleep parameters were evaluated by the three measurement modalities for the same night in 49 participants with CFS. Psychological and daytime functioning were measured by self-report. Results indicate that: (a) objectively measured nocturnal sleep time effectively approximated subjective experience although nocturnal wakefulness did not; (b) total sleep time and sleep efficiency differentiated individuals with and without insomnia complaints; (c) daytime sleepiness, fatigue, and non-refreshing sleep were not reflected by the objective sleep-related measures (polysomnography and actigraphy).
Crowhurst G.		XMRV: does this virus hold the key to myalgic encephalomyelitis/ CFS?	Br J Nurs. 2010 Jul 22-Aug 11;19(14):919-22.	In October 2009 a team of researchers from the Whittemore Peterson Institute, in association with the National Cancer Institute and the Cleveland Clinic in the USA, made a discovery that could potentially open the door to useful treatments for myalgic encephalomyelitis/chronic fatigue syndrome (ME/CFS). The researchers, led by Judy Mikovits, discovered a significant correlation between ME/CFS and an infectious retrovirus called xenotropic murine leukaemia virus-related virus (XMRV). XMRV is classified as a gammaretrovirus, belonging to the same broad family as HIV, but more closely related to a group of viruses that cause cancers such as leukaemia. XMRV is the first member of the gammaretrovirus genus of retroviruses to be found in humans; the research to fully understand the connection between ME/CFS and XMRV, as well as what it means to have the virus, is ongoing. The disastrous impact of AIDS on human health has significantly raised the profile of retroviruses as human pathogens, and XMRV has potentially serious health implications not only for patients, but also for those caring for people with ME/CFS.
Daniels J, Wearden AJ.	University of Bath, UK.	Socialization to the model: the active component in the therapeutic alliance? A preliminary study.	Behav Cogn Psychother. 2011 Mar;39(2):221-7. Epub 2010 Nov 22.	Background: Therapeutic alliance has been found to be a significant predictor of outcome in psychotherapy yet what constitutes therapeutic alliance remains unclear. Examining the common constructs of therapeutic alliance, it is possible that there may be a conceptual overlap between active components of therapeutic alliance and socialization to the treatment model. Aim: To investigate the relationship between socialization to the model and therapeutic alliance. Method: Participants (N = 43) were taken from the active treatment arm in a RCT for the treatment of chronic fatigue syndrome (CFS/ME). Therapeutic alliance was measured using a 5-item questionnaire (brief CALPAS) and socialization to the model was extracted from therapy tapes using a novel coding system. Results: Key findings were that when patients and therapists agreed about goals of treatment, there were higher levels of concordance, less evidence of applying principles incongruent to the model, and

				less resistance during the treatment sessions. Conclusions: The outcome of this preliminary study contributes to the potential understanding of active components in the therapeutic alliance, and supports further research to achieve a more detailed picture of "non-specific" factors in therapy, including the active process of socialization in therapeutic alliance.
Davenport TE, Stevens SR, VanNess MJ, Snell CR, Little T.	Department of Physical Therapy, Thomas J Long School of Pharmacy and Health Sciences, University of the Pacific, 3601 Pacific Ave, Stockton, CA 95211, USA. tdavenport@pacific.edu	Conceptual model for physical therapist management of chronic fatigue syndrome/myalgic encephalomyelitis.	Phys Ther. 2010 Apr;90(4):602-14. Epub 2010 Feb 25.	Fatigue is one of the most common reasons why people consult health care providers. Chronic fatigue syndrome/myalgic encephalomyelitis (CFS/ME) is one cause of clinically debilitating fatigue. The underdiagnosis of CFS/ME, along with the spectrum of symptoms that represent multiple reasons for entry into physical therapy settings, places physical therapists in a unique position to identify this health condition and direct its appropriate management. The diagnosis and clinical correlates of CFS/ME are becoming better understood, although the optimal clinical management of this condition remains controversial. The 4 aims of this perspective article are: (1) to summarize the diagnosis of CFS/ME with the goal of promoting the optimal recognition of this condition by physical therapists; (2) to discuss aerobic system and cognitive deficits that may lead to the clinical presentation of CFS/ME; (3) to review the evidence for graded exercise with the goal of addressing limitations in body structures and functions, activity, and participation in people with CFS/ME; and (4) to present a conceptual model for the clinical management of CFS/ME by physical therapists.
De Luca C, Scordo G, Cesareo E, Raskovic D, Genovesi G, Korkina L.	Laboratory of Tissue Engineering & Cutaneous Pathophysiology, Istituto Dermopatico dell'Immacolata, Rome, Italy.	Idiopathic environmental intolerances (IEI): from molecular epidemiology to molecular medicine.	Indian J Exp Biol. 2010 Jul;48(7):625-35.	Inherited or acquired impairment of xenobiotics metabolism is a postulated mechanism underlying environment-associated pathologies such as multiple chemical sensitivity, fibromyalgia, chronic fatigue syndrome, dental amalgam disease, and others, also collectively named idiopathic environmental intolerances (IEI). In view of the poor current knowledge of their etiology and pathogenesis, and the absence of recognised genetic and metabolic markers of the diseases. They are often considered "medically unexplained syndromes",. These disabling conditions share the features of polysymptomatic multi-organ syndromes, considered by part of the medical community to be aberrant responses triggered by exposure to low-dose organic and inorganic chemicals and metals, in concentrations far below average reference levels admitted for environmental toxicants. A genetic predisposition to altered biotransformation of environmental chemicals, drugs, and metals, and of endogenous low-molecular weight metabolites, caused by polymorphisms of genes coding for xenobiotic metabolizing enzymes, their receptors and transcription factors appears to be involved in the susceptibility to these environment-associated pathologies, along with epigenetic factors. Free radical/antioxidant homeostasis may also be heavily implicated, indirectly by affecting the regulation of xenobiotic metabolizing enzymes, and directly by causing increased levels of oxidative products, implicated in the chronic damage of cells and tissues, which is in part correlated with clinical symptoms. More systematic studies of molecular epidemiology, toxico- and pharmaco-genomics, elucidating the mechanisms of regulation, expression, induction, and activity of antioxidant/detoxifying enzymes, and the possible role of inflammatory mediators, promise a better understanding of this pathologically increased sensitivity to low-level chemical stimuli, and a solid basis for effective individualized antioxidant- and/or chelator-based treatments.
Deary V, Chalder T.	Institute of Health and Society,	Personality and perfectionism in	Psychol Health. 2010	OBJECTIVE: To test the hypothesis that people with chronic fatigue syndrome (CFS) would differ significantly from a healthy control group on measures of general personality and perfectionism,

	Newcastle University, UK. vincent.deary@ncl.ac.uk	chronic fatigue syndrome: a closer look.	Apr;25(4):465-75.	specifically on measures of neuroticism and unhealthy perfectionism. METHOD: A total of 27 female CFS outpatients and 30 female healthy controls completed questionnaires, including the NEO Personality Inventory-Revised, the Multi-dimensional Perfectionism Scale and measures of anxiety and depression. RESULTS: The CFS group was significantly more fatigued, anxious and depressed than healthy controls. They scored significantly higher on neuroticism and unhealthy perfectionism. Healthy and unhealthy perfectionism were positively correlated in the CFS group, but not in the control group. CONCLUSION: The present study confirms the link between neuroticism and fatigue and finds a link between unhealthy perfectionism and fatigue. A 'healthy trait', such as healthy perfectionism, when coupled with evaluative concerns is not necessarily healthy in a fatigued population. Researchers and clinicians should note the context in which apparently benign traits are expressed, and how they interact with other traits.
Decker MJ, Eyal S, Shinar Z, Fuxman Y, Cahan C, Reeves WC, Baharav A.	Chronic Viral Diseases Branch, National Center for Zoonotic, Vector-borne Enteric Diseases, Centers for Disease Control and Prevention, Atlanta, GA 30333, USA. mdecker@cdc.gov	Validation of ECG-derived sleep architecture and ventilation in sleep apnea and chronic fatigue syndrome.	Sleep Breath. 2010 Sep;14(3):233-9. Epub 2009 Oct 9.	PURPOSE: Newly developed algorithms putatively derive measures of sleep, wakefulness, and respiratory disturbance index (RDI) through detailed analysis of heart rate variability (HRV). Here, we establish levels of agreement for one such algorithm through comparative analysis of HRV-derived values of sleep-wake architecture and RDI with those calculated from manually scored polysomnographic (PSG) recordings. METHODS: Archived PSG data collected from 234 subjects who participated in a 3-day, 2-night study characterizing polysomnographic traits of chronic fatigue syndrome were scored manually. The electrocardiogram and pulse oximetry channels were scored separately with a novel scoring algorithm to derive values for wakefulness, sleep architecture, and RDI. RESULTS: Four hundred fifty-four whole-night PSG recordings were acquired, of which, 410 were technically acceptable. Comparative analyses demonstrated no difference for total minutes of sleep, wake, NREM, REM, nor sleep efficiency generated through manual scoring with those derived through HRV analyses. When NREM sleep was further partitioned into slow-wave sleep (stages 3-4) and light sleep (stages 1-2), values calculated through manual scoring differed significantly from those derived through HRV analyses. Levels of agreement between RDIs derived through the two methods revealed an R = 0.89. The Bland-Altman approach for determining levels of agreement between RDIs generated through manual scoring with those derived through HRV analysis revealed a mean difference of -0.7 +/- 8.8 (mean +/- two standard deviations). CONCLUSION: We found no difference between values of wakefulness, sleep, NREM, REM sleep, and RDI calculated from manually scored PSG recordings with those derived through analyses of HRV.
Den Eede FV, Moorkens G, Hulstijn W, Maas Y, Schrijvers D, Stevens SR, Cosyns P, Claes SJ, Sabbe BG.	Department of Psychiatry, Antwerp University Hospital (UZA), Antwerp, Belgium; Collaborative Antwerp Psychiatric Research Institute (CAPRI), Faculty of	Psychomotor function and response inhibition in chronic fatigue syndrome.	Psychiatry Res. 2010 Aug 24. [Epub ahead of print]	Most research points to cognitive slowing in chronic fatigue syndrome (CFS), although there have been negative reports. The present study is one of few that examines fine motor processing and the inhibition of automatic responses in a well-characterised CFS population. A total of 35 female CFS patients without current major depression and 25 female controls performed two computerised figure-copying tasks. The cognitive and fine motor processing of visual-spatial information was measured by recording reaction time (RT) and movement time (MT), respectively. The inhibition of automatic responses was assessed by introducing 'conflicting patterns' (i.e., patterns that were difficult to draw from the preferred left to right). A multivariate general linear model was adopted for the statistical analysis of the movement recordings. As a result, CFS was significantly associated with longer RT and MT in the pooled and in the task-specific analyses. However, there was no interaction

	Medicine, University of Antwerp (UA), Antwerp, Belgium.			between disease status and conflicting character of the patterns. In conclusion, these performance data on the figure-copying tasks provide confirmatory evidence for psychomotor slowing in CFS, but not for a disturbed inhibition of automatic responses. Computerised figure-copying tasks may be promising tools for use in neurobiological research and clinical trials in CFS.
Denner J.	Retrovirus induced immunosuppressio n, Robert Koch Institute, Nordufer 20, D-13353 Berlin, Germany. DennerJ@rki.de	Detection of a gammaretrovirus, XMRV, in the human population: open questions and implications for xenotransplantatio n.	Retrovirology. 2010 Mar 10;7:16.	XMRV (xenotropic murine leukaemia virus-related virus) is a gammaretrovirus that has been detected in human patients with prostate carcinoma, chronic fatigue syndrome (CFS) and also in a small percentage of clinically healthy individuals. It is not yet clear whether the distribution of this virus is primarily limited to the USA or whether it is causally associated with human disease. If future investigations confirm a broad distribution of XMRV and its association with disease, this would have an impact on xenotransplantation of porcine tissues and organs. Xenotransplantation is currently being developed to compensate for the increasing shortage of human material for the treatment of tissue and organ failure but could result in the transmission of porcine pathogens. Maintenance of pathogen-free donor animals will dramatically reduce this risk, but some of the porcine endogenous retroviruses (PERVs) found in the genome of all pigs, can produce infectious virus and infect cultured human cells. PERVs are closely related to XMRV so it is critical to develop tests that discriminate between them. Since recombination can occur between viruses, and recombinants can exhibit synergism, recipients should be tested for XMRV before xenotransplantation.
Dennison L, Stanbrook R, Moss-Morris R, Yardley L, Chalder T.	Centre for Clinical Applications of Health Psychology, University of Southampton, UK.	Cognitive behavioural therapy and psycho-education for chronic fatigue syndrome in young people: reflections from the families' perspective.	Br J Health Psychol. 2010 Feb;15(Pt 1):167-83. Epub 2009 May 6.	OBJECTIVES: Recent trials have produced optimistic results for family-focussed cognitive behavioural therapy (CBT) for chronic fatigue syndrome (CFS) in young people. This study sought to examine the under-researched question of the views and experiences of patients and families who take part. DESIGN: Semi-structured interviews and qualitative analysis were chosen in order to address clients' perspectives in depth. METHODS: Sixteen young people and sixteen parents who participated in a trial of CBT versus psycho-education (PE) for CFS were interviewed. Key themes were discerned using inductive thematic analysis. RESULTS: Most families had low expectations of a cure but hope for improvement. Generally speaking, participants found both CBT and PE acceptable and helpful. Behavioural aspects of CBT (e.g. goal-setting, graded activity) were found helpful. The opportunity to gain support, recognition and validation was important. Cognitive elements of therapy were sometimes deemed inappropriate and some felt emotional aspects of CFS were not adequately addressed. Participants were ambivalent towards the extent of family involvement. Negative experiences related to the therapy setting and feeling inappropriately labeled. Most participants felt therapy was a stepping-stone towards normal life, although many felt recovery was incomplete. Very few differences were found between themes from CBT and PE participants. A notable exception was that every young person who experienced CBT described therapy as helpful, whereas the participants who strongly opposed the therapy approach had all experienced PE. CONCLUSIONS: The detailed insights regarding families' therapy experiences suggest areas of improvement for service delivery and topics for further investigation.
Dittner AJ, Rimes K, Thorpe S.	South London & Maudsley NHS Trust, Chronic Fatigue Syndrome	Negative perfectionism increases the risk of fatigue following	Psychol Health. 2010 Feb 18:1-16. [Epub ahead of print]	Cognitive-behavioural models of excessive fatigue suggest that people who believe that failure to meet high standards indicates unacceptability to others (a form of 'negative perfectionism') are at risk of fatigue after a period of illness or stress. The present study investigates this using a prospective design and possible mediating factors between such beliefs and fatigue were also investigated.

	Unit, London, SE5 8AZ UK.	a period of stress.		Undergraduate students completed questionnaires at the beginning of the academic year (time 1; n = 436) and again following a time of academic pressure, 16 weeks later (time 2; n = 206). Participants were significantly more fatigued at time 2 than at time 1. Negative perfectionism was positively associated with all measures of fatigue and predicted subsequent levels of physical fatigue after controlling for time 1 fatigue. Time 1 negative perfectionism was not associated with time 2 perfectionist studying behaviours, distress about academic work or specific health behaviours, but was associated with time 2 depression. Results also indicated that time 2 depression may account for the relationship between baseline negative perfectionism and subsequent fatigue. This is the first prospective study to demonstrate a significant relationship between perfectionism and subsequent fatigue.

Egge C, Wyller VB.	Division of Pediatrics, Oslo University Hospital Rikshospitalet, Oslo, Norway. brwylle@online.no.	No differences in cardiovascular autonomic responses to mental stress in chronic fatigue syndrome adolescents as compared to healthy controls.	Biopsychosoc Med. 2010 Dec 14;4:22.	ABSTRACT: Chronic fatigue syndrome (CFS) is a disabling disease with unknown etiology. There is accumulating evidence of altered cardiovascular autonomic responses to different somatic stressors, in particular orthostatic stress, whereas autonomic responses to mental stress remain to be investigated. In this study, we explored cardiovascular autonomic responses to a simple mental stress test in CFS patients and healthy controls.A consecutive sample of 13 patients with CFS, aged 12 to 18 years, and a volunteer sample of 53 healthy control subjects of equal age and gender distribution were included. Blood pressure, heart rate and acral skin blood flow were continuously recorded during an arithmetic exercise.At baseline, heart rate was significantly higher among CFS patients than controls (p = 0.02). During the arithmetic exercise, however, there were no significant differences in the responses between the two groups.In conclusion, CFS patients have unaltered autonomic responses to simple mental stress as compared to healthy control subjects.

Erlwein O, Kaye S, McClure MO,	Jefferiss Research Trust Laboratories,	Failure to detect the novel	PLoS One. 2010 Jan 6;5(1):e8519.	BACKGROUND: In October 2009 it was reported that 68 of 101 patients with chronic fatigue syndrome (CFS) in the US were infected with a novel gamma retrovirus, xenotropic murine leukaemia

Weber J, Wills G, Collier D, Wessely S, Cleare A.	Section of Infectious Diseases, Wright-Fleming Institute, Faculty of Medicine, Imperial College London, St Mary's Campus, Norfolk Place, London, United Kingdom.	retrovirus XMRV in chronic fatigue syndrome.		virus-related virus (XMRV), a virus previously linked to prostate cancer. This finding, if confirmed, would have a profound effect on the understanding and treatment of an incapacitating disease affecting millions worldwide. We have investigated CFS sufferers in the UK to determine if they are carriers of XMRV. METHODOLOGY: Patients in our CFS cohort had undergone medical screening to exclude detectable organic illness and met the CDC criteria for CFS. DNA extracted from blood samples of 186 CFS patients were screened for XMRV provirus and for the closely related murine leukaemia virus by nested PCR using specific oligonucleotide primers. To control for the integrity of the DNA, the cellular beta-globin gene was amplified. Negative controls (water) and a positive control (XMRV infectious molecular clone DNA) were included. While the beta-globin gene was amplified in all 186 samples, neither XMRV nor MLV sequences were detected. CONCLUSION: XMRV or MLV sequences were not amplified from DNA originating from CFS patients in the UK. Although we found no evidence that XMRV is associated with CFS in the UK, this may be a result of population differences between North America and Europe regarding the general prevalence of XMRV infection, and might also explain the fact that two US groups found XMRV in prostate cancer tissue, while two European studies did not.
Erlwein O, Kaye S, Robinson M, McClure M.		Chronic fatigue syndrome: xenotropic murine leukemia virus-related virus, murine leukemia virus, both, or neither?	Proc Natl Acad Sci U S A. 2010 Oct 26;107(43):E161; author reply E163-4. Epub 2010 Sep 30. Comment on: Proc Natl Acad Sci U S A. 2010 Sep 7;107(36):15874-9.	
Evering RM, van Weering MG, Groothuis-Oudshoorn KC, Vollenbroek-Hutten MM.	Roessingh Research and Development, Enschede, The Netherlands.	Daily physical activity of patients with the chronic fatigue syndrome: a systematic review.	Clin Rehabil. 2010 Oct 13. [Epub ahead of print]	Objective: To give an overview of the physical activity level of patients with chronic fatigue syndrome in comparison with asymptomatic controls. Data sources: MEDLINE, Web of Science, EMBASE, PsycINFO, Picarta, the Cochrane Controlled Trial Register that is included in the Cochrane Library and reference tracking. Review methods: A systematic literature search was conducted focusing on studies concerning physical activity levels of patients with chronic fatigue syndrome compared to controls. A meta-analysis was performed to pool data of the studies. Results: Seventeen studies were included with 22 different comparisons between patients with chronic fatigue syndrome and controls. Fourteen studies, including 18 comparisons, showed lower physical activity levels in patients with chronic fatigue syndrome as compared to controls. Four studies, including four comparisons, showed no differences between both groups. The meta-analysis included seven studies and showed a daily physical activity level in patients with chronic fatigue syndrome of only 68% of the physical activity level observed in control subjects. The pooled mean coefficient of variation in patients with chronic fatigue syndrome was higher as compared to control subjects (34.3% versus 31.5%), but this difference did not reach significance. Conclusion: Patients with chronic fatigue syndrome appear to be less physically active compared with asymptomatic controls. There is no difference in variation of physical activity levels between patients with chronic fatigue syndrome and healthy control subjects,

				but the validity and reliability of some methods of measuring physical activity is questionable or unknown.
Falkenberg VR, Gurbaxani BM, Unger ER, Rajeevan MS.	Division of Viral and Rickettsial Diseases, Centers for Disease Control & Prevention, Atlanta, GA, 30333, USA.	Functional Genomics of Serotonin Receptor 2A (HTR2A): Interaction of Polymorphism, Methylation, Expression and Disease Association.	Neuromolecular Med. 2010 Oct 13. [Epub ahead of print]	Serotonergic neurotransmission plays a key role in the pathophysiology of neuropsychiatric illnesses. The functional significance of a promoter polymorphism, -1438G/A (rs6311), in one of the major genes of this system (serotonin receptor 2A, HTR2A) remains poorly understood in the context of epigenetic factors, transcription factors and endocrine influences. We used functional and structural equation modeling (SEM) approaches to assess the contributions of the polymorphism (rs6311), DNA methylation and clinical variables to HTR2A expression in chronic fatigue syndrome (CFS) subjects from a population-based study. HTR2A was up-regulated in CFS through allele-specific expression modulated by transcription factors at critical sites in its promoter: an E47 binding site at position -1,438, (created by the A-allele of rs6311 polymorphism), a glucocorticoid receptor (GR) binding site encompassing a CpG at position -1,420, and Sp1 binding at CpG methylation site -1,224. Methylation at -1,420 was strongly correlated with methylation at -1,439, a CpG site that is dependent upon the G-allele of rs6311 at position -1,438. SEM revealed a strong negative interaction between E47 and GR binding (in conjunction with cortisol level) on HTR2A expression. This study suggests that the promoter polymorphism (rs6311) can affect both transcription factor binding and promoter methylation, and this along with an individual's stress response can impact the rate of HTR2A transcription in a genotype and methylation-dependent manner. This study can serve as an example for deciphering the molecular determinants of transcriptional regulation of major genes of medical importance by integrating functional genomics and SEM approaches. Confirmation in an independent study population is required.
Fernell E, Landgren M.		Chronic fatigue could be a marker of ADHD in children and adolescents.	Acta Paediatr. 2010 Jan;99(1):5; author reply 5-6. Comment in: Acta Paediatr. 2010 Mar;99(3):324. Comment on: Acta Paediatr. 2009 Aug;98(8):1313-8.	
Fiest KM, Currie SR, Williams JV, Wang J.	Department of Psychiatry, University of Calgary, Canada.	Chronic conditions and major depression in community-dwelling older adults.	J Affect Disord. 2010 Dec 17. [Epub ahead of print]	OBJECTIVES: To estimate (1) the prevalence of long-term medical conditions and of comorbid major depression, and (2) the associations between major depression and various chronic medical conditions in a general population of older adults (over 50years of age) and in persons who are traditionally classified as seniors (65years and older). METHODS: Data from the Canadian Community Health Survey- Mental Health and Wellbeing (CCHS-1.2) were analyzed. Non-institutionalized individuals over 15years of age in the 10 Canadian provinces were sampled in the CCHS-1.2. The entire sample of the CCHS-1.2 consisted of 36,894 individuals, for the main analyses in this study the dataset was restricted to those aged 50 and over (n=15,591). Chronic health conditions were assessed using a self-report method of doctor diagnosis. The World Mental Health-Composite Diagnostic Interview was used to asses major depressive episodes based on DSM-IV criteria. RESULTS: The overall

				prevalence of having at least one chronic condition in those over 50years of age was 82.4%, compared to 62.0% in those under 50. The prevalence of a major depressive episode in those over 50 with one chronic condition was 3.7%, compared with 1.0% in those without a long-term medical condition. The top 3 chronic health conditions in seniors aged 65 or older were arthritis/rheumatism, high blood pressure and back problems. Chronic Fatigue Syndrome, fibromyalgia and migraine headache had the highest comorbidity with major depression in the senior population. LIMITATIONS: The use of self-report data on chronic health conditions, potential diagnostic overlap between conditions, and the inability to make causal inferences due to the cross-sectional nature of the data are all limitations of the current study. CONCLUSIONS: Differences were found between rates of chronic conditions and major depression between the general population, older adults and seniors in this study. Further research is needed to delineate the direction of these relationships in seniors. Primary and secondary prevention efforts should target seniors who exhibit symptoms of depression or highly prevalent chronic health conditions.
Fink P, Rosendal M, Dam ML, Schröder A.	Forskningsklinikken for Funktionelle Lidelser og Psykosomatik, Arhus Universitetshospital, Arhus Sygehus, 8000 Arhus C, Denmark. per.fink@aarhus.rm.dk	[New unifying diagnosis of functional diseases]. [Article in Danish]	Ugeskr Laeger. 2010 Jun 14;172(24):1835-8. Comment in: Ugeskr Laeger. 2010 Aug 23;172(34):2327; author reply 2327.	Functional somatic symptoms are prevalent in all medical settings, but their management is hampered by an obsolete theoretical framework and inadequate classification systems. Epidemiological and neurobiological studies suggest that the functional somatic syndromes, e.g. fibromyalgia, chronic fatigue syndrome, irritable bowel syndrome and somatoform disorders belong to the same family of disorders. An empirically based diagnosis including different subtypes and severities is proposed as a unifying diagnostic construct: bodily distress syndrome. This construct provides a common language for functional disorders across medical specialties.
Fink P, Schröder A.	The Research Clinic for Functional Disorders and Psychosomatics, Aarhus University Hospital, 8000 Aarhus, Denmark. per.fink@aarhus.rm.dk	One single diagnosis, bodily distress syndrome, succeeded to capture 10 diagnostic categories of functional somatic syndromes and somatoform disorders.	J Psychosom Res. 2010 May;68(5):415-26.	BACKGROUND: In order to clarify the classification of physical complaints not attributable to verifiable, conventionally defined diseases, a new diagnosis of bodily distress syndrome was introduced. The aim of this study was to test if patients diagnosed with one of six different functional somatic syndromes or a DSM-IV somatoform disorder characterized by physical symptoms were captured by the new diagnosis. METHOD: A stratified sample of 978 consecutive patients from neurological (n=120) and medical (n=157) departments and from primary care (n=701) was examined applying post-hoc diagnoses based on the Schedules for Clinical Assessment in Neuropsychiatry diagnostic instrument. Diagnoses were assigned only to clinically relevant cases, i.e., patients with impairing illness. RESULTS: Bodily distress syndrome included all patients with fibromyalgia (n=58); chronic fatigue syndrome (n=54) and hyperventilation syndrome (n=49); 98% of those with irritable bowel syndrome (n=43); and at least 90% of patients with noncardiac chest pain (n=129), pain syndrome (n=130), or any somatoform disorder (n=178). The overall agreement of bodily distress syndrome with any of these diagnostic categories was 95% (95% CI 93.1-96.0; kappa 0.86, P<.0001). Symptom profiles of bodily distress syndrome organ subtypes were similar to those of the corresponding functional somatic syndromes with diagnostic agreement ranging from 90% to 95%. CONCLUSION: Bodily distress syndrome seem to cover most of the relevant "somatoform" or

				"functional" syndromes presenting with physical symptoms, not explained by well-recognized medical illness, thereby offering a common ground for the understanding of functional somatic symptoms. This may help unifying research efforts across medical disciplines and facilitate delivery of evidence-based care.
Fischer N, Schulz C, Stieler K, Hohn O, Lange C, Drosten C, Aepfelbacher M.	Institute for Medical Microbiology and Virology, University Medical Center Hamburg-Eppendorf, Hamburg, Germany. nfischer@uke.de	Xenotropic murine leukemia virus-related gammaretrovirus in respiratory tract.	Emerg Infect Dis. 2010 Jun;16(6):1000-2.	Xenotropic murine leukemia virus-related gammaretrovirus (XMRV) has been recently associated with prostate cancer and chronic fatigue syndrome. To identify nucleic acid sequences, we examined respiratory secretions by using PCR. XMRV-specific sequences were detected in 2%-3% of samples from 168 immunocompetent carriers and approximately 10% of samples from 161 immunocompromised patients.
Fletcher MA, Rosenthal M, Antoni M, Ironson G, Zeng XR, Barnes Z, Harvey JM, Hurwitz B, Levis S, Broderick G, Klimas NG.	a	Plasma neuropeptide Y: a biomarker for symptom severity in chronic fatigue syndrome.	Behav Brain Funct. 2010 Dec 29;6(1):76. [Epub ahead of print]	ABSTRACT: BACKGROUND: Chronic fatigue syndrome (CFS) is a complex, multi-symptom illness with a multisystem pathogenesis involving alterations in the nervous, endocrine and immune systems. Abnormalities in stress responses have been identified as potential triggers or mediators of CFS symptoms. This study focused on the stress mediator neuropeptide Y (NPY). We hypothesized that NPY would be a useful biomarker for CFS. METHODS: The CFS patients (n = 93) were from the Chronic Fatigue and Related Disorders Clinic at the University of Miami and met the 1994 case definition of Fukuda and colleagues. Healthy sedentary controls (n = 100)) were from NIH or VA funded studies. Another fatiguing, multi-symptom illness, Gulf War Illness (GWI), was also compared to CFS. We measured NPY in plasma using a radioimmunoassay (RIA). Psychometric measures, available for a subset of CFS patients included: Perceived Stress Scale, Profile of Mood States, ATQ Positive & Negative Self-Talk Scores, the COPE, the Beck Depression Inventory, Fatigue Symptom Inventory, Cognitive Capacity Screening Examination, Medical Outcomes Survey Short Form-36, and the Quality of Life Scale. RESULTS: Plasma NPY was elevated in CFS subjects, compared to controls (p=.000) and to GWI cases (p=.000). Receiver operating characteristics (ROC) curve analyses indicated that the predictive ability of plasma NPY to distinguish CFS patients from healthy controls and from GWI was significantly better than chance alone. In 42 patients with CFS, plasma NPY had significant correlations (<0.05) with perceived stress, depression, anger/hostility, confusion, negative thoughts, positive thoughts, general health, and cognitive status. In each case the correlation (+ or -) was in the anticipated direction. CONCLUSIONS: This study is the first in the CFS literature to report that plasma NPY is elevated compared to healthy controls and to a fatigued comparison group, GWI patients. The significant correlations of NPY with stress, negative mood, general health, depression and cognitive function strongly suggest that this peptide be considered as a biomarker to distinguish subsets of CFS.
Fletcher MA, Zeng XR, Maher K, Levis S, Hurwitz B, Antoni M,	Department of Medicine, University of Miami Miller	Biomarkers in chronic fatigue syndrome: evaluation of	PLoS One. 2010 May 25;5(5):e10817.	BACKGROUND: Chronic Fatigue Syndrome (CFS) studies from our laboratory and others described decreased natural killer cell cytotoxicity (NKCC) and elevated proportion of lymphocytes expressing the activation marker, dipeptidyl peptidase IV (DPPIV) also known as CD26. However, neither these assays nor other laboratory tests are widely accepted for the diagnosis or prognosis of CFS. This study

Broderick G, Klimas NG.	School of Medicine, Miami, Florida, USA. mfletche@med.miami.edu	natural killer cell function and dipeptidyl peptidase IV/CD26.		sought to determine if NKCC or DPPIV/CD26 have diagnostic accuracy for CFS. METHODS/RESULTS: Subjects included female and male CFS cases and healthy controls. NK cell function was measured with a bioassay, using K562 cells and (51)Cr release. Lymphocyte associated DPPIV/CD26 was assayed by qualitative and quantitative flow cytometry. Serum DPPIV/CD26 was measured by ELISA. Analysis by receiver operating characteristic (ROC) curve assessed biomarker potential. Cytotoxic function of NK cells for 176 CFS subjects was significantly lower than in the 230 controls. According to ROC analysis, NKCC was a good predictor of CFS status. There was no significant difference in NK cell counts between cases and controls. Percent CD2+ lymphocytes (T cells and NK cells) positive for DPPIV/C26 was elevated in CFS cases, but there was a decrease in the number of molecules (rMol) of DPPIV/C26 expressed on T cells and NK cells and a decrease in the soluble form of the enzyme in serum. Analyses by ROC curves indicated that all three measurements of DPPIV/CD26 demonstrated potential as biomarkers for CFS. None of the DPPIV/C26 assays were significantly correlated with NKCC. CONCLUSIONS: By ROC analysis, NKCC and three methods of measuring DPPIV/C26 examined in this study had potential as biomarkers for CFS. Of these, NKCC, %CD2+CD26+ lymphocytes and rMol CD26/CD2+ lymphocyte, required flow cytometry, fresh blood and access to a high complexity laboratory. Soluble DPPIV/C26 in serum is done with a standard ELISA assay, or with other soluble factors in a multiplex type of ELISA. Dipeptidyl peptidase IV on lymphocytes or in serum was not predictive of NKCC suggesting that these should be considered as non-redundant biomarkers. Abnormalities in DPPIV/CD26 and in NK cell function have particular relevance to the possible role of infection in the initiation and/or the persistence of CFS.
Flor-Henry P, Lind JC, Koles ZJ.	Alberta Hospital Edmonton, Box 307, Edmonton, Edmonton, Alberta, Canada T5J 2J7. Pierre.Flor-Henry@capitalhealth.ca	EEG source analysis of chronic fatigue syndrome.	Psychiatry Res. 2010 Feb 28;181(2):155-64. Epub 2009 Dec 16.	Sixty-one dextral, unmedicated women with chronic fatigue syndrome (CFS) diagnosed according to the Fukuda criteria (1994) and referred for investigation by rheumatologists and internists were studied with quantitative EEG (43 channels) at rest with eyes open and during verbal and spatial cognitive activation. The EEGs from the patients were compared with recordings from 80 dextral healthy female controls. Only those subjects who could provide 20 1-s artefact-free segments of EEG were admitted into the study. The analysis consisted of the identification of the spatial patterns in the EEGs that maximally differentiated the two groups and the estimation of the cortical source distributions underlying these patterns. Spatial patterns were analyzed in the alpha (8-13Hz) and beta (14-20Hz) bands and the source distributions were estimated using the Borgiotti-Kaplan BEAMFORMER algorithm. The results indicate that the spatial patterns identified were effective in separating the two groups, providing a minimum correct retrospective classification rate of 72% in both frequency bands while the subjects were at rest to a maximum of 83% in the alpha band during the verbal cognitive condition. Underlying cortical source distributions showed significant differences between the two groups in both frequency bands and in all cognitive conditions. Lateralized cortical differences were evident between the two groups in the both frequency bands during both the verbal and spatial cognitive conditions. During these active cognitive conditions, the CFS group showed significantly greater source-current activity than the controls in the left frontal-temporal-parietal regions of the cortex.
Fomicheva EE, Filatenkova TA,	State Science Research Institute	Activity in the hypothalamo-	Neurosci Behav Physiol. 2010	Changes in the activity of the hypothalamo-hypophyseal-adrenocortical system (HHACS) were studied in an experimental model of chronic fatigue syndrome induced by i.p. administration of synthetic

Rybakina EG.	of Experimental Medicine, Russian Academy of Medical Sciences, 12 Academician Pavlov Street, 197376, St. Petersburg, Russia. eefomicheva@rambler.ru	hypophyseal-adrenocortical system on experimental induction of chronic fatigue syndrome.	Mar;40(3):245-50. Epub 2010 Feb 10.	doublestranded RNA (polyriboinosinic:polyribocytidylic acid, Poly I:C) at a dose of 3 mg/kg. Functional changes in the different components of the HHACS were detected using standard tests with i.p. ACTH or hydrocortisone on the background of cold stress and injections of Poly I:C. Single doses of Poly I:C were followed by the development of impairments to HHACS function, with decreases in the ACTH sensitivity of adrenal cells and suppression of the negative feedback mechanism, resulting in significant decreases in corticosterone concentrations in standard tests with administration of ACTH and hydrocortisone.
Friedberg F.	Putnam Hall/South Campus, Stony Brook University, Stony Brook, NY 11794-8790, USA. fred.friedberg@stonybrook.edu	Chronic fatigue syndrome, fibromyalgia, and related illnesses: a clinical model of assessment and intervention.	J Clin Psychol. 2010 Jun;66(6):641-65.	A clinically informative behavioral literature on chronic fatigue syndrome (CFS) and fibromyalgia (FM) has emerged over the past decade. The purpose of this article is to (a) define these conditions and their less severe counterparts, i.e., unexplained chronic fatigue (UCF) and chronic widespread pain; (b) briefly review the behavioral theory and intervention literature on CFS and FM; and (c) describe a user-friendly clinical model of assessment and intervention for these illnesses. The assessments described will facilitate understanding of the somewhat unusual and puzzling somatic presentations that characterize these patients. Using an individualized cognitive-behavioral approach the mental health clinician can offer significant help to these often stigmatized and medically underserved patients.
Fukuda S, Hashimoto R, Ohi K, Yamaguti K, Nakatomi Y, Yasuda Y, Kamino K, Takeda M, Tajima S, Kuratsune H, Nishizawa Y, Watanabe Y.	Department of Biomarker and Molecular Biophysics, Osaka City University Graduate School of Medicine, Osaka, Japan.	A functional polymorphism in the disrupted-in schizophrenia 1 gene is associated with chronic fatigue syndrome.	Life Sci. 2010 May 8;86(19-20):722-5. Epub 2010 Mar 20.	AIMS: Disrupted-in schizophrenia 1 (DISC1), identified in a pedigree with a familial psychosis with the chromosome translocation (1:11), is a putative susceptibility gene for psychoses such as schizophrenia and major depressive disorder (MDD). Patients with chronic fatigue syndrome (CFS) report having continuous severe fatigue and many overlapping symptoms with MDD; however, the mechanism and effective treatment of CFS are still unclear. We focused on the overlapping symptoms between CFS and MDD and performed an association study of the functional single-nucleotide polymorphism (SNP) in the DISC1 gene with CFS. MAIN METHODS: Venous blood was drawn from CFS patients and controls and genomic DNA was extracted from the whole blood according to standard procedures. Ser704Cys DISC1 SNP was genotyped using the TaqMan 5'-exonuclease allelic discrimination assay. KEY FINDINGS: We found that the Cys704 allele of Ser704Cys SNP was associated with an increased risk of CFS development compared with the Ser704 allele. SIGNIFICANCE: DISC1 Ser704Cys might be a functional variant that affects one of the mechanisms implicated in the biology of CFS. Some patients with CFS showed a phenotype similar to that of patients with MDD, but further studies are needed to clarify the biological mechanism, because this study is of a rather preliminary nature. Despite the variety of patients with CFS, DISC1 Ser704Cys has an association with CFS, which may also suggest that DISC1 plays a central role in the induction of various psychiatric diseases.
Fukuda S, Kuratsune H, Tajima S, Takashima S, Yamagutchi K,	Department of Physiology, Osaka City University Graduate School of Medicine, Osaka	Premorbid personality in chronic fatigue syndrome as determined by the	Compr Psychiatry. 2010 Jan-Feb;51(1):78-85. Epub 2009 Mar 12.	BACKGROUND: Using the Temperament and Character Inventory (TCI), we examined personality characteristics in patients with chronic fatigue syndrome (CFS) compared with healthy control subjects, and CFS patients with and without psychiatric diseases. There have been no previous reports assessing personality in CFS patients using the TCI. METHODS: A total of 211 CFS patients and 90 control subjects completed the TCI and the Chalder Fatigue Scale questionnaires. RESULTS: Compared

Nishizawa Y, Watanabe Y.	545-8585, Japan. fukuda@med.osaka-cu.ac.jp	Temperament and Character Inventory.		with control subjects, CFS patients demonstrated significantly lower premorbid Novelty Seeking, and higher Harm Avoidance and persistence. The fatigue score for CFS patients with psychiatric diseases was higher than that for CFS patients without psychiatric diseases. Patients with CFS with psychiatric diseases showed lower premorbid Self-Directedness when compared with CFS patients without psychiatric diseases. The fatigue score was negatively correlated with premorbid Self-Directedness and Cooperativeness, and positively correlated with Harm Avoidance among CFS patients. CONCLUSION: This study supported the stereotyped image of CFS patients as perfectionists, which is similar to the Persistence score, and neurotics, which is similar to the Harm Avoidance score. Patients displaying greater neuroticisms and poorer social and communication skills, similar to the Self-Directedness and Cooperativeness scores, tend to have intercurrent psychiatry diseases and show more severe symptoms of CFS.
Gagliardi L, Ho JT, Torpy DJ.	School of Medicine, University of Adelaide, Adelaide, SA 5005, Australia.	Corticosteroid-binding globulin: the clinical significance of altered levels and heritable mutations.	Mol Cell Endocrinol. 2010 Mar 5;316(1):24-34. Epub 2009 Jul 28.	Corticosteroid-binding globulin (CBG) is the specific high-affinity plasma transport glycoprotein for cortisol. Stress-induced falls in CBG levels may heighten hypothalamic-pituitary-adrenal axis responses and CBG:tissue interactions may allow targeted cortisol delivery. Three genetic variants of CBG have been identified that reduce cortisol binding affinity and/or CBG levels. These include the Leuven and Lyon mutations which reduce CBG:cortisol binding affinity 3- and 4-fold, respectively, and the null mutation resulting in a 50% (heterozygote) or 100% (homozygote) reduction in CBG levels. The three reported null homozygotes demonstrate that complete CBG deficiency is not lethal, although it may be associated with hypotension and fatigue. The phenotype of a CBG null murine model included fatigue and immune defects. One community-based study revealed that severe CBG mutations are rare in idiopathic fatigue disorders. The mechanisms by which CBG mutations may cause fatigue are unknown. There are preliminary data of altered CBG levels in hypertension and in the metabolic syndrome; however, the nature of these associations is uncertain. Further studies may clarify the functions of CBG, and clinical observations may validate and/or extend the phenotypic features of various CBG mutations.
Gardner A, Boles RG.	Karolinska Institutet, Department of Clinical Neuroscience, Stockholm, Sweden.	Beyond the serotonin hypothesis: Mitochondria, inflammation and neurodegeneration in major depression and affective spectrum disorders.	Prog Neuropsychopharmacol Biol Psychiatry. 2010 Aug 5. [Epub ahead of print]	For many years, a deficiency of monoamines including serotonin has been the prevailing hypothesis on depression, yet research has failed to confirm consistent relations between brain serotonin and depression. High degrees of overlapping comorbidities and common drug efficacies suggest that depression is one of a family of related conditions sometimes referred to as the "affective spectrum disorders", and variably including migraine, irritable bowel syndrome, chronic fatigue syndrome, fibromyalgia and generalized anxiety disorder, among many others. Herein, we present data from many different experimental modalities that strongly suggest components of mitochondrial dysfunction and inflammation in the pathogenesis of depression and other affective spectrum disorders. The three concepts of monoamines, energy metabolism and inflammatory pathways are inter-related in many complex manners. For example, the major categories of drugs used to treat depression have been demonstrated to exert effects on mitochondria and inflammation, as well as on monoamines. Furthermore, commonly-used mitochondrial-targeted treatments exert effects on mitochondria and inflammation, and are increasingly being shown to demonstrate efficacy in the affective spectrum disorders. We propose that interactions among monoamines, mitochondrial dysfunction and inflammation can inspire explanatory, rather than mere descriptive, models of these

				disorders.

Ghio M, Contini P, Setti M, Ubezio G, Mazzei C, Tripodi G.	Division of Clinical Immunology, Department of Internal Medicine, University of Genoa Medical School, 16132, Genoa, Italy. mghio@unige.it	sHLA-I Contamination, a novel mechanism to explain ex vivo/in vitro modulation of IL-10 synthesis and release in CD8(+) T lymphocytes and in neutrophils following intravenous immunoglobulin infusion.	J Clin Immunol. 2010 May;30(3):384-92. Epub 2010 Feb 2.	BACKGROUND: Numerous mechanisms have been proposed to explain the beneficial action of intravenous immune globulin (IVIG) in autoimmune and systemic inflammatory disorders; among others, they could decrease pro-inflammatory cytokine levels and also induce anti-inflammatory cytokines. MATERIALS AND METHODS: Ex vivo analysis of cells from ten IVIG recipients showed significant increase of IL-10 mRNA and intra-cellular IL-10 molecules in both leukotypes. RESULTS: In vitro comparable results were obtained incubating CD8(+) T lymphocytes and neutrophils from healthy donors with IVIG. sHLA-I and/or sFasL immunodepletion abolished IL-10 modulation. Co-culture with contaminant-free IgM or MabThera did not exert any mRNA modulation. Finally, IgM or MabThera plus purified sHLA-I molecules enhanced IL-10-mRNA in both leukotypes to levels comparable to those obtained with IVIG incubation. CONCLUSION: As IVIG infusion involves administration of soluble contaminants, these data consent to speculate that IVIG might modulate IL-10 via the immunomodulatory activities of sHLA-I contaminant molecules inducing transcriptional and post-transcriptional modulation of IL-10 in CD8(+) T lymphocytes and neutrophils.
Gordon BA, Knapman LM, Lubitz L.	Physiotherapy Department, Austin Health and Discipline of Exercise Science, RMIT University, Australia. brett.gordon@austin.org.au	Graduated exercise training and progressive resistance training in adolescents with chronic fatigue syndrome: a randomized controlled pilot study.	Clin Rehabil. 2010 Dec;24(12):1072-9. Epub 2010 Jul 6.	OBJECTIVE: to investigate the differential effects of aerobic graded exercise and progressive resistance training on exercise tolerance, fatigue and quality of life in adolescent patients with chronic fatigue syndrome (CFS). DESIGN: single-blind, randomized controlled pilot trial. SETTING: a major metropolitan hospital in Melbourne, Australia. SUBJECTS: twenty-two adolescents aged 13-18 years diagnosed with CFS and admitted to the inpatient chronic fatigue rehabilitation programme. INTERVENTION: patients were randomized to either graded aerobic exercise training or a progressive resistance training programme, for five days/week for four weeks. The graded aerobic training consisted of 20-40 minutes of stationary cycling and treadmill exercise. The progressive resistance training involved 16 exercises performed with single set, moderate load and high repetitions. MAIN MEASURES: exercise tolerance (time to fatigue) measured on a graded sub-maximal treadmill test, metabolic equivalents and quality of life, along with muscular strength (maximium push-ups) and endurance (sit-to-stand) and questionnaires evaluating depressive symptoms and fatigue severity. RESULTS: no intervention was significantly better than the other for any outcome. However, physical capacity and quality of life significantly improved in both groups, while fatigue severity and symptoms of depression improved only with aerobic training. CONCLUSIONS: resistance and aerobic training

				resulted in similar changes to physical capacity, quality of life and fatigue severity. Generally, patients who completed resistance training or aerobic training experienced significant improvements in outcomes from baseline when they entered the programme. Whether these improvements can be attributed to the treatment is unknown.
Groom HC, Boucherit VC, Makinson K, Randal E, Baptista S, Hagan S, Gow JW, Mattes FM, Breuer J, Kerr JR, Stoye JP, Bishop KN.	Division of Virology, MRC National Institute for Medical Research, The Ridgeway, Mill Hill, London NW7 1AA, UK.	Absence of xenotropic murine leukaemia virus-related virus in UK patients with chronic fatigue syndrome.	Retrovirology. 2010 Feb 15;7:10.	BACKGROUND: Detection of a retrovirus, xenotropic murine leukaemia virus-related virus (XMRV), has recently been reported in 67% of patients with chronic fatigue syndrome. We have studied a total of 170 samples from chronic fatigue syndrome patients from two UK cohorts and 395 controls for evidence of XMRV infection by looking either for the presence of viral nucleic acids using quantitative PCR (limit of detection <16 viral copies) or for the presence of serological responses using a virus neutralisation assay. RESULTS: We have not identified XMRV DNA in any samples by PCR (0/299). Some serum samples showed XMRV neutralising activity (26/565) but only one of these positive sera came from a CFS patient. Most of the positive sera were also able to neutralise MLV particles pseudotyped with envelope proteins from other viruses, including vesicular stomatitis virus, indicating significant cross-reactivity in serological responses. Four positive samples were specific for XMRV. CONCLUSIONS: No association between XMRV infection and CFS was observed in the samples tested, either by PCR or serological methodologies. The non-specific neutralisation observed in multiple serum samples suggests that it is unlikely that these responses were elicited by XMRV and highlights the danger of over-estimating XMRV frequency based on serological assays. In spite of this, we believe that the detection of neutralising activity that did not inhibit VSV-G pseudotyped MLV in at least four human serum samples indicates that XMRV infection may occur in the general population, although with currently uncertain outcomes.
Groom HC, Yap MW, Galão RP, Neil SJ, Bishop KN.	Division of Virology, MRC National Institute for Medical Research, London NW7 1AA, United Kingdom.	Susceptibility of xenotropic murine leukemia virus-related virus (XMRV) to retroviral restriction factors.	Proc Natl Acad Sci U S A. 2010 Mar 16;107(11):5166-71. Epub 2010 Mar 1.	Xenotropic murine leukemia virus-related virus (XMRV) is a recently discovered gammaretrovirus that has been linked to prostate cancer and chronic fatigue syndrome. This virus is therefore an important potential human pathogen and, as such, it is essential to understand its host cell tropism. Intriguingly, infectious virus has been recovered from patient-derived peripheral blood mononuclear cells. These cells express several antiviral restriction factors that are capable of inhibiting the replication of a wide range of retroviruses, including other gamma retroviruses. This raises the possibility that, similar to HIV, XMRV may have acquired resistance to restriction. We therefore investigated the susceptibility of XMRV to a panel of different restriction factors. We found that both human APOBEC3 and tetherin proteins are able to block XMRV replication. Expression of human TRIM5alpha, however, had no effect on viral infectivity. There was no evidence that XMRV expressed countermeasures to overcome restriction. In addition, the virus was inhibited by factors from nonhuman species, including mouse Apobec3, tetherin, and Fv1 proteins. These results have important implications for predicting the natural target cells for XMRV replication, for relating infection to viral pathogenicity and pathology, and for the design of model systems with which to study XMRV-related diseases.
Guise J, McVittie C, McKinlay A.	Tayside Institute for Health Studies, University of Abertay Dundee, Level 3, Kydd	A discourse analytic study of ME/CFS (Chronic Fatigue Syndrome) sufferers'	J Health Psychol. 2010 Apr;15(3):426-35.	The aetiology, symptoms, diagnosis and treatment of ME/CFS are controversial. Doctors and sufferers often have opposing perspectives, leading to problematic clinical interactions. We use discourse analysis to explore ME/CFS sufferers' descriptions of interactions with medical professionals taken from an asynchronous, online sufferers' support group. Participants described themselves as experiencing limited medical care and attention but restricted criticisms to 'legitimate', pragmatic or

	Building, Bell St., Dundee DD11HG, UK. j.guise@abertay.ac.uk	experiences of interactions with doctors.		ancillary matters such as a clinicians' unwillingness to prescribe untested treatments. Participants also described themselves as active in seeking a resolution to their problems. They thus attended to possible negative attributions of being 'complaining' or unmotivated to seek recovery.
Gupta A, Vij G, Chopra K.	Pharmacology Division, University Institute of Pharmaceutical Sciences, UGC Center of Advanced Study, Panjab University, Chandigarh 160014, India.	Possible role of oxidative stress and immunological activation in mouse model of chronic fatigue syndrome and its attenuation by olive extract.	J Neuroimmunol. 2010 Sep 14;226(1-2):3-7. Epub 2010 May 26.	Various putative theories involved in the development of chronic fatigue syndrome revolve around the role of stress, infection and oxidative stress. Scientific evidence highlighting the protective role of nutritional supplements in chronic fatigue syndrome is lacking. Based on these assumptions, the present study was designed to evaluate the effect of olive extract in a mouse model of immunologically-induced fatigue, wherein purified lipopolysaccharide (LPS) and Brucella abortus (BA) antigen were used as immunogens. The assessment of chronic fatigue syndrome was based on immobility period during chronic water-immersion stress test for 10 min daily. The stress-induced hyperalgesia was measured by tail withdrawal latency. Mice challenged with LPS or BA for 19 days showed significant increase in the immobility time, hyperalgesia and oxidative stress on the 19th day. Serum tumor necrosis factor-alpha (TNF-α) levels were also markedly increased with LPS or BA challenge. Concurrent treatment with olive extract resulted in a significant decrease in the immobility time as well as hyperalgesia. There was significant attenuation of oxidative stress as well as serum TNF-α levels. The results of the present study strongly indicate the role of oxidative stress and immunological activation in the pathophysiology of chronic fatigue syndrome and highlight the valuable role of olive extract in combating chronic fatigue syndrome.
Hambrook D, Oldershaw A, Rimes K, Schmidt U, Tchanturia K, Treasure J, Richards S, Chalder T.		Emotional expression, self-silencing, and distress tolerance in anorexia nervosa and chronic fatigue syndrome.	Br J Clin Psychol. 2010 Aug 10. [Epub ahead of print]	Objectives Difficulties in processing emotional states are implicated in the aetiology and maintenance of diverse health conditions, including anorexia nervosa (AN) and chronic fatigue syndrome (CFS). This study sought to explore distress tolerance, self-silencing, and beliefs regarding the experience and expression of emotions in individuals diagnosed with AN and CFS. These conditions were chosen for this study because their clinical presentation is characterized by physical symptoms, yet cognitive behavioural models suggest that emotional processing difficulties contribute to the aetiology and maintenance of both. Design A between-subjects cross-sectional design was employed. Methods Forty people with AN, 45 with CFS, and 48 healthy controls (HCs) completed the Distress Tolerance Scale (DTS), Silencing the Self Scale (STSS), Beliefs about Emotions Scale (BES), and measures of clinical symptomatology. Results Initial group comparisons found that both AN and CFS participants scored higher than HCs on a subscale measuring difficulties in distress tolerance. AN and CFS participants were also more likely to judge themselves by external standards, endorse statements reflecting a tendency to put the needs of others before themselves, and present an outwardly socially compliant image of themselves whilst feeling hostile within. Relative to HCs, AN participants reported more maladaptive beliefs regarding the experience of having negative thoughts and feelings and revealing these emotions to others, with CFS participants showing a non-significant trend in the same direction. After controlling for differences in age, anxiety, and depression the only significant difference to remain was that observed for the STSS care as self-sacrifice subscale. More maladaptive beliefs about the experience and expression of emotions were associated with greater degree of eating disorder symptomatology in the AN group. Conclusions Differences in emotional processing are present in AN

				and CFS compared to HCs, with some disorder-specific variation, and may be associated with greater clinical symptomatology. These findings support current explanatory models of both AN and CFS, and suggest that emotional processing should be addressed in the assessment and treatment of individuals with these illnesses.
Heins MJ, Knoop H, Prins JB, Stulemeijer M, van der Meer JW, Bleijenberg G.	Expert Centre Chronic Fatigue, Radboud University Nijmegen Medical Centre, Nijmegen, The Netherlands. m.heins@nkcv.umcn.nl	Possible detrimental effects of cognitive behaviour therapy for chronic fatigue syndrome.	Psychother Psychosom. 2010 Jun;79(4):249-56. Epub 2010 May 25.	BACKGROUND: Cognitive behaviour therapy (CBT) for chronic fatigue syndrome (CFS) can decrease the level of fatigue and disabilities, but it has been suggested that during therapy some patients experience a deterioration of their symptoms rather than an improvement. The aim of this study is to examine the frequency and severity of symptom deterioration during CBT for CFS. METHODS: Data from 3 randomised controlled trials on CBT for CFS were pooled and reanalysed. Symptom deterioration during the trial was rated by patients and measured as deterioration in fatigue, pain, functional impairment and psychological distress. Both the frequency and severity of deterioration in these domains were compared between the patients receiving CBT and those in the control group. Predictors of symptom deterioration were identified by comparing their means in patients with and without an increase in fatigue. Statistically significant predictors were then combined in a logistic regression model. RESULTS: The frequency of symptom deterioration varied from 2 to 12% in patients receiving CBT and from 7 to 17% in the control group. None of the measures showed a significantly higher frequency of symptom deterioration in the CBT group. The severity of deterioration was also comparable in the CBT and in the control group. No predictors of symptom deterioration specific to CBT were found. CONCLUSION: Patients receiving CBT do not experience more frequent or more severe symptom deterioration than untreated patients. The reported deterioration during CBT seems to reflect the natural variation in symptoms. Thus, CBT is not only a helpful, but also a safe treatment for CFS.
Henrich TJ, Li JZ, Felsenstein D, Kotton CN, Plenge RM, Pereyra F, Marty FM, Lin NH, Grazioso P, Crochiere DM, Eggers D, Kuritzkes DR, Tsibris AM.	Division of Infectious Diseases, Brigham and Women's Hospital, Boston, Massachusetts, USA.	Xenotropic murine leukemia virus-related virus prevalence in patients with chronic fatigue syndrome or chronic immunomodulatory conditions.	J Infect Dis. 2010 Nov 15;202(10):1478-81. Epub 2010 Oct 11. Comment in: J Infect Dis. 2010 Nov 15;202(10):1463-6.	We investigated the prevalence of xenotropic murine leukemia virus-related virus (XMRV) among 293 participants seen at academic hospitals in Boston, Massachusetts. Participants were recruited from the following 5 groups of patients: chronic fatigue syndrome (n = 32), human immunodeficiency virus infection (n = 43), rheumatoid arthritis (n = 97), hematopoietic stem-cell or solid organ transplant (n = 26), or a general cohort of patients presenting for medical care (n = 95). XMRV DNA was not detected in any participant samples. We found no association between XMRV and patients with chronic fatigue syndrome or chronic immunomodulatory conditions.
Hoeck AD, Pall ML.	Mariawald str. 750935, Cologne, Germany.	Will vitamin D supplementation ameliorate diseases characterized by chronic inflammation and fatigue?	Med Hypotheses. 2011 Feb;76(2):208-13. Epub 2010 Oct 25.	Chronic NF-κB activation has been supposed as a key event in chronic fatigue syndrome (CFS) and many other better-defined pro-inflammatory diseases. Knowledge about the impact of deficiency vitamin D on chronic NF-κB activation could open a new disease approach. Whereas NF-κB activation leads at first to a pro-inflammatory immune response, later on a vitamin D-dependent anti-inflammatory response ensues. Binding of the active vitamin D metabolite 1,25(OH)(2)D(3) to vitamin D receptor (VDR) yields a transcription factor which represses NF-κB activation, and additionally modulates and down-regulates adaptive, but enhances innate immune responses, and improves redox balance, thus counterbalancing inflammation on multiple levels. However, this built-in late

				counterbalance against inflammation works only when stores of calcium and 25(OH)D(3) are abundant. Therefore a connection between lowered vitamin D-metabolism and persistent NF-κB activation, augmented nitrosative-oxidative stress, redox imbalance, chronic inflammation, and concomitant fatigue can be postulated. In order to confirm this hypothesis, randomized controlled clinical studies about the clinical effects of supplementation of calcium and vitamin D(3) would be necessary in diseases characterized by persistent NF-κB activation and chronic inflammation and fatigue.
Hohn O, Strohschein K, Brandt AU, Seeher S, Klein S, Kurth R, Paul F, Meisel C, Scheibenbogen C, Bannert N.	Centre for Biological Security 4, Robert Koch-Institute, Berlin, Germany.	No Evidence for XMRV in German CFS and MS Patients with Fatigue Despite the Ability of the Virus to Infect Human Blood Cells In Vitro.	PLoS One. 2010 Dec 22;5(12):e15632.	BACKGROUND: Xenotropic murine leukemia virus-related virus (XMRV), a novel human retrovirus originally identified in prostate cancer tissues, has recently been associated with chronic fatigue syndrome (CFS), a disabling disease of unknown etiology affecting millions of people worldwide. However, several subsequent studies failed to detect the virus in patients suffering from these illnesses or in healthy subjects. Here we report the results of efforts to detect antibody responses and viral sequences in samples from a cohort of German CFS and relapsing remitting multiple sclerosis (MS) patients with fatigue symptoms. METHODOLOGY: Blood samples were taken from a cohort of 39 patients fulfilling the Fukuda/CDC criteria (CFS), from 112 patients with an established MS diagnosis and from 40 healthy donors. Fatigue severity in MS patients was assessed using the Fatigue Severity Scale (FSS). Validated Gag- and Env-ELISA assays were used to screen sera for XMRV antibodies. PHA-activated PBMC were cultured for seven days in the presence of IL-2 and DNA isolated from these cultures as well as from co-cultures of PBMC and highly permissive LNCaP cells was analyzed by nested PCR for the presence of the XMRV gag gene. In addition, PBMC cultures were exposed to 22Rv1-derived XMRV to assess infectivity and virus production. CONCLUSION: None of the screened sera from CFS and MS patients or healthy blood donors tested positive for XMRV specific antibodies and all PBMC (and PBMC plus LNCaP) cultures remained negative for XMRV sequences by nested PCR. These results argue against an association between XMRV infection and CFS and MS in Germany. However, we could confirm that PBMC cultures from healthy donors and from CFS patients can be experimentally infected by XMRV, resulting in the release of low levels of transmittable virus.
Hollingsworth KG, Jones DE, Taylor R, Blamire AM, Newton JL.	Institute of Cellular Medicine, Newcastle University, Newcastle upon Tyne, UK.	Impaired cardiovascular response to standing in chronic fatigue syndrome.	Eur J Clin Invest. 2010 Jul;40(7):608-15. Epub 2010 May 23.	BACKGROUND: Impaired skeletal muscle metabolism is recognized in chronic fatigue syndrome (CFS). This study examined the relationship between skeletal and cardiac muscle function and symptoms on standing in CFS using magnetic resonance spectroscopy (MRS) and impedance cardiography. MATERIALS AND METHODS: Phosphocreatine (PCr)/adenosine triphosphate (ATP) ratio by cardiac MRS, PCr/ADP and proton efflux by muscle MRS were performed in 12 CFS (Fukuda) and 8 controls. Head up tilt (HUT) and cardiac contractility (left ventricular work index, LVWI) (n = 64 CFS and matched controls) were found. Fatigue impact was accessed by Fatigue Impact Scale and orthostatic symptoms by Orthostatic Grading Scale (OGS). RESULTS: Cardiac PCr/ATP correlated with measures of muscle bioenergetic function (half-time PCr recovery [kappa = -0.71, P = 0.005] and half-time ADP recovery [kappa = -0.60, P = 0.02]) suggesting that the muscle and cardiac bioenergetic function correlate in CFS. Four of 12 (33.3%) CFS patients had PCr/ATP values consistent with significant cardiac impairment. Those with impaired cardiac energy metabolism had significantly reduced maximal and initial proton efflux rates (P < 0.05). Cardiac PCr/ATP ratio correlated with myocardial contractility (LVWI) in response to standing (P = 0.03). On HUT, LVWI on standing was significantly higher in CFS (P

				= 0.05) with symptoms on standing (OGS) occurring in 61/64 (95%) (vs. 25/64 [39%] controls; P < 0.0001). OGS scores were significantly higher in those with abnormal LVWI responses to standing (P = 0.04), with the LVWI on standing correlating with OGS scores (r(2) = 0.1; P = 0.03). HUT was positive in 19 (32%). CONCLUSIONS: Skeletal muscle and cardiac bioenergetic abnormalities associate in CFS. Cardiac bioenergetic metabolism associates with increase in cardiac contractility on standing. Haemodynamic assessment in CFS is well tolerated and safe with a high diagnostic yield comparable with unexplained syncope.
Hong P, Li J, Li Y.	Graduate School, Peking Union Medical College, Chinese Academy of Medical Sciences, Beijing, People's Republic of China.	Failure to detect Xenotropic murine leukaemia virus-related virus in Chinese patients with chronic fatigue syndrome.	Virol J. 2010 Sep 13;7:224.	BACKGROUND: Recent controversy has surrounded the question of whether xenotropic murine leukaemia virus-related virus (XMRV) contributes to the pathogenesis of chronic fatigue syndrome (CFS). To investigate the question in a Chinese population, 65 CFS patients and 85 blood donor controls were enrolled and multiplex real-time PCR or reverse transcriptase PCR (RT-PCR) was developed to analyze the XMRV infection status of the study participants. The assay was standardized by constructing plasmid DNAs and armored RNAs as XMRV standards and competitive internal controls (CICs), respectively. RESULTS: The sensitivities of the multiplex real-time PCR and RT-PCR assays were 20 copies/reaction and 10 IU/ml, respectively, with 100% specificity. The within-run precision coefficient of variation (CV) ranged from 1.76% to 2.80% and 1.70% to 2.59%, while the between-run CV ranged from 1.07% to 2.56% and 1.06% to 2.74%. XMRV was not detected in the 65 CFS patients and 65 normal individuals out of 85 controls. CONCLUSIONS: This study failed to show XMRV in peripheral blood mononuclear cells (PBMCs) and plasma of Chinese patients with CFS. The absence of XMRV nucleic acids does not support an association between XMRV infection and the development of CFS in Chinese.
Horton SM, Poland F, Kale S, Drachler Mde L, de Carvalho Leite JC, McArthur MA, Campion PD, Pheby D, Nacul L.	University of East Anglia, Norwich, UK. s.horton@uea.ac.uk	Chronic fatigue syndrome/myalgic encephalomyelitis (CFS/ME) in adults: a qualitative study of perspectives from professional practice.	BMC Fam Pract. 2010 Nov 15;11:89.	BACKGROUND: Chronic fatigue syndrome/myalgic encephalomyelitis (CFS/ME) can cause profound and prolonged illness and disability, and poses significant problems of uncertainty for healthcare professionals in its diagnosis and management. The aim of this qualitative study was to explore the nature of professional 'best practice' in working with people with CFS/ME. METHODS: The views and experiences of health care practitioners (HCPs) were sought, who had been judged by people with CFS/ME themselves to have been particularly helpful and effective. Qualitative semi-structured interviews following a topic guide were carried out with six health care practitioners. Interviews were audio-recorded, transcribed and subject to thematic analysis. RESULTS: Five main themes were developed: 1) Diagnosis; 2) Professional perspectives on living with CFS/ME; 3) Interventions for treatment and management; 4) Professional values and support for people with CFS/ME and their families; 5) Health professional roles and working practices. Key findings related to: the diagnostic process, especially the degree of uncertainty which may be shared by primary care physicians and patients alike; the continued denial in some quarters of the existence of CFS/ME as a condition; the variability, complexity, and serious impact of the condition on life and living; the onus on the person with CFS/ME to manage their condition, supported by HCPs; the wealth of often conflicting and confusing information on the condition and options for treatment; and the vital role of extended listening and trustful relationships with patients. CONCLUSIONS: While professional frustrations were clearly expressed about the variability of services both in primary and specialist care and continuing equivocal attitudes to CFS/ME as a condition, there were also strong positive messages for people

				with CFS/ME where the right services are in place. Many of the findings from these practitioners seen by their patients as helping them more effectively, accord with the existing literature identifying the particular importance of listening skills, respect and trust for establishing a therapeutic relationship which recognises key features of the patient trajectory and promotes effective person-centred management of this complex condition. These findings indicate the need to build such skills and knowledge more systematically into professional training informed by the experience of specialist services and those living with the condition.
Houghton CA, Steels EL, Fassett RG, Coombes JS.	School of Human Movement Studies, University of Queensland, St Lucia, Qld 4067, Australia.	Effects of a gliadin-combined plant superoxide dismutase extract on self-perceived fatigue in women aged 50-65 years.	Phytomedicine. 2010 Oct 31. [Epub ahead of print]	Fatigue syndromes exist on a continuum of severity from mild and transient to the disabling chronic fatigue syndrome, with oxidative stress linked to its pathogenesis. A thermolabile gliadin-combined plant superoxide dismutase (SOD) extract has shown potential in clinical trials as a therapeutic antioxidant. This study investigated the effects of 12 weeks of 500mg/day of a SOD/gliadin supplement on fatigue. Thirty-eight women aged 50-65 years with self-perceived fatigue entered this randomized, double-blind, placebo-controlled trial. The primary outcome measure was general fatigue determined by the Multidimensional Fatigue Inventory (MFI). Secondary outcome measures included other measures of fatigue from the MFI and blood measures of oxidative stress, antioxidant status and hormones. There were no significant (P>0.05) differences between, or within groups, for decreases in general fatigue (active=1.6%, placebo=4.1%). There were no within or between group differences (P>0.05) in other measures of fatigue (physical fatigue, reduced activity, reduced motivation, mental fatigue and total fatigue score). In regard to the biochemical measures, there were non-significant (P>0.05) differences in increases in plasma SOD activity (active=7.1%, placebo=12.2%), plasma GPx activity (active=2.4%, placebo=0.7%), red blood cell GPx activity (active=9.8%, placebo=4.4%). Markers of oxidative stress were decreased but there were no differences (P>0.05) within or between groups; malondialdehyde (active=4.1%, placebo=1.6%), F-2 isoprostanes (active=14.7%, placebo=22.4%). There was a trend (P=0.08) for a decrease in cortisol in the active group (24.6%), however this was not significantly different from the decrease in the placebo participants (4.1%). DHEA differences were not significant (P<0.05) and declined 1.3% in the active group and 14.4% in the placebo group. In summary, the thermolabile SOD/gliadin supplement had no significant effect on self-perceived fatigue, antioxidants, oxidative stress or hormones in women aged 50-65 years.
Huang Y, Katz BZ, Mears C, Kielhofner GW, Taylor R.	Department of Occupational Therapy, University of Illinois at Chicago, College of Applied Health Sciences, 1919 W Taylor Street, Chicago, IL 60612, USA.	Postinfectious fatigue in adolescents and physical activity.	Arch Pediatr Adolesc Med. 2010 Sep;164(9):803-9. Comment in: Arch Pediatr Adolesc Med. 2010 Sep;164(9):880-1.	OBJECTIVE: To compare adolescents who do and do not recover from acute infectious mononucleosis in terms of fatigue severity and activity levels before, during, and in the 2 years following infection. DESIGN: Prospective case-control study. SETTING: The baseline and 12- and 24-month evaluations occurred in the subjects' homes. The 6-month outpatient visit occurred at Children's Memorial Hospital in Chicago, Illinois. PARTICIPANTS: Three hundred one adolescents (aged 12-18 years) with acute infectious mononucleosis. MAIN EXPOSURES: All participants were evaluated at baseline (during active infection). Six months following infection, 39 of them met criteria for chronic fatigue syndrome. These subjects were matched by sex and Tanner stage to 39 randomly selected screened-negative subjects. Both groups were reevaluated at 12- and 24-month follow-ups. OUTCOME MEASURES: Scores from the Fatigue Severity Scale and the Modifiable Activity Questionnaire. RESULTS: For both groups, physical activity levels declined and sleep increased as a result of having mononucleosis.

				Compared with their matched controls, adolescents with chronic fatigue syndrome reported significantly higher levels of fatigue at all points and spent significantly more time sleeping during the day 6 and 12 months following infection. The 2 groups did not differ significantly in terms of physical activity levels before, during, or after infection. There was a consistent trend for decreased physical activity in the chronic fatigue syndrome group. CONCLUSIONS: Adolescents with chronic fatigue syndrome appear to be pushing themselves in an attempt to maintain similar activity levels as their peers, but paying for it in terms of fatigue severity and an increased need for sleep, particularly during the day.
Hurum H, Sulheim D, Thaulow E, Wyller VB.	Division of Paediatrics, Oslo University Hospital, Oslo, Norway Department of Pediatrics, Østfold Hospital, Fredrikstad, Norway Department of Pediatrics, Innlandet Hospital, Lillehammer, Norway.	Elevated nocturnal blood pressure and heart rate in adolescent chronic fatigue syndrome.	Acta Paediatr. 2011 Feb;100(2):289-92. doi: 10.1111/j.1651-2227.2010.02073.x . Epub 2010 Nov 17.	Aim: To compare ambulatory recordings of heart rate (HR) and blood pressure in adolescents with chronic fatigue syndrome (CFS) and healthy controls. We hypothesized both HR and blood pressure to be elevated among CFS patients. Methods: Forty-four CFS patients aged 12-18 years were recruited from our paediatric outpatient clinic. The controls were 52 healthy adolescents having similar distribution of age and gender. 24-h ambulatory blood pressure and HR were recorded using a validated, portable oscillometric device. Results: At night (sleep), HR, mean arterial blood pressure and diastolic blood pressure were significantly higher in CFS patients as compared with controls ($p < 0.01$). During daytime, HR was significantly higher among CFS patients ($p < 0.05$), whereas blood pressures were equal among the two groups. Conclusions: The findings support previous experimental evidence of sympathetic predominance of cardiovascular control in adolescent CFS patients. Also, the findings prompt increased focus on cardiovascular risk assessment and suggest a possible target for therapeutic intervention.
Hué S, Gray ER, Gall A, Katzourakis A, Tan CP, Houldcroft CJ, McLaren S, Pillay D, Futreal A, Garson JA, Pybus OG, Kellam P, Towers GJ.	MRC Centre for Medical Molecular Virology, Division of Infection and Immunity, University College London, 46 Cleveland St, London W1T 4JF, UK. pk5@sanger.ac.uk.	Disease-associated XMRV sequences are consistent with laboratory contamination.	Retrovirology. 2010 Dec 20;7(1):111.	ABSTRACT:BACKGROUND: Xenotropic murine leukaemia viruses (MLV-X) are endogenous gammaretroviruses that infect cells from many species, including humans. Xenotropic murine leukaemia virus-related virus (XMRV) is a retrovirus that has been the subject of intense debate since its detection in samples from humans with prostate cancer (PC) and chronic fatigue syndrome (CFS). Controversy has arisen from the failure of some studies to detect XMRV in PC or CFS patients and from inconsistent detection of XMRV in healthy controls. RESULTS: Here we demonstrate that Taqman PCR primers previously described as XMRV-specific can amplify common murine endogenous viral sequences from mouse suggesting that mouse DNA can contaminate patient samples and confound specific XMRV detection. To consider the provenance of XMRV we sequenced XMRV from the cell line 22Rv1, which is infected with an MLV-X that is indistinguishable from patient derived XMRV. Bayesian phylogenies clearly show that XMRV sequences reportedly derived from unlinked patients form a monophyletic clade with interspersed 22Rv1 clones (posterior probability >0.99). The cell line-derived sequences are ancestral to the patient-derived sequences (posterior probability >0.99). Furthermore, pol sequences apparently amplified from PC patient material (VP29 and VP184) are recombinants of XMRV and Moloney MLV (MoMLV) a virus with an envelope that lacks tropism for human cells. Considering the diversity of XMRV we show that the mean pairwise genetic distance among env and pol 22Rv1-derived sequences exceeds that of patient-associated sequences (Wilcoxon rank sum test:

				p = 0.005 and p < 0.001 for pol and env, respectively). Thus XMRV sequences acquire diversity in a cell line but not in patient samples. These observations are difficult to reconcile with the hypothesis that published XMRV sequences are related by a process of infectious transmission. CONCLUSIONS: We provide several independent lines of evidence that XMRV detected by sensitive PCR methods in patient samples is the likely result of PCR contamination with mouse DNA and that the described clones of XMRV arose from the tumour cell line 22Rv1, which was probably infected with XMRV during xenografting in mice. We propose that XMRV might not be a genuine human pathogen.
Israeli E, Pardo A.	The Chaim Zabludowicz Center for Autoimmune Diseases, Chaim Sheba Medical Center, 52621, Tel-Hashomer, Israel, eitanister@gmail.com.	The sick building syndrome as a part of the autoimmune (auto-inflammatory) syndrome induced by adjuvants.	Mod Rheumatol. 2010 Dec 29. [Epub ahead of print]	Sick building syndrome (SBS) is a term coined for a set of clinically recognizable symptoms and ailments without a clear cause reported by occupants of a building. In the 1990s the term "functional somatic syndromes" was applied to several syndromes, including SBS, multiple chemical sensitivity, repetition stress injury, the side effects of silicone breast implants, the Gulf War syndrome (GWS), chronic fatigue syndrome, the irritable bowel syndrome, and fibromyalgia. Recently, Shoenfeld and Agmon-Levin suggested that four conditions-siliconosis, macrophagic myofascitis, the GWS, and post-vaccination phenomena-which share clinical and pathogenic resemblances, may be included under a common syndrome entitled the "autoimmune (auto-inflammatory) syndrome induced by adjuvants". Comparison of the clinical manifestations, symptoms, and signs of the four conditions described by Shoenfeld and Agmon-Levin with those described for SBS shows that nine out of ten main symptoms are present in all 5 conditions. Shoenfeld and Agmon-Levin further propose several major and minor criteria, which, although requiring further validation, may aid in the diagnosis of this newly defined syndrome. We propose here that SBS may also be included as a part of "Shoenfeld's syndrome".
Jason L, Brown M, Evans M, Anderson V, Lerch A, Brown A, Hunnell J, Porter N.	Center for Community Research, DePaul University, Chicago, IL 60614, USA.	Measuring substantial reductions in functioning in patients with chronic fatigue syndrome.	Disabil Rehabil. 2010 Jul 9. [Epub ahead of print]	Purpose. All the major current case definitions for chronic fatigue syndrome (CFS) specify substantial reductions in previous levels of occupational, educational, social, or personal activities to meet criteria. Difficulties have been encountered in operationalizing 'substantial reductions.' For example, the Medical Outcomes Study Short Form-36 Health Survey (SF-36) has been used to determine whether individuals met the CFS disability criterion. However, previous methods of using the SF-36 have been prone to including people without substantial reductions in key areas of physical functioning when diagnosing CFS. This study sought to empirically identify the most appropriate SF-36 subscales for measuring substantial reductions in patients with CFS. Method. The SF-36 was administered to two samples of patients with CFS: one recruited from tertiary care and the other a community-based sample; as well as a non-fatigued control group. Receiver operating characteristics were used to determine the optimal cutoff scores for identifying patients with CFS. Results. The SF-36 Role-Emotional subscale had the worst sensitivity and specificity, whereas the Vitality, Role-Physical, and Social Functioning subscales had the best sensitivity and specificity. Conclusion. Based on the evidence from this study, the potential criteria for defining substantial reductions in functioning and diagnosing CFS is provided.
Jason LA, Boulton A, Porter NS, Jessen T, Njoku MG, Friedberg F.	Center for Community Research, 990 W. Fullerton Ave., Suite 3100,	Classification of myalgic encephalomyelitis/ chronic fatigue syndrome by types	Behav Med. 2010 Jan-Mar;36(1):24-31.	Persons with myalgic encephalomyelitis/chronic fatigue syndrome (ME/CFS) often complain of fatigue states (eg, postexertional malaise, brain fog) that are qualitatively different than normal, daily fatigue. Given the heterogeneous nature of ME/CFS, it is likely that individuals with this illness experience these fatigue types differently in terms of severity and frequency. It is also possible that meaningful subgroups of patients exist that exhibit different patterns of the fatigue experience. The purpose of

	Chicago, IL 60614, USA. ljason@depaul.edu	of fatigue.		this study was to investigate whether individuals with ME/CFS can be classified in a meaningful way according to the different types of fatigue they experience. One hundred individuals with ME/CFS participated in the study. Individuals that met inclusion criteria were administered the Multiple Fatigue Types Questionnaire (MFTQ), a 5-factor instrument that distinguishes between different types of fatigue. A cluster analysis was used to classify patients into various clusters based on factor subscale scores. Using a 3-factor solution, individuals were classified according to illness severity (low, moderate, severe) across the different fatigue factors. However, a 5-cluster solution enabled participants with moderate to severe fatigue levels to fall into more differentiated clusters and demonstrate distinct fatigue state patterns. These results suggest that fatigue patterns of individuals with ME/CFS are heterogeneous, and that patients may be classified into meaningful subgroups.
Jason LA, Evans M, Brown M, Porter N.	Center for Community Research, DePaul University, 990 W. Fullerton Ave., Chicago, IL 60614, USA. Ljason@depaul.edu	What is fatigue? Pathological and nonpathological fatigue.	PM R. 2010 May;2(5):327-31.	Aid in understanding issues surrounding the construct validity of fatigue including the distinction between pathological versus nonpathological fatigue. Fatigue is a universal symptom reported by individuals in the general population as well as by those suffering from different medical and psychological illnesses, including cancer, multiple sclerosis, chronic fatigue syndrome, depression, and anxiety. Chronic fatigue is a significant problem in many primary care settings, and the debilitating and prolonged nature of fatigue can pose significant economic consequences for society. Researchers have struggled to better assess and understand the etiology and classification of fatigue within different illness groups.
Jason LA, Paavola E, Porter N, Morello ML.	DePaul University, Center for Community Research, 990 W. Fullerton Avenue, Suite 3100, Chicago, IL 60614, USA. ljason@depaul.edu	Frequency and content analysis of chronic fatigue syndrome in medical text books.	Aust J Prim Health. 2010;16(2):174-8.	Text books are a cornerstone in the training of medical staff and students, and they are an important source of references and reviews for these professionals. The objective of this study was to determine both the quantity and quality of chronic fatigue syndrome (CFS) information included in medical texts. After reviewing 119 medical text books from various medical specialties, we found that 48 (40.3%) of the medical text books included information on CFS. However, among the 129 527 total pages within these medical text books, the CFS content was presented on only 116.3 (0.090%) pages. Other illnesses that are less prevalent, such as multiple sclerosis and Lyme disease, were more frequently represented in medical text books. These findings suggest that the topic ofCFS is underreported in published medical text books.
Jason LA, Roesner N, Porter N, Parenti B, Mortensen J, Till L.	DePaul University. Ljason@depaul.edu	Provision of social support to individuals with chronic fatigue syndrome.	J Clin Psychol. 2010 Mar;66(3):249-58.	The present study evaluated a buddy program designed to provide support for individuals with chronic fatigue syndrome (CFS). The intervention involved weekly visits by a student paraprofessional, who helped out with tasks that needed to be done in an effort to reduce some of the taxing demands and responsibilities that participants regularly encountered. This model of rehabilitation focused on avoiding overexertion in persons with CFS, aiming to avoid setbacks and relapses while increasing their tolerance for activity. Participants with CFS were randomly assigned to either a 4-month buddy intervention or a control condition. Posttest results showed that individuals who received a student buddy intervention had significantly greater reductions in fatigue severity and increases in vitality than individuals in the control condition. There were no significant changes between groups for physical functioning and stress. Buddy interventions that help patients with CFS reduce overexertion and possibly remain within their energy envelopes can be thought of as representing a different paradigm than nonpharmacologic interventions that focus only on increasing levels of activity through

				graded exercise.
Jelbert R, Stedmon J, Stephens A.	University of Plymouth, UK. beckyjelbert@yahoo.co.uk	A qualitative exploration of adolescents' experiences of chronic fatigue syndrome.	Clin Child Psychol Psychiatry. 2010 Apr;15(2):267-83. Epub 2010 Feb 23.	The aim of this study is to provide a qualitative perspective of adolescents' experiences of Chronic Fatigue Syndrome (CFS). Five adolescents who were considered to have recovered from CFS participated in semistructured interviews regarding their experience. The transcripts were then analysed using interpretative phenomenological analysis. Five main themes were identified to represent common shared experiences across participants.These related to seeking understanding around the illness, experiences of loss, perceived influences on the illness, difficult emotional experiences, and adolescents' status post recovery. While significant efforts are being made to increase knowledge and understanding of CFS within the child and adolescent population there is still much to be learned, as is evident from this direct account of adolescents' experiences. We identify implications for clinical practice and suggestions for future research in light of listening to the adolescents' stories.

Institut de Génétique Moléculaire de Montpellier UMR 5535 CNRS, 1919 route de Mende, 34293 Montpellier cedex 5, France.	No evidence for XMRV association in pediatric idiopathic diseases in France.	Retrovirology. 2010 Aug 2;7:63.	Retroviruses have been linked to a variety of diseases such as neoplastic and immunodeficiency disorders and neurologic and respiratory diseases. Recently, a novel infectious human retrovirus, the xenotropic murine leukemia virus-related virus (XMRV), has been identified in cohorts of patients with either a familial type of prostate cancer or chronic fatigue syndrome. The apparent unrelatedness of these diseases raised the question of the potential involvement of XMRV in other diseases.Here, we investigated the presence of XMRV in a selection of pediatric idiopathic infectious diseases with symptoms that are suggestive of a retroviral infection, as well as in children with respiratory diseases and in adult patients with spondyloarthritis (SpA). Using a XMRV env-nested PCR, we screened 72 DNA samples obtained from 62 children hospitalized in the Montpellier university hospital (France) for hematological, neurological or inflammatory pathologies, 80 DNA samples from nasopharyngeal aspirates from children with respiratory diseases and 19 DNA samples from SpA. None of the samples tested was positive for XMRV or MLV-like env sequences, indicating that XMRV is not involved in these pathologies.
Johnson SK, Schmaling KB, Dmochowski J, Bernstein D.	University of North Carolina at Charlotte, 9201 University City Blvd, Charlotte, NC 28223, USA. skjohnso@uncc.ed	An investigation of victimization and the clinical course of chronic fatigue syndrome.	J Health Psychol. 2010 Apr;15(3):351-61.	Medically unexplained syndromes, including chronic fatigue syndrome (CFS), have been associated with victimization in childhood and adulthood. The purpose of this study was to examine the associations of victimization experiences in childhood and adulthood with functional status and illness severity in a sample of patients with CFS using longitudinal data. In the sample of 93 patients with CFS, childhood abuse and neglect had greater impact than adulthood victimization. Overall, victimization experiences in childhood demonstrated modest associations with clinical outcomes in CFS, although several victimization experiences were in the opposite direction of expectations. Victimization

	u			predicted worse outcomes, but not worsening outcomes over time.
Jones DE, Gray J, Frith J, Newton JL.	UK NIHR Biomedical Centre in Ageing, Institute of Cellular Medicine, Institute for Ageing and Health, Newcastle University, Newcastle, UK.	Fatigue severity remains stable over time and independently associated with orthostatic symptoms in chronic fatigue syndrome: a longitudinal study.	J Intern Med. 2011 Feb;269(2):182-8. doi: 10.1111/j.1365-2796.2010.02306.x . Epub 2010 Nov 14.	Abstract. Jones DEJ, Gray J, Frith J, Newton JL (UK NIHR Biomedical Centre in Ageing, Institute of Cellular Medicine, Institute for Ageing and Health, Newcastle University, Newcastle, UK) Fatigue severity remains stable over time and independently associated with orthostatic symptoms in chronic fatigue syndrome: a longitudinal study. J Intern Med 2011; 269: 182-188. Objectives: To examine fatigue variability over time in chronic fatigue syndrome (CFS) and the effect of other symptoms on its predictability. Design: Longitudinal cohort study of patients with CFS (Fukuda criteria). Setting: Specialist CFS clinical service. Subjects: Phase 1: 100 patients who participated in a study of CFS symptoms in 2005 were revisited in 2009. Phase 2: 25 patients completed fatigue diaries to address intra- and inter-day variability in perceived fatigue. Main outcome measures: Phase 1: subjects completed fatigue impact scale (FIS), Epworth sleepiness scale (ESS), orthostatic grading scale (OGS) and hospital anxiety and depression scale (HADS). Changes in variables represented the differences between 2005 and 2009. Phase 2: subjects rated fatigue on a scale of 0 (no fatigue) to 10 (severe fatigue) four times a day for 5 weeks. Results: Symptom assessment tools were available in both 2005 and 2009 for 74% of patients. FIS and HADS depression (HAD-D) and anxiety (HAD-A) scores significantly improved during follow-up whereas ESS and OGS remained stable. FIS improved in 29/74 (39%) subjects, and by ≥10 points in 19 (26%). FIS worsened by ≥10 points in 33/74 (45%) subjects. On multivariate analysis, independent predictors of current fatigue (FIS in 2009) were FIS in 2005, HAD-D in 2009, OGS in 2009 and change in HAD-A. Reported fatigue was stable from week to week and from day to day. Patients reported higher fatigue in the morning (mean ± SD; 6.4 ± 2), becoming significantly lower at lunchtime (6.2 ± 2; P < 0.05) and increasing again to 7 ± 2 at bedtime. Conclusions: Current fatigue is independently associated with current autonomic symptom burden, current depression and change in anxiety during follow-up. These findings have implications for targeted symptom management in CFS.
Jones DE, Hollingsworth KG, Taylor R, Blamire AM, Newton JL.	Institute of Cellular Medicine, Newcastle University, Newcastle-upon-Tyne, UK.	Abnormalities in pH handling by peripheral muscle and potential regulation by the autonomic nervous system in chronic fatigue syndrome.	J Intern Med. 2010 Apr;267(4):394-401.	OBJECTIVES: To examine muscle acid handling following exercise in chronic fatigue syndrome (CFS/ME) and the relationship with autonomic dysfunction. DESIGN: Observational study. SETTING: Regional fatigue service. SUBJECTS & INTERVENTIONS: Chronic fatigue syndrome (n = 16) and age and sex matched normal controls (n = 8) underwent phosphorus magnetic resonance spectroscopy (MRS) to evaluate pH handling during exercise. Subjects performed plantar flexion at fixed 35% load maximum voluntary contraction. Heart rate variability was performed during 10 min supine rest using digital photophlethysmography as a measure of autonomic function. RESULTS: Compared to normal controls, the CFS/ME group had significant suppression of proton efflux both immediately postexercise (CFS: 1.1 +/- 0.5 mmol L(-1) min(-1) vs. normal: 3.6 +/- 1.5 mmol L(-1) min(-1), P < 0.001) and maximally (CFS: 2.7 +/- 3.4 mmol L(-1) min(-1) vs. control: 3.8 +/- 1.6 mmol L(-1) min(-1), P < 0.05). Furthermore, the time taken to reach maximum proton efflux was significantly prolonged in patients (CFS: 25.6 +/- 36.1 s vs. normal: 3.8 +/- 5.2 s, P < 0.05). In controls the rate of maximum proton efflux showed a strong inverse correlation with nadir muscle pH following exercise (r(2) = 0.6; P < 0.01). In CFS patients, in contrast, this significant normal relationship was lost (r(2) = 0.003; P = ns). In normal individuals, the maximum proton efflux following exercise were closely correlated with total heart rate variability (r(2) = 0.7; P = 0.007) this relationship was lost in CFS/ME patients (r(2) < 0.001; P = ns).

				CONCLUSION: Patients with CFS/ME have abnormalities in recovery of intramuscular pH following standardised exercise degree of which is related to autonomic dysfunction. This study identifies a novel biological abnormality in patients with CFS/ME which is potentially open to modification.
Kadota Y, Cooper G, Burton AR, Lemon J, Schall U, Lloyd A, Vollmer-Conna U.	School of Psychiatry, University of NSW, Sydney, Australia.	Autonomic hyper-vigilance in post-infective fatigue syndrome.	Biol Psychol. 2010 Sep;85(1):97-103. Epub 2010 Jun 2.	This study examined whether post-infective fatigue syndrome (PIFS) is associated with a disturbance in bidirectional autonomic signalling resulting in heightened perception of symptoms and sensations from the body in conjunction with autonomic hyper-reactivity to perceived challenges. We studied 23 patients with PIFS and 25 healthy matched control subjects. A heartbeat discrimination task and a pressure pain threshold test were used to assess interoceptive sensitivity. Cardiac response was assessed over a 4-min Stroop task. PIFS was associated with higher accuracy in heartbeat discrimination and a lower pressure pain threshold. Increased interoceptive sensitivity correlated strongly with current symptoms and potentiated differences in the cardiac response to the Stroop task, which in PIFS was characterized by insensitivity to task difficulty and lack of habituation. Our results provide the first evidence of heightened interoceptive sensitivity in PIFS. Together with the distinct pattern in cardiac responsivity these findings present a picture of physiological hyper-vigilance and response inflexibility.

Kato K, Sullivan PF, Pedersen NL.	School of Nursing and Rehabilitation, International University of Health and Welfare, Odawara, Japan. kenji-kato@umin.ac.jp	Latent class analysis of functional somatic symptoms in a population-based sample of twins.	J Psychosom Res. 2010 May;68(5):447-53. Epub 2010 Mar 1.	OBJECTIVE: This study aimed to investigate empirically how and in what way individuals with symptoms of functional somatic syndromes should be classified. We also aimed to look into genetic and environmental influences on the classification. METHOD: A total of 28,531 twins aged 41-64 underwent screening interviews via a computer-assisted data collection system from 1998 to 2002. Nine functional somatic symptoms (abnormal tiredness, general muscular pain, recurrent abdominal discomfort, back pain, gastroesophageal reflux, recurrent headache, recurrent urinary problem, dizziness, breathlessness at rest) were assessed using structured questions in a blinded manner. Latent class analysis was applied to the data. Structural equation modeling was further performed in order to estimate the relative importance of genetic and environmental influences on class probability. RESULTS: Latent class analysis resulted in a five-class solution. Individuals in the first class did not show any health problems. Those assigned to the second, third, and fourth classes tended to have abnormal tiredness, gastrointestinal problems, and pain-related symptoms, respectively. Individuals in the fifth class had multiple symptoms to a greater extent than the other classes. All the five classes showed modest genetic influences (7-29% of the total variation) with gender differences except Class 3; however, the majority of influences on the class membership derived from unique environmental effects. CONCLUSION: The findings suggested the necessity of redefining the existing classification criteria for functional somatic syndromes in terms of single (uncomplicated) or multiple (complicated) syndromes. Environmental influences are important for the etiology of functional somatic syndromes.
Katz BZ, Boas S,	Department of	Exercise tolerance	J Pediatr. 2010	OBJECTIVE: Six months after acute infectious mononucleosis (IM), 13% of adolescents meet criteria

Shiraishi Y, Mears CJ, Taylor R.	Pediatrics, Northwestern University, Feinberg School of Medicine and Children's Memorial Hospital, Chicago, IL 60614, USA. bkatz@northwestern.edu	testing in a prospective cohort of adolescents with chronic fatigue syndrome and recovered controls following infectious mononucleosis.	Sep;157(3):468-72, 472.e1. Epub 2010 May 6.	for chronic fatigue syndrome (CFS). We measured exercise tolerance in adolescents with CFS and control subjects 6 months after IM. STUDY DESIGN: Twenty-one adolescents with CFS 6 months after IM and 21 recovered control subjects performed a maximal incremental exercise tolerance test with breath-by-breath gas analysis. Values expressed are mean+/-standard deviation. RESULTS: The adolescents diagnosed with CFS and control subjects did not differ in age, weight, body mass index, or peak work capacity. Lower oxygen consumption peak percent of predicted was seen in adolescents with CFS compared with control subjects (CFS 99.3+/-16.6 vs control subject 110.7+/-19.9, P=.05). Peak oxygen pulse also was lower in adolescents with CFS compared with recovered control subjects (CFS 12.4+/-2.9 vs control subjects 14.9+/-4.3, P=.03). CONCLUSIONS: Adolescents with CFS 6 months after IM have a lower degree of fitness and efficiency of exercise than recovered adolescents. Whether these abnormal exercise findings are a cause or effect of CFS is unknown. IM can lead to both fatigue and measurable changes in exercise testing in a subset of adolescents.

Kempke S, Goossens L, Luyten P, Bekaert P, Van Houdenhove B, Van Wambeke P.	Department of Psychology, University of Leuven, Leuven, Belgium. stefan.kempke@psy.kuleuven.be	Predictors of outcome in a multi-component treatment program for chronic fatigue syndrome.	J Affect Disord. 2010 Oct;126(1-2):174-9. Epub 2010 Feb 18.	BACKGROUND: Little is known about factors predicting treatment outcome in chronic fatigue syndrome (CFS). METHODS: Based on Vercoulen et al.'s (1998) cognitive-behavioral model of perpetuating factors in CFS, the predictive value of the following patient characteristics were examined in a sample of 178 CFS patients who followed a multi-component treatment program: (1) somatic attributions, (2) psychological attributions, (3) sense of control over symptoms, (4) physical activity, (5) functional impairment, (6) somatic focus, and (7) severity of depression. RESULTS: Only pre-treatment severity of depression was associated with negative treatment outcome defined in terms of post-treatment fatigue and improvement in fatigue. LIMITATIONS: The study was conducted at a tertiary care centre and did not include a control group or a long-term follow-up. CONCLUSIONS:

				Level of depression may be the most important factor of the cognitive-behavioral model predicting post-treatment fatigue in CFS. Hence, findings suggest that treatment of CFS should include a focus on severity of depression.
Kempke S, Van Houdenhove B, Luyten P, Goossens L, Bekaert P, Van Wambeke P.	Department of Psychology, University of Leuven, Leuven, Belgium.	Unraveling the role of perfectionism in chronic fatigue syndrome: Is there a distinction between adaptive and maladaptive perfectionism?	Psychiatry Res. 2010 Oct 18. [Epub ahead of print]	In the current study, we investigated whether the distinction between adaptive (i.e. high personal standards) and maladaptive (i.e. concern over mistakes and doubt about actions) perfectionism that has been found in the literature, is also valid in patients with chronic fatigue syndrome (CFS). We hypothesized that maladaptive, but not adaptive, perfectionism would be significantly and positively related to severity of fatigue and depression in CFS. We examined this hypothesis in a sample of 192 CFS patients using structural equation modelling (SEM). Although the two perfectionism dimensions were related to each other, results supported a model in which only maladaptive perfectionism was positively related to severity of fatigue and depression. Further, we found that depression fully mediated the effect of maladaptive perfectionism on fatigue. The results suggest that adaptive and maladaptive perfectionism are two distinct, albeit related, dimensions in CFS. Findings of this study have important implications for theory and treatment of CFS, particularly for cognitive-behavioral treatment.
Kennedy G, Khan F, Hill A, Underwood C, Belch JJ.	Vascular and Inflammatory Diseases Research Unit, The Institute of Cardiovascular Research, Centre for Cardiovascular and Lung Biology, Division of Medical Sciences, Ninewells Hospital and Medical School, Dundee, Scotland, United Kingdom. g.y.kennedy@dundee.ac.uk	Biochemical and vascular aspects of pediatric chronic fatigue syndrome.	Arch Pediatr Adolesc Med. 2010 Sep;164(9):817-23. Comment in: Arch Pediatr Adolesc Med. 2010 Sep;164(9):880-1.	OBJECTIVE: To evaluate the biochemical and vascular aspects of pediatric chronic fatigue syndrome/myalgic encephalomyelitis (CFS/ME). DESIGN: Cross-sectional clinical study. SETTING: Tayside, Scotland, United Kingdom. PARTICIPANTS: Twenty-five children with CFS/ME and 23 healthy children recruited from throughout the United Kingdom. INTERVENTIONS: Participants underwent a full clinical examination to establish a diagnosis of CFS/ME and were asked to describe and score their CFS/ME symptoms. Biochemical markers were measured. Arterial wave reflection was estimated to assess systemic arterial stiffness. MAIN OUTCOME MEASURES: Markers of oxidative stress and free radicals, C-reactive protein level, white blood cell apoptosis, and arterial wave reflection. RESULTS: Children with CFS/ME had increased oxidative stress compared with control individuals (isoprostanes: 252.30 vs 215.60 pg/mL, P = .007; vitamin C, mean [SD]: 0.84 [0.26] vs 1.15 [0.28] mg/dL, P < .001; vitamin E, 8.72 [2.39] vs 10.94 [3.46] microg/mL, P = .01) and increased white blood cell apoptosis (neutrophils: 53.7% vs 35.7%, P = .005; lymphocytes: 40.1% vs 24.6%, P = .009). Arterial stiffness variables did not differ significantly between groups (mean augmentation index, -0.57% vs -0.47%, P = .09); however, the derived variables significantly correlated with total (r = 0.543, P = .02) and low-density lipoprotein (r = 0.631, P = .004) cholesterol in patients with CFS/ME but not in controls. CONCLUSIONS: Biomedical anomalies seen in adults with CFS/ME-increased oxidative stress and increased white blood cell apoptosis-can also be observed in children with clinically diagnosed CFS/ME compared with matched controls. Unlike in their adult counterparts, however, arterial stiffness remained within the reference range in these pediatric patients.
Kennedy G, Underwood C, Belch JJ.	Ninewells Hospital and Medical School, Division of Medical Sciences, Mail Box 1, Centre for Cardiovascular	Physical and functional impact of chronic fatigue syndrome/myalgic encephalomyelitis in childhood.	Pediatrics. 2010 Jun;125(6):e1324-30. Epub 2010 May 17.	OBJECTIVE: The aim of this study was to compare self-reported and parent-reported quality of life for a group of pediatric patients with chronic fatigue syndrome (CFS)/myalgic encephalomyelitis (ME) and age- and gender-matched healthy control children, to determine the extent of functional and physical impairment. METHODS: The Child Health Questionnaire was completed by 25 children with CFS/ME, who were recruited throughout the United Kingdom, and by 23 age-, gender-, and Tanner scale-matched control children. In addition, patients were asked questions about the background to their

	and Lung Biology, Vascular and Inflammatory Diseases Research Unit, Dundee DD1 9SY, United Kingdom. g.y.kennedy@dundee.ac.uk			illness (ie, precipitating factors), the status of their illness, and school attendance. RESULTS: The median illness duration for patients was 3 years. Sixty-eight percent of the children said that their illness developed quickly, and the illness had an infectious onset for 88%. Only 1 child (4%) attended school full-time, whereas 12 (48%) attended school part-time and 8 (32%) received home tuition only. Children with CFS/ME scored significantly lower for 10 of 14 Child Health Questionnaire concepts; the lowest scores were observed for global health (scores of 21.4 and 84.1 for patients and control subjects, respectively; P < .0001) and role/social limitations attributable to physical health problems (scores of 24.9 and 100, respectively; P < .0001). Quality of life for the children with CFS/ME compared unfavorably with previously published results for pediatric patients with type 1 diabetes mellitus or asthma. CONCLUSION: The quality of life of children with CFS/ME was profoundly reduced, compared with that of their healthy counterparts.
Kermode-Scott B.		Canada bans blood donations from people with history of chronic fatigue syndrome.	BMJ. 2010 Apr 9;340:c1974. doi: 10.1136/bmj.c1974.	
Kerr JR, Gough J, Richards SC, Main J, Enlander D, McCreary M, Komaroff AL, Chia JK.	Department of Cellular & Molecular Medicine, St George's University of London, London, UK. jkerr@sgul.ac.uk	Antibody to parvovirus B19 nonstructural protein is associated with chronic arthralgia in patients with chronic fatigue syndrome/myalgic encephalomyelitis.	J Gen Virol. 2010 Apr;91(Pt 4):893-7. Epub 2009 Dec 9.	Chronic fatigue syndrome/myalgic encephalomyelitis (CFS/ME) is a neuro-immune disease of uncertain pathogenesis. Human parvovirus B19 infection has been shown to occur just prior to development of the onset of CFS/ME in several cases, although B19 seroprevalence studies do not show any significant differences between CFS/ME and controls. In this study, we analysed parvovirus B19 markers in CFS/ME patients (n=200), diagnosed according to Fukuda CDC criteria, and normal blood donors (n=200). Serum from each subject was tested for anti-B19 VP2 IgM and IgG (by Biotrin ELISA), anti-B19 NS1 IgM and IgG (by immunofluorescence), and B19 DNA (by real-time PCR). CFS/ME patients and normal blood donors had a similar B19 seroprevalence (75 % versus 78 %, respectively). Eighty-three CFS patients (41.5 %) as compared with fourteen (7 %) normal blood donors tested positive for anti-B19 NS1 IgG (chi(2)=64.8; P<0.0001; odds ratio=9.42, CI 5.11-17.38). Of these 83 patients, 61 complained of chronic joint pain, while 22 did not. Parvovirus B19 DNA was detected in serum of 11 CFS patients and none of the controls by Taqman real-time PCR (chi(2)=9.35, P<0.002). Positivity for anti-B19 NS1 IgG was associated with higher expression levels of the human CFS-associated genes NHLH1 and GABPA. As NS1 antibodies are thought to indicate chronic or severe courses of B19 infection, these findings suggest that although the seroprevalence of B19 in CFS patients is similar to controls, the immune control of the virus in these patients may not be efficient.
Kim S, Rusmevichientong A, Dong B, Remenyi R, Silverman RH, Chow SA.	Biomedical Engineering Interdepartmental Program, University of California Los Angeles, Los Angeles, California,	Fidelity of target site duplication and sequence preference during integration of xenotropic murine leukemia virus-related virus.	PLoS One. 2010 Apr 20;5(4):e10255.	Xenotropic murine leukemia virus (MLV)-related virus (XMRV) is a new human retrovirus associated with prostate cancer and chronic fatigue syndrome. The causal relationship of XMRV infection to human disease and the mechanism of pathogenicity have not been established. During retrovirus replication, integration of the cDNA copy of the viral RNA genome into the host cell chromosome is an essential step and involves coordinated joining of the two ends of the linear viral DNA into staggered sites on target DNA. Correct integration produces proviruses that are flanked by a short direct repeat, which varies from 4 to 6 bp among the retroviruses but is invariant for each particular retrovirus. Uncoordinated joining of the two viral DNA ends into target DNA can cause insertions, deletions, or

	United States of America.			other genomic alterations at the integration site. To determine the fidelity of XMRV integration, cells infected with XMRV were clonally expanded and DNA sequences at the viral-host DNA junctions were determined and analyzed. We found that a majority of the provirus ends were correctly processed and flanked by a 4-bp direct repeat of host DNA. A weak consensus sequence was also detected at the XMRV integration sites. We conclude that integration of XMRV DNA involves a coordinated joining of two viral DNA ends that are spaced 4 bp apart on the target DNA and proceeds with high fidelity.

Kishi A, Natelson BH, Togo F, Struzik ZR, Rapoport DM, Yamamoto Y.	Educational Physiology Laboratory, Graduate School of Education, The University of Tokyo, 113-0033, Japan.	Sleep stage transitions in chronic fatigue syndrome patients with or without fibromyalgia.	Conf Proc IEEE Eng Med Biol Soc. 2010;1:5391-4.	Chronic fatigue syndrome (CFS) and fibromyalgia (FM) are medically unexplained conditions that share considerable overlapping symptoms, including sleep-related complaints. However, differences between the two conditions have been reported, and we hypothesized that dynamic aspects of sleep, recently attracting scientific interests, would be different in the two groups of patients. We thus study transition probabilities between sleep stages of CFS patients with or without FM. Subjects were 26 healthy controls, 14 CFS patients without FM (CFS alone) and 12 CFS patients with FM (CFS+FM) - all women. We studied transition probabilities between sleep stages (waking, REM sleep and Stage I, Stage II and slow-wave sleep (Stage III+IV)). We found that probabilities of transition from REM sleep to waking were significantly greater in CFS alone than in controls; we have reported previously this

				sleep disruption as the specific sleep problem for CFS alone [Kishi et al., 2008]. Probabilities of transitions from waking, REM sleep and Stage I to Stage II, and those from slow-wave sleep to Stage I, were significantly greater in CFS+FM than in controls; the former might indicate increased sleep pressure in CFS+FM and the latter may be the specific sleep problem of CFS+FM. These results suggest that CFS and FM are different illnesses associated with different problems of sleep regulation.
Knoop H, Prins JB, Moss-Morris R, Bleijenberg G.	Expert Centre Chronic Fatigue, Radboud University Nijmegen Medical Centre, 6500 HB Nijmegen, The Netherlands. j.knoop@nkcv.umcn.nl	The central role of cognitive processes in the perpetuation of chronic fatigue syndrome.	J Psychosom Res. 2010 May;68(5):489-94. Epub 2010 Mar 16.	OBJECTIVE: Chronic fatigue syndrome (CFS) is considered to be one of the functional somatic syndromes (FSS). Cognitions and behavior are thought to perpetuate the symptoms of CFS. Behavioral interventions based on the existing models of perpetuating factors are quite successful in reducing fatigue and disabilities. The evidence is reviewed that cognitive processes, particularly those that determine the perception of fatigue and its effect on behavior, play a central role in the maintenance of symptoms. METHOD: Narrative review. RESULTS: Findings from treatment studies suggest that cognitive factors mediate the positive effect of behavioral interventions on fatigue. Increased fitness or increased physical activity does not seem to mediate the treatment response. Additional evidence for the role of cognitive processes is found in studies comparing the subjective beliefs patients have of their functioning with their actual performance and in neurobiological research. CONCLUSION: Three different cognitive processes may play a role in the perpetuation of CFS symptoms. The first is a general cognitive representation in which fatigue is perceived as something negative and aversive and CFS is seen as an illness that is difficult to influence. The second process involved is the focusing on fatigue. The third element is formed by specific dysfunctional beliefs about activity and fatigue.
Krisciukaitis A, Simoliuniene R, Tamosiunas M, Saferis V, Vainoras A, Gargasas L.	Institute for Biomedical Research, Kaunas University of Medicine, Eiveniu 4, 50009 Kaunas, Lithuania. akri@kmu.lt	Efficiency evaluation of autonomic heart control by using the principal component analysis of ECG P-wave.	Methods Inf Med. 2010;49(2):161-7. Epub 2010 Feb 22.	BACKGROUND: Cardiac output is controlled by the autonomic nervous system by changing the heart rate and/or the contractions of the heart muscle in response to the hemodynamic needs of the whole body. Malfunction of these mechanisms causes the postural orthostatic tachycardia syndrome and/or the chronic fatigue syndrome. Evaluation of functionality and efficiency of the control mechanisms could give valuable diagnostic information in the early stages of dysfunction of the heart control systems and help to monitor the healing process in rehabilitation period after interventions. OBJECTIVES: In this study we demonstrate how P-wave changes evoked by an orthostatic test could be quantitatively evaluated by using the method based on the principal component analysis. METHODS: ECG signals were recorded during an orthostatic test performed according to the typical protocol in three groups of volunteer subjects representing healthy young and older persons, part of which had transient periods of supraventricular arrhythmias. Quantitative evaluation of P-wave morphology changes was performed by means of principal component analysis-based method. RESULTS: Principal component-based estimates showed certain variety of P-wave shape during orthostatic test, what revealed a possibility to evaluate the properties of parasympathetic heart control. CONCLUSIONS: Quantitative evaluation of ECG P-wave changes evoked by an orthostatic test by using a newly developed method provides a quantitative estimate for functionality and efficiency of the heart rate control mechanisms. The method could be used in eHealth systems.

		fatigue syndrome.		
Kumar A, Vashist A, Kumar P.	Pharmacology Division, University Institute of Pharmaceutical Sciences, UGC Centre of Advanced Study, Panjab University, Chandigarh, India. kumaruips@yahoo.com	Potential role of pioglitazone, caffeic acid and their combination against fatigue syndrome-induced behavioural, biochemical and mitochondrial alterations in mice.	Inflammopharmacology. 2010 Oct;18(5):241-51. Epub 2010 Jul 3.	Chronic fatigue is an illness characterised by persistent and relapsing fatigue, often accompanied by numerous neuropsychiatric problems, such as anxiety and depression. The aetiology of chronic fatigue remains unclear so far. However, recent studies suggested the involvement of oxidative stress in this chronic debilitating disease. Alternatively, antioxidants have also been reported to have beneficial effect against chronic fatigue-like conditions. Therefore, present study has been designed to explore the potential role of pioglitazone, caffeic acid and their combination against chronic fatigue-like condition in mice. In the experimental protocol, the mice were put on the running wheel apparatus for 6 min test session daily for 21 days which produced fatigue-like condition. The locomotor activity and anxiety levels were measured on 0, 8th, 15th and 22nd days. The brains were isolated on 22nd day immediately after the behavioural assessments, oxidative damage and mitochondrial enzyme complexes were then estimated subsequently. Three weeks pioglitazone (5 and 10 mg/kg) and caffeic acid (5 and 10 mg/kg) pretreatment significantly attenuated the chronic fatigue-like condition (restored running wheel activity, locomotor activity and reduced anxiety-like behaviour) as compared to that in control (chronic fatigue) animals. Further, pioglitazone (5 and 10 mg/kg) and caffeic acid (5 and 10 mg/kg) drug treatments for 3 weeks significantly attenuated oxidative damage (decreased lipid peroxidation, nitrite concentration, restored reduction in glutathione and catalase levels), altered mitochondrial enzymes complex (I, II and IV) activities and mitochondrial redox activity (MTT assay) when compared with control. Further, combination of lower dose of pioglitazone (5 mg/kg) and caffeic acid (5 mg/kg) showed significant synergism in their protective effect which was significant as compared to their effect per se. The present study highlights the potential role of pioglitazone, caffeic acid and their combination in the pathophysiology of chronic fatigue-like condition in mice.
Kunstman KJ, Bhattacharya T, Flaherty J, Phair JP, Wolinsky SM.	Northwestern University, Chicago, Illinois 60611, USA.	Absence of xenotropic murine leukemia virus-related virus in blood cells of men at risk for and infected with HIV.	AIDS. 2010 Jul 17;24(11):1784-5.	Xenotropic murine leukemia virus-related virus has been detected in blood cells of patients with chronic fatigue syndrome and in 3.7% of healthy controls from the same geographic region. We evaluated 996 men who were participants in the Multicenter AIDS Cohort Study for xenotropic murine leukemia virus-related virus sequences in blood cells by means of a real-time quantitative PCR assay. Xenotropic murine leukemia virus-related virus was detected in none of the men on the basis of the absence of xenotropic murine leukemia virus-related virus DNA, suggesting that infection may be population-specific.
Lacerda EM, Nacul L, Pheby D, Shepherd C, Spencer P.	London School of Hygiene & Tropical Medicine, EPH/NPHIRU/CFS/ME Observatory, London, UK. Eliana.Lacerda@lshtm.ac.uk	Exploring the feasibility of establishing a disease-specific post-mortem tissue bank in the UK: a case study in ME/CFS.	J Clin Pathol. 2010 Nov;63(11):1032-4. Epub 2010 Oct 5.	BACKGROUND: Myalgic encephalomyelitis/chronic fatigue syndrome (ME/CFS) is a condition, the aetiology of which remains controversial, and there is still no consensus on its nature and determination. It has rarely been studied in post-mortem examinations, despite increasing evidence of abnormalities from neuroimaging studies. AIM: To ascertain the feasibility of developing a national post-mortem ME/CFS tissue bank in the UK, to enhance studies on aetiology and pathogenesis, including cell and tissue abnormalities associated with the condition. METHODS: The case study was carried out combining qualitative methods, ie, key informant interviews, focus group discussions with people with ME/CFS, and a workshop with experts in ME/CFS or in tissue banking. RESULTS AND CONCLUSIONS: The study results suggest that the establishment of the post-mortem ME/CFS tissue bank is both desirable and feasible, and would be acceptable to the possible tissue donors, provided that some issues were explicitly addressed.

Lakhan SE, Kirchgessner A.	Global Neuroscience Initiative Foundation, Los Angeles, CA, USA. slakhan@gnif.org.	Gut inflammation in chronic fatigue syndrome.	Nutr Metab (Lond). 2010 Oct 12;7:79.	ABSTRACT: Chronic fatigue syndrome (CFS) is a debilitating disease characterized by unexplained disabling fatigue and a combination of accompanying symptoms the pathology of which is incompletely understood. Many CFS patients complain of gut dysfunction. In fact, patients with CFS are more likely to report a previous diagnosis of irritable bowel syndrome (IBS), a common functional disorder of the gut, and experience IBS-related symptoms. Recently, evidence for interactions between the intestinal microbiota, mucosal barrier function, and the immune system have been shown to play a role in the disorder's pathogenesis.Studies examining the microecology of the gastrointestinal (GI) tract have identified specific microorganisms whose presence appears related to disease; in CFS, a role for altered intestinal microbiota in the pathogenesis of the disease has recently been suggested. Mucosal barrier dysfunction promoting bacterial translocation has also been observed. Finally, an altered mucosal immune system has been associated with the disease. In this article, we discuss the interplay between these factors in CFS and how they could play a significant role in GI dysfunction by modulating the activity of the enteric nervous system, the intrinsic innervation of the gut.If an altered intestinal microbiota, mucosal barrier dysfunction, and aberrant intestinal immunity contribute to the pathogenesis of CFS, therapeutic efforts to modify gut microbiota could be a means to modulate the development and/or progression of this disorder. For example, the administration of probiotics could alter the gut microbiota, improve mucosal barrier function, decrease pro-inflammatory cytokines, and have the potential to positively influence mood in patients where both emotional symptoms and inflammatory immune signals are elevated. Probiotics also have the potential to improve gut motility, which is dysfunctional in many CFS patients.
Landmark-Høyvik H, Reinertsen KV, Loge JH, Kristensen VN, Dumeaux V, Fosså SD, Børresen-Dale AL, Edvardsen H.	Department of Genetics, Institute for Cancer Research, Oslo University Hospital Radiumhospitalet, Oslo, Montebello, Norway.	The genetics and epigenetics of fatigue.	PM R. 2010 May;2(5):456-65.	Fatigue is a common symptom and includes both physical and mental components. It can be associated with a variety of different syndromes and diseases, but in many cases is not associated with other comorbid conditions. Most humans have experienced acute fatigue in relation to different stressors. Acute fatigue typically decreases as the effect of the triggering factor is reduced and a normal homeostatic balance is restored. Fatigue that persists for 6 months or more is termed chronic fatigue. Chronic fatigue (CF) in combination with a minimum of 4 of 8 symptoms and the absence of diseases that could explain these symptoms, constitute the case definition for chronic fatigue syndrome. In spite of its prevalence, the biology of fatigue is relatively poorly understood and biological markers have not yet been identified. This literature search was performed in PubMed to identify research on the genetics and epigenetics of fatigue. Publications were included if fatigue was a major topic and the topic was combined with genetic and/or epigenetic measurements in adult humans. A total of 40 publications were identified. Although altered functioning in the hypothalamic-pituitary-adrenal axis, the serotonergic system, and associations with infectious agents have been identified, the search for genetic or epigenetic markers of fatigue, either in the context of CF or chronic fatigue syndrome (CFS) has been relatively unproductive or, in the case of epigenetics, nonexistent. Although several studies, both hypothesis-testing and hypothesis-generating, have been performed to search for biomarkers, they have mostly been underpowered, restricted by the heterogeneity of the phenotype, or limited by an unsystematic study design. To be able to confirm the hypothesis that risk for, or levels of, fatigue are influenced by the genetic or epigenetic background of an individual, studies need to be based on larger sample sizes with a more clearly defined phenotype.

				Studies need to focus not only on the influence of a single aspect such as single nucleotide polymorphisms (SNPs) or differential gene expression on disease risk or state, but also on the systems biology behind the disease in combination with information on environmental influences and validation of findings in functional studies.
Langenberg PW, Wallach EE, Clauw DJ, Howard FM, Diggs CM, Wesselmann U, Greenberg P, Warren JW.	Department of Epidemiology and Preventive Medicine, University of Maryland School of Medicine, Baltimore, MD, USA.	Pelvic pain and surgeries in women before interstitial cystitis/painful bladder syndrome.	Am J Obstet Gynecol. 2010 Mar;202(3):286.e1 -6. Epub 2009 Dec 22.	OBJECTIVE: The objective of the study was to compare subjects with interstitial cystitis/painful bladder syndrome (IC/PBS) with controls on prior surgeries. STUDY DESIGN: IC/PBS subjects were compared with matched controls on surgeries and possible surgical indications prior to their index dates. RESULTS: Adjusted for demographic variables, logistic regression showed subjects exceeded controls in surgeries longer than 12 months and less than 1 month before the index date. However, addition of possible surgical indications showed chronic pelvic pain (CPP) to have a strong association with IC/PBS, whereas associations with surgeries were reduced to nonsignificance. CONCLUSION: Although women with IC/PBS were more likely to have experienced prior surgeries than controls, the apparent indications for surgeries, not the surgeries themselves, were stronger risk factors for IC/PBS. In particular, a prior history of CPP had a strong association with IC/PBS. Several features of study design, including extensive medical record review, suggest that prior CPP was not undiagnosed IC/PBS. Further investigation of CPP may yield insight into the pathogenesis of IC/PBS.
Larun L, Malterud K.	Research Unit for General Practice, Uni Research, Bergen, Norway; Norwegian Knowledge Centre for the Health Services, Oslo, Norway.	Finding the right balance of physical activity A focus group study about experiences among patients with chronic fatigue syndrome.	Patient Educ Couns. 2010 Jun 25. [Epub ahead of print]	OBJECTIVE: To explore contexts of experiences of physical activity perceived as beneficial or harmful for CFS patients. METHODS: A qualitative study with empirical data from two focus groups with purposive sampling. Mean age was 50, two of ten participants were male, and social demographics varied. Participants were invited to share stories of good as well as bad experiences concerning physical activity. Data were analysed with systematic text condensation. RESULTS: Participants were not averse to physical activity, but specific preconditions would determine how the activity was perceived. Physical activity was experienced as helpful and enjoyable, especially related to leisure activities where flexible and individual adaptation was feasible. Non-customized activity may precipitate set-backs giving patients the impression of losing control and being betrayed by their bodies. Strategies to review energy usage in daily life could adjust expectations, diminish stress load and assist in approaching a more appropriate priority and balance. CONCLUSION: Self-management, body awareness and physical activity of choice combined with facilitation and advice from health care professionals is essential to achieve a positive outcome. PRACTICE IMPLICATIONS: Exercise programmes should be adapted, paced, and self-managed in accordance with personal preferences and activity levels to be beneficial and empowering for CFS patients.
Lavergne MR, Cole DC, Kerr K, Marshall LM.	Women's College Hospital, Family and Community Medicine, Toronto, ON M5S 1B2.	Functional impairment in chronic fatigue syndrome, fibromyalgia, and multiple chemical sensitivity.	Can Fam Physician. 2010 Feb;56(2):e57-65.	OBJECTIVE: To characterize patients diagnosed with multiple chemical sensitivity (MCS), chronic fatigue syndrome (CFS), or fibromyalgia (FM), to compare their level of function with Canadian population average values, and to assess factors associated with function. DESIGN: Chart review and abstraction of clinical information. SETTING: The Environmental Health Clinic (EHC) at Women's College Hospital in Toronto, Ont, which is a provincial referral centre for patients with illnesses with suspected environmental links, especially MCS, CFS, and FM. PARTICPANTS: A total of 128 consecutive patients diagnosed with 1 or more of MCS, CFS, or FM, seen between January 2005 and March 2006 at the EHC. MAIN OUTCOME MEASURES: Demographic and socioeconomic characteristics, comorbid diagnoses, duration of illness, health services usage, life stresses, helpful therapeutic strategies, and

				functional impairment measured by the Short Form-36, compared with Canadian population average values. Factors significantly associated with function in bivariate analyses were included in multiple linear and logistic regression models. RESULTS: The patient population was predominantly female (86.7%), with a mean age of 44.6 years. Seventy-eight patients had discrete diagnoses of 1 of MCS, CFS, or FM, while the remainder had 2 or 3 overlapping diagnoses. Most (68.8%) had stopped work, and on average this had occurred 3 years after symptom onset. On every Short Form-36 subscale, patients had markedly lower functional scores than population average values, more so when they had 2 or 3 of these diagnoses. Having FM, younger age at onset, and lower socioeconomic status were most consistently associated with poor function. CONCLUSION: Patients seen at the EHC demonstrated marked functional impairment, consistent with their reported difficulties working and caring for their homes and families during what should be their peak productive years. Early comprehensive assessment, medical management, and social and financial support might avoid the deterioration of function associated with prolonged illness. Education and information resources are required for health care professionals and the public, along with further etiologic and prognostic research.
Lawn T, Kumar P, Knight B, Sharpe M, White PD.	East London Foundation Trust , St Bartholomew's Hospital , London EC1A 7BE , UK.	Psychiatric misdiagnoses in patients with chronic fatigue syndrome.	JRSM Short Rep. 2010 Sep 6;1(4):28.	OBJECTIVES: The aim of this study was to examine the accuracy of doctors at diagnosing co-morbid psychiatric disorders in patients with chronic fatigue syndrome (CFS). DESIGN: Case series comparing clinical diagnoses with a standardized structured psychiatric interview. SETTING: Secondary care specialist chronic fatigue syndrome clinic. PARTICIPANTS: One hundred and thirty-five participants of a randomized controlled trial of non-pharmacological treatments at one centre in the PACE trial. MAIN OUTCOME MEASURES: Current psychiatric diagnoses made by CFS specialist doctors, compared with current psychiatric diagnoses made independently using a structured psychiatric interview. RESULTS: Clinicians identified 59 (44%, 95% CI 39-56%) of patients as suffering from a co-morbid psychiatric disorder compared to 76 (56%, CI 53-69%) by structured interview. Depressive and anxiety disorders were most common. Clinicians were twice as likely to miss diagnoses (30 patients, 22%) than misdiagnose them (13, 10%). Psychiatrists were less likely to miss diagnoses than other clinicians, but were as likely to misdiagnose them. CONCLUSIONS: Doctors assessing patients in a chronic fatigue syndrome clinic miss psychiatric diagnoses more often than misdiagnosing them. Missed diagnoses are common. CFS clinic doctors should be trained to diagnose psychiatric disorders.
Lee AK, Miller WC, Townson AF, Anton HA; F2N2 Research Group.	Faculty of Medicine, University of British Columbia, Vancouver, British Columbia, Canada.	Medication use is associated with fatigue in a sample of community-living individuals who have a spinal cord injury: a chart review.	Spinal Cord. 2010 May;48(5):429-33. Epub 2009 Nov 17.	OBJECTIVES: To investigate the relationship between medications known to cause fatigue in spinal cord injury (SCI) and fatigue severity and to describe the pattern of prescription of these medications. STUDY DESIGN: Retrospective chart review. SETTING: GF Strong Rehabilitation Centre, Vancouver, British Columbia, Canada. METHODS: Medical charts of 136 individuals admitted to the GF Strong Outpatient SCI Program between December 2004 and May 2007 were reviewed. Data collected included information on medications, clinical and demographic characteristics and Fatigue Severity Scale (FSS) scores. Multiple linear regression techniques were used to analyse the data. RESULTS: Fifty-two percent of the subjects had clinically relevant fatigue. As a group, the subjects were taking 147 different medications; 41/147 medications were identified as causing fatigue. The two most commonly prescribed categories of medications were antispasticity medications (75 subjects) and analgesic medications (61 subjects). Although several variables were found to contribute to the FSS

				scores including the use of fatigue-causing medications, the presence of pain (7.6% of variance) and the use of fatigue-causing analgesics (4.2% of variance) explained the most variance in the scores. CONCLUSION: Fatigue is prevalent in outpatients with SCI. Fatigue-causing medications contribute to a higher FSS score. Clinicians treating persons with SCI should be aware that fatigue is a common and significant problem. Clinicians should be aware that fatigue may be exacerbated by the use of medication and should enquire about the effects of medication on fatigue when assessing and prescribing new medications.

Leone SS, Wessely S, Huibers MJ, Knottnerus JA, Kant I.	Department of Epidemiology, Maastricht University, Maastricht, The Netherlands.	Two sides of the same coin? On the history and phenomenology of chronic fatigue and burnout.	Psychol Health. 2010 Apr 29:1-16. [Epub ahead of print]	Background: Burnout and chronic fatigue syndrome (CFS) are two fatigue syndromes which have developed largely independently from each other, yet whose similarities in symptoms can be a source of confusion. We aim to explore the phenomenology of burnout and CFS in a historical context as this may provide some insight into the links and relationship between these conditions. Method: A narrative review based on literature in the fields of history, social science and medicine. Results: The origins of CFS lie within medicine, whereas burnout developed in a psychological setting. As well as symptoms, burnout and CFS also share similar themes such as an overload process triggering illness onset, the need for restoration of depleted energy, external causal attributions and the characteristics of people suffering from these illnesses. However, these themes are expressed in either psychological or medical terms according to the historical background. Conclusion: Despite their similarities, there have been few direct comparisons of the two concepts. Culture, illness perceptions and accountability are important issues in both conditions and could contribute to their differences. Comparing burnout and CFS within one sample frame, thus looking beyond the psychology/medicine divide, could be a useful first step towards understanding their relationship.
Leone SS.		A disabling combination: fatigue and depression.	Br J Psychiatry. 2010 Aug;197:86-7. Comment on: Br J Psychiatry. 2010 Aug;197:106-13.	Fatigue and common psychiatric symptoms - depression in particular - have consistently been found to be strongly associated. All have a negative impact on functional status, but evidence suggests that functional impairment is especially marked when they co-occur. Therefore, it is pertinent to understand the relationship between fatigue and depression.

Limonard GJ, Peters JB, Nabuurs-Franssen MH, Weers-Pothoff G, Besselink R, Groot CA, Dekhuijzen PN, Vercoulen JH.	Department of Pulmonary Diseases, Canisius-Wilhelmina Hospital, Weg door Jonkerbos 100, 6525 SZ Nijmegen, The Netherlands. gjmlimonard@gmail.com	Detailed analysis of health status of Q fever patients 1 year after the first Dutch outbreak: a case-control study.	QJM. 2010 Dec;103(12):953-8. Epub 2010 Aug 27.	BACKGROUND: Q fever is a zoonosis caused by the obligate intracellular bacterium Coxiella burnetii. The two long-term complications, after primary infection, are chronic Q fever in ~1% of patients, and a chronic fatigue syndrome in 10-20%. However, the existence of a protracted decreased health status after Q fever remains controversial. AIM: To determine the health status of the patients of the Q fever outbreak in The Netherlands in 2007, 1 year after primary infection. DESIGN: Cross-sectional case-control study. METHODS: Health status of the patients from the 2007 Dutch Q fever outbreak was compared to age-, sex- and geographically matched and Q fever seronegative controls. Health status of both patients and controls was assessed with the Nijmegen Clinical Screening Instrument (NCSI). RESULTS: Fifty-four Q fever patients provided 34 years of age- and sex-matched controls from the same neighbourhood. Eleven controls had positive Q fever serology and were excluded. Q fever patients had significantly more problems on the subdomains of symptoms and functional impairment. Overall quality of life was decreased in both patients and controls, 59% vs. 39%, respectively, ns). Severe fatigue levels were present in 52% of patients vs. 26% in controls ($P < 0.05$). CONCLUSION: These data support a sustained decrease in many aspects of health status in Q fever patients in The Netherlands, 1 year after primary infection.
Lloyd A, White P, Wessely S, Sharpe M, Buchwald D.	Centre for Infection and Inflammation Research, University of New South Wales, Sydney, Australia 2052. a.lloyd@unsw.edu.au	Comment on "Detection of an infectious retrovirus, XMRV, in blood cells of patients with chronic fatigue syndrome".	Science. 2010 May 14;328(5980):825; author reply 825. Comment on: Science. 2009 Oct 23;326(5952):585-9.	Lombardi et al. (Reports, 23 October 2009, p. 585) reported a significant association between the human retrovirus XMRV and chronic fatigue syndrome (CFS). However, the cases with CFS and the control subjects in their study are poorly described and unlikely to be representative. Independent replication is a critical first step before accepting the validity of this finding.
Lo SC, Pripuzova N, Li B, Komaroff AL, Hung GC, Wang R, Alter HJ.	Center for Biologics Evaluation and Research, Bethesda, MD 20892, USA. shyhching.lo@FDA.hhs.gov	Detection of MLV-related virus gene sequences in blood of patients with chronic fatigue syndrome and healthy blood donors.	Proc Natl Acad Sci U S A. 2010 Sep 7;107(36):15874-9. Epub 2010 Aug 23. Erratum in: Proc Natl Acad Sci U S A. 2010 Nov 2;107(44):19132. Comment in: Proc Natl Acad Sci U S A. 2010 Oct 26;107(43):E161; author reply E163-4. Proc Natl Acad Sci U S A. 2010 Sep	Chronic fatigue syndrome (CFS) is a serious systemic illness of unknown cause. A recent study identified DNA from a xenotropic murine leukemia virus-related virus (XMRV) in peripheral blood mononuclear cells (PBMCs) from 68 of 101 patients (67%) by nested PCR, as compared with 8 of 218 (3.7%) healthy controls. However, four subsequent reports failed to detect any murine leukemia virus (MLV)-related virus gene sequences in blood of CFS patients. We examined 41 PBMC-derived DNA samples from 37 patients meeting accepted diagnostic criteria for CFS and found MLV-like virus gag gene sequences in 32 of 37 (86.5%) compared with only 3 of 44 (6.8%) healthy volunteer blood donors. No evidence of mouse DNA contamination was detected in the PCR assay system or the clinical samples. Seven of 8 gag-positive patients tested again positive in a sample obtained nearly 15 y later. In contrast to the reported findings of near-genetic identity of all XMRVs, we identified a genetically diverse group of MLV-related viruses. The gag and env sequences from CFS patients were more closely related to those of polytropic mouse endogenous retroviruses than to those of XMRVs and were even less closely related to those of ecotropic MLVs. Further studies are needed to determine whether the same strong association with MLV-related viruses is found in other groups of patients with CFS, whether these viruses play a causative role in the development of CFS, and whether

Maes M, Mihaylova I, Kubera M, Uytterhoeven M, Vrydags N, Bosmans E.	Maes Clinics, Belgium. crc.mh@telenet.be	Increased plasma peroxides and serum oxidized low density lipoprotein antibodies in major depression: markers that further explain the higher incidence of neurodegeneration and coronary artery disease.	J Affect Disord. 2010 Sep;125(1-3):287-94. Epub 2010 Jan 18.	BACKGROUND: Major depression is characterized by a decreased antioxidant status, an induction of the inflammatory and oxidative and nitrosative (IO&NS) pathways and inflammatory-neurodegenerative (I&ND) pathways. This study examines two markers of oxidative stress in depression, i.e. plasma peroxides and serum oxidized LDL (oxLDL) antibodies. METHODS: Blood was sampled in 54 patients with major depression (mean+/-SD age=43.5+/-11.6 years) and 37 normal volunteers (43.6+/-11.1 years). The severity of illness was measured by means of the Hamilton Depression Rating Scale. The Fibromyalgia and Chronic Fatigue Syndrome Rating Scale was used to measure severity of "psychosomatic" symptoms in depression. RESULTS: We found significantly higher plasma peroxides (p=0.002) and serum oxLDL antibodies (p=0.0002) in depressed patients as compared to normal controls. There was no significant correlation between both markers and both independently from each other predicted major depression. There were significant correlations between the oxLDL antibodies and the scores on two items of the FF scale, i.e. gastro-intestinal symptoms and headache. DISCUSSION: The results show that major depression is accompanied by increased oxidative stress and lipid peroxidation. These results further extend the IO&NS pathophysiology of major depression. Since increased peroxides and oxLDL antibodies are predictors of coronary artery disease (CAD) and neurodegeneration, our findings suggest that IO&NS pathways are involved in the increased incidence of both CAD and neurodegeneration in depression.
Maes M, Twisk FN.	Maes Clinics @ TRIA, Piyavate Hospital, Bangkok, Thailand. crc.mh@telenet.be	Chronic fatigue syndrome: Harvey and Wessely's (bio)psychosocial model versus a bio(psychosocial) model based on inflammatory and oxidative and nitrosative stress pathways.	BMC Med. 2010 Jun 15;8:35.	BACKGROUND: In a recently published paper, Harvey and Wessely put forward a 'biopsychosocial' explanatory model for myalgic encephalomyelitis/chronic fatigue syndrome (ME/CFS), which is proposed to be applicable to (chronic) fatigue even when apparent medical causes are present. METHODS: Here, we review the model proposed by Harvey and Wessely, which is the rationale for behaviourally oriented interventions, such as cognitive behaviour therapy (CBT) and graded exercise therapy (GET), and compare this model with a biological model, in which inflammatory, immune, oxidative and nitrosative (IO&NS) pathways are key elements. DISCUSSION: Although human and animal studies have established that the pathophysiology of ME/CFS includes IO&NS pathways, these abnormalities are not included in the model proposed by Harvey and Wessely. Activation of IO&NS pathways is known to induce fatigue and somatic (F&S) symptoms and can be induced or maintained by viral and bacterial infections, physical and psychosocial stressors, or organic disorders such as (auto)immune disorders. Studies have shown that ME/CFS and major depression are both clinical manifestations of shared IO&NS pathways, and that both disorders can be discriminated by specific symptoms and unshared or differentiating pathways. Interventions with CBT/GET are potentially

				harmful for many patients with ME/CFS, since the underlying pathophysiological abnormalities may be intensified by physical stressors. CONCLUSIONS: In contrast to Harvey and Wessely's (bio)psychosocial model for ME/CFS a bio(psychosocial) model based upon IO&NS abnormalities is likely more appropriate to this complex disorder. In clinical practice, we suggest physicians should also explore the IO&NS pathophysiology by applying laboratory tests that examine the pathways involved.
Maes M, Twisk FN.		Treatment of myalgic encephalomyelitis/ chronic fatigue syndrome (ME/CFS), a multisystem disease, should target the pathophysiological aberrations (inflammatory and oxidative and nitrosative stress pathways), not the psychosocial "barriers" for a new equilibrium.	Patient Educ Couns. 2010 Jul;80(1):148-9; author reply 147. Epub 2010 Mar 29. Comment on: Patient Educ Couns. 2009 Nov;77(2):153-4.	
Maes M.		An intriguing and hitherto unexplained co-occurrence: Depression and chronic fatigue syndrome are manifestations of shared inflammatory, oxidative and nitrosative (IO&NS) pathways.	Prog Neuropsychopharmacol Biol Psychiatry. 2010 Jul 4. [Epub ahead of print]	There is a significant 'comorbidity' between depression and myalgic encephalomyelitis/chronic fatigue syndrome (ME/CFS). Depressive symptoms frequently occur during the course of ME/CFS. Fatigue and somatic symptoms (F&S), like pain, muscle tension, and a flu-like malaise, are key components of depression. At the same time, depression and ME/CFS show major clinical differences, which allow to discriminate them with a 100% accuracy. This paper aims to review the shared pathways that underpin both disorders and the pathways that discriminate them. Numerous studies have shown that depression and ME/CFS are characterized by shared aberrations in inflammatory, oxidative and nitrosative (IO&NS) pathways, like systemic inflammation and its long-term sequels, including O&NS-induced damage to fatty acids, proteins and DNA; dysfunctional mitochondria; lowered antioxidant levels, like zinc and coenzyme Q10; autoimmune responses to neoepitopes formed by O&NS; lowered omega-3 polyunsaturated fatty acid levels; and increased translocation of gram-negative bacteria. Some IO&NS-related pathways, like the induction of indoleamine 2-3-dioxygenase, neurodegeneration and decreased neurogenesis, are more specific to depression, whereas other pathways, like the 2'-5' oligoadenylate synthetase/RNase L pathway, are specific to ME/CFS. Most current animal models of depression, e.g. those induced by cytokines, are not reminiscent of human depression but reflect a mixture of depressive and F&S symptoms. The latter symptoms, sometimes called sickness behavior, differ from depression and ME/CFS because the former is a (sub)acute

				response to infection-induced pro-inflammatory cytokines that aims to enhance recovery, whereas the latter are characterized by long-term sequels in multiple IO&NS pathways. Depression and ME/CFS are not 'comorbid' disorders, but should be regarded as 'co-associated disorders' that are clinical manifestations of shared pathways.
Maloney EM, Boneva RS, Lin JM, Reeves WC.	Centers for Disease Control and Prevention, Chronic Viral Diseases Branch, National Center for Zoonotic, Vector-borne and Enteric Diseases, MS-A15, 1600 Clifton Rd, Atlanta, GA 30333, USA. evm3@cdc.gov	Chronic fatigue syndrome is associated with metabolic syndrome: results from a case-control study in Georgia.	Metabolism. 2010 Sep;59(9):1351-7. Epub 2010 Jan 27.	We hypothesized that persons with chronic fatigue syndrome (CFS) would have a higher prevalence of metabolic syndrome compared with well controls, and that unwell persons with insufficient symptoms or fatigue for CFS (termed ISF) would have a prevalence of metabolic syndrome intermediate between those with CFS and the controls. We also sought to examine the relationship between metabolic syndrome and measures of functional impairment, fatigue, and other symptoms. Our analysis was based on a population-based case-control study conducted in metropolitan, urban, and rural areas of Georgia, United States, between September 2004 and July 2005. There were 111 persons with CFS, 259 with ISF, and 123 controls. Metabolic syndrome was determined based on having at least 3 of 5 standard risk components (abdominal obesity, high triglycerides, high blood pressure, elevated fasting glucose, and decreased high-density lipids) according to the National Cholesterol Education Program Adult Treatment Panel III definition. Persons with CFS were 2-fold as likely to have metabolic syndrome (odds ratio = 2.12, confidence interval = 1.06, 4.23) compared with the controls. There was a significant graded relationship between the number of metabolic syndrome factors and CFS; each additional factor was associated with a 37% increase in likelihood of having CFS. The association of ISF with metabolic syndrome was weaker (odds ratio = 1.72, confidence interval = 0.94-3.16). Among persons with CFS, the number of metabolic syndrome factors was significantly correlated with worse fatigue on a standardized summary measure of fatigue (r = 0.20, P = .04). In conclusion, CFS was associated with metabolic syndrome, which further exacerbated fatigue.
Maquet D, Croisier JL, Dupont C, Moutschen M, Ansseau M, Zeevaert B, Crielaard JM.	Department of Motricity Sciences, University of Liege, University Hospital Centre of Liege, ISEPK, B21, 4, allée des Sports, 4000 Liege, Belgium. d.maquet@ulg.ac.be	Fibromyalgia and related conditions: electromyogram profile during isometric muscle contraction.	Joint Bone Spine. 2010 May;77(3):264-7. Epub 2010 Apr 22.	OBJECTIVES: To evaluate electromyogram (EMG) profiles in patients with three related conditions: fibromyalgia, chronic fatigue syndrome, and depression. METHODS: We studied 44 healthy volunteers, 22 patients with fibromyalgia, 11 patients with chronic fatigue syndrome, and 10 patients admitted for depression. The trapezius electromyogram was recorded during maximally sustained, bilateral, 90 degrees abduction of the shoulders. EMG signal frequency and amplitude were measured throughout the test. RESULTS: In the fibromyalgia group, isometric contraction duration was significantly shorter than in the other two patient groups (P<0.001) and the EMG frequency and amplitude pattern indicated premature discontinuation of the muscle contraction. Findings in the chronic fatigue patients were similar to those in the healthy controls. The patients with depression had a distinctive EMG profile characterized by excessive initial motor-unit recruitment with a shift in the frequency spectrum. CONCLUSIONS: Fibromyalgia was associated with a specific EMG pattern indicating premature discontinuation of the muscle contraction. Therefore, maximal voluntary muscle contraction tests may be of limited value for assessing function in fibromyalgia patients. Chronic fatigue syndrome patients had similar EMG findings to those in the healthy controls. The EMG alterations in the patients with depression were consistent with manifestations of psychomotor retardation.
Marshall R, Paul L, Wood L.	Physiotherapist, Research Assistant,	The search for pain relief in people	Physiother Theory Pract. 2010 Nov 1.	The purpose of this study was to investigate the use and perceived benefit of complimentary and alternative medicine (CAM) and physiotherapy treatments tried by people with chronic fatigue

	Nursing & Health Care, Faculty of Medicine, University of Glasgow, Glasgow, Scotland, United Kingdom.	with chronic fatigue syndrome: A descriptive study.	[Epub ahead of print]	syndrome (CFS) to ease painful symptoms. This study used a descriptive, cross-sectional design. People with CFS who experienced pain were recruited to this study. Participants were asked during a semistructured interview about the treatments they had tried to relieve their pain. Each interview was conducted in the home of the participant. Fifty participants were recruited, of which, 10 participants were severely disabled by CFS. Eighteen participants were trying different forms of CAM treatment for pain relief at the time of assessment. Three participants were currently receiving physiotherapy. Throughout the duration of their illness 45 participants reported trying 19 different CAM treatments in the search for pain relief. Acupuncture was reported to provide the most pain relief (n=16). Twenty-seven participants reported a total of 16 different interventions prescribed by their physiotherapist. The results of this study suggest some physiotherapy and CAM treatments may help people manage painful CFS symptoms. Future research should be directed to evaluating the effectiveness of interventions such as acupuncture or gentle soft tissue therapies to reduce pain in people with CFS.
Martin M, Alexeeva I.	Department of Experimental Psychology, University of Oxford, UK.	Mood volatility with rumination but neither attentional nor interpretation biases in chronic fatigue syndrome.	Br J Health Psychol. 2010 Nov;15(Pt 4):779-96. Epub 2010 Jan 22.	OBJECTIVES: This study tested whether (1) chronic fatigue syndrome (CFS) individuals have a bias in the initial orientation of attention to illness-related information, which is enhanced by rumination. (2) CFS individuals have an illness interpretation bias (IB) in their early automatic processing of ambiguous information. (3) CFS individuals experience a greater degree of mood fluctuation following rumination and distraction inductions. DESIGN: Thirty-three CFS participants who had received a medical practitioner's diagnosis of CFS were compared to 33 healthy matched controls on an exogenous cueing task and a lexical decision task. METHOD: All participants underwent either a rumination or distraction induction. They then completed an exogenous cueing task to assess bias to illness and social threat compared with neutral stimuli, as well as a lexical decision task to assess their interpretation of ambiguous words having illness, social threat, or neutral interpretations. RESULTS: Reaction time data revealed that CFS individuals did not have an attentional bias (AB) in the initial orientation of attention to illness-related material. Nor was there an IB towards illness in CFS individual's automatic response to ambiguous information. However, as hypothesized, CFS individuals showed a greater degree of mood fluctuation following the rumination/distraction induction. CONCLUSION: Rumination and distraction lead to greater mood volatility in CFS individuals than in controls, but not to attentional nor interpretation biases in the early automatic stages of information processing in CFS individuals.
Martin WJ.	A	Possible widespread low-level occurrence of murine leukemia virus-related gene sequences in humans.	Proc Natl Acad Sci U S A. 2010 Oct 26;107(43):E162; author reply E163-4. Epub 2010 Sep 30. Comment on: Proc Natl Acad Sci U S A. 2010 Sep 7;107(36):15874-9.	a
Masruha MR, Lin J, de Souza Vieira	Department of Neurology and	Urinary 6-sulphatoxymelaton	Headache. 2010 Mar;50(3):413-9.	OBJECTIVE: To assess urinary 6-sulphatoxymelatonin levels in a large consecutive series of patients with migraine and several comorbidities (chronic fatigue, fibromyalgia, insomnia, anxiety, and

DS, Minett TS, Cipolla-Neto J, Zukerman E, Vilanova LC, Peres MF.	Neurosurgery - Federal University of São Paulo, São Paulo - Brazil.	in levels are depressed in chronic migraine and several comorbidities.	Epub 2009 Oct 8.	depression) as compared with controls. BACKGROUND: Urine analysis is widely used as a measure of melatonin secretion, as it is correlated with the nocturnal profile of plasma melatonin secretion. Melatonin has critical functions in human physiology and substantial evidence points to its importance in the regulation of circadian rhythms, sleep, and headache disorders. METHODS: Urine samples were collected into a single plastic container over a 12-hour period from 8:00 pm to 8:00 am of the next day, and 6-sulphatoxymelatonin was measured by quantitative ELISA. All of the patients were given a detailed questionnaire about headaches and additionally answered the following questionnaires: Chalder fatigue questionnaire, Epworth somnolence questionnaire, State-Trait Anxiety Inventory, and the Beck Depression Inventory. RESULTS: A total of 220 subjects were evaluated - 73 (33%) had episodic migraine, 73 (33%) had chronic migraine, and 74 (34%) were enrolled as control subjects. There was a strong correlation between the concentration of 6-sulphatoxymelatonin detected and chronic migraine. Regarding the comorbidities, this study objectively demonstrates an inverse relationship between 6-sulphatoxymelatonin levels and depression, anxiety, and fatigue. CONCLUSIONS: To our knowledge, this is the first study to evaluate the relationship between the urinary concentration of melatonin and migraine comorbidities. These results support hypothalamic involvement in migraine pathophysiology.
Matalliotakis IM, Cakmak H, Ziogos MD, Kalogeraki A, Kappou D, Arici A.	Department of Obstetrics and Gynecology, University of Crete, Heraklion, Crete, Greece. matakgr@yahoo.com	Endometriosis-associated Lyme disease.	J Obstet Gynaecol. 2010 Feb;30(2):184-6.	The aim of this study is to report three cases of patients with endometriosis and infertility, and associated with Lyme disease. The medical files of 405 women with endometriosis and 200 without endometriosis were studied retrospectively. We report 3 cases with endometriosis and Lyme disease. Of 405 patients with endometriosis treated in our study over a 6-year period, 3(0.8%) had Lyme disease. All cases presented with typical erythema migraines, fever and fatigue. The serological findings were positive for Borrelia burgdorferi, for 3 cases. Two out of 3 women underwent IVF-ET procedures and one of them conceived in the first cycle without complication during pregnancy or after childbirth recorded. We concluded that women with endometriosis are more likely to have chronic fatigue syndrome, systemic lupus erythematous, Sjögren's syndrome, rheumatoid arthritis, multiple sclerosis, and other autoimmune inflammatory and endocrine diseases. A review of the literature confirms the uniqueness of the co-existence of Lyme disease in women with endometriosis in these cases.
May M, Emond A, Crawley E.	Centre for Child and Adolescent Health, Hampton House, Cotham Hill, Bristol BS6 6JS, UK.	Phenotypes of chronic fatigue syndrome in children and young people.	Arch Dis Child. 2010 Apr;95(4):245-9. Epub 2009 Oct 19.	OBJECTIVE: To investigate the heterogeneity of chronic fatigue syndrome (CFS/ME) in children and young people. SETTING: Regional specialist CFS/ME service Patients Children and young people aged <19 years old. METHODS: Exploratory factor analysis was performed on symptoms present at assessment in 333 children and young people with CFS/ME. Linear and logistic regression analysis of data from self-completed assessment forms was used to explore the associations between the retained factors and sex, age, length of illness, depression, anxiety and markers of severity (fatigue, physical function, pain and school attendance). RESULTS: Three phenotypes were identified using factor analysis: muscoloskeletal (factor 1) had loadings on muscle and joint pain and hypersensitivity to touch, and was associated with worse fatigue (regression coefficient 0.47, 95% CI 0.25 to 0.68, p<0.001), physical function (regression coefficient -0.52, 95% CI -0.83 to -0.22, p=0.001) and pain. Factor 2 (migraine) loaded on noise and light hypersensitivity, headaches, nausea, abdominal pain and dizziness and was most strongly associated with physical function and pain. Sore throat phenotype

				(factor 3) had loadings on sore throat and tender lymph nodes and was not associated with fatigue or pain. There was no evidence that phenotypes were associated with age, length of illness or symptoms of depression (regression coefficient for association of depression with musculoskeletal pain -0.02, 95% CI -0.27 to 0.23, p=0.87). The migraine phenotype was associated with anxiety (0.40, 95% CI 0.06 to 0.74, p=0.02). IMPLICATIONS: CFS/ME is heterogeneous in children with three phenotypes at presentation that are differentially associated with severity and are unlikely to be due to age or length of illness.

McEwen BS, Kalia M.	Laboratory of Neuroendocrinology, The Rockefeller University, New York, NY 10065, USA. mcewen@rockefeller.edu	The role of corticosteroids and stress in chronic pain conditions.	Metabolism. 2010 Oct;59 Suppl 1:S9-15.	The relationship between corticosteroids (endogenous and exogenous) and stress is well known, as is the use of steroids as concomitant treatment in pain management during acute inflammation. In the past, steroids have not been considered the first line of treatment in pain management. In this review, we examine new scientific and clinical evidence that demonstrates the direct role that steroids play in the generation and clinical management of chronic pain. We will discuss the new findings demonstrating the fact that steroids and related mediators produce paradoxical effects on pain such as analgesia, hyperalgesia, and even placebo analgesia. In addition, we will examine the physiologic effect of stress, high allostatic load, and idiopathic disease states such as chronic fatigue syndrome, fibromyalgia, irritable bowel syndrome, and burnout. The recently observed positive relationship between glutaminergic activity in the insula and clinical pain will be examined in the context of understanding the central role of steroids in chronic pain. The complex role of the hypothalamic-pituitary-adrenal axis in pain will be discussed as well as other heterogeneous forms of chronic pain that involve many components of the central nervous system. Components of the hypothalamic-

				pituitary-adrenal axis have paradoxical effects on certain types of pain that are dependent on dose and on site (whether peripheral or central) and mode of application. Recent studies on glia have shown that they prolong a state of neuronal hypersensitization in the dorsal root ganglia by releasing growth factors and other substances that act on the immune system. We will discuss the implication of these new findings directly linking pain to steroids, stress, and key higher brain regions in the context of future therapeutic targets.
Meeus M, Nijs J, Huybrechts S, Truijen S.	Department of Health Sciences, Division of Musculoskeletal Physiotherapy, Artesis Hogeschool Antwerpen (AHA), Merksem, Belgium.	Evidence for generalized hyperalgesia in chronic fatigue syndrome: a case control study.	Clin Rheumatol. 2010 Apr;29(4):393-8.	Several studies provided evidence for generalized hyperalgesia in fibromyalgia or whiplash-associated disorders. In chronic fatigue syndrome, however, pain is a frequently reported complaint, but up to now, evidence for generalized hyperalgesia is lacking. The aim of this study is to examine whether the pressure pain thresholds (PPTs) at both symptomatic and asymptomatic sites differ in chronic fatigue syndrome (CFS) patients with chronic pain, compared to healthy controls. Therefore, 30 CFS patients with chronic pain and 30 age- and gender-matched healthy controls indicated on a Margolis Pain Diagram where they felt pain lasting longer than 24 h in the past 4 weeks. After completing a test battery of questionnaires evaluating pain cognitions, functional status and symptomatology, a blinded researcher assessed PPTs bilaterally at seven nonspecific sites on both trunk and extremities. PPTs were compared for the two complete groups. In addition, PPTs of patients and controls who did not report pain in a respective zone were compared. PPTs of the patients were significantly lower ($p<0.001$) compared to those of the control group, also when pain-free samples per zone were compared ($p<0.001$). The mean PPT was 3.30 kg/cm2 in all CFS patients and 8.09 kg/cm2 in the controls. No confounding factors responsible for the observed differences, as, e.g., catastrophizing and depression, could be revealed. These findings provide evidence for the existence of hyperalgesia even in asymptomatic areas (generalized secondary hyperalgesia). The generalized hyperalgesia may represent the involvement of a sensitized central nervous system.
Meeus M, Nijs J, Van Oosterwijck J, Van Alsenoy V, Truijen S.	Department of Health Sciences, Artesis University College, Antwerp, Belgium.	Pain physiology education improves pain beliefs in patients with chronic fatigue syndrome compared with pacing and self-management education: a double-blind randomized controlled trial.	Arch Phys Med Rehabil. 2010 Aug;91(8):1153-9.	OBJECTIVE: To examine whether pain physiology education was capable of changing pain cognitions and pain thresholds in patients with chronic fatigue syndrome (CFS) and chronic widespread pain. DESIGN: Double-blind randomized controlled trial. SETTING: Specialized chronic fatigue clinic in university hospital. PARTICIPANTS: A random sample of patients (N=48) with CFS patients (8 men, 40 women) experiencing chronic pain, randomly allocated to the control group (n=24) or experimental group (n=24). Two women in the experimental group did not complete the study because of practical issues (lack of time and restricted mobility). INTERVENTIONS: One individual pain physiology education session (experimental) or 1 pacing and self-management education session (control). MAIN OUTCOME MEASURES: Algometry, the Neurophysiology of Pain Test, and questionnaires evaluating pain cognitions-the Pain Coping Inventory, the Pain Catastrophizing Scale, and the Tampa Scale for Kinesiophobia-version CFS-were completed immediately before and immediately after the intervention. RESULTS: After the intervention, the experimental group demonstrated a significantly better understanding of the neurophysiology of pain ($P<.001$) and a reduction of the Pain Catastrophizing Scale subscale "ruminating" ($P=.009$) compared with controls. For these variables, moderate to large Cohen d effect sizes were revealed (.79-2.53). CONCLUSIONS: A 30-minute educational session on pain physiology imparts a better understanding of pain and brings about less rumination in the short term. Pain physiology education can be an important therapeutic modality in

				the approach of patients with CFS and chronic pain, given the clinical relevance of inappropriate pain cognitions.
Meeus M, Roussel NA, Truijen S, Nijs J.	Division of Musculoskeletal Physiotherapy, Department of Health Sciences, Artesis University College Antwerp, Merksem, Belgium.	Reduced pressure pain thresholds in response to exercise in chronic fatigue syndrome but not in chronic low back pain: an experimental study.	J Rehabil Med. 2010 Oct;42(9):884-90.	OBJECTIVE: The aims of this study were to examine: (i) baseline pressure pain thresholds in patients with chronic fatigue syndrome and those with chronic low back pain compared with healthy subjects; (ii) the change in mean pain threshold in response to exercise; and (iii) associations with exercise-induced increase in nitric oxide. PARTICIPANTS: Twenty-six patients with chronic fatigue syndrome suffering of chronic pain, 21 patients with chronic low back pain and 31 healthy subjects. METHODS: Participants underwent a submaximal aerobic exercise protocol on a bicycle ergometer, preceded and followed by venous blood sampling (nitric oxide) and algometry (hand, arm, calf, low back). RESULTS: Patients with chronic fatigue syndrome presented overall lower pain thresholds compared with healthy subjects and patients with chronic low back pain ($p < 0.05$). No significant differences were found between healthy subjects and patients with chronic low back pain. After submaximal aerobic exercise, mean pain thresholds decreased in patients with chronic fatigue syndrome, and increased in the others ($p < 0.01$). At baseline, nitric oxide levels were significantly higher in the chronic low back pain group. After controlling for body mass index, no significant differences were seen between the groups at baseline or in response to exercise. Nitric oxide was not related to pain thresholds in either group. CONCLUSION: The results suggest hyperalgesia and abnormal central pain processing during submaximal aerobic exercise in chronic fatigue syndrome, but not in chronic low back pain. Nitric oxide appeared to be unrelated to pain processing.
Meeus M, VAN Eupen I, Hondequin J, DE Hauwere L, Kos D, Nijs J.	Division of Musculoskeletal Physiotherapy, Artesis University College (AHA), Department of Health Sciences, Van Aertselaerstraat 31, 2170 Merksem, Belgium.	Nitric oxide concentrations are normal and unrelated to activity level in chronic fatigue syndrome: a case-control study.	In Vivo. 2010 Nov-Dec;24(6):865-9.	AIM: since patients with chronic fatigue syndrome (CFS) often present elevated levels of nitric oxide (NO) and low levels of physical activity, this study aimed at revealing possible correlations between NO concentration and physical activity. PATIENTS AND METHODS: thirty CFS patients and 29 age- and gender-matched sedentary controls wore an accelerometer for one week and underwent venous blood sampling at the beginning and the end of the week. RESULTS: CFS patients were significantly less active ($p=0.001$), but no significant differences in the amounts of NO ($p=0.464$ and 0.569) or interaction between NO levels and activity levels in either the CFS patients or controls were revealed. CONCLUSION: these results provide further evidence for reduced activity levels in CFS patients, but refute there being any interaction between the amount of blood NO and activity level in both groups. The blood NO was neither predictive of, nor dependent on the activity level in CFS.
Meeus M, Van Eupen I, Willems J, Kos D, Nijs J.	Division of Musculoskeletal Physiotherapy, Department of Health Sciences, Artesis University College Antwerp (AHA), Antwerp, Belgium.	Is the International Physical Activity Questionnaire-short form (IPAQ-SF) valid for assessing physical activity in Chronic Fatigue Syndrome?	Disabil Rehabil. 2011;33(1):9-16. Epub 2010 May 6.	PURPOSE: To evaluate the criterion validity and internal consistency of the International Physical Activity Questionnaire-short form (IPAQ-sf) in Chronic Fatigue Syndrome (CFS) patients. METHOD: Fifty-six CFS patients completed the IPAQ-sf after they wore a tri-axial accelerometer and filled out activity diaries during 1 week. Spearman rank correlation coefficients and Cronbach's Alpha were calculated. RESULTS: The IPAQ-sf correlated significantly with the energy expenditure and Metabolic Equivalents (METs) minutes spent moderately to vigorously active following the activity diary and accelerometer. These correlation coefficients were however low (r varying between 0.282 and 0.426) and rather irrelevant, since CFS patients hardly reach moderate or vigorous activity levels. Internal consistency between the three subitems used for the total score of the IPAQ-sf was 0.337. CONCLUSION: The observed associations between the IPAQ-sf data and the data obtained from the

				accelerometer (gold standard) and the diaries were too low to be in support of the use of the IPAQ-sf in patients with CFS. The IPAQ-sf does not seem an appropriate tool to assess physical activity in CFS patients. Further study is required to seek for a valid, practical and affordable tool.
Menéndez-Arias L.	Centro de Biología Molecular "Severo Ochoa" (Consejo Superior de Investigaciones Científicas and Universidad Autónoma de Madrid), Madrid, Spain.	Evidence and controversies on the role of XMRV in prostate cancer and chronic fatigue syndrome.	Rev Med Virol. 2010 Nov 26. [Epub ahead of print]	The recent discovery of xenotropic murine leukaemia virus-related virus (XMRV) in prostate cancer tissues and in the blood of individuals suffering from chronic fatigue syndrome has attracted considerable interest. However, the relevance and significance of XMRV to human disease remain unclear, since the association has not been confirmed in other studies. XMRV is the first gammaretrovirus to be found in humans. XMRV and murine leukaemia viruses share similar structures and genomic organisation. Human restriction factors such as APOBEC3 or tetherin inhibit XMRV replication. Although XMRV induces low rates of transformation in cell culture, it might be able to induce cancer by low-frequency insertional activation of oncogenes or through the generation of highly active transforming viruses. A preference for regulatory regions of transcriptional active genes has been observed after a genomic-wide analysis of XMRV integration sites. Genes related to carcinogenesis and androgen signalling have been identified in the vicinity of integration sites. The XMRV genome contains a glucocorticoid responsive element, and androgens could modulate viral replication in the prostate. Evidence supporting the involvement of XMRV in chronic fatigue syndrome is still very weak, and needs further confirmation and validation. Currently approved anti-retroviral drugs such as zidovudine, tenofovir and raltegravir are efficient inhibitors of XMRV replication in vitro. These drugs might be useful to treat XMRV infection in humans. The identification of XMRV has potentially serious health implications for the implementation of novel techniques including gene therapy or xenotransplantation, while raising concerns on the need for screening donated blood to prevent transmission through transfusion. Merkes M.	Australian Institute for Primary Care, La Trobe University, Bundoora, Vic. 3086, Australia. m.merkes@latrobe.edu.au	Mindfulness-based stress reduction for people with chronic diseases.	Aust J Prim Health. 2010;16(3):200-10.	Mindfulness-based stress reduction (MBSR) is a structured group program that uses mindfulness meditation to improve well-being and alleviate suffering. This article reviews the impact of MBSR for people with chronic diseases. The review includes original research that was published in English and peer-reviewed and reported outcomes for adults with chronic diseases who had participated in an MBSR program. Fifteen studies were identified. Outcomes related to mental and physical health, well-being, and quality of life. The studies included different research designs, and used self-report and physiological outcome measures. Participants' clinical diagnoses included fibromyalgia, chronic pain, rheumatoid arthritis, type 2 diabetes, chronic fatigue syndrome, multiple chemical sensitivity, and cardiovascular diagnoses. All 15 studies found that participation in an MBSR program resulted in improvements. No negative change was reported between baseline and follow up. Outcomes in regard to specific variables were difficult to compare and equivocal. Overall, positive change predominated. Chronic diseases are associated with a range of unwelcome psychological and physical consequences. Participation in an MBSR program is likely to result in coping better with symptoms, improved overall well-being and quality of life, and enhanced health outcomes. As an adjunct to standard care, MBSR has potential for much wider application in Australian primary care settings.
Mikovits JA, Huang Y, Pfost MA, Lombardi VC,	Whittemore-Peterson Institute for Neuroimmune	Distribution of xenotropic murine leukemia virus-	AIDS Rev. 2010 Jul-Sep;12(3):149-52.	In 2006, sequences described as xenotropic murine leukemia virus-related virus (XMRV) were discovered in prostate cancer patients. In October 2009, we published the first direct isolation of infectious XMRV from humans and the detection of infectious XMRV in patients with chronic fatigue

Bertolette DC, Hagen KS, Ruscetti FW.	Diseases, University of Nevada, Reno, NV 89557, USA. judym@wpinstitute.org	related virus (XMRV) infection in chronic fatigue syndrome and prostate cancer.		syndrome. In that study, a combination of classic retroviral methods were used including: DNA polymerase chain reaction and reverse transcriptase polymerase chain reaction for gag and env, full length genomic sequencing, immunoblotting for viral protein expression in activated peripheral blood mononuclear cells, passage of infectious virus in both plasma and peripheral blood mononuclear cells to indicator cell lines, and detection of antibodies to XMRV in plasma. A combination of these methods has since allowed us to confirm infection by XMRV in 85% of the 101 patients that were originally studied. Since 2009, seven studies, predominantly using DNA polymerase chain reaction of blood products or tumor tissue, have reported failures to detect XMRV infection in patients with either prostate cancer or chronic fatigue syndrome. A review of the current literature on XMRV supports the importance of applying multiple independent techniques in order to determine the presence of this virus. Detection methods based upon the biological and molecular amplification of XMRV, which is usually present at low levels in unstimulated blood cells and plasma, are more sensitive than assays for the virus by DNA polymerase chain reaction of unstimulated peripheral blood mononuclear cells. When we examined patient blood samples that had originally tested negative by DNA polymerase chain reaction by more sensitive methods, we observed that they were infected with XMRV; thus, the DNA polymerase chain reaction tests provided false negative results. Therefore, we conclude that molecular analyses using DNA from unstimulated peripheral blood mononuclear cells or from whole blood are not yet sufficient as stand-alone assays for the identification of XMRV-infected individuals. Complementary methods are reviewed, that if rigorously followed, will likely show a more accurate snapshot of the actual distribution of XMRV infection in humans.
Mikovits JA, Lombardi VC, Pfost MA, Hagen KS, Ruscetti FW.	Whittemore Peterson Institute, Reno, Nevada, USA. judym@wpinstitute.org	Detection of an infectious retrovirus, XMRV, in blood cells of patients with chronic fatigue syndrome.	Virulence. 2010 Sep-Oct;1(5):386-90.	In October 2009, we reported the first direct isolation of infectious xenotropic murine leukemia virus-related virus (XMRV). In that study, we used a combination of biological amplification and molecular enhancement techniques to detect XMRV in more than 75% of 101 patients with chronic fatigue syndrome (CFS). Since our report, controversy arose after the publication of several studies that failed to detect XMRV infection in their CFS patient populations. In this addenda, we further detail the multiple detection methods we used in order to observe XMRV infection in our CFS cohort. Our results indicate that PCR from DNA of unstimulated peripheral blood mononuclear cells is the least sensitive method for detection of XMRV in subjects' blood. We advocate the use of more than one type of assay in order to determine the frequency of XMRV infection in patient cohorts in future studies of the relevance of XMRV to human disease.
Miller E.	Oddział Rehabilitacji III Miejskiego Szpitala w Łodzi. betty.miller@interia.pl	[Cryostimulation factor supporting rehabilitation patients with multiple sclerosis and fatigue syndrome]. [Article in Polish]	Wiad Lek. 2010;63(2):41-5.	INTRODUCTION: Fatigue is considered to be one of the most prevalent and disabling symptoms among individuals with multiple sclerosis (MS). According to different studies, fatigue is reported by 75-95% of patients. Fatigue syndrome considerably affects quality of life. Characteristic feature of fatigue syndrome in multiple sclerosis is its relapse caused by warmth. There are only a few researches into fatigue in multiple sclerosis. The most commonly used scale to estimate fatigue is Fatigue Severity Scale (FSS). Cryostimulation has been applied to treat depression. AIM OF THE STUDY: Comparison of the influence of cryostimulation as a supporting factor of kinesytherapy on increasing strength of selected muscle groups of inferior extremities and degree of disability in case of patients with multiple sclerosis and fatigue syndrome and without the latter. MATERIAL AND METHODS: The examination included 60 randomized patients with diagnosed multiple sclerosis (ICD10-G35). To

				assess the results scales: EDSS, FSS and widespread Lovett scale (punctation with accuracy of measurement 0.5 point) were used. Interpretation of the FSS scale results was made according to Krupp and comp. Fatigue syndrome was diagnosed where results reached 6.5 and higher. Evaluaton of muscle strength concerning chosen muscles groups of inferior extremities: quadriceps femoris, illopsoas, biceps femoris. When the strength of leg muscles was asymmetric, lower values of Lovett scale were used. Patients were divided into 2 groups with regard to positive or negative fatigue syndrome. In the examined group (n = 24) fatigue syndrome was positive (FSS under 6.5) and control (n = 36) negative (FSS under 6.5). All patients were treated with cryostimulation and individual program of exercises adapted to their degree of disability. RESULTS: The use of cryostimulation and kinesytherapy to patients with MS and fatigue syndrome indicates statistically important (p = 0.05) decrease of disability degree in EDSS scale and improvement of muscle strength of quadriceps femoris and illiopsoas compared to MS patients without fatigue syndrome. CONCLUSIONS: Cryostimulation is a factor supporting rehabilitation patients with multiple sclerosis and fatigue syndrome.
Miwa K, Fujita M.	Department of Internal Medicine, Nanto Family and Community Medical Center, 577 Matsubara, Nanto, Toyama 939-1518, Japan. k-3wa@pm.ctt.ne.jp	Fluctuation of serum vitamin E (alpha-tocopherol) concentrations during exacerbation and remission phases in patients with chronic fatigue syndrome.	Heart Vessels. 2010 Jul;25(4):319-23. Epub 2010 Jul 31.	The etiology of chronic fatigue syndrome remains unknown. Oxidative stress may be involved in its pathogenesis. Vitamin E is a major endogenous lipid-soluble antioxidative substance, and is consumed during the lipid peroxidation process. We studied a population comprising 27 patients with chronic fatigue syndrome (10 men and 17 women, 29 +/- 6 years of age) and 27 age- and sex-matched control subjects. Serum vitamin E (alpha-tocopherol) concentrations were determined and expressed as mg/g total lipids (total cholesterol and triglyceride) to evaluate oxidative stress. Serum alpha-tocopherol concentrations (mg/g lipids) were significantly (P < 0.001) lower in the patients with chronic fatigue syndrome (2.81 +/- 0.73) than in the control subjects (3.88 +/- 0.65). The patients with chronic fatigue syndrome were re-examined during a follow-up interval. After 8 +/- 2 months, 16 patients exhibited a status that warranted re-examination during remission of the symptoms at a regular visit to our hospital (Group 1), while the remaining 11 did not (Group 2). The serum alpha-tocopherol levels were significantly elevated during remission as compared with those at baseline in Group 1 (2.71 +/- 0.62 --> 3.24 +/- 0.83, P < 0.001). The levels did not significantly change after the interval in Group 2 (2.97 +/- 0.86 --> 2.85 +/- 0.73, not significant). In conclusion, serum alpha-tocopherol concentrations were significantly lower in the patients with chronic fatigue syndrome as compared with the control subjects, suggesting increased oxidative stress in the former. The low level of serum alpha-tocopherol was ameliorated during the remission phase as compared with the exacerbation phase in the patients with chronic fatigue syndrome, suggesting that increased oxidative stress may be involved in the pathogenesis of chronic fatigue syndrome and might also be directly related to the severity of the symptoms of chronic fatigue syndrome.
Miyazawa T.	Laboratory of Signal Transduction, Department of Cell Biology, Institute for Virus Research,	Endogenous retroviruses as potential hazards for vaccines.	Biologicals. 2010 May;38(3):371-6. Epub 2010 Apr 8.	Retroviruses are classified as exogenous or endogenous according to their mode of transmission. Generally, endogenous retroviruses (ERVs) are not pathogenic in their original hosts; however, some ERVs induce diseases. In humans, a novel gammaretrovirus was discovered in patients with prostate cancer or chronic fatigue syndrome. This virus was closely related to xenotropic murine leukemia virus (X-MLV) and designated as xenotropic murine leukemia virus-related virus (XMRV). The origin and transmission route of XMRV are still unknown at present; however, XMRV may be derived from ERVs

	Kyoto University, 53 Shogoin-Kawaracho, Sakyo-ku, Kyoto 606-8507, Japan. takavet@gmail.com			of rodents because X-MLVs are ERVs of inbred and wild mice. Many live attenuated vaccines for animals are manufactured by using cell lines from animals, which are known to produce infectious ERVs; however, the risks of infection by ERVs from xenospecies through vaccination have been ignored. This brief review gives an overview of ERVs in cats, the potential risks of ERV infection by vaccination, the biological characteristics of RD-114 virus (a feline ERV), which possibly contaminates vaccines for companion animals, and the methods for detection of infectious RD-114 virus.
Mohammed RH, ElMakhzangy HI, Gamal A, Mekky F, El Kassas M, Mohammed N, Abdel Hamid M, Esmat G.	Department of Rheumatology and Rehabilitation, Faculty of Medicine, Cairo University Hospitals, Cairo, Egypt. rmhamdy@yahoo.com	Prevalence of rheumatologic manifestations of chronic hepatitis C virus infection among Egyptians.	Clin Rheumatol. 2010 Dec;29(12):1373-80. Epub 2010 Apr 22.	Chronic hepatitis C virus (HCV) viremia has been known to provoke a plethora of autoimmune syndromes referred to as extrahepatic manifestations of chronic HCV infection. Aim of the current study was to assess the prevalence of rheumatologic manifestations among Egyptians with hepatitis C infection and its' association with cryoglobulin profile. The current research represents a cross-sectional study where patients with chronic HCV infection attending the outpatient clinic of the National Hepatology and Tropical Medicine Research Institute over a period of 1 year were interviewed. Patients with decompensated liver disease, on interferon therapy, having end-stage renal disease or coexisting viral infection like hepatitis B surface antibody positive patients were all excluded from the research. Laboratory investigations as well as serological assay including cryoglobulin profile, rheumatoid factor, antinuclear antibody, HCV-PCR were performed. Three hundred and six patients having chronic HCV infection were interviewed in this research. The overall estimated prevalence of rheumatologic manifestations in the current research was 16.39%, chronic fatigue syndrome 9.5%, sicca symptoms 8.8%, arthralgia 6.5%, fibromyalgia 1.9%, myalgia 1.3%, arthritis 0.7%, cryoglobulinemic vasculitis 0.7%, autoimmune hemolytic anemia 0.7%, thrombocytopenia 0.7%. Xerophthalmia was significantly present in male population ($p = 0.04$), whereas fibromyalgia, cryoglobulinemic vasculitis, arthritis, and autoimmune hemolytic anemia were significantly present in female population under study ($p < 0.05$). In chronic HCV genotype 4 infection, the prevalence of rheumatologic manifestations was 16.3% with chronic fatigue syndrome and sicca symptoms being the most common with no significant correlation to the degree of elevation of liver disease or viral load.

Moore RA, Straube S, Paine J, Phillips CJ, Derry S,	Pain Research and Nuffield Department of	Fibromyalgia: Moderate and substantial pain	Pain. 2010 May;149(2):360-4. Epub 2010 Mar 26.	Chronic pain is associated with a range of other problems, including disturbed sleep, depression, anxiety, fatigue, reduced quality of life, and an inability to work or socialise. We investigated whether good symptom control of pain (using definitions of moderate and substantial benefit) is associated

McQuay HJ.	Anaesthetics, University of Oxford, John Radcliffe Hospital, Oxford, UK. andrew.moore@pru.ox.ac.uk	intensity reduction predicts improvement in other outcomes and substantial quality of life gain.		with improvement in other symptoms. Individual patient data from four randomised trials in fibromyalgia (2575 patients) lasting 8-14weeks were used to calculate percentage pain reduction for each completing patient (1858), divided into one of five groups according to pain reduction, irrespective of treatment: substantial benefit - 50% pain reduction; moderate - 30% to <50%; minimal - 15% to <30%; marginal - 0% to <15%; worse - <0% (increased pain intensity). We then calculated change from baseline to end of trial for measures of fatigue, function, sleep, depression, anxiety, ability to work, general health status, and quality-adjusted life year (QALY) gain over a 12-month period. Substantial and moderate pain intensity reductions were associated with statistically significant reduction from baseline by end of trial in all measures, with values by trial end at or approaching normative values. Substantial pain intensity reduction resulted in 0.11 QALYs gained, and moderate pain intensity reduction in 0.07 QALYs gained over a 12-month period. Substantial and moderate pain intensity reduction predicts broad beneficial outcomes and improved quality of life that do not occur without pain relief. Pain intensity reduction is a simple and effective predictor of which patients should continue treatment, and which should discontinue and try an alternative therapy.
Moss-Morris R, Hamilton W.		Pragmatic rehabilitation for chronic fatigue syndrome.	BMJ. 2010 Apr 23;340:c1799. doi: 10.1136/bmj.c1799. Comment on: BMJ. 2010;340:c1777.	
Moss-Morris R, Spence MJ, Hou R.	School of Psychology, University of Southampton, UK.	The pathway from glandular fever to chronic fatigue syndrome: can the cognitive behavioural model provide the map?	Psychol Med. 2010 Jul 21:1-9. [Epub ahead of print]	BACKGROUND: The cognitive behavioural model of chronic fatigue syndrome (CFS) suggests that the illness is caused through reciprocal interactions between physiology, cognition, emotion and behaviour. The purpose of this study was to investigate whether the psychological factors operationalized in this model could predict the onset of CFS following an acute episode of infectious mononucleosis commonly known as glandular fever (GF).MethodA total of 246 patients with GF were recruited into this prospective cohort study. Standardized self-report measures of perceived stress, perfectionism, somatization, mood, illness beliefs and behaviour were completed at the time of their acute illness. Follow-up questionnaires determined the incidence of new-onset chronic fatigue (CF) at 3 months and CFS at 6 months post-infection. RESULTS: Of the participants, 9.4% met the criteria for CF at 3 months and 7.8% met the criteria for CFS at 6 months. Logistic regression revealed that factors proposed to predispose people to CFS including anxiety, depression, somatization and perfectionism were associated with new-onset CFS. Negative illness beliefs including perceiving GF to be a serious, distressing condition, that will last a long time and is uncontrollable, and responding to symptoms in an all-or-nothing behavioural pattern were also significant predictors. All-or-nothing behaviour was the most significant predictor of CFS at 6 months. Perceived stress and consistently limiting activity at the time of GF were not significantly associated with CFS. CONCLUSIONS: The findings from this study provide support for the cognitive behavioural model and a good basis for developing prevention and early intervention strategies for CFS.

Murrough JW, Mao X, Collins KA, Kelly C, Andrade G, Nestadt P, Levine SM, Mathew SJ, Shungu DC.	Department of Psychiatry, Mount Sinai School of Medicine, New York, NY, USA.	Increased ventricular lactate in chronic fatigue syndrome measured by 1H MRS imaging at 3.0 T. II: comparison with major depressive disorder.	NMR Biomed. 2010 Jul;23(6):643-50.	Chronic fatigue syndrome (CFS), a complex illness characterized by fatigue, impaired concentration, and musculoskeletal pain, is often misdiagnosed as a psychiatric illness due to the overlap of its symptoms with mood and anxiety disorders. Using proton magnetic resonance spectroscopic imaging ((1)H MRSI), we previously measured levels of the major brain metabolites in CFS, in generalized anxiety disorder (GAD), and in healthy control subjects, and found significantly higher levels of ventricular cerebrospinal fluid (CSF) lactate in CFS compared to the other two groups. In the present study, we sought to assess the specificity of this observation for CFS by comparing ventricular lactate levels in a new cohort of 17 CFS subjects with those in 19 healthy volunteers and in 21 subjects with major depressive disorder (MDD), which, like GAD, is a neuropsychiatric disorder that has significant symptom overlap with CFS. Ventricular CSF lactate was significantly elevated in CFS compared to healthy volunteers, replicating the major result of our previous study. Ventricular lactate measures in MDD did not differ from those in either CFS or healthy volunteers. We found a significant correlation between ventricular CSF lactate and severity of mental fatigue that was specific to the CFS group. In an exploratory analysis, we did not find evidence for altered levels of the amino acid neurotransmitters, gamma-aminobutyric acid (GABA) and glutamate + glutamine ('Glx'), in CFS compared to MDD or healthy controls. Future (1)H MRS studies with larger sample sizes and well-characterized populations will be necessary to further clarify the sensitivity and specificity of neurometabolic abnormalities in CFS and MDD.
Naess H, Sundal E, Myhr KM, Nyland HI.	Department of Neurology, Haukeland University Hospital, University of Bergen, Bergen, Norway. halvor.naess@haukeland.no	Postinfectious and chronic fatigue syndromes: clinical experience from a tertiary-referral centre in Norway.	In Vivo. 2010 Mar-Apr;24(2):185-8.	BACKGROUND: We aimed to compare patients reporting acute infection with those reporting no infection at onset of chronic fatigue syndrome (CFS). PATIENTS AND METHODS: This study includes 873 patients with CFS referred to a tertiary centre on average 4.8 years after symptom onset. Assessment was by both observer query and self-reports. Antibody analyses against infectious agents including Epstein-Barr virus and enterovirus were performed in a majority of patients. RESULTS: Females comprised 75.3% of the patient group, and the mean age was 33 years. Initial infection was reported by 77%. There was no difference as to antibody analyses. Logistic regression showed that initial infection was independently associated with acute onset of fatigue, improvement of fatigue at referral, and the following symptoms at referral: fever, tender lymph nodes, and myalgia. CONCLUSION: CFS patients with initial infection as a precipitating factor more often report acute onset of fatigue, more frequent accompanying symptoms, and more frequent improvement on referral than do patients without initial infection.
Nakamura T, Schwander SK, Donnelly R, Ortega F, Togo F, Broderick G, Yamamoto Y,	Pain & Fatigue Study Center, UMDNJ--New Jersey Medical School, Newark, New Jersey 07103,	Cytokines across the night in chronic fatigue syndrome with and without fibromyalgia.	Clin Vaccine Immunol. 2010 Apr;17(4):582-7. Epub 2010 Feb 24.	The symptoms of chronic fatigue syndrome (CFS) are consistent with cytokine dysregulation. This has led to the hypothesis of immune dysregulation as the cause of this illness. To further test this hypothesis, we did repeated blood sampling for cytokines while patients and matched healthy controls slept in the sleep lab. Because no one method for assaying cytokines is acknowledged to be better than another, we assayed for protein in serum, message in peripheral blood lymphocytes (PBLs), and function in resting and stimulated PBLs. We found no evidence of proinflammatory

Cherniack NS, Rapoport D, Natelson BH.	USA.			cytokine upregulation. Instead, in line with some of our earlier studies, we did find some evidence to support a role for an increase in interleukin-10, an anti-inflammatory cytokine. Although the changes were small, they may contribute to the common complaint in CFS patients of disrupted sleep.
Nater UM, Jones JF, Lin JM, Maloney E, Reeves WC, Heim C.	Chronic Viral Diseases Branch, Coordinating Center for Infectious Diseases, Centers for Disease Control and Prevention, Atlanta, Ga., USA.	Personality features and personality disorders in chronic fatigue syndrome: a population-based study.	Psychother Psychosom. 2010;79(5):312-8. Epub 2010 Jul 28.	BACKGROUND: Chronic fatigue syndrome (CFS) presents unique diagnostic and management challenges. Personality may be a risk factor for CFS and may contribute to the maintenance of the illness. METHODS: 501 study participants were identified from the general population of Georgia: 113 people with CFS, 264 with unexplained unwellness but not CFS (insufficient fatigue, ISF) and 124 well controls. We used the Personality Diagnostic Questionnaire, 4th edition, to evaluate DSM-IV personality disorders. We used the NEO Five-Factor Inventory to assess personality features (neuroticism, extraversion, openness, agreeableness and conscientiousness). The Multidimensional Fatigue Inventory measured 5 dimensions of fatigue, and the Medical Outcomes Survey Short Form 36 measured 8 dimensions of functional impairment. RESULTS: Twenty-nine percent of the CFS cases had at least 1 personality disorder, compared to 28% of the ISF cases and 7% of the well controls. The prevalence of paranoid, schizoid, avoidant, obsessive-compulsive and depressive personality disorders were significantly higher in CFS and ISF compared to the well controls. The CFS cases had significantly higher scores on neuroticism, and significantly lower scores on extraversion than those with ISF or the well controls. Personality features were correlated with selected composite characteristics of fatigue. CONCLUSIONS: Our results suggest that CFS is associated with an increased prevalence of maladaptive personality features and personality disorders. This might be associated with being noncompliant with treatment suggestions, displaying unhealthy behavioral strategies and lacking a stable social environment. Since maladaptive personality is not specific to CFS, it might be associated with illness per se rather than with a specific condition.
Neu D, Kajosch H, Peigneux P, Verbanck P, Linkowski P, Le Bon O.	Brugmann University Hospital, Sleep Laboratory and Unit for Chronobiology U78, Department of Psychiatry, Université Libre de Bruxelles (U.L.B), Brussels, Belgium.	Cognitive impairment in fatigue and sleepiness associated conditions.	Psychiatry Res. 2010 Dec 31. [Epub ahead of print]	Although relating to very different concepts, sleepiness and fatigue are often confounded. However, both fatigue associated conditions as the chronic fatigue syndrome (CFS) and sleepiness associated conditions as the sleep apnea-hypopnea syndrome (SAHS) reported cognitive impairment with lowered attention, concentration and memory performances. Fifteen pure CFS patients, without primary sleep disorders or clinically relevant sleepiness, were compared to 15 untreated SAHS patients, without clinically relevant fatigue, and to 16 healthy controls of similar age. Auditory verbal learning test (AVLT), digit span, digit symbol and finger tapping test (FTT) were used as cognitive and behavioural measures. In addition we assessed daytime EEG spectral power and P300 evoked potentials. With exception for the digit span, all tests showed lower performances in patient groups. Recall on the AVLT did not differ between the two patient groups, but the digit and symbol spans showed more severe impairment in SAHS patients. Psychomotor performance on the FTT presented with slower hit rates in SAHS than in CFS. EEG theta power was highest in CFS patients. P300 latencies and amplitudes did not differ between groups. Fatigue and sleepiness associated conditions can both present with significant and objective impairment of cognitive functioning and behavioural motor performance. In our sample cognitive impairment and psychomotor performance were worse when associated to sleepiness in SAHS than to fatigue in CFS.
Newton JL, Mabillard H, Scott	NIHR Biomedical Research Centre in	The Newcastle NHS Chronic	J R Coll Physicians Edinb. 2010	In England the Department of Health has funded specialist clinical services aimed at diagnosing and managing the symptoms of chronic fatigue syndrome (CFS). These services are not available to those

A, Hoad A, Spickett G.	Ageing and Institute for Ageing & Health, Newcastle University, Newcastle upon Tyne NE1 4LP, UK. julia.newton@nuth.nhs.uk.	Fatigue Syndrome Service: not all fatigue is the same.	Dec;40(4):304-7.	who do not fulfil the diagnostic criteria for CFS. This service evaluation examined the proportion of those referred to a specialist CFS service fulfilling the Fukuda diagnostic criteria for CFS and the alternative fatigue-associated diagnoses. The CFS database was interrogated to include every patient referred to the Newcastle service from November 2008 to December 2009. All medical notes were reviewed and the diagnosis, sex and age recorded. Data were compared to a previous service evaluation (2005-07). In 2008-09, 260 subjects were referred: 19 referrals per month (260/14), compared with 17 referrals per month in 2005-07 (375/24). The proportion of patients diagnosed with CFS increased significantly compared with 2007 (36% [20/56] vs 60% [157/260]; p<0.0001). Of the 40% of patients subsequently found not to have CFS the most common diagnosis was fatigue associated with a chronic disease (47% of all alternative diagnoses); 20% had primary sleep disorders, 15% psychological/psychiatric illnesses and 4% a cardiovascular disorder. Thirteen per cent remained unexplained (5.2% of the total referrals). This study found a significant increase in the proportion of patients referred to National Health Service (NHS) CFS services diagnosed with CFS. A large proportion of patients presenting with fatigue are not eligible for referral to the Department of Health specialist fatigue services, which represents an unmet need in terms of symptom management in current NHS services.
Nickel JC, Tripp DA, Pontari M, Moldwin R, Mayer R, Carr LK, Doggweiler R, Yang CC, Mishra N, Nordling J.	Department of Urology, Queen's University, Kingston General Hospital, Kingston, Ontario, Canada. jcn@queensu.ca	Interstitial cystitis/painful bladder syndrome and associated medical conditions with an emphasis on irritable bowel syndrome, fibromyalgia and chronic fatigue syndrome.	J Urol. 2010 Oct;184(4):1358-63. Epub 2010 Aug 17.	PURPOSE: We characterized and compared the impact of clinical phenotypic associations between interstitial cystitis/painful bladder syndrome and controls in relation to potentially related conditions, particularly irritable bowel syndrome, fibromyalgia and chronic fatigue syndrome. MATERIALS AND METHODS: Female patients with interstitial cystitis/painful bladder syndrome and controls with no interstitial cystitis/painful bladder syndrome completed a biopsychosocial phenotyping questionnaire battery which included demographics/history form, self-reported history of associated conditions, and 10 validated questionnaires focused on symptoms, suffering/coping and behavioral/social factors. RESULTS: Questionnaires were completed by 205 patients with interstitial cystitis/painful bladder syndrome and 117 controls matched for age. Prevalence of self-reported associated condition diagnosis in interstitial cystitis/painful bladder syndrome vs controls was irritable bowel syndrome 38.6% vs 5.2%, fibromyalgia 17.7% vs 2.6% and chronic fatigue syndrome 9.5% vs 1.7% (all p <0.001). In the interstitial cystitis/painful bladder syndrome cohort 50.3% reported no other associated condition, 24.4% had interstitial cystitis/painful bladder syndrome + irritable bowel syndrome only, 2.5% had interstitial cystitis/painful bladder syndrome + fibromyalgia only, 1.5% had interstitial cystitis/painful bladder syndrome + chronic fatigue syndrome only, while 20.2% had multiple associated conditions. As the number of associated conditions increased (ie localized, regional, systemic), pain, stress, depression and sleep disturbance increased while social support, sexual functioning and quality of life deteriorated. Anxiety and catastrophizing remained increased in all groups. Symptom duration was associated with this apparent phenotypic progression. CONCLUSIONS: Irritable bowel syndrome, fibromyalgia and chronic fatigue syndrome are more prevalent in patients with interstitial cystitis/painful bladder syndrome than in asymptomatic control subjects, and result in significant impact. There are at least 3 distinct clinical phenotypes based on identification of overlapping syndrome patterns. A suggestion that remains to be proven with longitudinal studies is that there may be progression over time from an organ centric to a regional and finally to a systemic

				pain syndrome with progression of symptom severity, and deterioration of cognitive and psychosocial parameters.
Nicodemus CF, Berek JS.		TLR3 agonists as immunotherapeutic agents.	Immunotherapy. 2010 Mar;2(2):137-40.	
Nijs J, Aelbrecht S, Meeus M, Van Oosterwijck J, Zinzen E, Clarys P.	Department of Human Physiology, Faculty of Physical Education & Physiotherapy, Vrije Universiteit Brussel, Belgium.	Tired of being inactive: a systematic literature review of physical activity, physiological exercise capacity and muscle strength in patients with chronic fatigue syndrome.	Disabil Rehabil. 2010 Dec 20. [Epub ahead of print]	A systematic review was undertaken to examine whether patients with chronic fatigue syndrome (CFS) differ from healthy sedentary controls in physiological exercise capacity, physical activity level and muscle strength. From the available literature, it can be concluded that patients with CFS perform less physical activity during daily life, and have less peak isometric muscle strength compared to healthy sedentary control subjects. Conflicting data in relation to physiological exercise capacity of patients with CFS have been reported, but the weighted available evidence points towards a reduced physiological exercise capacity in CFS. Future studies should use a wash-out period for medication use, blinded assessments, a priori power calculation and a sedentary control group comparable for age, gender, body weight, body length and current physical activity level.
Nijs J, Van Oosterwijck J, Meeus M, Lambrecht L, Metzger K, Frémont M, Paul L.	Department of Human Physiology, Faculty of Physical Education & Physiotherapy, Vrije Universiteit Brussel, Brussels, Belgium. jo.nijs@vub.ac.be	Unravelling the nature of postexertional malaise in myalgic encephalomyelitis/ chronic fatigue syndrome: the role of elastase, complement C4a and interleukin-1beta.	J Intern Med. 2010 Apr;267(4):418-35.	OBJECTIVES: Too vigorous exercise or activity increase frequently triggers postexertional malaise in people with myalgic encephalomyelitis/chronic fatigue syndrome (ME/CFS), a primary characteristic evident in up to 95% of people with ME/CFS. The present study aimed at examining whether two different types of exercise results in changes in health status, circulating elastase activity, interleukin (IL)-1beta and complement C4a levels. DESIGN: Comparative experimental design. SETTING: University. SUBJECTS: Twenty-two women with ME/CFS and 22 healthy sedentary controls Interventions: participants were subjected to a submaximal exercise (day 8) and a self-paced, physiologically limited exercise (day 16). Each bout of exercise was preceded and followed by blood sampling, actigraphy and assessment of their health status. RESULTS: Both submaximal exercise and self-paced, physiologically limited exercise resulted in postexertional malaise in people with ME/CFS. However, neither exercise bout altered elastase activity, IL-1beta or complement C4a split product levels in people with ME/CFS or healthy sedentary control subjects ($P > 0.05$). Postexercise complement C4a level was identified as a clinically important biomarker for postexertional malaise in people with ME/CFS. CONCLUSIONS: Submaximal exercise as well as self-paced, physiologically limited exercise triggers postexertional malaise in people with ME/CFS, but neither types of exercise alter acute circulating levels of IL-1beta, complement C4a split product or elastase activity. Further studying of immune alterations in relation to postexertional malaise in people with ME/CFS using multiple measurement points postexercise is required.
Nogué Xarau S, Alarcón Romay M, Martínez Martínez JM, Delclós Clanchet J, Rovira	Unidad de Toxicología Clínica, Hospital Clínic, Barcelona, España.	[Multiple chemical sensitivity: Epidemiological, clinical and prognostic	Med Clin (Barc). 2010 Jun 12;135(2):52-8. Epub 2010 Mar 19.	BACKGROUND AND OBJECTIVE: The progressive increase in cases of multiple chemical sensitivity (MCS) syndrome and the lack of studies which associate the syndrome with possible occupational origins means that further research in this field is required. The objective of this study was to compare the epidemiological, clinical and prognostic aspects of cases of MCS of occupational and non-occupational origin. PATIENTS AND METHOD: Observational study of patients diagnosed with MCS by

Prat E, Fernández Solà J.		differences between occupational and non-occupational cases.]. [Article in Spanish]		the toxicology outpatients clinic of the Hospital Clinic of Barcelona between 2002 and 2007. The occupational and non-occupational origin of MCS was considered as an independent variable. The dependant variables were occupational activity, triggering agents of MCS, chemical agents associated with the development of clinical manifestations, severity of the symptoms, comorbidities and work disability. Percentages were compared between groups. RESULTS: A total of 165 patients were included: The mean age was 47.7 years and 90.9% were women. There were significant differences between patients of occupational and non-occupational origin with respect to comorbidities such as chronic fatigue syndrome (68.1% versus 88.5%; p=0.002) and fibromyalgia (49.3% versus 73.9%; p=0.002), temporary disability (60.9% versus 39.6%; p=0.006) and permanent disability (8.7% versus 22.9%; p=0.006). CONCLUSIONS: Cases of MCS attributed to an occupational origin had fewer comorbidities and less permanent disability than those of non-occupational origin.
Oakes B, Tai AK, Cingoz O, Henefield MH, Levine S, Coffin JM, Huber BT.		Contamination of human DNA samples with mouse DNA can lead to false detection of XMRV-like sequences.	Retrovirology. 2010 Dec 20;7(1):109. [Epub ahead of print]	ABSTRACT: BACKGROUND: In 2006, a novel gammaretrovirus, XMRV (xenotropic murine leukemia virus-related virus), was discovered in some prostate tumors. A more recent study indicated that this infectious retrovirus can be detected in 67% of patients suffering from chronic fatigue syndrome (CFS), but only very few healthy controls (4%). However, several groups have published to date that they could not identify XMRV RNA or DNA sequences in other cohorts of CFS patients, while another group detected murine leukemia virus (MLV)-like sequences in 87% of such patients, but only 7% of healthy controls. Since there is a high degree of similarity between XMRV and abundant endogenous MLV proviruses, it is important to distinguish contaminating mouse sequences from true infections. RESULTS: DNA from the peripheral blood of 112 CFS patients and 36 healthy controls was tested for XMRV with two different PCR assays. A TaqMan qPCR assay specific for XMRV pol sequences was able to detect viral DNA from 2 XMRV-infected cells (~ 10-12 pg DNA) in up to 5 g of human genomic DNA, but yielded negative results in the test of 600 ng genomic DNA from 100,000 peripheral blood cells of all samples tested. However, positive results were obtained with some of these samples, using a less specific nested PCR assay for a different XMRV sequence. DNA sequencing of the PCR products revealed a wide variety of virus-related sequences, some identical to those found in prostate cancer and CFS patients, others more closely related to known endogenous MLVs. However, all samples that tested positive for XMRV and/or MLV DNA were also positive for the highly abundant intracisternal A-type particle (IAP) long terminal repeat and most were positive for murine mitochondrial cytochrome oxidase sequences. No contamination was observed in any of the negative control samples, containing those with no DNA template, which were included in each assay. CONCLUSIONS: Mouse cells contain upwards of 100 copies each of endogenous MLV DNA. Even much less than one cell's worth of DNA can yield a detectable product using highly sensitive PCR technology. It is, therefore, vital that contamination by mouse DNA be monitored with adequately sensitive assays in all samples tested.

Human herpesvirus 6 discovered in 1986 is the most ancient human herpesvirus shown by molecular characteristics. Variant B infects children under the age of 2 years by droplets from asymptomatic virus shedding adults occasionally causing exanthema subitum. The virus infects CD4+ macrophages and lymphocytes; subsequently establishes lifelong latency and persistence with occasional shedding through the saliva. This variant frequently reactivates in bone marrow and organ transplant recipients

	Intézet, Budapest, Nagyvárad tér 4. 1089. ongjos@hotmail.com			with concomitant immunosuppression causing even fatal complications. It is a cofactor in the pathogenesis of multiple sclerosis, chronic fatigue syndrome, Hodgkin and non-Hodgkin lymphomas. The direct consequences of variant A infection and latency in CD4+ cells are not known. It transactivates HIV infection in vitro and in humans, and facilitates tumor progression induced by human papilloma viruses. Pathogenic effects of both variants are mediated by altered cytokine and chemokine profiles. Serological differentiation of the two variants is unreliable; however, it is possible by using PCR. Ganciclovir, foscarnet and cidofovir can be used for treatment and chemoprophylaxis of severe complications.
Paprotka T, Venkatachari NJ, Chaipan C, Burdick R, Delviks-Frankenberry KA, Hu WS, Pathak VK.	Viral Mutation Section, National Cancer Institute-Frederick, P.O. Box B, Frederick, MD 21702-1201, USA.	Inhibition of xenotropic murine leukemia virus-related virus by APOBEC3 proteins and antiviral drugs.	J Virol. 2010 Jun;84(11):5719-29. Epub 2010 Mar 24.	Xenotropic murine leukemia virus-related virus (XMRV), a gammaretrovirus, has been isolated from human prostate cancer tissue and from activated CD4(+) T cells and B cells of patients with chronic fatigue syndrome, suggesting an association between XMRV infection and these two diseases. Since APOBEC3G (A3G) and APOBEC3F (A3F), which are potent inhibitors of murine leukemia virus and Vif-deficient human immunodeficiency virus type 1 (HIV-1), are expressed in human CD4(+) T cells and B cells, we sought to determine how XMRV evades suppression of replication by APOBEC3 proteins. We found that expression of A3G, A3F, or murine A3 in virus-producing cells resulted in their virion incorporation, inhibition of XMRV replication, and G-to-A hypermutation of the viral DNA with all three APOBEC3 proteins. Quantitation of A3G and A3F mRNAs indicated that, compared to the human T-cell lines CEM and H9, prostate cell lines LNCaP and DU145 exhibited 50% lower A3F mRNA levels, whereas A3G expression in 22Rv1, LNCaP, and DU145 cells was nearly undetectable. XMRV proviral genomes in LNCaP and DU145 cells were hypermutated at low frequency with mutation patterns consistent with A3F activity. XMRV proviral genomes were extensively hypermutated upon replication in A3G/A3F-positive T cells (CEM and H9), but not in A3G/A3F-negative cells (CEM-SS). We also observed that XMRV replication was susceptible to the nucleoside reverse transcriptase (RT) inhibitors zidovudine (AZT) and tenofovir and the integrase inhibitor raltegravir. In summary, the establishment of XMRV infection in patients may be dependent on infection of A3G/A3F-deficient cells, and cells expressing low levels of A3G/A3F, such as prostate cancer cells, may be ideal producers of infectious XMRV. Furthermore, the anti-HIV-1 drugs AZT, tenofovir, and raltegravir may be useful for treatment of XMRV infection.
Pardini M, Guida S, Primavera A, Krueger F, Cocito L, Gialloreti LE.	Department of Neurosciences, Ophthalmology and Genetics, University of Genoa, Genoa, Italy; Magnetic Resonance Research Centre on Nervous System Diseases, University of	Amisulpride vs. fluoxetine treatment of Chronic Fatigue Syndrome: A pilot study.	Eur Neuropsychopharmacol. 2010 Nov 26. [Epub ahead of print]	Different pharmacologic agents have been evaluated in the treatment of Chronic Fatigue Syndrome (CFS), albeit with moderate efficacy. Among the compounds thought to present with potential to be efficacious in CFS patients stands out low-dose amisulpride, a substituted benzamide that has been shown to be an useful treatment for conditions which exhibit some overlap with CFS such as dysthymia and somatoform disorders. We thus recruited forty non-depressed CFS patients that were randomized to receive either amisulpride 25mg bid, or fluoxetine 20mg uid; all subjects were un-blinded to the treatment regimen. At the time of enrollment in the study and after twelve weeks of treatment, enrolled subjects completed the Krupp Fatigue Severity Scale, the Hospital Anxiety and Depression Scale and a visual analog scale focused on pain and bodily discomfort. Moreover, all subjects were evaluated by a clinician, blinded to the treatment regimen, using the Clinical Global Impression Severity Scale. Our data revealed a significant improvement both in self-report, and observer-based measures for the amisulpride-treated, but not for the fluoxetine-treated patients.

	Genoa, Genoa, Italy; Centre for Communication and Neurorehabilitation Research-CNAPP, Rome, Italy.			Amisulpride-treated subjects also presented with a significant reduction of somatic complaints, while the amisulpride effect on anxiety and mood levels was not significant. Both drugs were equally well tolerated. Summing up, we showed a positive symptomatic effect of amisulpride, compared to SSRI treatment, in a group of non-depressed CSF patients on self-report and on observer-based measures of fatigue and somatic complaints. If confirmed by larger, blinded studies, amisulpride thus could represent an effective approach to this difficult-to-treat condition.
Pellicano C, Gallo A, Li X, Ikonomidou VN, Evangelou IE, Ohayon JM, Stern SK, Ehrmantraut M, Cantor F, McFarland HF, Bagnato F.	Neuroimmunology Branch, National Institute of Neurological Disorders and Stroke, National Institutes of Health, 10 Center Dr, Bethesda, MD 20892-1400, USA.	Relationship of cortical atrophy to fatigue in patients with multiple sclerosis.	Arch Neurol. 2010 Apr;67(4):447-53.	BACKGROUND: Fatigue is a common and disabling symptom of multiple sclerosis (MS). Previous studies reported that damage of the corticostriatothalamocortical circuit is critical in its occurrence. OBJECTIVE: To investigate the relationship between fatigue in MS and regional cortical and subcortical gray matter atrophy. DESIGN: Case-control study. SETTING: National Institutes of Health. PARTICIPANTS: Twenty-four patients with MS and 24 matched healthy volunteers who underwent 3.0-T magnetic resonance imaging and evaluations of fatigue (Modified Fatigue Impact Scale) and depression (Center for Epidemiologic Studies Depression Scale). MAIN OUTCOME MEASURES: Relationship between thalamic and basal ganglia volume, cortical thickness of frontal and parietal lobes, and, in patients, T2 lesion volume and normal-appearing white matter volume and the extent of fatigue. RESULTS: Patients were more fatigued than healthy volunteers (P = .04), while controlling for the effect of depression. Modified Fatigue Impact Scale score correlated with cortical thickness of the parietal lobe (r = -0.50, P = .01), explaining 25% of its variance. The posterior parietal cortex was the only parietal area significantly associated with the Modified Fatigue Impact Scale scores. CONCLUSIONS: Cortical atrophy of the parietal lobe had the strongest relationship with fatigue. Given the implications of the posterior parietal cortex in motor planning and integration of information from different sources, our preliminary results suggest that dysfunctions in higher-order aspects of motor control may have a role in determining fatigue in MS.
Perrin R, Embleton K, Pentreath VW, Jackson A.	Department of Medicine, University of Manchester, UK.	Longitudinal MRI shows no cerebral abnormality in chronic fatigue syndrome.	Br J Radiol. 2010 May;83(989):419-23. Epub 2010 Mar 11.	MRI has previously provided conflicting results when used to search for brain abnormalities in sufferers of chronic fatigue syndrome (CFS). Eighteen CFS patients and nine healthy volunteers each underwent MRI on two occasions, one year apart. The resulting images were examined for abnormalities in brain atrophy, deep white matter hyperintensities (WMH) and cerebral blood and cerebrospinal fluid (CSF) flow. Mean proportionate CSF volume was not significantly different between subject groups. All participants showed a slight increase in CSF between scans, but no significant difference was found between those with CFS and those without. Between-group comparisons of ventricular volume revealed no significant differences at study commencement and no significant change over the year. No significant inter-group differences were found for any of the cerebral blood and CSF flow parameters. Low levels of WMH were found in all participants. Objective scoring of WMH using Scheltens' scale revealed no change in summary components (prosencephalic deep white matter hyperintensities, basal ganglia hyperintensities and infratentorial hyperintensities) or in individual component variables between the baseline and 1 year follow-up scans. No abnormal patterns in rate and extent of brain atrophy, ventricle volume, white matter lesions, cerebral blood flow or aqueductal CSF flow were detected in the CFS population. These results throw open the debate into whether MRI scanning can reveal diagnostic signs of CFS and clinically questions the

				diagnoses of CFS made on the basis of previous research conclusions.
Pinquart M, Shen Y.	Department of Psychology, Philipps University.	Depressive Symptoms in Children and Adolescents with Chronic Physical Illness: An Updated Meta-Analysis.	J Pediatr Psychol. 2010 Nov 18. [Epub ahead of print]	OBJECTIVE: To integrate results of available studies that compared levels of depressive symptoms of children and adolescents with chronic physical illness to healthy peers or test norms. METHODS: Random-effects meta-analysis was computed with 340 studies and 450 subsamples. RESULTS: Children and adolescents with chronic illness have, on average, higher levels of depressive symptoms than their healthy peers (d = .19 SD units). Differences are strongest for chronic fatigue syndrome (d = .94), fibromyalgia (d = .59), cleft lip and palate (d = .54), migraine/tension head ache (d = .51), and epilepsy (d = .39). Larger effect sizes were found in studies with higher proportion of girls, with a healthy control group, from developing countries, published before 1990, and that used parent rating or clinician ratings rather than child ratings. CONCLUSIONS: Pediatricians and others working with children with chronic illnesses should screen children with chronic physical illness for symptoms of psychological distress and make appropriate referrals for mental health services, when needed.
Popova NF, Kamchatnov PR, Riabukhina OV, Batysheva TT, Zaĭtsev KA, Boĭko AN.	Rossiĭskiĭ gosudarstvennyĭ meditsinskiĭ universitet.	[Omaron in the complex treatment of patients with multiple sclerosis.] [Article in Russian]	Zh Nevrol Psikhiatr Im S S Korsakova. 2010;110(11):17-20.	We studied efficacy and tolerability of the combined drug omaron (25 mg of cinnarizine and 400 mg of piracetam in one tablet) in patients with multiple sclerosis. The dosage of the drug was 1 tablet 3 times a day during 12 weeks in 33 patients (mean age 35.3±4.2 years) of the index group. A comparison group consisted of 27 patients matched for demographic and clinical characteristics who did not receive nootropics during the study. None of patients included in the study received disease modifying drugs. The significant ($p<0.05$) decrease in the severity of chronic fatigue syndrome (by 28.6% compared to baseline), improvement ($p<0.05$) of cognitive functions (increase of MMSE scores by 9.4%) were found in the index group compared to the comparison one. The statistically significant changes in the severity of disability assessed by EDSS were not observed. Omaron was well-tolerated with no serious adverse-effects.
Porter NS, Jason LA, Boulton A, Bothne N, Coleman B.	Center for Community Research, DePaul University, Chicago, IL 60614, USA.	Alternative medical interventions used in the treatment and management of myalgic encephalomyelitis/ chronic fatigue syndrome and fibromyalgia.	J Altern Complement Med. 2010 Mar;16(3):235-49.	BACKGROUND: There have been several systematic reviews attempting to evaluate the efficacy of possible treatments for myalgic encephalomyelitis/chronic fatigue syndrome (ME/CFS) and fibromyalgia (FM). However, information regarding the efficacy of complementary and alternative medicine (CAM) has not been comprehensively or systematically covered in these reviews, despite its frequent use in the patient community. PURPOSE: The purpose of this study was to systematically review and evaluate the current literature related to alternative and complementary treatments for ME/CFS and FM. It should be stressed that the treatments evaluated in this review do not reflect the clinical approach used by most practitioners to treat these illnesses, which include a mix of natural and unconventionally used medications and natural hormones tailored to each individual case. However, nearly all clinical research has focused on the utility of single CAM interventions, and thus is the primary focus of this review. METHODS: Several databases (e.g., PubMed, MEDLINE,((R)) PsychInfo) were systematically searched for randomized and nonrandomized controlled trials of alternative treatments and nonpharmacological supplements. Included studies were checked for references and several experts were contacted for referred articles. Two leading subspecialty journals were also searched by hand. Data were then extracted from included studies and quality assessments were conducted using the Jadad scale. RESULTS: Upon completion of the literature search and the exclusion of studies not meeting criterion, a total of 70 controlled clinical trials were included in the review. Sixty (60) of the 70 studies found at least one positive effect of the intervention (86%), and 52

				studies also found improvement in an illness-specific symptom (74%). The methodological quality of reporting was generally poor. CONCLUSIONS: Several types of alternative medicine have some potential for future clinical research. However, due to methodological inconsistencies across studies and the small body of evidence, no firm conclusions can be made at this time. Regarding alternative treatments, acupuncture and several types of meditative practice show the most promise for future scientific investigation. Likewise, magnesium, l-carnitine, and S-adenosylmethionine are nonpharmacological supplements with the most potential for further research. Individualized treatment plans that involve several pharmacological agents and natural remedies appear promising as well.
Prior KN, Bond MJ.	Discipline of General Practice, School of Medicine, Flinders University, Adelaide, Australia.	New dimensions of abnormal illness behaviour derived from the Illness Behaviour Questionnaire.	Psychol Health. 2010 Dec;25(10):1209-27.	The primary aim was to explore the factor structure of the Illness Behaviour Questionnaire (IBQ) and the generalisability of the derived dimensions to both general community members and four chronic illness groups. A questionnaire was administered to 675 participants, comprising 344 from the community, 80 with asthma, 95 with diabetes, 79 with chronic pain and 77 with chronic fatigue syndrome (CFS). Illness severity was calculated for all chronic illness participants (self-rated health for community members). Three IBQ scales were derived following an exploratory factor analysis for the whole sample: Affirmation of Illness (α = 0.71 (CFS)-0.79 (asthma, diabetes)), Concern for Health (α = 0.71 (asthma)-0.78 (pain)) and General Affective State (α = 0.70 (CFS)-0.80 (asthma)). Patterns of response across the five samples, and intercorrelations among the new scales and the original seven scales, were largely in accord with expectation. Long-standing criticisms of the IBQ were addressed by using systematic statistical principles to identify meaningful and psychometrically sound IBQ dimensions. The derived structure offers a more parsimonious account of possible illness responses, with the availability of a more concise yet informative index of abnormal illness behaviour having practical utility for researchers and clinicians alike.
Qiu X, Swanson P, Luk KC, Tu B, Villinger F, Das Gupta J, Silverman RH, Klein EA, Devare S, Schochetman G, Hackett J Jr.	Infectious Diseases R&D, Abbott Diagnostics, 100 Abbott Park Rd, Abbott Park, IL 60064, USA. xiaoxing.qiu@abbott.com	Characterization of antibodies elicited by XMRV infection and development of immunoassays useful for epidemiologic studies.	Retrovirology. 2010 Aug 17;7:68.	BACKGROUND: Xenotropic Murine Leukemia Virus-related Virus (XMRV) is a human gammaretrovirus recently identified in prostate cancer tissue and in lymphocytes of patients with chronic fatigue syndrome. To establish the etiologic role of XMRV infection in human disease requires large scale epidemiologic studies. Development of assays to detect XMRV-specific antibodies would greatly facilitate such studies. However, the nature and kinetics of the antibody response to XMRV infection have yet to be determined. RESULTS: Three rhesus macaques were infected with XMRV to determine the dynamics of the antibody responses elicited by infection with XMRV. All macaques developed antibodies to XMRV during the second week of infection, and the predominant responses were to the envelope protein gp70, transmembrane protein p15E, and capsid protein p30. In general, antibody responses to gp70 and p15E appeared early with higher titers than to p30, especially in the early period of seroconversion. Antibodies to gp70, p15E and p30 persisted to 158 days and were substantially boosted by re-infection, thus, were identified as useful serologic markers. Three high-throughput prototype assays were developed using recombinant proteins to detect antibodies to these viral proteins. Both gp70 and p15E prototype assays demonstrated 100% sensitivity by detecting all Western blot (WB) positive serial bleeds from the XMRV-infected macaques and good specificity (99.5-99.9%) with blood donors. Seroconversion sensitivity and specificity of the p30 prototype assay were 92% and 99.4% respectively. CONCLUSIONS: This study provides the first demonstration of

				seroconversion patterns elicited by XMRV infection. The nature and kinetics of antibody responses to XMRV in primates were fully characterized. Moreover, key serologic markers useful for detection of XMRV infection were identified. Three prototype immunoassays were developed to detect XMRV-specific antibodies. These assays demonstrated good sensitivity and specificity; thus, they will facilitate large scale epidemiologic studies of XMRV infection in humans.
Quinn C.		A mystery no more.	Nurs Stand. 2010 Sep 29-Oct 5;25(4):22-3.	New research has solved one of the puzzles surrounding chronic fatigue syndrome, which could help in its future treatment.
Rasmussen LB.		[Maharishi Ayurveda and unclear conditions]. [Article in Norwegian]	Tidsskr Nor Laegeforen. 2010 Apr 8;130(7):721. Comment on: Tidsskr Nor Laegeforen. 2009 Aug 13;129(15):1481-3.	
Reuter SE, Evans AM.	School of Pharmacy & Medical Sciences Sansom Institute for Health Research, University of South Australia, Adelaide, SA, AUSTRALIA.	Long-chain acylcarnitine deficiency in chronic fatigue syndrome patients. Potential involvement of altered carnitine palmitoyltransferase-I activity.	J Intern Med. 2010 Dec 22. doi: 10.1111/j.1365-2796.2010.02341.x. [Epub ahead of print]	Objective. The underlying aetiology of chronic fatigue syndrome is currently unknown; however, in light of carnitine's critical role in mitochondrial energy production, it has been suggested that chronic fatigue syndrome may be associated with altered carnitine homeostasis. This study was conducted to comparatively examine full endogenous carnitine profiles in chronic fatigue syndrome patients and healthy controls. Design. A cross-sectional, observational study. Setting and subjects. Forty-four patients with chronic fatigue syndrome and 49 age- and gender-matched healthy controls were recruited from the community and studied at the School of Pharmacy & Medical Sciences, University of South Australia. Main outcome measures. All participants completed a fatigue severity scale questionnaire and had a single fasting blood sample collected which was analysed for L-carnitine and 35 individual acylcarnitine concentrations in plasma by LC-MS/MS. Results. Chronic fatigue syndrome patients exhibited significantly altered concentrations of C8:1, C12DC, C14, C16:1, C18, C18:1, C18:2 and C18:1-OH acylcarnitines; of particular note, oleyl-L-carnitine (C18:1) and linoleyl-L-carnitine (C18:2) were, on average, 30-40% lower in patients than controls ($p<0.0001$). Significant correlations between acylcarnitine concentrations and clinical symptomology were also demonstrated. Conclusions. It is proposed that this disturbance in carnitine homeostasis is a result of a reduction in carnitine palmitoyltransferase-I (CPT-I) activity, possibly due to the accumulation of omega-6 fatty acids previously observed in this patient population. It is hypothesised that the administration of omega-3 fatty acids in combination with L-carnitine would increase CPT-I activity and improve chronic fatigue syndrome symptomology.
Rimes KA, Chalder T.	Department of Psychological Medicine, King's College London, Institute of	The Beliefs about Emotions Scale: validity, reliability and sensitivity to change.	J Psychosom Res. 2010 Mar;68(3):285-92. Epub 2009 Dec 9.	OBJECTIVE: Beliefs about the unacceptability of experiencing or expressing negative emotions have been noted in individuals with a range of problems, including chronic fatigue syndrome (CFS), irritable bowel syndrome, somatization disorder, depression, eating disorders, social phobia, posttraumatic stress disorder, and borderline personality disorder. These beliefs are likely to have implications for emotion regulation and processing, and are addressed explicitly or implicitly within many therapies

	Psychiatry, London, UK. katharine.rimes@kcl.ac.uk			including cognitive behavior therapy (CBT), mindfulness-based cognitive therapy (MBCT), and Acceptance and Commitment Therapy (ACT). This article describes the development, validation, and internal reliability of the Beliefs about Emotions Scale (BES), a self-report questionnaire to assess such beliefs. METHODS: The new scale was completed by people with CFS (n=121) and healthy controls (n=73). Twenty-two individuals with CFS completed the scale before and after CBT. RESULTS: People with CFS had significantly higher scores on this new questionnaire than healthy controls. Principal components analysis identified one factor, and the scale had high internal consistency (0.91). Scores on the BES were most highly correlated with a measure of negative perfectionism (r=0.59) and also showed significant correlations with measures of dysfunctional attitudes, self-sacrifice, depression, anxiety, and fatigue. When completed before and after CBT for CFS, the questionnaire was sufficiently sensitive to detect a significant reduction in endorsement of unhelpful beliefs about emotions. CONCLUSION: The new Beliefs about Emotions Scale showed good internal reliability, validity and sensitivity to change.
Roberts AD, Charler ML, Papadopoulos A, Wessely S, Chalder T, Cleare AJ.	King's College London, Institute of Psychiatry, Department of Psychological Medicine, London, UK.	Does hypocortisolism predict a poor response to cognitive behavioural therapy in chronic fatigue syndrome?	Psychol Med. 2010 Mar;40(3):515-22. Epub 2009 Jul 17.	BACKGROUND: There is evidence that patients with chronic fatigue syndrome (CFS) have mild hypocortisolism. The clinical significance of this is unclear. We aimed to determine whether hypocortisolism exerted any effect on the response of CFS to cognitive behavioural therapy (CBT). METHOD: We measured 24-h urinary free cortisol (UFC) in 84 patients with Centers for Disease Control and Prevention (CDC)-defined CFS (of whom 64 were free from psychotropic medication) who then received CBT in a specialist, tertiary out-patient clinic as part of their usual clinical care. We also measured salivary cortisol output from 0800 to 2000 h in a subsample of 56 psychotropic medication-free patients. RESULTS: Overall, 39% of patients responded to CBT after 6 months of treatment. Lower 24-h UFC output was associated with a poorer response to CBT but only in psychotropic medication-free patients. A flattened diurnal profile of salivary cortisol was also associated with a poor response to CBT. CONCLUSIONS: Low cortisol is of clinical relevance in CFS, as it is associated with a poorer response to CBT. Hypocortisolism could be one of several maintaining factors that interact in the persistence of CFS.
Robinson M, Gray SR, Watson MS, Kennedy G, Hill A, Belch JJ, Nimmo MA.	Strathclyde Institute of Pharmacy and Biomedical Sciences, University of Strathclyde, Glasgow, UK.	Plasma IL-6, its soluble receptors and F2-isoprostanes at rest and during exercise in chronic fatigue syndrome.	Scand J Med Sci Sports. 2010 Apr;20(2):282-90. Epub 2009 Apr 13.	The aim of the current study was to investigate the levels of interleukin-6 (IL-6), its soluble receptors (sIL-6R and sgp130) and F(2)-isoprostanes, at rest and during exercise, in patients with chronic fatigue syndrome (CFS). Six male CFS patients and six healthy controls performed an incremental exercise test to exhaustion and a submaximal exercise bout to exhaustion. Blood samples taken in the submaximal test at rest, immediately post-exercise and 24 h post-exercise were analyzed for IL-6, sIL-6R, sgp130 and F(2)-isoprostanes. A further 33 CFS and 33 healthy control participants gave a resting blood sample for IL-6 and sIL-6R measurement. During the incremental exercise test only power output at the lactate threshold was lower ($P<0.05$) in the CFS group. F(2)-isoprostanes were higher ($P<0.05$) in CFS patients at rest and this difference persisted immediately and 24 h post-exercise. The exercise study found no differences in IL-6, sIL-6R or sgp130 at any time point between groups. In the larger resting group, there were no differences in IL-6 and sIL-6R between CFS and control groups. This investigation has demonstrated that patients with CFS do not have altered plasma levels of IL-6, sIL-6R or sgp130 either at rest or following exercise. F(2)-isoprostanes, however, were consistently higher in CFS patients.

Robinson MJ, Erlwein OW, Kaye S, Weber J, Cingoz O, Patel A, Walker MM, Kim WJ, Uiprasertkul M, Coffin JM, McClure MO.		Mouse DNA contamination in human tissue tested for XMRV.	Retrovirology. 2010 Dec 20;7(1):108. [Epub ahead of print]	ABSTRACT: BACKGROUND: We used a PCR-based approach to study the prevalence of genetic sequences related to a gammaretrovirus, xenotropic murine leukemia virus-related virus, XMRV, in human prostate cancer. This virus has been identified in the US in prostate cancer patients and in those with chronic fatigue syndrome. However, with the exception of two patients in Germany, XMRV has not been identified in prostate cancer tissue in Europe. Most putative associations of new or old human retroviruses with diseases have turned out to be due to contamination. We have looked for XMRV sequences in DNA extracted from formalin-fixed paraffin- embedded prostate tissues. To control for contamination, PCR assays to detect either mouse mitochondrial DNA (mtDNA) or intracisternal A particle (IAP) long terminal repeat DNA were run on all samples, owing to their very high copy number in mouse cells. RESULTS: In general agreement with the US prevalence, XMRV-like sequences were found in 4.8% of prostate cancers. However, these were also positive, as were 21.5% of XMRV-negative cases, for IAP sequences, and many, but not all were positive for mtDNA sequences. CONCLUSIONS: These results show that contamination with mouse DNA is widespread and detectable by the highly sensitive IAP assay, but not always with less sensitive assays, such as murine mtDNA PCR. This study highlights the ubiquitous presence of mouse DNA in laboratory specimens and offers a means of rigorous validation for future studies of murine retroviruses in human disease.
Rusmevichientong A, Chow SA.	Department of Molecular and Medical Pharmacology, Molecular Biology Institute, 650 Charles E. Young Drive, Los Angeles, CA 90095, USA.	Biology and pathophysiology of the new human retrovirus XMRV and its association with human disease.	Immunol Res. 2010 Dec;48(1-3):27-39.	Xenotropic murine leukemia virus-related virus (XMRV) is a new human retrovirus originally identified in prostate cancer patients with a deficiency in the antiviral enzyme RNase L. XMRV has been detected with varying frequencies in cases of prostate cancer and chronic fatigue syndrome (CFS), as well as in a small proportion of healthy individuals. An etiologic link between XMRV infection and human disease, however, has yet to be established. Here, we summarize existing knowledge regarding the characteristics of XMRV replication, association of XMRV with prostate cancer and CFS, and potential mechanisms of XMRV pathophysiology. We also highlight several areas, such as the establishment of standardized assays and the development of animal models, as future directions to advance our current understanding of XMRV and its relevance to human disease.
Sachdeva AK, Kuhad A, Tiwari V, Arora V, Chopra K.	Pharmacology Research Laboratory, University Institute of Pharmaceutical Sciences, UGC Centre of Advanced Study, Panjab University, Chandigarh, India.	Protective effect of epigallocatechin gallate in murine water-immersion stress model of chronic fatigue syndrome.	Basic Clin Pharmacol Toxicol. 2010 Jun;106(6):490-6. Epub 2010 Jan 18.	Chronic fatigue syndrome (CFS) is a specific clinical condition that characterizes unexplained disabling fatigue. In the present study, chronic fatigue was produced in mice by subjecting them to forced swim inside a rectangular jar of specific dimensions for 6 min. daily for 15 days. Epigallocatechin gallate (EGCG; 25, 50 and 100 mg/kg, p.o.) was administered daily 30 min. before forced swim session. Immobility period and post-swim fatigue was assessed on alternate days. On the 16th day, after assessment of various behavioural parameters, mice were killed to harvest the brain, spleen and thymus. There was significant increase in oxidative-nitrosative stress and tumour necrosis factor-alpha levels in the brain of mice subjected to water-immersion stress as compared with naive group. These behavioural and biochemical alterations were restored after chronic treatment with EGCG. The present study points out that EGCG could be of therapeutic potential in the treatment of chronic fatigue.

Llobet G, Sáez N, Alegre J, Jacas C.	Universitario Vall d'Hebron, Universitat Autònoma de Barcelona, Barcelona, España.	inpairment in patients with chronic fatigue syndrome.] [Article in Spanish]		PASAT, forward and backward digits (WAIS-III), symbol digit modalities test (SDMT); executive functions: Stroop Test, Trail Making Test (TMT A y B), FAS, Tower of London; memory: Auditory-Verbal Learning Test (AVL), Rey Complex Figure (RCF), and psychomotor skills: Grooved Pegboard. The raw scores on the tests were adjusted according to normative data and transformed to T scores. The sample was divided into two groups based on the presence or absence of depression, assessed by clinical interview and administration of the Hospital Anxiety and Depression Scale (HADS). This study compared neuropsychological test scores between the two groups. RESULTS: CFS patients showed cognitive deficit in attention and executive functions, regardless of the presence of depression. There were no significant differences between the two CFS groups. CONCLUSIONS: The cognitive impairments in patients with CFS are not secondary to the presence of depression. These results should be taken into account in the implementation of therapeutic programs in these patients.

Sathyapalan T, Beckett S, Rigby AS, Mellor DD, Atkin SL.	Department of Endocrinology, Diabetes and Metabolism, Hull York Medical School, Michael White Diabetes Centre, Hull Royal Infirmary, 220-236 Anlaby Road, Hull, HU32RW UK. thozhukat.sathyapalan@hyms.ac.uk	High cocoa polyphenol rich chocolate may reduce the burden of the symptoms in chronic fatigue syndrome.	Nutr J. 2010 Nov 22;9:55.	BACKGROUND: Chocolate is rich in flavonoids that have been shown to be of benefit in disparate conditions including cardiovascular disease and cancer. The effect of polyphenol rich chocolate in subjects with chronic fatigue syndrome (CFS) has not been studied previously. METHODS: We conducted a double blinded, randomised, clinical pilot crossover study comparing high cocoa liquor/polyphenol rich chocolate (HCL/PR) in comparison to simulated iso-calorific chocolate (cocoa liquor free/low polyphenols(CLF/LP)) on fatigue and residual function in subjects with chronic fatigue syndrome. Subjects with CFS having severe fatigue of at least 10 out of 11 on the Chalder Fatigue Scale were enrolled. Subjects had either 8 weeks of intervention in the form of HCL/PR or CLF/LP, with a 2 week wash out period followed by 8 weeks of intervention with the other chocolate. RESULTS: Ten subjects were enrolled in the study. The Chalder Fatigue Scale score improved significantly after 8 weeks of the HCL/PR chocolate arm [median (range) Exact Sig. (2-tailed)] [33 (25 - 38) vs. 21.5 (6 - 35) 0.01], but that deteriorated significantly when subjects were given simulated iso-calorific chocolate (CLF/CP) [28.5 (17 - 20) vs. 34.5 (13-26) 0.03]. The residual function, as assessed by the London Handicap scale, also improved significantly after the HCL/PR arm [0.49 (0.33 - 0.62) vs. 0.64 (0.44 - 0.83) 0.01] and deteriorated after iso-calorific chocolate [00.44 (0.43 - 0.68) vs. 0.36 (0.33 - 0.62)0.03]. Likewise the Hospital Anxiety and Depression score also improved after the HCL/PR arm, but deteriorated after CLF/CP. Mean weight remained unchanged throughout the trial. CONCLUSION: This study suggests that HCL/PR chocolate may improve symptoms in subjects with chronic fatigue syndrome.
Sato E, Furuta RA, Miyazawa T.		An endogenous murine leukemia viral genome contaminant in a commercial RT-	Retrovirology. 2010 Dec 20;7(1):110. [Epub ahead of print]	ABSTRACT: During pilot studies to investigate the presence of viral RNA of xenotropic murine leukemia virus (MLV)-related virus (XMRV) infection in sera from chronic fatigue syndrome (CFS) patients in Japan, a positive band was frequently detected at the expected product size in negative control samples when detecting a partial gag region of XMRV using a one-step RT-PCR kit. We suspected that the kit itself might have been contaminated with small traces of endogenous MLV

		PCR Kit is amplified using standard primers for XMRV.		genome or XMRV and attempted to evaluate the quality of the kit in two independent laboratories. We purchased four one-step RT-PCR kits from Invitrogen, TaKaRa, Promega and QIAGEN in Japan. To amplify the partial gag gene of XMRV or other MLV-related viruses, primer sets (419F and 1154R, and GAG-I-F and GAG-I-R) which have been widely used in XMRV studies were employed. The nucleotide sequences of the amplicons were determined and compared with deposited sequences of a polytropic endogenous MLV (PmERV), XMRV and endogenous MLV-related viruses derived from CFS patients. We found that the enzyme mixtures of the one-step RT-PCR kit from Invitrogen were contaminated with RNA derived from PmERV. The nucleotide sequence of a partial gag region of the contaminant amplified by RT-PCR was nearly identical (99.4 % identity) to a PmERV on chromosome 7 and highly similar (96.9 to 97.6 %) to recently identified MLV-like viruses derived from CFS patients. We also determined the nucleotide sequence of a partial env region of the contaminant and found that it was almost identical (99.6 %) to the PmERV. In the investigation of XMRV infection in patients of CFS and prostate cancer, researchers should prudently evaluate the test kits for the presence of endogenous MLV as well as XMRV genomes prior to PCR and RT-PCR tests.
Satterfield BC, Garcia RA, Gurrieri F, Schwartz CE.	Cooperative Diagnostics, LLC, Greenwood, SC 29646, USA. brent@codiagnostics.com.	PCR and serology find no association between xenotropic murine leukemia virus-related virus (XMRV) and autism.	Mol Autism. 2010 Oct 14;1(1):14.	ABSTRACT: Xenotropic murine leukemia virus-related virus (XMRV) is a retrovirus implicated in prostate cancer and chronic fatigue syndrome (CFS). Press releases have suggested that it could contribute to autism spectrum disorder (ASD). In this study we used two PCR assays and one antibody assay to screen 25 blood samples from autistic children born to mothers with CFS and from 20 mixed controls including family members of the children assayed, people with fibromyalgia and people with chronic Lyme disease. Using a real-time PCR assay, we screened an additional 48 South Carolina autism disorder samples, 96 Italian ASD samples, 61 South Carolina ASD samples and 184 healthy controls. Despite having the ability to detect low copy number XMRV DNA in a large background of cellular DNA, none of the PCR assays found any evidence of XMRV infection in blood cells from patients or controls. Further, no anti-XMRV antibodies were detected, ruling out possible low level or abortive infections in blood or in other reservoirs. These results imply that XMRV is not associated with autism.
Scully P, McKernan DP, Keohane J, Groeger D, Shanahan F, Dinan TG, Quigley EM.	Alimentary Pharmabiotic Centre, University College Cork, Ireland.	Plasma cytokine profiles in females with irritable bowel syndrome and extra-intestinal co-morbidity.	Am J Gastroenterol. 2010 Oct;105(10):2235-43. Epub 2010 Apr 20.	OBJECTIVES: Irritable bowel syndrome (IBS) is a functional disorder that is associated with a number of extra-intestinal co-morbidities and a pro-inflammatory profile. This study was designed to examine the cytokine profile among a group of IBS patients with the extra-intestinal co-morbidities fibromyalgia, premenstrual dysmorphic disorder, and chronic fatigue syndrome. METHODS: In all, 100 female IBS patients with these co-morbidities, 21 IBS subjects without co-morbidity ("pure" IBS; Rome II), and 54 age-matched female controls took part in the study. Blood was drawn for measurement of the plasma cytokines interleukin (IL)-1β, IL-6, IL-8, IL-10, IL-12p70, IL-13, tumor necrosis factor (TNF)α, and interferon γ. The presence of the selected extra-intestinal manifestations was assessed using standard international criteria. RESULTS: Patients with IBS have increased plasma levels of IL-6 and IL-8; those with these extra-intestinal co-morbidities were found to have, in addition, increased levels of IL-1β and TNFα. No associations were evident between cytokine profiles and the nature of the co-morbidity or number of extra-intestinal co-morbidities present. CONCLUSIONS: Although IBS is characterized by a pro-inflammatory profile featuring the pro-inflammatory cytokines IL-6 and IL-8, IBS patients with certain extra-intestinal co-morbid conditions are distinguished by additional

				elevations in IL-1β and TNFα.
Sharp NC.	Centre for Sports Medicine and Human Performance, Brunel University, Uxbridge, West London, UK.	The human genome and sport, including epigenetics, gene doping, and athleticogenomics.	Endocrinol Metab Clin North Am. 2010 Mar;39(1):201-15, xi.	Hugh Montgomery's discovery of the first of more than 239 fitness genes together with rapid advances in human gene therapy have created a prospect of using genes, genetic elements, and cells that have the capacity to enhance athletic performance (to paraphrase the World Anti-Doping Agency's definition of gene doping). This brief overview covers the main areas of interface between genetics and sport, attempts to provide a context against which gene doping may be viewed, and predicts a futuristic legitimate use of genomic (and possibly epigenetic) information in sport.
Shepherd CB.		Chronic fatigue syndrome. Severely affected, severely neglected.	BMJ. 2010 Mar 2;340:c1181. doi: 10.1136/bmj.c1181. Comment on: BMJ. 2010;340:c738.	
Shishioh-Ikejima N, Ogawa T, Yamaguti K, Watanabe Y, Kuratsune H, Kiyama H.	Department of Anatomy & Neurobiology, Osaka City University, Graduate School of Medicine, Osaka 545-8585, Japan.	The increase of alpha-melanocyte-stimulating hormone in the plasma of chronic fatigue syndrome patients.	BMC Neurol. 2010 Aug 23;10:73.	BACKGROUND: Despite extensive research, no reliable biological marker for chronic fatigue syndrome (CFS) has yet been identified. However, hyperactivation of melanotrophs in the pituitary gland and increased levels of plasma alpha-melanocyte-stimulating hormone (alpha-MSH) have recently been detected in an animal model of chronic stress. Because CFS is considered to be caused partly by chronic stress events, increased alpha-MSH plasma levels may also occur in CFS patients. We therefore examined alpha-MSH levels in CFS patients. METHODS: Fifty-five CFS patients, who were previously diagnosed within 10 years of with the disease, were enrolled in this study. Thirty healthy volunteers were studied as controls. Fasting bloods samples were collected in the morning and evaluated for their plasma levels of alpha-MSH, adrenocorticotropic hormone (ACTH), serum cortisol and dehydroepiandrosterone sulfate (DHEA-S). Mean levels of alpha-MSH were compared between the CFS and control groups using Welch's t test. RESULTS: The mean plasma alpha-MSH concentration in the CFS group (17.9 +/- 1.0 pg/mL) was significantly higher than that in healthy controls (14.5 +/- 1.0 pg/mL, p = 0.02). However, there was a wide range of values in the CFS group. The factors correlated with the plasma alpha-MSH values were analyzed using Spearman's rank correlation. A negative correlation was found between the duration of the CFS and the plasma alpha-MSH values (p = 0.04, rs = -0.28), but no correlations with ACTH, cortisol or DHEA-S levels were identified (p = 0.55, 0.26, 0.33, respectively). The CFS patients were divided into two groups: patients diagnosed for <or= 5 years' duration, and those diagnosed for 5-10 years' duration. They were compared with the healthy controls using one-way ANOVA and Tukey-Kramer multiple comparison tests. The mean alpha-MSH concentration in the <or= 5 years group was 20.8 +/- 1.2 pg/mL, which was significantly higher than that in the healthy controls (p < 0.01). There was no significant difference between the 5-10 year group (15.6 +/- 1.4 pg/mL) and the healthy controls. CONCLUSIONS: CFS patients with a disease duration of <or= 5 years had significantly higher levels of alpha-MSH in their peripheral blood. alpha-MSH could be a potent biological marker for the diagnosis of CFS, at least during the first 5 years after onset of the disease.
Silverman MN,	Section on	Neuroendocrine	PM R. 2010	Central fatigue, a persistent and subjective sense of tiredness, generally correlates poorly with

Heim CM, Nater UM, Marques AH, Sternberg EM.	Neuroendocrine Immunology and Behavior, National Institute of Mental Health, National Institutes of Health, Rockville, MD(dagger).	and immune contributors to fatigue.	May;2(5):338-46.	traditional markers of disease. It is frequently associated with psychosocial factors, such as depression, sleep disorder, anxiety, and coping style, which suggest that dysregulation of the body's stress systems may serve as an underlying mechanism in the maintenance of chronic fatigue (CF). This article addresses the endocrine, neural, and immune factors that contribute to fatigue and describes research regarding the role of these factors in chronic fatigue syndrome as a model for addressing the biology of CF. In general, hypoactivity of the hypothalamic-pituitary-adrenal axis, autonomic nervous system alterations characterized by sympathetic overactivity and low vagal tone, as well as immune abnormalities, may contribute to the expression of CF. Noninvasive methods for evaluating endocrine, neural, and immune function are also discussed. Simultaneous evaluation of neuroendocrine and immune systems with noninvasive techniques will help elucidate the underlying interactions of these systems, their role in disease susceptibility, and progression of stress-related disorders.
Silverman RH, Nguyen C, Weight CJ, Klein EA.	Department of Cancer Biology, Lerner Research Institute, Cleveland Clinic, 9500 Euclid Avenue, Cleveland, OH 44195, USA. silverr@ccf.org	The human retrovirus XMRV in prostate cancer and chronic fatigue syndrome.	Nat Rev Urol. 2010 Jul;7(7):392-402. Epub 2010 Jun 1.	Xenotropic murine leukemia virus-related virus (XMRV) is an authentic, newly recognized human retrovirus first identified in prostate cancer tissues from men with a deficiency in the innate immunity gene RNASEL. At present, studies have detected XMRV at widely different rates in prostate cancer cases (0-27%) and in patients with chronic fatigue syndrome (CFS; 0-67%). Indirect or direct modes of carcinogenesis by XMRV have been suggested depending on whether the virus was found in stroma or malignant epithelium. Viral replication in the prostate might be affected by androgens, which stimulate XMRV through a transcriptional enhancer site in viral DNA. By contrast, host restriction factors, such as APOBEC3 and tetherin, inhibit virus replication. Immune dysfunction mediated by XMRV has been suggested as a possible factor in CFS. Recent studies show that some existing antiretroviral drugs suppress XMRV infections and diagnostic assays are under development. Although other retroviruses of the same genus as XMRV (gammaretroviruses) cause cancer and neurological disease in animals, whether XMRV is a cause of either prostate cancer or CFS remains unknown. Emerging science surrounding XMRV is contributing to our knowledge of retroviral infections while focusing intense interest on two major human diseases.
Singh IR, Gorzynski JE, Drobysheva D, Bassit L, Schinazi RF.	Department of Pathology, University of Utah, Salt Lake City, Utah, United States of America. ila.singh@path.utah.edu	Raltegravir is a potent inhibitor of XMRV, a virus implicated in prostate cancer and chronic fatigue syndrome.	PLoS One. 2010 Apr 1;5(4):e9948.	BACKGROUND: Xenotropic murine leukemia-related retrovirus (XMRV) is a recently discovered retrovirus that has been linked to human prostate cancer and chronic fatigue syndrome (CFS). Both diseases affect a large fraction of the world population, with prostate cancer affecting one in six men, and CFS affecting an estimated 0.4 to 1% of the population. PRINCIPAL FINDINGS: Forty-five compounds, including twenty-eight drugs approved for use in humans, were evaluated against XMRV replication in vitro. We found that the retroviral integrase inhibitor, raltegravir, was potent and selective against XMRV at submicromolar concentrations, in MCF-7 and LNCaP cells, a breast cancer and prostate cancer cell line, respectively. Another integrase inhibitor, L-000870812, and two nucleoside reverse transcriptase inhibitors, zidovudine (ZDV), and tenofovir disoproxil fumarate (TDF) also inhibited XMRV replication. When combined, these drugs displayed mostly synergistic effects against this virus, suggesting that combination therapy may delay or prevent the selection of resistant viruses. CONCLUSIONS: If XMRV proves to be a causal factor in prostate cancer or CFS, these discoveries may allow for rational design of clinical trials.
Smith HS, Barkin	Albany Medical	Fibromyalgia	Am J Ther. 2010	Fibromyalgia is a complex condition that is characterized by chronic widespread pain and multiple

RL.	College, Department of Anesthesiology, Albany, NY 12208, USA. smithh@mail.amc.edu	syndrome: a discussion of the syndrome and pharmacotherapy.	Jul-Aug;17(4):418-39.	other symptoms, including fatigue, sleep disturbances, cognitive dysfunction, stiffness, and depressive episodes. Fibromyalgia may coexist and/or overlap with other conditions that may involve central sensitivity, including chronic fatigue syndrome, irritable bowel syndrome, irritable bladder syndrome or interstitial cystitis, and temporomandibular disorder. The pathophysiology of fibromyalgia remains uncertain but is believed to be partly the result of central systems affecting afferent processing as well as impaired endogenous pain-inhibitory systems. Abnormal central nociceptive processing may contribute to fibromyalgia, producing heightened responses to various noxious stimuli with resulting mechanical hyperalgesia. Fibromyalgia remains a clinical diagnosis. There has been a recent paradigm shift away from requiring 11 or more out of 18 tender points and instead focusing on the presence of chronic widespread pain as well as symptoms of fatigue, unrefreshed sleep, and other somatic complaints. Although there is no known cure for fibromyalgia, multidisciplinary team efforts using combined treatment approaches, including patient education, aerobic exercise, cognitive behavioral therapy, and pharmacologic therapies (serotonin norepinephrine reuptake inhibitors [eg, duloxetine, milnacipran] and alpha 2-delta receptor ligands [eg, pregabalin]) may improve symptoms as well as function of patients with fibromyalgia.
Smith MS, Buchwald DS, Bogart A, Goldberg J, Smith WR, Afari N.	Department of Pediatrics, University of Washington, Seattle, Washington, USA.	Adolescent offspring of mothers with chronic fatigue syndrome.	J Adolesc Health. 2010 Mar;46(3):284-91. Epub 2009 Oct 13.	PURPOSE: The goal of this study was to determine whether adolescent offspring of mothers with chronic fatigue syndrome (CFS) have higher prevalence of CFS and report more fatigue, greater pain sensitivity, more sleep problems, and poorer cardiopulmonary fitness in comparison with offspring with no exposure to maternal CFS. METHODS: A total of 26 adolescent offspring of 20 mothers diagnosed with CFS were compared with 45 adolescent offspring of 30 age-matched healthy control mothers. Study measures included structured interviews and medical and laboratory examinations for CFS; tender point examination; maximum oxygen uptake and perceived exertion; dolorimetry pain ratings; and questionnaires on fatigue severity and sleepiness. RESULTS: In comparison with offspring of healthy mothers, those exposed to mothers with CFS reported higher prevalence of fatigue of at least 1-month duration (23% vs. 4%), fatigue of 6 months or longer (15% vs. 2%), and met criteria for CFS (12% vs. 2%), although these differences only approached statistical significance. CFS and healthy mothers differed on almost all study outcomes, but offspring groups did not differ on measures of current fatigue severity, pain sensitivity, sleep, mean number of tender points, and cardiopulmonary fitness. CONCLUSIONS: The higher prevalence of fatiguing states in offspring of CFS mothers, despite the lack of statistical significance, suggests that familial factors may potentially play a role in developing chronically fatiguing states. Alternately, perturbations in pain sensitivity and cardiopulmonary fitness may be consequences of CFS. Future studies should focus on examining the impact of maternal CFS and associated disability on psychosocial functioning of offspring.
Smith RA.		Contamination of clinical specimens with MLV-encoding nucleic acids: implications for XMRV and other candidate	Retrovirology. 2010 Dec 20;7(1):112. [Epub ahead of print]	ABSTRACT: Efforts to assess the prevalence of xenotropic murine leukemia virus-related virus (XMRV) in patients with prostate cancer and chronic fatigue syndrome have relied heavily on PCR-based testing of clinical samples and have yielded widely divergent findings. This week in Retrovirology, reports from four independent research groups illustrate the extreme care needed to exclude DNA or RNA contamination in PCR analyses of XMRV. In addition, phylogenetic evidence suggesting that previously-published XMRV sequences originated from a commonly-used prostate carcinoma cell line (22Rv1) is presented. These findings raise important questions regarding the provenance of XMRV and

		human retroviruses.		its potential connection to human disease.
Sommerfeldt L, Portilla H, Jacobsen L, Gjerstad J, Wyller VB.	Division of Paediatrics, Oslo University Hospital, Oslo, Norway STAMI, The National Institute of Occupational Health, Oslo, Norway Department of Molecular Biosciences, University of Oslo, Norway.	Polymorphisms of adrenergic cardiovascular control genes are associated with adolescent chronic fatigue syndrome.	Acta Paediatr. 2011 Feb;100(2):293-8. doi: 10.1111/j.1651-2227.2010.02072.x. Epub 2010 Nov 18.	Aim: To explore the frequency of polymorphisms in adrenergic cardiovascular control genes in adolescent with chronic fatigue syndrome (CFS) and the relation of such polymorphisms to cardiovascular variables. Methods: DNA from 53 patients with CFS, 12-18 years old, was analysed for five single nucleotide polymorphisms (SNPs) in the genes catechol-O-methyltransferase (COMT), the β(2) -adrenergic receptor (two SNPs), the β(1) -adrenergic receptor and the α(2a) -adrenergic receptor. Frequencies were compared to a reference population constructed from the National Center for Biotechnology Information (NCBI) database, and associations between frequencies and autonomic cardiovascular responses during a 20° head-uptilt-test were explored. Results: For the COMT SNP Rs4680, patients with CFS had a higher frequency of the AA genotype and a lower frequency of the G containing genotypes (AG and GG), when compared to the reference sample (p = 0.046). Also, the AA genotype was associated with a smaller increase in LF/HF ratio (low-frequency:high-frequency heart rate variability ratio, an index of cardiac sympathovagal balance) during head-up tilt when compared to the AG/GG genotypes. For the β(2) -adrenergic receptor SNP Rs1042714, patients with CFS had a lower frequency of the GG genotype and a higher frequency of the genotypes containing C (CG and CC) (p = 0.044). Conclusions: CFS might be related to polymorphisms of COMT and the β(2) -adrenergic receptor. More details of the molecular mechanisms remain to be investigated.
Sperber AD, Dekel R.	Department of Gastroenterology, Tel-Aviv Medical Center, Tel-Aviv, Israel.	Irritable Bowel Syndrome and Co-morbid Gastrointestinal and Extra-gastrointestinal Functional Syndromes.	J Neurogastroenterol Motil. 2010 Apr;16(2):113-9. Epub 2010 Apr 27.	The irritable bowel syndrome (IBS) is the best known of the functional gastrointestinal tract disorders. Many IBS patients have at least one co-morbid somatic complaint and many meet diagnostic criteria for other functional disorders. Patients with IBS and another functional disorder, in comparison with patients with IBS only, have more severe IBS symptoms, a higher rate of psychopathology, greater impairment of quality of life, and more illness-related work absenteeism. Estimates of the prevalence of IBS in patients with fibromyalgia range from 30-35% to as high as 70%. Studies of IBS among patients with chronic fatigue syndrome have reported a prevalence ranging from 35-92%. The prevalence of IBS among patients with chronic fatigue syndrome is reported to be 14%. IBS patients with other co-morbid functional disorders appear to manifest a greater degree of somatization. It has been suggested that the presence of multiple co-morbid disorders may be a marker for psychological influences on etiology. This raises the question of whether the functional syndromes represent the same pathophysiological process, i.e., are the same entity that has been separated into different clinical entities because of medical sub-specialization, or are indeed separate disorders. While the answer to this question awaits further research, it would appear that most functional patients who meet formal diagnostic criteria for more than one functional disorder manifest one disorder clinically more that the others and seek consultation differentially for that set of symptoms.
Spitzer AR, Broadman M.	Wayne State University School of Medicine, Detroit, Michigan, USA.	A retrospective review of the sleep characteristics in patients with chronic fatigue	Pain Pract. 2010 Jul-Aug;10(4):294-300. Epub 2010 Mar 2.	This study characterizes findings on sleep testing and Human Leukocyte Antigen (HLA) markers in a group of patients with fibromyalgia (FM) and chronic fatigue syndrome (CFS). One hundred eighteen patients seen in a general neurology practice over 5 years meeting standard clinical criteria for FM or CFS were analyzed retrospectively. Cases of untreated sleep apnea or restless legs syndrome were excluded prior to inclusion in this study. Ninety-two patients had multiple sleep latency testing

	raidl@ieee.org	syndrome and fibromyalgia.		(MSLT). Seventy-three (80%) were abnormal by standard criteria. Of 57 females having positive MSLTs, 22 (39%) had one or more periods of sleep onset rapid eye movement (SOREM), and 5 of 16 (31%) males with positive MSLTs had one or more SOREM. Highly fragmented sleep, as previously described in FM, was seen but not analyzed quantitatively. HLA DQB1*0602 was obtained in 74 patients, and positive in 32 (43%), P < 0.0001 compared with published values in 228 populations. In our patients, who presented with neuromuscular fatigue or generalized pain, we found a sleep disorder characterized by objective hypersomnia. Some patients had characteristics of narcolepsy. Objective assessment by sleep studies can assist the diagnostic process, aid future research, and provide rationale for treatment.
Spitzer AR, Broadman M.	Neurology Department, Wayne State University School of Medicine, Detroit, Michigan, USA. raidl@ieee.org	Treatment of the narcoleptiform sleep disorder in chronic fatigue syndrome and fibromyalgia with sodium oxybate.	Pain Pract. 2010 Jan-Feb;10(1):54-9.	This study investigates the response of the underlying sleep disorder associated with Chronic Fatigue Syndrome (CFS) and fibromyalgia (FM) to treatment. We retrospectively reviewed 118 cases clinically consistent with CFS or FM, treated in a neurology practice. Abnormal findings on sleep studies and associated human leukocyte antigen markers, and a clinical pattern suggestive of narcolepsy, are present in a high proportion of patients. When considered appropriate based on the clinical picture and test results, treatment with sodium oxybate was offered to these patients. Sixty percent of patients treated with oxybate experienced significant relief of pain, while 75% experienced significant relief of fatigue. We postulate that the response to oxybate in CFS and FM suggests a disturbance of sleep similar to narcolepsy. These findings support this novel approach to intervention and further research. The inability to distinguish CFS and FM by testing and response to treatment suggests that they may represent variations of the same disorder or may be closely related disorders.
Staniszewska S, Crowe S, Badenoch D, Edwards C, Savage J, Norman W.	RCN Research Institute, School of Health & Social Studies University of Warwick, Coventry, UK. Sophie.Staniszewska@warwick.ac.uk	The PRIME project: developing a patient evidence-base.	Health Expect. 2010 Sep;13(3):312-22. Epub 2010 Jun 23.	BACKGROUND: The concept of evidence has become firmly rooted in health care, with most importance placed on the outcome of research in clinical and economic spheres. Much less emphasis is placed on the patient's contribution to evidence which remains relatively vague, of low status and often difficult to integrate with other forms of knowledge. AIM: This article proposes a concept of patient-based evidence, to complement clinical and economic forms of evidence, and demonstrates one way in which it has been operationalized. The PRIME project developed a patient evidence-base to capture the lived experience of individuals with myalgic encephalitis (ME) or chronic fatigue syndrome (CFS). DESIGN: Interviews were performed with 40 individuals with ME/CFS who varied in a range of demographic characteristics, including age, gender, and how severely affected individuals were. RESULTS: PRIME has developed a patient evidence-base which has an extensive array of experiences data to provide researchers, clinicians and others with an in-depth insight into the lived experience of ME/CFS that can be used and analysed. Data are grouped into a wide range of themes, which can be downloaded and used in a variety of ways as a source of evidence to enable understanding of the lived experience of ME/CFS and so contribute to the development of a more patient-focused research agenda in ME/CFS. CONCLUSIONS: While patient-based evidence used in the PRIME Project provides a useful start, further work is required to develop this area conceptually and methodologically, particularly in relation to how patient-based evidence can be considered alongside clinical and economic evidence.
Stieler K, Fischer N.	Institute for Medical	Apobec 3G efficiently reduces	PLoS One. 2010 Jul 23;5(7):e11738.	BACKGROUND: The human exogenous gammaretrovirus XMRV is thought to be implicated in prostate cancer and chronic fatigue syndrome. Besides pressing epidemiologic questions, the elucidation of the

	Microbiology, Virology and Hygiene, University Medical Center Eppendorf, Hamburg, Germany.	infectivity of the human exogenous gammaretrovirus XMRV.		tissue and cell tropism of the virus, as well as its sensitivity to retroviral restriction factors is of fundamental importance. The Apobec3 (A3) proteins, a family of cytidine deaminases, are one important group of host proteins that control primary infection and efficient viral spread. METHODOLOGY/PRINCIPAL FINDINGS: Here we demonstrate that XMRV is resistant to human Apobec 3B, 3C and 3F, while being highly susceptible to the human A3G protein, a factor which is known to confer antiviral activity against most retroviruses. We show that XMRV as well as MoMLV virions package Apobec proteins independent of their specific restriction activity. hA3G was found to be a potent inhibitor of XMRV as well as of MoMLV infectivity. In contrast to MoMLV, XMRV infection can also be partially reduced by low concentrations of mA3. Interestingly, established prostate cancer cell lines, which are highly susceptible to XMRV infection, do not or only weakly express hA3G. CONCLUSIONS: Our findings confirm and extend recently published data that show restriction of XMRV infection by hA3G. The results will be of value to explore which cells are infected with XMRV and efficiently support viral spread in vivo. Furthermore, the observation that XMRV infection can be reduced by mA3 is of interest with regard to the current natural reservoir of XMRV infection.
Stieler K, Schulz C, Lavanya M, Aepfelbacher M, Stocking C, Fischer N.	Institute for Medical Microbiology and Virology, University Medical Center Eppendorf, Martinistrasse 52, 20246 Hamburg, Germany.	Host range and cellular tropism of the human exogenous gammaretrovirus XMRV.	Virology. 2010 Mar 30;399(1):23-30. Epub 2010 Jan 27.	Recently, the first human infection with an exogenous gammaretrovirus (XMRV) was reported. In its initial description, XMRV was confined to prostate stromal fibroblasts, although subsequent reports demonstrated XMRV protein expression in prostate epithelial cells. Most recently, XMRV has been detected in blood cells of patients with chronic fatigue syndrome. The aim of this study was to elucidate the transmission routes and tissue tropism of XMRV by comparing its host range, receptor usage and LTR functionality with other MLV isolates. We demonstrate using pseudotype experiments that XMRV Env mediates efficient infection of cells from different species. We show that replication competent XMRV infects various human cell types, including hematopoietic cell lines and prostate stromal fibroblasts. XMRV-LTR activity is significantly higher in the prostate cancer cell line LNCaP and in prostate stromal fibroblasts, compared to other cell types tested and could be one factor contributing to efficient viral spread in prostate tissue.
Stoye JP, Silverman RH, Boucher CA, Le Grice SF.		The Xenotropic Murine Leukemia Virus-Related Retrovirus Debate Continues at First International Workshop.	Retrovirology. 2010 Dec 22;7(1):113. [Epub ahead of print]	ABSTRACT: The 1st International Workshop on Xenotropic Murine Leukemia Virus-Related Retrovirus (XMRV), co-sponsored by the National Institutes of Health, The Department of Health and Human Services and Abbott Diagnostics, was convened on September 7/8 on the NIH campus, Bethesda, MD. Attracting an international audience of over 200 participants, the 2-day event combined a series of plenary talks with updates on different aspects of XMRV research, addressing basic gammaretrovirus biology, host response, association of XMRV with chronic fatigue syndrome and prostate cancer, assay development and epidemiology. The current status of XMRV research, concerns among the scientific community and suggestions for future actions are summarized in this meeting report.
Sudlow C, Macleod M, Al-Shahi Salman R, Stone J.	Division of Clinical Neurosciences, University of Edinburgh, Western General Hospital, Edinburgh EH4	Comment on "Detection of an infectious retrovirus, XMRV, in blood cells of patients with chronic fatigue	Science. 2010 May 14;328(5980):825; author reply 825. Comment on: Science. 2009 Oct 23;326(5952):585-9.	Lombardi et al. (Reports, 23 October 2009, p. 585) reported an association between the human gammaretrovirus XMRV and chronic fatigue syndrome. However, their results may be misleading because of various potential sources of bias and confounding. If real, the association may lack generalizability because of the specific characteristics of the cases studied and could be due to reverse causality.

	2XU, UK. cathie.sudlow@ed.ac.uk	syndrome".		
Sutcliffe K, Gray J, Tan MP, Pairman J, Wilton K, Parry SW, Newton JL.	UK NIHR Biomedical Research Centre in Ageing - Cardiovascular Theme, Newcastle, UK.	Home orthostatic training in chronic fatigue syndrome--a randomized, placebo-controlled feasibility study.	Eur J Clin Invest. 2010 Jan;40(1):18-24. Epub 2009 Nov 12.	BACKGROUND: Orthostatic (Tilt)-training is an effective treatment for neurally mediated hypotension (NMH). NMH is a frequent finding in chronic fatigue syndrome (CFS). We evaluated home orthostatic training (HOT) in CFS in a randomized placebo-controlled feasibility study. METHODS: Thirty-eight patients with CFS (Fukuda Criteria) were randomly allocated to daily tilt training (n = 19) or sham training (n = 19) for 6 months. Haemodynamic responses to standing were performed in all subjects using continuous technology (Taskforce) at enrolment, week 1, 4 and 24. Symptom response and compliance were assessed using diaries. RESULTS: Two patients (one from each arm) withdrew from the study. Fourteen patients in each group complied completely or partially, and patients found the training manageable and achievable. Compared to the sham group, blood pressure while standing dropped to 8.0 mmHg less in the HOT group at 4 weeks (95% CI: 1.0 to 15.0, P = 0.03). At 4 weeks, the HOT group had higher total peripheral resistance compared to the sham group; mean difference 70.2, 95% CI: -371.4 to 511.8. Changes were maintained at 6 months. There was no significant difference in fatigue between groups at 4 weeks (mean difference 1.4, 95% CI: -13.5 to 16.2), but there was a trend towards improvement in fatigue at 6 months. Compliers had lower fatigue compared to non-compliers. CONCLUSIONS: A placebo-controlled study of HOT in CFS is feasible. HOT is well tolerated and generally complied with. A likely physiological rationale for HOT in CFS is related to reductions in orthostatic intolerance. An adequately powered study including strategies to enhance compliance is warranted.
Suárez A, Guillamó E, Roig T, Blázquez A, Alegre J, Bermúdez J, Ventura JL, García-Quintana AM, Comella A, Segura R, Javierre C.	Department of Physiological Sciences II, Medical School, University of Barcelona, L'Hospitalet, Barcelona, Spain.	Nitric oxide metabolite production during exercise in chronic fatigue syndrome: a case-control study.	J Womens Health (Larchmt). 2010 Jun;19(6):1073-7.	BACKGROUND: Chronic fatigue syndrome (CFS) is a disabling illness of unknown etiology that is characterized by fatigue associated with a reduced ability to work, lasting for more than 6 months, and accompanied by a specific set of symptoms. The diagnosis remains difficult because of the absence of laboratory tests and is, therefore, made largely on the basis of the symptoms reported by the patient. The aim of this study was to analyze differences in blood nitrate levels in CFS patients and a matched control group after a physical exercise test. METHODS: Forty-four consecutive female patients with CFS and 25 healthy women performed an exercise test using a cycle ergometer with monitoring of cardiopulmonary response. Blood samples were obtained for biochemical analyses of glucose, lactate, and nitrates at the beginning (under resting conditions) and after the maximal and supramaximal tests. RESULTS: Plasma nitrates differed between the groups, with higher values in the CFS group ($F = 6.93$, $p = 0.003$). Nitrate concentration increased in relation to workload and reached higher values in the CFS group, the maximum difference with respect to the control group being 295% ($t = 4.88$, $p < 0.001$). CONCLUSIONS: The main result of the present study is that nitric oxide (NO) metabolites (nitrates) showed a much higher increase after a maximal physical test in CFS patients than in a group of matched subjects. This combination (exercise plus NO response evaluation) may be useful in the assessment of CFS.
Switzer WM, Jia H, Hohn O, Zheng H, Tang S, Shankar A,	Laboratory Branch, Division of HIV/AIDS	Absence of evidence of xenotropic murine	Retrovirology. 2010 Jul 1;7:57.	BACKGROUND: XMRV, a xenotropic murine leukemia virus (MuLV)-related virus, was recently identified by PCR testing in 67% of persons with chronic fatigue syndrome (CFS) and in 3.7% of healthy persons from the United States. To investigate the association of XMRV with CFS we tested blood

Bannert N, Simmons G, Hendry RM, Falkenberg VR, Reeves WC, Heneine W.	Prevention, National Center for HIV/AIDS, Viral Hepatitis, STD, and TB Prevention, Centers for Disease Control and Prevention, Atlanta, GA 30333, USA. bswitzer@cdc.gov	leukemia virus-related virus infection in persons with chronic fatigue syndrome and healthy controls in the United States.		specimens from 51 persons with CFS and 56 healthy persons from the US for evidence of XMRV infection by using serologic and molecular assays. Blinded PCR and serologic testing were performed at the US Centers for Disease Control and Prevention (CDC) and at two additional laboratories. RESULTS: Archived blood specimens were tested from persons with CFS defined by the 1994 international research case definition and matched healthy controls from Wichita, Kansas and metropolitan, urban, and rural Georgia populations. Serologic testing at CDC utilized a Western blot (WB) assay that showed excellent sensitivity to MuLV and XMRV polyclonal or monoclonal antibodies, and no reactivity on sera from 121 US blood donors or 26 HTLV-and HIV-infected sera. Plasma from 51 CFS cases and plasma from 53 controls were all WB negative. Additional blinded screening of the 51 cases and 53 controls at the Robert Koch Institute using an ELISA employing recombinant Gag and Env XMRV proteins identified weak seroreactivity in one CFS case and a healthy control, which was not confirmed by immunofluorescence. PCR testing at CDC employed a gag and a pol nested PCR assay with a detection threshold of 10 copies in 1 ug of human DNA. DNA specimens from 50 CFS patients and 56 controls and 41 US blood donors were all PCR-negative. Blinded testing by a second nested gag PCR assay at the Blood Systems Research Institute was also negative for DNA specimens from the 50 CFS cases and 56 controls. CONCLUSIONS: We did not find any evidence of infection with XMRV in our U.S. study population of CFS patients or healthy controls by using multiple molecular and serologic assays. These data do not support an association of XMRV with CFS.
Sánchez-Barceló EJ, Mediavilla MD, Tan DX, Reiter RJ.	Department of Physiology & Pharmacology, School of Medicine, University of Cantabria, 39011 Santander, Spain. barcelo@unican.es	Clinical uses of melatonin: evaluation of human trials.	Curr Med Chem. 2010;17(19):2070-95.	During the last 20 years, numerous clinical trials have examined the therapeutic usefulness of melatonin in different fields of medicine. The objective of this article is to review, in depth, the science regarding clinical trials performed to date. The efficacy of melatonin has been assessed as a treatment of ocular diseases, blood diseases, gastrointestinal tract diseases, cardiovascular diseases, diabetes, rheumatoid arthritis, fibromyalgia, chronic fatigue syndrome, infectious diseases, neurological diseases, sleep disturbances, aging and depression. Melatonin has been also used as a complementary treatment in anaesthesia, hemodialysis, in vitro fertilization and neonatal care. The conclusion of the current review is that the use of melatonin as an adjuvant therapy seems to be well funded for macular degeneration, glaucoma, protection of the gastric mucosa, irritable bowel syndrome, arterial hypertension, diabetes, side effects of chemotherapy and radiation in cancer patients or hemodialysis in patients with renal insufficiency and, especially, for sleep disorders of circadian etiology (jet lag, delayed sleep phase syndrome, sleep deterioration associated with aging, etc.) as well as in those related with neurological degenerative diseases (Alzheimer, etc.,) or Smith-Magenis syndrome. The utility of melatonin in anesthetic procedures has been also confirmed. More clinical studies are required to clarify whether, as the preliminary data suggest, melatonin is useful for treatment of fibromyalgia, chronic fatigue syndrome, infectious diseases, neoplasias or neonatal care. Preliminary data regarding the utility of melatonin in the treatment of ulcerative colitis, Crohn's disease, rheumatoid arthritis are either ambiguous or negative. Although in a few cases melatonin seems to aggravate some conditions, the vast majority of studies document the very low toxicity of melatonin over a wide range of doses.
Tanaka M, Watanabe Y.	Department of Physiology, Osaka	A new hypothesis of chronic fatigue	Med Hypotheses. 2010	Chronic fatigue syndrome is an illness characterized by a profound, disabling, and unexplained sensation of fatigue lasting at least 6 months, which severely impairs daily functioning and is

	City University Graduate School of Medicine, 1-4-3 Asahimachi, Abeno-ku, Osaka 545-8585, Japan. masa-t@msic.med.osaka-cu.ac.jp	syndrome: co-conditioning theory.	Aug;75(2):244-9. Epub 2010 Mar 24.	accompanied by a combination of non-specific symptoms. Many potential causes of chronic fatigue syndrome have been investigated, including viral infections, immune dysfunctions, abnormal neuroendocrine responses, central nervous system abnormalities, autonomic dysfunctions, impaired exercise capacities, sleep disruptions, genetic backgrounds, psychiatric abnormalities, personality, and abnormal psychological processes. However, no etiology, specific physical signs or laboratory test abnormalities have been found. It is essential to establish a conceptual theory of chronic fatigue syndrome that can explain its pathophysiology in order to identify the clinical entity and to develop effective treatment methods. In this article, a new conceptual hypothesis about the pathophysiology of chronic fatigue syndrome, the co-conditioning theory, is presented: after repetitive overwork and/or stress, alarm signal to rest and fatigue sensation may cause in response to an unconditioned stimulus (impaired homeostasis and function) that has been paired with a conditioned stimulus (overwork and/or stress). In the future, a new treatment strategy for patients with chronic fatigue syndrome, re-co-conditioning therapy, may be developed on the basis of the co-conditioning theory. In addition, this theory will likely contribute to a better understanding of the pathophysiology of chronic fatigue syndrome.
Tang S, Zhao J, Viswanath R, Nyambi PN, Redd AD, Dastyar A, Spacek LA, Quinn TC, Wang X, Wood O, Gaddam D, Devadas K, Hewlett IK.	From the Laboratory of Molecular Virology, Center for Biologics Evaluation and Research, Food and Drug Administration, Bethesda, Maryland; the Department of Pathology, New York University School of Medicine, New York, New York; and the Division of Intramural Research, NIAID, NIH, Johns Hopkins University School of Medicine, Baltimore, Maryland.	Absence of detectable xenotropic murine leukemia virus-related virus in plasma or peripheral blood mononuclear cells of human immunodeficiency virus Type 1-infected blood donors or individuals in Africa.	Transfusion. 2010 Nov 15. doi: 10.1111/j.1537-2995.2010.02932.x. [Epub ahead of print]	BACKGROUND: Since the identification of xenotropic murine leukemia virus-related virus (XMRV) in prostate cancer patients in 2006 and in chronic fatigue syndrome patients in 2009, conflicting findings have been reported regarding its etiologic role in human diseases and prevalence in general populations. In this study, we screened both plasma and peripheral blood mononuclear cells (PBMNCs) collected in Africa from blood donors and human immunodeficiency virus Type 1 (HIV-1)-infected individuals to gain evidence of XMRV infection in this geographic region. STUDY DESIGN AND METHODS: A total of 199 plasma samples, 19 PBMNC samples, and 50 culture supernatants from PBMNCs of blood donors from Cameroon found to be infected with HIV-1 and HIV-1 patients from Uganda were screened for XMRV infection using a sensitive nested polymerase chain reaction (PCR) or reverse transcription (RT)-PCR assay. RESULTS: Using highly sensitive nested PCR or RT-PCR and real-time PCR assays capable of detecting at least 10 copies of XMRV plasmid DNA per reaction, none of the 268 samples tested were found to be XMRV DNA or RNA positive. CONCLUSIONS: Our results failed to demonstrate the presence of XMRV infection in African blood donors or individuals infected with HIV-1. More studies are needed to understand the prevalence, epidemiology, and geographic distribution of XMRV infection worldwide.

The GK, Bleijenberg G, Buitelaar JK, van der Meer JW.	Radboud University Nijmegen Medical Centre, Department of Psychiatry, 966, Reinier Postlaan 10, 6525 GC Nijmegen, The Netherlands. g.the@aig.umcn.nl	The effect of ondansetron, a 5-HT3 receptor antagonist, in chronic fatigue syndrome: a randomized controlled trial.	J Clin Psychiatry. 2010 May;71(5):528-33. Epub 2010 Jan 26.	BACKGROUND: Accumulating data support the involvement of the serotonin (5-hydroxytryptamine [5-HT]) system in the pathophysiology of chronic fatigue syndrome. Neuropharmacologic studies point to a hyperactive 5-HT system, and open-label treatment studies with 5-HT(3) receptor antagonists have shown promising results. In this randomized controlled clinical trial, the effect of ondansetron, a 5-HT(3) receptor antagonist, was assessed on fatigue severity and functional impairment in adult patients with chronic fatigue syndrome. METHOD: A randomized, placebo-controlled, double-blind clinical trial was conducted at Radboud University Nijmegen Medical Centre, The Netherlands. Sixty-seven adult patients who fulfilled the US Centers for Disease Control and Prevention (CDC) criteria for chronic fatigue syndrome and who were free from current psychiatric comorbidity participated in the clinical trial. Participants received either ondansetron 16 mg per day or placebo for 10 weeks. The primary outcome variables were fatigue severity (Checklist Individual Strength fatigue severity subscale [CIS-fatigue]) and functional impairment (Sickness Impact Profile-8 [SIP-8]). The effect of ondansetron was assessed by analysis of covariance. Data were analyzed on an intention-to-treat basis. All patients were recruited between June 2003 and March 2006. RESULTS: Thirty-three patients were allocated to the ondansetron condition, 34 to the placebo condition. The 2 groups were well matched in terms of age, sex, fatigue severity, functional impairment, and CDC symptoms. Analysis of covariance showed no significant differences between the ondansetron- and placebo-treated groups during the 10-week treatment period in fatigue severity and functional impairment. CONCLUSIONS: This clinical trial demonstrates no benefit of ondansetron compared to placebo in the treatment of chronic fatigue syndrome. TRIAL REGISTRATION: www.trialregister.nl: ISRCTN02536681.
Thomas PW, Thomas S, Kersten P, Jones R, Nock A, Slingsby V, Green C, Baker R, Galvin K, Hillier C.	Dorset Research and Development Support Unit, Poole Hospital NHS Foundation Trust, Poole, Dorset, UK.	Multi-centre parallel arm randomised controlled trial to assess the effectiveness and cost-effectiveness of a group-based cognitive behavioural approach to managing fatigue in people with multiple sclerosis.	BMC Neurol. 2010 Jun 16;10:43.	BACKGROUND: Fatigue is one of the most commonly reported and debilitating symptoms of multiple sclerosis (MS); approximately two-thirds of people with MS consider it to be one of their three most troubling symptoms. It may limit or prevent participation in everyday activities, work, leisure, and social pursuits, reduce psychological well-being and is one of the key precipitants of early retirement. Energy effectiveness approaches have been shown to be effective in reducing MS-fatigue, increasing self-efficacy and improving quality of life. Cognitive behavioural approaches have been found to be effective for managing fatigue in other conditions, such as chronic fatigue syndrome, and more recently, in MS. The aim of this pragmatic trial is to evaluate the clinical and cost-effectiveness of a recently developed group-based fatigue management intervention (that blends cognitive behavioural and energy effectiveness approaches) compared with current local practice. METHODS/DESIGN: This is a multi-centre parallel arm block-randomised controlled trial (RCT) of a six session group-based fatigue management intervention, delivered by health professionals, compared with current local practice. 180 consenting adults with a confirmed diagnosis of MS and significant fatigue levels, recruited via secondary/primary care or newsletters/websites, will be randomised to receive the fatigue management intervention or current local practice. An economic evaluation will be undertaken alongside the trial. Primary outcomes are fatigue severity, self-efficacy and disease-specific quality of life. Secondary outcomes include fatigue impact, general quality of life, mood, activity patterns, and cost-effectiveness. Outcomes in those receiving the fatigue management intervention will be measured 1 week prior to, and 1, 4, and 12 months after the intervention (and at equivalent times in those receiving current local practice). A qualitative component will examine what

				aspects of the fatigue management intervention participants found helpful/unhelpful and barriers to change. DISCUSSION: This trial is the fourth stage of a research programme that has followed the Medical Research Council guidance for developing and evaluating complex interventions. What makes the intervention unique is that it blends cognitive behavioural and energy effectiveness approaches. A potential strength of the intervention is that it could be integrated into existing service delivery models as it has been designed to be delivered by staff already working with people with MS. Service users will be involved throughout this research. TRIAL REGISTRATION: Current Controlled Trials ISRCTN76517470.
Tietjen GE, Brandes JL, Peterlin BL, Eloff A, Dafer RM, Stein MR, Drexler E, Martin VT, Hutchinson S, Aurora SK, Recober A, Herial NA, Utley C, White L, Khuder SA.	University of Toledo College of Medicine, Toledo, OH, USA.	Childhood maltreatment and migraine (part III). Association with comorbid pain conditions.	Headache. 2010 Jan;50(1):42-51. Epub 2009 Oct 21.	OBJECTIVE: To evaluate in a headache clinic population the relationship of childhood maltreatment on the prevalence of pain conditions comorbid with migraine. BACKGROUND: Childhood maltreatment is highly prevalent and has been frequently associated with recurrent headache. The relationship of maltreatment and pain has, however, been a subject of some debate. METHODS: Cross-sectional data on self-reported physician-diagnosed pain conditions were electronically collected from persons with migraine (diagnosed according to International Classification of Headache Disorders-2), seeking treatment in headache clinics at 11 centers across the US and Canada. These included irritable bowel syndrome (IBS), chronic fatigue syndrome (CFS), fibromyalgia (FM), interstitial cystitis (IC), arthritis, endometriosis, and uterine fibroids. Other information included demographics, migraine characteristics (frequency, headache-related disability), remote and current depression (The Patient Health Questionnaire-9), and remote and current anxiety (The Beck Anxiety Inventory). Patients also completed the Childhood Trauma Questionnaire regarding sexual, emotional, and physical abuse, and emotional and physical neglect under the age of 18 years old. Statistical analyses accounted for the survey design and appropriate procedures in SAS such as surveymeans, surveyfreq, and surveylogistic were applied to the weighted data. RESULTS: A total of 1348 migraineurs (88% women) were included in this study (mean age 41 years). Based on physician diagnosis or validated criteria, 31% had IBS, 16% had CFS, and 10% had FM. Diagnosis of IC was reported by 6.5%, arthritis by 25%, and in women, endometriosis was reported by 15% and uterine fibroids by 14%. At least 1 comorbid pain condition was reported by 61%, 2 conditions by 18%, and 3 or more by 13%. Childhood maltreatment was reported by 58% of the patients. Emotional abuse was associated with increased prevalence of IBS, CFS, arthritis, and physical neglect with arthritis. In women, physical abuse was associated with endometriosis and physical neglect with uterine fibroids. Emotional abuse, and physical abuse and neglect ($P < .0001$ for all) were also associated with increased total number of comorbid conditions. In ordinal logistic regression models, adjusted for sociodemographics and current depression (prevalence 28%) and anxiety (prevalence 56%), emotional abuse (odds ratios [OR] = 1.69, 95% confidence intervals [CI]: 1.224-2.33) and physical neglect (OR = 1.73, 95% CI: 1.22-2.46) were independently associated with an increased number of pain conditions. The cohort of women, similarly, had associations of emotional abuse (OR = 1.94, 95% CI: 1.40-2.72) and physical neglect (OR = 1.90, 95% CI: 1.34-2.68) with an increased number of pain comorbidities. CONCLUSION: The association of childhood maltreatment and pain was stronger in those reporting multiple pain conditions and multiple maltreatment types. This finding suggests that in migraineurs childhood maltreatment may be a risk factor for development of comorbid pain disorders.

Togo F, Natelson BH, Cherniack NS, Klapholz M, Rapoport DM, Cook DB.	Pain & Fatigue Study Center, Department of Neurosciences, UMDNJ-New Jersey Medical School, Newark, NJ 07103, USA.	Sleep is not disrupted by exercise in patients with chronic fatigue syndromes.	Med Sci Sports Exerc. 2010 Jan;42(1):16-22.	PURPOSE: Patients with chronic fatigue syndrome (CFS) report that exertion produces dramatic symptom worsening. We hypothesized this might be due to the exacerbation of an underlying sleep disorder, which we have previously demonstrated to exist. METHODS: Female patients with CFS and matched healthy controls with no evidence of major depressive disorder were studied with overnight polysomnography on a baseline night and on a night after their performance of a maximal exercise test. RESULTS: CFS patients as a group had evidence for disturbed sleep compared with controls. Although exercise improved sleep for healthy subjects, it did not do this for the group as a whole. When we stratified the sample on the basis of self-reported sleepiness after a night's sleep, the patient group with reduced morning sleepiness showed improvement in sleep structure, whereas those with increased morning sleepiness continued to show evidence for sleep disruption. CONCLUSIONS: Sleep is disturbed in CFS patients as a group, but exercise does not exacerbate this sleep disturbance. Approximately half the patients studied actually sleep better after exercise. Therefore, activity-related symptom worsening is not caused by worsened sleep.

Toussaint L, Overvold-Ronningen M, Vincent A, Luedtke C, Whipple M, Schriever T, Luskin F.	Department of Psychology, Luther College, Decorah, Iowa 52101, USA. touslo01@luther.edu	Implications of forgiveness enhancement in patients with fibromyalgia and chronic fatigue syndrome.	J Health Care Chaplain. 2010 Jul;16(3-4):123-39.	The purpose of this review is to examine forgiveness as a means to enhance coping with the emotional sequelae of two disorders, fibromyalgia and chronic fatigue. As with many chronic illnesses, fibromyalgia and chronic fatigue often result in a host of negative emotions including, anger, stress, fear, and depression. We contend that learning to become more forgiving may be a complementary treatment to cope with the ongoing stress, frustration, and negative emotions that result from these two conditions. Our review includes descriptive information on fibromyalgia and chronic fatigue, a brief review of the literature on anger and its influence on health, a review of the connections between forgiveness and well-being, and methods to enhance forgiveness in patients' lives. We conclude with a conceptual model that we hope will be useful to design and/or evaluate work on forgiveness in these patients.

[Article in Russian]	Vopr Kurortol Fizioter Lech Fiz Kult. 2010 Mar-Apr;(2):16-8.	The possibility to apply natural medicinal factors of a spa-and-resort facility along with targeted physiotherapeutic exposure (succinic acid electrophoresis, reflexo-segmental peloidotherapy) and polyoxidonium injections was evaluated. The study demonstrated high effectiveness of the proposed approach to medical rehabilitation of patients with chronic fatigue syndrome.
Tummers M, Knoop H, Bleijenberg G.	Radboud University Nijmegen Medical Centre, Expert Centre for Chronic Fatigue, 4628, P.O. Box 9101, 6500 HB Nijmegen, The Netherlands. m.tummers@nkcv.umcn.nl	Effectiveness of stepped care for chronic fatigue syndrome: a randomized noninferiority trial.	J Consult Clin Psychol. 2010 Oct;78(5):724-31.	OBJECTIVE: In this randomized noninferiority study, the effectiveness and efficiency of stepped care for chronic fatigue syndrome (CFS) was compared to care as usual. Stepped care was formed by guided self-instruction, followed by cognitive behavior therapy (CBT) if the patient desired it. Care as usual encompassed CBT after a waiting period. METHOD: A total of 171 CFS patients were randomly allocated to stepped care or care as usual. Patients in both conditions were assessed 3 times: at baseline, after guided self-instruction or the waiting period, and after CBT. The primary outcome variables were fatigue severity (Checklist Individual Strength) and disabilities (Sickness Impact Profile and Medical Outcomes Survey Short Form-36). RESULTS: An intention to treat analysis showed that stepped care (N = 84) for CFS is noninferior to care as usual (N = 85). Both conditions were equivalent in reducing fatigue severity, reducing disabilities, and increasing physical functioning. The treatment results of both conditions were in accordance with those of previous randomized controlled trials testing the effectiveness of CBT for CFS. The total therapist time needed to treat a patient was significantly less in the stepped care condition. CONCLUSIONS: Stepped care is as effective as CBT and is more time efficient for the therapist.

J Neurol. 2010 Mar;257(3):452-6. Epub 2009 Oct 20.	Fatigue is common in Parkinson's disease (PD), occurring in up to 42% of patients (2). There is no recognized treatment. This is a study of modafinil for Parkinson's disease related fatigue. Ethical approval was given. Patients with idiopathic PD were recruited from a Movement Disorders clinic. Those with depression, dementia, and other causes for fatigue were excluded. Patients were assessed using the Fatigue Severity Scale (FSS), Hospital Anxiety and Depression Scale (HADS), self-rating of improvement, Epworth Sleepiness Scale (ESS), and UPDRS. Modafinil was titrated up over 4 weeks to maximum of 400 mg/day. There followed a 5 week maintenance phase before reassessment. Thirteen patients participated. No significant change was seen in any safety measure. The FSS did not change significantly, however those on modafinil rated an improvement in their fatigue compared to placebo. The Modafinil group had a statistically significant improvement on ESS ($p < 0.05$). This is a small study of modafinil in selected PD patients. There is a suggestion of improvement on the global clinical impression scale for fatigue, but no significant change on FSS. A larger study is needed to further evaluate this drug in PD fatigue. This study highlights the problems with recruitment when trialing treatments of non-motor symptoms in PD. A significant improvement in EDS was seen.
Ulas UH, Chelimsky TC, Chelimsky G, Mandawat A, McNeeley K, Alshekhlee A.	Autonomic Laboratory, Neurological Institute, University Hospitals Case Medical Center, Case Western Reserve University, Cleveland, OH 44106-5040, USA. Umit.Ulas@uhhospitals.org	Comorbid health conditions in women with syncope.	Clin Auton Res. 2010 Aug;20(4):223-7. Epub 2010 May 11.	OBJECTIVE: We determine the comorbid conditions associated with syncope in women. In addition, we hypothesize a higher proportion of autonomic comorbid conditions during the female reproductive age. METHODS: We identified a cohort of patients admitted to US hospitals with the principal diagnosis of syncope. We compare patient demographics stratified by gender as well as syncope associated comorbidities. We compared these comorbidities in female of reproductive age (15-45) to men as control. RESULTS: From a total sample of 305,932, females constituted 56.7% (n = 173,434). Females were slightly older (mean age 70.9 +/- 17.9 vs. 66.7 +/- 17.3; $P < 0.0001$); with similar racial distribution (white 57.8 vs. 57.5%), and similar length of hospital stay (mean 2.66 +/- 2.63 vs. 2.68 +/- 2.72 days; $P > 0.05$). Females had higher proportion of migraine (1.65 vs. 1.29%; odds ratio 'OR' 1.29; 95% confidence interval 'CI' 1.21, 1.36); chronic fatigue syndrome (1.73 vs. 1.3%; OR 1.32; 95% CI 1.25, 1.4); gastroparesis (0.2 vs. 0.12%; OR 1.64; 95% CI 1.35, 1.98); interstitial cystitis (0.07 vs. 0.01%; OR 7.44; 95% CI 4.10, 13.5); and postural tachycardia syndrome (0.49 vs. 0.44%; OR 1.1; 95% CI 1.001, 1.23). Orthostatic hypotension was not different between the groups ($P = 0.24$). When the sample was stratified by age category, the odds ratio for gastroparesis, orthostatic hypotension, and postural tachycardia syndrome was increased ($P < 0.05$). INTERPRETATION: A higher proportion of autonomic dysfunction was present in women compared to men. In addition, these comorbid autonomic conditions were especially prominent during the female reproductive age.

[Article in Italian]	Clin Ter. 2010 Sep-Oct;161(5):461-4.	Chronic fatigue syndrome (CFS) is a clinical syndrome characterized by profound disabling chronic fatigue associated with a wide array of other physical symptoms. Its etiology is currently unknown. Among the various hypotheses, considerable interest has been placed in the hypothalamus-pituitary-adrenal axis as a possible target of the pathogenesis of CFS. This article reviews the available scientific evidence about a role of hypothalamic-pituitary-adrenal axis in the pathogenesis of chronic fatigue syndrome.

Arch Pediatr Adolesc Med. 2010 Sep;164(9):810-4.	OBJECTIVE: To describe the symptomatic and educational long-term outcomes, health care use, and risk factors of nonrecovery in adolescent chronic fatigue syndrome (CFS). DESIGN: Follow-up study. SETTING: Academic pediatric hospital. PARTICIPANTS: Sixty adolescents with CFS. INTERVENTIONS: Regular care. OUTCOME MEASURES: The Checklist Individual Strength, Child Health Questionnaire, and a general questionnaire regarding further symptoms, school attendance, work attendance, and treatment. RESULTS: Complete measurements were returned for 54 adolescents (90%). At initial assessment, their mean (SD) age was 16.0 (1.5) years and 20.4% were male. The mean follow-up duration was 2.2 years. At follow-up, the mean (SD) age was 18.2 (1.5) years; 28 adolescents (51.9%) had nearly complete improvement of symptoms but 26 (48.1%) did not experience improvement. Adolescents who attended school (n = 41) had missed an average of 33% of classes during the last month. The rest (n = 13) had worked an average of 38.7% of a full-time job during the last month. A total of 66.7% of subjects were treated by a physiotherapist, 38.9% were clinically treated in rehabilitation, 48.1% had received psychological support, and 53.7% had used alternative treatment. CONCLUSIONS: About half of the adolescents had recovered from CFS at follow-up. The other half was still severely fatigued and physically impaired. Health care use had been high, and school and work attendance were low. Older age at inclusion was a risk factor, and pain, poor mental health, self-esteem, and general health perception at outcome were associated with an unfavorable outcome. Future research should focus on customizing existing treatment and studying additional treatment options.
van Geelen SM,	Division of	Self-investigation	Patient Educ	OBJECTIVE: A small-scale intervention study into narrative self-investigation in adolescent chronic

Fuchs CE, Sinnema G, van de Putte EM, van Geel R, Hermans HJ, Kuis W.	Pediatric Psychology, University Medical Center Utrecht, Utrecht, The Netherlands.	in adolescent chronic fatigue syndrome: Narrative changes and health improvement.	Couns. 2010 Jun 23. [Epub ahead of print]	fatigue syndrome (CFS). METHOD: The self-confrontation method (SCM) is an instrument to assess and change personal life stories. Forty-two adolescents diagnosed with CFS were included and randomly assigned to either 6 or 12 sessions with the SCM. Twenty-five healthy adolescents were assigned to 6 sessions. Outcome was measured directly after the self-investigation procedure at 4 months. Follow-up measurements were made 10 months later. The Checklist Individual Strength and the Child Health Questionnaire were used to measure changes in fatigue, physical and psychosocial functioning. RESULTS: Self-investigation resulted in significant changes in participants' narratives. Moreover, after self-investigation there was a significant improvement in fatigue, physical and psychosocial functioning for the adolescents with CFS. The patients who completed 12 sessions improved most. At follow-up, the positive effects were maintained. CONCLUSION: Self-investigation enables a move beyond the symptoms of CFS in an individualized, patient centered way. Narrative transformation seems to contribute to improved physical and psychosocial outcome in adolescent CFS. PRACTICE IMPLICATIONS: The SCM allows adolescents to discover (for themselves) factors that might cause or perpetuate their fatigue. The results suggest that self-investigation is a useful instrument in the management of adolescent CFS.
van Hoogmoed D, Fransen J, Bleijenberg G, van Riel P.	Nijmegen Expert Centre of Chronic Fatigue, Radboud University Nijmegen Medical Centre, Nijmegen, The Netherlands. d.vanhoogmoed@reuma.umcn.nl	Physical and psychosocial correlates of severe fatigue in rheumatoid arthritis.	Rheumatology (Oxford). 2010 Jul;49(7):1294-302. Epub 2010 Mar 29.	OBJECTIVES: Fatigue is a frequently experienced and patient-relevant complaint in RA. Disease activity, anaemia and pain are regarded as disease-related factors that may lead to fatigue in RA. However, psychosocial factors may also play a role in maintaining severe fatigue. The objectives of this study were to determine the prevalence of severe fatigue in RA patients, to study patient perceptions of fatigue and to determine which disease-related factors and psychosocial factors are independently associated with fatigue severity. METHODS: For this study consecutive RA outpatients were enrolled (n = 228). The patients filled out questionnaires regarding fatigue using the Checklist Individual Strength (CIS), including psychosocial factors, pain and disability. The clinical data that were collected included ESR, CRP, haemoglobin level and 28-joint disease activity score (DAS-28). Chunk-wise backward linear regression was used for analysis. RESULTS: Severe fatigue (CIS > or = 35) was experienced by 42% of the RA patients, and they perceived their fatigue as frustrating or exhausting. The severely fatigued RA patients scored worse on all measured psychosocial items, compared with patients without severe fatigue. Pain severity, role functioning, depressive mood, self-efficacy on fatigue, worrying, helplessness and non-restorative sleep were the factors most strongly associated with fatigue level. CONCLUSIONS: A considerable proportion of RA patients had severe fatigue, with fatigue levels similar to chronic fatigue syndrome. Fatigue in RA was related to pain and functioning, not inflammation, as disease-related factors and to several psychosocial factors including coping and cognitions concerning fatigue.
Van Houdenhove B, Kempke S, Luyten P.	Dienst Liaisonpsychiatrie, UZ Leuven, Herestraat 49, Leuven 3000, Belgium. boudewijn.vanhou	Psychiatric aspects of chronic fatigue syndrome and fibromyalgia.	Curr Psychiatry Rep. 2010 Jun;12(3):208-14.	Chronic fatigue syndrome and/or fibromyalgia (CFS/FM) consists of highly overlapping, medically unexplained symptoms, including long-lasting fatigue, effort intolerance, cognitive dysfunction, and widespread pain and tenderness. CFS/FM often seems to be triggered by infections and physical trauma, but depression, sleep disturbances, and personality may also be involved. Moreover, dysregulation of the stress system, the immune system, and central pain mechanisms may determine the pathophysiology of the illness, leading to a loss of capacity to adapt to all kind of stressors. CFS/FM patients can be best helped by a pragmatic and individualized approach aimed at adjusting

	denhove@uz.kuleuven.ac.be			lifestyle and optimizing self-care, which in the long run may contribute to a restoration of physical and mental adaptability. Future psychiatric research into CFS/FM should focus on the complex interrelationships among pain/fatigue, stress/depression, and personality, as well as on processes of therapeutic change and the advantages of customized treatment.
Van Houdenhove B, Luyten P.		Chronic fatigue syndrome reflects loss of adaptability.	J Intern Med. 2010 Sep;268(3):249-51. Comment on: J Intern Med. 2010 Sep;268(3):265-78.	
Van Houdenhove B, Pae CU, Luyten P.	University Hospitals Leuven and Chronic Fatigue Reference Centre, UZ Leuven, Herestraat 49, B-3000 Leuven, Belgium. boudewijn.vanhoudenhove@uz.kuleuven.ac.be	Chronic fatigue syndrome: is there a role for non-antidepressant pharmacotherapy?	Expert Opin Pharmacother. 2010 Feb;11(2):215-23.	IMPORTANCE OF THE FIELD: Chronic fatigue syndrome (CFS) is a prevalent but poorly understood condition mainly characterized by debilitating, persistent or recurrent fatigue; increased physical and mental fatigability; cognitive impairment and widespread musculoskeletal pain. Despite intensive treatment research, the role of pharmacotherapy in the illness remains uncertain. AREAS COVERED IN THIS REVIEW: An updated review is given of pharmacotherapy in CFS, with a focus on non-antidepressant, controlled drug trials performed between 1988 and August 2009. WHAT THE READER WILL GAIN: Antiviral, immunological and antibiotic therapies, although sometimes associated with symptom amelioration, can be more harmful than beneficial in CFS. Stimulants seem to benefit some CFS patients but their long-term effects is uncertain. Although antidepressants are not curative for the illness, they might be useful for some symptomatic aspects and co-morbid anxiety and depression. There is little or no evidence that CFS patients benefit from other pharmacological agents (e.g., steroids) or from dietary supplements and complementary medicine products. Future research into treatment should take specific subgroups into account and should target immunological aspects of the illness as well as the complex relationships between CFS, stress and depression. TAKE HOME MESSAGE: Pharmacotherapy can currently not be considered first-line treatment in CFS and should always be used in a context of self-management and rehabilitation.
van Kuppeveld FJ, de Jong AS, Lanke KH, Verhaegh GW, Melchers WJ, Swanink CM, Bleijenberg G, Netea MG, Galama JM, van der Meer JW.	Department of Medical Microbiology, Radboud University Nijmegen Medical Centre, 6500 HB Nijmegen, Netherlands. f.vankuppeveld@ncmls.ru.nl	Prevalence of xenotropic murine leukaemia virus-related virus in patients with chronic fatigue syndrome in the Netherlands: retrospective analysis of samples from an established cohort.	BMJ. 2010 Feb 25;340:c1018. doi: 10.1136/bmj.c1018. Comment in: BMJ. 2010;340:c1099.	OBJECTIVE: The presence of the retrovirus xenotropic murine leukaemia virus-related virus (XMRV) has been reported in peripheral blood mononuclear cells of patients with chronic fatigue syndrome. Considering the potentially great medical and social relevance of such a discovery, we investigated whether this finding could be confirmed in an independent European cohort of patients with chronic fatigue syndrome. DESIGN: Analysis of a well defined cohort of patients and matched neighbourhood controls by polymerase chain reaction. SETTING: Certified (ISO 15189) laboratory of clinical virology in a university hospital in the Netherlands. Population Between December 1991 and April 1992, peripheral blood mononuclear cells were isolated from 76 patients and 69 matched neighbourhood controls. In this study we tested cells from 32 patients and 43 controls from whom original cryopreserved phials were still available. MAIN OUTCOME MEASURES: Detection of XMRV in peripheral blood mononuclear cells by real time polymerase chain reaction assay targeting the XMRV integrase gene and/or a nested polymerase chain reaction assay targeting the XMRV gag gene. RESULTS: We detected no XMRV sequences in any of the patients or controls in either of the assays, in which relevant positive and negative isolation controls and polymerase chain reaction controls were included. Spiking experiments showed that we were able to detect at least 10 copies of XMRV

				sequences per 10(5) peripheral blood mononuclear cells by real time as well as by nested polymerase chain reaction, demonstrating high sensitivity of both assays. CONCLUSIONS: This study failed to show the presence of XMRV in peripheral blood mononuclear cells of patients with chronic fatigue syndrome from a Dutch cohort. These data cast doubt on the claim that XMRV is associated with chronic fatigue syndrome in the majority of patients.
van Luijtelaar G, Verbraak M, van den Bunt M, Keijsers G, Arns M.	Radboud University Nijmegen, PO Box 9104, 6500 HE, Nijmegen, The Netherlands. g.vanluijtelaar@donders.ru.nl	EEG findings in burnout patients.	J Neuropsychiatry Clin Neurosci. 2010 Spring;22(2):208-17.	The concept of burnout remains enigmatic since it is only determined by behavioral characteristics. Moreover, the differential diagnosis with depression and chronic fatigue syndrome is difficult. EEG-related variables in 13 patients diagnosed with burnout syndrome were compared with 13 healthy comparison subjects in order to explore the existence of neurobiological markers for burnout. Burnout patients showed reduced P300 amplitude, a lower alpha peak frequency and reduced beta power. These EEG-related differences in burnout patients differ from those described in the literature in depression and chronic fatigue patients. Our preliminary findings suggest that burnout might be considered as a separate clinical syndrome.
Van Oosterwijck J, Nijs J, Meeus M, Lefever I, Huybrechts L, Lambrecht L, Paul L.	Department of Human Physiology, Faculty of Physical Education & Physiotherapy, Vrije Universiteit Brussel, Belgium.	Pain inhibition and postexertional malaise in myalgic encephalomyelitis/ chronic fatigue syndrome: an experimental study.	J Intern Med. 2010 Sep;268(3):265-78. Epub 2010 Mar 3. Comment in: J Intern Med. 2010 Sep;268(3):249-51.	OBJECTIVES: To examine the efficacy of the pain inhibitory systems in patients with myalgic encephalomyelitis/chronic fatigue syndrome (ME/CFS) during two different types of exercise and to examine whether the (mal)functioning of pain inhibitory systems is associated with symptom increases following exercise. DESIGN: A controlled experimental study. SETTING AND SUBJECTS: Twenty-two women with ME/CFS and 22 healthy sedentary controls were studied at the Department of Human Physiology, Vrije Universiteit Brussel. INTERVENTIONS: All subjects performed a submaximal exercise test and a self-paced, physiologically limited exercise test on a cycle ergometer. The exercise tests were undertaken with continuous cardiorespiratory monitoring. Before and after the exercise bouts, subjects filled out questionnaires to assess health status, and underwent pressure pain threshold measurements. Throughout the study, subjects' activity levels were assessed using accelerometry. RESULTS: In patients with ME/CFS, pain thresholds decreased following both types of exercise, whereas they increased in healthy subjects. This was accompanied by a worsening of the ME/CFS symptom complex post-exercise. Decreased pressure thresholds during submaximal exercise were associated with postexertional fatigue in the ME/CFS group ($r = 0.454$; $P = 0.034$). CONCLUSIONS: These observations indicate the presence of abnormal central pain processing during exercise in patients with ME/CFS and demonstrate that both submaximal exercise and self-paced, physiologically limited exercise trigger postexertional malaise in these patients. Further study is required to identify specific modes and intensity of exercise that can be performed in people with ME/CFS without exacerbating symptoms.
van't Leven M, Zielhuis GA, van der Meer JW, Verbeek AL, Bleijenberg G.	Department of Epidemiology, Biostatistics and HTA, Radboud University Nijmegen Medical Centre, the Netherlands.	Fatigue and chronic fatigue syndrome-like complaints in the general population.	Eur J Public Health. 2010 Jun;20(3):251-7. Epub 2009 Aug 18.	BACKGROUND: Most knowledge on chronic fatigue (CF) and chronic fatigue syndrome (CFS) is based on clinical studies, not representative of the general population. This study aimed to assess the prevalence of fatigue in an adult general population and to identify associations with lifestyle factors. METHODS: Total 22,500 residents of Nijmegen were selected at random and interviewed by questionnaire. Data on 9062 respondents (43% response) were analysed, taken into account age, gender and concomitant disease. Subjects were classified into four groups: not fatigued (NF, reference group), short-term fatigue (SF, <6 months), chronic fatigue (CF, >or=6 months) and CFS-like fatigue (in accordance with the Center for Disease Control criteria for CFS, without clinical confirmation).

				RESULTS: Our study population showed the following breakdown: NF 64.4% (95% CI 63.6-65.6%), SF 4.9% (95% CI 4.5-5.4%), CF 30.5% (95% CI 29.5-31.4%) and CFS-like fatigue 1.0% (95% CI 0.8-1.2%). Compared with the NF group, more of the CFS respondents were female [odds ratio (OR) = 1.9], obese (OR = 4.1), using analgesics (OR = 7.8), had a low alcohol intake (OR = 0.4), were eating less healthy food (OR = 0.5) and were physically less active (OR = 0.1). These associations largely applied to the SF and CF group. The fatigue could have been due to a concomitant disease in 34 and 55.5% of the SF and CF cases, respectively. CONCLUSION: The prevalence of CF in the general population appears to be much higher than previously indicated. Even with strict criteria for CFS, it is estimated that approximately 1% of the adult population experiences this condition. Interestingly, a large part of this group remains unrecognized by the general practitioner. A striking similarity in lifestyle pattern between SF, CF and CFS calls for further research.
Vanheule S, Vandenbergen J, Verhaeghe P, Desmet M.		Interpersonal problems in alexithymia: A study in three primary care groups.	Psychol Psychother. 2010 Feb 11. [Epub ahead of print]	Objectives The present study investigated the relation between alexithymia and interpersonal problems in a sample of primary care patients with either chronic fatigue syndrome (CFS); a chronic cardiovascular or auto-immune disease; or a minor medical condition. It was hypothesized that the relation between cold interpersonal functioning would account for the differences in alexithymia scores between the patient groups. Design and methods Participants were 155 primary care patients that were recruited through 52 general practitioners: 52 CFS patients; 52 patients with a chronic cardiovascular or auto-immune disease; 51 patients with a minor medical condition. Interpersonal problems were assessed by means of the Inventory of Interpersonal Problems and alexithymia was assessed by means of the Toronto Alexithymia Scale. Results CFS patients and patients with a chronic cardiovascular or auto-immune disease have substantially higher alexithymia scores than patients with a minor medical condition. Alexithymia is positively related to cold and distant interpersonal functioning; negatively related to self-sacrificing and overly accommodating in relation to others; and positively related to vindictiveness and self-centredness. The relation between alexithymia and these interpersonal problems accounts for the differences in alexithymia scores between the patient groups. Conclusions Alexithymia and interpersonal problems should be considered together, in terms of one deficient affect regulatory system, and the relation between alexithymia and specific illness conditions is secondary to this. Clinical assessment of patients with problems in naming and discussing affective states should never be isolated from an examination of their interpersonal problems, and vice versa. Mentalization-based therapy is recommended for patients with problems in naming affective states, interpersonal problems, and concomitant CFS or other alexithymia-related diseases.
VanNess JM, Stevens SR, Bateman L, Stiles TL, Snell CR.	Pacific Fatigue Laboratory, University of the Pacific, Stockton, California 95211, USA. mvanness@pacific.edu	Postexertional malaise in women with chronic fatigue syndrome.	J Womens Health (Larchmt). 2010 Feb;19(2):239-44.	OBJECTIVE: Postexertional malaise (PEM) is a defining characteristic of chronic fatigue syndrome (CFS) that remains a source of some controversy. The purpose of this study was to explore the effects of an exercise challenge on CFS symptoms from a patient perspective. METHODS: This study included 25 female CFS patients and 23 age-matched sedentary controls. All participants underwent a maximal cardiopulmonary exercise test. Subjects completed a health and well-being survey (SF-36) 7 days postexercise. Subjects also provided, approximately 7 days after testing, written answers to open-ended questions pertaining to physical and cognitive responses to the test and length of recovery. SF-36 data were compared using multivariate analyses. Written questionnaire responses were used to determine recovery time as well as number and type of symptoms experienced. RESULTS: Written

				questionnaires revealed that within 24 hours of the test, 85% of controls indicated full recovery, in contrast to 0 CFS patients. The remaining 15% of controls recovered within 48 hours of the test. In contrast, only 1 CFS patient recovered within 48 hours. Symptoms reported after the exercise test included fatigue, light-headedness, muscular/joint pain, cognitive dysfunction, headache, nausea, physical weakness, trembling/instability, insomnia, and sore throat/glands. A significant multivariate effect for the SF-36 responses ($p < 0.001$) indicated lower functioning among the CFS patients, which was most pronounced for items measuring physiological function. CONCLUSIONS: The results of this study suggest that PEM is both a real and an incapacitating condition for women with CFS and that their responses to exercise are distinctively different from those of sedentary controls.
Vermeulen RC, Kurk RM, Visser FC, Sluiter W, Scholte HR.	CFS/ME and Pain Research Center Amsterdam, Waalstraat 25-31, 1078 BR Amsterdam, The Netherlands. rv@cvscentrum.nl	Patients with chronic fatigue syndrome performed worse than controls in a controlled repeated exercise study despite a normal oxidative phosphorylation capacity.	J Transl Med. 2010 Oct 11;8:93.	BACKGROUND: The aim of this study was to investigate the possibility that a decreased mitochondrial ATP synthesis causes muscular and mental fatigue and plays a role in the pathophysiology of the chronic fatigue syndrome (CFS/ME). METHODS: Female patients (n = 15) and controls (n = 15) performed a cardiopulmonary exercise test (CPET) by cycling at a continuously increased work rate till maximal exertion. The CPET was repeated 24 h later. Before the tests, blood was taken for the isolation of peripheral blood mononuclear cells (PBMC), which were processed in a special way to preserve their oxidative phosphorylation, which was tested later in the presence of ADP and phosphate in permeabilized cells with glutamate, malate and malonate plus or minus the complex I inhibitor rotenone, and succinate with rotenone plus or minus the complex II inhibitor malonate in order to measure the ATP production via Complex I and II, respectively. Plasma CK was determined as a surrogate measure of a decreased oxidative phosphorylation in muscle, since the previous finding that in a group of patients with external ophthalmoplegia the oxygen consumption by isolated muscle mitochondria correlated negatively with plasma creatine kinase, 24 h after exercise. RESULTS: At both exercise tests the patients reached the anaerobic threshold and the maximal exercise at a much lower oxygen consumption than the controls and this worsened in the second test. This implies an increase of lactate, the product of anaerobic glycolysis, and a decrease of the mitochondrial ATP production in the patients. In the past this was also found in patients with defects in the mitochondrial oxidative phosphorylation. However the oxidative phosphorylation in PBMC was similar in CFS/ME patients and controls. The plasma creatine kinase levels before and 24 h after exercise were low in patients and controls, suggesting normality of the muscular mitochondrial oxidative phosphorylation. CONCLUSION: The decrease in mitochondrial ATP synthesis in the CFS/ME patients is not caused by a defect in the enzyme complexes catalyzing oxidative phosphorylation, but in another factor. TRIAL REGISTRATION: Clinical trials registration number: NL16031.040.07.
Voet NB, Bleijenberg G, Padberg GW, van Engelen BG, Geurts AC.	Nijmegen Centre for Evidence Based Practice; Department of Rehabilitation, Radboud University Nijmegen Medical	Effect of aerobic exercise training and cognitive behavioural therapy on reduction of chronic fatigue in patients with	BMC Neurol. 2010 Jun 30;10:56.	BACKGROUND: In facioscapulohumeral dystrophy (FSHD) muscle function is impaired and declines over time. Currently there is no effective treatment available to slow down this decline. We have previously reported that loss of muscle strength contributes to chronic fatigue through a decreased level of physical activity, while fatigue and physical inactivity both determine loss of societal participation. To decrease chronic fatigue, two distinctly different therapeutic approaches can be proposed: aerobic exercise training (AET) to improve physical capacity and cognitive behavioural therapy (CBT) to stimulate an active life-style yet avoiding excessive physical strain. The primary aim of the FACTS-2-FSHD (acronym for Fitness And Cognitive behavioural TherapieS/for Fatigue and

	Centre, Nijmegen, The Netherlands. N.Voet@reval.umcn.nl	facioscapulohumeral dystrophy: protocol of the FACTS-2-FSHD trial.		ACTivitieS in FSHD) trial is to study the effect of AET and CBT on the reduction of chronic fatigue as assessed with the Checklist Individual Strength subscale fatigue (CIS-fatigue) in patients with FSHD. Additionally, possible working mechanisms and the effects on various secondary outcome measures at all levels of the International Classification of Functioning, Disability and Health (ICF) are evaluated. METHODS/DESIGN: A multi-centre, assessor-blinded, randomized controlled trial is conducted. A sample of 75 FSHD patients with severe chronic fatigue (CIS-fatigue > or = 35) will be recruited and randomized to one of three groups: (1) AET + usual care, (2) CBT + usual care or (3) usual care alone, which consists of no therapy at all or occasional (conventional) physical therapy. After an intervention period of 16 weeks and a follow-up of 3 months, the third (control) group will as yet be randomized to either AET or CBT (approximately 7 months after inclusion). Outcomes will be assessed at baseline, immediately post intervention and at 3 and 6 months follow up. DISCUSSION: The FACTS-2-FSHD study is the first theory-based randomized clinical trial which evaluates the effect and the maintenance of effects of AET and CBT on the reduction of chronic fatigue in patients with FSHD. The interventions are based on a theoretical model of chronic fatigue in patients with FSHD. The study will provide a unique set of data with which the relationships between outcome measures at all levels of the ICF could be assessed. TRIAL REGISTRATION: Dutch Trial Register, NTR1447.
Vollmer-Conna U.		Chronic fatigue syndrome in adolescence: where to from here?	Arch Pediatr Adolesc Med. 2010 Sep;164(9):880-1. Comment on: Arch Pediatr Adolesc Med. 2010 Sep;164(9):803-9. Arch Pediatr Adolesc Med. 2010 Sep;164(9):817-23.	
Walters SJ.	Medical Statistics Group, School of Health and Related Research, University of Sheffield, Sheffield S1 4DA, UK. s.j.walters@sheffield.ac.uk	Therapist effects in randomised controlled trials: what to do about them.	J Clin Nurs. 2010 Apr;19(7-8):1102-12.	AIMS AND OBJECTIVES: The aim of this study is to describe and compare three statistical methods to allow for therapist effects in individually randomised controlled trials. BACKGROUND: In an individually randomised controlled trial where the intervention is delivered by a health professional it seems likely that the effectiveness of the intervention, independent of any treatment effect, could depend on the skill of the health professional delivering it. This leads to a potential clustering of the outcomes for the patients being treated by the same health professional. DESIGN: Retrospective statistical analysis of outcomes from four example randomised controlled trial datasets with potential clustering by health professional. METHODS: Three methods to allow for clustering are described: cluster level analysis; random effects models and marginal models. These models were fitted to continuous outcome data from four example randomised controlled trial datasets with potential clustering by health professional. RESULTS: The cluster level models produced the widest confidence intervals. Little difference was found between the estimates of the regression coefficients for the treatment effect and confidence intervals between the individual patient level models for the datasets. The conclusions reached for each dataset match those published in the original papers. The

				intracluster correlation coefficient ranged from <0.001-0.04 for the outcomes, which shows only minor levels of clustering within the datasets. CONCLUSIONS: The models, which use individual level data are to be preferred. Treatment coefficients from these models have different interpretations. The choice of model should depend on the scientific question being asked. RELEVANCE TO CLINICAL PRACTICE: We recommend that researchers should be aware of any potential clustering, by health professional, in their randomised controlled trial and use appropriate methods to account for this clustering in the statistical analysis of the data.
Wearden AJ, Dowrick C, Chew-Graham C, Bentall RP, Morriss RK, Peters S, Riste L, Richardson G, Lovell K, Dunn G; Fatigue Intervention by Nurses Evaluation (FINE) trial writing group and the FINE trial group. Collaborators: Bennett C, Bentall R, Booth L, Brocki J, Cahill G, Chapman A, Chew-Graham C, Connell S, Dowrick C, Dunn G, Fleetwood D, Ibbotson L, Jerman D, Lovell K, Mann J, Morriss R, Peters S, Powell P, Quarmby D, Richardson G, Riste L, Wearden A, Williams J.	School of Psychological Sciences, University of Manchester, Manchester. alison.wearden@manchester.ac.uk	Nurse led, home based self help treatment for patients in primary care with chronic fatigue syndrome: randomised controlled trial.	BMJ. 2010 Apr 23;340:c1777. doi: 10.1136/bmj.c1777. Comment in: BMJ. 2010;340:c1799. Evid Based Nurs. 2010 Oct;13(4):125-6.	OBJECTIVE: To evaluate the effectiveness of home delivered pragmatic rehabilitation-a programme of gradually increasing activity designed collaboratively by the patient and the therapist-and supportive listening-an approach based on non-directive counselling-for patients in primary care with chronic fatigue syndrome/myalgic encephalomyelitis or encephalitis (CFS/ME). DESIGN: Single blind, randomised, controlled trial. SETTING: 186 general practices across the north west of England between February 2005 and May 2007. PARTICIPANTS: 296 patients aged 18 or over with CFS/ME (median illness duration seven years) diagnosed using the Oxford criteria. INTERVENTIONS: Participants were randomly allocated to pragmatic rehabilitation, supportive listening, or general practitioner treatment as usual. Both therapies were delivered at home in 10 sessions over 18 weeks by one of three adult specialty general nurses who had received four months' training, including supervised practice, in each of the interventions. GP treatment as usual was unconstrained except that patients were not to be referred for systematic psychological therapies during the treatment period. Main outcome measures The primary clinical outcomes were fatigue and physical functioning at the end of treatment (20 weeks) and 70 weeks from recruitment compared with GP treatment as usual. Lower fatigue scores and higher physical functioning scores denote better outcomes. RESULTS: A total of 257 (87%) of the 296 patients who entered the trial were assessed at 70 weeks, the primary outcome point. Analysis was on an intention to treat basis, with robust treatment effects estimated after adjustment for missing data using probability weights. Immediately after treatment (at 20 weeks), patients allocated to pragmatic rehabilitation (n=95) had significantly improved fatigue (effect estimate -1.18, 95% confidence interval -2.18 to -0.18; P=0.021) but not physical functioning (-0.18, 95% CI -5.88 to +5.52; P=0.950) compared with patients allocated to treatment as usual (n=100). At one year after finishing treatment (70 weeks), there were no statistically significant differences in fatigue or physical functioning between patients allocated to pragmatic rehabilitation and those on treatment as usual (-1.00, 95% CI -2.10 to +0.11; P=0.076 and +2.57, 95% CI 3.90 to +9.03; P=0.435). At 20 weeks, patients allocated to supportive listening (n=101) had poorer physical functioning than those allocated to treatment as usual (-7.54, 95% CI -12.76 to -2.33; P=0.005) and no difference in fatigue. At 70 weeks, patients allocated to supportive listening did not differ significantly from those allocated to treatment as usual on either primary outcome. CONCLUSIONS: For patients with CFS/ME in primary care, pragmatic rehabilitation delivered by trained nurse therapists improves fatigue in the short term compared with unconstrained GP treatment as usual, but the effect is small and not statistically significant at one year follow-up. Supportive listening delivered by trained nurse therapists is not an effective treatment for CFS/ME. Trial registration International Standard Randomised Controlled Trial Number IRCTN74156610.

Weaver SA, Janal MN, Aktan N, Ottenweller JE, Natelson BH.	Department of Neurology & Neurosciences, UMDNJ-New Jersey Medical School, Newark, New Jersey, USA.	Sex differences in plasma prolactin response to tryptophan in chronic fatigue syndrome patients with and without comorbid fibromyalgia.	J Womens Health (Larchmt). 2010 May;19(5):951-8.	BACKGROUND: Some think chronic fatigue syndrome (CFS) and fibromyalgia (FM) are variants of the same illness process. This would imply that CFS patients with and without comorbid FM have similar biological underpinnings. To test this, we compared serotonergic-based responses, plasma prolactin (PRL), and self-reported measures of fatigue to intravenous infusion of tryptophan among patients with CFS alone, CFS + FM, and healthy controls. METHODS: Men and women with CFS alone or CFS + FM and healthy subjects, none with current major depressive disorder (MDD), were given 120 mg of L-tryptophan per kg lean body mass intravenously (i.v.). Before and after tryptophan infusion, blood samples were collected, and plasma PRL, tryptophan, and kynurenine concentrations were determined. RESULTS: Women with CFS alone, but not CFS + FM, showed upregulated plasma PRL responses compared with controls. There were no differences among groups of men. Plasma tryptophan and kynurenine concentrations did not differ among groups. CONCLUSIONS: These results indicate that women with CFS alone have upregulated serotonergic tone that is not seen in those with comorbid FM. The lack of effect in men suggests a mechanism that might explain, in part, the increased prevalence of CFS in women. The data support the interpretation that CFS in women is a different illness from FM.

BMC Biol. 2010 Sep 27;8:124.	The recent identification of the gammaretrovirus XMRV and a second gammaretrovirus of a different subtype in chronic fatigue syndrome has aroused much interest, not least among sufferers. However, it remains highly controversial whether the detection of these viruses represents true infection or laboratory artifacts.
White AT, Light AR, Hughen RW, Bateman L, Martins TB, Hill HR, Light KC.	Department of Exercise and Sport Science, University of Utah, Salt Lake City, Utah, USA.	Severity of symptom flare after moderate exercise is linked to cytokine activity in chronic fatigue syndrome.	Psychophysiology. 2010 Jul 1;47(4):615-24. Epub 2010 Mar 4.	Chronic fatigue syndrome (CFS) patients often report symptom flare (SF) for >24 h after moderate exercise (post-ex). We hypothesized that SF is linked to increases in circulating cytokines and CD40 Ligand (CD40L). In 19 CFS patients and 17 controls, mental and physical fatigue and pain symptom ratings were obtained together with serum for 11 cytokines and CD40L before and at 0.5, 8, 24, and 48 h post-ex. Before exercise, CFS had lower CD40L ($p<.05$) but similar cytokines versus controls. In subgroups based on SF at 48 h, high SF patients (n=11) increased in IL-1beta, IL-12, IL-6, IL-8, IL-10, and IL-13 ($p<.05$) 8 h post-ex. Low SF patients (n=8) showed post-ex decreases in IL-10, IL-13, and CD40L, and controls decreased in IL-10, CD40L, and TNFalpha ($p<.05$). Thus, in CFS, cytokine activity may vary directly with SF, which may explain prior inconsistent findings.
White PD.	Wolfson Institute of Preventive Health, Barts and The London School of Medicine and Dentistry, Queen Mary University of	Chronic fatigue syndrome: Is it one discrete syndrome or many? Implications for the "one vs. many" functional somatic	J Psychosom Res. 2010 May;68(5):455-9. Epub 2010 Mar 17.	There is a current debate as to whether "functional somatic syndromes" (FSSs) are more similar to or different from each other. While at the same time, there is evidence of heterogeneity within single syndromes. So, it could be that these syndromes are all part of one big process/illness, are discrete in their own right, or that they are heterogeneous collections of different illnesses lumped together by common symptoms but separated by uncommon pathophysiologies. The example of chronic fatigue syndrome (CFS) is instructive. There is evidence to support all three models of understanding. Three recent large studies have suggested that FSSs are both similar and dissimilar at the same time. The

	London, London, UK. p.d.white@qmul.ac.uk	syndromes debate.		solution to the debate is that we need to both "lump" and "split." We need to study both the similarities between syndromes and their dissimilarities to better understand what we currently call the FSSs.

Wiborg JF, Knoop H, Stulemeijer M, Prins JB, Bleijenberg G.	Department of Medical Psychology, Radboud University Nijmegen Medical Centre, Expert Centre Chronic Fatigue, The Netherlands. j.wiborg@nkcv.umcn.nl	How does cognitive behaviour therapy reduce fatigue in patients with chronic fatigue syndrome? The role of physical activity.	Psychol Med. 2010 Aug;40(8):1281-7. Epub 2010 Jan 5.	BACKGROUND: Cognitive behaviour therapy (CBT) is known to reduce fatigue severity in chronic fatigue syndrome (CFS). How this change in symptomatology is accomplished is not yet understood. The purpose of the present study was to determine whether the effect of CBT on fatigue is mediated by an increase in physical activity. METHOD: Three randomized controlled trials were reanalysed, previously conducted to evaluate the efficacy of CBT for CFS. In all samples, actigraphy was used to assess the level of physical activity prior and subsequent to treatment or a control group period. The mediation hypothesis was analysed according to guidelines of Baron & Kenny [Journal of Personality and Social Psychology (1986)51, 1173-1182]. A non-parametric bootstrap approach was used to test statistical significance of the mediation effect. RESULTS: Although CBT effectively reduced fatigue, it did not change the level of physical activity. Furthermore, changes in physical activity were not related to changes in fatigue. Across the samples, the mean mediation effect of physical activity averaged about 1% of the total treatment effect. This effect did not yield significance in any of the samples. CONCLUSIONS: The effect of CBT on fatigue in CFS is not mediated by a persistent increase in physical activity.
Wiborg JF, van der Werf S, Prins JB, Bleijenberg G.	Expert Centre Chronic Fatigue, Radboud University Nijmegen, Medical Centre, PO Box 9101, 6500 HB Nijmegen, The Netherlands. j.wiborg@nkcv.umcn.nl	Being homebound with chronic fatigue syndrome: A multidimensional comparison with outpatients.	Psychiatry Res. 2010 May 15;177(1-2):246-9. Epub 2010 Mar 5.	Many patients with chronic fatigue syndrome (CFS) seem to experience periods in which they are homebound due to their symptomatology. Despite a growing body of research about CFS, little is known about patients who no longer feel able to leave their homes. The purpose of the present study was to examine whether homebound patients differ from other CFS patients on illness-specific characteristics. Besides experiencing more impairment in daily functioning than participants of an outpatient intervention study, homebound patients were characterised by extremely high levels of daily fatigue, predominant somatic attributions, and pervasively passive activity patterns. The course of symptomatology was similarly stable in both groups. Our findings suggest that homebound patients form a distinct subgroup of CFS patients who might profit from a treatment approach that is tailored to their specific needs. The exploratory nature of this first systematic investigation of homebound CFS patients is stressed, and suggestions for future research are made.
Wyller VB, Barbieri R, Saul JP.	Department of Pediatrics, Rikshospitalet University Hospital, 0027,	Blood pressure variability and closed-loop baroreflex assessment in	Eur J Appl Physiol. 2010 Oct 2. [Epub ahead of print]	Hemodynamic abnormalities have been documented in the chronic fatigue syndrome (CFS), indicating functional disturbances of the autonomic nervous system responsible for cardiovascular regulation. The aim of this study was to explore blood pressure variability and closed-loop baroreflex function at rest and during mild orthostatic stress in adolescents with CFS. We included a consecutive sample of 14 adolescents 12-18 years old with CFS diagnosed according to a thorough and standardized set of

	Oslo, Norway, brwylle@online.no.	adolescent chronic fatigue syndrome during supine rest and orthostatic stress.		investigations and 56 healthy control subjects of equal sex and age distribution. Heart rate and blood pressure were recorded continuously and non-invasively during supine rest and during lower body negative pressure (LBNP) of -20 mmHg to simulate mild orthostatic stress. Indices of blood pressure variability and baroreflex function (α-gain) were computed from monovariate and bivariate spectra in the low-frequency (LF) band (0.04-0.15 Hz) and the high-frequency (HF) band (0.15-0.50 Hz), using an autoregressive algorithm. Variability of systolic blood pressure in the HF range was lower among CFS patients as compared to controls both at rest and during LBNP. During LBNP, compared to controls, α-gain HF decreased more, and α-gain LF and the ratio of α-gain LF/α-gain HF increased more in CFS patients, all suggesting greater shift from parasympathetic to sympathetic baroreflex control. CFS in adolescents is characterized by reduced systolic blood pressure variability and a sympathetic predominance of baroreflex heart rate control during orthostatic stress. These findings may have implications for the pathophysiology of CFS in adolescents.
Wyller VB, Evang JA, Godang K, Solhjell KK, Bollerslev J.	Division of Paediatrics, Oslo University Hospital, Oslo, Norway. asa.myrelid@kbh.uu.se	Hormonal alterations in adolescent chronic fatigue syndrome.	Acta Paediatr. 2010 May;99(5):770-3. Epub 2010 Mar 1.	AIM: The chronic fatigue syndrome is associated with alterations in the hypothalamus-pituitary-adrenal axis and cardiovascular autonomic nervous activity, suggesting a central dysregulation. This study explored differences among adolescent chronic fatigue syndrome patients and healthy controls regarding antidiuretic hormone, the renin-angiotensin-aldosterone-system, sex hormones and cardiac peptides. METHODS: We included a consecutive sample of 67 adolescents aged 12-18 years with chronic fatigue syndrome diagnosed according to a thorough and standardized set of investigations, and a volunteer sample of 55 healthy control subjects of equal gender and age distribution. Hormones were assayed with standard laboratory methods. RESULTS: Among patients, plasma antidiuretic hormone was significantly decreased and serum osmolality and plasma renin activity were significantly increased ($p <$ or $= 0.001$). Serum concentration of aldosterone, cortisol, NT-proBNP and sex hormones were not significantly different in the two groups. CONCLUSION: Chronic fatigue syndrome in adolescents is associated with alterations in hormonal systems controlling osmolality and blood volume, possibly supporting a theory of central dysregulation.
Yan Y, Liu Q, Wollenberg K, Martin C, Buckler-White A, Kozak CA.	NIH, NIAID, LMM, Bldg. 4, Room 329, 4 Center Drive MSC 0460, Bethesda, MD 20892-0460. ckozak@niaid.nih.gov.	Evolution of functional and sequence variants of the mammalian XPR1 receptor for mouse xenotropic gammaretroviruses and the human-derived retrovirus XMRV.	J Virol. 2010 Nov;84(22):11970-80. Epub 2010 Sep 15.	Genetic conflicts between retroviruses and their receptors result in the evolution of novel host entry restrictions and novel virus envelopes, and such variants can influence trans-species transmission. We screened rodents and other mammals for sequence variation in the Xpr1 receptor for the mouse xenotropic or polytropic mouse leukemia viruses (X-MLVs or P-MLVs, respectively) of the gammaretrovirus family and for susceptibility to mouse-derived X/P-MLVs and to XMRV (xenotropic murine leukemia virus-related virus), an X-MLV-like virus isolated from humans with prostate cancer and chronic fatigue syndrome. We identified multiple distinct susceptibility phenotypes; these include the four known Xpr1 variants in Mus and a novel fifth Xpr1 gene found in Mus molossinus and Mus musculus. We describe the geographic and species distribution of the Mus Xpr1 variants but failed to find the X-MLV-restrictive laboratory mouse allele in any wild mouse. We used mutagenesis and phylogenetic analysis to evaluate the functional contributions made by constrained, variable, and deleted residues. Rodent Xpr1 is under positive selection, indicating a history of host-pathogen conflicts; several codons under selection have known roles in virus entry. All non-Mus mammals are susceptible to mouse X-MLVs, but some restrict other members of the X/P-MLV family, and the resistance of hamster and gerbil cells to XMRV indicates that XMRV has unique receptor

				requirements. We show that the hypervariable fourth extracellular XPR1 loop (ECL4) contains three evolutionarily constrained residues that do not contribute to receptor function, we identify two novel residues important for virus entry (I579 and T583), and we describe a unique pattern of ECL4 variation in the three virus-restrictive Xpr1 variants found in MLV-infected house mice; these mice carry different deletions in ECL4, suggesting either that these sites or loop size affects receptor function.

An onco-informatics database for anticancer drug interactions with complementary and alternative medicines used in cancer treatment and supportive care: an overview of the OncoRx project.	Support Care Cancer. 2010 Jul;18(7):883-91. Epub 2009 Sep 9.	PURPOSE: Cancer patients are at high risk of manifesting interactions from use of anticancer drugs (ACDs) and complementary and alternative medicines (CAMs). These interactions can result in sub-therapeutic effects or increased toxicities which may compromise the outcome of chemotherapy. It is important for practitioners to gain convenient access to ACD-CAM interaction information so as to make better-informed decisions in daily practice. This paper describes the creation of an oncology database (OncoRx) that documents ACD-CAM interactions, including traditional Chinese medicines (TCMs) that are commonly used for cancer treatment, prevention, and supportive care therapy. METHODS: Information regarding ACDs, CAMs, and drug interactions were collated from 14 sources, inclusive of hardcopy and online resources, and input into a modified web server with a database engine and a programming interface using a combination of software and programming scripts. RESULTS: OncoRx currently contains a total of 117 ACDs and 166 CAMs. Users are able to search for interactions based on various CAM uses: cancer treatment or prevention, immune-system-related, alopecia, nausea, and vomiting, peripheral neuropathy and pain, inflammation, fatigue, and non-cancer related. Pharmacokinetic data on ACDs and CAMs, characteristics of CAMs based on TCM principles, and drug interaction parameters such as effects, mechanisms, evidences, and proposed management plans, are shown in the search results. CONCLUSION: OncoRx is an oncology database which detects ACD interactions. It is currently able to detect interactions with CAMs. It is hoped that OncoRx will serve as a useful resource to clinicians, educators, trainers, and students working in the oncology setting.
Young P, Finn BC, Bruetman J, Pellegrini D, Kremer A.	Servicios de Clínica Médica, Hospital Británico de Buenos Aires, Argentina. pabloyoung2003@	[The chronic asthenia syndrome: a clinical approach]. [Article in Spanish]	Medicina (B Aires). 2010;70(3):284-92.	The term asthenia comes from the Greek (centsqsneia, a: privation, without; esthénos: vigor, force), it means absence of strength, vigor or force. It is a symptom, difficult to define, with a set of vague sensations, different for each patient. It is a frequent cause of consult, almost 30% in ambulatory settings. The chronic fatigue represents up to 10% of these cases, and the 0.2-0.7% belongs to the chronic fatigue syndrome. It is very important to differentiate asthenia from weakness, dizziness or dyspnoea, since patients may confuse them. The factor time in asthenia is very useful for its

	yahoo.com.ar			characterization, it was defined to the prolonged fatigue when it lasts for more than a month and chronic when the duration is greater than 6 months. The depression is the commonest fatigue cause, representing approximately half of the cases. The most effective treatment of the asthenia is to solve the underlying cause, although up to 20% of the patients remain without diagnosis. The diagnosis of the chronic fatigue syndrome is of exclusion and the criteria of the international consensus of year 1994 are due to use. The high frequency of the symptom entails an enormous social and economic cost and it is for that reason so important for physicians to have a correct manage of this symptom.
Zhang L, Gough J, Christmas D, Mattey DL, Richards SC, Main J, Enlander D, Honeybourne D, Ayres JG, Nutt DJ, Kerr JR.	Department of Cellular & Molecular Medicine, St George's University of London, London, UK.	Microbial infections in eight genomic subtypes of chronic fatigue syndrome/myalgic encephalomyelitis.	J Clin Pathol. 2010 Feb;63(2):156-64. Epub 2009 Dec 2.	BACKGROUND: The authors have previously reported genomic subtypes of chronic fatigue syndrome/myalgic encephalomyelitis (CFS/ME) based on expression of 88 human genes. AIM: To attempt to reproduce these findings, determine the specificity of this signature to CFS/ME, and test for associations between CFS/ME subtype and infection. METHODS: Expression levels of 88 human genes were determined in blood of 62 new patients with idiopathic CFS/ME (according to Fukuda criteria), six patients with Q-fever-associated CFS/ME from the Birmingham Q-fever outbreak (according to Fukuda criteria), 14 patients with endogenous depression (according to DSM-IV criteria) and 29 normal blood donors. RESULTS: In patients with CFS/ME, differential expression was confirmed for all 88 genes. Q-CFS/ME had similar patterns of gene expression to idiopathic CFS/ME. Gene expression in patients with endogenous depression was similar to that in the normal controls, except for upregulation of five genes (APP, CREBBP, GNAS, PDCD2 and PDCD6). Clustering of combined gene data in CFS/ME patients for this and the authors' previous study (117 CFS/ME patients) revealed genomic subtypes with distinct differences in SF36 scores, clinical phenotypes, severity and geographical distribution. Antibody testing for Epstein-Barr virus, enterovirus, Coxiella burnetii and parvovirus B19 revealed evidence of subtype-specific relationships for Epstein-Barr virus and enterovirus, the two most common infectious triggers of CFS/ME. CONCLUSIONS: This study confirms the involvement of these genes in CFS/ME.
Zou J, Yuan J, Lv S, Tu J.	Scientific Research Department, Shanghai University of Sports, Shanghai, 200438, China. zoujun777@126.com	Effects of exercise on behavior and peripheral blood lymphocyte apoptosis in a rat model of chronic fatigue syndrome.	J Huazhong Univ Sci Technolog Med Sci. 2010 Apr;30(2):258-64. Epub 2010 Apr 21.	This study examined the effects of exercise on behavior and peripheral blood leukocyte apoptosis in a rat model of chronic fatigue syndrome (CFS). Thirty-six healthy male Sprague-Dawley rats were equally randomized into 3 groups: the control group, CFS model group and the exercise group in terms of body weight. A total of 25 rats entered the final statistical analysis due to 11 deaths during the study. CFS model was established by subjecting the rats in CFS model group and exercise group to electric shock, chronic restraint stress and cold water swim. Besides, rats in the exercise group took running wheel exercise. After a week of conditioning feeding, model construction and running wheel exercise were performed simultaneously, and lasted for 23 consecutive days. The behavior experiments, including running wheel exercise, open-field test, tail suspension test and Morris water maze test, were conducted, either before or after the model establishment. Rats were sacrificed and peripheral blood was obtained for the assessment of lymphocyte apoptosis index by flow cytometry (FCM). It was found that as compared with those in the control group, the weight of the rats was decreased obviously ($P<0.01$), the mobility time in the open-field and the tail suspension tests was shortened significantly ($P<0.01$), the time to locate the platform was enhanced ($P<0.01$) and the cell apoptosis index was increased substantially ($P<0.01$) in the CSF model group. Meanwhile, in comparison to the model group, the behavior in the open-field and the tail suspension tests was

				improved significantly (P<0.05), and the apoptosis index decreased remarkably (P<0.01) in the exercise group. It is concluded that sport intervention can prevent lymphocyte apoptosis and improve animal behavior rather than the memory.
Zou N, Kubota M, Kuruma E, Kojima C, Nagai A.	Department of Human Life and Environment, Nara Women's University, Kitauoya-nishimachi, Nara 630-8506, Japan.	Fatigue status in relation to lifestyle in healthy Japanese adolescents.	Int J Pediatr. 2010;2010. pii: 520320. Epub 2010 Sep 19.	In order to investigate the prevalence of physical, mental, and chronic fatigue syndrome-(CFS-) related fatigue and its relation to lifestyle, 1,225 adolescents (591 males, 634 females) aged 11 to 16 years were asked to complete a self-reported questionnaire on fatigue status and lifestyle in the past one month. There was no gender difference in physical and mental fatigue scores, but CFS-related scores were significantly higher in females than in males. These scores were found to increase with the increase of age. After adjusting for age and gender, multiple regression analysis showed that physical and mental fatigue scores were associated with sleeping hours, extracurricular sports activity, food balance, the frequencies of snacks between regular meals, intake of sugar-sweetened beverages, and visits to the nurse's room. This paper is the first large cross-sectional study on fatigue in healthy adolescents in Japan, albeit there were numerous such studies in Western countries.

Ablin JN, Buskila D, Clauw DJ.	University of Michigan Chronic Pain and Fatigue Research Center, Ann Arbor, MI 48106, USA.	Biomarkers in fibromyalgia.	Curr Pain Headache Rep. 2009 Oct;13(5):343-9.	Fibromyalgia is a common pain syndrome characterized by widespread pain, tenderness, and a number of other somatic symptoms and syndromes. Although there was original skepticism that any objective abnormalities would be identified in these individuals, at present there are many that have been reproducibly identified, and most point to dysregulation of central nervous system function as a key underlying pathogenic mechanism in this and related illnesses. This article reviews several objective abnormalities or measures that have been identified or used in fibromyalgia, and indicates which of these may be most promising to eventually use as biomarkers to follow the response to treatment or progress of disease over time.
Ablin JN, Odes L, Neumann L, Buskila D.	Institute of Rheumatology and Internal Medicine 6, Tel Aviv Sourasky Medical Center, Tel Aviv, Israel, ajacob@post.tau.ac.il.	The Hebrew version of the FibroFatigue scale: validation of a questionnaire for assessment of fibromyalgia and chronic fatigue syndrome.	Rheumatol Int. 2009 Sep 25. [Epub ahead of print]	The objective of this study is to validate a translated Hebrew version of the FibroFatigue Scale (FFS). The Hebrew version of the FFS was administered to 100 patients fulfilling ACR criteria for classification of FM together with the validated Hebrew version of the Fibromyalgia Impact Questionnaire (FIQ), the validated Hebrew version of the Short Form-36 (SF-36) and a Visual Analogue Scale (VAS) measurement of pain, anxiety, depression, morning stiffness and global well being. Test-retest reliability was assessed using Spearman correlations. Internal consistency was evaluated with Cronbach's alpha of reliability. Construct validity of the FFS was evaluated by correlations among the FFS, the FIQ and the subscales of the SF-36. Mean duration of symptoms was 10.7 years, and mean age of participants was 53.5 years. Test-retest reliability was between 0.46 and 0.85 for the various FFS items. Internal consistency was 0.89 for the overall FFS. Significant correlations were obtained between the FFS items and the SF-36. These results support the reliability and validity of the data obtained with the Hebrew version of the FSS for detecting and measuring symptom severity in Hebrew speaking patients with FM.
Adams D, Wu T, Yang X, Tai S, Vohra S.	CARE Program, Department of Pediatrics, University of Alberta, 8B19 11111 Jasper Avenue, Edmonton, Alberta, Canada, T5K 0L4.	Traditional Chinese medicinal herbs for the treatment of idiopathic chronic fatigue and chronic fatigue syndrome.	Cochrane Database Syst Rev. 2009 Oct 7;(4):CD006348.	BACKGROUND: Chronic fatigue is increasingly common. Conventional medical care is limited in treating chronic fatigue, leading some patients to use traditional Chinese medicine therapies, including herbal medicine. OBJECTIVES: To assess the effectiveness of traditional Chinese medicine herbal products in treating idiopathic chronic fatigue and chronic fatigue syndrome. SEARCH STRATEGY: The following databases were searched for terms related to traditional Chinese medicine, chronic fatigue, and clinical trials: CCDAN Controlled Trials Register (July 2009), MEDLINE (1966-2008), EMBASE (1980-2008), AMED (1985-2008), CINAHL (1982-2008), PSYCHINFO (1985-2008), CENTRAL (Issue 2 2008), the Chalmers Research Group PedCAM Database (2004), VIP Information (1989-2008), CNKI (1976-2008), OCLC Proceedings First (1992-2008), Conference Papers Index (1982-2008), and Dissertation Abstracts (1980-2008). Reference lists of included studies and review articles were examined and experts in the field were contacted for knowledge of additional studies. SELECTION CRITERIA: Selection criteria included published or unpublished randomized controlled trials (RCTs) of participants diagnosed with idiopathic chronic fatigue or chronic fatigue syndrome comparing traditional Chinese medicinal herbs with placebo, conventional standard of care (SOC), or no treatment/wait lists. The outcome of interest was fatigue. DATA COLLECTION AND ANALYSIS: 13 databases were searched for RCTs investigating TCM herbal products for the treatment of chronic fatigue. Over 2400 references were located. Studies were screened and assessed for inclusion criteria

				by two authors. MAIN RESULTS: No studies that met all inclusion criteria were identified. AUTHORS' CONCLUSIONS: Although studies examining the use of TCM herbal products for chronic fatigue were located, methodologic limitations resulted in the exclusion of all studies. Of note, many of the studies labelled as RCTs and conducted in China did not utilize rigorous randomization procedures. Improvements in methodology in future studies is required for meaningful synthesis of data.
Ament W, Verkerke GJ.	Department of Biometrics, Faculty of Health and Technology, Zuyd University, Heerlen, the Netherlands. wim.ament@xendo.com	Exercise and fatigue.	Sports Med. 2009;39(5):389-422. doi: 10.2165/00007256-200939050-00005.	Physical exercise affects the equilibrium of the internal environment. During exercise the contracting muscles generate force or power and heat. So physical exercise is in fact a form of mechanical energy. This generated energy will deplete the energy stocks within the body. During exercise, metabolites and heat are generated, which affect the steady state of the internal environment. Depending on the form of exercise, sooner or later sensations of fatigue and exhaustion will occur. The physiological role of these sensations is protection of the exercising subject from the deleterious effects of exercise. Because of these sensations the subject will adapt his or her exercise strategy. The relationship between physical exercise and fatigue has been the scope of interest of many researchers for more than a century and is very complex. The exercise intensity, exercise endurance time and type of exercise are all variables that cause different effects within the body systems, which in turn create different types of sensation within the subject's mind during the exercise. Physical exercise affects the biochemical equilibrium within the exercising muscle cells. Among others, inorganic phosphate, protons, lactate and free Mg2+ accumulate within these cells. They directly affect the mechanical machinery of the muscle cell. Furthermore, they negatively affect the different muscle cell organelles that are involved in the transmission of neuronal signals. The muscle metabolites produced and the generated heat of muscle contraction are released into the internal environment, putting stress on its steady state. The tremendous increase in muscle metabolism compared with rest conditions induces an immense increase in muscle blood supply, causing an increase in the blood circulatory system and gas exchange. Nutrients have to be supplied to the exercising muscle, emptying the energy stocks elsewhere in body. Furthermore, the contracting muscle fibres release cytokines, which in their turn create many effects in other organs, including the brain. All these different mechanisms sooner or later create sensations of fatigue and exhaustion in the mind of the exercising subject. The final effect is a reduction or complete cessation of the exercise. Many diseases speed up the depletion of the energy stocks within the body. So diseases amplify the effect of energy stock depletion that accompanies exercise. In addition, many diseases produce a change of mind-set before exercise. These changes of mind-set can create sensations of fatigue and exercise-avoiding behaviour at the onset of an exercise. One might consider these sensations during disease as a feed-forward mechanism to protect the subject from an excessive depletion of their energy stocks, to enhance the survival of the individual during disease.
Armitage R, Landis C, Hoffmann R, Lentz M, Watson N, Goldberg J, Buchwald D.	Department of Psychiatry, University of Michigan, Ann Arbor, MI, USA. rosearmi@umich.e	Power spectral analysis of sleep EEG in twins discordant for chronic fatigue syndrome.	J Psychosom Res. 2009 Jan;66(1):51-7. Epub 2008 Nov 25.	OBJECTIVE: The purpose of the study was to evaluate quantitative sleep electroencephalogram (EEG) frequencies in monozygotic twins discordant for chronic fatigue syndrome. METHODS: Thirteen pairs of female twins underwent polysomnography. During the first night, they adapted to the sleep laboratory, and during the second night, their baseline sleep was assessed. Visual stage scoring was conducted on sleep electroencephalographic records according to standard criteria, and power spectral analysis was used to quantify delta through beta frequency bands, processed in 6-s blocks.

	du			Data were averaged across sleep stage within each twin and coded for sleep stage and the presence or absence of chronic fatigue syndrome (CFS). A completely within-subjects repeated measure multivariate analysis of variance evaluated twin pairs by frequency band by sleep stage interactions and simple effects. The relationship between alpha and delta EEG was also assessed across twin pairs. RESULTS: No significant differences in spectral power in any frequency band were found between those with CFS and their nonfatigued cotwins. Phasic alpha activity, coupled with delta was noted in five subjects with CFS but was also present in 4/5 healthy twins, indicating this finding likely reflects genetic influences on the sleep electroencephalogram rather than disease-specific sleep pathology. CONCLUSIONS: The genetic influences on sleep polysomnography and microarchitecture appear to be stronger than the disease influence of chronic fatigue syndrome, despite greater subjective sleep complaint among the CFS twins. EEG techniques that focus on short duration events or paradigms that probe sleep regulation may provide a better description of sleep abnormalities in CFS.
Arnold LM.	Department of Psychiatry, University of Cincinnati College of Medicine, Cincinnati, Ohio, USA.	Pain and the brain: chronic widespread pain.	J Clin Psychiatry. 2009 Apr;70(4):e10.	Chronic widespread pain is associated with several medical and psychiatric disorders including, but not limited to, chronic fatigue syndrome, fibromyalgia, mood disorders, hepatitis, endocrine disorders such as hypothyroidism, and rheumatologic disorders such as rheumatoid arthritis. Careful and comprehensive differential diagnosis must be performed to ensure a correct diagnosis before an appropriate treatment can be selected. Fibromyalgia, in particular, is challenging to diagnose and treat because it shares many characteristics with other disorders and is commonly concurrent with major mood disorders. A comprehensive disease management strategy including patient education, pharmacotherapy, cognitivebehavioral therapy, and aerobic and other forms of exercise can be beneficial for many patients with fibromyalgia. 2009 Physicians Postgraduate Press, Inc.
Aslakson E, Vollmer-Conna U, Reeves WC, White PD.	Centers for Disease Control and Prevention, Atlanta, Georgia, USA. wcr1@cdc.gov.	Replication of an empirical approach to delineate the heterogeneity of chronic unexplained fatigue.	Popul Health Metr. 2009 Oct 5;7:17.	ABSTRACT: BACKGROUND: Chronic fatigue syndrome (CFS) is defined by self-reported symptoms. There are no diagnostic signs or laboratory markers, and the pathophysiology remains inchoate. In part, difficulties identifying and replicating biomarkers and elucidating the pathophysiology reflect the heterogeneous nature of the syndromic illness CFS. We conducted this analysis of people from defined metropolitan, urban, and rural populations to replicate our earlier empirical delineation of medically unexplained chronic fatigue and CFS into discrete endophenotypes. Both the earlier and current analyses utilized quantitative measures of functional impairment and symptoms as well as laboratory data. This study and the earlier one enrolled participants from defined populations and measured the internal milieu, which differentiates them from studies of clinic referrals that examine only clinical phenotypes. METHODS: This analysis evaluated 386 women identified in a population-based survey of chronic fatigue and unwellness in metropolitan, urban, and rural populations of the state of Georgia, USA. We used variables previously demonstrated to effectively delineate endophenotypes in an attempt to replicate identification of these endophenotypes. Latent class analyses were used to derive the classes, and these were compared and contrasted to those described in the previous study based in Wichita, Kansas. RESULTS: We identified five classes in the best fit analysis. Participants in Class 1 (25%) were polysymptomatic, with sleep problems and depressed mood. Class 2 (24%) was also polysymptomatic, with insomnia and depression, but participants were also obese with associated metabolic strain. Class 3 (20%) had more selective symptoms but was equally obese with metabolic strain. Class 4 (20%) and Class 5 (11%) consisted of nonfatigued, less

				symptomatic individuals, Class 4 being older and Class 5 younger. The classes were generally validated by independent variables. People with CFS fell equally into Classes 1 and 2. Similarities to the Wichita findings included the same four main defining variables of obesity, sleep problems, depression, and the multiplicity of symptoms. Four out of five classes were similar across both studies. CONCLUSION: These data support the hypothesis that chronic medically unexplained fatigue is heterogeneous and can be delineated into discrete endophenotypes that can be replicated. The data do not support the current perception that CFS represents a unique homogeneous disease and suggests broader criteria may be more explanatory. This replication suggests that delineation of endophenotypes of CFS and associated ill health may be necessary in order to better understand etiology and provide more patient-focused treatments.
Attree EA, Dancey CP, Pope AL.	University of East London, School of Psychology, London, United Kingdom. e.a.attree@uel.ac.uk	An assessment of prospective memory retrieval in women with chronic fatigue syndrome using a virtual-reality environment: an initial study.	Cyberpsychol Behav. 2009 Aug;12(4):379-85.	People with chronic fatigue syndrome (CFS) have increased rates of depression, anxiety, and illness intrusiveness; they may also suffer from cognitive problems such as retrospective memory (RM) deficits and concentration difficulties that can stem from diminished information-processing capability. We predicted that this diminished capacity may also lead to deficits in other cognitive functions, such as prospective memory (ProM). Event-, time-, and activity-based ProM was assessed in 11 women with CFS and 12 healthy women using a computer-generated virtual environment (VE). RM was assessed using a free-recall test, and subjective assessment of both ProM and RM was assessed by questionnaire. Groups were equivalent in age and measures of IQ. People with CFS performed slightly worse than healthy controls on both the event- and time-based ProM measures, although these were not statistically significant. However, the CFS group performed significantly worse than the healthy controls on both the free recall-task and on subjective assessment of both RM and ProM. Women with CFS do have some subtle decrements in memory, particularly RM. However, it is possible that the decrements found in the present sample would be greater in real life. Further studies utilizing both healthy controls and illness controls are now needed to ascertain how sensitive the VE measure is and to inform the development of tasks in the VE that place progressively increasing demands on working memory capacity.
Avellaneda Fernández A, Pérez Martín A, Izquierdo Martínez M, Arruti Bustillo M, Barbado Hernández FJ, de la Cruz Labrado J, Díaz-Delgado Peñas R, Gutiérrez Rivas E, Palacín Delgado C, Rivera Redondo J, Ramón	Carlos III Health Institute, Sinesio Delgado, n degrees 6, 28029, Madrid, Spanish Society of Primary Care Physicians, Narváez, 15 1 degrees Izda, 28009, Madrid, Spain. alfavel@gmail.com	Chronic fatigue syndrome: aetiology, diagnosis and treatment.	BMC Psychiatry. 2009 Oct 23;9 Suppl 1:S1.	Chronic fatigue syndrome is characterised by intense fatigue, with duration of over six months and associated to other related symptoms. The latter include asthenia and easily induced tiredness that is not recovered after a night's sleep. The fatigue becomes so severe that it forces a 50% reduction in daily activities. Given its unknown aetiology, different hypotheses have been considered to explain the origin of the condition (from immunological disorders to the presence of post-traumatic oxidative stress), although there are no conclusive diagnostic tests. Diagnosis is established through the exclusion of other diseases causing fatigue. This syndrome is rare in childhood and adolescence, although the fatigue symptom per se is quite common in paediatric patients. Currently, no curative treatment exists for patients with chronic fatigue syndrome. The therapeutic approach to this syndrome requires a combination of different therapeutic modalities. The specific characteristics of the symptomatology of patients with chronic fatigue require a rapid adaptation of the educational, healthcare and social systems to prevent the problems derived from current systems. Such patients require multidisciplinary management due to the multiple and different issues affecting them. This document was realized by one of the Interdisciplinary Work Groups from the Institute for Rare

Giménez JR.				Diseases, and its aim is to point out the main social and care needs for people affected with Chronic Fatigue Syndrome. For this, it includes not only the view of representatives for different scientific societies, but also the patient associations view, because they know the true history of their social and sanitary needs. In an interdisciplinary approach, this work also reviews the principal scientific, medical, socio-sanitary and psychological aspects of Chronic Fatigue Syndrome.

Bartley EJ, Rhudy JL, Williams AE.	Department of Psychology, The University of Tulsa, Oklahoma 74104, USA.	Experimental assessment of affective processing in fibromyalgia.	J Pain. 2009 Nov;10(11):1151-60. Epub 2009 Jul 24.	Fibromyalgia syndrome (FMS) is a chronic pain disorder associated with widespread musculoskeletal pain, tenderness, and fatigue. Additionally, correlational research suggests negative affect (eg, depression, anxiety) and deficits in positive affect may contribute to FMS symptomatology. However, well-controlled, experimental research is necessary to ascertain whether patients with FMS have problems in affective processing. The present study used a well-validated picture-viewing paradigm to evoke emotional responses in 17 patients with FMS and 17 sex- and age-matched healthy control participants. Each participant viewed pleasant (erotica), neutral, and unpleasant (attack related) pictures, and abrupt white noises were delivered during two-thirds of the pictures to evoke startle eyeblinks. Appetitive and defensive responding was assessed from subjective (valence/pleasure and arousal ratings) and physiological (corrugator EMG, heart rate, skin-conductance response, startle-reflex modulation) reactions to pictures. Results suggested FMS was associated with greater defensive activation (displeasure, subjective arousal, corrugator EMG) to the unpleasant, threat-related pictures, but not deficits in appetitive activation to erotic pictures. Although preliminary, these data suggest individuals with FMS have deficits in affective processing, but this dysregulation may be limited to defensive activation. Implications for treatment and future research are discussed.

				PERSPECTIVE: Fibromyalgia is a debilitating disease associated with affective distress. Results from the present study suggest that FMS is associated with enhanced defensive activation to nonpainful threat-related stimuli, but not deficits in appetitive reactions to erotic stimuli. These findings have implications for the treatment and study of FMS.
Baumann K, Krayenbühl P.	Klinik und Poliklinik für Innere Medizin, Universitätsspital Zürich.	[Fatigue][Article in German]	Praxis (Bern 1994). 2009 Apr 29;98(9):465-71.	
Beever R.	Richard.beever@northernhealth.ca	Far-infrared saunas for treatment of cardiovascular risk factors: summary of published evidence.	Can Fam Physician. 2009 Jul;55(7):691-6.	OBJECTIVE: To review the literature about the health benefits of far-infrared sauna (FIRS) use. QUALITY OF EVIDENCE: A search of Web of Science, EBSCO, Ovid MEDLINE, Ovid HealthSTAR, and EMBASE using the terms far-infrared and sauna, refined by limiting the search to studies of humans published in English, yielded 9 relevant papers (level I or level II evidence). MAIN MESSAGE: Far-infrared saunas are approved by the Canadian Standards Association and are sold to the public. The manufacturers claim numerous health benefits; however, the published evidence to substantiate these claims is limited. Four papers support the use of FIRS therapy for those with congestive heart failure and 5 papers support its use for those with coronary risk factors. CONCLUSION: There is limited moderate evidence supporting FIRS efficacy in normalizing blood pressure and treating congestive heart failure; fair evidence, from a single study, supporting FIRS therapy in chronic pain; weak evidence, from a single study, supporting FIRS therapy in chronic fatigue syndrome; weak evidence, from a single study, supporting FIRS therapy for obesity; and consistent fair evidence to refute claims regarding the role of FIRSs in cholesterol reduction.
Ben-Zvi A, Vernon SD, Broderick G.	Department of Chemical and Materials Engineering, University of Alberta, Edmonton, Alberta, Canada.	Model-based therapeutic correction of hypothalamic-pituitary-adrenal axis dysfunction.	PLoS Comput Biol. 2009 Jan;5(1):e1000273. Epub 2009 Jan 23.	The hypothalamic-pituitary-adrenal (HPA) axis is a major system maintaining body homeostasis by regulating the neuroendocrine and sympathetic nervous systems as well modulating immune function. Recent work has shown that the complex dynamics of this system accommodate several stable steady states, one of which corresponds to the hypocortisol state observed in patients with chronic fatigue syndrome (CFS). At present these dynamics are not formally considered in the development of treatment strategies. Here we use model-based predictive control (MPC) methodology to estimate robust treatment courses for displacing the HPA axis from an abnormal hypocortisol steady state back to a healthy cortisol level. This approach was applied to a recent model of HPA axis dynamics incorporating glucocorticoid receptor kinetics. A candidate treatment that displays robust properties in the face of significant biological variability and measurement uncertainty requires that cortisol be further suppressed for a short period until adrenocorticotropic hormone levels exceed 30% of baseline. Treatment may then be discontinued, and the HPA axis will naturally progress to a stable attractor defined by normal hormone levels. Suppression of biologically available cortisol may be achieved through the use of binding proteins such as CBG and certain metabolizing enzymes, thus offering possible avenues for deployment in a clinical setting. Treatment strategies can therefore be designed that maximally exploit system dynamics to provide a robust response to treatment and ensure a positive outcome over a wide range of conditions. Perhaps most importantly, a treatment course involving further reduction in cortisol, even transient, is quite counterintuitive and challenges the conventional strategy of supplementing cortisol levels, an approach based on steady-

				state reasoning.
Bito S.	Department of Clinical Education, National Hospital Organization Tokyo Medical Center.	[Functional somatic syndrome in general practice] [Article in Japanese]	Nippon Rinsho. 2009 Sep;67(9):1715-9.	General practitioners (GPs) see many patients with various symptoms such as dizziness, general fatigue, chronic headache, numbness, chronic upper abdominal pain and chronic diarrhea and these patients often have no abnormal findings in diagnostic tests. Even some specific conditions are categorized as "diseases" such as "fibromyalgia" and "non-ulcer dyspepsia", the patients actually suffer from various illnesses and have common questions. One is "Why am I suffering from such illness?" and the other is "How can I waive from the suffering?". GPs should usually face with these patients' questions. Even without categorization by "functional somatic syndrome", GPs provide continuity of care and sometimes provide prescriptions for such patients. The concept of postmodern is essential in management of functional somatic syndrome.
Bjørkum T, Wang CE, Waterloo K.	Sogndal BUP, Postboks 184, 6851 Sogndal. torunn.bjoerkum@helse-forde.no	[Patients' experience with treatment of chronic fatigue syndrome][Article in Norwegian]	Tidsskr Nor Laegeforen. 2009 Jun 11;129(12):1214-6.	BACKGROUND: Chronic fatigue syndrome is a highly debated condition. Little is known about causes and treatment. Patients" experience is important in this context. MATERIAL AND METHODS:828 persons with chronic fatigue syndrome (ICD-10 code: G93.3) were included in the study. They were recruited through two Norwegian patient organizations (ME-association and MENiN). The participants filled in a questionnaire on their experience with various approaches to alleviate their condition. RESULTS: Pacing was evaluated as useful by 96% of the participants, rest by 97%, and 96% of the participants considered complete shielding and quietness to be useful. 57% of the participants who had received help to identify and challenge negative thought patterns regarded this useful. 79% of the participants with experience from graded training regarded this to worsen their health status. Overall, the results were similar, irrelevant of the severity of the condition. INTERPRETATION:Most participants in this study evaluated pacing, rest and complete shielding and quietness to be useful. The experience of the participants indicate that cognitive behaviour therapy can be useful for some patients, but that graded training may cause deterioration of the condition in many patients. The results must, however, be interpreted with care, as the participants are not a representative sample, and we do not know the specific content of the approaches.
Blaney GP, Albert PJ, Proal AD.	Stillpoint Centre, Vancouver, British Columbia, Canada. gregblaney@shaw.ca	Vitamin D metabolites as clinical markers in autoimmune and chronic disease.	Ann N Y Acad Sci. 2009 Sep;1173:384-90.	Recent research has implicated vitamin D deficiency (serum levels of 25-hydroxyvitamin D <50 nmol/L) with a number of chronic conditions, including autoimmune conditions such as multiple sclerosis, lupus, and psoriasis, and chronic conditions such as osteoporosis, osteoarthritis, metabolic syndrome, fibromyalgia and chronic fatigue syndrome. It has been assumed that low levels of 25-hydroxyvitamin D (25-D) accurately indicate vitamin D storage and vitamin D receptor (VDR)-mediated control of calcium metabolism and innate immunity. To evaluate this assumption, 25-D and 1,25-dihydroxyvitamin D3 (1,25-D) levels were measured in 100 Canadian patients with these conditions. Additionally, other inflammatory markers (CK, CRP) were measured. Results showed a strong positive association between these autoimmune conditions and levels of 1,25-D >110 pmol/L. However, there was little association with vitamin D deficiency or the other inflammatory markers, meaning that the results challenge the assumption that serum levels of 25-D are a sensitive measure of the autoimmune disease state. Rather, these findings support the use of 1,25-D as a clinical marker in autoimmune conditions. High levels of 1,25-D may result when dysregulation of the VDR by bacterial ligands prevents the receptor from expressing enzymes necessary to keep 1,25-D in a normal range.
Bol Y, Duits AA,	Department of	The psychology of	J Psychosom Res.	Fatigue is a frequent and disabling symptom in patients with multiple sclerosis (MS), but it is difficult

Hupperts RM, Vlaeyen JW, Verhey FR.	Psychology, Maastricht University Medical Center, Maastricht, The Netherlands. y.bol@np.unimaas.nl	fatigue in patients with multiple sclerosis: a review.	2009 Jan;66(1):3-11. Epub 2008 Sep 24.	to define and measure. Today, MS-related fatigue is not fully understood, and evidence related to explanatory pathophysiological factors are conflicting. Here, we evaluate the contribution of psychological factors to MS-related fatigue. Insight into the possible underlying psychological mechanisms might help us to develop adequate psychological interventions and to improve the overall management of fatigue. Conceptual issues and the relationships between MS-related fatigue and mood, anxiety, cognition, personality, and cognitive-behavioral factors are discussed, and the implications for clinical practice and research are presented.
Boneva RS, Lin JM, Maloney EM, Jones JF, Reeves WC.	Centers for Disease Control and Prevention, Atlanta, Georgia 30333, USA. rboneva@cdc.gov	Use of medications by people with chronic fatigue syndrome and healthy persons: a population-based study of fatiguing illness in Georgia.	Health Qual Life Outcomes. 2009 Jul 20;7:67.	BACKGROUND: Chronic fatigue syndrome (CFS) is a debilitating condition of unknown etiology and no definitive pharmacotherapy. Patients are usually prescribed symptomatic treatment or self-medicate. We evaluated prescription and non-prescription drug use among persons with CFS in Georgia and compared it to that in non-fatigued Well controls and also to chronically Unwell individuals not fully meeting criteria for CFS. METHODS: A population-based, case-control study. To identify persons with possible CFS-like illness and controls, we conducted a random-digit dialing telephone screening of 19,807 Georgia residents, followed by a detailed telephone interview of 5,630 to identify subjects with CFS-like illness, other chronically Unwell, and Well subjects. All those with CFS-like illness (n = 469), a random sample of chronically Unwell subjects (n = 505), and Well individuals (n = 641) who were age-, sex-, race-, and geographically matched to those with CFS-like illness were invited for a clinical evaluation and 783 participated (48% overall response rate). Clinical evaluation identified 113 persons with CFS, 264 Unwell subjects with insufficient symptoms for CFS (named ISF), and 124 Well controls; the remaining 280 subjects had exclusionary medical or psychiatric conditions, and 2 subjects could not be classified. Subjects were asked to bring all medications taken in the past 2 weeks to the clinic where a research nurse viewed and recorded the name and the dose of each medication. RESULTS: More than 90% of persons with CFS used at least one drug or supplement within the preceding two weeks. Among users, people with CFS used an average of 5.8 drugs or supplements, compared to 4.1 by ISF and 3.7 by Well controls. Persons with CFS were significantly more likely to use antidepressants, sedatives, muscle relaxants, and anti-acids than either Well controls or the ISF group. In addition, persons with CFS were significantly more likely to use pain-relievers, anti-histamines and cold/sinus medications than were Well controls. CONCLUSION: Medical care providers of patients with chronic fatigue syndrome should be aware of polypharmacy as a problem in such patients, and the related potential iatrogenic effects and drug interactions.
Boone KB.	Center for Forensic Studies, Alliant International University - LA, 1000 South Fremont Avenue, Alhambra, CA91803, USA. kboone@labiomed.org	Fixed belief in cognitive dysfunction despite normal neuropsychological scores: neurocognitive hypochondriasis?	Clin Neuropsychol. 2009 Aug;23(6):1016-36.	A subset of patients who present for neuropsychological testing report dysfunction in daily life activities secondary to cognitive deficits, but are found on formal testing to have no objective abnormalities, raising the possibility of "neurocognitive hypochondriasis." Such a case is presented, and the factors that appear to give rise to this presentation are explored. Cases of hypochondriacal overconcern regarding cognitive function are likely not rare, particularly given research showing there is little correlation between objective report of cognitive dysfunction and actual test scores in such conditions as mild traumatic brain injury, chronic fatigue syndrome, fibromyalgia, toxic mold exposure, and post-polio syndrome.

Bramsen I.		Can CBT substantially change grey matter volume in chronic fatigue syndrome? Comment in: Brain. 2009 Jul;132(Pt 7):e119; author reply e120.Comment on: Brain. 2008 Aug;131(Pt 8):2172-80.	Brain. 2009 Jun;132(Pt 6):e110; author reply e111. Epub 2008 Aug 29.	
Brimmer DJ, McCleary KK, Lupton TA, Faryna KM, Reeves WC.	Chronic Viral Diseases Branch, Coordinating Center for Infectious Diseases, Centers for Disease Control and Prevention, Atlanta, GA 30333, USA. dyv4@cdc.gov	Continuing medical education challenges in chronic fatigue syndrome.	BMC Med Educ. 2009 Dec 2;9:70.	BACKGROUND: Chronic fatigue syndrome (CFS) affects at least 4 million people in the United States, yet only 16% of people with CFS have received a diagnosis or medical care for their illness. Educating health care professionals about the diagnosis and management of CFS may help to reduce population morbidity associated with CFS. METHODS: This report presents findings over a 5-year period from May 2000 to June 2006 during which we developed and implemented a health care professional educational program. The objective of the program was to distribute CFS continuing education materials to providers at professional conferences, offer online continuing education credits in different formats (e.g., print, video, and online), and evaluate the number of accreditation certificates awarded. RESULTS: We found that smaller conference size (OR = 80.17; 95% CI 8.80, 730.25), CFS illness related target audiences (OR = 36.0; 95% CI 2.94, 436.34), and conferences in which CFS research was highlighted (OR = 4.15; 95% CI 1.16, 14.83) significantly contributed to higher dissemination levels, as measured by visit rates to the education booth. While print and online courses were equally requested for continuing education credit opportunities, the online course resulted in 84% of the overall award certificates, compared to 14% for the print course. This remained consistent across all provider occupations: physicians, nurses, physician assistants, and allied health professionals. CONCLUSION: These findings suggest that educational programs promoting materials at conferences may increase dissemination efforts by targeting audiences, examining conference characteristics, and promoting online continuing education forums.

Burkhard B, Kittel R.	Medizinischen Dienst der Krankenversicherung in Bayern, München.	[Visualisation methods for etheric formative forces] [Article in German]	Versicherungsmedizin. 2009 Sep 1;61(3):126-8.	Rudolf Steiner, the founder of anthroposophy, suggested the development of visualisation methods for "etheric formative forces". The essential methods, their "spiritual scientific" basis and indications are described and their claims critically tested. Summary: The methods are not validated, the key criteria for diagnostic tests (reproducibility, sensitivity, specifity) are not given.
Burton C, Knoop H, Popovic N, Sharpe M, Bleijenberg G.	Division of Community Health Sciences, General Practice Section, University of Edinburgh, West Richmond Street, Edinburgh, UK. chris.burton@ed.ac.uk.	Reduced complexity of activity patterns in patients with Chronic Fatigue Syndrome: a case control study.	Biopsychosoc Med. 2009 Jun 2;3:7.	ABSTRACT: BACKGROUND: Chronic fatigue syndrome (CFS) is an illness characterised by pervasive physical and mental fatigue without specific identified pathological changes. Many patients with CFS show reduced physical activity which, though quantifiable, has yielded little information to date. Nonlinear dynamic analysis of physiological data can be used to measure complexity in terms of dissimilarity within timescales and similarity across timescales. A reduction in these objective measures has been associated with disease and ageing. We aimed to test the hypothesis that activity patterns of patients with CFS would show reduced complexity compared to healthy controls. METHODS: We analysed continuous activity data over 12 days from 42 patients with CFS and 21 matched healthy controls. We estimated complexity in two ways, measuring dissimilarity within timescales by calculating entropy after a symbolic dynamic transformation of the data and similarity across timescales by calculating the fractal dimension using allometric aggregation. RESULTS: CFS cases showed reduced complexity compared to controls, as evidenced by reduced dissimilarity within timescales (mean (SD) Renyi(3) entropy 4.05 (0.21) vs. 4.30 (0.09), $t = -6.6$, $p < 0.001$) and reduced similarity across timescales (fractal dimension 1.19 (0.04) vs. 1.14 (0.04), $t = 4.2$, $p < 0.001$). This reduction in complexity persisted after adjustment for total activity. CONCLUSION: Patients with CFS show evidence of reduced complexity of activity patterns. Measures of complexity applied to activity have potential value as objective indicators for CFS.

Department of Genetics, University of North Carolina at Chapel Hill, Chapel Hill, North Carolina, United States of America.	Gene expression in peripheral blood leukocytes in monozygotic twins discordant for chronic fatigue: no evidence of a biomarker.	PLoS One. 2009 Jun 5;4(6):e5805.	BACKGROUND: Chronic fatiguing illness remains a poorly understood syndrome of unknown pathogenesis. We attempted to identify biomarkers for chronic fatiguing illness using microarrays to query the transcriptome in peripheral blood leukocytes. METHODS: Cases were 44 individuals who were clinically evaluated and found to meet standard international criteria for chronic fatigue syndrome or idiopathic chronic fatigue, and controls were their monozygotic co-twins who were clinically evaluated and never had even one month of impairing fatigue. Biological sampling conditions were standardized and RNA stabilizing media were used. These methodological features provide rigorous control for bias resulting from case-control mismatched ancestry and experimental error. Individual gene expression profiles were assessed using Affymetrix Human Genome U133 Plus 2.0 arrays. FINDINGS: There were no significant differences in gene expression for any transcript. CONCLUSIONS: Contrary to our expectations, we were unable to identify a biomarker for chronic fatiguing illness in the transcriptome of peripheral blood leukocytes suggesting that positive findings in prior studies may have resulted from experimental bias.
Carlo-Stella N, Bozzini S, De Silvestri A, Sbarsi I,	Genetics and Microbiology Department,	Molecular study of receptor for advanced glycation	Int J Immunopathol Pharmacol. 2009	The receptor for advanced glycation end product (RAGE) is thought to play an important role in inflammation. Chronic fatigue syndrome (CFS) is a long-lasting fatigue that compromises at least 50% of a subject's daily activities without other known cause. Immune dysfunction has been implicated

Pizzochero C, Lorusso L, Martinetti M, Cuccia M.	University of Pavia, Pavia, Italy.	endproduct gene promoter and identification of specific HLA haplotypes possibly involved in chronic fatigue syndrome.	Jul-Sep;22(3):745-54.	and an association with a peculiar genetic cytokine profile, predisposing to an immunomodulatory response of inflammatory nature, was found. The aim of this study is to analyse RAGE polymorphisms and HLA-DRB1 alleles in seventy-five Italian CFS patients and 141 controls matched for age, sex and ethnicity. These two groups underwent genomic study for RAGE 374T/A and 429C/T promoter polymorphisms; moreover, 46 patients and 186 controls were typed for HLA-DRB1 at low resolution molecular level. Of these, 31 patients and 99 controls also underwent high resolution analysis to define the HLA-DRB1*11 and DRB1*13 alleles. The haplotypes RAGE-374T, DRB1*04; RAGE-374T, DRB1*09; RAGE-374T, DRB1*11; RAGE-374A, DRB1*13; RAGE-429T, DRB1*04 and RAGE-429C, DRB1*11 were significantly more frequent in CFS patients, whereas RAGE-429C, DRB1*07 would seem protective. A significantly lower frequency of DRB1*1104 (5.4% vs 12.9% p=0.04, OR=0.39) and a significantly higher frequency of HLA-DRB1*1301 (13.0% vs 5.1% p=0.006, OR= 2.79) were found in CFS patients. A synergic effect was observed with RAGE polymorphism. The OR values strengthened in the following cis combinations: RAGE-374A, HLA-DRB1*1104 (OR=0.27) and RAGE-374A, HLADRB1*1301 (OR=6.23). HLA haplotypes rather than single alleles of RAGE or of DRB1 genes seem to be involved in CFS, probably including a subregion of major interest.
Cathébras P, Lauwers A.	Service de médecine interne, hôpital Nord, CHU de Saint-Etienne, 42055 Saint-Etienne Cedex 2, France. pascal.cathebras@chu-st-etienne.fr	[Should we make the diagnosis of fibromyalgia?][Article in French]	Rev Prat. 2009 Jan 20;59(1):25-31.	Fibromyalgia is a functional somatic syndrome characterized by widespread musculoskeletal pain, fatigue, poor sleep, and exercise intolerance, frequently (but inconstantly) associated with psychological distress. Fibromyalgia is a common condition, affecting predominantly middle-aged women, with a chronic course. Fibromaylgia should be differentiated from, and may be associated with, a number of metabolic, rheumatic, neurological or psychiatric conditions. The most plausible pathophysiologic mechanism involves an alteration of pain modulation at the peripheral and central levels of the nervous system ("sensitization"). Psychosocial factors play an important role in precipitating and maintaining symptoms, health care utilization, and disablement. Treatments of fibromyalgia rely mainly on the acknowledgement of pain and distress, patient education, analgesics, balneotherapy and physiotherapy, physical reconditioning (aerobic exercise), and certain antidepressants.
Chalder T, Deary V, Husain K, Walwyn R.	Department of Psychological Medicine and Psychiatry, King's College London, Weston Education Centre, London, UK.	Family-focused cognitive behaviour therapy versus psycho-education for chronic fatigue syndrome in 11- to 18-year-olds: a randomized controlled treatment trial.	Psychol Med. 2009 Nov 6:1-11. [Epub ahead of print]	BACKGROUND: Only one previous randomized controlled trial (RCT) has examined the efficacy of cognitive behaviour therapy (CBT) for chronic fatigue syndrome (CFS) in children. The aim of this study was to compare family-focused CBT with psycho-education for CFS in adolescents.MethodSixty-three 11- to 18-year-olds (43 girls, 20 boys) with CFS were randomly assigned to either family-focused CBT or psycho-education delivered over 6 months. School attendance was the main outcome, which was assessed at the end of treatment and at 3, 6 and 12 months follow-up. RESULTS: At the main outcome point (the 6-month follow-up) both groups had improved similarly. However, although those who received family-focused CBT were attending school for longer than those who received psycho-education, at discharge from treatment and at 3 months follow-up, they improved less quickly across the follow-up period. CONCLUSIONS: Adolescents with CFS get back to school more quickly after family-focused CBT. This is important as they are at a crucial stage of their development. However, the finding that psycho-education was as effective as family-focused CBT at 6 and 12 months follow-up has important implications for health service delivery.
Chastin SF, Granat	Glasgow	Methods for	Gait Posture. 2009	The purpose of this study was to develop and test a generic technique to robustly quantify the pattern

MH.	Caledonian University, School of Health and Social Care, Cowcaddens Road, Glasgow G4 0BA, Scotland, UK.	objective measure, quantification and analysis of sedentary behaviour and inactivity.	Oct 23. [Epub ahead of print]	of sedentary behaviour from objective records. The technique was applied to four groups of subjects: a healthy group with an active occupation (N=54), a healthy group with a sedentary occupation (N=53), a group of subjects with chronic low back pain (N=5) and a group of subjects with chronic fatigue syndrome (N=14). This study presents the first evidence that bouts of sedentary activity are power law distributed. Results showed that there was no significant difference in total sedentary time between the groups, however, the patterns of accumulation of sedentary time were significantly different for the groups. Sedentary groups accumulated their total sedentary time from a small number of longer sedentary bouts. Active groups tended to break their sedentary time into a greater number of shorter bouts. This suggests that the power law exponent alpha and the GINI index G, used to describe the pattern of accumulation of sedentary time, could be used to evaluate and quantify sedentary behaviour.
Chen LH, Wilson ME, Davis X, Loutan L, Schwartz E, Keystone J, Hale D, Lim PL, McCarthy A, Gkrania-Klotsas E, Schlagenhauf P; GeoSentinel Surveillance Network. Collaborators: von Sonnenburg F, Gelman SS, Chappuis F, Kain KC, Field V, Burchard GD, Libman MD, Maclean JD, Leder K, Torresi J, Brown G, Parola P, Simon F, Delmont J, Kass R, Carosi G, Castelli F, Pandey P, Shaw M, Kozarsky PE, Franco-Paredes C, Piyaphanee W, Silachamroon U,	Harvard University, Boston, Massachusetts, USA. lchen@hms.harvard.edu	Illness in long-term travelers visiting GeoSentinel clinics.	Emerg Infect Dis. 2009 Nov;15(11):1773-82.	Length of travel appears to be associated with health risks. GeoSentinel Surveillance Network data for 4,039 long-term travelers (trip duration >6 months) seen after travel during June 1, 1996, through December 31, 2008, were compared with data for 24,807 short-term travelers (trip duration <1 month). Long-term travelers traveled more often than short-term travelers for volunteer activities (39.7% vs. 7.0%) and business (25.2% vs. 13.8%). More long-term travelers were men (57.2% vs. 50.1%) and expatriates (54.0% vs. 8.9%); most had pretravel medical advice (70.3% vs. 48.9%). Per 1,000 travelers, long-term travelers more often experienced chronic diarrhea, giardiasis, Plasmodium falciparum and P. vivax malaria, irritable bowel syndrome (postinfectious), fatigue >1 month, eosinophilia, cutaneous leishmaniasis, schistosomiasis, and Entamoeba histolytica diarrhea. Areas of concern for long-term travelers were vector-borne diseases, contact-transmitted diseases, and psychological problems. Our results can help prioritize screening for and diagnosis of illness in long-term travelers and provide evidence-based pretravel advice.

Tachikawa N, Sagara H, Connor BA, Kanagawa S, Kato Y, Jensenius M, Haulman NJ, Roesel D, Jong EC, Coyle CM, Wittner M, López-Vélez R, Pérez-Molina JA, Nutman TB, Klion AD, Hagmann S, Miller A, Weber R, Steffen R, Stauffer WM, Walker PF, Freedman DO, Ansdell V, Wilder-Smith A, Sack B, McKenzie R, Caumes E, Pérignon A, Licitra C, Crespo A, Barnett ED, Gurtman A, Perret C, Valdivieso F, Muller R, Cahill JD, McKinley G, McLellan S, MacDonald S, Lynch MW, Borwein S, Anglim A.				
Chew-Graham C, Dixon R, Shaw JW, Smyth N, Lovell K, Peters S.	School of Community-Based Medicine, University of Manchester, Manchester, M13 9PL, UK. cchew@manchester.ac.uk.	Practice Nurses' views of their role in the management of Chronic Fatigue Syndrome/Myalagic Encephalitis: a qualitative study.	BMC Nurs. 2009 Jan 22;8:2.	ABSTRACT: BACKGROUND: NICE guidelines suggest that patients with Chronic Fatigue Syndrome/Myalgic Encephalitis (CFS/ME) should be managed in Primary Care. Practice Nurses are increasingly being involved in the management of long-term conditions, so are likely to also have a growing role in managing CFS/ME. However their attitudes to, and experiences of patients with CFS/ME and its management must be explored to understand what barriers may exist in developing their role for this group of patients. The aim of this study was to explore Practice Nurses' understanding and beliefs about CFS/ME and its management. METHODS: Semi-structured interviews with 29 Practice Nurses. Interviews were transcribed verbatim and an iterative approach used to develop themes from the dataset. RESULTS: Practice nurses had limited understanding about CFS/ME

				which had been largely gained through contact with patients, friends, personal experiences and the media rather than formal training. They had difficulty seeing CFS/ME as a long term condition. They did identify a potential role they could have in management of CFS/ME but devalued their own skills in psychological intervention, and suggested counselling would be an appropriate therapeutic option. They recognised a need for further training and on going supervision from both medical and psychological colleagues. Some viewed the condition as contentious and held pejorative views about CFS/ME. Such scepticism and negative attitudes will be a significant barrier to the management of patients with CFS/ME in primary care. CONCLUSION: The current role of Practice Nurses in the ongoing management of patients with CFS/ME is limited. Practice Nurses have little understanding of the evidence-base for treatment of CFS/ME, particularly psychological therapies, describing management options in terms of advice giving, self-help or counselling. Practice Nurses largely welcomed the potential development of their role in this area, but identified barriers and training needs which must be addressed to enable them to feel confident managing of patients with this condition. Training must begin by addressing negative attitudes to patients with CFS/ME.
Chia JK, Chia AY, Voeller M, Lee TM, Chang R.	EV Med Research, United States;	Acute enterovirus infection followed by myalgic encephalomyelitis/ chronic fatigue syndrome (ME/CFS) and viral persistence.	J Clin Pathol. 2009 Oct 14. [Epub ahead of print]	A number of infections have been associated with myalgia encephalomyelitis/chronic fatigue syndrome (ME/CFS). Often occurring in epidemics, enteroviruses are significant causes of respiratory, gastrointestinal infections, non-specific flu-like illnesses, and many disseminated infections. It has been difficult to demonstrate causality for chronic diseases without having well-documented cases of acute enterovirus infections. In this report, we described 3 patients presenting with acute enterovirus infections, which were followed by ME/CFS, and the persistent viral infections were demonstrated by finding enterovirus VP1 protein and RNA in the stomach.
Cho HJ, Menezes PR, Hotopf M, Bhugra D, Wessely S.	Department of Preventive Medicine, University of São Paulo Medical School, University Hospital, University of São Paulo, Brazil. h.cho@iop.kcl.ac.uk	Comparative epidemiology of chronic fatigue syndrome in Brazilian and British primary care: prevalence and recognition.	Br J Psychiatry. 2009 Feb;194(2):117-22.	BACKGROUND: Although fatigue is a ubiquitous symptom across countries, clinical descriptions of chronic fatigue syndrome have arisen from a limited number of high-income countries. This might reflect differences in true prevalence or clinical recognition influenced by sociocultural factors. AIMS: To compare the prevalence, physician recognition and diagnosis of chronic fatigue syndrome in London and São Paulo. METHOD: Primary care patients in London (n=2459) and São Paulo (n=3914) were surveyed for the prevalence of chronic fatigue syndrome. Medical records were reviewed for the physician recognition and diagnosis. RESULTS: The prevalence of chronic fatigue syndrome according to Centers for Disease Control 1994 criteria was comparable in Britain and Brazil: 2.1% v. 1.6% (P=0.20). Medical records review identified 11 diagnosed cases of chronic fatigue syndrome in Britain, but none in Brazil (P<0.001). CONCLUSIONS: The primary care prevalence of chronic fatigue syndrome was similar in two culturally and economically distinct nations. However, doctors are unlikely to recognise and label chronic fatigue syndrome as a discrete disorder in Brazil. The recognition of this illness rather than the illness itself may be culturally induced.
Cho JH, Cho CK, Shin JW, Son JY, Kang W, Son CG.	East-West Cancer Center, Dunsan Oriental Hospital of Oriental Medical College of Daejeon	Myelophil, an extract mix of Astragali Radix and Salviae Radix, ameliorates	Complement Ther Med. 2009 Jun;17(3):141-6. Epub 2009 Jan 23.	OBJECTIVES: To investigate the anti-fatigue effects of Myelophil, an extract of a mix of Astragali Radix and Salviae Radix, which has been used to treat patients with chronic fatigue. SUBJECTS AND DESIGN: A randomised, double-blind, controlled clinical trial was performed with 36 adults who complained of chronic fatigue. The subjects were divided among a control group and low- and high-dose groups (3 or 6g of oral Myelophil per day, respectively) and were monitored for 4 weeks. Fatigue severity was

	University, Seo-gu, Daejeon, South Korea.	chronic fatigue: a randomised, double-blind, controlled pilot study.		subjectively characterised, and the expression of 42 cytokines was evaluated using an antibody array. RESULTS: Myelophil administration (3g per day) significantly decreased the fatigue severity score compared with the control ($p<0.05$). No changes were noted in cytokine expression. CONCLUSIONS: Myelophil appears to have a pharmacological effect against fatigue, suggesting the clinical relevance of the traditional medicinal plants, Astragalus membranaceus and Salvia miltiorrhiza.
Chong YY, Ng BY.	Department of Rheumatology and Immunology, Singapore General Hospital, Singapore. chong.yong.yeow@sgh.com.sg	Clinical aspects and management of fibromyalgia syndrome.	Ann Acad Med Singapore. 2009 Nov;38(11):967-73.	Fibromyalgia syndrome (FMS) is a chronic and debilitating musculoskeletal pain disorder of unknown aetiology with usual accompanying features of fatigue, sleep disturbances and stiffness. Its place in medical textbooks was controversial with rheumatologists holding the helm of its management for many years. Over the last decade, abnormalities have been identified at multiple levels in the peripheral, central, and sympathetic nervous systems as well as the hypothalomo-pituitary-adrenal axis stress response system. With the elucidation of these pathways of pain, FMS is known more as a central sensitivity syndrome. This led to tremendous increment in interest in both pharmacological and non-pharmacological treatment of FMS. The United States Food and Drug Administration (FDA) has also successively approved 3 drugs for the management of fibromyalgia--pregabalin, duloxetine and milnacipran. Non-pharmacological modalities showed aerobic exercise, patient education and cognitive behavioural therapy to be most effective. Overall, management of FMS requires a multi-disciplinary approach.
Chrousos GP, Kino T.	First Department of Pediatrics, Athens University Medical School, Athens, Greece. chrousge@med.uoa.gr	Glucocorticoid signaling in the cell. Expanding clinical implications to complex human behavioral and somatic disorders.	Ann N Y Acad Sci. 2009 Oct;1179:153-66.	Glucocorticoids contribute to the maintenance of basal and stress-related homeostasis in all higher organisms, and influence a large proportion of the expressed human genome, and their effects spare almost no organs or tissues. Glucocorticoids regulate many functions of the central nervous system, such as arousal, cognition, mood, sleep, the activity and direction of intermediary metabolism, the maintenance of a proper cardiovascular tone, the activity and quality of the immune and inflammatory reaction, including the manifestations of the sickness syndrome, and growth and reproduction. The numerous actions of glucocorticoids are mediated by a set of at least 16 glucocorticoid receptor (GR) isoforms forming homo- or hetero-dimers. The GRs consist of multifunctional domain proteins operating as ligand-dependent transcription factors that interact with many other cell signaling systems, including large and small G proteins. The presence of multiple GR monomers and homo- or hetero-dimers expressed in a cell-specific fashion at different quantities with quantitatively and qualitatively different transcriptional activities suggest that the glucocorticoid signaling system is highly stochastic. Glucocorticoids are heavily involved in human pathophysiology and influence life expectancy. Common behavioral and/or somatic complex disorders, such as anxiety, depression, insomnia, chronic pain and fatigue syndromes, obesity, the metabolic syndrome, essential hypertension, diabetes type 2, atherosclerosis with its cardiovascular sequelae, and osteoporosis, as well as autoimmune inflammatory and allergic disorders, all appear to have a glucocorticoid-regulated component.
Clauw DJ.	Chronic Pain & Fatigue Research Center, Department of Anesthesiology,	Fibromyalgia: an overview.	Am J Med. 2009 Dec;122(12 Suppl):S3-S13.	Fibromyalgia is the diagnosis given to individuals with chronic widespread musculoskeletal pain for which no alternative cause, such as tissue inflammation or damage, can be identified. Fibromyalgia is now believed to be, at least in part, a disorder of central pain processing that produces heightened responses to painful stimuli (hyperalgesia) and painful responses to nonpainful stimuli (allodynia). Aberrations in central pain processing may also be partly responsible for symptoms experienced in

	University of Michigan, Ann Arbor, Michigan 48106, USA. dclauw@med.umich.edu			several chronic pain disorders that coaggregate with fibromyalgia, which is itself a product of genetic and environmental factors. Thus, aberrational central pain processing is implicated in irritable bowel syndrome, temporomandibular disorder, chronic low back pain, and certain other chronic pain disorders. Fibromyalgia and related disorders appear to reflect deficiencies in serotonergic and noradrenergic, but not opioidergic, transmission in the central nervous system. The heightened state of pain transmission may also be owing to increases in pronociceptive neurotransmitters such as glutamate and substance P. In some cases, psychological and behavioral factors are also in play. Although the overlapping symptomatology between fibromyalgia and related disorders may present diagnostic challenges, proper examination and observation can help clinicians make an accurate diagnosis. In recent years, the vastly improved understanding of the mechanism underlying fibromyalgia and the related spectrum of diseases has fostered rapid advances in the therapy of these chronic pain disorders by both pharmacologic and nonpharmacologic interventions. Courjaret J, Schotte CK, Wijnants H, Moorkens G, Cosyns P.	Department of Psychiatry, University Hospital Antwerp, Edegem, Belgium. kim.courjaret@uza.be	Chronic fatigue syndrome and DSM-IV personality disorders.	J Psychosom Res. 2009 Jan;66(1):13-20. Epub 2008 Nov 22.	OBJECTIVE: Personality is an important factor in the research of the chronic fatigue syndrome (CFS). Although some studies report a high rate of personality disorders--around the 40% level--in samples of patients with CFS, the generalizability of these findings can be questioned. The present study evaluates the prevalence of Diagnostic and Statistical Manual for Mental Disorders, Fourth Edition, Text Revision (DSM-IV-TR) personality disorders in a sample of female CFS patients and in two control groups. METHOD: The ADP-IV questionnaire (Assessment of DSM Personality Disorders IV) was used to assess the DSM-IV-TR personality disorders at a dimensional and categorical level in a sample of 50 female CFS patients and in two matched control samples of Flemish civilians (n=50) and psychiatric patients (n=50). RESULTS: The results indicate a striking lack of statistical significant differences between the CFS sample and the Flemish control group at the level of dimensional Trait scores, number of criteria, and prevalence rates of personality disorder diagnoses. Unsurprisingly, higher scores at these levels were obtained within the psychiatric sample. The prevalence of an Axis II disorder was 12% in the Flemish and CFS samples, whereas the psychiatric sample obtained a prevalence of 54%. CONCLUSION: The prominent absence of any significant difference in personality disorder characteristics between the female Flemish general population and the CFS samples seems to suggest only a minor etiological role for personality pathology, as defined by the DSM-IV Axis II, within CFS.
Crawley E, Hunt L, Stallard P.	Centre of Child and Adolescent Health, Hampton House,	Anxiety in children with CFS/ME.	Eur Child Adolesc Psychiatry. 2009 Nov;18(11):683-9.	Anxiety symptoms are commonly described in children with chronic fatigue syndrome or myalgic encephalopathy (CFS/ME) but to date there has been little information on the type of anxiety children experience or the relationship between anxiety and school attendance, disability or fatigue. The aim

	Cotham Hill, Bristol BS6 6JS, UK. esther.crawley@bristol.ac.uk		Epub 2009 May 19.	of this study was to first describe the prevalence and type of anxiety symptoms in children with CFS/ME compared with a normal European population, and secondly to investigate the association of anxiety symptoms with age, gender, school attendance, fatigue, and physical function in paediatric CFS/ME. Data were prospectively collected on children and young people with CFS/ME referred to a large specialist CFS/ME service. One hundred and sixty-four children with CFS/ME had complete data for the Spence Children's Anxiety Scale. Teenage girls had the highest rates of total anxiety symptoms with 38% (95% CI 27-49) over the cut off (top 10% of normal European population) and significantly higher rates of symptoms in each subscale. Younger girls were more likely to score over the cut off in separation anxiety (37%, 19-40) and social phobia (39%, 25-47). There was no evidence of association between total anxiety symptoms and: time at school, time to assessment, pain or age. Associations with fatigue and physical function were attenuated when adjusted for other variables. Although anxiety symptoms are high in CFS/ME, particularly in teenage girls, it does not appear to be associated with school attendance or other measures of disability. Separation anxiety and social phobia were the most clearly elevated in paediatric CFS/ME.
Crawley E, Sterne JA.	Centre for Child and Adolescent Health, University of Bristol, Bristol, UK. esther.crawley@bristol.ac.uk	Association between school absence and physical function in paediatric chronic fatigue syndrome/myalgic encephalopathy.	Arch Dis Child. 2009 Oct;94(10):752-6. Epub 2008 Nov 11.	OBJECTIVE: To investigate factors associated with school attendance and physical function in paediatric chronic fatigue syndrome/myalgic encephalopathy (CFS/ME). DESIGN: Cross-sectional study. SETTING: Regional specialist CFS/ME service. PATIENTS: Children and young people aged under 18 years. OUTCOME MEASURES: Self-reported school attendance and physical function measured using the physical function subscale of the Short Form 36. METHODS: Linear and logistic regression analysis of data from self-completed assessment forms on children attending a regional specialist service between 2004 and 2007. Analyses were done in two groups of children: with a completed Spence Children's Anxiety Scale (SCAS) and with a completed Hospital Anxiety and Depression Scale (HADS). RESULTS: Of 211 children with CFS/ME, 62% attended 40% of school or less. In children with completed SCAS, those with better physical function were more likely to attend school (adjusted odds ratio (OR) 1.70; 95% CI 1.36 to 2.13). This was also true for those with completed HADS (adjusted OR 2.05; 95% CI 1.4 to 3.01). Increasing fatigue and pain and low mood were associated with worse physical function. There was no evidence that anxiety, gender, age at assessment, family history of CFS/ME or time from onset of symptoms to assessment in clinic were associated with school attendance or physical function. IMPLICATIONS: Paediatricians should recognise that reduced school attendance is associated with reduced physical function rather than anxiety. Improving school attendance in children with CFS/ME should focus on evidence-based interventions to improve physical function, particularly concentrating on interventions that are likely to reduce pain and fatigue.
Creavin ST, Dunn KM, Mallen CD, Nijrolder I, van der Windt DA.	Arthritis Research Campaign National Primary Care Centre, Keele University, Staffordshire ST5 5BG, United Kingdom.	Co-occurrence and associations of pain and fatigue in a community sample of Dutch adults.	Eur J Pain. 2009 Jun 17. [Epub ahead of print]	Widespread pain and chronic fatigue are common in the general population. Previous research has demonstrated co-occurrence of syndromes that are associated with pain and fatigue (fibromyalgia and chronic fatigue syndrome), but there is limited existing data on the co-occurrence of these symptoms in general. This study investigates the co-occurrence of pain and fatigue, and characterises people with these symptoms individually, and in combination. A postal questionnaire was sent to a random sample of 4741 community dwelling Dutch adults registered with five general practices. There were 2447 participants (adjusted response=53.5%). Persistent fatigue was reported by 60% of the 451 subjects with chronic widespread pain. Chronic widespread pain was reported by 33% of the 809

				responders with persistent fatigue. Anxiety and depression were more common in subjects who reported both symptoms than those who reported either one or neither. Participants who had chronic disease, high body mass index, low activity levels or did not perceive ability to influence health had higher adjusted odds of reporting both symptoms (but not one alone) than subjects not having these characteristics. Pain and fatigue occur more often than would be expected by chance and there are a number of reasons for this. Clinicians should be aware that co-occurrence of the symptoms is common, especially in people who have high BMI or chronic disease, and that people with both symptoms are often anxious or depressed. Further work should address longitudinal associations of pain and fatigue.
Cuadros J, Vargas M.	jcuadros@fivmadrid.es	A new mind-body approach for a total healing of fibromyalgia: a case report.	Am J Clin Hypn. 2009 Jul;52(1):3-12.	Fibromyalgia is a severe, chronic and widespread pain syndrome with no definite treatment protocol. Several medications are currently in use to treat this condition. Various pharmacological treatments, as well as alternative mind-body therapies, have been directed towards reducing fatigue and pain, but these treatments have only resulted in a partial relief of symptoms with no long-term or permanent effects. This study shows the results obtained from four female patients suffering from fibromyalgia after undergoing a mind-body treatment in which psychosocial genomic postulates as well as ideodynamic hand movements were the main tools employed in their healing. It is suggested that a mind-body oriented treatment could generate stable and permanent changes that enable patients to experience a total recovery from fibromyalgia.
Daley M, Morin CM, LeBlanc M, Grégoire JP, Savard J, Baillargeon L.	Ecole de Psychologie, Université Laval, Quebec, Canada G1K 0A6.	Insomnia and its relationship to health-care utilization, work absenteeism, productivity and accidents.	Sleep Med. 2009 Apr;10(4):427-38. Epub 2008 Aug 26.	BACKGROUND AND PURPOSE: To document and provide a micro analysis of the relationship between insomnia and health problems, health-care use, absenteeism, productivity and accidents. PARTICIPANTS AND METHODS: A population-based sample of 953 French-speaking adults from Québec, Canada. Participants were categorized as having insomnia syndrome (SYND) or insomnia symptoms (SYMPT) or as good sleepers (GS). They completed questionnaires on sleep, health, use of health-care services and products, accidents, work absences and reduced work productivity. Data were also obtained from the Québec-government-administered health insurance board on selected variables (e.g., consultations with health-care professionals, diagnoses). RESULTS: There were significantly more individuals in the SYND group relative to the GS group reporting at least one chronic health problem (83% vs. 53%; OR: 2.78) and who had consulted a health-care professional in the past year (81% vs. 60%; OR: 2.8). There were also higher proportions of individuals in the SYND group than in the GS group who had used prescription medications (57% vs. 30.7%; OR: 2.8), most notably to treat insomnia, mood and anxiety disorders, or who had used over-the-counter products (75.6% vs. 62.0%; OR: 1.8) and alcohol as a sleep aid (17.8% vs. 3.9%; OR: 4.6). In terms of daytime function, 25.0% of the SYND had been absent from work relative to 17.1% of GS (OR: 1.7), 40.6% reported having experienced reduced productivity compared to 12.3% of GS (OR: 4.8) and non-motor-vehicle accidents occurred at higher rates in the SYND group (12.5% vs. 6.4% for GS; OR: 2.4). No differences were found for hospitalisations or motor-vehicle accidents. Most of the associations remained significant even after controlling for psychiatric comorbidity. Rates for the SYMPT group were situated between SYND and GS on all major dependent variables. Furthermore, insomnia and fatigue were perceived as contributing significantly to accidents, absences and decreased work productivity, regardless of insomnia status. CONCLUSIONS: This study indicates that insomnia is

				associated with significant morbidity in terms of health problems and health-care utilization, work absenteeism and reduced productivity, and risk of non-motor-vehicle accidents. Future studies should evaluate whether treating insomnia can reverse this morbidity.
De Lange FP, Knoop H, Bleijenberg G, Van der Meer JW, Hagoort P, Toni I.		The experience of fatigue in the brain.Comment on: Psychol Med. 2008 Jul;38(7):941-51.	Psychol Med. 2009 Mar;39(3):523-4. Epub 2008 Dec 18.	
de Tommaso M, Sardaro M, Serpino C, Costantini F, Vecchio E, Prudenzano MP, Lamberti P, Livrea P.	Neurological and Psychiatric Sciences Department, Neurophysiopathology of Pain Unit, University of Bari, Bari, Italy. m.detommaso@neurol.uniba.it	Fibromyalgia comorbidity in primary headaches.	Cephalalgia. 2009 Apr;29(4):453-64. Epub 2009 Dec 15.	Fibromyalgia syndrome (FMS) is a chronic pain condition of unknown aetiology characterized by diffuse pain and tenderness at tender points. The aim of the study was to assess the prevalence and clinical features of FMS in the different forms of primary headaches, in a tertiary headache centre. Primary headache patients (n = 217) were selected and submitted to the Total Tenderness Score, anxiety and depression scales, Migraine Disability Assessment, allodynia questionnaire, Short Form 36 Health Survey and the Medical Outcomes Study-Sleep Scale. In patients with FMS, the Multidimensional Assessment of Fatigue, the Pain Visual Analog Scale, the Manual Tender Point Survey and the Fibromyalgia Impact Questionnaire were employed. FMS was present in 36.4% of patients and prevailed significantly in tension-type headache and in patients with higher headache frequency. Headache frequency, pericranial muscle tenderness, anxiety and sleep inadequacy were especially associated with FMS comorbidity. In the FMS patients, fatigue and pain at tender points were significantly correlated with headache frequency. FMS seems increasingly prevalent with increased headache frequency, for the facilitation of central sensitization phenomena favoured by anxiety and sleep disturbances.
Deangelis TM, Shen L.	Mount Sinai School of Medicine, New York, NY, USA.	Outbreak of progressive inflammatory neuropathy following exposure to aerosolized porcine neural tissue.	Mt Sinai J Med. 2009 Oct;76(5):442-7.	In the fall of 2007, the Minnesota Department of Health was notified of 11 cases of an unexplained neurological illness, all linked to a pork processing plant, Quality Pork Processors, Inc., in Austin, MN. The cluster of workers had been experiencing similar symptoms, including fatigue, pain, numbness, and tingling in their extremities as well as weakness. The symptoms were described as more sensory than motor, and all patients had evidence of polyradiculoneuropathy with signs of nerve root irritation. An epidemiological investigation revealed that the only commonality between cases was their exposure to a pork brain extraction procedure involving compressed air. As relatives of the cases remained asymptomatic and all cultures for known pathogens were negative, the etiology of the syndrome seemed not to be infectious. Clinically, the syndrome was most akin to chronic inflammatory demyelinating polyneuropathy. Laboratory tests corroborated the clinical findings, revealing inflammation of peripheral nerves and nerve roots; however, these cases also had features clinically distinct from chronic inflammatory demyelinating polyneuropathy as well as laboratory testing revealing a novel immunoglobulin G immunostaining pattern. This suggested that the observed inflammation was the result of 1 or more unidentified antigens. This syndrome was ultimately dubbed progressive inflammatory neuropathy and was theorized to be an autoimmune reaction to aerosolized porcine neural tissue. Since the investigation's outset, 18 cases of progressive inflammatory neuropathy have been identified at the Minnesota pork processing plant, with 5 similar

				cases at an Indiana plant and 1 case at a Nebraskan plant. The plants in which cases have been identified have since stopped the use of compressed air in removing pork brains. All cases have stabilized or improved, with some requiring immunosuppressive and analgesic treatment. The study of progressive inflammatory neuropathy is ongoing, and the details of this investigation highlight the value of epidemiological principles in the identification and containment of outbreaks while researchers attempt to uncover the unique pathophysiology and potential etiology of the illness. Mt Sinai J Med 76:442-447, 2009. (c) 2009 Mount Sinai School of Medicine.
Decker MJ, Eyal S, Shinar Z, Fuxman Y, Cahan C, Reeves WC, Baharav A.	Chronic Viral Diseases Branch, National Center for Zoonotic, Vector-borne Enteric Diseases, Centers for Disease Control and Prevention, 1600 Clifton Road, Mail Stop A-15, Atlanta, GA, 30333, USA, mdecker@cdc.gov.	Validation of ECG-derived sleep architecture and ventilation in sleep apnea and chronic fatigue syndrome.	Sleep Breath. 2009 Oct 9. [Epub ahead of print]	PURPOSE: Newly developed algorithms putatively derive measures of sleep, wakefulness, and respiratory disturbance index (RDI) through detailed analysis of heart rate variability (HRV). Here, we establish levels of agreement for one such algorithm through comparative analysis of HRV-derived values of sleep-wake architecture and RDI with those calculated from manually scored polysomnographic (PSG) recordings. METHODS: Archived PSG data collected from 234 subjects who participated in a 3-day, 2-night study characterizing polysomnographic traits of chronic fatigue syndrome were scored manually. The electrocardiogram and pulse oximetry channels were scored separately with a novel scoring algorithm to derive values for wakefulness, sleep architecture, and RDI. RESULTS: Four hundred fifty-four whole-night PSG recordings were acquired, of which, 410 were technically acceptable. Comparative analyses demonstrated no difference for total minutes of sleep, wake, NREM, REM, nor sleep efficiency generated through manual scoring with those derived through HRV analyses. When NREM sleep was further partitioned into slow-wave sleep (stages 3-4) and light sleep (stages 1-2), values calculated through manual scoring differed significantly from those derived through HRV analyses. Levels of agreement between RDIs derived through the two methods revealed an R = 0.89. The Bland-Altman approach for determining levels of agreement between RDIs generated through manual scoring with those derived through HRV analysis revealed a mean difference of -0.7 +/- 8.8 (mean +/- two standard deviations). CONCLUSION: We found no difference between values of wakefulness, sleep, NREM, REM sleep, and RDI calculated from manually scored PSG recordings with those derived through analyses of HRV.
Decker MJ, Tabassum H, Lin JM, Reeves WC.	Chronic Viral Diseases Branch, National Center for Zoonotic, Vector-borne Enteric Diseases, Centers for Disease Control and Prevention, 1600 Clifton Road, Mail Stop A-15, Atlanta, Georgia, USA. mdecker@cdc.gov.	Electroencephalographic correlates of Chronic Fatigue Syndrome.	Behav Brain Funct. 2009 Oct 6;5:43.	ABSTRACT: BACKGROUND: Unremitting fatigue and unrefreshing sleep, hallmark traits of Chronic Fatigue Syndrome (CFS), are also pathognomonic of sleep disorders. Yet, no reproducible perturbations of sleep architecture, multiple sleep latency times or Epworth Sleepiness Scores are found to be associated consistently with CFS. This led us to hypothesize that sleep homeostasis, rather than sleep architecture, may be perturbed in CFS. To probe this hypothesis, we measured and compared EEG frequencies associated with restorative sleep between persons with CFS and matched controls, both derived from a population-based sample. METHODS: We evaluated overnight polysomnography (PSG) in 35 CFS and 40 control subjects. PSG records were manually scored and epochs containing artifact removed. Fast Fourier Transformation was utilized to deconstruct individual EEG signals into primary frequency bands of alpha, delta, theta, sigma, and beta frequency domains. The spectral power of each frequency domain for each sleep state was compared between persons with CFS and matched controls. RESULTS: In persons with CFS, delta power was diminished during slow wave sleep, but elevated during both stage 1 and REM. Alpha power was reduced during stage 2, slow wave, and REM sleep. Those with CFS also had significantly lower theta, sigma, and beta spectral

				power during stage 2, Slow Wave Sleep, and REM. DISCUSSION: Employing quantitative EEG analysis we demonstrate reduced spectral power of cortical delta activity during SWS. We also establish reduced spectral power of cortical alpha activity, with the greatest reduction occurring during REM sleep. Reductions in theta, beta, and sigma spectral power were also apparent. CONCLUSION: Unremitting fatigue and unrefreshing sleep, the waking manifestations of CFS, may be the consequence of impaired sleep homeostasis rather than a primary sleep disorder.
Dennis D, Robertson D, Curtis L, Black J.	Northside Hospital, USA. ddennis@mindspring.com	Fungal exposure endocrinopathy in sinusitis with growth hormone deficiency: Dennis-Robertson syndrome.	Toxicol Ind Health. 2009 Oct-Nov;25(9-10):669-80. Epub 2009 Oct 6.	A retrospective study was carried out on 79 patients with a history of mold exposure, fatigue, and chronic rhinosinusitis (CRS) to determine whether there is a causal relationship between fungal exposure and chronic sinusitis, fatigue, and anterior hypopituitarism, especially growth hormone deficiency (GHD). Of the patients, 94% had a history of CRS, endoscopically and/or computed tomography (CT) confirmed; 100% had chronic fatigue and 100% had either significant history of indoor mold exposure and/or positive mold plate testing as measured by settle plates, with an average colony count of 21 (0-4 normal). A total of 62 had positive mold plate testing and 17 had positive history of mold exposure. Of 75, 73 (97.3%) had positive serum immunoglobulin G (IgG)-specific antibodies to fungal antigens. Out of 8, 7 were positive for urinary trichothecenes. Resting levels of insulin-like growth factor 1 (IGF-1) averaged 123 ng/mL (range 43-285, normal 88-249 ng/mL). Despite normal resting levels of IGF-1, significant deficiency of serum human growth hormone (GH) was confirmed by insulin tolerance test (ITT) in 40 of 50 tested. In all, 51% (40/79) were GH deficient. Primary or secondary hypothyroidism in T3 and/or T4 was seen in 81% (64/79) patients; 75% (59/79) had adrenocorticotrophic hormone (ACTH) deficiency. Fungal exposure endocrinopathy likely represents the major cause of GHD, affecting approximately 4.8 million people compared to approximately known 60,000 cases from all other causes. A literature review indicates a possible mechanism of GHD in fungal exposure is that the fungal glucan receptors in the lenticulostellate cells of the anterior pituitary bind to fungal cells wall glucans and activate the innate immune system, which activates macrophages that destroy the fungus and lenticulostellate tissue. Treatment of patients included normal saline nasal irrigations, antifungal and antibiotic nasal sprays, appropriate use of oral antibiotics and antifungals, facial steamer with CitriDrops. Thymate and/or Intramax vitamin supplements, hormone replacement, and reduction of indoor mold levels. Resolution of rhinosinusitis was seen in 93% (41 of 45) of the patients who achieved a mold count by settling plates of 0-4 colonies. Thirty patients were unable to lower their mold counts below four colonies and had various degrees of mucosal disease and fatigue remaining. Fatigue was improved in all 37 patients who received GH and cortisol and/or thyroid hormone, which were deficient. Fatigue was partially relieved in 7 of the 37 who did not achieve mold counts of fewer than four colonies.
Dennison L, Stanbrook R, Moss-Morris R, Yardley L, Chalder T.		Cognitive behavioural therapy and psycho-education for chronic fatigue syndrome in young people: Reflections	Br J Health Psychol. 2009 May 6. [Epub ahead of print]	Objectives Recent trials have produced optimistic results for family-focussed cognitive behavioural therapy (CBT) for chronic fatigue syndrome (CFS) in young people. This study sought to examine the under-researched question of the views and experiences of patients and families who take part. Design Semi-structured interviews and qualitative analysis were chosen in order to address clients' perspectives in depth. Methods Sixteen young people and sixteen parents who participated in a trial of CBT versus psycho-education (PE) for CFS were interviewed. Key themes were discerned using inductive thematic analysis. Results Most families had low expectations of a cure but hope for

		from the families' perspective.		improvement. Generally speaking, participants found both CBT and PE acceptable and helpful. Behavioural aspects of CBT (e.g. goal-setting, graded activity) were found helpful. The opportunity to gain support, recognition and validation was important. Cognitive elements of therapy were sometimes deemed inappropriate and some felt emotional aspects of CFS were not adequately addressed. Participants were ambivalent towards the extent of family involvement. Negative experiences related to the therapy setting and feeling inappropriately labeled. Most participants felt therapy was a stepping-stone towards normal life, although many felt recovery was incomplete. Very few differences were found between themes from CBT and PE participants. A notable exception was that every young person who experienced CBT described therapy as helpful, whereas the participants who strongly opposed the therapy approach had all experienced PE. Conclusions The detailed insights regarding families' therapy experiences suggest areas of improvement for service delivery and topics for further investigation.
Dickson A, Toft A, O'Carroll RE.	School of Health and Social Sciences, Napier University, Edinburgh, UK. a.dickson@napier.ac.uk	Neuropsychological functioning, illness perception, mood and quality of life in chronic fatigue syndrome, autoimmune thyroid disease and healthy participants.	Psychol Med. 2009 Sep;39(9):1567-76. Epub 2009 Jan 15.	BACKGROUND: This study attempted to longitudinally investigate neuropsychological function, illness representations, self-esteem, mood and quality of life (QoL) in individuals with chronic fatigue syndrome (CFS) and compared them with both healthy participants and a clinical comparison group of individuals with autoimmune thyroid disease (AITD). METHOD: Neuropsychological evaluation was administered at two time points, five weeks apart. Twenty-one individuals with CFS, 20 individuals with AITD and 21 healthy participants were matched for age, pre-morbid intelligence, education level and socio-economic status (SES). All groups also completed measures of illness perceptions, mood, self-esteem and QoL at both time points. RESULTS: The CFS group showed significantly greater impairment on measures of immediate and delayed memory, attention and visuo-constructional ability, and reported significantly higher levels of anxiety and depression. After controlling for the effects of mood, the CFS group still demonstrated significant impairment in attention. The CFS group also reported significantly lower self-reported QoL than the AITD and healthy participants. In terms of illness perceptions, the AITD group believed that their condition would last longer, that they had more treatment control over their condition, and reported less concern than the CFS group. CONCLUSIONS: These results suggest that the primary cognitive impairment in CFS is attention and that this is not secondary to affective status. The lower treatment control perceptions and greater illness concerns that CFS patients report may be causally related to their affective status.
Dinos S, Khoshaba B, Ashby D, White PD, Nazroo J, Wessely S, Bhui KS.	Centre for Psychiatry, Barts and the London School of Medicine and Dentistry, Queen Mary University of London, London, UK. s.dinos@qmul.ac.uk	A systematic review of chronic fatigue, its syndromes and ethnicity: prevalence, severity, co-morbidity and coping.	Int J Epidemiol. 2009 Dec;38(6):1554-70. Epub 2009 Apr 6.	BACKGROUND: Chronic Fatigue Syndrome (CFS) is characterized by unexplained fatigue that lasts for at least 6 months alongside a constellation of other symptoms. CFS was historically thought to be most common among White women of higher socio-economic status. However, some recent studies in the USA suggest that the prevalence is actually higher in some minority ethnic groups. If there are convincing differences in prevalence and risk factors across all or some ethnic groups, investigating the causes of these can help unravel the pathophysiology of CFS. METHODS: A systematic review was conducted to explore the relationship between fatigue, chronic fatigue (CF--fatigue lasting for 6 months), CFS and ethnicity. Studies were population-based and health service-based. Meta-analysis was also conducted to examine the population prevalence of CF and CFS across ethnic groups. RESULTS: Meta-analysis showed that compared with the White American majority, African Americans and Native Americans have a higher risk of CFS [Odds Ratio (OR) 2.95, 95% confidence interval (CI):

				0.69-10.4; OR = 11.5, CI: 1.1-56.4, respectively] and CF (OR = 1.56, CI: 1.03-2.24; OR = 3.28, CI: 1.63-5.88, respectively). Minority ethnic groups with CF and CFS experience more severe symptoms and may be more likely to use religion, denial and behavioural disengagement to cope with their condition compared with the White majority. CONCLUSIONS: Although available studies and data are limited, it does appear that some ethnic minority groups are more likely to suffer from CF and CFS compared with White people. Ethnic minority status alone is insufficient to explain ethnic variation of prevalence. Psychosocial risk factors found in high-risk groups and ethnicity warrant further investigation to improve our understanding of aetiology and the management of this complex condition.
Donalek JG.	Department of Nursing, DePaul University, Chicago, IL 60614, USA. jdonalek@depaul.edu	When a parent is chronically ill: chronic fatigue syndrome.	Nurs Res. 2009 Sep-Oct;58(5):332-9.	BACKGROUND: Chronic illness may reshape not only the life of the ill parent but also that of the entire family, but research in this area remains limited. More specifically, little is known about how an ill parent and the family respond to a particularly devastating and controversial chronic illness, chronic fatigue syndrome (CFS). OBJECTIVES: The objective of this study was to describe the responses of the parent and the ensuing family system responses to the presence of chronic fatigue syndrome as a chronic parental illness. METHODS: Parents were interviewed individually, and then the ill parent and as many immediate family members as possible were interviewed collectively. After consent or assent, interviews were audiotaped and transcribed. Thematic analyses at the individual, intrafamily, and across-family levels were used to explore these phenomena. RESULTS: Eight ill parents first described the onset of illness, an ongoing struggle to receive diagnosis and care, and the significance of the illness in transforming present and future roles. Multiple members of the family together with the ill parent described how they struggled with the reality of the illness, the shifting roles and responsibilities, the reduced family income, and the frequent social isolation that could be exacerbated by the controversial nature of the illness. Families described and demonstrated their struggles to maintain normal family life and plans in the face of continuing uncertainty. DISCUSSION: This study is situated within current scholarship on family responses to chronic parental illness. The value of the family research interview is affirmed. Recommendations are made for future directions in family nursing research exploring responses of families in which a parent is chronically ill.
Drachler Mde L, Leite JC, Hooper L, Hong CS, Pheby D, Nacul L, Lacerda E, Campion P, Killett A, McArthur M, Poland F.	School of Allied Health Professions, University of East Anglia, Norwich, NR4 7TJ, UK. malu.drachler@gmail.com	The expressed needs of people with chronic fatigue syndrome/myalgic encephalomyelitis: a systematic review.	BMC Public Health. 2009 Dec 11;9:458.	BACKGROUND: We aimed to review systematically the needs for support in managing illness and maintaining social inclusion expressed by people with chronic fatigue syndrome/myalgic encephalomyelitis (CFS/ME) METHODS: We carried out a systematic review of primary research and personal ('own') stories expressing the needs of people with CFS/ME. Structured searches were carried out on Medline, AMED, CINAHL, EMBASE, ASSIA, CENTRAL, and other health, social and legal databases from inception to November 2007. Study inclusion, data extraction and risk of bias were assessed independently in duplicate. Expressed needs were tabulated and a conceptual framework developed through an iterative process. RESULTS: Thirty two quantitative and qualitative studies, including the views of over 2500 people with CFS/ME with mainly moderate or severe illness severity, met the inclusion criteria. The following major support needs emerged: 1) The need to make sense of symptoms and gain diagnosis, 2) for respect and empathy from service providers, 3) for positive attitudes and support from family and friends, 4) for information on CFS/ME, 5) to adjust views and priorities, 6) to develop strategies to manage impairments and activity limitations, and 7) to develop

				strategies to maintain/regain social participation. CONCLUSIONS: Although the studies were heterogeneous, there was consistent evidence that substantial support is needed to rebuild lives. Gaining support depends - most importantly - on the ability of providers of health and social care, colleagues, friends and relatives, and those providing educational and leisure services, to understand and respond to those needs.
Dworzańska E, Mitosek-Szewczyk K, Stelmasiak Z.	Katedra i Klinika Neurologii, Uniwersytet Medyczny w Lublinie, Samodzielny Publiczny Szpital Kliniczny nr 4, ul. Jaczewskiego 8, 20-954 Lublin, Poland. cieckoewa@interia.pl	[Fatigue in multiple sclerosis][Article in Polish]	Neurol Neurochir Pol. 2009 Jan-Feb;43(1):71-6.	Fatigue is one of the most common symptoms of multiple sclerosis (MS) and is associated with reduced quality of life. The fatigue syndrome is characterized by uncontrollable apathy, exhaustion, fatigability and lack of energy. The mechanisms underlying fatigue in MS are still poorly understood but studies suggest that immune and neuroendocrine factors may play a causative role in the development of fatigue. The first step in management of MS-related fatigue is identifying and eliminating any secondary causes (adverse effects of drugs, infections, sleep disorders, metabolic diseases). As the fatigue syndrome in patients with MS cannot be evaluated objectively in the routine clinical setting, a number of scales have been developed. The Fatigue Severity Scale is a general scale. Additional scales that have been tested in MS include the Fatigue Impact Scale. Therapy of fatigue syndrome consists of modafinil, amantadine, pemoline and non-pharmacological management.
Dyer C.		High court rejects challenge to NICE guidelines on chronic fatigue syndrome.	BMJ. 2009 Mar 17;338:b1110. doi: 10.1136/bmj.b1110.	
Edd EM, Flores S.	College of Nursing, New York University, John A. Hartford Institute for Geriatric Nursing, New York University, New York, NY, USA.	Sleepiness or excessive daytime somnolence.	Geriatr Nurs. 2009 Jan-Feb;30(1):53-60.	Excessive daytime somnolence (EDS) is associated with age-related changes, environment, circadian rhythm or sleep pattern disorder, insomnia, medications, lifestyle factors, depression, pain, and illness. The notion of "sleep architecture" connotes a structure that describes the sleep cycle (i.e., stages) and wakefulness during a single sleep period-that is, rapid eye movement (REM) and non-REM sleep. Circadian rhythms perform a variety of functions including regulation of the quality and distribution of the stages of sleep. Insomnia includes delayed sleep onset as well as premature wakening; sleep is nonrestorative. Comorbidities associated with insomnia are Alzheimer's disease and other dementias, delirium, depression, congestive heart failure, chronic obstructive pulmonary disease, gastroesophageal reflux disease, pain, degenerative diseases of the neurological system, and sleep apnea. Continuous inadequate sleep affects cognitive function, physical performance, overall well-being, and quality of life. There is a greater risk of falls from insomnia than is the use of hypnotics to manage it. Sleep disruption among older adults is underrecognized and undertreated. Assessment using valid tools can be performed rapidly. There are a variety of treatment options, including sleep hygiene and pharmacological and alternative modalities.
Evans KM, Flanagan DE, Wilkin TJ.	Department of Endocrinology and Metabolism,	Chronic fatigue: is it endocrinology?	Clin Med. 2009 Feb;9(1):34-8.	Fatigue and stress-related illnesses often become diagnoses of exclusion after extensive investigation. 'Tired all the time' is a frequent reason for referral to the endocrine clinic, the implicit question being--is there a subtle endocrine pathology contributing to the patient's symptoms? Often initial

	Peninsula Medical School, Plymouth and Derriford Hospital, Plymouth. kme@doctors.org.uk			assessment suggests not but there are no clear data to address the question of whether overt pathology will develop in the future. This study observed outcomes after five years in 101 consecutive and unselected referrals to secondary care for 'fatigue?cause', where initial assessment did not suggest treatable endocrine pathology. The findings suggest that the clinical diagnosis of fatigue, based on history and tests to exclude anaemia, hypothyroidism and diabetes, is secure: these patients do not subsequently demonstrate excess morbidity and mortality, and their presenting symptoms are not early features of significant endocrine pathology.
Exley C, Swarbrick L, Gherardi RK, Authier FJ.	Birchall Centre for Inorganic Chemistry and Materials Science, Keele University, Staffordshire ST5 5BG, UK. c.exley@chem.keele.ac.uk	A role for the body burden of aluminium in vaccine-associated macrophagic myofasciitis and chronic fatigue syndrome.	Med Hypotheses. 2009 Feb;72(2):135-9. Epub 2008 Nov 11.	Macrophagic myofasciitis and chronic fatigue syndrome are severely disabling conditions which may be caused by adverse reactions to aluminium-containing adjuvants in vaccines. While a little is known of disease aetiology both conditions are characterised by an aberrant immune response, have a number of prominent symptoms in common and are coincident in many individuals. Herein, we have described a case of vaccine-associated chronic fatigue syndrome and macrophagic myofasciitis in an individual demonstrating aluminium overload. This is the first report linking the latter with either of these two conditions and the possibility is considered that the coincident aluminium overload contributed significantly to the severity of these conditions in this individual. This case has highlighted potential dangers associated with aluminium-containing adjuvants and we have elucidated a possible mechanism whereby vaccination involving aluminium-containing adjuvants could trigger the cascade of immunological events which are associated with autoimmune conditions including chronic fatigue syndrome and macrophagic myofasciitis.
Fletcher MA, Zeng XR, Barnes Z, Levis S, Klimas NG.	Department of Medicine, University of Miami Miller School of Medicine, 1600 NW 10th Ave, Miami, FL, USA. mfletche@med.miami.edu	Plasma cytokines in women with chronic fatigue syndrome.	J Transl Med. 2009 Nov 12;7:96.	BACKGROUND: Chronic Fatigue Syndrome (CFS) studies from our laboratory and others have described cytokine abnormalities. Other studies reported no difference between CFS and controls. However, methodologies varied widely and few studies measured more than 4 or 5 cytokines. Multiplex technology permits the determination of cytokines for a large panel of cytokines simultaneously with high sensitivity and with only 30 ul of plasma per sample. No widely accepted laboratory test or marker is available for the diagnosis or prognosis of CFS. This study screened plasma factors to identify circulating biomarkers associated with CFS. METHODS: Cytokines were measured in plasma from female CFS cases and female healthy controls. Multiplex technology provided profiles of 16 plasma factors including the pro -inflammatory cytokines: tumor necrosis factor alpha (TNFalpha), lymphotoxin alpha (LTalpha), interleukin (IL) - IL-Ialpha, IL-1beta, IL-6; TH1 cytokines: interferon gamma (IFNgamma), IL-12p70, IL-2, IL-15; TH2: IL-4, IL-5; TH17 cytokines, IL-17 and IL-23; anti-inflammatory cytokines IL-10, IL-13; the inflammatory mediator and neutrophil attracting chemokine IL-8 (CXCL8). Analysis by receiver operating characteristic (ROC) curve assessed the biomarker potential of each cytokine. RESULTS: The following cytokines were elevated in CFS compared to controls: LTalpha, IL-1alpha, IL-1beta, IL-4, IL-5, IL-6 and IL-12. The following cytokines were decreased in CFS: IL-8, IL-13 and IL-15. The following cytokines were not different: TNFalpha, IFNgamma, IL-2, IL-10, IL-23 and IL-17. Applying (ROC) curve analyses, areas under the curves (AUC) for IL-5 (0. 84), LTalpha (0.77), IL-4 (0.77), IL-12 (0.76) indicated good biomarker potential. The AUC of IL-6 (0.73), IL-15 (0.73), IL-8 (0.69), IL-13 (0.68) IL-1alpha (0.62), IL-1beta (0.62) showed fair potential as biomarkers. CONCLUSION: Cytokine abnormalities are common in CFS. In this study, 10 of 16 cytokines examined showed good to fair promise as biomarkers. However, the cytokine changes observed are likely to

				more indicative of immune activation and inflammation, rather than specific for CFS. As such, they are targets for herapeutic strategies. Newer techniques allow evaluation of large panels of cytokines in a cost effective fashion.
Flor-Henry P, Lind JC, Koles ZJ.	Alberta Hospital Edmonton, Box 307, Edmonton, Edmonton, Alberta, Canada T5J 2J7.	EEG source analysis of chronic fatigue syndrome.	Psychiatry Res.. [Epub ahead of print]	Sixty-one dextral, unmedicated women with chronic fatigue syndrome (CFS) diagnosed according to the Fukuda criteria (1994) and referred for investigation by rheumatologists and internists were studied with quantitative EEG (43 channels) at rest with eyes open and during verbal and spatial cognitive activation. The EEGs from the patients were compared with recordings from 80 dextral healthy female controls. Only those subjects who could provide 20 1-s artefact-free segments of EEG were admitted into the study. The analysis consisted of the identification of the spatial patterns in the EEGs that maximally differentiated the two groups and the estimation of the cortical source distributions underlying these patterns. Spatial patterns were analyzed in the alpha (8-13Hz) and beta (14-20Hz) bands and the source distributions were estimated using the Borgiotti-Kaplan BEAMFORMER algorithm. The results indicate that the spatial patterns identified were effective in separating the two groups, providing a minimum correct retrospective classification rate of 72% in both frequency bands while the subjects were at rest to a maximum of 83% in the alpha band during the verbal cognitive condition. Underlying cortical source distributions showed significant differences between the two groups in both frequency bands and in all cognitive conditions. Lateralized cortical differences were evident between the two groups in the both frequency bands during both the verbal and spatial cognitive conditions. During these active cognitive conditions, the CFS group showed significantly greater source-current activity than the controls in the left frontal-temporal-parietal regions of the cortex.
Fluge Ø, Mella O.	Department of Oncology and Medical Physics, Haukeland University Hospital, N-5021 Bergen, Norway. oystein.fluge@gmail.com	Clinical impact of B-cell depletion with the anti-CD20 antibody rituximab in chronic fatigue syndrome: a preliminary case series.	BMC Neurol. 2009 Jul 1;9:28.	BACKGROUND: Chronic fatigue syndrome (CFS) is a disease of unknown aetiology. A patient with CFS had unexpected, marked recovery of CFS symptoms lasting for five months during and after cytotoxic chemotherapy for Hodgkin's disease. We reasoned that the transient CFS recovery was related to methotrexate treatment, which induces immunomodulation in part through B-cell depletion. METHODS: In a case series, this patient and two additional CFS patients were B-cell depleted by infusion of the monoclonal anti-CD20 antibody rituximab. RESULTS: All three had improvement of all CFS symptoms. Patients 1 and 2 had major amelioration from 6 weeks after intervention, patient 3 slight improvement from the same time, but then improved markedly from 26 weeks after intervention. The symptomatic effect lasted until weeks 16, 18 and 44, respectively. At relapse, all were retreated with a single (patient 1) or double rituximab infusion (patients 2 and 3). Again, all three had marked symptom improvement, mimicking their first response. After new symptom recurrence, patients 1 and 2 were given weekly oral methotrexate, patient 1 having effect also from this agent. Patients 1 and 2 were again treated for a third rituximab infusion after new relapse, again with a marked clinical benefit. No unexpected toxicity was seen. CONCLUSION: These observations suggest that B-lymphocytes are involved in CFS pathogenesis for a subset of patients. Benefit for all CFS symptoms, the delayed symptom relief following B-cell depletion, the kinetics of relapses, and the effect also from methotrexate treatment, provide suggestive evidence that B-cells play a significant role in the ongoing clinical features, and that CFS may be amenable to therapeutic interventions aimed at modifying B-cell number and function. More systematic investigations of this therapeutic

				strategy, and of its biological basis, are now needed.

Fomicheva EE, Filatenkova TA, Rybakina EG.		[Activity of hypotnalamic-pituitary-adrenal axis by induction of experimental chronic fatigue syndrom][Article in Russian]	Ross Fiziol Zh Im I M Sechenova. 2009 Jan;95(1):11-8.	Changes in the activity of hypothalamic-pituitary adrenal (HPA) axis were investigated in experimental model of chronic fatigue syndrome (CFS) induced by intraperitoneal administration of synthetic double-stranded RNA (polyriboinosinic: polyribocytidylic acid, Poly I : C) to rats in the dose of 3 mg/kg body weight. In order to reveal functional changes in different links of the HPA axis, standard probes with intraperitoneal administration of ACTH and hydrocortisone against the background of cold stress application and Poly I : C injections were performed. A single injection of Poly I : C led to disordered HPA axis functions which was manifested by decreased sensitivity of the cells in the adrenal gland in response to ACTH, and suppression of the mechanism of negative feedback resulting in significant fall of cortisocterone concentration in standard assays with ACTH and hydrocortisone administration.

Frémont M, Metzger K, Rady H, Hulstaert J, De Meirleir K.	Protea Biopharma, Z.1-Researchpark 100, 1731 Zellik, Belgium. mfremont@protea	Detection of herpesviruses and parvovirus B19 in gastric and intestinal mucosa	In Vivo. 2009 Mar-Apr;23(2):209-13.	BACKGROUND: Human herpesvirus-6 (HHV-6), Epstein-Barr virus and parvovirus B19 have been suggested as etiological agents of chronic fatigue syndrome but none of these viruses is consistently detected in all patients. However, active viral infections may be localized in specific tissues, and, therefore, are not easily detectable. The aim of this study was to investigate the presence of HHV-6, HHV-7, EBV and parvovirus B19 in the gastro-intestinal tract of CFS patients. PATIENTS AND

	biopharma.com	of chronic fatigue syndrome patients.		METHODS: Using real-time PCR, viral DNA loads were quantified in gastro-intestinal biopsies of 48 CFS patients and 35 controls. RESULTS: High loads of HHV-7 DNA were detected in most CFS and control biopsies. EBV and HHV-6 were detected in 15-30% of all biopsies. Parvovirus B19 DNA was detected in 40% of the patients versus less than 15% of the controls. CONCLUSION: Parvovirus B19 may be involved in the pathogenesis of CFS, at least for a subset of patients. The gastro-intestinal tract appears as an important reservoir of infection for several potentially pathogenic viruses.
Frenger P.	A Working Hypothesis, Inc., Houston, TX.	Multi-system fibromyalgia syndrome emulator - biomed 2009.	Biomed Sci Instrum. 2009;45:292-8.	Fibromyalgia Syndrome is a chronic disorder characterized by abnormal pain, fatigue, depression, cognitive dysfunction and sleep disturbance. The body's immune, hormonal, and nervous systems are involved. The author proposes a model from his clinical practice where a relapsing human Herpesvirus 4 infection of ss-lymphocytes causes inappropriate activation of immune system components, thus leading to typical FMS signs and symptoms. This clinical model was subsequently embodied in a computer based on the author's human nervous system function emulator, which imitates the brain's biochemicalneural-cognitive operations. This Forth language emulator program runs on a multiprocessor network recently enhanced with 8-core 32-bit CPUs. Supplemental analog circuit boards provide support for an artificial neural network, synthetic emotion and cellular substrate-receptor binding activity simulation. The effects of antiviral antibiotics and other chemicals on this disease are included in the emulator.
Friedberg F, Sohl S.	Stony Brook University. Fred.Friedberg@stonybrook.edu	Cognitive-behavior therapy in chronic fatigue syndrome: is improvement related to increased physical activity?	J Clin Psychol. 2009 Apr;65(4):423-42.	This multiple case study of cognitive-behavioral treatment (CBT) for chronic fatigue syndrome (CFS) compared self-report and behavioral outcomes. Eleven relatively high-functioning participants with CFS received 6-32 sessions of outpatient graded-activity oriented CBT. Self-report outcomes included measures of fatigue impact, physical function, depression, anxiety, and global change. Behavioral outcomes included actigraphy and the 6-minute walking test. Global change ratings were very much improved (n=2), much improved (n=2), improved (n=5), and no change (n=2). Of those reporting improvement, clinically significant actigraphy increases (n=3) and decreases (n=4) were found, as well as no significant change (n=2). The nature of clinical improvement in CBT trials for high-functioning CFS patients may be more ambiguous than that postulated by the cognitive-behavioral model.
Friedberg F, Sohl SJ.	Department of Psychiatry and Behavioral Science Putnam Hall, Stony Brook University, NY 11794-8790, USA. fred.friedberg@stonybrook.edu	Longitudinal change in chronic fatigue syndrome: what home-based assessments reveal.	J Behav Med. 2009 Apr;32(2):209-18. Epub 2008 Dec 20.	The purpose of this 2-year prospective study was to compare standard self-report and ecologically-based outcome measures in patients with chronic fatigue syndrome (CFS). Standard measures assessed physical function, fatigue impact, psychological variables, and global impression of change ratings. Ecological measures included actigraphy, a structured activity record, and an electronic fatigue/energy diary. Results for this high functioning sample (N = 75) revealed that self-report global improvement was significantly associated with lower momentary fatigue and fatigue impact, and a higher frequency of standing up (at home), but not with actigraphy or psychological variables. However, actigraphy change was significantly correlated with change in self-report physical function. At follow-up, only a small minority (<20%) scored in the healthy adult range for fatigue impact and physical function. The findings suggest that home-based measures of symptom severity and physical functioning may provide evidence of change (or lack of change) that is important for interpreting standard self-report outcomes in CFS.
Frykholm BO.	aion.terapi@yahoo.com	On the question of infectious	Med Hypotheses. 2009	Close similarities in the courses of multiple sclerosis and schizophrenia laid the theoretical ground for attempting to find a common infectious aetiology for the two diseases. Chlamydia pneumoniae, which

		aetiologies for multiple sclerosis, schizophrenia and the chronic fatigue syndrome and their treatment with antibiotics.	Jun;72(6):736-9. Epub 2009 Mar 6.	belongs to the rickettsial family of microorganisms has been linked to both diseases. It is postulated that since rickettsial microorganisms are ubiquitous in human populations they and the human species normally live in peaceful coexistence. In rare cases, for unknown reasons, varieties of them may become aggressive and pathogenic. The kynurenic acid hypothesis of schizophrenia has attracted much attention. It also seems to have initiated a paradigmatic shift from the hitherto prevailing serological research approach to one which focuses on immunological factors. An open clinical pilot study in which, during 2006, eight female and five male patients with psychotic symptoms were treated with a combination of antibiotics is presented, to which, in the beginning of 2007 two female patients suffering from severe and long standing chronic fatigue syndrome were added. On one year follow-up, six out of the eight female patients showed stable excellent treatment results, whereas two were rated as showing significant treatment results. Four of the five men who entered the study were suffering from chronic schizophrenia, whereas the fifth, was a case of severe acute catatonic schizophrenia. Two of the male patients showed significant treatment results, whereas three of them were rated as having had a slight to moderate improvement. No less than three of the women had suffered their first episode of psychosis after giving birth to their first (and only) child. This finding, as these women all responded excellently to treatment with antibiotics, indicates that post partum psychosis could be regarded as an infectious complication of childbirth of, as to the causative agent, unknown aetiology. High priority ought therefore be given to initiate controlled clinical trials with antibiotic treatment of this serious condition. The otherwise promising results of the pilot study seem to warrant further and controlled clinical trials with treatment with antibiotics of patients with psychotic symptoms. As the second patient with psychotic symptoms to enter the study, had a long standing history of chronic fatigue, where an initial treatment with the antidepressant fluoxetine had only worsened her condition, whereas ninety days of treatment with antibiotics, combined with vitamin B injections, effected a complete recovery, the author decided, when two patients with long standing and incapacitating chronic fatigue syndromes sought the clinic in February and March 2007, to include them in the study. The first of them, after sixty days of treatment with antibiotics showed excellent treatment results on follow-up one year later, whereas the second, who also took the combination of antibiotics for sixty days, was rated as having shown a significant improvement.

Godás Sieso T, Gómez Gil E, Salamero Baró M, Fernandez-Huerta JM, Fernandez-Solá J.	Instituto de Neurociencias, Servicio de Psicología, Unidad de fatiga crónica, Hospital Clínic de	[Relationship between chronic fatigue syndrome and type A behaviour] [Article in Spanish]	Med Clin (Barc). 2009 Oct 17;133(14):539-41. Epub 2009 Jul 10.	BACKGROUND AND OBJECTIVE: To quantify the relationship between Chronic Fatigue Syndrome (CFS) and Type A Behaviour Pattern (TABP) PATIENTS AND METHOD: The Jenkins Activity Survey (JAS) was administered to 82 patients diagnosed with CFS to determine the prevalence of TABP. Subjects' mean z scores on the JAS were compared with those from the general population (healthy controls) and from patients with ischemic cardiopathy (pathologic controls). RESULTS: CFS patients' mean score on the JAS was 5 points higher than that of the general population (healthy controls) and 2 points higher

	Barcelona, Barcelona, España.			than that of patients with ischemic cardiopathy. CONCLUSIONS: TABP appears to be related with CFS and should be taken into account in the treatment of these patients.
Godfrey E, Cleare A, Coddington A, Roberts A, Weinman J, Chalder T.	Department of Psychology, Kings College London, London, UK.	Chronic fatigue syndrome in adolescents: do parental expectations of their child's intellectual ability match the child's ability?	J Psychosom Res. 2009 Aug;67(2):165-8. Epub 2009 Apr 16.	OBJECTIVE: This cross-sectional study aimed to measure the discrepancy between actual and perceived IQ in a sample of adolescents with CFS compared to healthy controls. We hypothesized that adolescents with CFS and their parent would have higher expectations of the adolescent's intellectual ability than healthy adolescents and their parent. METHODS: The sample was 28 CFS patients and 29 healthy controls aged 11-19 years and the parent of each participant. IQ was assessed using the AH4 group test of general intelligence and a self-rating scale which measured perceived IQ. RESULTS: Parents' perceptions of their children's IQ were significantly higher for individuals with CFS than healthy controls. CONCLUSIONS: High expectations may need to be addressed within the context of treatment.
Goedendorp MM, Knoop H, Schippers GM, Bleijenberg G.	Expert Centre for Chronic Fatigue, Radboud University Nijmegen Medical Centre, Nijmegen, The Netherlands. m.goedendorp@nkcv.umcn.nl	The lifestyle of patients with chronic fatigue syndrome and the effect on fatigue and functional impairments.	J Hum Nutr Diet. 2009 Jun;22(3):226-31. Epub 2009 Feb 17.	BACKGROUND: Little is known about the lifestyle of patients with chronic fatigue syndrome (CFS) and its influence on symptoms of CFS. The present study aimed to investigate the lifestyle of patients with CFS, and to assess whether lifestyle factors are related to fatigue and functional impairments. METHODS: Two hundred and forty-seven patients fulfilling the Center for Disease Control criteria for CFS were included. Validated questionnaires were used to collect data on lifestyle factors, smoking, intake of alcohol, fat, fibres, fruit and vegetables, body mass index (BMI), fatigue severity and functional impairments. RESULTS: Of the CFS patients, 23% smoked, 32% had an unhealthy BMI, and none had an unhealthy alcohol intake. A majority had an unhealthy food intake: 70% had unhealthy fat, fruit and vegetable intake, and 95% had unhealthy fibre intake. Compared with the general Dutch population, significantly fewer CFS patients were overweight. Significantly more female CFS patients abstained from alcohol, and fewer male CFS patients smoked. Unhealthy lifestyle factors were not significantly associated with fatigue severity or functional impairments. CONCLUSIONS: CFS patients tend to lead a healthier lifestyle compared to the general Dutch population. However, no relationship was found between lifestyle factors and fatigue severity and functional impairments in CFS.
Goldenberg DL.	Department of Rheumatology, Newton-Wellesley Hospital, Newton, Massachusetts 02462, USA. dgoldenb@massmed.org	Diagnosis and differential diagnosis of fibromyalgia.	Am J Med. 2009 Dec;122(12 Suppl):S14-21.	Fibromyalgia is a chronic functional illness that presents with widespread musculoskeletal pain as well as a constellation of symptoms including fatigue, cognitive dysfunction, sleep difficulties, stiffness, anxiety, and depressed mood. The diagnosis of fibromyalgia, similar to other functional disorders, requires that organic diseases are not causing the symptoms. Systemic and rheumatic diseases can be ruled out by a patient history, physical examination, and laboratory investigations. Because there are no specific laboratory tests for fibromyalgia, the 1990 American College of Rheumatology (ACR) classification criteria have been used in clinical settings; however, they are not ideal for individual patient diagnosis. Clinicians should be aware of limitations inherent in using tender points in the diagnosis of fibromyalgia. The multiple symptoms of fibromyalgia often overlap with those of related disorders and may further complicate the diagnosis. One of the most challenging diagnostic dilemmas that clinicians face is distinguishing fibromyalgia from other central pain disorders (e.g., irritable bowel syndrome, chronic fatigue syndrome, migraine). Screening questions based on published criteria can be used as a first approach in diagnosing functional illnesses. Numerous studies report a higher prevalence of psychiatric disorders in patients with fibromyalgia. Therefore, a careful history and evaluation should be taken for the presence of primary mood disturbances. To date, there is no

				"gold standard" for diagnosing fibromyalgia. Until a better clinical case definition of fibromyalgia exists, all diagnostic criteria should be interpreted with caution, considered rudimentary, and subject to modification. (c) 2009 Elsevier Inc.
Gordon B, Lubitz L.	Physiotherapy Department, Austin Hospital, Heidelberg, Vic, Australia. brett.gordon@austin.org.au	Promising outcomes of an adolescent chronic fatigue syndrome inpatient programme.	J Paediatr Child Health. 2009 May;45(5):286-90.	INTRODUCTION: Chronic fatigue syndrome (CFS) is a condition of prolonged and disabling fatigue, which is accompanied by characteristic constitutional and neuropsychiatric symptoms. In children and adolescents, this condition occurring at a developmentally vulnerable time adds to the disability affecting self-concept, autonomy, body image, socialisation, sexuality and academic problems. This case series looks at the effects of a graded exercise programme on physical outcomes, fatigue and mental state in an adolescent population. METHODS: Data sets from 16 adolescents who completed combined exercise training as part of the 4-week inpatient intensive CFS programme at the Austin Hospital, Melbourne were analysed. All patients completed an exercise assessment and three questionnaires before beginning any training. A paediatrician (LL) confirmed the diagnosis according to the Fukuda criteria in all patients. Exercise was carefully supervised and prescribed daily by an exercise physiologist (BG) according to each individual's ability and response with the basic aim of increasing exercise tolerance and improving muscle strength and endurance. RESULTS: There was an 18% improvement in volitional time to fatigue (P= 0.02) and 17% improvement in peak oxygen uptake (VO(2peak)) (P= 0.01). Upper body strength and function improved with a remarkable 70% increase in the number of push-ups. Fatigue severity was reported to improve by 13% (P= 0.01) and depression index improved significantly by 42% (P= 0.02). CONCLUSIONS: The significance of these improvements cannot be underestimated as an improvement in physical capacity through increased time to fatigue and less severe fatigue allows adolescents to resume school, social and family activities.

Goudsmit EM, Ho-Yen DO, Dancey CP.	School of Psychology, University of East London, London, UK. ellengoudsmit@hotmail.com	Learning to cope with chronic illness. Efficacy of a multi-component treatment for people with chronic fatigue syndrome.	Patient Educ Couns. 2009 Nov;77(2):231-6. Epub 2009 Jul 2. Comment in: Patient Educ Couns. 2009 Nov;77(2):153-4.	OBJECTIVE: The aim of this study was to determine the efficacy of an out-patient, multi-component programme developed for patients with chronic fatigue syndrome (CFS). METHODS: Twenty-two patients were assessed before and after six months of treatment. Findings were compared with 22 individuals on the waiting list. The programme offered medical care as well as information and counselling to help patients to understand, accept and cope with their illness. RESULTS: At six months, there were significant differences between the groups for fatigue, self-efficacy and anxiety. Overall, 82% of the treated patients reported feeling better and 23% had improved to such a degree that they were discharged from the clinic. The gains were maintained at twelve months. CONCLUSION: This programme was found to be both helpful and acceptable and may provide a useful first-line intervention for many patients with CFS. PRACTICE IMPLICATIONS: Short, pragmatic programmes may be as effective as cognitive-behaviour therapy.

Goudsmit EM, Stouten B, Howes S.	University of East London, UK. ellengoudsmit@hotmail.com	Illness intrusiveness in myalgic encephalomyelitis: an exploratory study.	J Health Psychol. 2009 Mar;14(2):215-21.	This study assessed the relationship between illness intrusiveness, symptoms, disability and depression in patients with myalgic encephalomyelitis (ME). Participants were 16 patients with ME and eight patients with ME plus co-morbid disorders. The patients with co-morbid disorders reported greater illness intrusiveness than the patients with ME alone, but there were no differences between the groups on the other variables. Significant correlations were found between illness intrusiveness on the one hand, and fatigue, cognitive dysfunction, disability and depression, on the other. We conclude that ME is a disabling illness, which has a major impact on various life domains.
Gow JW, Hagan S, Herzyk P, Cannon C, Behan PO, Chaudhuri A.	Essex Centre for Neurological Sciences, Oldchurch Hospital, Romford, RM7 0BE, UK. chaudhuria@gmail.com.	A gene signature for post-infectious chronic fatigue syndrome.	BMC Med Genomics. 2009 Jun 25;2:38.	ABSTRACT: BACKGROUND: At present, there are no clinically reliable disease markers for chronic fatigue syndrome. DNA chip microarray technology provides a method for examining the differential expression of mRNA from a large number of genes. Our hypothesis was that a gene expression signature, generated by microarray assays, could help identify genes which are dysregulated in patients with post-infectious CFS and so help identify biomarkers for the condition. METHODS: Human genome-wide Affymetrix GeneChip arrays (39,000 transcripts derived from 33,000 gene sequences) were used to compare the levels of gene expression in the peripheral blood mononuclear cells of male patients with post-infectious chronic fatigue (n = 8) and male healthy control subjects (n = 7). RESULTS: Patients and healthy subjects differed significantly in the level of expression of 366 genes. Analysis of the differentially expressed genes indicated functional implications in immune modulation, oxidative stress and apoptosis. Prototype biomarkers were identified on the basis of differential levels of gene expression and possible biological significance CONCLUSION: Differential expression of key genes identified in this study offer an insight into the possible mechanism of chronic fatigue following infection. The representative biomarkers identified in this research appear promising as potential biomarkers for diagnosis and treatment.
Gupta A, Vij G, Sharma S, Tirkey N, Rishi P, Chopra K.	Pharmacology Division, University Institute of Pharmaceutical Sciences, Panjab University, Chandigarh 160014, India.	Curcumin, a polyphenolic antioxidant, attenuates chronic fatigue syndrome in murine water immersion stress model.	Immunobiology. 2009;214(1):33-9. Epub 2008 Jun 17.	Chronic fatigue syndrome, infection and oxidative stress are interrelated in epidemiological case studies. However, data demonstrating scientific validation of epidemiological claims regarding effectiveness of nutritional supplements for chronic fatigue syndrome are lacking. This study is designed to evaluate the effect of natural polyphenol, curcumin, in a mouse model of immunologically induced fatigue, where purified lipopolysaccharide (LPS) and Brucella abortus (BA) antigens were used as immunogens. The assessment of chronic fatigue syndrome was based on chronic water-immersion stress test for 10 min daily for 19 days and the immobility time was taken as the marker of fatigue. Mice challenged with LPS or BA for 19 days showed significant increase in the immobility time and hyperalgesia on day 19, as well as marked increase in serum tumor necrosis factor-alpha (TNF-alpha) levels. Concurrent treatment with curcumin resulted in significantly decreased immobility time as well as hyperalgesia. There was significant attenuation of oxidative stress as well as TNF-alpha levels. These findings strongly suggest that during immunological activation, there is significant increase in oxidative stress and curcumin can be a valuable option in the treatment of chronic fatigue syndrome.
Hadlandsmyth K, Vowles KE.	Bath and Wiltshire Adult Chronic Fatigue Syndrome Service, Royal National Hospital	Does depression mediate the relation between fatigue severity and disability in	J Psychosom Res. 2009 Jan;66(1):31-5. Epub 2008 Nov 22.	OBJECTIVE: Chronic fatigue syndrome (CFS) is often associated with significant levels of disability. Although fatigue and depression have been found to be independently related to severity of disability, it is not clear how these three factors are mutually related. The present study sought to address this issue by specifically testing a model of mediation whereby depression was hypothesized to influence relations between fatigue and disability. METHODS: Participants included 90 individuals seeking

	for Rheumatic Diseases, Bath, UK. kehb8c@umsl.edu	chronic fatigue syndrome sufferers?		treatment for CFS at a tertiary care facility. Each provided demographic information and completed standardized measures of depression and fatigue severity, as well as a measure of disability, which assessed difficulties in physical, psychosocial, and independence domains. RESULTS: Analyses indicated that depression and fatigue were positively correlated with one another, as well as all three disability domains. Analyses of mediation indicated that depression completely mediated the relation between fatigue and psychosocial disability and partially mediated the relation between fatigue and the other two disability domains. Indirect effects tests indicated that the inclusion of depression in the statistical models was statistically meaningful. CONCLUSIONS: These results replicate previous findings that fatigue and depression are independently related to disability in those with CFS. A more complex statistical model, however, suggested that depression severity substantially influenced the strength of the relation between fatigue and disability levels across a range of domains, including complete mediation in areas involving psychosocial functioning. These results may aid in clarifying contemporary conceptualizations of CFS and provide guidance in the identification of appropriate treatment targets.
Haig-Ferguson A, Tucker P, Eaton N, Hunt L, Crawley E.	Centre for Child and Adolescent Health, University of Bristol, Bristol, UK. andrew.haig-ferguson@bristol.ac.uk	Memory and attention problems in children with chronic fatigue syndrome or myalgic encephalopathy.	Arch Dis Child. 2009 Oct;94(10):757-62. Epub 2008 Nov 11.	OBJECTIVE: To understand more about the problems children with chronic fatigue syndrome (CFS) or myalgic encephalopathy (ME) experience with memory and attention, and to test the feasibility of quantitative measurement of both memory and attention. DESIGN: Four-item semistructured questionnaire and neuropsychological test battery with 10 psychometric subtests. SETTING: Family home of the child taking part. PATIENTS: 20 children with a diagnosis of CFS/ME experiencing memory and/or concentration problems were recruited between April and October 2007 from a regional CFS/ME clinical service (female 13; average age 13.5 years; range 8-16). METHODS: Each child, parent and teacher was asked to describe the child's memory and attention problems. Responses were subject to thematic analysis by two independent researchers. In addition, each child completed a battery of 10 tests to measure: processing speed; attention; immediate and delayed memory; working memory; executive function. Raw scores were converted into age-scaled scores and the children's psychometric scores on the 10 tests taken were compared with normative data using t tests. RESULTS: Children with CFS/ME, their parents and teachers described problems with focussed attention, sustained attention, recall and stress. Scores for sustained attention (mean 8.1, 95% CI 6.3 to 9.9), switching attention (7.5, 5.5 to 9.4), divided attention (6.9, 5.5 to 8.2), auditory learning (8.2, 6.8 to 9.6) and immediate recall (8.7, 7.3 to 10.0) appeared lower than the normative mean of 10. CONCLUSIONS: Children with CFS/ME appear to experience problems with attention, which may have adverse implications for verbal memory. These cognitive problems may explain some of the educational difficulties associated with CFS.
Hamilton WT, Gallagher AM, Thomas JM, White PD.	Academic Unit of Primary Health Care, University of Bristol, Bristol, UK.	Risk markers for both chronic fatigue and irritable bowel syndromes: a prospective case-control study in	Psychol Med. 2009 Nov;39(11):1913-21. Epub 2009 Apr 15.	BACKGROUND: Fatigue syndromes and irritable bowel syndrome (IBS) often occur together. Explanations include being different manifestations of the same condition and simply sharing some symptoms. METHOD: A matched case-control study in UK primary care, using data collected prospectively in the General Practice Research Database (GPRD). The main outcome measures were: health-care utilization, specific symptoms and diagnoses. Risk markers were divided into distant (from 3 years to 1 year before diagnosis) and recent (1 year before diagnosis). RESULTS: A total of 4388 patients with any fatigue syndrome were matched to two groups of patients: those attending for IBS

		primary care.		and those attending for another reason. Infections were specific risk markers for both syndromes, with viral infections being a risk marker for a fatigue syndrome [odds ratios (ORs) 2.3-6.3], with a higher risk closer to onset, and gastroenteritis a risk for IBS (OR 1.47, compared to a fatigue syndrome). Chronic fatigue syndrome (CFS) shared more distant risk markers with IBS than other fatigue syndromes, particularly other symptom-based disorders (OR 3.8) and depressive disorders (OR 2.3), but depressive disorders were a greater risk for CFS than IBS (OR 2.4). Viral infections were more of a recent risk marker for CFS compared to IBS (OR 2.8), with gastroenteritis a greater risk for IBS (OR 2.4). CONCLUSIONS: Both fatigue and irritable bowel syndromes share predisposing risk markers, but triggering risk markers differ. Fatigue syndromes are heterogeneous, with CFS sharing predisposing risks with IBS, suggesting a common predisposing pathophysiology.
Hannonen P.	Keski-Suomen keskussairaala, sisätautien vastuualue, Keskussairaalantie 19, 40620 Jyväskylä.	[Is diagnosing fibromyalgia necessary?][Article in Finnish]	Duodecim. 2009;125(5):521-6.	Fibromyalgia is a controversial pain syndrome with chronic widespread pain (occurring on both sides of the body as well as axially below and above the waist) and unexplained fatigue as the predominating features. Fibromyalgia involves lots of symptoms focusing on different organ systems. In sensory examination the most significant finding is general allodynia. The widespread chronic pain and tender points at certain locations as reported by the patient differentiate fibromyalgia patients from those suffering from other diseases of the musculoskeletal system.
Hardy SE.	Division of Geriatric Medicine, University of Pittsburgh School of Medicine, Pittsburgh, Pennsylvania 15213, USA. hardysdom.pitt.edu	Methylphenidate for the treatment of depressive symptoms, including fatigue and apathy, in medically ill older adults and terminally ill adults.	Am J Geriatr Pharmacother. 2009 Feb;7(1):34-59.	BACKGROUND: Depressive symptoms, fatigue, and apathy are common symptoms among medically ill older adults and patients with advanced disease, and have been associated with morbidity and mortality. Methylphenidate has been used to treat these symptoms because of its rapid effect. Despite the long history of methylphenidate use for the treatment of depressive symptoms, fatigue, and apathy, there is little definitive evidence to support its use. OBJECTIVE: The aim of this paper was to review the efficacy and tolerability of methylphenidate in the treatment of depressive symptoms, fatigue, and apathy in medically ill older adults and adults receiving palliative care. METHODS: English-language articles presenting systematic reviews, clinical trials, or case series describing the use of methylphenidate for the treatment of depressive symptoms, fatigue, or apathy in medically ill older adults or adults receiving palliative care were identified. The key words methylphenidate and either depressive, depression, fatigue, or apathy were used to search the Cochrane Database, MEDLINE, PsycINFO, and International Pharmaceutical Abstracts. Included articles addressed depressive symptoms, fatigue, or apathy in (1) older adults (generally, age > or =65 years), particularly those with comorbid medical illness; (2) adults receiving palliative care; and (3) adults with other chronic illnesses. I excluded articles regarding treatment of depression in healthy young adults; bipolar disorder and attention-deficit/hyperactivity disorder; and narcolepsy, chronic fatigue syndrome, and related disorders. RESULTS: A total of 19 controlled trials of methylphenidate in medically ill older adults or patients in palliative care were identified. Unfortunately, their conflicting results, small sample sizes, and poor methodologic quality limited the ability to draw inferences regarding the efficacy of methylphenidate, although evidence of tolerability was stronger. The available evidence suggests possible effectiveness of methylphenidate for depressive symptoms, fatigue, and apathy in various medically ill populations. CONCLUSION: In the absence of definitive evidence of effectiveness, trials of low-dose methylphenidate in medically ill adults with depression, fatigue, or apathy, with

				monitoring for response and adverse effects, are appropriate.
Harvey SB, Wessely S, Kuh D, Hotopf M.	Institute of Psychiatry, King's College London, London, UK. s.harvey@iop.kcl.ac.uk	The relationship between fatigue and psychiatric disorders: evidence for the concept of neurasthenia.	J Psychosom Res. 2009 May;66(5):445-54. Epub 2009 Mar 3.	OBJECTIVE: Fatigue and psychiatric disorders frequently occur comorbidly and share similar phenomenological features. There has been debate as to whether chronic fatigue, or neurasthenia, should be considered an independent syndrome distinct from psychiatric disorders. We aimed to establish whether persistent fatigue can occur independently from psychiatric disorders and to test the hypothesis that fatigue without comorbid psychiatric symptoms has unique premorbid risk factors. We also aimed to investigate the psychological outcome of any individuals with fatigue. METHODS: The MRC National Survey of Health and Development was used to prospectively follow 5362 participants from birth. A sample of nonfatigued individuals without psychiatric disorder was selected at age 36 and followed until age 43 years (n=2714). At age 43, the presence of new onset fatigue and/or psychiatric disorder was assessed. Information on a number of potential premorbid risk factors was collected between ages 0 and 36 years. Individuals with fatigue but no comorbid psychiatric disorder were then followed up at age 53 years. RESULTS: At age 43 years, 201 (7.4%) participants reported significant levels of new onset fatigue in the absence of comorbid psychiatric disorder. Despite the absence of case level psychiatric disorder, these individuals did report increased levels of some psychological symptoms. Excessive childhood energy (adjusted OR 2.63, 95% CI 1.55-4.48, P<.001) and being overweight at age 36 (adjusted OR 1.62, 95% CI 1.05-2.49, P=.03) were specific risk factors for fatigue without psychiatric disorder but not fatigue with comorbid psychiatric illness. Neuroticism was a risk factor for fatigue both with and without comorbid psychiatric disorder. Negative life events and a family history of psychiatric illness were only risk factors for fatigue when it occurred comorbidly with psychiatric illness. CONCLUSIONS: A significant proportion of the adult population will suffer from fatigue without comorbid psychiatric disorder. While fatigue and psychiatric disorders share some risk factors, excessive energy in childhood and being overweight as an adult appear to be specific risk factors for fatigue. Our results confirm the significant overlap between fatigue and psychiatric disorders, while also providing evidence for neurasthenia as a separate diagnosis.
Harvey SB, Wessely S.		Tired all the time: can new research on fatigue help clinicians?Comment on: Br J Gen Pract. 2009 Apr;59(561):e93-100.	Br J Gen Pract. 2009 Apr;59(561):237-9.	
Harvey SB, Wessely S.	Institute of Psychiatry, King's College London, London, UK. samuel.b.harvey@kcl.ac.uk	Chronic fatigue syndrome: identifying zebras amongst the horses.	BMC Med. 2009 Oct 12;7:58. Comment on: BMC Med. 2009;7:57.	There are currently no investigative tools or physical signs that can confirm or refute the presence of chronic fatigue syndrome (CFS). As a result, clinicians must decide how long to keep looking for alternative explanations for fatigue before settling on a diagnosis of CFS. Too little investigation risks serious or easily treatable causes of fatigue being overlooked, whilst too many increases the risk of iatrogenic harm and reduces the opportunity for early focused treatment. A paper by Jones et al published this month in BMC Medicine may help clinicians in deciding how to undertake such

				investigations. Their results suggest that if clinicians look for common psychiatric and medical conditions in those complaining of prolonged fatigue, the rate of detection will be higher than previously estimated. The most common co-morbid condition identified was depression, suggesting a simple mental state examination remains the most productive single investigation in any new person presenting with unexplained fatigue. Currently, most diagnostic criteria advice CFS should not be diagnosed when an active medical or psychiatric condition which may explain the fatigue is identified. We discuss a number of recent prospective studies that have provided valuable insights into the aetiology of chronic fatigue and describe a model for understanding chronic fatigue which may be equally relevant regardless of whether or not an apparent medical cause for fatigue can be identified. See the associated research paper by Jones et al: http://www.biomedcentral.com/1741-7015/7/57.
Häuser W, Bernardy K, Uçeyler N, Sommer C.	Department of Internal Medicine, Klinikum Saarbrücken, Winterberg 1, D-66119 Saarbrücken, Germany. whaeuser@klinikum-saarbruecken.de	Treatment of fibromyalgia syndrome with antidepressants: a meta-analysis.	JAMA. 2009 Jan 14;301(2):198-209.	CONTEXT: Fibromyalgia syndrome (FMS) is a chronic pain disorder associated with multiple debilitating symptoms and high disease-related costs. Effective treatment options are needed. OBJECTIVES: To determine the efficacy of antidepressants in the treatment of FMS by performing a meta-analysis of randomized controlled clinical trials. DATA SOURCES: MEDLINE, PsycINFO, Scopus, and the Cochrane Library databases were searched through August 2008. Reference sections of original studies, meta-analyses, and reviews on antidepressants in FMS were reviewed. STUDY SELECTION: Randomized placebo-controlled trials with tricyclic and tetracyclic antidepressants (TCAs), selective serotonin reuptake inhibitors (SSRIs), serotonin and noradrenaline reuptake inhibitors (SNRIs), and monoamine oxidase inhibitors (MAOIs) were analyzed. DATA EXTRACTION AND DATA SYNTHESIS: Two authors independently extracted data. Effects were summarized using standardized mean differences (SMDs) by a random-effects model. RESULTS: Eighteen randomized controlled trials (median duration, 8 weeks; range, 4-28 weeks) involving 1427 participants were included. Overall, there was strong evidence for an association of antidepressants with reduction in pain (SMD, -0.43; 95% confidence interval [CI], -0.55 to -0.30), fatigue (SMD, -0.13; 95% CI, -0.26 to -0.01), depressed mood (SMD, -0.26; 95% CI, -0.39 to -0.12), and sleep disturbances (SMD, -0.32; 95% CI, -0.46 to -0.18). There was strong evidence for an association of antidepressants with improved health-related quality of life (SMD, -0.31; 95% CI, -0.42 to -0.20). Effect sizes for pain reduction were large for TCAs (SMD, -1.64; 95% CI, -2.57 to -0.71), medium for MAOIs (SMD, -0.54; 95% CI, -1.02 to -0.07), and small for SSRIs (SMD, -0.39; 95% CI, -0.77 to -0.01) and SNRIs (SMD, -0.36; 95% CI, -0.46 to -0.25). CONCLUSION: Antidepressant medications are associated with improvements in pain, depression, fatigue, sleep disturbances, and health-related quality of life in patients with FMS.
Häuser W, Grulke N, Michalski D, Hoffmann A, Akritidou I, Klauenberg S, Maier C, Hinz A.	Zentrum für interdisziplinäre Schmerztherapie/Innere Medizin I, Klinikum Saarbrücken gGmbH, Saarbrücken, Deutschland.	[Intensity of limb pain and fatigue in fibromyalgia syndrome, depressive disorders and chronic back pain. A criterion for differentiation][Art	Schmerz. 2009 Jun;23(3):267-74.	BACKGROUND: A symptom-based diagnosis of fibromyalgia syndrome (FMS) without tender point examination is needed for primary care. We tested if a symptom-based diagnosis of FMS can be founded on the intensity of the symptoms musculoskeletal pain and fatigue. METHODS: FMS patients from 4 different settings (n=464 members of the German Fibromyalgia Association DFV, n=33 from a private practice of rheumatology, n=36 from a tertiary care pain department, n=162 from medical expertise), patients with depressive disorders from 2 different settings (n=24 from a university department of psychiatry, n=311 from an out-patient university psychosomatic department), patients with chronic back pain from an out-patient training center (n=691) and persons from a representative German population sample (n=1977) were compared using the subscales of the Giessen subjective

	whaeuser@klinikum-saarbruecken.de	icle in German]		complaints list GBB 24. RESULTS: The greatest mean differences between FMS patients and the other samples were found within the subscales "limb pains" and "fatigue". FMS patients scored higher in the subscales "heart problems" and "dyspepsia", but both subscales did not contribute to a differentiation of the samples. The rates of reclassification of the subsamples based on the subscales "limb pains" and "fatigue" ranged between 80 and 93%. CONCLUSION: High levels of the intensity of chronic widespread musculoskeletal pain and chronic fatigue may form the basis of a symptom-based diagnosis of FMS.
Heim C, Nater UM, Maloney E, Boneva R, Jones JF, Reeves WC.	Department of Psychiatry and Behavioral Sciences, Emory University School of Medicine, Woodruff Memorial Research Bldg, Ste 4311, Atlanta, GA 30322, USA. cmheim@emory.edu	Childhood trauma and risk for chronic fatigue syndrome: association with neuroendocrine dysfunction.	Arch Gen Psychiatry. 2009 Jan;66(1):72-80.	CONTEXT: Childhood trauma appears to be a potent risk factor for chronic fatigue syndrome (CFS). Evidence from developmental neuroscience suggests that early experience programs the development of regulatory systems that are implicated in the pathophysiology of CFS, including the hypothalamic-pituitary-adrenal axis. However, the contribution of childhood trauma to neuroendocrine dysfunction in CFS remains obscure. OBJECTIVES: To replicate findings on the relationship between childhood trauma and risk for CFS and to evaluate the association between childhood trauma and neuroendocrine dysfunction in CFS. Design, Setting, and PARTICIPANTS: A case-control study of 113 persons with CFS and 124 well control subjects identified from a general population sample of 19 381 adult residents of Georgia. MAIN OUTCOME MEASURES: Self-reported childhood trauma (sexual, physical, and emotional abuse; emotional and physical neglect), psychopathology (depression, anxiety, and posttraumatic stress disorder), and salivary cortisol response to awakening. RESULTS: Individuals with CFS reported significantly higher levels of childhood trauma and psychopathological symptoms than control subjects. Exposure to childhood trauma was associated with a 6-fold increased risk of CFS. Sexual abuse, emotional abuse, and emotional neglect were most effective in discriminating CFS cases from controls. There was a graded relationship between exposure level and CFS risk. The risk of CFS conveyed by childhood trauma further increased with the presence of posttraumatic stress disorder symptoms. Only individuals with CFS and with childhood trauma exposure, but not individuals with CFS without exposure, exhibited decreased salivary cortisol concentrations after awakening compared with control subjects. CONCLUSIONS: Our results confirm childhood trauma as an important risk factor of CFS. In addition, neuroendocrine dysfunction, a hallmark feature of CFS, appears to be associated with childhood trauma. This possibly reflects a biological correlate of vulnerability due to early developmental insults. Our findings are critical to inform pathophysiological research and to devise targets for the prevention of CFS.
Hickie I, Davenport T, Vernon SD, Nisenbaum R, Reeves WC, Hadzi-Pavlovic D, Lloyd A; International Chronic Fatigue Syndrome Study Group.	Brain and Mind Research Institute, Camperdown, NSW, Australia. ianh@med.usyd.edu.au	Are chronic fatigue and chronic fatigue syndrome valid clinical entities across countries and health-care settings?	Aust N Z J Psychiatry. 2009 Jan;43(1):25-35.	OBJECTIVE: The validity of the diagnosis of chronic fatigue syndrome and related chronic fatigue states remains controversial, particularly in psychiatry. This project utilized international epidemiological and clinical research data to test construct validity across diagnostic categories, health-care settings and countries. Relevant demographic, symptom and diagnostic data were obtained from 33 studies in 21 countries. The subjects had fatigue lasting 1-6 months (prolonged fatigue), or >6 months (chronic fatigue), or met diagnostic criteria for chronic fatigue syndrome. METHOD: Common symptom domains were derived by factor analytic techniques. Mean scores on each symptom factor were compared across diagnostic categories, health-care settings and countries. RESULTS: Data were obtained on 37,724 subjects (n = 20,845 female, 57%), including from population-based studies (n = 15,749, 42%), studies in primary care (n = 19 472, 52%), and secondary or specialist

				tertiary referral clinics (n = 2503, 7%). The sample included 2013 subjects with chronic fatigue, and 1958 with chronic fatigue syndrome. A five-factor model of the key symptom domains was preferred ('musculoskeletal pain/fatigue', 'neurocognitive difficulties', 'inflammation', 'sleep disturbance/fatigue' and 'mood disturbance') and was comparable across subject groups and settings. Although the core symptom profiles were similar, some differences in symptoms were observed across diagnostic categories, health-care settings and between countries. CONCLUSIONS: The construct validity of chronic fatigue and chronic fatigue syndrome is supported by an empirically derived factor structure from existing international datasets.
Hokama Y, Campora CE, Hara C, Kuribayashi T, Le Huynh D, Yabusaki K.	Department of Pathology, John A. Burns School of Medicine, University of Hawaii at Mânoa, Honolulu, Hawaii 96822, USA.	Anticardiolipin antibodies in the sera of patients with diagnosed chronic fatigue syndrome.	J Clin Lab Anal. 2009;23(4):210-2.	Examination of anticardiolipin antibodies (ACAs) in the sera of patients clinically diagnosed with chronic fatigue syndrome (CFS) using an enzyme-linked immunoassay procedure demonstrated the presence of immunoglobulin M isotypes in 95% of CFS serum samples tested. The presence of immunoglobulin G and immunoglobulin A isotypes were also detected in a subset of the samples. Future studies will focus on elucidating whether alterations to mitochondrial inner membranes and/or metabolic functions play a possible role in the expression of ACAs.
Huang LC, Hsu SY, Lin E.	Department of Psychiatry, National Taiwan University Hospital Yun-Lin Branch, Taiwan. psychidr@gmail.com	A comparison of classification methods for predicting Chronic Fatigue Syndrome based on genetic data.	J Transl Med. 2009 Sep 22;7:81.	BACKGROUND: In the studies of genomics, it is essential to select a small number of genes that are more significant than the others for the association studies of disease susceptibility. In this work, our goal was to compare computational tools with and without feature selection for predicting chronic fatigue syndrome (CFS) using genetic factors such as single nucleotide polymorphisms (SNPs). METHODS: We employed the dataset that was original to the previous study by the CDC Chronic Fatigue Syndrome Research Group. To uncover relationships between CFS and SNPs, we applied three classification algorithms including naive Bayes, the support vector machine algorithm, and the C4.5 decision tree algorithm. Furthermore, we utilized feature selection methods to identify a subset of influential SNPs. One was the hybrid feature selection approach combining the chi-squared and information-gain methods. The other was the wrapper-based feature selection method. RESULTS: The naive Bayes model with the wrapper-based approach performed maximally among predictive models to infer the disease susceptibility dealing with the complex relationship between CFS and SNPs. CONCLUSION: We demonstrated that our approach is a promising method to assess the associations between CFS and SNPs.

Hurwitz BE, Coryell VT, Parker M, Martin P,	Behavioral Medicine Research Center, University	Chronic fatigue syndrome: illness severity, sedentary	Clin Sci (Lond). 2009 Oct 19;118(2):125-35.	The study examined whether deficits in cardiac output and blood volume in a CFS (chronic fatigue syndrome) cohort were present and linked to illness severity and sedentary lifestyle. Follow-up analyses assessed whether differences in cardiac output levels between CFS and control groups were

Laperriere A, Klimas NG, Sfakianakis GN, Bilsker MS.	of Miami, Miami, FL 33136, USA. bhurwitz@miami.edu	lifestyle, blood volume and evidence of diminished cardiac function.	Comment in: Clin Sci (Lond). 2010 Jan;118(2):121-3.	corrected by controlling for cardiac contractility and TBV (total blood volume). The 146 participants were subdivided into two CFS groups based on symptom severity data, severe (n=30) and non-severe (n=26), and two healthy non-CFS control groups based on physical activity, sedentary (n=58) and non-sedentary (n=32). Controls were matched to CFS participants using age, gender, ethnicity and body mass. Echocardiographic measures indicated that the severe CFS participants had 10.2% lower cardiac volume (i.e. stroke index and end-diastolic volume) and 25.1% lower contractility (velocity of circumferential shortening corrected by heart rate) than the control groups. Dual tag blood volume assessments indicated that the CFS groups had lower TBV, PV (plasma volume) and RBCV (red blood cell volume) than control groups. Of the CFS subjects with a TBV deficit (i.e. > or = 8% below ideal levels), the mean+/-S.D. percentage deficit in TBV, PV and RBCV were -15.4+/-4.0, -13.2+/-5.0 and -19.1+/-6.3% respectively. Lower cardiac volume levels in CFS were substantially corrected by controlling for prevailing TBV deficits, but were not affected by controlling for cardiac contractility levels. Analyses indicated that the TBV deficit explained 91-94% of the group differences in cardiac volume indices. Group differences in cardiac structure were offsetting and, hence, no differences emerged for left ventricular mass index. Therefore the findings indicate that lower cardiac volume levels, displayed primarily by subjects with severe CFS, were not linked to diminished cardiac contractility levels, but were probably a consequence of a co-morbid hypovolaemic condition. Further study is needed to address the extent to which the cardiac and blood volume alterations in CFS have physiological and clinical significance.
Inamitsu T.	Section of Psychosomatic Medicine, Fukuoka Dental College.	[Functional somatic syndrome in dental practice] [Article in Japanese]	Nippon Rinsho. 2009 Sep;67(9):1749-54.	Functional somatic syndromes (FSSs) are common in dental as well as medical practice. Many patients with unexplained symptoms in oro-maxillo-facial areas visit dentists, but they are not diagnosed and treated properly. Temporomandibular disorder, atypical facial pain, and glossodynia (burning mouth syndrome) are included in dental FSSs. These diseases overlap with each other and with FSSs in other organs, such as myofacial pain syndrome, tension-type headache, fibromyalgia, and chronic fatigue syndrome. They coexist with mental disorders, such as anxiety disorder, mood disorder, and somatoform disorder. Multidisciplinary and holistic approaches should be applied to dental FSSs; pharmacological therapy (antidepressants), physical therapy, and cognitive-behavioral therapy. Clinicians have to support a patient in"enjoying his/her life with symptoms". Dental specialists in "oral medicine" with psychosomatic viewpoints are now required.
Jammes Y, Steinberg JG, Delliaux S, Brégeon F.	UMR MD2 (P2COE), Faculté de Médecine, Université de la Méditerranée, North Hospital, Assistance Publique - Hôpitaux de Marseille, France. yves.jammes@univ	Chronic fatigue syndrome combines increased exercise-induced oxidative stress and reduced cytokine and Hsp responses.	J Intern Med. 2009 Aug;266(2):196-206. Epub 2009 May 19.	OBJECTIVES: As heat shock proteins (Hsp) protect the cells against the deleterious effects of oxidative stress, we hypothesized that Hsp expression might be reduced in patients suffering from chronic fatigue syndrome (CFS) who present an accentuated exercise-induced oxidative stress. DESIGN: This case-control study compared nine CFS patients to a gender-, age- and weight-matched control group of nine healthy sedentary subjects. INTERVENTIONS: All subjects performed an incremental cycling exercise continued until exhaustion. We measured ventilation and respiratory gas exchange and evoked compound muscle potential (M-wave) recorded from vastus lateralis. Repetitive venous blood sampling allowed measurements of two markers of oxidative stress [thiobarbituric acid reactive substances (TBARS) and reduced ascorbic acid (RAA)], two cytokines (IL-6 and TNF-alpha) and two Hsp (Hsp27 and Hsp70) at rest, during maximal exercise and the 60-min recovery period. RESULTS: Compared with controls, resting CFS patients had low baseline levels of RAA and Hsp70. Their

	med.fr			response to maximal exercise associated (i) M-wave alterations indicating reduced muscle membrane excitability, (ii) early and accentuated TBARS increase accompanying reduced changes in RAA level, (iii) absence of significant increase in IL-6 and TNF-alpha, and (iv) delayed and marked reduction of Hsp27 and Hsp70 variations. The post-exercise increase in TBARS was accentuated in individuals having the lowest variations of Hsp27 and Hsp70. CONCLUSIONS: The response of CFS patients to incremental exercise associates a lengthened and accentuated oxidative stress, which might result from delayed and insufficient Hsp production.
Jason L, Benton M, Torres-Harding S, Muldowney K.	DePaul University, Center for Community Research, Chicago, IL 60614, USA. Ljason@depaul.edu	The impact of energy modulation on physical functioning and fatigue severity among patients with ME/CFS.	Patient Educ Couns. 2009 Nov;77(2):237-41. Epub 2009 Apr 8. Comment in: Patient Educ Couns. 2009 Nov;77(2):153-4.	OBJECTIVE: The energy envelope postulates that patients with Myalgic Encephalomyelitis/chronic fatigue syndrome (ME/CFS) will improve functioning when maintaining expended energy levels at the same level as available energy level. METHODS: Estimated weekly Energy Quotients were established by dividing expended energy level by perceived energy level and multiplying by 100. Two groups of patients were identified following participation in a non-pharmacologic intervention trial. Some were able to keep expended energy close to available energy and others were not successful at this task. RESULTS: Those who were able to stay within their energy envelope had significant improvements in physical functioning and fatigue severity. CONCLUSION: Findings suggest that helping patients with ME/CFS maintain appropriate energy expenditures in coordination with available energy reserves can help improve functioning over time. PRACTICE IMPLICATIONS: Health care professionals that treat patients with ME/CFS might incorporate strategies that help patients self-monitor and self-regulate energy expenditures.
Jason L, Porter N, Shelleby E, Till L, Bell DS, Lapp CW, Rowe K, De Meirleir K.	Center for Community Research, DePaul University, Chicago, IL 60614, USA. Ljason@depaul.edu	Severe versus Moderate criteria for the new pediatric case definition for ME/CFS.	Child Psychiatry Hum Dev. 2009 Dec;40(4):609-20. Epub 2009 Jun 10.	The new diagnostic criteria for pediatric ME/CFS are structurally based on the Canadian Clinical Adult case definition, and have more required specific symptoms than the (Fukuda et al. Ann Intern Med 121:953-959, 1994) adult case definition. Physicians specializing in pediatric ME/CFS referred thirty-three pediatric patients with ME/CFS and 21 youth without the illness. Those who met ME/CFS criteria were separated into Severe and Moderate categories. Significant differences were found for symptoms within each of the six major categories: fatigue, post-exertional malaise, sleep, pain, neurocognitive difficulties, and autonomic/neuroendocrine/immune manifestations. In general, the results showed participants who met the Severe ME/CFS criteria reported the highest scores, the Moderate ME/CFS group show scores that were a little lower, and the control group evidenced the lowest scores. Findings indicate that the Pediatric Case Definition for ME/CFS can distinguish between those with this illness and controls, and between those with Severe versus Moderate manifestations of the illness.
Jason LA, Roesner N, Porter N, Parenti B, Mortensen J, Till L.	DePaul University.	Provision of social support to individuals with chronic fatigue syndrome.	J Clin Psychol. 2009 Nov 9. [Epub ahead of print]	The present study evaluated a buddy program designed to provide support for individuals with chronic fatigue syndrome (CFS). The intervention involved weekly visits by a student paraprofessional, who helped out with tasks that needed to be done in an effort to reduce some of the taxing demands and responsibilities that participants regularly encountered. This model of rehabilitation focused on avoiding overexertion in persons with CFS, aiming to avoid setbacks and relapses while increasing their tolerance for activity. Participants with CFS were randomly assigned to either a 4-month buddy intervention or a control condition. Posttest results showed that individuals who received a student buddy intervention had significantly greater reductions in fatigue severity and increases in vitality than individuals in the control condition. There were no significant changes between groups for

				physical functioning and stress. Buddy interventions that help patients with CFS reduce overexertion and possibly remain within their energy envelopes can be thought of as representing a different paradigm than nonpharmacologic interventions that focus only on increasing levels of activity through graded exercise. Jones JF, Lin JM, Maloney EM, Boneva RS, Nater UM, Unger ER, Reeves WC.	Chronic Viral Diseases Branch, Coordinating Center for Infectious Diseases, Centers for Disease Control and Prevention, 1600 Clifton Road, MS A15, Atlanta, GA 30333, USA. jaj9@cdc.gov	An evaluation of exclusionary medical/psychiatric conditions in the definition of chronic fatigue syndrome.	BMC Med. 2009 Oct 12;7:57. Comment in: BMC Med. 2009;7:58.	BACKGROUND: The diagnosis of chronic fatigue syndrome (CFS) in research studies requires the exclusion of subjects with medical and psychiatric conditions that could confound the analysis and interpretation of results. This study compares illness parameters between individuals with CFS who have and those who do not have exclusionary conditions. METHODS: We used a population-based telephone survey of randomly selected individuals, followed by a clinical evaluation in the study metropolitan, urban, and rural counties of Georgia, USA. The medical and psychiatric histories of the subjects were examined and they underwent physical and psychiatric examinations and laboratory screening. We also employed the multidimensional fatigue inventory (MFI), the medical outcomes survey short form-36 (SF-36) and the US Centres for Disease Control and Prevention symptom inventory (SI). RESULTS: Twenty-nine percent (1,609) of the 5623 subjects who completed the detailed telephone interview reported exclusionary diagnoses and we diagnosed an exclusionary condition in 36% of 781 clinically evaluated subjects. Both medical and psychiatric exclusionary conditions were more common in women, blacks and participants from rural areas. Subjects with and without exclusions had similar levels of fatigue and impairment as measured by the MFI and SF-36; those with CFS-like illness (not meeting the formal CFS definition) were more likely to have an exclusionary diagnosis. After adjusting for demographics, body mass index, fatigue subscales, SF-36 subscales and CFS symptoms, CFS-like illness did not remain significantly associated with having an exclusionary diagnosis. CONCLUSION: Medical and psychiatric illnesses associated with fatigue are common among the unwell. Those who fulfill CFS-like criteria need to be evaluated for potentially treatable conditions. Those with exclusionary conditions are equally impaired as those without exclusions.

Epub 2008 Jun 12.	Q fever is a common zoonosis with almost a worldwide distribution caused by Coxiella burnetii. Farm animals and pets are the main reservoirs of infection and transmission to humans is usually via inhalation of contaminated aerosols. Infection in humans is often asymptomatic, but it can manifest as an acute disease (usually a self-limited flu-like illness, pneumonia or hepatitis) or as a chronic form (mainly endocarditis, but also hepatitis and chronic-fatigue syndrome). In Tunisia, although

	Mohamed-Karoui, 4000 Sousse, Tunisie. naoufelkaabia2001@yahoo.fr			prevalence of anti-Coxiella burnetii was high among blood donors, Q fever was rarely reported and frequently miss diagnosed by physicians. This study is a review of epidemiological and clinical particularities of Q fever in Tunisia.
Kane JM, Correll CU, Goff DC, Kirkpatrick B, Marder SR, Vester-Blokland E, Sun W, Carson WH, Pikalov A, Assunção-Talbott S.	Department of Psychiatry, The Zucker Hillside Hospital, Glen Oaks, NY 11004-1150, USA. psychiatry@lij.edu	A multicenter, randomized, double-blind, placebo-controlled, 16-week study of adjunctive aripiprazole for schizophrenia or schizoaffective disorder inadequately treated with quetiapine or risperidone monotherapy.	J Clin Psychiatry. 2009 Oct;70(10):1348-57.	OBJECTIVE: Combining antipsychotics is common practice in the treatment of schizophrenia. This study investigated aripiprazole adjunctive to risperidone or quetiapine for treating schizophrenia and schizoaffective disorder. METHOD: In this multicenter, double-blind, 16-week, placebo-controlled study conducted at 43 American sites from July 2006 to October 2007, patients with chronic, stable schizophrenia or schizoaffective disorder diagnosed with DSM-IV-TR were randomly assigned to receive aripiprazole (2-15 mg/d) or placebo in addition to a stable regimen of quetiapine (400-800 mg/d) or risperidone (4-8 mg/d). The primary outcome measure was the mean change from baseline to endpoint (week 16, last observation carried forward) in the Positive and Negative Syndrome Scale (PANSS) total score. RESULTS: 323 subjects being treated with either risperidone (n = 177) or quetiapine (n = 146) were randomly assigned to receive adjunctive aripiprazole (n = 168) or placebo (n = 155). Baseline characteristics were similar (mean PANSS total score: aripiprazole, 74.5; placebo, 75.9) except for history of suicide attempts (aripiprazole, 27%; placebo, 40%). Nearly 70% of subjects in each arm completed the trial. Adjunctive aripiprazole and placebo groups were similar in the mean change from baseline to endpoint in the PANSS total score (aripiprazole, -8.8; placebo, -8.9; P = .942). The incidence of treatment-emergent adverse events was similar between groups. Mean changes in Simpson-Angus Scale, Abnormal Involuntary Movement Scale, and Barnes Akathisia Rating Scale scores were not statistically significantly different. Adjunctive aripiprazole was associated with statistically significantly greater decreases in mean serum prolactin levels from baseline than was adjunctive placebo (-12.6 ng/mL for aripiprazole vs -2.2 ng/mL for placebo; P < .001), an effect that was seen in the risperidone subgroup (-18.7 ng/mL vs -1.9 ng/mL; P < .001) but not in the quetiapine subgroup (-3.01 ng/mL vs +0.15 ng/mL; P = .104). CONCLUSIONS: The addition of aripiprazole to risperidone or quetiapine was not associated with improvement in psychiatric symptoms but was generally safe and well tolerated. Further research is warranted to explore whether antipsychotic combination therapy offers benefits to particular patient populations-for example, in cases of hyperprolactinemia. J Occup Environ Med. 2009 Apr;51(4):401-10.	OBJECTIVE: To assess periodically the health status of a cohort of 1991 Gulf War veterans by comparing various health outcomes with those of their military peers who were not deployed to the Gulf. METHODS: We conducted a follow-up health survey to collect health information among population-based samples of 30,000 veterans (15,000 Gulf War veterans and 15,000 Gulf Era veterans) using a structured questionnaire. RESULTS: Gulf veterans reported significantly higher rates of unexplained multi-symptom illness, chronic fatigue syndrome-like illness, posttraumatic stress disorder, functional impairment, health care utilization, a majority of selected physical conditions and all mental disorders queried during the survey than did Gulf Era veteran controls. CONCLUSIONS: Fourteen years after deployment, 1991 Gulf War veterans continue to report a higher prevalence of

				many adverse health outcomes, compared with Gulf Era veterans.

Kato K, Sullivan PF, Evengård B, Pedersen NL.	School of Nursing and Rehabilitation, International University of Health and Welfare at Odawara, Kanagawa, Japan. kenji-kato@umin.ac.jp	A population-based twin study of functional somatic syndromes.	Psychol Med. 2009 Mar;39(3):497-505. Epub 2008 Jun 26.	BACKGROUND: The mechanisms underlying the co-occurrence of the functional somatic syndromes are largely unknown. No empirical study has explicitly examined how genetic and environmental factors influence the co-morbidity of these syndromes. We aimed to examine how the co-morbidity of functional somatic syndromes is influenced by genetic and environmental factors that are in common to the syndromes. METHOD: A total of 31318 twins in the Swedish Twin Registry aged 41-64 years underwent screening interviews via a computer-assisted telephone system from 1998 to 2002. Four functional somatic syndromes (chronic widespread pain, chronic fatigue, irritable bowel syndrome, and recurrent headache) and two psychiatric disorders (major depression and generalized anxiety disorder) were assessed using structured questions based on standard criteria for each illness in a blinded manner. RESULTS: Multivariate twin analyses revealed that a common pathway model with two latent traits that were shared by the six illnesses fit best to the women's data. One of the two latent traits loaded heavily on the psychiatric disorders, whereas the other trait loaded on all four of the functional somatic syndromes, particularly chronic widespread pain, but not on the psychiatric disorders. All illnesses except the psychiatric disorders were also affected by genetic influences that were specific to each. CONCLUSIONS: The co-occurrence of functional somatic syndromes in women can be best explained by affective and sensory components in common to all these syndromes, as well as by unique influences specific to each of them. The findings clearly suggest a complex view of the multifactorial pathogenesis of these illnesses.

Katz BZ, Shiraishi Y, Mears CJ, Binns HJ, Taylor R.	Department of Pediatrics, Division of Infectious Diseases, Northwestern University Feinberg School of Medicine and Children's Memorial Hospital, Chicago, Illinois 60614, USA. bkatz@northwestern.edu	Chronic fatigue syndrome after infectious mononucleosis in adolescents.	Pediatrics. 2009 Jul;124(1):189-93.	OBJECTIVE: The goal was to characterize prospectively the course and outcome of chronic fatigue syndrome in adolescents during a 2-year period after infectious mononucleosis. METHODS: A total of 301 adolescents (12-18 years of age) with infectious mononucleosis were identified and screened for nonrecovery 6 months after infectious mononucleosis by using a telephone screening interview. Nonrecovered adolescents underwent a medical evaluation, with follow-up screening 12 and 24 months after infectious mononucleosis. After blind review, final diagnoses of chronic fatigue syndrome at 6, 12, and 24 months were made by using established pediatric criteria. RESULTS: Six, 12, and 24 months after infectious mononucleosis, 13%, 7%, and 4% of adolescents, respectively, met the criteria for chronic fatigue syndrome. Most individuals recovered with time; only 2 adolescents with chronic fatigue syndrome at 24 months seemed to have recovered or had an explanation for chronic fatigue at 12 months but then were reclassified as having chronic fatigue syndrome at 24 months. All 13 adolescents with chronic fatigue syndrome 24 months after infectious mononucleosis were female and, on average, they reported greater fatigue severity at 12 months. Reported use of steroid therapy during the acute phase of infectious mononucleosis did not increase the risk of developing chronic fatigue syndrome. CONCLUSIONS: Infectious mononucleosis may be a risk factor for chronic fatigue syndrome in adolescents. Female gender and greater fatigue severity, but not reported steroid use during the acute illness, were associated with the development of chronic fatigue syndrome in adolescents. Additional research is needed to determine other predictors of persistent fatigue after infectious mononucleosis.

Kelsall HL, McKenzie DP, Sim MR, Leder K, Forbes AB, Dwyer T.	Monash Centre for Occupational and Environmental Health, Department of Epidemiology and Preventive Medicine, Monash University, Alfred Hospital, Melbourne, Australia. helen.kelsall@med.monash.edu.au	Physical, psychological, and functional comorbidities of multisymptom illness in Australian male veterans of the 1991 Gulf War.	Am J Epidemiol. 2009 Oct 15;170(8):1048-56. Epub 2009 Sep 17.	Multisymptom illness is more prevalent in 1991 Gulf War veterans than in military comparison groups; less is known about comorbidities. The authors compared physical, psychological, and functional comorbidities in Australian male Gulf War I veterans with those in actively (non-Gulf) deployed and nondeployed military personnel by using a questionnaire and medical assessment in 2000-2002. Multisymptom illness was more common in male Gulf War veterans than in the comparison group (odds ratio (OR) = 1.80, 95% confidence interval (CI): 1.48, 2.19). Stratifying by deployment status in the comparison group made little difference in this association. Gulf War veterans with multisymptom illness had increased psychiatric disorders, including major depression (OR = 6.31, 95% CI: 4.19, 9.52) and posttraumatic stress disorder (OR = 9.77, 95% CI: 5.39, 18.59); increased unexplained chronic fatigue (OR = 13.32, 95% CI: 7.70, 23.05); and more reported functional impairment and poorer quality of life, but objective physical and laboratory outcomes were similar to those for veterans without multisymptom illness. Similar patterns were found in the comparison groups; differences across the 3 groups were statistically significant for only hospitalization, obstructive liver disease, and Epstein-Barr virus exposure. Multisymptom illness is more prevalent in Gulf War I veterans, but the pattern of comorbidities is similar for actively deployed and nondeployed military personnel.
Kerr JR, Gough J,	St George's	Antibody to	J Gen Virol.. [Epub	Chronic Fatigue Syndrome / Myalgic Encephalomyelitis (CFS/ME) is a neuro-immune disease of

Richards SC, Main J, Enlander D, McCreary M, Komaroff AL, Chia JK.	University of London;	parvovirus B19 nonstructural protein is associated with chronic arthralgia in patients with Chronic Fatigue Syndrome / Myalgic Encephalomyelitis (CFS/ME).	ahead of print]	uncertain pathogenesis. Human parvovirus B19 infection has been shown to occur just prior to development of the onset of CFS/ME in several cases, although B19 seroprevalence studies do not shown any significant differences between CFS/ME and controls. In this study, we analysed parvovirus B19 markers in CFS/ME patients (n=200), diagnosed according to Fukuda CDC criteria, and normal blood donors (n=200). Serum from each subject was tested for anti-B19 VP2 IgM and IgG (by Biotrin ELISA), anti-B19 NS1 IgM and IgG (by immunoflourescence), and B19 DNA by real-time PCR. CFS/ME patients and normal blood donors had a similar B19 seroprevalence (75% versus 78%, respectively). Eighty-three CFS patients (41.5%) as compared with fourteen (7%) of normal blood donors tested positive for anti-B19 NS1 IgG (chi(2)= 64.8; P<0.0001; Odds ratio = 9.42, CI 5.11 - 17.38). Of these 83 patients, 61 complained of chronic joint pain, while 22 did not. Parvovirus B19 DNA was detected in serum of 11 CFS patients and none of the controls by Taqman real-time PCR (chi(2) = 9.35, P<0.002. Positivity for anti-B19 NS1 IgG was associated with higher expression levels of the human CFS-associated genes NHLH1 and GABPA. As NS1 antibodies are thought to indicate chronic or severe courses of B19 infection, these findings suggest that although the seroprevalence of B19 in CFS patients is similar to controls, the immune control of the virus may not be efficient.

Department of Neurology, Erasmus MC, University Medical Center, Rotterdam, The Netherlands. k.kuitwaard@erasmusmc.nl	Recurrences, vaccinations and long-term symptoms in GBS and CIDP.	J Peripher Nerv Syst. 2009 Dec;14(4):310-5.	We determined the frequency of recurrent Guillain-Barré syndrome (GBS), whether vaccinations led to recurrences of GBS or an increase of disability in chronic inflammatory demyelinating polyradiculoneuropathy (CIDP) and we assessed the prevalence of pain, fatigue and the impact on quality of life after GBS and CIDP. Additionally, we assessed the presence of common auto-immune disorders. Four hundred and sixty-one members of the Dutch society of neuromuscular disorders received a questionnaire. Two hundred and forty-five GBS and seventy-six CIDP patients were included (response rate 70%). Nine patients had a confirmed recurrent GBS, and two patients had experienced both GBS and CIDP. Common auto-immune diseases were reported in 9% of GBS and 5% of CIDP patients. None of the 106 GBS patients who received a flu vaccination (range 1-37 times, total 775 vaccinations) reported a recurrence thereafter. Five out of twenty-four CIDP patients who received a flu vaccination (range 1-17 times) reported an increase in symptoms. Pain or severe fatigue was reported in about 70% of patients after the diagnosis of GBS (median 10 years) or after onset of CIDP (median 6 years), and quality of life was significantly reduced. Flu vaccinations seem relatively safe. GBS and CIDP patients often experience pain, fatigue and a reduced quality of life for many years after the diagnosis.
Kumar A, Garg R.	Pharmacology Division, University Institute of Pharmaceutical Sciences, Panjab University, Chandigarh 160014, India. kumaruips@yahoo.com	Protective effects of antidepressants against chronic fatigue syndrome-induced behavioral changes and biochemical alterations.	Fundam Clin Pharmacol. 2009 Feb;23(1):89-95. Epub 2009 Jan 10.	Chronic fatigue syndrome (CFS) is characterized by profound fatigue, which substantially interferes with daily activities. The aim of this study was to explore the protective effects of antidepressants in an animal model of CFS in mice. Male albino mice were forced to swim individually for a period of 6-min session each for 7 days. Imipramine (10 and 20 mg/kg), desipramine (10 and 20 mg/kg) and citalopram (5 and 10 mg/kg) were administered 30 min before forced swimming test on each day. Various behavior tests (immobility time, locomotor activity, anxiety-like behavior by plus maze and mirror chamber) followed by biochemical parameters (lipid peroxidation, reduced glutathione, catalase and nitrite level) were assessed in chronic stressed mice. Chronic forced swimming for 7 days significantly caused increase in immobility period, impairment in locomotor activity, anxiety-like behavior, and oxidative stress (raised lipid peroxidation, nitrite activity and reduced glutathione and catalase activity) as compared with naïve mice ($P < 0.05$). Seven days of pretreatment with imipramine (10 and 20 mg/kg), desipramine (10 and 20 mg/kg), and citalopram (5 and 10 mg/kg) significantly reduced immobility time, improved locomotor activity and anti-anxiety effect (in both plus maze and mirror chamber test), and attenuated oxidative stress in chronic stressed mice as compared with control (chronic fatigues) ($P < 0.05$). These results suggested that these drugs have protective effect and could be used in the management of chronic fatigue like conditions.
Kuo YH, Tsai WJ, Loke SH, Wu TS, Chiou WF.	National Research Institute of Chinese Medicine, Taipei, Taiwan, ROC.	Astragalus membranaceus flavonoids (AMF) ameliorate chronic fatigue syndrome induced by food	J Ethnopharmacol. 2009 Feb 25;122(1):28-34. Epub 2008 Dec 6.	AIM OF THE STUDY: Alteration of immune function may be associated with chronic fatigue syndrome (CFS) and this study reveals the immunoregulatory effect of Astragalus membranaceus flavonoids (AMF). MATERIALS AND METHODS: CF rats were induced by food intake restriction plus forced swimming for 6 weeks. RESULTS: An atrophied spleen associated with a significantly decreased spleen/body weight ratio and a reduced spleen cells proliferation was found in CF rats when compared with home cage controls. AMF given orally at 20, 50 and 100 mg/kg body weight once a day

		intake restriction plus forced swimming.		consecutively for 6 weeks could recover the reduced cell proliferation. A switch to Th1-dominated immune regulation was observed in CF rats as the cultured splenocytes produced more interleukin-2 (IL-2) but less IL-4 when compared with controls. Supplementation with AMF could significantly counteract the aberrant cytokine production and rats received AMF exhibited higher endurance capacity to swim when compared with those without AMF administration. Checking the spectrum signals confirmed that the three major isoflavones contained in AMF were ononin, formononetin, and demethylhomopterocarpin. CONCLUSION: Alterations of immune function may be associated with CFS and the tonic effects of AMF against CF may be attributable to balance the abnormal cytokine level by isoflavones.
Kuwabara N, Itoh Y, Igarshi T, Fukunaga Y.	Department of Pediatrics, Nippon Medical School, Bunkyo City, Tokyo, Japan.	Autoantibodies to lens epithelium-derived growth factor/transcription co-activator P75 (LEDGF/P75) in children with chronic nonspecific complaints and with positive antinuclear antibodies.	Autoimmunity. 2009 Sep;42(6):492-6.	Autoimmune fatigue syndrome (AIFS) is characterized by chronic nonspecific complaints, consistently positive antinuclear antibodies (ANA), and lack of alternate medical explanations. A newly recognized antibody, named anti-Sa, was detected in approximately 40% of the patients by Western blot (WB) using HeLa extract. Some patients with AIFS later develop chronic fatigue syndrome (CFS), and most of them are positive for anti-Sa. On the other hand, Muro et al. reported anti-DFS70 in patients with CFS. Anti-Sa and anti-DFS70 were turned out to be same specificities by exchanging studies of blind sera. The target antigen of anti-DFS70 was identified as lens epithelium derived growth factor/transcription co-activator p75 (LEDGF/p75). The objectives of this study are to confirm whether the target antigen of anti-Sa is also LEDGF/p75, and to develop ELISA system by using recombinant protein. Recombinant protein of LEDGF/p75 was purchased from Protein One (Bethesda, MD, USA). We developed an ELISA system to detect anti-LEDGF/p75 by coating this recombinant protein. 226 sera of AIFS patients (including 36 CFS patients) were applied to this ELISA assay and Western immunoblot, and it was revealed that anti-Sa-positive sera defined by WB and sera positive for anti-LEDGF/p75 on ELISA were identical. Moreover, reactivities of anti-Sa on WB were inhibited by pre-incubating with recombinant LEDGF/p75, and eluted antibodies from the nitrocellulose membrane could react on the ELISA. These results confirm that the Sa antigen is LEDGF/p75. The ELISA assay using recombinant LEDGF/p75 could be a promising tool for measuring anti-Sa and consequently for diagnosing CFS.
Lam MH, Wing YK, Yu MW, Leung CM, Ma RC, Kong AP, So WY, Fong SY, Lam SP.	Department of Psychiatry, The Chinese University of Hong Kong, China.	Mental morbidities and chronic fatigue in severe acute respiratory syndrome survivors: long-term follow-up.	Arch Intern Med. 2009 Dec 14;169(22):2142-7.	BACKGROUND: Short-term follow-up studies of severe acute respiratory syndrome (SARS) survivors suggested that their physical conditions continuously improved in the first year but that their mental health did not. We investigated long-term psychiatric morbidities and chronic fatigue among SARS survivors. METHODS: All SARS survivors from the hospitals of a local region in Hong Kong were assessed by a constellation of psychometric questionnaires and a semistructured clinical interview for the Diagnostic and Statistical Manual of Mental Disorders (Fourth Edition) to determine the presence of psychiatric disorders and chronic fatigue problems. RESULTS: Of 369 SARS survivors, 233 (63.1%) participated in the study (mean period of time after SARS, 41.3 months). Over 40% of the respondents had active psychiatric illnesses, 40.3% reported a chronic fatigue problem, and 27.1% met the modified 1994 Centers for Disease Control and Prevention criteria for chronic fatigue syndrome. Logistic regression analysis suggested that being a health care worker at the time of SARS infection (odds ratio [OR], 3.24; 95% confidence interval [CI], 1.12- 9.39; P = .03), being unemployed at follow-up (OR, 4.71; 95% CI, 1.50-14.78; P = .008), having a perception of social stigmatization (OR, 3.03; 95% CI, 1.20-7.60; P = .02), and having applied to the SARS survivors' fund (OR, 2.92; 95% CI, 1.18-7.22; P =

				.02) were associated with an increased risk of psychiatric morbidities at follow-up, whereas application to the SARS survivors' fund (OR, 2.64; 95% CI, 1.07-6.51; P = .04) was associated with increased risk of chronic fatigue problems. CONCLUSIONS: Psychiatric morbidities and chronic fatigue persisted and continued to be clinically significant among the survivors at the 4-year follow-up. Optimization of the treatment of mental health morbidities by a multidisciplinary approach with a view for long-term rehabilitation, especially targeting psychiatric and fatigue problems and functional and occupational rehabilitation, would be needed.
Land ST.	Loddon, Norwich, UK. derek.land@electramail.co.uk	20 years ago: The British Homoeopathic Journal, January 1989.	Homeopathy. 2009 Jan;98(1):65-7; discussion 71-2.	
Lansang MC, Farmer T, Kennedy L.	Department of Medicine, Division of Endocrinology, University of Florida, Gainesville, Florida 32610, USA. lansamc@medicine.ufl.edu	Diagnosing the unrecognized systemic absorption of intra-articular and epidural steroid injections.	Endocr Pract. 2009 May-Jun;15(3):225-8.	OBJECTIVE: To present a case series of patients who were misdiagnosed with endocrine disorders because of failure to recognize the systemic absorption of intra-articular and epidural steroids and to discuss the utility of performing a urine screen to detect synthetic glucocorticoids. METHODS: In this case series, we describe the clinical, laboratory, and imaging findings of 3 patients referred to our clinic, each with a presumed endocrine disorder. RESULTS: Patient 1 was a 54-year-old woman with weakness, loss of appetite, and a hormonal profile suggestive of hypopituitarism. Patient 2 was a 49-year-old woman with chronic fatigue and history of physical abuse, whose history and test results were compatible with growth hormone deficiency secondary to head trauma. Patient 3 was a 46-year-old woman who was diagnosed with endogenous Cushing syndrome despite normal 24-hour urinary cortisol excretion. In each case, we subsequently elicited a history of intra-articular or epidural glucocorticoid injections, and a urine screen documented the presence of synthetic glucocorticoids. Systemic absorption of the injected steroids was thus determined to be the cause of the symptoms and abnormal laboratory findings in each case. CONCLUSIONS: The potential for harm from intra-articular and epidural glucocorticoid administration is underrecognized by physicians, leading to expensive investigation, false diagnoses, and unnecessary treatment. A urine screen for synthetic glucocorticoids is a valuable adjunct towards appropriate diagnosis.
Lee E, Cho S, Kim K, Park T.	Interdisciplinary Program in Bioinformatics, Seoul National University, Seoul, Republic of Korea. eunjee01@gmail.com	An integrated approach to infer causal associations among gene expression, genotype variation, and disease.	Genomics. 2009 Oct;94(4):269-77. Epub 2009 Jun 18.	Gene expression data and genotype variation data are now capable of providing genome-wide patterns across many different clinical conditions. However, the separate analysis of these data has limitations in elucidating the complex network of gene interactions underlying complex traits, such as common human diseases. More information about the identity of key driver genes of common diseases comes from integrating these two heterogeneous types of data. We developed a two-step procedure to characterize complex diseases by integrating genotype variation data and gene expression data. The first step elucidates the causal relationship among genetic variation, gene expression level, and disease. Based on the causal relationship determined at the first step, the second step identifies significant gene expression traits whose effects on disease status or whose responses to disease status are modified by the specific genotype variation. For the selected significant genes, a pathway enrichment analysis can be performed to identify the genetic mechanism of a complex disease. The proposed two-step procedure was shown to be an effective method for

				integrating three different levels of data, i.e., genotype variation, gene expression and disease status. By applying the proposed procedure to a chronic fatigue syndrome (CFS) dataset, we identified a list of potential causal genes for CFS, and found an evidence for difference in genetic mechanisms of the etiology between CFS without 'a major depressive disorder with melancholic features' (CFS) and CFS with 'a major depressive disorder with melancholic features' (CFS-MDD/m). Especially, the SNPs within NR3C1 gene were shown to differently influence the susceptibility of developing CFS and CFS-MDD/m through integrative action with gene expression levels.

Li H, Meng S, Levine SM, Stratton CW, Tang YW.	Department of Pathology, Vanderbilt University School of Medicine, Nashville, TN 37232, United States.	Sensitive, qualitative detection of human herpesvirus-6 and simultaneous differentiation of variants A and B.	J Clin Virol. 2009 Sep;46(1):20-3. Epub 2009 Jun 21.	BACKGROUND: The current limitations of laboratory testing for the detection of human herpesvirus virus 6 (HHV-6) in clinical specimens with low HHV-6 viral loads make this area a priority for further research and development. OBJECTIVES: To develop and validate a sensitive qualitative assay for simultaneous HHV-6 detection and variant differentiation. METHODS: We developed a diagnostic procedure, which combines a magnetic bead-based nucleic acid extraction, PCR amplification, and colorimetric microtiter plate identification (MAG-PCR-EIA), for the sensitive detection of HHV-6 and the simultaneous differentiation of HHV-6A and HHV-6B. RESULTS: Analytic sensitivities of the MAG-PCR-EIA assay were 10 copies per reaction for both HHV-6A and HHV-6B variants, which is equivalent to 20 copies/ml when 1ml of clinical specimen was processed. A proficiency panel containing 11 blinded specimens covering HHV-6A viral loads from 0 to 100,000 copies was tested, and the MAG-PCR-EIA was able to detect the lowest concentration at one copy in 200microl. A panel of 27 urine specimens, which were collected from patients with and without chronic fatigue syndrome, was tested by the MAG-PCR-EIA. HHV-6 was detected in two (HHV-6A) patients who have chromosomally integrated HHV-6A and in one (HHV-6B) patient who was a healthy control and diagnosed as cervical cancer later on. The HHV-6 results did not correlate with results previously determined by HHV-6 antigenemia in urine. CONCLUSION: With large specimen volumes processed and an additional signal amplification incorporated, the MAG-PCR-EIA provides a sensitive and qualitative system for HHV-6 detection and simultaneous variant differentiation. Clinical relevance of the assay awaits further investigation.
Li ZC, Zhao Y, Dou ZH, Yu L, Wu H,	Department of Infectious	[Clinical features of 66 children with	Zhongguo Dang Dai Er Ke Za Zhi.	OBJECTIVE: To study the clinical features of pediatric acquired immunodeficiency syndrome(AIDS). METHODS: The epidemiological, clinical and laboratory data of 66 children with AIDS were

Zhang FJ.	Diseases, Beijing Youan Hospital, Capital Medical University, Beijing 100069, China.	acquired immunodeficiency syndrome][Article in Chinese]	2009 Feb;11(2):93-5.	retrospectively studied. RESULTS: Of the 66 patients, 46 (69.7%) were male and 20 (30.3%) were female, with a mean age of 8.7 years (ranged 2-16 years). The mean age at diagnosis was 7.7 years (ranged 2-15 years). Vertical transmission as the route of infection was documented in 48 cases (72.7%). Fourteen children (21.2%) were infected through blood or blood products. The route of infection could not be identified in 4 cases (6.1%). Body weight loss was noted in 43 cases (65.2%), anemia in 42 cases (63.7%), fever in 40 cases (60.6%), fatigue in 38 cases (57.6%), rash in 31 cases (47.0%), chronic cough in 28 cases (12.1%), chronic diarrhea in 24 cases (36.4%), CNS involvement in 16 cases (24.2%), oral thrush in 13 cases (19.7%), and hepatosplenomegaly in 12 cases (18.2%). Body height of 30 cases (45.4%) and body weight of 26 cases (39.4%) ranked the lower level. The immune system was severely suppressed in 59 cases (89.4%) and moderately suppressed in 7 cases (10.6%). CONCLUSIONS: Vertical transmission remained the most common route of pediatric HIV infection. There were various clinical manifestations in children with AIDS. The immune systems of the majority of children with this disorder were severely suppressed.
Liang CZ, Li HJ, Wang ZP, Xing JP, Hu WL, Zhang TF, Ge WW, Hao ZY, Zhang XS, Zhou J, Li Y, Zhou ZX, Tang ZG, Tai S.	Department of Urology, The First Affiliated Hospital of Anhui Medical University, Hefei, China.	The prevalence of prostatitis-like symptoms in China.	J Urol. 2009 Aug;182(2):558-63. Epub 2009 Jun 13. Comment in: J Urol. 2009 Aug;182(2):427-8.	PURPOSE: We studied the prevalence of prostatitis-like symptoms and identified their associated risk factors in a population based Chinese sample. MATERIALS AND METHODS: A volunteer group of 15,000 eligible men residing in Beijing, Anhui, Xi'an, Guangzhou and Gansu cities or provinces were invited randomly to take part in the survey to complete a questionnaire that elicited information regarding sociodemographics, Eysenck personality questionnaire, current stress and health ratings, lifestyle, medical history, expressed prostatic secretion evaluation, score of the National Institutes of Health Chronic Prostatitis Symptom Index and International Index of Erectile Function-5. RESULTS: Information on 12,743 (84.95%) men was collected. Of these men 1,071 (8.4%) reported prostatitis-like symptoms (mean National Institutes of Health Chronic Prostatitis Symptom Index pain score 7.55 +/- 3.22). The percent of chronic prostatitis was 4.5% (571) among the symptoms group according to past urological history and expressed prostatic secretion evaluation. Subjects with prostatitis-like symptoms (mean age 34.56 +/- 13.48 years) had higher mean pain and urinary symptoms scores (7.53 +/- 3.22 and 2.84 +/- 2.72, respectively) compared with subjects without prostatitis-like symptoms (1.18 +/- 2.32 and 0.72 +/- 1.66 for pain and urinary symptoms scores, respectively, mean age 30.7 +/- 10.17) (pain and symptoms scores, p <0.05). The quality of life score was 6.03 +/- 2.88 and 3.83 +/- 2.55 in groups with symptoms or nonsymptoms, respectively (p <0.05). CONCLUSIONS: Prostatitis-like symptoms are a multifactorial problem affecting men of all ages (15 to 60 years) and demographics, and the prevalence is high in China. The syndrome is closely related to alcohol consumption, cigarette smoking, frequent intercourse, as well as fatigue, pressure and too little sleep. These findings suggest that risk factors for this condition are largely modifiable and highlight potential targets for future prevention.
Libman E, Creti L, Baltzan M, Rizzo D, Fichten CS, Bailes S.	Department of Psychiatry, SMBD-Jewish General Hospital, Concordia University,	Sleep apnea and psychological functioning in chronic fatigue syndrome.	J Health Psychol. 2009 Nov;14(8):1251-67.	Objectives were to explore: (1) whether sleep apnea/hypopnea syndrome (SAHS) should be considered a chronic fatigue syndrome (CFS) comorbidity, rather than a diagnostic exclusion criterion; and (2) to compare sleep/wake/ psychopathology in individuals with CFS, controls and another illness. Participants (CFS, SAHS, controls) completed questionnaires and were evaluated for SAHS; 68 percent were subsequently diagnosed with SAHS. CFS participants with and without SAHS did not differ. Both clinical groups were less well adjusted than controls. We conclude that SAHS should not be an

	Montreal, Quebec, Canada. eva.libman@mcgill.ca			exclusion criterion for CFS and that psychological problems in CFS seem a consequence of coping with illness.
Light AR, White AT, Hughen RW, Light KC.	Department of Anesthesiology, University of Utah, Salt Lake City, Utah 84132-2304, USA. alan.light@hsc.utah.edu	Moderate exercise increases expression for sensory, adrenergic, and immune genes in chronic fatigue syndrome patients but not in normal subjects.	J Pain. 2009 Oct;10(10):1099-112. Epub 2009 Jul 31.	Chronic fatigue syndrome (CFS) is characterized by debilitating fatigue, often accompanied by widespread muscle pain that meets criteria for fibromyalgia syndrome (FMS). Symptoms become markedly worse after exercise. Previous studies implicated dysregulation of the sympathetic nervous system (SNS), and immune system (IS) in CFS and FMS. We recently demonstrated that acid sensing ion channel (probably ASIC3), purinergic type 2X receptors (probably P2X4 and P2X5) and the transient receptor potential vanilloid type 1 (TRPV1) are molecular receptors in mouse sensory neurons detecting metabolites that cause acute muscle pain and possibly muscle fatigue. These molecular receptors are found on human leukocytes along with SNS and IS genes. Real-time, quantitative PCR showed that 19 CFS patients had lower expression of beta-2 adrenergic receptors but otherwise did not differ from 16 control subjects before exercise. After a sustained moderate exercise test, CFS patients showed greater increases than control subjects in gene expression for metabolite detecting receptors ASIC3, P2X4, and P2X5, for SNS receptors alpha-2A, beta-1, beta-2, and COMT and IS genes for IL10 and TLR4 lasting from 0.5 to 48 hours ($P < .05$). These increases were also seen in the CFS subgroup with comorbid FMS and were highly correlated with symptoms of physical fatigue, mental fatigue, and pain. These new findings suggest dysregulation of metabolite detecting receptors as well as SNS and IS in CFS and CFS-FMS. PERSPECTIVE: Muscle fatigue and pain are major symptoms of CFS. After moderate exercise, CFS and CFS-FMS patients show enhanced gene expression for receptors detecting muscle metabolites and for SNS and IS, which correlate with these symptoms. These findings suggest possible new causes, points for intervention, and objective biomarkers for these disorders.
Lim JY, Kim KE, Choe G.	Department of Rehabilitation, Seoul National University College of Medicine, Seoul National University Bundang Hospital, Korea.	Myotonic dystrophy mimicking postpolio syndrome in a polio survivor.	Am J Phys Med Rehabil. 2009 Feb;88(2):161-4.	We describe a 38-yr-old polio survivor with newly developed weakness from myotonic dystrophy. He suffered muscle atrophy and weakness in his legs as a result of poliomyelitis at the age of 3 yrs. After a stable interval of about 30 yrs, he felt new weakness and fatigue in his legs. Electromyography revealed generalized myotonic discharges, early recruitment, and findings of chronic denervation in his left leg. Genetic testing was consistent with myotonic dystrophy type 1. A biopsy from the right gastrocnemius revealed findings of both myotonic dystrophy and chronic denervation. This case report shows the importance of considering other uncommon conditions in the differential diagnoses of postpolio syndrome.
Lin E, Hsu SY.	Vita Genomics, Inc., Jung-Shing Road, Wugu Shiang, Taipei, Taiwan. eugene.lin@vitagenomics.com	A Bayesian approach to gene-gene and gene-environment interactions in chronic fatigue syndrome.	Pharmacogenomics. 2009 Jan;10(1):35-42.	INTRODUCTION: In the study of genomics, it is essential to address gene-gene and gene-environment interactions for describing the complex traits that involves disease-related mechanisms. In this work, our goal is to detect gene-gene and gene-environment interactions resulting from the analysis of chronic fatigue syndrome patients' genetic and demographic factors including SNPs, age, gender and BMI. MATERIALS & METHODS: We employed the dataset that was original to the previous study by the Centers for Disease Control and Prevention Chronic Fatigue Syndrome Research Group. To investigate gene-gene and gene-environment interactions, we implemented a Bayesian based method for identifying significant interactions between factors. Here, we employed a two-stage Bayesian

				variable selection methodology based on Markov Chain Monte Carlo approaches. RESULTS: By applying our Bayesian based approach, NR3C1 was found in the significant two-locus gene-gene effect model, as well as in the significant two-factor gene-environment effect model. Furthermore, a significant gene-environment interaction was identified between NR3C1 and gender. These results support the hypothesis that NR3C1 and gender may play a role in biological mechanisms associated with chronic fatigue syndrome. CONCLUSION: We demonstrated that our Bayesian based approach is a promising method to assess the gene-gene and gene-environment interactions in chronic fatigue syndrome patients by using genetic factors, such as SNPs, and demographic factors such as age, gender and BMI.
Lin JM, Brimmer DJ, Boneva RS, Jones JF, Reeves WC.	Chronic Viral Diseases Branch, National Center for Zoonotic, Vector-Borne and Enteric Diseases, Centers for Disease Control and Prevention, Atlanta, GA 30333, USA. dwe3@cdc.gov	Barriers to healthcare utilization in fatiguing illness: a population-based study in Georgia.	BMC Health Serv Res. 2009 Jan 20;9:13.	BACKGROUND: The purpose of this study was to determine the prevalence of barriers to healthcare utilization in persons with fatiguing illness and describe its association with socio-demographics, the number of health conditions, and frequency of healthcare utilization. Furthermore, we sought to identify what types of barriers interfered with healthcare utilization and why they occurred. METHODS: In a cross-sectional population-based survey, 780 subjects, 112 of them with chronic fatigue syndrome (CFS), completed a healthcare utilization questionnaire. Text analysis was used to create the emerging themes from verbatim responses regarding barriers to healthcare utilization. Multiple logistic regression was performed to examine the association between barriers to healthcare utilization and other factors. RESULTS: Forty percent of subjects reported at least one barrier to healthcare utilization. Of 112 subjects with CFS, 55% reported at least one barrier to healthcare utilization. Fatiguing status, reported duration of fatigue, insurance, and BMI were significant risk factors for barriers to healthcare utilization. After adjusting for socio-demographics, medication use, the number of health problems, and frequency of healthcare utilization, fatiguing status remained significantly associated with barriers to healthcare utilization. Subjects with CFS were nearly 4 times more likely to forego needed healthcare during the preceding year than non-fatigued subjects while those with insufficient fatigue (ISF) were nearly 3 times more likely.Three domains emerged from text analysis on barriers to healthcare utilization: 1) accessibility; 2) knowledge-attitudes-beliefs (KABs); and, 3) healthcare system. CFS and reported duration of fatigue were significantly associated with each of these domains. Persons with CFS reported high levels of healthcare utilization barriers for each domain: accessibility (34%), healthcare system (25%), and KABs (19%). In further examination of barrier domains to healthcare utilization, compared to non-fatigued persons adjusted ORs for CFS having "accessibility", "KAB" and "Healthcare System" barrier domains decreased by 40%, 30%, and 19%, respectively. CONCLUSION: Barriers to healthcare utilization pose a significant problem in persons with fatiguing illnesses. Study results suggested two-fold implications: a symptom-targeted model focusing on symptoms associated with fatigue; and an interactive model requiring efforts from patients and providers to improve interactions between them by reducing barriers in accessibility, KABs, and healthcare system.
Lin JM, Brimmer DJ, Maloney EM, Nyarko E, Belue R, Reeves WC.	Chronic Viral Diseases Branch, National Center for Zoonotic, Vector-	Further validation of the Multidimensional Fatigue Inventory	Popul Health Metr. 2009 Dec 15;7:18.	ABSTRACT: BACKGROUND: The Multidimensional Fatigue Inventory (MFI-20) was developed in 1995. Since then, it has been widely used in cancer research and cancer-related illnesses but has never been validated in fatiguing illnesses or in a large US population-selected sample. In this study, we sought to examine the reliability and validity of the MFI-20 in the population of the state of Georgia, USA.

	borne and Enteric Diseases, Centers for Disease Control and Prevention, Mail Stop A-15, 1600 Clifton Rd, NE, Atlanta, GA, USA. dwe3@cdc.gov.	in a US adult population sample.		Further, we assessed whether the MFI-20 could serve as a complementary diagnostic tool in chronically fatigued and unwell populations. METHODS: The data derive from a cross-sectional population-based study investigating the prevalence of chronic fatigue syndrome (CFS) in Georgia. The study sample was comprised of three diagnostic groups: CFS-like (292), chronically unwell (269), and well (222). Participants completed the MFI-20 along with several other measures of psychosocial functioning, including the Medical Outcomes Survey Short Form-36 (SF-36), the Zung Self-Rating Depression Scale (SDS), and the Spielberger State-Trait Anxiety Inventory (STAI). We assessed the five MFI-20 subscales using several criteria: inter-item correlations, corrected item-total correlations, internal consistency reliability (Cronbach's alpha coefficients), construct validity, discriminant (known-group) validity, floor/ceiling effects, and convergent validity through correlations with the SF-36, SDS, and STAI instruments. RESULTS: Averaged inter-item correlations ranged from 0.38 to 0.61, indicating no item redundancy. Corrected item-total correlations for all MFI-20 subscales were greater than 0.30, and Cronbach's alpha coefficients achieved an acceptable level of 0.70. No significant floor/ceiling effect was observed. Factor analysis demonstrated factorial complexity. The MFI-20 also distinguished clearly between three diagnostic groups on all subscales. Furthermore, correlations with depression (SDS), anxiety (STAI), and functional impairment (SF-36) demonstrated strong convergent validity. CONCLUSIONS: This study provides support for the MFI-20 as a valuable tool when used in chronically unwell and well populations. It also suggests that the MFI-20 could serve as a complementary diagnostic tool in fatiguing illnesses, such as CFS.
Lombardi VC, Ruscetti FW, Das Gupta J, Pfost MA, Hagen KS, Peterson DL, Ruscetti SK, Bagni RK, Petrow-Sadowski C, Gold B, Dean M, Silverman RH, Mikovits JA.	Whittemore Peterson Institute, Reno, NV 89557, USA.	Detection of an infectious retrovirus, XMRV, in blood cells of patients with chronic fatigue syndrome.	Science. 2009 Oct 23;326(5952):585-9. Epub 2009 Oct 8. Comment in: Science. 2009 Oct 23;326(5952):530-1.	Chronic fatigue syndrome (CFS) is a debilitating disease of unknown etiology that is estimated to affect 17 million people worldwide. Studying peripheral blood mononuclear cells (PBMCs) from CFS patients, we identified DNA from a human gammaretrovirus, xenotropic murine leukemia virus-related virus (XMRV), in 68 of 101 patients (67%) as compared to 8 of 218 (3.7%) healthy controls. Cell culture experiments revealed that patient-derived XMRV is infectious and that both cell-associated and cell-free transmission of the virus are possible. Secondary viral infections were established in uninfected primary lymphocytes and indicator cell lines after their exposure to activated PBMCs, B cells, T cells, or plasma derived from CFS patients. These findings raise the possibility that XMRV may be a contributing factor in the pathogenesis of CFS.
Lorusso L, Mikhaylova SV, Capelli E, Ferrari D, Ngonga GK, Ricevuti G.	Department of Neurology, Mellino Mellini Hospital, Chiari, Brescia, Italy.	Immunological aspects of chronic fatigue syndrome.	Autoimmun Rev. 2009 Feb;8(4):287-91. Epub 2008 Sep 16.	Chronic fatigue syndrome (CFS) is a specific clinical condition that characterises unexplained disabling fatigue and a combination of non-specific accompanying symptoms for at least 6 months, in the absence of a medical diagnosis that would otherwise explain the clinical presentation. Other common symptoms include headaches, myalgia, arthralgia, and post-exertional malaise; cognitive difficulties, with impaired memory and concentration; unrefreshing sleep; and mood changes. Similar disorders have been described for at least two centuries and have been differently named neurasthenia, post-viral fatigue, myalgic encephalomyelitis and chronic mononucleosis. Recent longitudinal studies suggest that some people affected by chronic fatigue syndrome improve with time but that most remain functionally impaired for several years. The estimated worldwide prevalence of CFS is 0.4-1% and it affects over 800,000 people in the United States and approximately 240,000 patients in the UK.

				No physical examination signs are specific to CFS and no diagnostic tests identify this syndrome. The pathophysiological mechanism of CFS is unclear. The main hypotheses include altered central nervous system functioning resulting from an abnormal immune response against a common antigen; a neuroendocrine disturbance; cognitive impairment caused by response to infection or other stimuli in sentient people. The current concept is that CFS pathogenesis is a multifactorial condition. Various studies have sought evidence for a disturbance in immunity in people with CFS. An alteration in cytokine profile, a decreased function of natural killer (NK) cells, a presence of autoantibodies and a reduced responses of T cells to mitogens and other specific antigens have been reported. The observed high level of pro-inflammatory cytokines may explain some of the manifestations such as fatigue and flu-like symptoms and influence NK activity. Abnormal activation of the T lymphocyte subsets and a decrease in antibody-dependent cell-mediated cytotoxicity have been described. An increased number of CD8+ cytotoxic T lymphocytes and CD38 and HLA-DR activation markers have been reported, and a decrease in CD11b expression associated with an increased expression of CD28+ T subsets has been observed. This review discusses the immunological aspects of CFS and offers an immunological hypothesis for the disease processes.

Bose Road, Kolkata 700020, India. lyle.nazmun@gmail.com	The role of antioxidant properties of Nardostachys jatamansi in alleviation of the symptoms of the chronic fatigue syndrome.	Behav Brain Res. 2009 Sep 14;202(2):285-90. Epub 2009 Apr 16.	An experimental model of chronic fatigue syndrome (CFS) is utilized for evaluation of antidepressant, anti-stress effects, wherein the rat is forced to swim in water for 15 min/day on 21 consecutive days. Rats were divided into stressed control, stressed plus standard drug (Panax ginseng) and stressed plus 200 and 500 mg/kg of test drug, i.e., Nardostachys jatamansi extract (NJE) given orally. The immobility during each 5 min periods of 0-5, 5-10 and 10-15 min of stress were noted. Similarly the climbing (struggling) behaviour was noted in the above four groups of rats in intervals of 5 min. The locomotor activity and also the anxiety state in animals were evaluated in an elevated plus maze after CFS in all the four groups. There was a significant increase in despair behaviour and anxiety in stressed control animals on successive days of CFS. Locomotor activity gradually decreased in stressed control group. Treatment with NJE (200 and 500 mg/kg) significantly reversed both paradigms. Biochemical analysis showed that CFS significantly increased lipid peroxidation, nitrite and superoxide dismutase levels and decreased catalase level in rat brain. Administration of NJE (200 and 500 mg/kg) tended to normalize both augmented lipid peroxidation, nitrite, superoxide dismutase activities and catalase level significantly. NJE per se has an antioxidant effect. The results indicate that CFS may lead to oxidative stress, which is mitigated by NJE and so its antioxidant property may be responsible for anti-stress effect of NJE.
Maes M, Mihaylova I, Kubera M,	Maes Clinics, Antwerp, Belgium. crc.mh@telenet.be	Increased 8-hydroxy-deoxyguanosine, a	Neuro Endocrinol Lett. 2009 Dec 30;30(6). [Epub	There is now evidence that major depression and myalgic encephalomyelitis / chronic fatigue syndrome (ME/CFS) are accompanied by partially overlapping pathophysiological mechanisms, i.e. activation of various inflammatory and oxidative & nitrosative (IO&NS) pathways. The aim of the

Uytterhoeven M, Vrydags N, Bosmans E.	.	marker of oxidative damage to DNA, in major depression and myalgic encephalomyelitis / chronic fatigue syndrome.	ahead of print]	present study was to examine the urinary excretion of 8-hydroxy-deoxyguanosine (8-OhdG), a marker of oxidative damage to DNA, in depression; ME/CFS; and depression and ME/CFS. Toward this end, morning urine was sampled for the assays of 8-OHdG and creatinine, in 44 patients with ME/CFS; 25 with major depression; 23 with depression and ME/CFS; and 17 normal controls. Severity of fatigue and somatic symptoms was measured by means of the Fibromyalgia and CFS Rating (FF) scale. We found that 49.0% of the variance in the urinary excretion of 8-OHdG was predicted by the regression on creatinine. Consequently, the urinary 8-OHdG excretion should be expressed as the residualized 8-OHdG values after partialling out the effects of creatinine and not by computing the 8-OHdG / creatinine ratio. We found that the residualized urinary excretion of 8-OHdG (adjusted for creatinine) was significantly higher in patients with depression and ME/CFS than in normal controls and all other patients. In the patient group, there were significant correlations between the urinary 8-OHdG and the total score on the FF scale and sadness and flu-like malaise. The findings show increased oxidatively generated DNA damage in patients with major depression and ME/CFS and, therefore, further extent the role played by IO&NS pathways in the pathophysiology of both disorders. Since oxidatively damage to DNA is a risk factor for atherosclerosis and neurodegeneration, our results also explain previous findings on increased cardiovascular morbidity in depression and ME/CFS, and neurodegenerative processes in depression.
Maes M, Twisk FN.	Maes Clinics, Antwerp, Belgium. crc.mh@telenet.be .	Why myalgic encephalomyelitis/ chronic fatigue syndrome (ME/CFS) may kill you: disorders in the inflammatory and oxidative and nitrosative stress (IO&NS) pathways may explain cardiovascular disorders in ME/CFS.	Neuro Endocrinol Lett. 2009 Dec 30;30(6). [Epub ahead of print]	There is evidence that disorders in inflammatory and oxidative and nitrosative (IO&NS) pathways and a lowered antioxidant status are important pathophysiological mechanisms underpinning myalgic encephalomyelitis / chronic fatigue syndrome (ME/CFS). Important precipitating and perpetuating factors for ME/CFS are (amongst others) bacterial and viral infections; bacterial translocation due to an increased gut permeability; and psychological stress. Recently, Jason et al (2006) reported that the mean age of patients with myalgic encephalomyelitis/chronic fatigue syndrome dying from heart failure, i.e. 58.7 years, is significantly lower than the age of those dying from heart failure in the general US population, i.e. 83.1 years. These findings implicate that ME/CFS is a risk factor to cardio-vascular disorder. This review demonstrates that disorders in various IO&NS pathways provide explanations for the earlier mortality due to cardiovascular disorders in ME/CFS. These pathways are: a) chronic low grade inflammation with extended production of nuclear factor kappa B and COX-2 and increased levels of tumour necrosis factor alpha; b) increased O&NS with increased peroxide levels, and phospholipid oxidation including oxidative damage to phosphatidylinositol; c) decreased levels of specific antioxidants, i.e. coenzyme Q10, zinc and dehydroepiandrosterone-sulphate; d) bacterial translocation as a result of leaky gut; e) decreased omega-3 polyunsatutared fatty acids (PUFAs), and increased omega-6 PUFA and saturated fatty acid levels; and f) the presence of viral and bacterial infections and psychological stressors. The mechanisms whereby each of these factors may contribute towards cardio-vascular disorder in ME/CFS are discussed. ME/CFS is a multisystemic metabolic-inflammatory disorder. The aberrations in IO&NS pathways may increase the risk for cardiovascular disorders.
Maes M, Twisk FN.	Maes Clinics, Antwerp, Belgium. crc.mh@telenet.be	Chronic fatigue syndrome: la bête noire of the	Neuro Endocrinol Lett. 2009;30(3):300-11.	The World Health Organization acknowledges Myalgic Encephalomyelitis (ME)/Chronic Fatigue Syndrome (CFS) to be a medical illness. ME/CFS is characterized by disorders in the inflammatory and oxidative and nitrosative stress (IO&NS) pathways. In 2002, the Belgian government started with the

		Belgian health care system.		development of CFS "Reference Centers", which implement a "psychosocial" model. The medical practices of these CFS Centers are defined by the Superior Health Council, e.g. treatment should be based upon Cognitive Behavioral Therapy (CBT) and Graded Exercise Therapy (GET); and biological assessments and treatments of ME/CFS should not be employed. Recently, the Belgian government has evaluated the outcome of the treatments at the CFS Centers. They concluded that a "rehabilitation therapy" with CBT/GET yielded no significant efficacy in the treatment of ME/CFS and that CBT/GET cannot be considered to be curative therapies. In case reports, we have shown that patients who were "treated" at those CFS centers with CBT/GET in fact suffered from IO&NS disorders, including intracellular inflammation, an increased translocation of gram-negative enterobacteria (leaky gut), autoimmune reactions and damage by O&NS. Considering the fact that these findings are exemplary for ME/CFS patients and that GET may even be harmful, it means that many patients are maltreated by the Belgian CFS Centers. Notwithstanding the above, the government and the CFS Centers not only continue this unethical and immoral policy, but also reinforce their use of CBT/GET in patients with ME/CFS treated at those Centers.
Maes M.	Clinical Research Centre of Mental Health (CRC-MH), Antwerp, Belgium. crc.mh@telenet.be	Inflammatory and oxidative and nitrosative stress pathways underpinning chronic fatigue, somatization and psychosomatic symptoms.	Curr Opin Psychiatry. 2009 Jan;22(1):75-83.	PURPOSE OF REVIEW: The aim of this paper is to review recent findings on inflammatory and oxidative and nitrosative stress (IO&NS) pathways in chronic fatigue and somatization disorder. RECENT FINDINGS: Activation of IO&NS pathways is the key phenomenon underpinning chronic fatigue syndrome (CFS): intracellular inflammation, with an increased production of nuclear factor kappa beta (NFkappabeta), cyclo-oxygenase-2 (COX-2) and inducible NO synthase (iNOS); and damage caused by O&NS to membrane fatty acids and functional proteins. These IO&NS pathways are induced by a number of trigger factors, for example psychological stress, strenuous exercise, viral infections and an increased translocation of LPS from gram-bacteria (leaky gut). The 'psychosomatic' symptoms experienced by CFS patients are caused by intracellular inflammation (aches and pain, muscular tension, fatigue, irritability, sadness, and the subjective feeling of infection); damage caused by O&NS (aches and pain, muscular tension and fatigue); and gut-derived inflammation (complaints of irritable bowel). Inflammatory pathways (monocytic activation) are also detected in somatizing disorder. SUMMARY: 'Functional' symptoms, as occurring in CFS and somatization, have a genuine organic cause, that is activation of peripheral and central IO&NS pathways and gut-derived inflammation. The development of new drugs, aimed at treating those disorders, should target these IO&NS pathways.
Maes M.	Maes Clinics, Antwerp, Belgium. crc.mh@telenet.be .	"Functional" or "psychosomatic" symptoms, e.g. a flu-like malaise, aches and pain and fatigue, are major features of major and in particular of melancholic depression: time to amend the	Neuro Endocrinol Lett. 2009 Nov 29;30(5). [Epub ahead of print]	FULL TITLE: "Functional" or "psychosomatic" symptoms, e.g. a flu-like malaise, aches and pain and fatigue, are major features of major and in particular of melancholic depression: time to amend the diagnostic criteria for major depression and the rating scales that measure severity of illness. BACKGROUND: Major depression is characterized by multifarious symptoms and symptoms clusters, such as the melancholic and anxiety symptom clusters. There is a strong comorbidity and a biological similarity between major depression and myalgic encephalomyelitis / chronic fatigue syndrome (ME/CFS). AIM: The aim of the present study was to examine "psychosomatic" symptoms reminiscent of ME/CFS in major depression. Toward this end, we examined the 12-item Fibromyalgia and Chronic Fatigue Syndrome Rating (FF) Scale and the Hamilton Depression Rating Scale (HDRS) in 103 major depressed patients by means of multivariate pattern recognition methods. RESULTS: Our findings support the existence of two factors, i.e. a fatigue and somatic (F&S) factor, i.e aches and pain,

		diagnostic criteria for major depression and.		muscular tension, fatigue, concentration difficulties, failing memory, irritability, irritable bowel, headache, and a subjective experience of infection; and a depression factor, i.e. sadness, irritability, sleep disorders, autonomic symptoms, and a subjective experience of infection. Cluster analysis performed on the 12 FF items found two different clusters, which were separated by highly significant differences in the F&S items, the most significant being a subjective experience of infection, aches and pain, muscular tension, fatigue, concentration difficulties and failing memory. Multivariate analyses showed that the differences between both clusters were quantitatively, and not qualitatively, and reflected the severity of the F&S dimension. There was a strong association between the F&S symptoms and melancholia and chronic depression. Treatment resistant depression was characterized by higher scores on the depression factor score. There was a strong correlation between the HDRS score and the FF items, fatigue, a subjective experience of infection, and sadness. CONCLUSIONS: Our findings show that F&S symptoms are a major feature of depression and largely predict severity of illness, and chronic and melancholic depression. It is concluded that the diagnostic criteria of depression and melancholia and rating scales to measure severity of illness should be modified to include the F&S symptom profile.
Magnus P, Brubakk O, Nyland H, Wold BH, Gjessing HK, Brandt I, Eidem T, Nøkleby H, Stene-Larsen G.	Division of Epidemiology, Norwegian Institute of Public Health, Oslo, Norway. per.magnus@fhi.no	Vaccination as teenagers against meningococcal disease and the risk of the chronic fatigue syndrome.	Vaccine. 2009 Jan 1;27(1):23-7. Epub 2008 Nov 5.	The etiology of chronic fatigue syndrome (CFS)/myalgic encephalomyelitis (ME) is unknown. In Norway, a vaccine against Neisseria meningitides group B was administered to teenagers in 1988--1989 in a protection trial. In order to estimate the relative risk of CFS/ME according to vaccine history, we conducted a case-control study in 2007, with 201 cases diagnosed at one of two hospitals and 389 controls. The adjusted odds ratio for CFS/ME was 1.06 (95% CI: 0.67-1.66) for subjects who received the active vaccine contrasted to subjects who did not. Using this design, no statistically significant association between vaccination against meningococcal disease in teenagers and occurrence of CFS/ME could be observed.
Maloney EM, Boneva R, Nater UM, Reeves WC.	Chronic Viral Diseases Branch, National Center for Zoonotic, Vector-borne and Enteric Diseases, Centers for Disease Control and Prevention, 1600 Clifton Road, MS A-15, Atlanta, GA 30333, USA. evm3@cdc.gov	Chronic fatigue syndrome and high allostatic load: results from a population-based case-control study in Georgia.	Psychosom Med. 2009 Jun;71(5):549-56. Epub 2009 May 4.	OBJECTIVE: To confirm the association of chronic fatigue syndrome (CFS) with high allostatic load (AL) level, examine the association of subsyndromal CFS with AL level, and investigate the effect of depression on these relationships and the association of AL with functional impairment, fatigue, symptom severity, fatigue duration, and type of CFS onset. AL represents the cumulative physiologic effect of demands to adapt to stress. METHODS: Population-based case-control study of 83 persons with CFS, 202 persons with insufficient symptoms or fatigue for CFS (ISF), and 109 well controls living in Georgia. Unconditional logistic regression was used to generate odds ratios (ORs) as measures of the association of AL with CFS. RESULTS: Relative to well controls, each 1-point increase in allostatic load index (ALI) was associated with a 26% increase in likelihood of having CFS (OR(adjusted) = 1.26, 95% Confidence Interval (CI) = 1.00, 1.59). This association remained in the presence and absence of depression (OR(adjusted) = 1.35, CI = 1.07, 1.72; OR(adjusted) = 1.35, CI = 1.10, 1.65). Compared with the ISF group, each 1-point increase in ALI was associated with a 10% increase in likelihood of having CFS (OR(adjusted) = 1.10, CI = 0.93, 1.31). Among persons with CFS, the duration of fatigue was inversely correlated with ALI (r = -.26, p = .047). CONCLUSIONS: Compared with well controls, persons with CFS were significantly more likely to have a high AL. AL increased in a gradient across well, ISF, and CFS groups.
Mantovani G,	Department of	Phase II	J Mol Med. 2009	Chronic inflammation is one of the main features of cancer cachexia. Experimental and clinical studies

Macciò A, Madeddu C, Serpe R, Antoni G, Massa E, Dessì M, Panzone F.	Medical Oncology, University of Cagliari, Cagliari, Italy, mantovan@medicina.unica.it.	nonrandomized study of the efficacy and safety of COX-2 inhibitor celecoxib on patients with cancer cachexia.	Oct 3. [Epub ahead of print]	showed that cyclooxygenase-2 inhibitors, such as celecoxib, may be beneficial in counteracting major symptoms of this devastating syndrome. We carried out a prospective phase II clinical trial to test the safety and effectiveness of an intervention with the COX-2 inhibitor celecoxib (300 mg/day for 4 months) on key variables of cachexia (lean body mass, resting energy expenditure, serum levels of proinflammatory cytokines, and fatigue) in patients with advanced cancer at different sites. A sample of 24 patients was enrolled from January to December 2008 and all were deemed assessable. A significant increase of lean body mass and a significant decrease of TNF-alpha were observed. Moreover, an improvement of grip strength, quality of life, performance status, and Glasgow prognostic score was shown. There were no grade 3/4 toxicities. Patient compliance was very good; no patient had to reduce the celecoxib dosage nor interrupt treatment. Our results showed that the COX-2 selective inhibitor celecoxib is an effective single agent for the treatment of cancer cachexia. Although the treatment of cancer cachexia, a multifactorial syndrome, is more likely to yield success with a multitargeted approach; in the present study, we were able to show that a treatment, such as celecoxib, addressing a single target, albeit very important as chronic inflammation, could have positive effects. Therefore, phase III clinical trials are warranted to test the efficacy and safety of celecoxib.
Marchesini G, Bianchi G.		Nonalcoholic fatty liver disease: Disease and comorbidity--effects on quality of life.	Nat Rev Gastroenterol Hepatol. 2009 Sep;6(9):504-6.	Nonalcoholic fatty liver disease has long been neglected by health-care professionals unless affected patients develop cirrhosis; however, new research shows this disease impairs health-related quality of life. The association of nonalcoholic fatty liver disease with chronic metabolic diseases and cardiovascular complications restricts our ability to define a specific role for liver damage in the poor perceived health status of these patients.
Marmion BP, Sukocheva O, Storm PA, Lockhart M, Turra M, Kok T, Ayres J, Routledge H, Graves S.	Q fever Research Group, SA Pathology/Hanson Institute, Adelaide, Australia. bpmarmion@iprimus.com.au	Q fever: persistence of antigenic non-viable cell residues of Coxiella burnetii in the host--implications for post Q fever infection fatigue syndrome and other chronic sequelae.	QJM. 2009 Oct;102(10):673-84. Epub 2009 Jun 25. Comment in: QJM. 2009 Oct;102(10):671-2.	BACKGROUND: Our previous studies of persistence of Coxiella burnetii in humans after an initial acute Q fever infection revealed raised, maintained antibody levels and low levels of coxiella genomic DNA at the age of 5 years from onset in Australian patients and at 12 years in patients in the 1989 Birmingham UK Q fever outbreak. Attempts to isolate the coxiella in standard cell culture and susceptible mice by serial passage of PCR positive PBMC and bone marrow were negative. AIM: To retest PCR positive patient samples by more sensitive methods for viable coxiellas and for the coxiella cell components of antigen and specific lipopolysaccharide (LPS). To re-interpret the previous results in the light of the new information. To review the pertinent literature for a concept of an immuno-modulatory complex generated by the current studies. DESIGN: Laboratory case study. METHODS: Stored patient samples were inoculated into SCID mice that were followed for 60 days. Mouse spleen and liver samples were then examined by PCR assay for targets in the COM1 and IS1111a sequences and for antigens by IFA with a polyclonal rabbit antiserum to C. burnetii Phase 1 and a monoclonal antiserum to Phase 1 LPS (details; O. Sukocheva et al., unpublished data). RESULTS: All specimens, including a recently excised heart valve from a Birmingham patient with late developing endocarditis, were infection negative in SCID mice. Dilutions of SCID mouse spleen and liver homogenates titrated in PCR assays were negative at dilutions attained by control mice inoculated with an endpoint dilution of a viable prototype strain of C. burnetii. Sections of the spleens from all specimens showed a complex of coxiella antigen-LPS by IFA. DISCUSSION/REVIEW: We advance a concept of long-term

				persistence of a non-infective, non-biodegraded complex of coxiella cell components with its antigens and specific LPS [so called Immunomodulatory complex (IMC)] associated with traces of genomic DNA that signalled its presence in our earlier studies. The IMC's survival in patients for at least 12 years, and in one patient for 70 years implies a capacity for serial passage in macrophages with effective down-regulation of their biodegrading functions. The review assesses the compatibility of the IMC concept in relation to cogent literature on C. burnetii interactions with macrophage and cell-mediated immunity. Some remaining gaps in our knowledge of the organ sites and duration of carriage of viable coxiellas after initial infection are also identified.
Martinez D, Cassol CM, Rahmeier L.		How much sleep apnea is too much?	Arthritis Res Ther. 2009;11(4):409; author reply 410-1. Epub 2009 Jul 15. Comment on: Arthritis Res Ther. 2008;10(3):R56.	
Mathew SJ, Mao X, Keegan KA, Levine SM, Smith EL, Heier LA, Otcheretko V, Coplan JD, Shungu DC.	Department of Psychiatry, Mount Sinai School of Medicine, New York, NY, USA.	Ventricular cerebrospinal fluid lactate is increased in chronic fatigue syndrome compared with generalized anxiety disorder: an in vivo 3.0 T (1)H MRS imaging study.	NMR Biomed. 2009 Apr;22(3):251-8.	Chronic fatigue syndrome (CFS) is a controversial diagnosis because of the lack of biomarkers for the illness and its symptom overlap with neuropsychiatric, infectious, and rheumatological disorders. We compared lateral ventricular volumes derived from tissue-segmented T(1)-weighted volumetric MRI data and cerebrospinal fluid (CSF) lactate concentrations measured by proton MRS imaging ((1)H MRSI) in 16 subjects with CFS (modified US Centers for Disease Control and Prevention criteria) with those in 14 patients with generalized anxiety disorder (GAD) and in 15 healthy volunteers, matched group-wise for age, sex, body mass index, handedness, and IQ. Mean lateral ventricular lactate concentrations measured by (1)H MRSI in CFS were increased by 297% compared with those in GAD ($P < 0.001$) and by 348% compared with those in healthy volunteers ($P < 0.001$), even after controlling for ventricular volume, which did not differ significantly between the groups. Regression analysis revealed that diagnosis accounted for 43% of the variance in ventricular lactate. CFS is associated with significantly raised concentrations of ventricular lactate, potentially consistent with recent evidence of decreased cortical blood flow, secondary mitochondrial dysfunction, and/or oxidative stress abnormalities in the disorder.
Matsuda Y, Matsui T, Kataoka K, Fukada R, Fukuda S, Kuratsune H, Tajima S, Yamaguti K, Kato YH, Kiriike N.	Department of Neuropsychiatry, Osaka City University Graduate School of Medicine, Osaka, Japan. mackham10@yahoo.co.jp	A two-year follow-up study of chronic fatigue syndrome comorbid with psychiatric disorders.	Psychiatry Clin Neurosci. 2009 Jun;63(3):365-73.	AIMS: Chronic fatigue syndrome patients often have comorbid psychiatric disorders such as major depressive disorders and anxiety disorders. However, the outcomes of chronic fatigue syndrome and the comorbid psychiatric disorders and the interactions between them are unknown. Therefore, a two-year prospective follow-up study was carried out on chronic fatigue syndrome patients with comorbid psychiatric disorders. METHODS: A total of 155 patients who met the Japanese case definition of chronic fatigue syndrome were enrolled in this study. Comorbid psychiatric disorders were diagnosed according to the Diagnostic and Statistical Manual of Mental Disorders 4th edition criteria. Patients with comorbid psychiatric disorders received psychiatric treatment in addition to medical therapy for chronic fatigue syndrome. Seventy patients participated in a follow-up interview approximately 24 months later. RESULTS: Of the 70 patients with chronic fatigue syndrome, 33 patients were diagnosed as having comorbid psychiatric disorders including 18 major depressive

				disorders. Sixteen patients with psychiatric disorders and eight patients with major depressive disorders did not fulfill the criteria of any psychiatric disorders at the follow up. As for chronic fatigue syndrome, nine out of the 70 patients had recovered at the follow up. There is no significant influence of comorbid psychiatric disorders on the outcome of chronic fatigue syndrome. CONCLUSIONS: Chronic fatigue syndrome patients have a relatively high prevalence of comorbid psychiatric disorders, especially major depressive disorders. The outcomes of chronic fatigue syndrome and psychiatric disorders are independent. Therefore treatment of comorbid psychiatric disorders is necessary in addition to the medical treatment given for chronic fatigue syndrome.
Maurer MS, Cuddihy P, Weisenberg J, Delisle S, Strong BM, Gao Q, Kachnowski S, Howell J.	Cardiology Division, Department of Medicine, Columbia University Medical Center, New York, New York, USA. msm10@columbia.edu	The prevalence and impact of anergia (lack of energy) in subjects with heart failure and its associations with actigraphy.	J Card Fail. 2009 Mar;15(2):145-51. Epub 2008 Dec 6.	BACKGROUND: Anergia (lack of energy) is a newly delineated, criterion-based geriatric syndrome. Because heart failure (HF) is a common chronic condition among older adults and a because a cardinal symptom of HF is reduced energy, we characterized the degree of anergia in subjects with HF and evaluated its relevance to disease severity, functional performance, and quality of life. METHODS AND RESULTS: Prospective 3-month cohort study among a convenience sample of 61 subjects (61 +/- 15 years, 48% women, ejection fraction 41 +/- 16%) with New York Heart Association (NYHA) Class I-III HF were studied. The criterion for anergia was based on the major criterion "sits around for lack of energy" and any 2 of 6 minor criteria. Principal measures in addition to demographic and clinical characteristics included functional performance (NYHA class, 6-minute walk, cardiopulmonary exercise testing), plasma B-type natriuretic peptide, and quality of life (SF-12 and Minnesota Living with Heart Failure Questionnaire). To evaluate the relevance of anergia to daily function, each subject wore an Actigraph, a watch-like wrist device that continuously and automatically monitors patient activity levels and energy expenditure, for 3 months. Anergia was prevalent in 39% of this population. Anergia was associated with decrements in functional capacity (higher NYHA Class and lower 6-minute walk distance) as well as reduction in quality of life, but was not associated with ejection fraction. Actigraphy data demonstrated that HF subjects with anergia spent significantly less time performing moderate physical activity and the peak activity counts per day were significantly lower than HF subjects without anergia. Additionally, the amplitude of circadian rhythm was lower, suggesting altered sleep and activity patterns in HF subjects with anergia compared with those without anergia. Over the 3 months of follow-up, there was a significant association between anergia and intercurrent hospitalization. CONCLUSIONS: Anergia is significantly associated with several of the cardinal domains of HF. Its presence is associated with demonstrable differences in both physical activity and circadian rhythm as measured by actigraphy and an increased risk of hospitalizations. Accordingly, anergia may be a target for intervention among HF subjects.
May M, Emond A, Crawley E.	Bristol University, United Kingdom.	Phenotypes of Chronic Fatigue Syndrome in Children and Young People.	Arch Dis Child. 2009 Oct 19. [Epub ahead of print]	OBJECTIVE: To investigate the heterogeneity of chronic fatigue syndrome (CFS/ME) in children and young people. SETTING: Regional specialist CFS/ME service. Patients: Children and young people aged < 19 years old. METHODS: Exploratory factor analysis was performed on symptoms present at assessment in 333 children and young people with CFS/ME. Linear and logistic regression analysis of data from self completed assessment forms was used to explore the associations between the retained factors and sex, age, length of illness, depression, anxiety and markers of severity (fatigue, physical function, pain and school attendance). RESULTS: Three phenotypes were identified using factor analysis: Musculoskeletal (Factor 1) had loadings on muscle and joint pain and hypersensitivity

				to touch, and was associated with worse fatigue (regression coefficient 0.47, 95% CI 0.25, 0.68, p <0.001), physical function (regression coefficient -0.52, 95% CI -0.83, -0.22, p= 0.001) and pain. . Factor 2 (Migraine) loaded on noise and light hypersensitivity, headaches, nausea, abdominal pain and dizziness and was most strongly associated with physical function and pain. Sore throat phenotype, (Factor 3) had loadings on sore throat and tender lymph nodes and was not associated with fatigue or pain. There was no evidence that phenotypes were associated with age, length of illness or symptoms of depression (regression coefficient for association of depression with Musculoskeletal pain -0.02, 95% CI -0.27, 0.23, p= 0.87). The Migraine phenotype was associated with anxiety (0.40, 95% CI 0.06, 0.74, p=0.02). Implications: CFS/ME is heterogeneous in children with 3 phenotypes at presentation that are differentially associated with severity and are unlikely to be due to age or length of illness.
McKay PG, Duffy T, Martin CR.	School of Health, Nursing and Midwifery, University of West of Scotland, Ayr, UK.	Are chronic fatigue syndrome and fibromyalgia the same? Implications for the provision of appropriate mental health intervention.	J Psychiatr Ment Health Nurs. 2009 Dec;16(10):884-94.	Chronic fatigue syndrome and fibromyalgia represent distinct diagnostic entities within both the clinical and research literature. A common feature of both presentations is that they are often accompanied by a significant mental health burden. A further salient feature of both conditions is that there is no consistent consensus on aetiology. Evaluation of the features of each disorder seems to present a convincing case that both disorders may indeed have a common aetiology and further, the possibility exists that chronic fatigue syndrome and fibromyalgia represent the same underlying disorder. Paradoxically, given this possibility it is remarkable that both patient groups are treated clinically with considerably different approaches to care and management. Mental health practitioners will come into contact with both groups of patients when support for the psychological consequences of diagnosis are necessary; however, many practitioners will be unaware of the debate regarding the aetiological ambiguities surrounding these presentations. The purpose of this review is to highlight the above issues in order to both facilitate awareness of the current aetiological/diagnostic impasse and facilitate provision of optimum mental health support.
Mease PJ, Clauw DJ, Gendreau RM, Rao SG, Kranzler J, Chen W, Palmer RH.	Seattle Rheumatology Associates, 1101 Madison Street, Suite 1000, Seattle, WA 98104, USA. pmease@philipmease.com	The efficacy and safety of milnacipran for treatment of fibromyalgia. a randomized, double-blind, placebo-controlled trial.Erratum in: J Rheumatol. 2009 Mar;36(3):661.	J Rheumatol. 2009 Feb;36(2):398-409.	OBJECTIVE: To evaluate the safety and efficacy of milnacipran, a dual norepinephrine and serotonin reuptake inhibitor, in the treatment of fibromyalgia (FM). METHODS: A 27-week, randomized, double-blind, multicenter study compared milnacipran 100 and 200 mg/day with placebo in the treatment of 888 patients with FM. Two composite responder definitions were used to classify each patient's individual response to therapy. "FM responders" concurrently satisfied response criteria for improvements in pain (visual analog scale 24-h morning recall), patient global impression of change (PGIC), and physical functioning (SF-36 Physical Component Summary); while "FM pain responders" concurrently satisfied response criteria for improvements in pain and PGIC. RESULTS: At the primary endpoint, after 3-month stable dose treatment, a significantly higher percentage of milnacipran-treated patients met criteria as FM responders versus placebo (milnacipran 200 mg/day, p = 0.017; milnacipran 100 mg/day, p = 0.028). A significantly higher percentage of patients treated with milnacipran 200 mg/day also met criteria as FM pain responders versus placebo (p = 0.032). Significant pain reductions were observed after Week 1 with both milnacipran doses. At 15 weeks, milnacipran 200 mg/day led to significant improvements over placebo in pain (realtime, daily and weekly recall; all measures, p < 0.05), PGIC (p < 0.001), fatigue (p = 0.016), cognition (p = 0.025), and multiple SF-36 domains. Milnacipran was safe and well tolerated by the majority of patients during 27 weeks of treatment; nausea and headache were the most common adverse events. CONCLUSION:

				Milnacipran is safe and effective for the treatment of multiple symptoms of FM.
Mease PJ.	Seattle Rheumatology Associates, Swedish Medical Center, Seattle, Washington, USA. pmease@nwlink.com	Further strategies for treating fibromyalgia: the role of serotonin and norepinephrine reuptake inhibitors.	Am J Med. 2009 Dec;122(12 Suppl):S44-55.	Fibromyalgia and associated conditions such as irritable bowel syndrome and temporomandibular disorder involve dysfunctions in central sensitization and pain modulation. Central nervous system dysfunction may also contribute to other symptoms characteristic of fibromyalgia, such as fatigue and sleep disturbance. Two key neurotransmitters in the pain modulation pathway are serotonin and norepinephrine. Preclinical studies using animal models of chronic pain have shown that pharmacologic agents that combine serotonergic and noradrenergic reuptake inhibition, thus augmenting the function of these neurotransmitters, have stronger analgesic effects than agents that inhibit reuptake of either neurotransmitter alone. Although tricyclic antidepressants (TCAs) inhibit reuptake of both serotonin and norepinephrine and have shown efficacy for the treatment of fibromyalgia, long-term use of these drugs is limited owing to poor tolerability. Unlike TCAs, the newer dual reuptake inhibitors of serotonin and norepinephrine, such as the drugs approved by the US Food and Drug Administration (FDA) for fibromyalgia, milnacipran and duloxetine, do not possess significant affinity for other neurotransmitter systems, resulting in diminished side effects and enhanced tolerability. Both duloxetine and milnacipran have shown efficacy in clinical trials by improving pain and other symptoms associated with fibromyalgia. Both compounds inhibit the serotonin and norepinephrine transporters; however, there is a difference in their affinities and selectivity for these transporters. Although duloxetine has affinity for both receptors, it is somewhat more selective for the serotonin transporter. In contrast, milnacipran is somewhat more selective for norepinephrine than serotonin reuptake inhibition. Pharmacologic agents that specifically target serotonin and norepinephrine reuptake may prove to be valuable tools in the treatment of fibromyalgia. (c) 2009 Elsevier Inc.
Meeus M, Mistiaen W, Lambrecht L, Nijs J.	Department of Health Sciences, Van Aertselaerstraat 31, 2170 Merksem, Belgium.	Immunological similarities between cancer and chronic fatigue syndrome: the common link to fatigue?	Anticancer Res. 2009 Nov;29(11):4717-26.	Cancer and chronic fatigue syndrome (CFS) are both characterised by fatigue and severe disability. Besides fatigue, certain aspects of immune dysfunctions appear to be present in both illnesses. In this regard, a literature review of overlapping immune dysfunctions in CFS and cancer is provided. Special emphasis is given to the relationship between immune dysfunctions and fatigue. Abnormalities in ribonuclease (RNase) L and hyperactivation of nuclear factor kappa beta (NF-kappaB) are present in CFS and in prostate cancer. Malfunctioning of natural killer (NK) cells has long been recognised as an important factor in the development and reoccurrence of cancer, and has been documented repeatedly in CFS patients. The dysregulation of the RNase L pathway, hyperactive NF-kappaB leading to disturbed apoptotic mechanisms and oxidative stress or excessive nitric oxide, and low NK activity may play a role in the two diseases and in the physiopathology of the common symptom fatigue. However, in cancer the relation between the immune dysfunctions and fatigue has been poorly studied. Immunological abnormalities to such as a dysregulated RNase L pathway, hyperactive NF-kappaB, increased oxidative stress and reduced NK cytotoxicity, among others, are present in both diseases. These anomalies may be part of the physiopathology of some of the common complaints, such as fatigue. Further studies to confirm the hypotheses given here are warranted.
Menzies V, Lyon DE.		Integrated Review of the Association of Cytokines With	Biol Res Nurs. 2009 Nov 22. [Epub ahead of print]	Fibromyalgia (FMS) is a chronic widespread pain (CWP) and fatigue syndrome that affects three to six million adults in the United States. Core symptoms of FMS include pain, fatigue, and mood and sleep disturbances. To date, consensus has not been reached among researchers regarding the

		Fibromyalgia and Fibromyalgia Core Symptoms.		pathogenesis of FMS nor the specific role of cytokine activation on the neuroendocrine-immune response patterns in persons with FMS. The purpose of this article is to describe and synthesize the results of research studies focused on the relationship between cytokines and FMS and among cytokines and core symptoms of FMS. There is some support in the literature for relationships among FMS symptoms and cytokines; however, there are discrepant findings related to whether proinflammatory and anti-inflammatory cytokines are elevated or reduced in persons with FMS and whether their levels correlate with the core symptoms of this disorder. Although the use of cytokine biomarkers must be considered exploratory at this time due to the lack of consistent empirical findings, biobehavioral research focused on understanding the relationship of FMS with cytokines may lead to a better understanding of this complex syndrome. This knowledge may ultimately contribute to the development of interventions for symptom management that address not only the symptom manifestation but also a biological mediator of symptoms.
Million M, Lepidi H, Raoult D.	CNRS, UMR 6236, IRD 198, unité de recherche sur les maladies infectieuses et tropicales émergentes, faculté de médecine, université de la Méditerranée, 27, boulevard Jean-Moulin, 13385 Marseille cedex 05, France. matthieumillion@gmail.com	[Q fever: current diagnosis and treatment options][Article in French]	Med Mal Infect. 2009 Feb;39(2):82-94. Epub 2008 Nov 14.	Q fever is a zoonotic disease caused by the ubiquitous pathogen Coxiella burnetii responsible for acute and chronic clinical manifestations. Its geographically heterogeneous prevalence seems mainly related to the clinician interest and the availability of a reference center. Its polymorphic clinical expression imposes reference to diagnosis in presence of pneumonia, hepatitis, prolonged fever or endocarditis with no proof of its etiology. The diagnosis is mainly serological. If acute Q fever is most often benign, endocarditis is constantly fatal without treatment. The treatment is effective and well tolerated, but must be adapted to the acute or chronic pattern, the presence of a heart valve disease, an aneurysm or a vascular prosthesis, an immunodeficiency and the specific problem of pregnancy.
Miwa K, Fujita M.		Increased oxidative stress suggested by low serum vitamin E concentrations in patients with chronic fatigue syndrome.	Int J Cardiol. 2009 Aug 14;136(2):238-9. Epub 2008 Aug 6.	Serum alpha-tocopherol concentrations were determined in 50 patients with chronic fatigue syndrome (CFS) and 40 control subjects (Control). Prevalence of each or any coronary risk factor was not significantly different between CFS and Control. CFS had significantly lower alpha-tocopherol concentrations than Control. The concentrations were significantly lower in the subjects with any coronary risk factors than those without in CFS as well as Control. Even among the subjects with any coronary risk factors and also among those without, CFS had significantly lower alpha-tocopherol concentrations than Control. In conclusion, CFS had significantly lower alpha-tocopherol concentrations irrespective of coronary risk factors than Control, suggesting the presence of increased oxidative stress in CFS.
Miwa K, Fujita M.	Department of Internal Medicine,	Cardiac function fluctuates during	J Cardiol. 2009 Aug;54(1):29-35.	BACKGROUND: "Small heart syndrome", previously referred to as so-called "neurocirculatory asthenia" associated with a small heart shadow on the chest roentgenogram, is characterized by

	Nanto Family and Community Medical Center, 577 Matsubara, Nanto, Toyama 939-1518, Japan.	exacerbation and remission in young adults with chronic fatigue syndrome and "small heart".	Epub 2009 Mar 28.	weakness or fatigue even after mild exertion, palpitation, dyspnea, and fainting, many of which resemble symptoms in patients with chronic fatigue syndrome (CFS). METHODS AND RESULTS: The study population comprised 42 patients with CFS younger than 40 years of age. Cardiothoracic ratio was determined on the chest roentgenogram and echocardiographic examination was performed to evaluate both the cardiac chamber size and function. "Small heart" (cardiothoracic ratio </=42%) on the chest X-ray photograph was noted in 26 (62%) of the study CFS patients. Echocardiographic examination demonstrated significantly smaller mean values of both the left ventricular (LV) end-diastolic and end-systolic dimensions, stroke volume indexes and cardiac indexes in CFS patients with "small heart" than in those without it and also in 20 control subjects. Thus, CFS patients with "small heart" had an actually small LV chamber and poor cardiac performance. During a long follow-up period of 10 CFS patients with "small heart", all echocardiographic parameters mentioned above improved and cardiothoracic ratios increased significantly during the remission phase as compared with exacerbation phase. CONCLUSIONS: "Small heart" on the chest X-ray photograph was prevalently noted in CFS patients. Echocardiographic examination revealed that CFS patients with "small heart" had an actually small LV chamber and poor cardiac performance. Cardiac functional changes evaluated by repeated examinations appeared to be directly associated with the severity of their symptoms. Small heart syndrome with impaired cardiac function may contribute to the development of CFS through low cardiac output as a constitutional factor.
Miwa K, Fujita M.	Department of Internal Medicine, Nanto Family and Community Medical Center, Nanto, Toyama, Japan. miwa.kunihisa@city.nanto.lg.jp	Cardiovascular dysfunction with low cardiac output due to a small heart in patients with chronic fatigue syndrome.	Intern Med. 2009;48(21):1849-54. Epub 2009 Nov 2.	OBJECTIVE: Little attention has been paid to possible cardiovascular involvement in patients with chronic fatigue syndrome (CFS), although many of their symptoms and signs suggest cardiovascular dysfunction. Possible cardiovascular symptoms and cardiac function were investigated in CFS patients. METHODS: Cardiovascular symptoms were intensively investigated and cardiac function was evaluated echocardiographically. PATIENTS: Fifty-three patients (23 men and 30 women, mean age: 31+/-7 years) with CFS under 50 years were studied. RESULTS: Slender build (body mass index <20 kg/m(2)) was common (47%). Possible cardiovascular symptoms including shortness of breath (32%), dyspnea on effort (28%), rapid heartbeat (38%), chest pain (43%), fainting (43%), orthostatic dizziness (45%) and coldness of feet (42%), were all frequent complaints. Hypotension (28%) was occasionally noted. Electrocardiograms frequently revealed right axis deviation (21%) and severe sinus arrhythmia (34%) suggesting accentuated parasympathetic nervous activity. Small heart shadow (cardiothoracic ratio <or=42%) was noted on the chest roentgenogram in 32 patients (60%). Echocardiographic examination demonstrated low cardiac indexes (<2 L/min/m(2)) with low stroke volume indexes (<30 mL/m(2)) due to a small left ventricular chamber in 19 (36%, p<0.05 vs. 8% in 36 controls). None had reduced left ventricular ejection fraction. CONCLUSION: Cardiovascular symptoms are common in CFS patients. Cardiac dysfunction with low cardiac output due to small left ventricular chamber may contribute to the development of chronic fatigue as a constitutional factor in a considerable number of CFS patients.
Miyaoka H, Miyachi H, Oishi S.	Department of Psychiatry, Kitasato University, School of	[Is "functional somatic syndrome" clinically useful?] [Article in	Nippon Rinsho. 2009 Sep;67(9):1726-30.	The functional somatic syndrome is applied to several syndromes characterized by medically unexplained physical symptoms, such as irritable bowel syndrome, fibromyalgia, chronic fatigue syndrome, etc. Both physical and psychiatric treatments are usually necessary for these syndromes and the term functional somatic syndrome was advocated to inform clinicians in America of this fact.

	Medicine.	Japanese]		However, We believe this term will not be useful in Japan, because most Japanese clinicians are already aware of this fact and treatment is different in each syndrome included in FSS.
Moniuszko A, Czupryna P, Zajkowska J, Pancewicz SA, Grygorczuk S, Kondrusik M.	Department of Infectious Diseases and Neuroinfections, Medical University of Bialystok, Poland. annamoniuszko@op.pl	[Post Lyme syndrome as a clinical problem][Article in Polish]	Pol Merkur Lekarski. 2009 Mar;26(153):227-30.	Lyme disease is a chronic tick borne disease, caused by spirochetes B. burgdorferi. The condition influences mostly on skin, nervous system, skeletal system and circulatory system. Recently more and more reports of so called "Post Lyme syndrome (PLS)" have appeared. PLS is a new clinical, diagnostic and therapeutic problem connected with patients with a history of Lyme disease (with proper antibiotic treatment). The symptoms of Post Lyme Syndrome may be present throughout months or even years. These are: fatigue, widespread musculoskeletal pain, dysmnesia, concentration difficulties. Pathogenesis of PLS is unknown. It is suspected that main factors responsible for PLS are: slow regression of infection, its turning into chronic process and permanent destruction of tissues or induction of immunological response against B. burgdorferi. Diagnostic of PLS is difficult. Mostly results of serological examination are negative. In some cases antibodies titer is positive as a sign of past disease. So far there is no causative treatment of PLS. Antidepressants, painkillers and anti-inflammatory medicines are recommended.
Murakami M.	Department of Psychosomatic Internal Medicine, Nihon University Itabashi Hospital.	[Treatment of myalgia] [Article in Japanese]	Nippon Rinsho. 2009 Sep;67(9):1759-65.	Fibromyalgia (FM) conceptualized by the American College of Rheumatology is characterized by long-lasting chronic widespread pain and stiffness of the fibro-muscular system associated with various unidentified symptoms. Since most of the patients are female and the onset and clinical course of FM involves various kinds of bio-psychosocial stress factors, it is very important to consider the psychosomatic background of the patient. The symptom of FM is not readily improved with conventional analgesic drugs, antirheumatic agents or various kinds of physiotherapy, however current guidelines recommend tricyclic antidepressants, SSRIs and SNRIs as first-line therapies to treat the multiple symptom of the FM. It is considered that antidepressants may operate the functional impairment of descending (efferent) analgesic system, in which serotonin and noradrenaline take an important role. Among 199 certified physicians of the Japanese Society of Psychosomatic Medicine, the largest number of respondents selected SSRI, SNRI and other antidepressants as first-line drugs. Because the psychological and physical exhaustion due to an irregular life style, physical strain, and accumulated fatigue may be the key stress factors for the organization of symptoms, psychosomatic approach and guidance should be conducted to enable patients to reduce stress in daily life. For the problems of personality and psychological stress, counseling and advanced psychotherapy such as cognitive behavioral therapy (CBT) should be also conducted.
Mutsuura H, Kanbara K, Fukunaga M, Yamamoto K, Ban I, Kitamura K, Nakai Y.	Department of Psychosomatic Medicine, Kansai Medical University, Moriguchi-shi, Osaka 570-8507, Japan. mutsuurh@takii.kmu.ac.jp	Depression and anxiety correlate differently with salivary free cortisol in the morning in patients with functional somatic syndrome.	Appl Psychophysiol Biofeedback. 2009 Dec;34(4):291-8. Epub 2009 Aug 7.	Patients presenting with functional somatic syndrome (FSS) are common, and the symptoms are persistent and difficult to treat for doctors and costly for society. The aim of this study was to clarify the common pathophysiology of FSS, especially the relationship between hypothalamic-pituitary-adrenal (HPA) axis function and psychological characteristics of patients with FSS. The subjects were 45 patients with FSS and 29 healthy controls. Salivary free cortisol was measured in the morning, and psychological tests examining depression, anxiety and quality of life (QOL) were performed on the same day. In patients with FSS, depressive scores showed a significant negative correlation with salivary free cortisol in the morning, although in healthy controls, cortisol showed a significant positive correlation with depressive scores. In addition, the correlation between other psychological test scores and cortisol secretion in patients with FSS contrasted with that of controls. The

				relationship between cortisol and depression, anxiety or QOL, suggests that the HPA axis of patients with FSS is dysfunctional and does not function properly when patients with FSS are under stress. This dysfunction may explain the pathology of medically unexplained persistent symptoms of patients with FSS.
Myhill S, Booth NE, McLaren-Howard J.		Chronic fatigue syndrome and mitochondrial dysfunction.	Int J Clin Exp Med. 2009;2(1):1-16. Epub 2009 Jan 15.	This study aims to improve the health of patients suffering from chronic fatigue syndrome (CFS) by interventions based on the biochemistry of the illness, specifically the function of mitochondria in producing ATP (adenosine triphosphate), the energy currency for all body functions, and recycling ADP (adenosine diphosphate) to replenish the ATP supply as needed. Patients attending a private medical practice specializing in CFS were diagnosed using the Centers for Disease Control criteria. In consultation with each patient, an integer on the Bell Ability Scale was assigned, and a blood sample was taken for the "ATP profile" test, designed for CFS and other fatigue conditions. Each test produced 5 numerical factors which describe the availability of ATP in neutrophils, the fraction complexed with magnesium, the efficiency of oxidative phosphorylation, and the transfer efficiencies of ADP into the mitochondria and ATP into the cytosol where the energy is used. With the consent of each of 71 patients and 53 normal, healthy controls the 5 factors have been collated and compared with the Bell Ability Scale. The individual numerical factors show that patients have different combinations of biochemical lesions. When the factors are combined, a remarkable correlation is observed between the degree of mitochondrial dysfunction and the severity of illness ($P<0.001$). Only 1 of the 71 patients overlaps the normal region. The "ATP profile" test is a powerful diagnostic tool and can differentiate patients who have fatigue and other symptoms as a result of energy wastage by stress and psychological factors from those who have insufficient energy due to cellular respiration dysfunction. The individual factors indicate which remedial actions, in the form of dietary supplements, drugs and detoxification, are most likely to be of benefit, and what further tests should be carried out.
Nakagami A, Tsujiuchi T.	Graduate School of Human Sciences, Waseda University.	[Functional somatic syndromes from the view of cultural anthropology] [Article in Japanese]	Nippon Rinsho. 2009 Sep;67(9):1683-8.	The functional somatic syndromes have acquired major socio-cultural and political dimensions. Socio-cultural factors clearly affect symptoms, suffering, and disability perception and reporting. And knowledge of explanatory models of bodily distress for patients from different cultural backgrounds is useful in the establishment of a stable doctor -patient relationship. FSS may be an operational category to bridge between medical explanatory model and patient's model. According to medical anthropology, sickness has two faces; illness and disease. "Disease" is the problem from the practitioner's perspective, and "illness" is the human experience of symptoms and suffering. In this paper, the anthropological research on chronic fatigue syndrome as "not real" illness experience was described.
Nakao M.	Department of Hygiene and Public Health & Division of Psychosomatic Medicine, Teikyo University School of Medicine.	[Etiology of functional somatic syndromes] [Article in Japanese]	Nippon Rinsho. 2009 Sep;67(9):1661-8.	Functional somatic syndromes are defined as several related syndromes that are characterized more by symptoms, suffering, and disability than by structural or functional abnormality. These syndromes include irritable bowel syndrome, tension-type headache, chronic fatigue syndrome, and fibromyalgia. Such syndromes have similarities in terms of definition, diagnosis, etiology, and treatment. To elucidate the pathogenesis of functional somatic syndromes, it is important to focus on gender-related factors, comorbidities of depression and anxiety, physiological responses like autonomic nervous function and hypothalamic-pituitary-adrenal axis, and patient-doctor relationship. Based on

				recent literatures, mood state and somatosensory amplification are suggested to play an important role in the psychopathological mechanism of functional somatic syndromes, and genetic and environmental factors need to be considered as well.
Nater UM, Lin JM, Maloney EM, Jones JF, Tian H, Boneva RS, Raison CL, Reeves WC, Heim C.	Chronic Viral Diseases Branch, National Center for Zoonotic, Vector-borne and Enteric Diseases, Centers for Disease Control and Prevention, Atlanta, GA 30333, USA.	Psychiatric comorbidity in persons with chronic fatigue syndrome identified from the Georgia population.	Psychosom Med. 2009 Jun;71(5):557-65. Epub 2009 May 4.	OBJECTIVE: To compare the prevalence of psychiatric disorders in persons with chronic fatigue syndrome (CFS) identified from the general population and a chronically ill group of people presenting with subsyndromic CFS-like illness ("insufficient symptoms or fatigue" (ISF)). Previous studies in CFS patients from primary and tertiary care clinics have found high rates of psychiatric disturbance, but this may reflect referral bias rather than true patterns of comorbidity with CFS. METHODS: We used random digit dialing to identify unwell individuals. A detailed telephone interview identified those with CFS-like illness. These individuals participated in a 1-day clinical evaluation to confirm CFS or ISF status. We identified 113 cases of CFS and 264 persons with ISF. To identify current and lifetime psychiatric disorders, participants completed the Structured Clinical Interview for DSM-IV. RESULTS: Sixty-four persons (57%) with CFS had at least one current psychiatric diagnosis, in contrast to 118 persons (45%) with ISF. One hundred one persons (89%) with CFS had at least one lifetime psychiatric diagnosis compared with 208 persons (79%) with ISF. Of note, only 11 persons (9.8%) with CFS and 25 persons (9.5%) with ISF reported having seen a mental healthcare specialist during the past 6 months. CONCLUSIONS: Our findings indicate that current and lifetime psychiatric disorders commonly accompany CFS in the general population. Most CFS cases with comorbid psychiatric conditions had not sought appropriate help during the past 6 months. These results demonstrate an urgent need to address psychiatric disorders in the clinical care of CFS cases.
Neu D, Cappeliez B, Hoffmann G, Verbanck P, Linkowski P, Le Bon O.	Brugmann University Hospital, Sleep Laboratory, and Unit for Chronobiology U78, Université Libre de Bruxelles (U.L.B), Brussels, Belgium. daniel.neu@chu-brugmann.be	High slow-wave sleep and low-light sleep: chronic fatigue syndrome is not likely to be a primary sleep disorder.	J Clin Neurophysiol. 2009 Jun;26(3):207-12.	The status of chronic fatigue syndrome (CFS) is still under debate. Mainstream views still often consider it as an undetected primary sleep disorder or as the psychosomatic expression of a related anxiety or depression syndrome. Both primary sleep disorder and CFS are often related to unrefreshing sleep and affective daytime symptoms. The present study compares nonrapid eye movement sleep distribution between patients with a primary sleep disorder and "pure" CFS patients without sleep or mood disorders. Intensity measures of affective symptoms are also analyzed. Sleep variables of 32 pure CFS (mean age, 41.9 +/- 8.7 years; 25 women), 30 Sleep Apnea Hypopnea Syndrome patients (mean age, 43.7 +/- 6.7 years; 13 women), and 14 healthy controls (mean age, 40.2 +/- 7.6 years; 9 women) were compared. Related affective symptoms were assessed using the self-reported Zung anxiety and depression scales. The study confirms previous reports on increased slow-wave sleep in CFS patients. Both patient groups showed similar sleep duration and efficiency. Sleep efficiency was lower in both patient groups compared with controls. CFS patients showed a higher microarousal index than controls. Anxiety, but not depression symptoms were more intense in the CFS group. The distribution of nonrapid eye movement sleep in CFS differs sizeably from what can be observed in a primary sleep disorder.
Newton JL, Sheth A, Shin J, Pairman J, Wilton K, Burt JA, Jones DE.	Cardiovascular Investigation Unit, Institute of Cellular Medicine, Newcastle	Lower ambulatory blood pressure in chronic fatigue syndrome.	Psychosom Med. 2009 Apr;71(3):361-5. Epub 2009 Mar 17.	OBJECTIVE: To examine blood pressure circadian rhythm in subjects with chronic fatigue syndrome (CFS) and appropriate normal and fatigued controls to correlate parameters of blood pressure regulation with perception of fatigue in an observational cohort study. The cause of CFS remains unknown and there are no effective treatments. METHODS: To address whether inactivity was a confounder, we performed a 24-hour ambulatory blood pressure monitoring in the following three

	University, Newcastle NE2 4HH, UK. julia.newton@nuth.northy.nhs.uk			subject groups: 1) CFS patients (Fukuda Diagnostic criteria) (n = 38); 2) normal controls (n = 120); and 3) a fatigue comparison group (n = 47) with the autoimmune liver disease primary biliary cirrhosis (PBC). All patients completed a measure of fatigue severity (Fatigue Impact Scale). In view of the different demographics between the patient groups, patients were age- and sex-matched on a case-by-case basis to normal controls and blood pressure parameters were compared. RESULTS: Compared with the control population, the CFS group had significantly lower systolic blood pressure ($p < .0001$) and mean arterial blood pressure ($p = .0002$) and exaggerated diurnal variation ($p = .009$). There was a significant inverse relationship between increasing fatigue and diurnal variation of blood pressure in both the CFS and PBC groups ($p < .05$). CONCLUSION: Lower blood pressure and abnormal diurnal blood pressure regulation occur in patients with CFS. We would suggest the need for a randomized, placebo-controlled trial of agents to increase blood pressure such as midodrine in CFS patients with an autonomic phenotype.
Ocon AJ, Medow MS, Taneja I, Clarke D, Stewart JM.	Department of Physiology, The Center for Hypotension, New York Medical College, Valhalla, New York 10532, USA.	Decreased upright cerebral blood flow and cerebral autoregulation in normocapnic postural tachycardia syndrome.	Am J Physiol Heart Circ Physiol. 2009 Aug;297(2):H664-73. Epub 2009 Jun 5.	Postural tachycardia syndrome (POTS), a chronic form of orthostatic intolerance, has signs and symptoms of lightheadedness, loss of vision, headache, fatigue, and neurocognitive deficits consistent with reductions in cerebrovascular perfusion. We hypothesized that young, normocapnic POTS patients exhibit abnormal cerebral autoregulation (CA) that results in decreased static and dynamic cerebral blood flow (CBF) autoregulation. All subjects had continuous recordings of mean arterial pressure (MAP) and CBF velocity (CBFV) using transcranial Doppler sonography in both the supine supine position and during a 70 degrees head-up tilt. During tilt, POTS patients (n = 9) demonstrated a higher heart rate than controls (n = 7) (109 +/- 6 vs. 80 +/- 2 beats/min, $P < 0.05$), whereas controls demonstrated a higher MAP than POTS (87 +/- 2 vs. 77 +/- 3 mmHg, $P < 0.05$). Also during tilt, mean CBFV decreased 19.5 +/- 2.6% in POTS patients versus 10.3 +/- 2.0% in controls ($P < 0.05$). We then used a transfer function analysis of MAP and CFBV in the frequency domain to quantify these changes. The low-frequency (LF; 0.04-0.15 Hz) component of CBFV variability increased during tilt in POTS patients (supine: 3 +/- 0.9 vs. tilt: 9 +/- 2, $P < 0.02$). In POTS patients, there was an increase in LF and high-frequency coherence between MAP and CBFV, an increase in LF gain, and a lack of significant change in phase. Static CA may be less effective in POTS patients compared with controls, since immediately after tilt CBFV decreased more in POTS patients and was highly oscillatory and autoregulation did not restore CBFV to baseline values until the subjects became supine. Dynamic CA may be less effective in POTS patients because MAP and CBFV during tilt became almost perfectly synchronous. We conclude that dynamic and static autoregulation of CBF are less effective in POTS patients compared with control subjects during orthostatic challenge.
Ogawa H, Hida W.	Health Administration Center, Tohoku University.	[Chronic obstructive pulmonary disease (COPD)] [Article in Japanese]	Nippon Rinsho. 2009 Aug;67(8):1518-24.	Insomnia is common in many patients with chronic obstructive pulmonary disease (COPD). The causes of insomnia are sleep induced pathophysiological effect of COPD itself, COPD comorbidities and the presence of coexisted obstructive sleep apnea. Sleep has profound adverse effects on respiration and gas exchange in patients with COPD. There are several mechanisms underlying oxygen desaturation during sleep. They include decreased functional residual capacity, decreased ventilatory responses to hypoxia and hypercapnia, impaired respiratory mechanical effectiveness, respiratory muscle fatigue, decreased respiratory drive, and increased upper airway resistance. COPD comorbidities include DM, cardiovascular diseases, osteoporosis, depression, and GERD. The coexistence of COPD and sleep

				apnea-hypopnea syndrome has been denominated "overlap syndrome".
Oka T, Kanemitsu Y.	Department of Psychosomatic Medicine, Graduate School of Medical Sciences, Kyushu University.	[Biomedical and psychosocial treatment of fatigue in functional somatic syndrome] [Article in Japanese]	Nippon Rinsho. 2009 Sep;67(9):1778-82.	Fatigue is one of the most common complaints of patients with functional somatic syndrome (FSS), which includes chronic fatigue syndrome (CFS). Although the etiology of fatigue related to FSS remains unclear, accumulating evidence has shown that cognitive behavioral therapy and graded exercise therapy are effective for treating fatigue in patients with CFS. This suggests that psychosocial intervention and physical rehabilitation, as well as biomedical treatment, play an important role in treating fatigue in FSS patients. Here we provide an overview of the biomedical and psychosocial treatments for fatigue in cases of FSS.
Oliveira WR, Ferreira GN, Rady PL, Festa C, Tyring SK.	Department of Dermatology, University of São Paulo, São Paulo, Brazil. walmarroncalli@uol.com.br	Epidermodysplasia verruciformis associated with myelodysplastic syndrome: an intriguing association.	J Cutan Med Surg. 2009 Nov-Dec;13(6):317-20.	BACKGROUND: Epidermodysplasia verruciformis (EV) is a rare genodermatosis characterized by massive infection with human papillomaviruses (HPVs) and development of skin cancer. Myelodysplastic syndromes (MDSs) are a group of chronic conditions that involve dysplastic hematopoiesis, peripheral blood cytopenias, and a high incidence of progression into leukemia. METHODS: We describe the intriguing association of these two premalignant conditions (EV and MDS) in one patient. These diagnoses were confirmed by histopathologic examination and cytogenetic abnormalities of bone marrow cells. RESULTS: The patient presented initially with clinical features typical of EV and impairment of cell-mediated immunity. In the skin lesions, HPVs 23 and 25 were identified by nested polymerase chain reaction. Six years later, he had recurrent episodes of mucosal bleeding with fever, weakness, and fatigue. At this time, severe refractory anemia and neutropenia were observed, and bone marrow smears showed hypercellularity with abnormal dysplastic megakaryocytes. The cytogenetic pattern showed abnormalities involving trisomy of chromosomes 8 and 21. The patient received a diagnosis of the indolent subtype of MDS. CONCLUSIONS: Through the observation of our patient and review of the literature, we hypothesized that the pathomechanisms, including the role of oncogenes and cytokines, are connected to the progression to malignancy in these settings.
Ortega-Hernandez OD, Cuccia M, Bozzini S, Bassi N, Moscavitch S, Diaz-Gallo LM, Blank M, Agmon-Levin N, Shoenfeld Y.	Department of Medicine B and Center for Autoimmune Diseases, Sheba Medical Center, Sackler Faculty of Medicine, Tel Aviv University, Tel Aviv, Israel.	Autoantibodies, polymorphisms in the serotonin pathway, and human leukocyte antigen class II alleles in chronic fatigue syndrome: are they associated with age at onset and specific symptoms?	Ann N Y Acad Sci. 2009 Sep;1173:589-99.	This study aimed to determine the influence of autoantibodies, polymorphisms in the serotonin pathway, and human leukocyte antigen (HLA) class II genes on age at chronic fatigue syndrome (CFS) onset and symptoms. Eighty-one CFS patients were enrolled, and clinical data were recorded. Autoantibodies to different components of the central nervous system were tested. Polymorphisms in the promoter of the serotonin transporter gene (I/s) and a single nucleotide polymorphism in the serotonin receptor-2A gene (A/G) as well as HLA class II alleles were determined. Multivariate logistic-regression analyses were carried out. The mean age at CFS onset +/- SD was 33.5 +/- 12.5 years. An age at CFS onset (ACFSO) during the third decade of life was associated with the serotonin receptor AA genotype and the HLA-DRB1*03 allele. An ACFSO during the fourth decade of life was associated with the HLA-DRB1*07 allele, whereas an ACFSO > or = 43 years was associated with having at least one copy of the serotonin G allele. Concerning CFS symptoms, the serotonin AG genotype was protective against depressive symptoms. Although having at least one copy of the serotonin A allele and being female were associated with risk for arthralgia, the presence of antineuronal cell antibodies was protective against this. Episodes of unexplained fever were associated with the HLA-DRB1*11 allele. None of the genetic or serological features was associated with myalgia. None of the antibodies determined correlated with any ACFSO or other symptoms. Our results reveal that in CFS, like other

				autoimmune diseases, different genetic features are related to age at CFS onset and symptoms.
Ortega-Hernandez OD, Shoenfeld Y.	Department of Internal Medicine B and Research for Autoimmune Diseases, Sheba Medical Center, Tel Hashomer, Israel.	Infection, vaccination, and autoantibodies in chronic fatigue syndrome, cause or coincidence?	Ann N Y Acad Sci. 2009 Sep;1173:600-9.	Chronic fatigue syndrome (CFS) is a heterogeneous syndrome of unknown etiology and physiopathology. CFS patients complain about disabling fatigue, depression, difficulty with memory, and concomitant skeletal and muscular pain. Interestingly enough, there is certain overlap between CFS symptoms, autoimmune rheumatic disease, and infectious diseases. Certain neuroendocrine-immune abnormalities have also been described, and autoantibodies commonly described in some autoimmune diseases have been found in CFS patients as well. An increasing number of autoantibodies, mainly directed against other nuclear cell components, have been illustrated. Likewise, an association between some infectious agents, antibody production, and later CFS onset has been reported. Similarly, vaccination is depicted as playing an important role in CFS onset. Recently, a case report pointed toward a causal association between silicone breast linkage, hepatitis B virus vaccination, and CFS onset in a previous healthy woman. Such findings suggest that there is a likely deregulation of the immune system influenced by specific agents (infections, vaccination, and products, such as silicone). Evidence suggests that CFS is a complex disease in which several risk factors might interact to cause its full expression. Thus, although different alterations have been found in CFS patients, undoubtedly the main feature is central nervous system involvement with immunological alterations. Therefore, a new term neuro-psycho-immunology must be quoted. New studies based on this concept are needed in order to investigate syndromes, such as CFS, in which immunological alterations are thought to be associated with concomitant psychological and health disturbances.
Øyane N, van den Hoven AM, Fetveit A, Pallesen S, Bjorvatn B.	Institutt for samfunnsmedisinske fag, Universitetet i Bergen og Nasjonalt kompetansesenter for søvnsykdommer, Haukeland universitetssykehus, 5021 Bergen og Bergen Søvnsenter, Norway. nicolas.oyane@isf.uib.no	[Symptom patterns in chronic sleep disorders] [Article in Norwegian]	Tidsskr Nor Laegeforen. 2009 Oct 8;129(19):2011-4.	BACKGROUND: Sleep disorders are classified into six main categories: insomnias, circadian rhythm disorders, sleep-related movement disorders, sleep-related breathing disorders, hypersomnias and parasomnias. The aim of this article is to shed light on differences between these categories with respect to symptom patterns. MATERIAL AND METHODS: The main sources of information are the diagnosis manual published by the American Academy of Sleep Medicine in 2005 and papers identified through non-systematic searches in Pubmed. RESULTS: Long sleep onset latency is most common in patients with insomnia, delayed sleep phase syndrome and restless legs while nightly awakenings are most common in patients with insomnia, restless legs and the sleep apnoea syndrome. Excessive daytime sleepiness is most pronounced in patients with hypersomnia, sleep apnoea syndrome and delayed sleep phase syndrome, whereas patients with insomnia rarely have this problem. Fatigue is a common feature of all sleep disorders, especially insomnia. The diagnosis of insomnia, circadian rhythm disturbances, restless legs and most parasomnias is mainly based on anamnestic data. Objective sleep recordings are necessary to diagnose sleep apnoea syndrome, hypersomnia and periodic leg movement during sleep. INTERPRETATION: The six sleep disorder categories differ substantially with respect to symptom patterns. Sleep disorders can often be distinguished from each other by use of anamnestic data without resorting to further assessment, but objective sleep recordings are needed for accurate diagnosis of some patients.
Pae CU, Marks DM, Patkar AA, Masand PS, Luyten	Holy Family Hospital, The Catholic University	Pharmacological treatment of chronic fatigue	Expert Opin Pharmacother. 2009	Chronic fatigue syndrome (CFS) is characterized by chronic, medically unexplained fatigue associated with effort- and stress-intolerance, widespread pain, and impairment in sleep and concentration. Although this constellation of symptoms is highly prevalent in clinical practice, the pathophysiological

P, Serretti A.	of Korea College of Medicine, Department of Psychiatry, Bucheon 420717, Kyeonggi-Do, South Korea. pae@catholic.ac.kr	syndrome: focusing on the role of antidepressants.	Jul;10(10):1561-70.	mechanisms underlying CFS are poorly understood. Current evidence indicates similarities in symptomatology, and possibly etiology and pathogenesis, between CFS and depression. Additionally, there is significant overlap between CFS and the syndrome of fibromyalgia for which antidepressants have shown consistent efficacy. Data regarding antidepressant treatment of CFS is less copious and less uniformly positive, such that antidepressant use in CFS remains controversial. The current review aims to summarize available data related to antidepressants and other psychotropic agents in CFS to provide a platform for clinicians to make decisions in their treatment of this challenging syndrome. We identified relevant studies through a PubMed literature search with a combination of the following search terms: 'fatigue,' 'depression,' 'antidepressant,' 'etiology' (e.g., 'neurobiology,' 'neurotransmitter,' 'genetic'), 'diagnosis,' and 'treatment' (e.g., 'antidepressant' plus the specific name). In addition, studies were also identified via the reference sections of retrieved articles. The authors thoroughly reviewed major findings from the scanned literatures and eventually synthesized them, providing summary, interpretation, and future directions.
Pall ML.	The Tenth Paradigm Research Group and School of Molecular Biosciences (WSU), 638 NE 41st Ave., Portland, OR 97232-3312, USA. martin_pall@wsu.edu	Do sauna therapy and exercise act by raising the availability of tetrahydrobiopterin?	Med Hypotheses. 2009 Oct;73(4):610-3. Epub 2009 Jul 5.	Sauna therapy has been used to treat a number of different diseases known or thought to have a tetrahydrobiopterin (BH4) deficiency. It has been interpreted to act in multiple chemical sensitivity by increasing chemical detoxification and excretion but there is no evidence that this is its main mode of action. Sauna therapy may act to increase BH4 availability via two distinct pathways. Increased blood flow in heated surface tissues leads to increased vascular shear stress, inducing increased activity of GTP cyclohydrolase I (GTPCH-I) in those vascular tissues which will lead to increasing BH4 synthesis. A second mechanism involves the heat shock protein Hsp90, which is induced by even modest heating of mammalian tissues. Sauna heating of these surface tissues may act via Hsp90, which interacts with the GTPCH-I complex and is reported to produce increased GTPCH-I activity by lowering its degradation. The increased consequent availability of BH4 may lead to lowered nitric oxide synthase uncoupling, such as has been reported for the eNOS enzyme. Increased BH4 synthesis in surface tissues of the body will produce increased circulating BH4 which will feed BH4 to other body tissues that may have been BH4 deficient. Similar mechanisms may act in vigorous exercise due to the increased blood shear stresses and possibly also heating of the exercising tissues and heart. There is a large and rapidly increasing number of diseases that are associated with BH4 depletion and these may be candidates for sauna therapy. Such diseases as hypertension, vascular endothelial dysfunction, multiple chemical sensitivity and heart failure are thought to be helped by sauna therapy and chronic fatigue syndrome and fibromyalgia may also be helped and there are others that may be good candidates for sauna therapy.
Panossian A, Wikman G.	Swedish Herbal Institute Research and Development, Spårvägen 2, SE-43296 Askloster, Sweden. alexander.panossian@shi.se	Evidence-based efficacy of adaptogens in fatigue, and molecular mechanisms related to their stress-protective	Curr Clin Pharmacol. 2009 Sep;4(3):198-219. Epub 2009 Sep 1.	The aim of this review article is to assess the level of scientific evidence presented by clinical trials of adaptogens in fatigue, and to provide a rationale at the molecular level for verified effects. Strong scientific evidence is available for Rhodiola rosea SHR-5 extract, which improved attention, cognitive function and mental performance in fatigue and in chronic fatigue syndrome. Good scientific evidence has been documented in trails in which Schisandra chinensis and Eleutherococcus senticosus increased endurance and mental performance in patients with mild fatigue and weakness. Based on their efficacy in clinical studies, adaptogens can be defined as a pharmacological group of herbal preparations that increase tolerance to mental exhaustion and enhance attention and mental

		activity.		endurance in situations of decreased performance. The beneficial stress-protective effect of adaptogens is related to regulation of homeostasis via several mechanisms of action associated with the hypothalamic-pituitary-adrenal axis and the control of key mediators of stress response such as molecular chaperons (e.g. Hsp70), stress-activated c-Jun N-terminal protein kinase (JNK1), Forkhead Box O transcription factor DAF-16, cortisol and nitric oxide (NO). The key point of action of phytoadaptogens appears to be their up-regulating and stress-mimetic effects on the "stress-sensor" protein Hsp70, which plays an important role in cell survival and apoptosis. Hsp70 inhibits the expression of NO synthase II gene and interacts with glucocorticoid receptors directly and via the JNK pathway, thus affecting the levels of circulating cortisol and NO. Prevention of stress-induced increase in NO, and the associated decrease in ATP production, results in increased performance and endurance. Adaptogen-induced up-regulation of Hsp70 triggers stress-induced JNK-1 and DAF-16-mediated pathways regulating the resistance to stress and resulting in enhanced mental and physical performance and, possibly, increased longevity.
Papadopoulos A, Ebrecht M, Roberts AD, Poon L, Rohleder N, Cleare AJ.	King's College London, Institute of Psychiatry, Section of Neurobiology of Mood Disorders, Division of Psychological Medicine, London SE5 8AF, United Kingdom.	Glucocorticoid receptor mediated negative feedback in chronic fatigue syndrome using the low dose (0.5 mg) dexamethasone suppression test.	J Affect Disord. 2009 Jan;112(1-3):289-94. Epub 2008 Jun 24.	BACKGROUND: Chronic fatigue syndrome (CFS) is associated with hypocortisolism, but it is not yet clear the extent to which enhanced negative feedback may underlie this finding. METHODS: We undertook a low-dose dexamethasone (0.5 mg) suppression test in 18 CFS patients and 20 matched, healthy controls. We measured salivary cortisol levels at 0800 h, 1200 h, 1600 h and 2000 h before and after the administration of 0.5 mg of dexamethasone. RESULTS: Basal cortisol output was raised in this group of CFS patients compared to controls. Overall, the percentage suppression following dexamethasone administration was no different between CFS (mean+/-sem: 80.4+/-4.4%) and controls (76.2+/-4.9 %). However, the sub-group of patients with CFS and comorbid depression (n=9) showed a significant hypersuppression of salivary cortisol in response to dexamethasone (89.0+/-1.9%; $p<0.05$ v controls). LIMITATIONS: The sub-group analysis was on small numbers and should be considered preliminary. Dexamethasone probes only glucocorticoid medicated negative feedback but does not probe mineralocorticoid feedback, the other main physiological feedback mechanism. CONCLUSION: We found partial support for the hypothesis of enhanced negative feedback in CFS but only in patients with comorbid depression and also in the context of a sample of patients with elevated basal cortisol levels, which is an atypical finding in the literature.

Frequent ejaculation associated free radical and lactic acid accumulation cause noninfectious inflammation and muscle dysfunction: a potential mechanism for symptoms in Chronic Prostatitis/Chronic Pelvic Pain Syndrome.	Med Hypotheses. 2009 Sep;73(3):372-3. Epub 2009 May 10.	BACKGROUND: The prevalence of prostatitis is extremely high, with vast majority belongs to National Institutes of Health Category III: Chronic Prostatitis (CP)/Chronic Pelvic Pain Syndromes (CPPS). The etiology of CP/CPPS is noninfectious, with no precise mechanisms has been elucidated to date. HYPOTHESIS: During male ejaculation, the pelvic muscles undergo coordinated intense contraction to expel the semen out of the male genital tract, a process associated with locally increased levels of lactic acid and free radicals as byproducts. In this regards, repetitive sexual activities with frequent ejaculation would impede the drainage and cause accumulation of these byproducts in the pelvic region, triggering consequent local pathophysiological changes such as edema, venous dilation and muscular malfunction, which further leads to common complaints in CP/CPPS patients such as lower urinary tract symptoms, pelvic discomfort and pain. RATIONALE: Large cohort studies have revealed that frequent ejaculation is associated with higher risk of prostatitis, especially in young men. Also, clear evidences from sports medical research has shown that intense muscular contraction will lead to locally increased production of free radicals and lactic acid. Therefore, the pelvic muscles during ejaculation would induce substantial increase of these byproducts, which if not cleared effectively, could trigger series of local cellular/tissue damages resulting in inflammation, muscular fatigue and dysfunction. If our hypothesis were validated, it could be suggested that at least in some patients, the treatment of CP/CPPS could be tuned as dealing with post-sports recovery, such as hot bath to promote local blood circulation and free radical scavenger drugs such as vitamin C and E to neutralize free radicals.
Pietrangelo T, Mancinelli R, Toniolo L, Montanari G, Vecchiet J, Fanò G, Fulle S.	Department of Basic and Applied Medical Sciences (BAMS), Center for Excellence on Aging (CeSI), University G. d'Annunzio Chieti-Pescara, Chieti, Italy. tiziana@unich.it	Transcription profile analysis of vastus lateralis muscle from patients with chronic fatigue syndrome.	Int J Immunopathol Pharmacol. 2009 Jul-Sep;22(3):795-807.	Chronic fatigue syndrome (CFS) is a disabling condition characterized by unexplained chronic fatigue that impairs normal activities. Many body systems are affected and etiology has not yet been identified. In addition to immunological and psychological aspects, skeletal muscle symptoms are prominent in CFS patients. In an effort to establish which pathways might be involved in the onset and development of muscle symptoms, we used global transcriptome analysis to identify genes that were differentially expressed in the vastus lateralis muscle of female and male CFS patients. We found that the expression of genes that play key roles in mitochondrial function and oxidative balance, including superoxide dismutase 2, were altered, as were genes involved in energy production, muscular trophism and fiber phenotype determination. Importantly, the expression of a gene encoding a component of the nicotinic cholinergic receptor binding site was reduced, suggesting impaired neuromuscular transmission. We argue that these major biological processes could be involved in

				and/or responsible for the muscle symptoms of CFS.
Pietrangelo T, Toniolo L, Paoli A, Fulle S, Puglielli C, Fanò G, Reggiani C.	Dept. Basic and Applied Medical Sciences (BAMS), Center for Excellence on Ageing (CeSI), University - G. dAnnunzio- Chieti-Pescara, Chieti, Italy. tiziana@unich.it	Functional characterization of muscle fibres from patients with chronic fatigue syndrome: case-control study.	Int J Immunopathol Pharmacol. 2009 Apr-Jun;22(2):427-36.	Chronic fatigue syndrome (CFS) is a disabling condition characterized by unexplained chronic fatigue that impairs normal activities. Although immunological and psychological aspects are present, symptoms related to skeletal muscles, such as muscle soreness, fatigability and increased lactate accumulation, are prominent in CFS patients. In this case-control study, the phenotype of the same biopsy samples was analyzed by determining i) fibre-type proportion using myosin isoforms as fibre type molecular marker and gel electrophoresis as a tool to separate and quantify myosin isoforms, and ii) contractile properties of manually dissected, chemically made permeable and calcium-activated single muscle fibres. The results showed that fibre-type proportion was significantly altered in CSF samples, which showed a shift from the slow- to the fast-twitch phenotype. Cross sectional area, force, maximum shortening velocity and calcium sensitivity were not significantly changed in single muscle fibres from CSF samples. Thus, the contractile properties of muscle fibres were preserved but their proportion was changed, with an increase in the more fatigue-prone, energetically expensive fast fibre type. Taken together, these results support the view that muscle tissue is directly involved in the pathogenesis of CSF and it might contribute to the early onset of fatigue typical of the skeletal muscles of CFS patients.
Plastiras S, Kampessi O.	Department of Pathophysiology, University of Athens School of Medicine Laiko University Hospital, 11527 Athens Greece.	Acute lymphocytic crisis following herpes simplex type 1 virus hepatitis in a nonimmunocompromised man: a case report.	J Med Case Reports. 2009 Aug 3;3:7492.	INTRODUCTION: An increase in circulating lymphocytes can be seen following infections such as infectious mononucleosis and pertussis, or in lymphoproliferative disorders such as acute and chronic lymphocytic leukemia. Acute lymphocytic crisis following herpes simplex virus hepatitis has not been described in the literature. CASE PRESENTATION: A 52-year-old man was admitted to our hospital reporting low-grade fever for the previous seven days, and fatigue. During the fifth day of hospitalization, the patient developed a lymphocytic crisis and, after further tests the patient was diagnosed as having herpes simplex virus hepatitis. CONCLUSION: This case report shows that herpes simplex virus type 1 is a possible cause of an acute lymphocytic crisis similar to other well known infectious agents such as Epstein-Barr virus, cytomegalovirus, human immunodeficiency virus, human herpes virus type 6, adenovirus, toxoplasma and human T-cell lymphotropic virus. Furthermore, this case report expands the clinical spectrum of herpes simplex virus hepatitis, since it is reported in a nonimmunocompromised patient presenting with atypical acute lymphocytic syndrome.
Podolecki T, Podolecki A, Hrycek A.	Independent Public Central Clinical Hospital, Katowice, Poland. tomekpod@interia.pl	Fibromyalgia: pathogenetic, diagnostic and therapeutic concerns.	Pol Arch Med Wewn. 2009 Mar;119(3):157-61.	Musculoskeletal pains are one of the most common complaints reported by patients. In 1972, Smythe described the generalized pain and tenderness on palpation at specific points and, 4 years later, the term fibromyalgia was introduced for determining the disease syndrome. The etiology and pathogenesis of fibromyalgia are still unknown. This disease appears probably multi-factorial. It is considered that the changes in the neuronal activity in the central nervous system, abnormal metabolism of biogenic amines and immunological disorders may among other things, contribute to the development of the disease. The complaints are non characteristic and highly sujective, which makes it substantially difficult to differentiate between fibromialgia and both chronic fatigue syndrome and psychosomatic diseases. The treatment of fibromyalgia is complex and long-term. The antidepressants and psychotherapy is of vital importance. The effectiveness of locally used agents is also being emphasized. Fibromyalgia has become a serious social problem in the well developed countries in the recent years. Therefore, of importance are efforts to appropriately diagnose

				fibromyalgia and to implement its appropriate treatment that resolves disease symptoms in a possibly maximum degree.
Puri BK, Agour M, Gunatilake KD, Fernando KA, Gurusinghe AI, Treasaden IH.	MRI Unit, Imaging Sciences Department, MRC Clinical Sciences Centre, Imperial College School of Medicine, Hammersmith Hospital, Du Cane Road, London W12 0HS, England, UK. basant.puri@imperial.ac.uk	An in vivo proton neurospectroscopy study of cerebral oxidative stress in myalgic encephalomyelitis (chronic fatigue syndrome).	Prostaglandins Leukot Essent Fatty Acids. 2009 Nov-Dec;81(5-6):303-5. Epub 2009 Nov 10.	A particularly important family of antioxidant defence enzymes in the body are the glutathione peroxidases, which remove H(2)O(2) by coupling its reduction to H(2)O with oxidation of reduced glutathione (GSH) to oxidised glutathione (GSSG). There are suggestions that GSH in the peripheral blood may be reduced in myalgic encephalomyelitis, which is a highly disabling neurological disease of unknown aetiology. Since many of the symptoms relate to cerebral functioning, it would seem probable that peripheral blood GSH findings would be reflected in lower cerebral GSH levels. The aim of this study was to carry out the first direct assessment of cerebral GSH levels in myalgic encephalomyelitis; the hypothesis being tested was that cerebral GSH levels would be reduced in myalgic encephalomyelitis. Cerebral proton neurospectroscopy was carried out at a magnetic field strength of 3T in 26 subjects; spectra were obtained from 20x20x20mm(3) voxels using a point-resolved spectroscopy pulse sequence. The mean cerebral GSH level in the myalgic encephalomyelitis patients was 2.703 (SD 2.311) which did not differ significantly from that in age- and gender-matched normal controls who did not have any history of neurological or other major medical disorder (5.191, SD 8.984; NS). Therefore our study does not suggest that GSH is reduced in the brain in myalgic encephalomyelitis. At the present time, based on the results of this study, there is no evidence to support the suggestion that, by taking glutathione supplements, an improvement in the brain-related symptomatology of myalgic encephalomyelitis may occur.

Quillinan N, Mohammad A, Mannion G, O'Keeffe D, Bergin D, Coughlan R, Mc Dermott MF,	1 Department of Rheumatology, Merlin Park Hospital (Galway University Hospital),	Imaging evidence for persistent subclincal fasciitis and arthritis in TNF Receptor-Associated	Ann Rheum Dis. 2009 Nov 12. [Epub ahead of print]	TNF Receptor-Associated Periodic Syndrome (TRAPS) [1], formerly known as familial Hibernian fever (FHF) [2, 3] is an archetypal hereditary periodic fever syndrome and is an autosomal dominant condition characterised by mutations in the TNFRSF1A gene [4, 5]. Periodicity of fevers is typical of TRAPS with peritonitis, arthritis and fasciitis. It is also well recognised that some patients continue to feel unwell between attacks. That subclincal TRAPS is still ongoing in such circumstances is supported by persistent acute phase response [6, 7]. There are no specific features to localise a site for this

McGonagle D.	Renmore, Galway, Ireland;	Periodic Syndrome (TRAPS) between febrile attacks.		persistent inflammatory response and, to date, no studies have been done to investigate this interesting observation. Whole body magnetic resonance imaging (MRI) has recently been introduced for the assessment of various skeletal pathologies including malignancy, myositis and arthritis [8-12]. MRI in inflammatory disorders has the capacity to show both soft tissue inflammatory changes and osteitis. We hypothesised that patients with TRAPS without obvious clinical manifestations and the absence of fevers have subclincal disease affecting the anatomical territories that are prone to inflammation during acute attacks. Herein, we confirm that some cases of TRAPS do indeed have ongoing soft tissue and joint inflammation between attacks. Given that autoinflammatory disorders, like TRAPS, are diseases of the innate immune system, these findings support the concept of persistent innate immune activation between attacks. The Galway (Ireland) TRAPS cohort consists of 15 affected family members, 2 of whom have amyloidosis and all having the T50M mutation in the TNFRSF1A gene [13]. A total of 9 members of this family attend the clinic regularly. Persistently raised inflammatory markers were found in 7 of these patients, 2 members did not give consent for MRI due to claustrophobia. A total of 5 members participated in the study, however during the course of the study; one of these patients had normal inflammatory markers in spite of having persistently raised markers before screening. Interview and clinical examination were performed to document symptoms, frequency of flares, inflammatory markers and medications (Table 1). All cases described classical attacks of fever, sweats, abdominal pain and serositis. They also had symptoms between attacks including prominent myalgia, arthralgia, malaise and fatigue, with persistently elevated inflammatory markers in 4 out of 5 patients confirming ongoing disease activity between attacks. After obtaining informed consent, all 5 cases had whole body scanning on a Siemens 1.5 T MRI (Siemens-AG, Symphony). Images were reviewed on Agfa PACS High resolution workstation by two fellowship trained musculoskeletal radiologists. One patient had a flare during the MRI and was rescanned between flares. MRI results are shown in Table 1. Bilateral knee and hip effusions and bone oedema of left tibia were found in one patient, who was asymptomatic at the time of his scan and did not have osteoarthritis clinically or radiologically in this knee. Repeat MRI of the left knee was done. It is possible that the knee changes could have been contributed to by ligament injury and joint degeneration that was asymptomatic. Only one MRI of 5 was completely normal with corresponding normal inflammatory markers (Figure 1). In conclusion, we provide MRI evidence for persistent subclinical tissue inflammation in an identical pattern to that seen during classical attacks of TRAPS. This suggests that the innate immune driven pathology is actually chronic and most likely represents recurrent acute attacks of subclinical tissue inflammation. Unlike some other conditions of chronic innate immune activation including Blau syndrome, the inflammation in TRAPS does not appear to lead to target organ destruction [14]. The utility of whole body MRI for exploring febrile illness with a TRAPS phenotype without TNFRS1A mutations is also worthy of consideration.
Raison CL, Lin JM, Reeves WC.	Department of Psychiatry and Behavioral Sciences, Emory University School	Association of peripheral inflammatory markers with chronic fatigue in a	Brain Behav Immun. 2009 Mar;23(3):327-37. Epub 2008 Dec 11.	Alterations in the innate immune response may contribute to the pathogenesis of chronic fatigue syndrome (CFS). However, studies have been limited by small sample sizes, use of patients from tertiary care settings, inappropriate selection of controls, and failure to control for confounding demographic, medical and behavioral factors independently associated with immune activity. It is also not known whether specific symptoms account for observed associations between CFS and the

	of Medicine, 1365C Clifton Road, Room 5004, Atlanta, GA 30322, USA. craison@emory.edu	population-based sample.Comment in: Brain Behav Immun. 2009 Mar;23(3):325-6.		innate immune response. To address these limitations, the current study examined plasma concentrations of high-sensitivity c-reactive protein (hs-CRP), white blood cell count (WBC) and a combined inflammation factor in a large population-based sample. Log-transformed mean plasma concentrations of hs-CRP were increased in subjects with CFS (n=102) and in subjects with unwellness symptoms that did not meet diagnostic criteria for CFS (defined as "insufficient fatigue" [ISF]) (n=240) when compared to subjects who were well (n=115). Log transformed WBC was increased in ISF and was increased at a trend level in CFS. The combined inflammation factor was increased in both CFS and ISF. Subjects with CFS and ISF did not differ on any of the inflammation measures. In the entire subject population, the physical component summary score (PCS), but not the mental component summary score (MCS), from the Medical Outcomes Study Short Form-36 (SF-36) was negatively associated with each of the inflammation measures. Depressive symptoms were also associated with increased log hs-CRP. After adjustment for age, sex, race, location of residence, BMI, depressive status and immune-modulating medications, subjects classified as ISF continued to demonstrate increased log hs-CRP, WBC and elevations on the inflammation factor when compared to well controls; however, associations between CFS and log hs-CRP and the inflammation factor were no longer statistically significant. After adjustment, PCS score also remained independently associated with each of the inflammation measures. These findings support a role for innate immune activation in unexplained fatigue and unwellness, but do not suggest that immune activation is specific to CFS.
Ramdharry GM, Day BL, Reilly MM, Marsden JF.	St. George's School of Physiotherapy Kingston University, London, UK.	Hip flexor fatigue limits walking in Charcot-Marie-Tooth disease.	Muscle Nerve. 2009 Jul;40(1):103-11.	Charcot-Marie-Tooth (CMT) disease results in distal lower limb weakness that affects walking. In this study we assess the role of the hip flexors in compensating for distal weakness while walking and the effects of prolonged walking on these putative compensatory strategies. Eighteen subjects with CMT disease were compared with 14 matched controls while they walked on a treadmill to a predetermined point of perceived effort. A significant reduction was observed in peak hip flexor velocity during walking and hip flexor maximal voluntary contraction. In a second session following selective fatigue of the hip flexors, hip flexor velocity decreased immediately on walking, and walking duration was greatly reduced. This study suggests that hip flexors compensate for distal weakness and that fatigue in the hip flexors can limit walking duration. Treatments directed toward improving proximal muscle strength may therefore help to delay onset of hip flexor fatigue and thus prolong walking duration.
Rao AV, Bested AC, Beaulne TM, Katzman MA, Iorio C, Berardi JM, Logan AC.	Integrative Care Centre of Toronto, 3600 Ellesmere Road, Unit 4, Toronto, Ontario M1C 4Y8, Canada. aclnd@cfs-fm.org.	A randomized, double-blind, placebo-controlled pilot study of a probiotic in emotional symptoms of chronic fatigue syndrome.	Gut Pathog. 2009 Mar 19;1(1):6.	ABSTRACT: Chronic fatigue syndrome (CFS) is complex illness of unknown etiology. Among the broad range of symptoms, many patients report disturbances in the emotional realm, the most frequent of which is anxiety. Research shows that patients with CFS and other so-called functional somatic disorders have alterations in the intestinal microbial flora. Emerging studies have suggested that pathogenic and non-pathogenic gut bacteria might influence mood-related symptoms and even behavior in animals and humans. In this pilot study, 39 CFS patients were randomized to receive either 24 billion colony forming units of Lactobacillus casei strain Shirota (LcS) or a placebo daily for two months. Patients provided stool samples and completed the Beck Depression and Beck Anxiety Inventories before and after the intervention. We found a significant rise in both Lactobacillus and Bifidobacteria in those taking the LcS, and there was also a significant decrease in anxiety symptoms among those taking the probiotic vs controls (p = 0.01). These results lend further support to the

				presence of a gut-brain interface, one that may be mediated by microbes that reside or pass through the intestinal tract.

Reynolds NL, Brown MM, Jason LA.	DePaul University.	The relationship of Fennell phases to symptoms among patients with chronic fatigue syndrome.	Eval Health Prof. 2009 Sep;32(3):264-80. Epub 2009 Aug 20.	The Fennell Phase Inventory (FPI) is an instrument designed to measure phases of the illnesses known as Myalgic Encephalomyelitis/Chronic Fatigue Syndrome (ME/CFS). The current study explored how the FPI was related to physical and psychological functioning as well as coping style. Based on FPI scores, 111 adults with ME/CFS were placed in one of three groups: crisis, stabilization, or resolution. Results showed that the crisis group demonstrated significantly worse functioning than at least one other group for depression, quality of life, mental functioning, anxiety, and self-efficacy; and utilized less adaptive coping styles. These results indicate that patients with ME/CFS who are in the crisis phase tend to experience more severe psychological and physical symptoms and utilize poorer coping strategies. Those in the resolution phase maintain the most adaptive coping strategies. Implications for these findings are discussed.
Roberts AD, Charler ML, Papadopoulos A, Wessely S, Chalder T, Cleare AJ.	King's College London, Institute of Psychiatry, Department of Psychological Medicine, London, UK.	Does hypocortisolism predict a poor response to cognitive behavioural therapy in chronic fatigue syndrome?	Psychol Med. 2009 Jul 17:1-8. [Epub ahead of print]	BACKGROUND: There is evidence that patients with chronic fatigue syndrome (CFS) have mild hypocortisolism. The clinical significance of this is unclear. We aimed to determine whether hypocortisolism exerted any effect on the response of CFS to cognitive behavioural therapy (CBT).MethodWe measured 24-h urinary free cortisol (UFC) in 84 patients with Centers for Disease Control and Prevention (CDC)-defined CFS (of whom 64 were free from psychotropic medication) who then received CBT in a specialist, tertiary out-patient clinic as part of their usual clinical care. We also measured salivary cortisol output from 0800 to 2000 h in a subsample of 56 psychotropic medication-free patients. RESULTS: Overall, 39% of patients responded to CBT after 6 months of treatment. Lower 24-h UFC output was associated with a poorer response to CBT but only in psychotropic medication-free patients. A flattened diurnal profile of salivary cortisol was also associated with a poor response to CBT. CONCLUSIONS: Low cortisol is of clinical relevance in CFS, as it is associated with a poorer response to CBT. Hypocortisolism could be one of several maintaining factors that interact in the persistence of CFS.
Roberts AD,	King's College	Salivary cortisol	J Affect Disord.	BACKGROUND: There is evidence that patients with chronic fatigue syndrome (CFS) have mild

Papadopoulos AS, Wessely S, Chalder T, Cleare AJ.	London, Institute of Psychiatry, Department of Psychological Medicine, De Crespigny Park, London SE5 8AF, UK.	output before and after cognitive behavioural therapy for chronic fatigue syndrome.	2009 May;115(1-2):280-6. Epub 2008 Oct 19.	hypocortisolism. One theory about the aetiology of this hypocortisolism is that it occurs late in the course of CFS via factors such as inactivity, sleep disturbance, chronic stress and deconditioning. We aimed to determine whether therapy aimed at reversing these factors--cognitive behavioural therapy for CFS--could increase cortisol output in CFS. METHODS: We measured diurnal salivary cortisol output between 0800 and 2000 h before and after 15 sessions (or 6 months) of CBT in 41 patients with CDC-defined CFS attending a specialist, tertiary outpatient clinic. RESULTS: There was a significant clinical response to CBT, and a significant rise in salivary cortisol output after CBT. LIMITATIONS: We were unable to control for the passage of time using a non-treated CFS group. CONCLUSIONS: Hypocortisolism in CFS is potentially reversible by CBT. Given previous suggestions that lowered cortisol may be a maintaining factor in CFS, CBT offers a potential way to address this.
Robinson M, Gray SR, Watson MS, Kennedy G, Hill A, Belch JJ, Nimmo MA.	Strathclyde Institute of Pharmacy and Biomedical Sciences, University of Strathclyde, Glasgow, UK.	Plasma IL-6, its soluble receptors and F-isoprostanes at rest and during exercise in chronic fatigue syndrome.	Scand J Med Sci Sports. 2009 Apr 13. [Epub ahead of print]	The aim of the current study was to investigate the levels of interleukin-6 (IL-6), its soluble receptors (sIL-6R and sgp130) and F(2)-isoprostanes, at rest and during exercise, in patients with chronic fatigue syndrome (CFS). Six male CFS patients and six healthy controls performed an incremental exercise test to exhaustion and a submaximal exercise bout to exhaustion. Blood samples taken in the submaximal test at rest, immediately post-exercise and 24 h post-exercise were analyzed for IL-6, sIL-6R, sgp130 and F(2)-isoprostanes. A further 33 CFS and 33 healthy control participants gave a resting blood sample for IL-6 and sIL-6R measurement. During the incremental exercise test only power output at the lactate threshold was lower ($P<0.05$) in the CFS group. F(2)-isoprostanes were higher ($P<0.05$) in CFS patients at rest and this difference persisted immediately and 24 h post-exercise. The exercise study found no differences in IL-6, sIL-6R or sgp130 at any time point between groups. In the larger resting group, there were no differences in IL-6 and sIL-6R between CFS and control groups. This investigation has demonstrated that patients with CFS do not have altered plasma levels of IL-6, sIL-6R or sgp130 either at rest or following exercise. F(2)-isoprostanes, however, were consistently higher in CFS patients.
Rodríguez MA, Afari N, Buchwald DS; National Institute of Diabetes and Digestive and Kidney Diseases Working Group on Urological Chronic Pelvic Pain. Collaborators: Afari N, Buchwald DS, Clauw D, Dimitrakov J, Kusek J, Mullins C, Nyberg L, Payne C,	Department of Psychology, University Rey Juan Carlos, Madrid, Spain.	Evidence for overlap between urological and nonurological unexplained clinical conditions.	J Urol. 2009 Nov;182(5):2123-31. Epub 2009 Sep 16.	PURPOSE: Unexplained clinical conditions share common features such as pain, fatigue, disability out of proportion to physical examination findings, inconsistent laboratory abnormalities, and an association with stress and psychosocial factors. We examined the extent of the overlap among urological and nonurological unexplained clinical conditions characterized by pain. We describe the limitations of previous research and suggest several possible explanatory models. MATERIALS AND METHODS: Using hallmark symptoms and syndromes as search terms a search of 12 databases identified a total of 1,037 full-length published articles in 8 languages from 1966 to April 2008. The search focused on the overlap of chronic pelvic pain, interstitial cystitis, painful bladder syndrome, chronic prostatitis/chronic pelvic pain syndrome or vulvodynia with fibromyalgia, chronic fatigue syndrome, temporomandibular joint and muscle disorders or irritable bowel syndrome. We abstracted information on authorship, type of case and control groups, eligibility criteria, case definitions, study methods and major findings. RESULTS: The literature suggests considerable comorbidity between urological and nonurological unexplained clinical conditions. The most robust evidence for overlap was for irritable bowel syndrome and urological unexplained syndromes with some estimates of up to 79% comorbidity between chronic pelvic pain and symptoms of irritable bowel syndrome. However, most studies were limited by methodological problems, such as varying

Peñacoba C, Pezzone M, Pontari M, Potts J, Rodríguez MA, Warren J.				case definitions and selection of controls. CONCLUSIONS: The overlap between urological and selected nonurological unexplained clinical conditions is substantial. Future research should focus on using standardized definitions, and rigorously designed, well controlled studies to further assess comorbidity, clarify the magnitude of the association and examine common pathophysiological mechanisms.
Romano JM, Jensen MP, Schmaling KB, Hops H, Buchwald DS.	Department of Psychiatry and Behavioral Sciences, University of Washington, Box 356560, Seattle, WA, 98195, USA, jromano@u.washington.edu.	Illness behaviors in patients with unexplained chronic fatigue are associated with significant other responses.	J Behav Med. 2009 Nov 14. [Epub ahead of print]	Chronic fatigue syndrome (CFS) and unexplained chronic fatigue (CF) are characterized by compromised functional status and physical disability. Prior research on chronic pain has suggested that social factors may contribute to disability. This study examined the relationship between significant other responses and patient outcomes in patients with unexplained CF. Questionnaire data were collected from 117 patients on physical function, fatigue, pain, illness behaviors and responses of significant others to them, and depression. Ninety-four SOs reported their perceptions of patient illness behavior and their responses. Thirty-seven of these dyads also completed a series of household activities while being videotaped. Dyadic interactions were coded and analyzed. Both reported and observed solicitous responses by the significant other were associated with reported and observed patient illness behavior. Negative responses to patient illness behavior by significant others were associated with higher levels of patient depressive symptoms. The findings provide support for the role of operant behavioral factors in the context of chronic fatigue. They also suggest that further research on the relationship between dysfunction and significant other responses in patients with CFS or CF appears warranted and may have implications for treatment development.
Rudolph T, Larsen JP, Farbu E.	Department of Neurology, Stavanger University Hospital, Stavanger, Norway. mokum99@online.no	Is there a need for long-term follow-up in chronic idiopathic polyneuropathy?	Acta Neurol Scand. 2009 Nov;120(5):347-52. Epub 2009 Sep 10.	OBJECTIVE: To evaluate the long-term functional status and well-being in patients with chronic idiopathic polyneuropathy (CIP) in comparison to Guillain-Barré syndrome (GBS) and healthy controls. MATERIALS AND METHODS: Forty-two CIP and 42 GBS-patients were examined at median 5 and 6 years after disease onset and were compared with 50 healthy controls. The Fatigue Severity Scale (FSS), Visual Analogue Scale for pain (VAS), Disability Rating Index (DRI) and Medical Outcome Study 36-item short-form health status scale (SF-36) were used. Variables at onset and symptoms at follow-up were correlated with outcome measurements in GBS. RESULTS: Patients with CIP and GBS had more pain and disability than healthy controls. Additionally, CIP-patients were more fatigued than healthy controls. Patients with CIP were more fatigued [FSS 4.9 (SD 1.6) vs 3.8 (SD 1.8); $P < 0.01$] and disabled [DRI 4.1 (SD 2.3) vs 2.5 (SD 2.1); $P = 0.05$] than those with GBS. Physical functioning on the SF-36 was more impaired in CIP than GBS, compared with healthy controls. CONCLUSIONS: Patients with CIP and GBS seem to develop persistent impairment on long-term functional status and well-being, more clearly in CIP, reflecting the importance of long-term follow-up in further disease management.
Sachdeva AK, Kuhad A, Tiwari V, Chopra K.	Pharmacology Research Laboratory, University Institute of Pharmaceutical Sciences, UGC Centre of Advanced Study,	Epigallocatechin gallate ameliorates chronic fatigue syndrome in mice: behavioral and biochemical evidence.	Behav Brain Res. 2009 Dec 28;205(2):414-20. Epub 2009 Jul 28.	Three decades after the coining of the term chronic fatigue syndrome, the diagnosis of this illness is still symptom based and the aetiology remains elusive. Chronic fatigue syndrome pathogenesis seems to be multifactorial and the possible involvement of immune system is supported. The present study was designed to evaluate the effects of the epigallocatechin gallate in a mouse model of immunologically induced chronic fatigue. On 19th day, after lipopolysaccharide/Brucella abortus administration, the mice showed significant increase in immobility period, post swim fatigue and thermal hyperalgesia. Behavioral deficits were coupled with enhanced oxidative-nitrosative stress as evident by increased lipid peroxidation, nitrite levels and decreased endogenous antioxidant enzymes

	Punjab University, Chandigarh 160 014, India.			(superoxide dismutase, reduced glutathione and catalase) and inflammation (increased levels of tumor necrosis factor-alpha and tissue growth factor-beta). Chronic treatment with epigallocatechin gallate restored these behavioral and biochemical alterations in mice. The present study points out towards the beneficial effect of epigallocatechin gallate in the amelioration of chronic fatigue syndrome and thus may provide a new, effective and powerful strategy to treat chronic fatigue syndrome.
Sakudo A, Kato YH, Tajima S, Kuratsune H, Ikuta K.	Department of Virology, Center for Infectious Disease Control, Research Institute for Microbial Diseases, Osaka University, Yamadaoka, Suita, Osaka 565-0871, Japan. sakudo@biken.osaka-u.ac.jp	Visible and near-infrared spectral changes in the thumb of patients with chronic fatigue syndrome.	Clin Chim Acta. 2009 May;403(1-2):163-6. Epub 2009 Feb 25.	BACKGROUND: Chronic fatigue syndrome (CFS) patients show a persistent fatigue condition with muscle pain and impairment of concentration, memory, and sleep. Presently, the physiological basis of CFS remains unclear. In this study, spectroscopic differences in the thumb were compared between 103 CFS patients and 122 healthy controls to examine possible changes of levels of oxygenated or deoxygenated hemoglobin. METHODS: Visible and near-infrared (Vis-NIR) spectroscopy was used to examine possible changes in the region of 600-1100 nm. RESULTS: Vis-NIR spectra showed sharp peaks at 694, 970 and 1060 nm and broad peaks in the regions of 740-760 and 830-850 nm. As these peaks are possibly related to oxyhemoglobin, cytochrome c oxidase and water, levels of these factors were compared between the two groups. Statistical analysis of the absorbance of Vis-NIR spectra showed a significant decrease in water content, a significant increase in oxyhemoglobin content, and a significant increase in the oxidation of heme a+a(3) and copper in cytochrome c oxidase in CFS patients. CONCLUSIONS: These changes imply accelerated blood flow and energy metabolism in the thumbs of CFS patients.
Sakudo A, Kuratsune H, Kato YH, Ikuta K.	Department of Virology, Center for Infectious Disease Control, Research Institute for Microbial Diseases, Osaka University, Yamadaoka, Suita, Osaka 565-0871, Japan. sakudo@biken.osaka-u.ac.jp	Secondary structural changes of proteins in fingernails of chronic fatigue syndrome patients from Fourier-transform infrared spectra.	Clin Chim Acta. 2009 Apr;402(1-2):75-8. Epub 2008 Dec 30.	BACKGROUND: Generally, nails can be an index of health, with abnormalities sometimes found under diseased conditions. Fatigue is also supposed to affect the condition of nails. Possible differences in infrared (IR) spectra of nail plates of chronic fatigue syndrome (CFS) patients compared to healthy control subjects were investigated in this study. METHODS: Using an attenuated total reflection (ATR)-Fourier-transform infrared (FTIR) spectrophotometer, spectra in the region of 4000-600 cm(-1) were obtained. The amide I region was then separated by Fourier deconvolution and curve fitting based on the Gauss and Lorentz formula and revealed differences in the secondary structural content of proteins compared to healthy donors. RESULTS: The specific secondary structural pattern commonly observed in nails of male and female CFS patients in the absence and presence of medication indicated a decreased alpha-helix content and increased beta-sheet content, suggesting reduced levels of normal elements of the nail plate. CONCLUSIONS: This provides the first evidence of alterations in the fingernails of CFS patients which could be detected by IR spectroscopy. Possible explanations for the alterations will be discussed.
Sampogna F, Frontani M, Baliva G, Lombardo GA, Alvetreti G, Di Pietro C, Tabolli S, Russo G, Abeni D.	Health Services Research Unit, Instituto Dermopatico dell'Immacolata, Rome, Italy.	Quality of life and psychological distress in patients with cutaneous lymphoma.	Br J Dermatol. 2009 Apr;160(4):815-22. Epub 2008 Dec 16.	BACKGROUND: Cutaneous lymphomas may have a profound impact on patients' health-related quality of life (HRQoL) and psychological well-being. OBJECTIVES: To evaluate HRQoL and psychological distress in patients with cutaneous lymphoma, and to evaluate them in relation to personal and clinical characteristics. METHODS: Patients with cutaneous T-cell lymphoma or cutaneous B-cell lymphoma (CBCL) were consecutively recruited in a dermatological hospital. Data on HRQoL were collected using a dermatology-specific questionnaire, the Skindex-29, and an oncology-specific questionnaire, the EORTC QLQ-C30. RESULTS: Of 95 patients, there were 24 with CBCL, 59 with mycosis fungoides (MF) and 12 with Sézary syndrome (SS). The most frequent items reported in

				Skindex-29 were itching and sensitive skin, being annoyed by the disease, worry that it could get worse, affected interactions, and impairment in sexual life. The most frequent problems appearing from the EORTC QLQ-C30 analysis were fatigue, pain and insomnia. A worse HRQoL was observed for all the scales in patients with SS, followed by MF, and CBCL. HRQoL impairment in all histotypes was higher in women than in men, in patients with probable anxiety or depression, and when the disease worsened. The highest prevalence of probable anxiety or depression was observed in patients treated with systemic steroids (60%) and interferon (50%). CONCLUSIONS: The detailed evaluation of HRQoL and psychological problems in patients with cutaneous lymphomas, and their relationship with clinical variables, may give important information on the burden of the disease for patients, and thus improve communication and satisfaction with care.
Santhouse AM.	South London and Maudsley NHS Foundation Trust, London, UK.	Review: CBT reduces fatigue in adults with chronic fatigue syndrome but effects at follow-up unclear.Comment on: Cochrane Database Syst Rev. 2008;(3):CD001027 .	Evid Based Ment Health. 2009 Feb;12(1):16.	
Scheeres K, Knoop H, Meer J, Bleijenberg G.	Expert Centre Chronic Fatigue, Radboud University Nijmegen Medical Centre (4628), PO Box 9101, 6500 HB Nijmegen, The Netherlands. korinescheeres@gmail.com	Clinical assessment of the physical activity pattern of chronic fatigue syndrome patients: a validation of three methods.	Health Qual Life Outcomes. 2009 Apr 1;7:29.	BACKGROUND: Effective treatment of chronic fatigue syndrome (CFS) with cognitive behavioural therapy (CBT) relies on a correct classification of so called 'fluctuating active' versus 'passive' patients. For successful treatment with CBT is it especially important to recognise the passive patients and give them a tailored treatment protocol. In the present study it was evaluated whether CFS patient's physical activity pattern can be assessed most accurately with the 'Activity Pattern Interview' (API), the International Physical Activity Questionnaire (IPAQ) or the CFS-Activity Questionnaire (CFS-AQ). METHODS: The three instruments were validated compared to actometers. Actometers are until now the best and most objective instrument to measure physical activity, but they are too expensive and time consuming for most clinical practice settings. In total 226 CFS patients enrolled for CBT therapy answered the API at intake and filled in the two questionnaires. Directly after intake they wore the actometer for two weeks. Based on receiver operating characteristic (ROC) curves the validity of the three methods were assessed and compared. RESULTS: Both the API and the two questionnaires had an acceptable validity (0.64 to 0.71). None of the three instruments was significantly better than the others. The proportion of false predictions was rather high for all three instrument. The IPAQ had the highest proportion of correct passive predictions (sensitivity 70.1%). CONCLUSION: The validity of all three instruments appeared to be fair, and all showed rather high proportions of false classifications. Hence in fact none of the tested instruments could really be called satisfactory. Because the IPAQ showed to be the best in correctly predicting 'passive' CFS patients, which is most essentially related to treatment results, it was concluded that the IPAQ is the preferable alternative for an actometer

				when treating CFS patients in clinical practice.
Schrijvers D, Van Den Eede F, Maas Y, Cosyns P, Hulstijn W, Sabbe BG.	Collaborative Antwerp Psychiatric Research Institute, Faculty of Medicine, University of Antwerp, Universiteitsplein 1, 2610 Antwerp, Belgium. didier.schrijvers@ua.ac.be	Psychomotor functioning in chronic fatigue syndrome and major depressive disorder: a comparative study.	J Affect Disord. 2009 May;115(1-2):46-53. Epub 2008 Sep 24.	BACKGROUND: Studies comparing chronic fatigue syndrome (CFS) and major depressive disorder (MDD) reported similarities as well as differences between the two disorders. However, whereas psychomotor symptoms have been studied extensively in MDD, such research in CFS is more limited. Moreover, the few studies that compared cognitive and motor performance in MDD and CFS yielded inconsistent results. This study hence directly compares fine psychomotor functioning in both syndromes. METHODS: Thirty-eight patients diagnosed with CFS without a current major depressive episode (MDE), 32 MDD patients with a current MDE and 38 healthy controls performed two computerized copying tasks differing in complexity: a line-copying task that mainly requires motor effort and a figure-copying task requiring additional cognitive efforts. All participants were female. A multivariate general linear model was used to compute group differences. RESULT: Overall, both patient groups performed more slowly than the controls. Compared to CFS patients, patients with MDD needed significantly more time to copy the single lines but no such between-group performance difference was observed for the figure reproductions. In this latter copying task, the increasing complexity of the figures resulted in prolonged reaction times for all three participant groups with the effect being larger and the magnitude similar for the two patient groups. LIMITATIONS: All patients were female and most were on psychotropic medication. CONCLUSIONS: Both the MDD and CFS patients tested demonstrated an overall fine motor slowing, with the motor component being more affected in the MDD patients than in the CFS patients while both patient groups showed similar cognitive impairments.
Shapiro JS.	shapirjs@umich.edu	Does varicella-zoster virus infection of the peripheral ganglia cause Chronic Fatigue Syndrome?	Med Hypotheses. 2009 Nov;73(5):728-34. Epub 2009 Jun 10.	This article posits that infection of the peripheral ganglia causes at least some cases of Chronic Fatigue Syndrome (CFS), with a neurotropic herpesvirus, particularly varicella-zoster virus (VZV), as the most likely cause of the infection. Virtually all CFS symptoms could be produced by an infection of the peripheral ganglia, with infection of the autonomic ganglia causing fatigue, postural hypotension, and sleep disturbances, and infection of the sensory ganglia causing sensory symptoms such as chronic pain. Furthermore, infections of the peripheral ganglia are known to cause long-term nerve dysfunction, which would help explain the chronic course of CFS. Herpesviruses have long been suspected as the cause of CFS; this theory has recently been supported by studies showing that administering antiherpes agents causes substantial improvement in some CFS patients. VZV is known to frequently reactivate in the peripheral ganglia of previously healthy adults and cause sudden, debilitating illness, making it a likely candidate as a cause of CFS. Moreover, many of the symptoms of CFS overlap with those of herpes zoster (shingles), with the exception that painful rash is not one of the symptoms of CFS. A model is therefore proposed in which CFS is one of the many manifestations of zoster sine herpete; that is, herpes zoster without rash. Furthermore, re-exposure to VZV in the form of chickenpox has become less common in the past few decades; without such re-exposure, immunity to VZV drops, which could explain the increased incidence of CFS. Co-infection with multiple herpesviruses is a possibility, as some CFS patients show signs of infection with other herpesviruses including Epstein-Barr, Cytomegalovirus, and HHV6. These three herpesviruses can attack immune cells, and may therefore promote neurotropic herpesvirus reactivation in the ganglia. The possibility of VZV as the causal agent in CFS has previously received almost no attention; the possibility that CFS

				involves infection of the peripheral ganglia has likewise been largely overlooked. This suggests that the search for a viral cause of CFS has been far from exhaustive. Several antiherpes drugs are available, as is a vaccine for VZV; more research into such agents as possible treatments for CFS is urgently needed.
Sheedy JR, Wettenhall RE, Scanlon D, Gooley PR, Lewis DP, McGregor N, Stapleton DI, Butt HL, DE Meirleir KL.	Bio21 Institute of Biotechnology and Molecular Science, Department of Biochemistry and Molecular Biology, Victoria, Australia.	Increased d-lactic Acid intestinal bacteria in patients with chronic fatigue syndrome.	In Vivo. 2009 Jul-Aug;23(4):621-8.	Patients with chronic fatigue syndrome (CFS) are affected by symptoms of cognitive dysfunction and neurological impairment, the cause of which has yet to be elucidated. However, these symptoms are strikingly similar to those of patients presented with D-lactic acidosis. A significant increase of Gram positive facultative anaerobic faecal microorganisms in 108 CFS patients as compared to 177 control subjects ($p<0.01$) is presented in this report. The viable count of D-lactic acid producing Enterococcus and Streptococcus spp. in the faecal samples from the CFS group (3.5 x 10(7) cfu/L and 9.8 x 10(7) cfu/L respectively) were significantly higher than those for the control group (5.0 x 10(6) cfu/L and 8.9 x 10(4) cfu/L respectively). Analysis of exometabolic profiles of Enterococcus faecalis and Streptococcus sanguinis, representatives of Enterococcus and Streptococcus spp. respectively, by NMR and HPLC showed that these organisms produced significantly more lactic acid ($p<0.01$) from (13)C-labeled glucose, than the Gram negative Escherichia coli. Further, both E. faecalis and S. sanguinis secrete more D-lactic acid than E. coli. This study suggests a probable link between intestinal colonization of Gram positive facultative anaerobic D-lactic acid bacteria and symptom expressions in a subgroup of patients with CFS. Given the fact that this might explain not only neurocognitive dysfunction in CFS patients but also mitochondrial dysfunction, these findings may have important clinical implications.
Sheng R, Xu X, Tang Q, Bian D, Li Y, Qian C, He X, Gao X, Pan R, Wang C, Luo Y, Xia Y, Dai Y.	Department of Pharmacology of Chinese Materia Medica, China Pharmaceutical University, 24 Tong Jia Xiang Road, Nanjing 210009, China, yuedaicpu@hotmail.com.	Polysaccharide of Radix Pseudostellariae Improves Chronic Fatigue Syndrome Induced by Poly I:C in Mice.	Evid Based Complement Alternat Med.. [Epub ahead of print]	Radix Pseudostellariae is used as a tonic drug in traditional Chinese medicine with immunomodulating and anti-fatigue activities, and the polysaccharide is considered as the main active component. The purpose of this study is to examine the effect of the polysaccharide isolated from Radix Pseudostellariae (PRP) on mouse chronic fatigue syndrome (CFS) induced by intraperitoneal injection of polyriboinosinic:polyribocytidylic acid (poly I:C), a double-stranded synthetic RNA. It has shown that the fatigue symptom of mice lasted at least 1 week as evaluated by forced swimming time. PRP (100, 200, 400 mg kg(-1)), orally administered 3 days before poly I:C injection, showed dose-dependent anti-fatigue effects. In addition, poly I:C led to evident alternations in neuroendocrine and immune systems of mice, such as reduced spontaneous activity and learning ability, declined serum level of corticosterone, increased weight indexes and T lymphocyte numbers in thymuses and spleens, and increased CD4(+)/CD8(+) ratio but decreased proliferation ability of T lymphocytes in spleens. PRP alleviated the abnormalities caused by poly I:C, and restored the function of hosts to normal conditions. The findings suggest that PRP is beneficial to CFS, and the underlying mechanisms of action involve neuroendocrine and immune systems.
Sigmon SC, Herning RI, Better W, Cadet JL, Griffiths RR.	Department of Psychiatry, University of Vermont College of Medicine, SATC-UHC, Room 1415,	Caffeine withdrawal, acute effects, tolerance, and absence of net beneficial effects of chronic	Psychopharmacology (Berl). 2009 Jul;204(4):573-85. Epub 2009 Feb 25.	RATIONALE: Although the subjective effects of caffeine abstinence, acute and chronic administration, and tolerance are well described, the corresponding neurophysiological effects are not. OBJECTIVES: Caffeine withdrawal, acute caffeine effects, caffeine tolerance, and net beneficial effects of chronic caffeine administration were investigated using cerebral blood flow velocity, quantitative electroencephalography (EEG), and subjective effects. MATERIALS AND METHODS: Sixteen regular caffeine users participated in this double-blind, within-subject study during which they received acute

	Burlington, VT, 05401, USA. stacey.sigmon@uvm.edu	administration: cerebral blood flow velocity, quantitative EEG, and subjective effects.		caffeine and placebo challenges (1) while maintained on 400 mg caffeine daily for > or =14 days and (2) while maintained on placebo for > or =14 days. Blood flow velocity was determined for the middle (MCA) and anterior (ACA) cerebral arteries using pulsed transcranial Doppler sonography. EEG was recorded from 16 scalp sites. Subjective effects were assessed with questionnaires. RESULTS: Acute caffeine abstinence (evaluated 24 h after placebo substitution) increased mean, systolic, and diastolic velocity in the MCA and ACA and decreased pulsatility index in the MCA. Acute caffeine abstinence increased EEG theta and decreased beta 2 power. Acute caffeine abstinence also increased measures of Tired, Fatigue, Sluggish, and Weary and decreased ratings of Energetic, Friendly, Lively, and Vigor. Acute caffeine effects were demonstrated across a wide range of measures, including cerebral blood flow, EEG, and subjective effects. Tolerance and "complete" tolerance were observed on subjective but not physiological measures. Chronic caffeine effects were demonstrated only on the measure of EEG beta 2 power. CONCLUSION: Acute caffeine abstinence and administration produced changes in cerebral blood flow velocity, EEG, and subjective effects. Tolerance to subjective but not physiological measures was demonstrated. There was almost no evidence for net effects of chronic caffeine administration on these measures. Overall, these findings provide the most rigorous demonstration to date of physiological effects of caffeine withdrawal.
Silva-Tinoco R, Castillo-Martínez L, Orea-Tejeda A, Orozco-Gutiérrez JJ, Vázquez-Díaz O, Montaño-Hernández P, Flores-Rebollar A, Reza-Albarrán A.	Heart Failure Clinic, Instituto Nacional de Ciencias Médicas y Nutrición "Salvador Zubirán", Mexico City, Mexico.	Developing thyroid disorders is associated with poor prognosis factors in patient with stable chronic heart failure.	Int J Cardiol. 2009 Feb 8. [Epub ahead of print]	We sought to assess the developing of thyroid disorders in forty eight patients with chronic stable heart failure and without thyroid abnormalities during six months follow-up. Thyroid function disorders were observed in 27.1% of the subjects: sick euthyroid syndrome (12.5%), subclinical hypothyroidism (10.4%) and overt hypothyroidism (6.2%). Subjects with higher thyroid stimulating hormone (TSH) levels at the end of the study had more hospitalizations. The developing of altered thyroid profile was related to lower hemoglobin levels, smaller phase angle with bioelectrical impedance method and more fatigue perception by the patients. This abnormal thyroid function behavior on stable chronic heart failure and was observed as part of the disease progress and was associated to worse prognosis factors as lower phase angle and anemia.
Smith AK, Maloney EM, Falkenberg VR, Dimulescu I, Rajeevan MS.	Division of Viral and Rickettsial Diseases, National Center for Zoonotic, Vector-Borne and Enteric Diseases, Centers for Disease Control and Prevention, 1600 Clifton Road, MSG41, Atlanta, GA 30333, USA.	An angiotensin-1 converting enzyme polymorphism is associated with allostatic load mediated by C-reactive protein, interleukin-6 and cortisol.	Psychoneuroendocrinology. 2009 May;34(4):597-606. Epub 2008 Dec 10.	Allostatic load (AL) is a theoretical framework that describes the cumulative physiologic effects of adaptation to change or stress throughout the lifespan. AL is operationalized by a composite index of multiple biomarkers. Accordingly, genes, behavior and environment contribute to AL. To determine if individual differences in AL may be influenced by inherent genetic variation, we calculated an allostatic load index (ALI) for 182 Caucasian subjects derived from a population-based study of chronic fatigue syndrome. Nearly 65% of the subjects in this study sample reported fatiguing illness. ALI was calculated based on 11 measures representing metabolic, cardiovascular, inflammatory, hypothalamic-pituitary-adrenal (HPA) axis and sympathetic nervous system (SNS) activities. Subjects were dichotomized into high (ALI > or = 3) or low (ALI < 3) AL groups, and the association between high AL and 129 polymorphisms in 32 genes related to the HPA axis, neurotransmission, inflammation, cardiovascular and metabolic functions were evaluated. Polymorphisms in angiotensin-1 converting enzyme (ACE), corticotropin-releasing hormone receptor 1 (CRHR1), and serotonin receptors (HTR3A and HTR4) were associated with AL (p=0.0007-0.0486), but only one polymorphism, rs4968591, in ACE remained significant after correction for multiple comparisons. The T allele of ACE rs4968591 was more common in subjects with high AL (67.5%) than in subjects with low AL (49.3%)

				(p=0.0007), and this effect appeared independent of age, sex, body mass index and fatigue status. Additionally, high interleukin-6 (IL-6; p(trend)=0.04), and C-reactive protein (CRP; p(trend)=0.01) levels, as well as low urinary cortisol levels in females (p=0.03) were associated with the T allele, which may result in allele-specific binding of the transcription factor, E2F1. Our results suggest a role for ACE in the bidirectional communication between the central nervous and immune systems in response to stress. Further studies will be needed (a) to replicate the association between AL and ACE polymorphisms in population studies designed to differentiate the effects of sex, age and racial/ethnic background, (b) to evaluate the effect of allele-specific binding of E2F1 at rs4968591, and (c) to examine the role of ACE in the co-regulation of CRP, IL-6 and cortisol.
Smith WR, Strachan ED, Buchwald D.	Department of Psychiatry and Behavioral Sciences, School of Medicine, University of Washington, Seattle, WA 98195, USA. wrsmith@u.washington.edu	Coping, self-efficacy and psychiatric history in patients with both chronic widespread pain and chronic fatigue.	Gen Hosp Psychiatry. 2009 Jul-Aug;31(4):347-52. Epub 2009 May 2.	OBJECTIVE: To investigate the relationship of coping style and self-efficacy to functional impairment in a group of patients with both chronic widespread pain (CWP) and chronic fatigue, as well as the possible mediating role of psychiatric diagnosis. METHODS: We identified 138 consecutive clinic patients who met criteria for CWP and chronic fatigue. We collected demographic and clinical characteristics, as well as measures of emotion-focused and problem-focused coping styles, fatigue-related self-efficacy and self-reported general health. Psychiatric diagnoses were determined with a structured interview. Short Form-36 subscales of pain-related and fatigue-related functioning were the dependent variables in ordinal multiple regression analyses to identify the best-fit model for each. RESULTS: In the final model for pain, increased functional impairment was associated with increased emotion-focused coping as well as less education, lower general health scores and higher body mass index. Conversely, in the final model for fatigue, increased functional impairment was significantly associated with less emotion-focused coping, lower general health scores and lower self-efficacy. CONCLUSIONS: The unexpected finding that emotion-focused coping was associated differently with chronic pain and fatigue among patients who experience both symptoms is discussed in the context of the research on the effects of self-efficacy and possible treatment approaches.
Sorensen B, Jones JF, Vernon SD, Rajeevan MS.	Division of Viral and Rickettsial Diseases, National Center for Zoonotic, Vector-Borne, and Enteric Diseases, Centers for Disease Control and Prevention, Atlanta, Georgia 30333, United States of America.	Transcriptional control of complement activation in an exercise model of chronic fatigue syndrome.	Mol Med. 2009 Jan-Feb;15(1-2):34-42. Epub 2008 Nov 10.	Complement activation resulting in significant increases of C4a split product may be a marker of postexertional malaise in individuals with chronic fatigue syndrome (CFS). This study focused on identification of the transcriptional control that may contribute to the increased C4a in CFS subjects after exercise. We used quantitative reverse-transcription polymerase chain reaction to evaluate differential expression of genes in the classical and lectin pathways in peripheral blood mononuclear cells (PBMCs). Calibrated expression values were normalized to the internal reference gene peptidylpropyl isomerase B (PPIB), the external reference gene ribulose-1,5-bisphosphate carboxylase/oxygenase large subunit (rbcL), or the geometric mean (GM) of the genes ribosomal protein, large, P0 (RPLP0) and phosphoglycerate kinase 1 (PGK1). All nine genes tested, except mannose-binding lectin 2 (MBL2), were expressed in PBMCs. At 1 hour postexercise, C4, mannan-binding lectin serine protease 2 (MASP2) and ficolin 1 (FCN1) transcripts were detected at higher levels (> or = 2-fold) in at least 50% (4 of 8) of CFS subjects and were detected in 88% (7 of 8) CFS subjects when subjects with overexpression of either C4 or MASP2 were combined. Only an increase in the MASP2 transcript was statistically significant (PPIB, P = 0.001; GM, P = 0.047; rbcL, P = 0.045). This result may be due to the significant but transient downregulation of MASP2 in control subjects (PPIB, P = 0.023; rbcL, P = 0.027). By 6 hours postexercise, MASP2 expression was similar in both

				groups. In conclusion, lectin pathway responded to exercise differentially in CFS than in control subjects. MASP2 down-regulation may act as an antiinflammatory acute-phase response in healthy subjects, whereas its elevated level may account for increased C4a and inflammation-mediated postexertional malaise in CFS subjects.
Stahl SM.	Department of Psychiatry, University of California, San Diego, CA, USA. smstahl@neiglobal.com	Fibromyalgia--pathways and neurotransmitters.	Hum Psychopharmacol. 2009 Jun;24 Suppl 1:S11-7.	Fibromyalgia is a syndrome of widespread chronic pain associated with sleep disorders, depressed mood, cognitive impairment and fatigue. Its etiology and pharmacopathology are poorly understood but it is thought to result from a dysfunction of central pain processing mechanisms leading to generalised pain sensitisation. Pain perception is the result of a bidirectional process of ascending and descending pathways. Nociceptive input from peripheral afferent neurons is sent via the dorsal horn of the spinal cord to the higher brain centres involved in pain perception. Some descending inhibitory projections to the spinal cord attenuate the nociceptive effects. Numerous neurotransmitters including serotonin, dopamine, noradrenaline and substance P are involved in these processes. In other neuronal pathways in the brain, the same neurotransmitters are involved in mood control, sleep regulation and cognitive function providing a neurochemical substrate for the wide range of symptoms seen in fibromyalgia. Attenuation of neuronal hyperactivity through ligands acting at the alpha2-delta subunits of voltage-dependent calcium channels and increased inhibitory activity of the descending pathways by inhibition of serotonin and noradrenaline reuptake are two mechanisms that are currently exploited by new medication for the treatment of fibromyalgia. Staines DR, Brenu EW, Marshall-Gradisnik S.	Queensland Health, Gold Coast Population Health Unit, Southport, Gold Coast, Queensland, Australia;	Postulated vasoactive neuropeptide immunopathology affecting the blood-brain/blood-spinal barrier in certain neuropsychiatric fatigue-related conditions: A role for phosphodiesterase inhibitors in treatment?	Neuropsychiatr Dis Treat. 2009;5:81-9. Epub 2009 Apr 8.	Neuropsychiatric symptoms occur in a number of neurological fatigue-related conditions including multiple sclerosis (MS), Parkinson's disease (PD), amyotrophic lateral sclerosis (ALS), and chronic fatigue syndrome (CFS). These conditions have been attributed variably to neuroinflammatory and neurodegenerative processes. While autoimmune pathology, at least in part, has long been suspected in these conditions proof has been elusive. Autoimmune pathomechanisms affecting the blood-brain barrier (BBB) or blood-spinal barrier (BSB) may predispose the BBB/BSB to 'leakiness' and be a precursor to additional autoimmune events resulting in neuroinflammatory or neurodegenerative processes. The aim of the paper is to postulate immunopathology of the cerebrospinal perivascular compartment involving certain vasoactive neuropeptides, specifically pituitary adenylate cyclase-activating polypeptide (PACAP) and vasoactive intestinal peptide (VIP), in the etiology of certain neuropsychiatric fatigue-related conditions such as MS, ALS, PD, and CFS. Vasoactive neuropeptides (VNs) such as PACAP and VIP have critical roles as neurotransmitters, vasodilators including perfusion and hypoxia regulators, and immune and nociception modulators. PACAP and VIP are widely distributed in the central nervous system (CNS) and have key roles in CNS blood vessels including maintaining functional integrity of the BBB and BSB. Autoimmunity affecting these VNs would likely have a detrimental effect on BBB and BSB functioning arguably predisposing to further pathological processes. Virchow-Robin spaces (VRS) are perivascular compartments surrounding small vessels within the CNS which contribute to the BBB and BSB integrity and contain PACAP and VIP receptors. Autoimmunity of these receptors would likely affect BBB and VRS function and therefore may contribute to the etiology of these conditions by affecting CNS and immunological homeostasis, including promoting neuropsychological symptomatology. PACAP and VIP, as potent activators of

				adenylate cyclase (AC), have a key role in cyclic adenosine monophosphate (cAMP) production affecting regulatory T cell (Treg) and other immune functions. Phosphodiesterase enzymes (PDEs) catalyze cAMP and PDE inhibitors (PDEIs) maintain cAMP levels and have proven and well known therapeutic benefit in animal models such as experimental allergic encephalomyelitis (EAE). Therefore PDEIs may have a role in therapy for certain neuropsychiatric fatigue-related conditions.
Stewart JM.	Department of Pediatrics and Physiology, New York Medical College, Hawthorne, NY 10532, USA. stewart@nymc.edu	Chronic fatigue syndrome: comments on deconditioning, blood volume and resulting cardiac function.	Clin Sci (Lond). 2009 Oct 19;118(2):121-3. Comment on: Clin Sci (Lond). 2010 Jan;118(2):125-35.	Cardiovascular and autonomic dysfunction have been suggested to underlie the symptoms accompanying CFS (chronic fatigue syndrome). In the present issue of Clinical Science, Hurwitz and co-workers have investigated whether deficits were present in cardiac output and blood volume in a cohort of patients with CFS and if these were linked to illness severity and sedentary lifestyle. The results clearly demonstrate reduced cardiac stroke volume and cardiac output in more severely afflicted patients with CFS, which is primarily attributable to a measurable reduction in blood volume. Similar findings are observed in microgravity and bed rest deconditioning, in forms of orthostatic intolerance and, to a lesser extent, in sedentary people. The circulatory consequences of reduced cardiac output may help to account for many of the findings of the syndrome.
Stubhaug B.		[Treatment of chronic fatigue syndrome][Article in Norwegian]	Tidsskr Nor Laegeforen. 2009 Jun 11;129(12):1209.	
Sullivan A, Nord CE, Evengård B.	Division of Clinical Microbiology, F82, Department of Laboratory Medicine, Karolinska University Hospital Huddinge, Karolinska Institutet, SE-14186 Stockholm, Sweden. asa.sullivan@ki.se	Effect of supplement with lactic-acid producing bacteria on fatigue and physical activity in patients with chronic fatigue syndrome.	Nutr J. 2009 Jan 26;8:4.	Disturbances in intestinal microbial ecology and in the immune system of the host have been implicated as a part of the pathogenesis in chronic fatigue syndrome. Probiotic lactic acid producing bacteria have been shown to prevent and alleviate gastrointestinal disturbances and to normalize the cytokine profile which might be of an advantage for patients suffering from chronic fatigue syndrome. The aim of the study was to evaluate the effect of Lactobacillus paracasei ssp. paracasei F19, Lactobacillus acidophilus NCFB 1748 and Bifidobacterium lactis Bb12 on fatigue and physical activity in CFS patients. Fifteen patients fulfilling the criteria set by international researchers in the field at the US Centre for Disease Control and Prevention in 1994 for chronic fatigue syndrome, were included in the study. The patients had high fatigue severity scores and high disability scores. During the first two weeks baseline observations without treatment were assessed, succeeded by four weeks of intake of a probiotic product and a four-week follow-up period. The fatigue, health and physical activity was assessed by the use of the Visual Analogue Scales and the SF-12 Health Survey. Faecal samples were collected and the normal microflora was analysed. Neurocognitive functions improved during the study period while there were no significant changes in fatigue and physical activity scores. No major changes occurred in the gastrointestinal microflora. At the end of the study 6 of 15 patients reported that they had improved according to the assessment described. The findings in this study that improvement of health is possible to achieve should encourage further studies with interventions with probiotics in patients with CFS.
Sun JF, Wu RR, Norris C, Noone AM, Amankwa-Sakyi M, Slack R,	Lombardi Comprehensive Cancer Center, Georgetown	Safety of chronic low-dose capecitabine as maintenance	Gastrointest Cancer Res. 2009 Jul;3(4):134-40.	BACKGROUND: Maintenance chemotherapy is not routinely used in gastrointestinal (GI) cancers. Capecitabine is an oral formulation that is enzymatically converted to 5-fluorouracil preferentially in tumor tissue. We hypothesize that capecitabine could be used as a long-term maintenance therapy to improve outcomes in patients with high-risk GI cancers following standard chemotherapy regimens.

Marshall JL.	University Medical Center, Washington, DC.	therapy in gastrointestinal cancers.		METHODS: We conducted a retrospective study to assess the toxicity of maintenance capecitabine in 28 patients with a variety of advanced GI malignancies. Capecitabine 1,000 mg twice daily without interruption was used for the first 11 patients. The dose was reduced to 1,000 mg twice daily 5 days per week in 8 patients who developed hand-foot syndrome. The remaining patients began treatment on the same abbreviated schedule. All documented clinical adverse events were graded according to the National Cancer Institute Common Terminology Criteria for Adverse Events (v3.0, 2003). RESULTS: Main toxicities were grade 1/2 fatigue and hand-foot syndrome. Only one grade 3 toxicity was observed and no grade 4 toxicities were seen. We also observed a significant increase in red blood cell mean corpuscular volume in participants, which may have potential use as a biomarker to monitor therapeutic response. CONCLUSIONS: Fixed therapeutic doses of oral capecitabine 1,000 mg twice daily, 5 days on, 2 days off, can be administered chronically with a high level of safety and should be explored in larger prospective studies to demonstrate efficacy in GI malignancies, especially pancreatic and metastatic colorectal cancers.
Sutcliffe K, Gray J, Tan MP, Pairman J, Wilton K, Parry SW, Newton JL.	UK NIHR Biomedical Research Centre in Ageing - Cardiovascular Theme, Newcastle, UK.	Home orthostatic training in chronic fatigue syndrome--a randomized, placebo-controlled feasibility study.	Eur J Clin Invest. 2010 Jan;40(1):18-24. Epub 2009 Nov 12.	BACKGROUND: Orthostatic (Tilt)-training is an effective treatment for neurally mediated hypotension (NMH). NMH is a frequent finding in chronic fatigue syndrome (CFS). We evaluated home orthostatic training (HOT) in CFS in a randomized placebo-controlled feasibility study. METHODS: Thirty-eight patients with CFS (Fukuda Criteria) were randomly allocated to daily tilt training (n = 19) or sham training (n = 19) for 6 months. Haemodynamic responses to standing were performed in all subjects using continuous technology (Taskforce) at enrolment, week 1, 4 and 24. Symptom response and compliance were assessed using diaries. RESULTS: Two patients (one from each arm) withdrew from the study. Fourteen patients in each group complied completely or partially, and patients found the training manageable and achievable. Compared to the sham group, blood pressure while standing dropped to 8.0 mmHg less in the HOT group at 4 weeks (95% CI: 1.0 to 15.0, P = 0.03). At 4 weeks, the HOT group had higher total peripheral resistance compared to the sham group; mean difference 70.2, 95% CI: -371.4 to 511.8. Changes were maintained at 6 months. There was no significant difference in fatigue between groups at 4 weeks (mean difference 1.4, 95% CI: -13.5 to 16.2), but there was a trend towards improvement in fatigue at 6 months. Compliers had lower fatigue compared to non-compliers. CONCLUSIONS: A placebo-controlled study of HOT in CFS is feasible. HOT is well tolerated and generally complied with. A likely physiological rationale for HOT in CFS is related to reductions in orthostatic intolerance. An adequately powered study including strategies to enhance compliance is warranted.
Tak LM, Riese H, de Bock GH, Manoharan A, Kok IC, Rosmalen JG.	Interdisciplinary Center for Psychiatric Epidemiology, University Medical Center Groningen, University of Groningen, Hanzeplein 1, 9700	As good as it gets? A meta-analysis and systematic review of methodological quality of heart rate variability studies in functional somatic	Biol Psychol. 2009 Oct;82(2):101-10. Epub 2009 May 20.	Autonomic nervous system (ANS) dysfunction is a potential mechanism connecting psychosocial stress to functional somatic disorders (FSD), such as chronic fatigue syndrome, fibromyalgia and irritable bowel syndrome. We present the first meta-analysis and systematic review of methodological study quality on the association between cardiac ANS dysfunction, measured as parasympathetic nervous system (PNS) activity using heart rate variability (HRV), and FSD. Literature search revealed 23 available studies including data on 533 FSD patients. Meta-analysis on a subgroup of 14 studies with suitable outcome measures indicated lower PNS activity in FSD patients compared to controls (weighted standardized mean difference (SMD)=-0.32, 95% CI -0.63 to -0.01, p=0.04). The reliability of this summary estimate was, however, significantly limited by unexplained heterogeneity in the effect

	RB, Groningen, The Netherlands.	disorders.		sizes and potential publication bias (weighted SMD after correction for funnel plot asymmetry=0.01, 95% CI -0.34 to 0.36, p=0.95). The systematic review of overall methodological quality of HRV studies in FSD demonstrates that there is substantial room for improvement, especially in selection of healthy control subjects, blinding of researchers performing HRV measurements, report of adequate HRV outcomes, and assessment of and adjustment for potential confounders. Methodological study quality was, however, not a significant predictor of study findings. We conclude that current available evidence is not adequate to firmly reject or accept a role of ANS dysfunction in FSD. Quality criteria and recommendations to improve future research on HRV in FSD are provided.
Tan PJ, Xu M, Sessler DI, Bashour CA.	Anesthesiology Institute, Department of Quantitative Health Sciences, Cleveland Clinic, 9500 Euclid Avenue, Cleveland, OH 44195, USA.	Operation timing does not affect outcome after coronary artery bypass graft surgery.	Anesthesiology. 2009 Oct;111(4):785-9.	BACKGROUND: Human factors such as fatigue, circadian rhythms, scheduling, and staffing may have an impact on patient care over the course of a day across all medical specialties. Research by the transportation industry concludes that human performance is degraded by shift work, circadian rhythm disturbances, and prolonged duty. This study investigated whether the timing of coronary artery bypass graft surgery affects outcomes. METHODS: The outcomes of coronary artery bypass graft surgery patients were analyzed according to the hour of the day, day of the workweek, month, and moon phase in which the surgery started. All patients who underwent isolated coronary artery bypass graft surgery between January 1, 1993 and July 1, 2006 were considered for the study.The primary outcome measurement was a compound morbidity outcome of six variables defined by the Society of Thoracic Surgeons. These outcomes included (1) in-hospital death, (2) acute postoperative myocardial infarction, (3) neurologic morbidity, including focal or global neurologic deficits or death without awakening, (4) serious infection morbidity consisting of sepsis syndrome or septic shock, (5) new-onset renal failure requiring dialysis, and (6) postoperative ventilatory support exceeding 72 h. RESULTS: The composite morbidity and in-hospital mortality rates were 4.8% and 1.4%, respectively. The number of cases each weekday, each month of the year, and during each phase of the moon were consistent. None of the time factors significantly affected the composite morbidity outcome. CONCLUSIONS: Elective coronary artery bypass graft surgery can be scheduled throughout the workday, any day of the work week and in any month of the year without compromising outcome.
Taylor A, Glover V, Marks M, Kammerer M.	Imperial College London, Institute of Reproductive and Developmental Biology, Hammersmith Campus, Du Cane Road, London W12 0NN, UK. alyx.taylor@imperial.ac.uk	Diurnal pattern of cortisol output in postnatal depression.	Psychoneuroendocrinology. 2009 Sep;34(8):1184-8. Epub 2009 Apr 29.	This study investigated the diurnal output of saliva cortisol in women with symptoms of depression postnatally. Twenty-one depressed and 30 non-depressed women at 7.5 weeks postpartum, and 21 non-perinatal controls, collected saliva at waking, 30 min, and 3 and 12h postwaking. Women who were not depressed postnatally showed a pattern of cortisol secretion over the day similar to non-perinatal controls. There was a significant difference in diurnal pattern between postnatally depressed and postnatally non-depressed women, due to a difference in the first two time points (waking and +30 min): compared to the other two groups who each had a significant increase in cortisol levels from waking to +30 min, the depressed women had significantly higher cortisol levels at waking and no increase at +30 min. The lack of a morning rise in the depressed women is similar to that reported for posttraumatic stress disorder and chronic fatigue syndrome and may reflect a response, in vulnerable women, to the marked cortisol withdrawal that occurs after delivery.
Thomas M, Smith A.	Centre for Occupational and	An investigation into the cognitive	Open Neurol J. 2009 Feb 27;3:13-	This study addresses, among other things, the debate as to whether cognitive deficits do occur with a diagnosis of Chronic Fatigue Syndrome (CFS). Previous studies have indicated a potential mismatch

	Health Psychology, School of Psychology, Cardiff University, UK.	deficits associated with chronic fatigue syndrome.	23.	between subjective patient ratings of impairment and clinical assessment. In an attempt to tackle some of the methodological problems faced by previous research in this field, this study recruited a large sample of CFS patients where adequate diagnosis had been made and administered an extensive battery of measures. In doing so this study was able to replicate previous published evidence of clear cognitive impairment in this group and demonstrate also that these deficits occurred independent of psychopathology. The conclusion drawn is that cognitive impairments can be identified if appropriate measures are used. Furthermore, the authors have shown that performance changes in these measures have been used to assess both efficacy of a treatment regime and rates of recovery.
Tian H, Brimmer DJ, Lin JM, Tumpey AJ, Reeves WC.	Centers for Diseases Control and Prevention, Chronic Viral Disease Branch, Division of Viral and Rickettsial Diseases, Atlanta, GA 30333, USA. ejq7@cdc.gov	Web usage data as a means of evaluating public health messaging and outreach.	J Med Internet Res. 2009 Dec 21;11(4):e52.	BACKGROUND: The Internet is increasingly utilized by researchers, health care providers, and the public to seek medical information. The Internet also provides a powerful tool for public health messaging. Understanding the needs of the intended audience and how they use websites is critical for website developers to provide better services to the intended users. OBJECTIVE: The aim of the study was to examine the utilization of the chronic fatigue syndrome (CFS) website at the Centers for Disease Control and Prevention (CDC). We evaluated (1) CFS website utilization, (2) outcomes of a CDC CFS public awareness campaign, and (3) user behavior related to public awareness campaign materials and CFS continuing medical education courses. METHODS: To describe and evaluate Web utilization, we collected Web usage data over an 18-month period and extracted page views, visits, referring domains, and geographic locations. We used page views as the primary measure for the CFS awareness outreach effort. We utilized market basket analysis and Markov chain model techniques to describe user behavior related to utilization of campaign materials and continuing medical education courses. RESULTS: The CDC CFS website received 3,647,736 views from more than 50 countries over the 18-month period and was the 33rd most popular CDC website. States with formal CFS programs had higher visiting density, such as Washington, DC; Georgia; and New Jersey. Most visits (71%) were from Web search engines, with 16% from non-search-engine sites and 12% from visitors who had bookmarked the site. The public awareness campaign was associated with a sharp increase and subsequent quick drop in Web traffic. Following the campaign, user interest shifted from information targeting consumer basic knowledge to information for health care professionals. The market basket analysis showed that visitors preferred the 60-second radio clip public service announcement over the 30-second one. Markov chain model results revealed that most visitors took the online continuing education courses in sequential order and were less likely to drop out after they reached the Introduction pages of the courses. CONCLUSIONS: The utilization of the CFS website reflects a high level of interest in the illness by visitors to the site. The high utilization shows the website to be an important online resource for people seeking basic information about CFS and for those looking for professional health care and research information. Public health programs should consider analytic methods to further public health by understanding the characteristics of those seeking information and by evaluating the outcomes of public health campaigns. The website was an effective means to provide health information about CFS and serves as an important public health tool for community outreach.

Hutchinson); Swedish Headache Center, Seattle,	Migraine (Part III). Association With Comorbid Pain Conditions.	ahead of print]	Childhood maltreatment is highly prevalent and has been frequently associated with recurrent headache. The relationship of maltreatment and pain has, however, been a subject of some debate. Methods.- Cross-sectional data on self-reported physician-diagnosed pain conditions were electronically collected from persons with migraine (diagnosed according to International Classification of Headache Disorders-2), seeking treatment in headache clinics at 11 centers across the US and Canada. These included irritable bowel syndrome (IBS), chronic fatigue syndrome (CFS), fibromyalgia (FM), interstitial cystitis (IC), arthritis, endometriosis, and uterine fibroids. Other information included demographics, migraine characteristics (frequency, headache-related disability), remote and current depression (The Patient Health Questionnaire-9), and remote and current anxiety (The Beck Anxiety Inventory). Patients also completed the Childhood Trauma Questionnaire regarding sexual, emotional, and physical abuse, and emotional and physical neglect under the age of 18 years old. Statistical analyses accounted for the survey design and appropriate procedures in SAS such as surveymeans, surveyfreq, and surveylogistic were applied to the weighted data. Results.- A total of 1348 migraineurs (88% women) were included in this study (mean age 41 years). Based on physician diagnosis or validated criteria, 31% had IBS, 16% had CFS, and 10% had FM. Diagnosis of IC was reported by 6.5%, arthritis by 25%, and in women, endometriosis was reported by 15% and uterine fibroids by 14%. At least 1 comorbid pain condition was reported by 61%, 2 conditions by 18%, and 3 or more by 13%. Childhood maltreatment was reported by 58% of the patients. Emotional abuse was associated with increased prevalence of IBS, CFS, arthritis, and physical neglect with arthritis. In women, physical abuse was associated with endometriosis and physical neglect with uterine fibroids. Emotional abuse, and physical abuse and neglect ($P < .0001$ for all) were also associated with increased total number of comorbid conditions. In ordinal logistic regression models, adjusted for sociodemographics and current depression (prevalence 28%) and anxiety (prevalence 56%), emotional abuse (odds ratios [OR] = 1.69, 95% confidence intervals [CI]: 1.224-2.33) and physical neglect (OR = 1.73, 95% CI: 1.22-2.46) were independently associated with an increased number of pain conditions. The cohort of women, similarly, had associations of emotional abuse (OR = 1.94, 95% CI: 1.40-2.72) and physical neglect (OR = 1.90, 95% CI: 1.34-2.68) with an increased number of pain comorbidities. Conclusion.- The association of childhood maltreatment and pain was stronger in those reporting multiple pain conditions and multiple maltreatment types. This finding suggests that in migraineurs childhood maltreatment may be a risk factor for development of comorbid pain disorders.

	WA, USA (S.K. Aurora); University of Iowa, Iowa City, IA, USA (A. Recober).			
Tietjen GE, Brandes JL, Peterlin BL, Eloff A, Dafer RM, Stein MR, Drexler E, Martin VT, Hutchinson S, Aurora SK, Recober A, Herial NA, Utley C, White L, Khuder SA.	The University of Toledo College of Medicine, Toledo, OH, USA.	Allodynia in migraine: association with comorbid pain conditions.	Headache. 2009 Oct;49(9):1333-44.	BACKGROUND: Cutaneous allodynia (CA) in migraine is a clinical manifestation of central nervous system sensitization. Several chronic pain syndromes and mood disorders are comorbid with migraine. In this study we examine the relationship of migraine-associated CA with these comorbid conditions. We also evaluate the association of CA with factors such as demographic profiles, migraine characteristics, and smoking status that may have an influence on the relationships of CA to pain and mood. METHODS: Data are from a cross-sectional multicenter study of comorbid conditions in persons seeking treatment in headache clinics. Diagnosis of migraine was determined by a physician based on the International Classification of Headache Disorders-II criteria. Participants completed a self-administered questionnaire ascertaining sociodemographics, migraine-associated allodynia, physician-diagnosed comorbid medical and psychiatric disorders, headache-related disability, current depression, and anxiety. RESULTS: A total of 1413 migraineurs (mean age = 42 years, 89% women) from 11 different headache treatment centers completed a survey on the prevalence of comorbid conditions. Aura was reported by 38% and chronic headache by 35% of the participants. Sixty percent of the study population reported at least one migraine-related allodynic symptom, 10% reported > or =4 symptoms. Symptoms of CA were associated with female gender, body mass index, current smoking, presence of aura, chronic headaches, transformed headaches, severe headache-related disability, and duration of migraine illness from onset. The prevalence of self-reported physician diagnosis of comorbid pain conditions (irritable bowel syndrome, chronic fatigue syndrome, fibromyalgia) and psychiatric conditions (current depression and anxiety) was also associated with symptoms of CA. Adjusted ordinal regression indicated a significant association between number of pain conditions and severity of CA (based on symptom count). Adjusting for sociodemographics, migraine characteristics, and current depression and anxiety, the likelihood of reporting symptoms of severe allodynia was much higher in those with 3 or more pain conditions (odds ratio = 3.03, 95% confidence interval: 1.78-5.17), and 2 pain conditions (odds ratio = 2.67, 95% confidence interval: 1.78-4.01) when compared with those with no comorbid pain condition. CONCLUSION: Symptoms of CA in migraine were associated with current anxiety, depression, and several chronic pain conditions. A graded relationship was observed between number of allodynic symptoms and the number of pain conditions, even after adjusting for confounding factors. This study also presents the novel association of CA symptoms with younger age of migraine onset, and with cigarette smoking, in addition to confirming several previously reported findings.

Turan T, Izgi HB, Ozsoy S, Tanrıverdi F, Basturk M, Asdemir A, Beşirli A, Esel E, Sofuoglu S.	Department of Psychiatry, Erciyes University Medical School, Kayseri, Turkey.	The Effects of Galantamine Hydrobromide Treatment on Dehydroepiandrosterone Sulfate and Cortisol Levels in Patients with Chronic Fatigue Syndrome.	Psychiatry Investig. 2009 Sep;6(3):204-210. Epub 2009 Jun 23.	OBJECTIVE: Mental fatigue, cognitive disorders, and sleep disturbances seen in chronic fatigue syndrome (CFS) may be attributed to cholinergic deficit. A functional deficiency of cholinergic neurotransmission may cause the hypothalamic-pituitary-adrenal axis hypoactivity seen in CFS. Therefore, we investigated the alterations in stress hormones such as cortisol and dehydroepiandrosterone sulfate (DHEAS) in CFS patients before and after 4-week administration of galantamine hydrobromide, a selective acetylcholinesterase inhibitor, and aimed to investigate whether there are any relationships between the probable hormonal changes and cholinergic treatment. METHODS: Basal levels of cortisol and DHEAS were measured in 29 untreated CFS patients who were diagnosed according to Centers for Disease Control (CDC) criteria and in 20 healthy controls. In the patient group, four weeks after 8 mg/d galantamine hydrobromide treatment, cortisol and DHEAS levels were measured again. After the treatment 22 patients who stayed in study were divided into two subgroups as responders and nonresponders according to the reduction in their Newcastle Research Group ME/CFS Score Card (NRG) scores. RESULTS: Important findings of this study are lower pre-and post-treatment cortisol levels and in all CFS patients compared to controls (F=4.129, p=0.049; F=4.803, p=0.035, respectively); higher basal DHEAS values and higher DHEAS/cortisol molar ratios which were normalized following four weeks' treatment with 8 mg/d galantamine hydrobromide in the treatment-respondent group (F=5.382, p=0.029; F=5.722, p=0.025, respectively). CONCLUSION: The findings of the decrease in basal DHEAS levels and DHEAS/cortisol molar ratios normalizing with galantamine treatment may give some support to the cholinergic deficit hypothesis in CFS.
Twisk FNM, Maes M.	ME-de-patiënten Foundation, Limmen, the Netherlands, the Netherlands	A review on cognitive behavorial therapy (CBT) and graded exercise therapy (GET) in myalgic encephalomyelitis (ME) / chronic fatigue syndrome (CFS): CBT/GET is not only ineffective and not evidence-based, but also potentially harm	Neuroendocrinol Lett. 2009;30(3):275-420.	Benign Myalgic Encephalomyelitis (ME) / Chronic Fatigue Syndrome (CFS) is a debilitating disease which, despite numerous biological abnormalities has remained highly controversial. Notwithstanding the medical pathogenesis of ME/CFS, the (bio)psychosocial model is adopted by many governmental organizations and medical profes-sio-nals to legitimize the combination of Cognitive Behavioral Therapy (CBT) and Graded Exercise Therapy (GET) for ME/CFS. Justified by this model CBT and GET aim at eliminating presumed psychogenic and socially induced maintaining factors and reversing deconditioning, respectively. In this review we invalidate the (bio)psychosocial model for ME/CFS and demonstrate that the success claim for CBT/GET to treat ME/CFS is unjust. CBT/GET is not only hardly more effective than non-interventions or standard medical care, but many patients report that the therapy had affected them adversely, the majority of them even reporting substantial deterioration. Moreover, this review shows that exertion and thus GET most likely have a negative impact on many ME/CFS patients. Exertion induces post-exertional malaise with a decreased physical performan-ce/aerobic capacity, increased muscoskeletal pain, neurocognitive impairment, “fatigue”, and weakness, and a long lasting “recovery” time. This can be explained by findings that exertion may amplify pre-existing pa-thophysiological abnormalities underpinning ME/CFS, such as inflammation, immune dysfunction, oxidative and nitrosative stress, channelopathy, defec-tive stress response mechanisms and a hypoactive hypothalamic-pituitary-adrenal axis. We conclude that it is unethical to

				treat patients with ME/CFS with ineffective, non-evidence-based and potentially harmful "rehabilitation therapies", such as CBT/GET.
Ulvestad E.	Avdeling for mikrobiologi og immunologi Haukeland universitetssjukehus og Gades Institutt Universitetet i Bergen 5021 Bergen. elling.ulvestad@helse-bergen.no	[Expert--but on what?][Article in NorwegianComment in: Tidsskr Nor Laegeforen. 2009 Jun 25;129(13):1352.	Tidsskr Nor Laegeforen. 2009 Mar 26;129(7):642-3.	Chronic fatigue syndrome has received much attention owing to its debilitating character. The question as to whether the vaccine against meningococcus group B can provoke chronic fatigue syndrome has recently been addressed. Consensus in Norway seems to be that the vaccine does not provoke the syndrome. The article presents my reasons for questioning this conclusion.

van Alfen N, van der Werf SP, van Engelen BG.	Department of Neurology, Neuromuscular Centre Nijmegen, Donders Center for Neuroscience, Radboud University Nijmegen Medical Centre, Nijmegen, The Netherlands. n.vanalfen@neuro.umcn.nl	Long-term pain, fatigue, and impairment in neuralgic amyotrophy.	Arch Phys Med Rehabil. 2009 Mar;90(3):435-9.	OBJECTIVES: Recently, it has become clear that neuralgic amyotrophy (NA; idiopathic and hereditary brachial plexus neuropathy) has a less optimistic prognosis than usually assumed. To optimize treatment and management of these patients, one needs to know the residual symptoms and impairments they suffer. Therefore, the objective of this study was to describe the prevalence of pain, psychologic symptoms, fatigue, functional status, and quality of life in patients with NA. SETTING: Neurology outpatient department of an academic teaching hospital. PARTICIPANTS: NA patients (N=89) were studied, and clinical details were recorded. Self-report data were on average collected 2 years after the onset of the last NA episode. MAIN OUTCOME MEASURES: Pain was assessed with the McGill Pain Questionnaire, fatigue with the Checklist Individual Strength, and psychologic distress with the Symptom Checklist 90. Functional status and handicap were assessed with the modified Rankin Scale and Medical Outcomes Study 36-Item Short-Form Health Survey. RESULTS: Pain was usually localized in the right shoulder and upper arm, matching the clinical predilection site for paresis in NA. About a quarter to a third of the patients reported significant long-term pain and fatigue, and half to two thirds still experienced impairments in daily life. Over one third of the individual patients suffered from severe fatigue. The group did not fulfill the criteria of chronic fatigue or major psychologic distress. There was no correlation of pain or fatigue with the level of residual paresis on a Medical Research Council scale, but patients with a comorbid condition fared worse than patients without. CONCLUSIONS: A significant number of NA patients suffer from persistent pain and fatigue, leading to impairment. Symptoms were not correlated with psychologic distress. This makes it likely that they are caused by residual shoulder or arm dysfunction but not as part of a chronic pain or fatigue syndrome in these patients.

Van Campen E, Van Den Eede F, Moorkens G, Schotte C, Schacht R, Sabbe BG, Cosyns P, Claes SJ.	Dept. of Psychiatry, Antwerp University Hospital, Antwerp, Belgium.	Use of the Temperament and Character Inventory (TCI) for assessment of personality in chronic fatigue syndrome.	Psychosomatics. 2009 Mar-Apr;50(2):147-54.	BACKGROUND: Chronic fatigue syndrome (CFS) is characterized by severe and prolonged fatigue, along with a set of nonspecific symptoms and signs, such as sore throat, muscle pain, headaches, and difficulties with concentration or memory. OBJECTIVE: The study examined whether CFS is associated with specific dimensions of Cloninger's psychobiological model of personality. METHOD: Personality profiles were compared between 38 CFS patients and 42 control subjects by means of the Temperament and Character Inventory (TCI). RESULTS: The CFS group showed significantly higher scores on Harm-Avoidance and Persistence. CONCLUSION: The current study shows a significant association between specific personality characteristics and CFS. These personality traits may be implicated in the onset and/or perpetuation of CFS and may be a productive focus for psychotherapy.
Van Houdenhove B, Luyten P. Patient Educ Couns. 2009 Nov;77(2):153-4. Epub 2009 Sep 20. Comment on: Patient Educ Couns. 2009 Nov;77(2):237-41. Patient Educ Couns. 2009 Nov;77(2):231-6.	
Van Houdenhove B, Van Den Eede F, Luyten P.	Department of Liaison Psychiatry, University Hospitals K.U. Leuven, Herestraat 49, B-3000 Leuven, Belgium. boudewijn.vanhoudenhove@uz.kuleuven.ac.be	Does hypothalamic-pituitary-adrenal axis hypofunction in chronic fatigue syndrome reflect a 'crash' in the stress system?	Med Hypotheses. 2009 Jun;72(6):701-5. Epub 2009 Feb 23.	The etiopathogenesis of chronic fatigue syndrome (CFS) remains poorly understood. Although neuroendocrine disturbances - and hypothalamic-pituitary-adrenal (HPA) axis hypofunction in particular - have been found in a large proportion of CFS patients, it is not clear whether these disturbances are cause or consequence of the illness. After a review of the available evidence we hypothesize that that HPA axis hypofunction in CFS, conceptualized within a system-biological perspective, primarily reflects a fundamental and persistent dysregulation of the neurobiological stress system. As a result, a disturbed balance between glucocorticoid and inflammatory signaling pathways may give rise to a pathological cytokine-induced sickness response that may be the final common pathway underlying central CFS symptoms, i.e. effort/stress intolerance and pain hypersensitivity. This comprehensive hypothesis on HPA axis hypofunction in CFS may stimulate diagnostic refinement of the illness, inform treatment approaches and suggest directions for future research, particularly focusing on the neuroendocrine-immune interface and possible links between CFS, early and recent life stress, and depression.
Van Houdenhove B, Van Hoof E, Becq K, Kempke S, Luyten P, De Meirleir K.	Department of Liaison Psychiatry, University Hospital Gasthuisberg, Herestraat 49, Leuven B-3000, Belgium.	A comparison of patients with chronic fatigue syndrome in two "ideologically" contrasting clinics.	J Nerv Ment Dis. 2009 May;197(5):348-53.	Aim of the present study was to compare chronic fatigue syndrome (CFS) patients, attending 2 "ideologically" contrasting clinics for CFS, on various patient and illness characteristics. Fifty-nine CFS patients of each clinic, located in Leuven and Brussels (Belgium), participated. Patients did not differ with regard to age, levels of fatigue, psychopathology, and self-efficacy. However, patients from the psychosocially-oriented clinic had a lower level of education, reported more progressive illness onset, and attributed their illness more to psychological causes. Patients in the biologically-oriented clinic reported more pain, and showed higher levels of social functioning, motivation and vitality, as well as

	boudewijn.vanhoudenhove@uz.kuleuven.ac.be			fewer limitations related to emotional problems. It is concluded that CFS patients attending the 2 clinics could not be distinguished along dualistic biological/psychosocial lines, but those reporting sudden illness onset and making somatic attributions were more likely to be represented in the biologically-oriented clinic.
van Ittersum MW, van Wilgen CP, Hilberdink WK, Groothoff JW, van der Schans CP.	Hanze University Groningen, University of Applied Sciences, Center for Research and Development in Health Care and in Nursing, Groningen, The Netherlands. m.w.van.ittersum@pl.hanze.nl	Illness perceptions in patients with fibromyalgia.	Patient Educ Couns. 2009 Jan;74(1):53-60. Epub 2008 Sep 23.	OBJECTIVE: Former studies in chronic diseases showed the importance of patients' beliefs and perceptions. The Revised Illness Perception Questionnaire was developed to assess these illness perceptions. Our goal was to investigate psychometric properties of the IPQ-R for Fibromyalgia Dutch language version (IPQ-R FM-Dlv) and to describe illness perceptions of participants with FM. METHODS: 196 patients completed the IPQ-R FM-Dlv. Internal consistency, domain structure and inter domain correlations were calculated and compared to the IPQ-R English language version. Scores were compared with chronic fatigue syndrome (CFS), rheumatoid arthritis (RA), and coronary heart disease (CHD). RESULTS: Most psychometric properties were comparable to those of the original IPQ-R. Participants showed a lack of understanding of their illness, expected their FM to be chronic and to have a lot of negative consequences on functioning. In 17 out of 24 domains significant differences were found between FM and CFS, RA, and CHD patients. CONCLUSION: The IPQ-R FM-Dlv showed acceptable psychometric properties, although some aspects need closer examination. Illness perceptions of FM patients on the Dutch questionnaire were non-comparable to CFS, RA, and CHD patients on the English questionnaire. PRACTICE IMPLICATIONS: The IPQ-R FM-Dlv can be used to assess illness perceptions of Dutch FM patients.
van Nes SI, Vanhoutte EK, Faber CG, Garssen M, van Doorn PA, Merkies IS; PeriNomS Study Group. Collaborators: Bennett D, van den Berg LH, Van den Bergh PY, Cornblath DR, Dalakas M, Devigili G, van Doorn PA, Faber CG, Gorson KC, Hadden RD, Hahn AF, Hartung HP, Hughes RA, Lauria G, Léger JM, Lewis RA, Lunn MP, Merkies IS,	Department of Neurology, Erasmus Medical Centre Rotterdam, Rotterdam, The Netherlands. s.vannes@erasmusmc.nl	Improving fatigue assessment in immune-mediated neuropathies: the modified Rasch-built fatigue severity scale.	J Peripher Nerv Syst. 2009 Dec;14(4):268-78.	Fatigue is a major disabling complaint in patients with immune-mediated neuropathies (IN). The 9-item fatigue severity scale (FSS) has been used to assess fatigue in these conditions, despite having limitations due to its classic ordinal construct. The aim was to improve fatigue assessment in IN through evaluation of the FSS using a modern clinimetric approach [Rasch unidimensional measurement model (RUMM2020)]. Included were 192 stable patients with Guillain-Barré syndrome (GBS), chronic inflammatory demyelinating polyradiculoneuropathy (CIDP) or polyneuropathy associated with monoclonal gammopathy of undetermined significance (MGUSP). The obtained FSS data were exposed to RUMM2020 model to investigate whether this scale would meet its expectations. Also, reliability and validity studies were performed. The original FSS did not meet the Rasch model expectations, primarily based on two misfitting items, one of these also showing bias towards the factor 'walking independent.' After removing these two items and collapsing the original 7-point Likert options to 4-point response categories for the remaining items, we succeeded in constructing a 7-item Rasch-built scale that fulfilled all requirements of unidimensionality, linearity, and rating scale model. Good reliability and validity were also obtained for the modified FSS scale. In conclusion, a 7-item linearly weighted Rasch-built modified FSS is presented for more proper assessment of fatigue in future studies in patients with immune-mediated neuropathies.

van Wilgen CP, Dijkstra PU, Versteegen GJ, Fleuren MJ, Stewart R, van Wijhe M.	Pain Centre, Department of Anesthesiology, University Medical Centre Groningen, University of Groningen, Groningen, The Netherlands. c.p.van.wilgen@sport.umcg.nl	Chronic pain and severe disuse syndrome: long-term outcome of an inpatient multidisciplinary cognitive behavioural programme.	J Rehabil Med. 2009 Feb;41(3):122-8.	OBJECTIVE: Patients with chronic pain and severe disuse syndrome have pain with physiological, psychological and social adaptations. The duration and severity of complaints, combined with previously failed treatments, makes them unsuitable for treatment in primary care. DESIGN: A prospective waiting list controlled study. PATIENTS: A total of 32 patients with chronic pain for at least one year and severe disuse syndrome were included in an inpatient multidisciplinary cognitive behavioural treatment. METHODS: Patients were assessed before the waiting list period, before the clinical phase, after the clinical phase and after follow-ups of 6 months and one year. The visual analogue scale for pain and fatigue were assessed. Muscle strength of the arms and legs, arm endurance and a 6-minute walking test were used to assess physical outcome. The Symptom Checklist-90, RAND-36, pain cognition list and the Tampa scale for kinesiophobia were used to assess psychological outcome. RESULTS: Long-term significant ($p < 0.001$) improvements were found for pain, fatigue, walking distance, muscle strength, anxiety, depression, somatization, negative self-efficacy, and catastrophizing in the intervention period. CONCLUSION: An inpatient multidisciplinary cognitive behavioural programme is beneficial for patients with chronic pain and a severe disuse syndrome.
Vandenbergen J, Vanheule S, Rosseel Y, Desmet M, Verhaeghe P.	Department of Psychoanalysis and Clinical Consulting, Ghent University, Ghent, Belgium. jan.vandenbergen@telenet.be	Unexplained chronic fatigue and core conflictual relationship themes: A study in a chronically fatigued population.	Psychol Psychother. 2009 Mar;82(Pt 1):31-40. Epub 2008 Aug 25.	OBJECTIVE: Unexplained fatigue syndromes are multidimensional phenomena that involve a constellation of symptoms. This paper explores whether typical relationship patterns are associated with self-reported and clinically rated fatigue symptoms in chronically fatigued patients. METHOD: Relationship patterns were assessed by means of the core conflictual relationship theme (CCRT) method. This method examines transference patterns, and was applied to interview data collected from chronically fatigued patients (N=30). Chronic fatigue was assessed by means of a self-report questionnaire and was also rated clinically. RESULTS: Both self-reported and clinically rated fatigue correlated with relationship themes. The intensity of fatigue related to the perception of others as not respecting and as negatively interfering. The typical reaction of the self to relationships consists of feeling disrespected, anger, passivity, and reduced feelings of self-consistency. CONCLUSION: Patients' perception of interpersonal relationships as distressing may be pivotal in understanding these results. Implications for clinical intervention and future research are indicated.
Van't Leven M, Zielhuis GA, van der Meer JW, Verbeek AL, Bleijenberg G.	1 Department of Epidemiology, Biostatistics and HTA, Radboud University Nijmegen Medical Centre, the Netherlands.	Fatigue and chronic fatigue syndrome-like complaints in the general population.	Eur J Public Health. 2009 Aug 18. [Epub ahead of print]	BACKGROUND: Most knowledge on chronic fatigue (CF) and chronic fatigue syndrome (CFS) is based on clinical studies, not representative of the general population. This study aimed to assess the prevalence of fatigue in an adult general population and to identify associations with lifestyle factors. METHODS: Total 22 500 residents of Nijmegen were selected at random and interviewed by questionnaire. Data on 9062 respondents (43% response) were analysed, taken into account age, gender and concomitant disease. Subjects were classified into four groups: not fatigued (NF, reference group), short-term fatigue (SF, <6 months), chronic fatigue (CF, >/=6 months) and CFS-like fatigue (in accordance with the Center for Disease Control criteria for CFS, without clinical confirmation). RESULTS: Our study population showed the following breakdown: NF 64.4% (95% CI 63.6-65.6%), SF

				4.9% (95% CI 4.5-5.4%), CF 30.5% (95% CI 29.5-31.4%) and CFS-like fatigue 1.0% (95% CI 0.8-1.2%). Compared with the NF group, more of the CFS respondents were female [odds ratio (OR) = 1.9], obese (OR = 4.1), using analgesics (OR = 7.8), had a low alcohol intake (OR = 0.4), were eating less healthy food (OR = 0.5) and were physically less active (OR = 0.1). These associations largely applied to the SF and CF group. The fatigue could have been due to a concomitant disease in 34 and 55.5% of the SF and CF cases, respectively. CONCLUSION: The prevalence of CF in the general population appears to be much higher than previously indicated. Even with strict criteria for CFS, it is estimated that approximately 1% of the adult population experiences this condition. Interestingly, a large part of this group remains unrecognized by the general practitioner. A striking similarity in lifestyle pattern between SF, CF and CFS calls for further research.
Veldman J, Van Houdenhove B, Verguts J.	Department of Obstetrics and Gynaecology, University Hospital Gasthuisberg, Catholic University Leuven, Louvain, Belgium.	Chronic fatigue syndrome: a hormonal origin? A rare case of dysmenorrhea membranacea.	Arch Gynecol Obstet. 2009 May;279(5):717-20. Epub 2008 Sep 12.	BACKGROUND: Membranous dysmenorrhea is a rare entity involving expulsion of fragments of endometrium retaining the shape of the uterus. The condition is often linked to high progesterone levels. An association with a chronic fatigue syndrome was never described. CASE: A 44-year-old woman with a chronic fatigue syndrome (CFS), presented with membranous dysmenorrhea after taking an oral contraceptive pill containing ethinylestradiol 0.02 mg and desogestrel 0.15 mg for 3 months in a continuous regimen as treatment for dysfunctional bleeding. Oral contraception was discontinued and she resumed normal menstruations. Remarkably, she mentioned complete disappearance of the CFS since expulsion of the tissue and started working again. CONCLUSION: The occurrence of membranous dysmenorrhea with a dissolving chronic fatigue syndrome is very rare and was never described before. This case suggests a hormonal dysfunction as a possible cause of chronic fatigue syndrome. A review of the literature on membranous dysmenorrhea is presented.
Viaene M, Vermeir G, Godderis L.	Department of Occupational, Environmental and Insurance Medicine, Catholic University of Leuven, UZ St. Rafaël, Leuven, Belgium. m.k.viaene@opzgeel.be	Sleep disturbances and occupational exposure to solvents.	Sleep Med Rev. 2009 Jun;13(3):235-43. Epub 2009 Feb 7.	A solvent can be defined as "a liquid that has the ability to dissolve, suspend or extract other materials, without chemical change to the material or solvent". Numerous chemical or technical processes rely on these specific properties of organic solvents in industry. Occupational exposure to solvents is not rare and some activities may cause substantial exposure to these substances in the workforce. Short-term or acute exposures cause a prenarcotic syndrome, and long lasting exposure conditions have been associated with various neurological and neuropsychiatric disorders, e.g., anosmia, hearing loss, colour vision dysfunctions, peripheral polyneuropathy and depression, but most significantly with the gradual development of an irreversible toxic encephalopathy. For the last 3 decades reports and epidemiological studies have been published reporting sleep disturbances among other complaints, related to long-term exposure to these compounds. In addition, the question has been posed if solvents can be the cause of a sleep apnoea syndrome in exposed workers, or on the contrary, if these workers are misdiagnosed and 'common' sleep apnoea syndromes are the cause of their chronic symptoms of fatigue and memory and attentional disturbances.
Vij G, Gupta A, Chopra K.	Pharmacology Division, University Institute of Pharmaceutical Sciences, Punjab	Modulation of antigen-induced chronic fatigue in mouse model of water immersion	Fundam Clin Pharmacol. 2009 Jun;23(3):331-7. Epub 2009 Mar 11.	It is believed that physical stress, infection and oxidative stress are involved in the development of chronic fatigue syndrome. There is little evidence stating the beneficial role of nutritional supplements in chronic fatigue syndrome. Based on this, this study was designed to evaluate the effect of naringin, a natural polyphenol, in a mouse model of immunologically-induced fatigue, wherein purified lipopolysaccharide (LPS) as well as Brucella abortus (BA) antigen was used as

	University, Chandigarh-160014, India.	stress by naringin, a polyphenolic antioxidant.		immunogens. The assessment of chronic fatigue syndrome was based on chronic water-immersion stress test for 10 mins as well as measurement of hyperalgesia for 19 days. Immobility time and tail withdrawal latency as well as oxidative stress were taken as the markers of fatigue. Mice challenged with LPS or BA for 19 days showed significant increase in the immobility time, hyperalgesia and oxidative stress on 19th day. Serum tumor necrosis factor-alpha (TNF-alpha) levels markedly increased with LPS or BA challenge. Concurrent treatment with naringin resulted in the significant decrease in the immobility time as well as hyperalgesia. There was significant attenuation of oxidative stress as well as in TNF-alpha levels. Present findings strongly suggest the role of oxidative stress and immunological activation in the pathophysiology of chronic fatigue syndrome, and treatment with naringin can be a valuable option in chronic fatigue syndrome.
Walker K, Lindner H, Noonan M.	School of Psychology, Australian Catholic University, Melbourne, Victoria, Australia. mskarenwalker.@gmail.com	The role of coping in the relationship between depression and illness severity in chronic fatigue syndrome.	J Allied Health. 2009 Summer;38(2):91-9.	The self-regulatory model (SRM) proposes that both cognitive and emotional illness representations influence the coping processes adopted in response to an illness. AIM: This study used the SRM to explore the role of coping in the relationship between depression and self-appraisals of illness severity in a population of patients with chronic fatigue syndrome (CFS). METHODS: The sample comprised 156 participants, 34 men and 121 women, aged between 18 and 78 yrs, who had been medically diagnosed with CFS. Participants were asked to complete three questionnaires: the Cardiac Depression Scale, Ways of Coping Questionnaire, and Severity Subscale of the Illness Perceptions Questionnaire-Revised. RESULTS: Analyses revealed that almost 70% of the participants were moderately or severely depressed. Additionally, two particular subscales, social support seeking and positive reappraisals, emerged as positively contributing to self-appraisals of illness severity (beta = 0.20 [$p < 0.05$] and beta = 0.21 [$p < 0.05$], respectively), thereby supporting the SRM. Furthermore, results indicated that a combination of depression and coping was a better predictor of illness severity than depression alone, accounting for 22% of the variance compared with 8%, respectively. CONCLUSIONS: The findings suggest that focusing on depression, and particularly coping styles, during treatment interventions could have important implications for therapeutic interventions. This could lead to better treatment strategies for health professionals who work with patients with CFS.
Wang JH, Chai TQ, Lin GH, Luo L.	The First Hospital Affiliated to Guangzhou TCM University, Guangzhou 510405, China.	Effects of the intelligent-turtle massage on the physical symptoms and immune functions in patients with chronic fatigue syndrome.	J Tradit Chin Med. 2009 Mar;29(1):24-8.	OBJECTIVE: To evaluate the effects of the intelligent-turtle massage on the physical symptoms and immune functions in patients with chronic fatigue syndrome (CFS). METHODS: 182 cases of CFS were randomly divided into an experimental group of 91 cases treated by the intelligent-turtle massage, and a control group of 91 cases treated with the conventional massage method. After 2 courses of treatment, the therapeutic effects were statistically analyzed with the accumulated score for the improved clinical symptoms; and the changes of IgA, IgM and IgG were compared in 96 cases. RESULTS: There was a significant difference between the two groups in the accumulated scores for improvement of the symptoms ($P<0.05$). A remarkable difference was found in the therapeutic effect. And there was a significant difference in the IgA, IgM and IgG levels between the two groups ($P<0.05$). CONCLUSION: The intelligent-turtle massage is an effective therapy for relieving the physical symptoms of CFS, and it may show certain effects on the immune functions.
Wang JJ, Song YJ, Wu ZC, Chu XO, Wang QM, Wei	Hospital of Acupuncture and Moxibustion, China	[Randomized controlled study on influence of	Zhongguo Zhen Jiu. 2009 Oct;29(10):780-4.	OBJECTIVE: To observe effects of acupuncture on quality of life of patients with chronic fatigue syndrome (CFS). METHODS: Randomized, controlled and single-blinded study method was used, 70 cases were divided into an observation group and a control group, 35 cases in each group. The

LN, Wang XJ, Meng H.	Academy of Chinese Medical Sciences, Beijing 100700, China. wjj751@sina.com	acupuncture for life quality of patients with chronic fatigue syndrome] [Article in Chinese]		observation group was treated with acupuncture at Baihui (GV 20), Danzhong (CV 17), Zhongwan (CV 12), Qihai (CV 6), Guanyuan (CV 4), Hegu (LI 4), Zusanli (ST 36), etc.; the control group was treated with acupuncture at non-meridian points (2 cm to the acupoints), thrice a week. The treatment was given for 14 times. The World Health Organization Quality of Life (WHOQOL-BREF) scale was used to evaluate the patients' quality of life before and after treatment. RESULTS: The physiological field, individuals own perception of his health condition and total score were significantly improved after treatment in the observation group (all P<0.05); there were no obvious changes in the psychology, social relationships, environment and subjective feelings about the quality of life (all P>0.05). The score of the environmental field in the control group was significantly decreased compared to that before treatment (P<0.05), and there were no significant changes in the other scores. There were no adverse effects in patients. CONCLUSION: Acupuncture can improve the quality of life of CFS patients, especially in physiological field and the individual perception to his well being. Acupuncture has high safety, and the acupoints has high specific degree than non-meridian points.
Warren JW, Howard FM, Cross RK, Good JL, Weissman MM, Wesselmann U, Langenberg P, Greenberg P, Clauw DJ.	Department of Medicine, Epidemiology and Preventive Medicine, and Neurology, University of Maryland School of Medicine, Baltimore, Maryland, USA.	Antecedent nonbladder syndromes in case-control study of interstitial cystitis/painful bladder syndrome.	Urology. 2009 Jan;73(1):52-7. Epub 2008 Nov 8.	OBJECTIVES: Probing for clues to the pathogenesis of interstitial cystitis/painful bladder syndrome (IC/PBS), we sought antecedent nonbladder syndromes that distinguished incident IC/PBS cases from matched controls. METHODS: Female incident IC/PBS cases were recruited nationally, and their IC/PBS onset date (index date) was established. The controls were recruited by national random digit dialing and matched to the cases by sex, age, region, and interval between the (assigned) index date and interview. The prevalence of 24 nonbladder syndromes before the index date was assessed, 7 by multiple methods. RESULTS: The cases with IC/PBS had greater antecedent prevalence of 11 syndromes, and 243 of 313 cases (78%) vs 145 of 313 controls (45%) had multiple syndromes (P < .001). Fibromyalgia-chronic widespread pain (FM-CWP), chronic fatigue syndrome, sicca syndrome, and irritable bowel syndrome were associated with each other by pairwise and factor analyses using numerous assumptions. Cases with FM-CWP, chronic fatigue syndrome, sicca syndrome, and/or irritable bowel syndrome (n = 141, 45%) were more likely to have other syndromes (ie, migraine, chronic pelvic pain, depression, and allergy). Three other syndrome clusters were identified; each was associated with this FM-CWP cluster. CONCLUSIONS: Eleven antecedent syndromes were more often diagnosed in those with IC/PBS, and most syndromes appeared in clusters. The most prominent cluster comprised FM-CWP, chronic fatigue syndrome, sicca syndrome, and irritable bowel syndrome; most of the other syndromes and identified clusters were associated with it. Among the hypotheses generated was that some patients with IC/PBS have a systemic syndrome and not one confined to the bladder.
Watanabe K.	Department of Neuropsychiatry, Watanabe Hospital.	[Paroxysmal perceptual alteration in comparison with hallucination--a review of its clinical reports and discussion of its	Seishin Shinkeigaku Zasshi. 2009;111(2):127-36.	The syndrome of paroxysmal perceptual alteration (PPA) was first described by Yamaguchi in 1985. Since then, many PPA cases have been reported, and its pathophysiological mechanism has been proposed: a suppressed (blocked) mesolimbic and mesocortical dopaminergic system and sequential compensatory increase of noradrenergic neuronal activity are crucial for the occurrence of PPA. PPA is characterized by hypersensitivity of perception, psychedelic experience (brightening of colors, sharpening of contrast, visual distortion, etc.), and somatic schema disorder (one feels that one is floating, one's extremities are being pulled and elongated, etc.). PPA in chronic schizophrenic patients occurs abruptly like an attack mainly in the evening, often precipitated by fatigue. During the attack,

		pathophysiological mechanism in the present day, when second generation antipsychotics are widely used][Article in Japanese		patients also suffer from mood and thought alteration (anxiety, agitation, depressive mood, and inability to distract their thoughts from one thing), but they are aware that symptoms of PPA are not real and apprehensive about them. The attack ceases gradually and spontaneously while the patient rests or sleeps. These clinical features are clearly different from those of schizophrenic hallucinations. It is believed that PPA is closely related to neuroleptic treatment by conventional antipsychotics. I reported the prevalence of PPA as 4.0% in 1991 when high potential D2 blocking agents were prevailing. The occurrence of PPA has been significantly reduced to the present, when second generation (atypical) antipsychotics are prevailing. However, in my inquiry in 2004, the prevalence of PPA was 3.6% in cases treated with risperidone (RIS), while the rates were 0 in cases treated with olanzapine (OLZ), quetiapine (QTP), and perospirone (PRS). Several cases of PPA have been reported in patients who were treated with OLZ and PRS. Until now, no cases of PPA have been reported who were treated with QTP and aripiprazole (APZ). The prevalence of PPA among cases treated with these second generation antipsychotics might be related to the differences in these agents regarding their affinity for the D2 receptor: RIS has a sustained and close binding affinity, which might be similar to those of conventional antipsychotics, OLZ shows a sustained and loose binding affinity, PRS exhibits a transient and close binding affinity, whereas QTP has a transient and loose binding affinity. APZ is a partial agonist of the D2 receptor; APZ acts as an agonist under the condition of intrinsic dopaminergic dysfunction, which might prevent the occurrence of PPA.
Weinstein AA, Drinkard BM, Diao G, Furst G, Dale JK, Straus SE, Gerber LH.	Center for Study of Chronic Illness and Disability, George Mason University, Fairfax, VA 22030, USA. aweinst2@gmu.edu	Exploratory analysis of the relationships between aerobic capacity and self-reported fatigue in patients with rheumatoid arthritis, polymyositis, and chronic fatigue syndrome.	PM R. 2009 Jul;1(7):620-8.	OBJECTIVE: To determine if self-reported levels of physical activity and fatigue are related to peak oxygen uptake (VO(2peak)) and whether these relationships differ among the patient groups (rheumatoid arthritis [RA], polymyositis [PM], and chronic fatigue syndrome [CFS]). DESIGN: Correlational investigation. SETTING: Two ambulatory research clinics at the National Institutes of Health, Clinical Center, Bethesda, MD. PARTICIPANTS: There were 9 patients with PM, 10 with RA, and 10 with CFS. All patients met case criteria for their respective diagnoses. METHODS/MAIN OUTCOME MEASUREMENTS: VO(2peak) during bicycle ergometry and self-reported fatigability, fatigue, and physical activity. VO(2peak) was used as the criterion measurement of physiological fatigue with which the self-reported variables were compared. RESULTS: The Pearson r revealed that self-reported physical activity correlated with VO(2peak) (r = 61, P = .01). However, fatigability and fatigue did not correlate with VO(2peak). Linear regression analysis was performed to assess the effects of diagnosis group, self-reported activity level or fatigue, and their interaction. A trend in the data showed a distinctive relationship between fatigue/fatigability within the 3 groups. In addition, when controlling for group status, self-reported activity predicted aerobic capacity as measured by VO(2peak). CONCLUSIONS: This study confirms that patients with chronic, but stable RA, PM, or CFS are fatigued and have significantly decreased aerobic capacity. Self-reports of physical activity predicted VO(2peak), and may be used as an indicator of activity-based aerobic capacity. Self-reports of fatigue, however, did not correlate with VO(2peak) and hence are assessing something other than an index of aerobic capacity, and provide additional information about patients' perceptions, which will require further investigation.
Wells DL.	School of Psychology,	Associations between pet	J Altern Complement Med.	OBJECTIVE: This study explored the association between pet ownership and self-reported health in people suffering from chronic fatigue syndrome (CFS). METHODS: One hundred and ninety-three

	Queen's University Belfast, Northern Ireland, United Kingdom. d.wells@qub.ac.uk	ownership and self-reported health status in people suffering from chronic fatigue syndrome.	2009 Apr;15(4):407-13.	(193) people with medically diagnosed CFS completed a postal survey designed to collect information on illness severity, physical and psychologic health, and pet ownership practices. RESULTS: Most of the participants were female (72.0%), over 45 years of age (57.1%) and married (41.1%) with no children (63.1%). Pets were owned by 58.3% of the sample, with dogs and cats being the most commonly kept types of companion animal. The general health of the participants was discovered to be poor, as assessed by scores on the Chalder Fatigue Questionnaire (CFQ), General Health Questionnaire-12 (GHQ-12), and Short-Form-36 (SF-36) health survey. Pet ownership was not significantly associated with scores on the CFQ, GHQ-12, or SF-36 scales, although pet owners considered their animals to offer them a range of health benefits, notably those associated with mental well-being. CONCLUSIONS: Overall, findings suggest no statistically significant association between pet ownership and self-reported health in people with CFS. Nonetheless, people suffering from this condition believe that their pets have the potential to enhance quality of life. Although animals should not be regarded as a panacea for people with long-term conditions such as CFS, they may, nonetheless, serve a valuable, and currently underutilized, role in promoting well-being, whether in their own right, or in conjunction with more traditional forms of therapy.

The Shropshire Enablement Team, a specialist community rehabilitation team, has produced a DVD and booklet on pacing for people with chronic fatigue syndrome/ME. Pacing is a technique for managing fatigue, and involves achieving the correct balance between rest and activity. This article explains the benefits of pacing, and how the DVD and booklet have enabled the team to better support clients.
Wormser GP, Schwartz I.	Division of Infectious Diseases, Department of Medicine, York Medical College, Munger Pavilion Room 245, Valhalla, NY 10595, USA.	Antibiotic treatment of animals infected with Borrelia burgdorferi.	Clin Microbiol Rev. 2009 Jul;22(3):387-95.	Despite resolution of the objective manifestations of Lyme disease after antibiotic treatment, a minority of patients have fatigue, musculoskeletal pain, and/or difficulties with concentration or short-term memory of uncertain etiology; these are called post-Lyme disease symptoms or, in more severe cases, post-Lyme disease syndrome or "chronic Lyme disease." Several recent studies in which Borrelia burgdorferi-infected animals were treated with antibiotic therapy have demonstrated the presence of PCR positivity for B. burgdorferi DNA in the absence of culture positivity. In mice that were treated with antibiotic therapy, residual spirochetes could be taken up by ticks during a blood meal and could be transmitted to SCID mice. These spirochetes are attenuated; their presence is not associated with either inflammation or disease. In this review the methodology and findings of these studies are critically analyzed, and the significance of the results with regard to human Lyme disease is

	gary_wormser@nymc.edu			evaluated, with special emphasis on whether these studies provide useful insights into post-Lyme disease syndrome. A serious methodological concern is the failure to consider the pharmacokinetic-pharmacodynamic properties of the antibiotic in choosing the dosage regimen used. We conclude that there is no scientific evidence to support the hypothesis that such spirochetes, should they exist in humans, are the cause of post-Lyme disease syndrome.
Wormser GP, Shapiro ED.	Division of Infectious Diseases, Department of Medicine, New York Medical College, Munger Pavilion Room 245, Valhalla, NY 10595, USA. gary_wormser@nymc.edu	Implications of gender in chronic Lyme disease.	J Womens Health (Larchmt). 2009 Jun;18(6):831-4.	BACKGROUND: "Post-Lyme disease syndrome" refers to prolonged subjective symptoms after antibiotic treatment and resolution of an objective manifestation of Borrelia burgdorferi infection (Lyme disease). "Chronic Lyme disease" is a vaguely defined term that has been applied to patients with unexplained prolonged subjective symptoms, whether or not there was or is evidence of B. burgdorferi infection. OBJECTIVE: To determine if the population of patients with chronic Lyme disease differs from the populations of patients with either Lyme disease or post-Lyme disease syndrome by examining the gender of patients with these diagnoses. Methods: Data on gender were compiled in this cross-sectional study based on a systematic review of published studies of antibiotic treatment in United States patients with post-Lyme disease syndrome (n = 184) or chronic Lyme disease (n = 490), and on cases of adults with Lyme disease reported to the Centers for Disease Control and Prevention from 2003 to 2005 (n = 43,282). RESULTS: Patients with chronic Lyme disease were significantly more likely to be female than were patients diagnosed with either Lyme disease (odds ratio [OR] 2.42, 95% confidence interval [CI] 1.98-2.94, $p < 0.0001$) or with post-Lyme disease syndrome (OR 2.32, 95% CI 1.62-3.34, $p < 0.0001$). CONCLUSIONS: Patients with chronic Lyme disease differ with regard to gender from those with either B. burgdorferi infection or post-Lyme disease syndrome. This finding suggests that illnesses with a female preponderance, such as fibromyalgia, chronic fatigue syndrome, or depression, may be misdiagnosed as chronic Lyme disease.
Wu J, Ding HS, Ye DT.	Graduate School at Shenzhen, Tsinghua University, Shenzhen 518055, China. wuj@sz.tsinghua.edu.cn	[Evaluating fatigue resistance effect of health food by near-infrared tissue oximeter] [Article in Chinese]	Guang Pu Xue Yu Guang Pu Fen Xi. 2009 Sep;29(9):2357-60.	Currently, chronic fatigue syndrome (CFS) seriously affects people's normal living and work. In the present paper, the physiological parameters, such as tissue oxygenation saturation and heart rate, were used to evaluate the subjects' fatigue degree, and the fatigue resistance capsule and coffee were taken as a measure to adjust the fatigue. Human tissue oxygen saturation (rSO2) can be monitored noninvasively and in real time by near infrared spectroscopy (NIRS) based on spatially-resolved spectroscopy. Aiming at those brainworkers who need to work in an office for a long time; two static experiments were designed to evaluate the fatigue degree of the subjects who either take the fatigue resistance capsules/coffee or not. The rSO2 and heart rate (HR) of the subjects in the experiment group and contrast group were measured respectively for fatigue evaluation. This work particularly analyzed the changes in rSO2 in these two groups. The results show that the rSO2 of subjects in the experiment group evidently increased compared to that in the contrast group when the subjects took the fatigue resistance capsule or coffee, thereby show that the health food can reduce the fatigue to a certain extent.
Wyller VB, Eriksen HR, Malterud K.	Division of Paediatrics, Rikshospitalet University Hospital, Oslo,	Can sustained arousal explain the Chronic Fatigue Syndrome?	Behav Brain Funct. 2009 Feb 23;5:10.	ABSTRACT: We present an integrative model of disease mechanisms in the Chronic Fatigue Syndrome (CFS), unifying empirical findings from different research traditions. Based upon the Cognitive activation theory of stress (CATS), we argue that new data on cardiovascular and thermoregulatory regulation indicate a state of permanent arousal responses - sustained arousal - in this condition. We suggest that sustained arousal can originate from different precipitating factors (infections,

	Norway. brwylle@online.no.			psychosocial challenges) interacting with predisposing factors (genetic traits, personality) and learned expectancies (classical and operant conditioning). Furthermore, sustained arousal may explain documented alterations by establishing vicious circles within immunology (Th2 (humoral) vs Th1 (cellular) predominance), endocrinology (attenuated HPA axis), skeletal muscle function (attenuated cortical activation, increased oxidative stress) and cognition (impaired memory and information processing). Finally, we propose a causal link between sustained arousal and the experience of fatigue. The model of sustained arousal embraces all main findings concerning CFS disease mechanisms within one theoretical framework.
Yan S, Li HZ, Zhang XY, Li HJ.	Department of Urology, Peking Union Medical College Hospital, Peking Union Medical College, Chinese Academy of Medical Science, Beijing 100730, China.	[Retrospective analysis of the combined therapy of terazosin with chlormezanone for chronic prostatitis/chronic pelvic pain syndrome] [Article in Chinese]	Zhonghua Nan Ke Xue. 2009 Aug;15(8):717-20.	OBJECTIVE: To investigate the efficacy and safety of the alpha1-receptor inhibitor terazosin combined with chlormezanone in the treatment of chronic prostatitis/chronic pelvic pain syndrome (CP/CPPS). METHODS: A total of 168 CPPS patients, aged 20 -50 (mean 32.9) years and with the disease course of 3 months to 7 years (mean 17 months), were equally randomized into a terazosin group (n = 58), a chlormezanone group (n = 38) and a terazosin + chlormezanone (T + C) group (n = 72), and treated accordingly for 4 weeks. All the patients were scored on NIH-CPSI (National Institute of Health-Chronic Prostatitis Symptom Index) after the treatment and the therapeutic effects were compared among the three groups. RESULTS: Of the total number of patients, 159 completed the treatment and were evaluated, including 55 of the terazosin group, 35 of the chlormezanone group and 69 of the T + C group. After the treatment, the NIH-CPSI scores of the three groups decreased from 24.05 +/- 3.02 to 16.15 +/- 3.25 (mean 7.90), from 23.43 +/- 3.58 to 17.51 +/- 3.08 (mean 5.92), and from 23.93 +/- 3.30 to 15.01 +/- 3.08 (mean 8.92), respectively, with statistically significant differences from pretreatment ($P < 0.05$) as well as between the combined therapy group and the other two ($P < 0.05$). The adverse events included postural hypotension (17.1% in the terazosin group and 15.4% in the T + C group), dysspermatism (3.4% in the terazosin group only), lassitude, fatigue and anorexia (18.5% in the chlormezanone group and 12.6% in the T + C group). Nine of the patients failed to accomplish the treatment because of adverse events, 3 (5.2%) in the terazosin group, 3 (7.9%) in the chlormezanone group and 3 (12.6%) in the T + C group. CONCLUSION: Both terazosin and chlormezanone can relieve the symptoms in CP/CPPS patients and improve their life quality, but their combined use may produce a better efficacy than either terazosin or chlormezanone used alone.
Zhang L, Goudh J, Christmas D, Mattey D, Richards S, Main J, Enlander D, Honeybourne D, Ayres J, Nutt DJ, Kerr J.	St George's University of London, United Kingdom;	Microbial infections in eight genomic subtypes of Chronic Fatigue Syndrome / Myalgic Encephalomyelitis (CFS/ME).	J Clin Pathol. 2009 Dec 2. [Epub ahead of print]	We have previously reported genomic subtypes of CFS/ME based on expression of 88 human genes. In this study we attempted to reproduce these findings, determine specificity of this signature to CFS/ME, and test for associations between CFS/ME subtype and infection. We determined expression levels of 88 human genes in blood of 61 new patients with idiopathic CFS/ME (according to Fukuda criteria), 6 patients with Q-fever associated CFS/ME form the Birmingham Q-fever outbreak (according to Fukuda criteria), 14 patients with endogenous depression (according to DSM-IV criteria) and 18 normal blood donors. In patients with CFS/ME differential expression was confirmed for all 88 genes. Q-CFS/ME patients had similar patterns of gene expression to idiopathic CFS/ME. Gene expression in endogenous depression patients was similar to that in the normal controls, except for upregulation of five genes (APP, CREBBP, GNAS, PDCD2, PDCD6). Clustering of combined gene data in CFS/ME patients for this and our previous study (n=117 CFS/ME patients) revealed genomic subtypes with distinct differences in SF-36 scores, clinical phenotypes, severity and geographical distribution. Antibody

				testing for Epstein-Barr virus (EBV), enterovirus, Coxiella burnetii and parvovirus B19 revealed subtype-specific relationships for EBV and enterovirus, the two most common infectious triggers of CFS/ME.
Ziemssen T.	MS Center, Neurological University Clinic, Dresden, Germany. Tjalf.Ziemssen@uniklinikum-dresden.de	Multiple sclerosis beyond EDSS: depression and fatigue.	J Neurol Sci. 2009 Feb 1;277 Suppl 1:S37-41.	Depression and fatigue are common symptoms of multiple sclerosis and are the primary determinants of impaired quality of life in this demyelinating neurological disease. The twelve-month prevalence of major depression in patients with multiple sclerosis is around 15%. Untreated depression is associated with suicidal ideation, impaired cognitive function and poor adherence to immunomodulatory treatment. For these reasons, systematic screening and management of depressive symptoms is recommended for all patients with multiple sclerosis. There is some evidence that interferon-beta treatment may exacerbate depressive symptoms and a switch to glatiramer acetate can be envisaged in patients treated with an interferon-beta in whom depressive symptoms become an issue. Fatigue is present in over three-quarters of patients with multiple sclerosis. It is considered the most debilitating symptom of the disease and is a major reason for work absenteeism. There is growing evidence that immunomodulatory treatments, in particular glatiramer acetate, improve fatigue symptoms in patients with multiple sclerosis.

Abeles M, Solitar BM, Pillinger MH, Abeles AM.	Division of Rheumatology, Department of Medicine, The University of Connecticut School of Medicine, Farmington, USA.	Update on fibromyalgia therapy.	Am J Med. 2008 Jul;121(7):555-61.	Primary fibromyalgia, a poorly-understood chronic pain syndrome, is characterized by widespread musculoskeletal pain, nonrestorative sleep, fatigue, psychological distress, and specific regions of localized tenderness, all in the absence of otherwise apparent organic disease. While the etiology of fibromyalgia is unclear, accumulating data suggest that disordered central pain processing likely plays a role in the pathogenesis of symptoms. Although various pharmacological treatments have been studied and espoused for treating fibromyalgia, no single drug or group of drugs has proved to be particularly useful in treating fibromyalgia patients as a whole, and only one drug to date has earned U.S. Food and Drug Administration approval for treating the syndrome in the United States. This

	aabeles@uchc.edu			review critically and systematically evaluates clinical investigations of medicinal and nonmedicinal treatments for fibromyalgia dating from 1970 to 2007.
Ablin JN, Buskila D.	Tel Aviv Sourasky Medical Center, Rheumatology Institute, Tel Aviv, Israel.	Emerging therapies for fibromyalgia.	Expert Opin Emerg Drugs. 2008 Mar;13(1):53-62.	BACKGROUND: Fibromyalgia syndrome (FMS) is a disorder characterized by widespread pain, tenderness, and fatigue. High prevalence marks the syndrome which is considered to reflect altered central pain processing. Fibromyalgia syndrome runs a chronic, non-progressive course, extracting high price owing to impaired quality of life, restricted vocational capacity, and increased health care utilization. OBJECTIVE: To review current and emerging trends in the treatment of FMS. Methods: A rigorous search of published literature, abstract presentations, and industry provided data was performed. RESULTS/CONCLUSION: The recent FDA approval of pregabalin as a first specific medication for FMS may herald a new era for the development of medications with higher specificity and efficacy for this hitherto frustrating condition.

Br Dent J. 2008 Aug 9;205(3):E6; discussion 140-1. Epub 2008 Jul 4. Comment in: Br Dent J. 2008 Oct 25;205(8):414; author reply 414.	Aim To identify distinct characteristics of unexplained orofacial pain that could be used by dental practitioners in making an early diagnosis.Methods Subjects reporting orofacial pain in a postal questionnaire-based cross-sectional survey were invited for clinical examination. The interviewer was blinded to the questionnaire responses of the subjects. A diagnosis was made following the examination and subjects were assigned into two groups: unexplained pain and dental pain. The questionnaire responses of subjects who had consulted a healthcare professional within these two groups were then compared with particular attention to demographics, orofacial pain characteristics, consultation behaviour and relationship with other unexplained syndromes.Results Subjects who had consulted for their pain and were assigned to the unexplained orofacial pain group were significantly ($p < 0.05$) more likely to report the following characteristics: pain descriptors (nagging, aching, tingling), pain pattern (worse with stress), site (poorly localised), duration (persistent/chronic), high disability, multiple consultations and co-morbidities (teeth grinding, reporting of other unexplained syndromes).Conclusion This study has shown that unexplained orofacial pain has distinct characteristics that differentiate it from other common dental conditions. This provides a good evidence base which can reduce uncertainty among dental practitioners, allowing them to make an early diagnosis.

Ahboucha S, Butterworth RF, Pomier-Layrargues G, Vincent C, Hassoun Z, Baker GB.	Neuroscience Research Unit, University de Montreal, Montreal, QC, Canada. samir.ahboucha@ualberta.ca	Neuroactive steroids and fatigue severity in patients with primary biliary cirrhosis and hepatitis C.	Neurogastroenterol Motil. 2008 Jun;20(6):671-9. Epub 2008 Feb 13.	Fatigue is one of the most common non-specific symptoms associated with several disease states including liver diseases. Recently, it was reported that levels of progesterone metabolites such as allopregnanolone (3alpha,5alpha-tetrahydroprogesterone; 3alpha,5alpha-THP) and isopregnanolone (3beta,5alpha-THP) were increased in plasma of patients with chronic fatigue syndrome. We hypothesize that THP metabolites might be associated with fatigue commonly observed in chronic liver diseases. We evaluated fatigue scores and plasma levels of five progesterone metabolites in 16 patients with primary biliary cirrhosis (PBC), 12 patients with chronic hepatitis C (CHC) and 11 age-matched controls. The fatigue impact scale (FIS) ratio was significantly increased ($P < 0.01$) in patients with PBC and CHC compared to controls. Plasma levels of 3alpha,5alpha-THP and pregnanolone (3alpha,5beta-THP) were significantly increased in PBC and CHC patients. The other progesterone metabolites, i.e. 3beta,5alpha-THP, 3beta,5beta-THP and 3alpha,5alpha-tetrahydrodeoxycorticosterone were either undetectable or detected only in some patients. Plasma levels of 3alpha,5alpha-THP and 3alpha,5beta-THP were found to be significantly higher in patients with fatigue ($P < 0.05$), while those of patients without fatigue were not significantly different from controls. Both 3alpha,5alpha-THP and 3alpha,5beta-THP are positive allosteric modulators of the gamma-aminobutyric acid type A (GABA-A) receptor and readily cross the blood-brain barrier. The present preliminary findings suggest that increased inhibition through GABA-A receptors due to the accumulation of neuroinhibitory steroids may represent an important pathophysiological mechanism of fatigue in chronic liver diseases.
Ahboucha S, Pomier-Layrargues G, Vincent C, Hassoun Z, Tamaz R, Baker G, Butterworth RF.	Neuroscience Research Unit, CHUM-Hôpital Saint-Luc, 1058 St.-Denis, Montreal, Quebec 2X 3J4, Canada.	Reduced plasma dehydroepiandrosterone sulfate levels are significantly correlated with fatigue severity in patients with primary biliary cirrhosis.	Neurochem Int. 2008 Mar-Apr;52(4-5):569-74. Epub 2007 Jun 19.	Fatigue is a common debilitating complication of primary biliary cirrhosis (PBC), the pathophysiologic mechanism of which is poorly understood. Recently, the neuroactive steroid dehydroepinadrosterone sulfate (DHEAS) was reported to be implicated in Chronic Fatigue Syndrome in the absence of liver disease. The present study was undertaken to analyse fatigue scores and their relationship with disease severity and circulating levels of DHEAS as well as its precursors DHEA and pregnenolone in PBC patients with (n=15) or without fatigue (n=10) compared to control subjects (n=11). Fatigue was assessed using the fatigue impact scale (FIS) including cognitive, physical and psychosocial subclasses. Steroids were measured by radioimmunoassay or gas chromatography/mass spectrometry. Plasma concentrations of DHEAS were significantly reduced in PBC patients with fatigue as compared to controls, while those of its precursors DHEA and pregnenolone remained within the control range. Plasma levels of DHEAS in PBC patients were significantly correlated with fatigue severity as reflected by total FIS scores including total ($rp=-0.42$; $p=0.018$), as well as the cognitive ($rp=-0.37$; $p=0.03$), physical ($rp=-0.48$; $p=0.006$) and psychosocial ($rp=-0.35$; $p=0.04$) subclasses of fatigue scores. No correlation of fatigue scores was observed with indices of liver function. These findings suggest that reduced levels of the neurosteroid DHEAS may contribute to fatigue in patients with PBC; substitutive therapy using DHEAS or its precursor DHEA could be beneficial in the management of fatigue in patients with low levels of DHEAS.

J Midwifery Womens Health. 2008 Jul-Aug;53(4):289-301; quiz 399.	Chronic fatigue syndrome is a complex debilitating medical disorder that affects approximately 4 million persons in the United States, predominantly women. There has been little scientific exploration about the experience of pregnancy, childbirth, and the postpartum period for women with this disorder. A review of the literature and current research findings addressing the epidemiology, diagnosis, symptoms, and treatment of chronic fatigue syndrome are presented, as well as the currently available data regarding the experience of women with chronic fatigue syndrome anticipating or experiencing pregnancy and the postpartum period. Expert opinion is presented along with current evidence to provide guidelines for the care of women with chronic fatigue syndrome during pregnancy, labor and birth, lactation, and the postpartum period.
Amsterdam JD, Shults J, Rutherford N.	Depression Research Unit, Department of Psychiatry, University of Pennsylvania School of Medicine, Philadelphia, PA, United States. jamsterd@mail.med.upenn.edu	Open-label study of s-citalopram therapy of chronic fatigue syndrome and co-morbid major depressive disorder.	Prog Neuropsychopharmacol Biol Psychiatry. 2008 Jan 1;32(1):100-6. Epub 2007 Aug 3.	OBJECTIVE: Chronic fatigue syndrome (CFS) is a debilitating disorder with prominent symptoms of malaise, fatigue, myalgia, arthralgia, and impaired concentration. The symptoms of CFS may often overlap those of Major Depressive Disorder (MDD). Treatment of CFS has generally been disappointing. We hypothesized that s-citalopram therapy may improve the symptoms of both disorders in CFS patients with co-morbid depression. METHODS: 16 patients received s-citalopram 10 mg to 20 mg daily for up to 12 weeks. Outcome measures of CFS included the Chalder Fatigue Questionnaire (CFQ), the multi-dimensional Fatigue Impact Scale (FIS), the CFS symptom rating (CFS-SR) 100 mm visual analogue scale, and the clinical global impressions severity (CGI/S) and change (CGI/C) ratings. Secondary outcomes of MDD included the Hamilton Depression Rating (HAM-D), Beck Depression Inventory (BDI), and the CGI/S and CGI/C ratings of MDD. RESULTS: We observed reductions in the mean CFQ score ($p<0.0005$), FIS score ($p<0.0005$), and CGI/S ($p<0.0005$) and CGI/C ($p<0.0005$) ratings over time. There was a significant improvement in 5 of the 8 CFS-SR symptoms: post-exertion malaise ($p=0.001$), headaches ($p<0.0005$), un-refreshing sleep ($p<0.0005$), and impaired memory and concentration ($p<0.0005$). There was also a reduction in mean HAM-D ($p<0.0005$), BDI ($p<0.0005$), CGI/S ($p=0.001$) and CGI/C ($p<0.0005$) ratings of MDD. LIMITATIONS: The sample size was limited and the study design was not double-blind or placebo controlled. CONCLUSION: We observed a significant reduction in both CFS and co-morbid MDD symptom severity ratings, and improvement in 5 of 8 core somatic symptoms of CFS during s-citalopram therapy.
Annoni JM, Staub F, Bogousslavsky J, Brioschi A.	Neurological Department, Lausanne University Hospital and Medical School, 1011, Lausanne, Switzerland. Jean-Marie.Annoni@hcuge.ch	Frequency, characterisation and therapies of fatigue after stroke.	Neurol Sci. 2008 Sep;29 Suppl 2:S244-6.	Post-stroke objective or subjective fatigue occurs in around 50% of patients and is frequent (30%) even after minor strokes. It can last more than one year after the event, and is characterised by a different quality from usual fatigue and good response to rest. Associated risk factors include age, single patients, female, disability, depression, attentional impairment and sometimes posterior strokes, but also inactivity, overweight, alcohol and sleep apnoea syndrome. There are few therapy studies, but treatment may include low-intensity training, cognitive therapy, treatment of associated depression, wakefulness-promoting agents like modafinil, correction of risk factors and adaptation of activities.
Anthenelli RM, Blom TJ, McElroy	Tri-State Tobacco and Alcohol	Preliminary evidence for	Addiction. 2008 Apr;103(4):687-94.	AIMS: Study aims were threefold: (i) to determine the feasibility, potential efficacy and safety of topiramate as an aid to smoking cessation; (ii) to examine potential predictors of abstinence including

SL, Keck PE Jr.	Research Center, Cincinnati Veterans Affairs Medical Center, Cincinnati, OH 45220, USA. robert.anthenelli@va.gov	gender-specific effects of topiramate as a potential aid to smoking cessation.		gender; and (iii) to explore topiramate's effects on tobacco withdrawal and post-cessation weight gain. DESIGN: Randomized, double-blind, placebo-controlled, 11-week clinical trial with a 6-week dosage titration period and 5 weeks of maintenance treatment. SETTING: Single-site, out-patient, randomized clinical trial. PARTICIPANTS: Thirty-eight adult male and 49 female chronic smokers who smoked an average of > 10 cigarettes per day and who were motivated to try to quit smoking. INTERVENTION: Random assignment to receive either topiramate (n = 43) up to 200 mg daily in divided doses or placebo (n = 44) orally combined with brief counseling over an 11-week period. MEASUREMENTS: Carbon monoxide (CO)-confirmed 4-week prolonged abstinence rate during weeks 8-11. Changes in tobacco withdrawal, body weight and safety parameters were also assessed. FINDINGS: Overall, no significant increase in the prolonged abstinence rate was detected, but logistic regression analysis indicated significant gender-specific differences. Men treated with topiramate were nearly 16 times more likely to quit smoking than women on topiramate [37.5% versus 3.7%; odds ratio (OR) = 15.6; P = 0.016] and were roughly four times more likely to quit smoking than placebo-treated men (37.5% versus 13.6%; OR = 3.8; P = 0.098). Topiramate-treated men reported significantly lower tobacco withdrawal scores than both women taking topiramate and men on placebo. On average, male cessators on placebo gained 3.30 kg, whereas topiramate led to a 0.72 kg weight loss (P = 0.03). Study discontinuation rates due to adverse events (AEs) were significantly higher in the topiramate group (topiramate 23% versus placebo 2%). The most commonly reported AEs in the topiramate arm were paraesthesia, fatigue, difficulty with concentration/attention and nervousness. CONCLUSIONS: Topiramate produced gender-specific effects on smoking cessation. Male smokers had markedly greater quit rates than female smokers and men were roughly four times more likely to quit smoking when treated with topiramate as compared to placebo. Topiramate was fairly well tolerated, although higher discontinuation rates were seen. Topiramate's triple effects aiding smoking abstinence, attenuating nicotine withdrawal and preventing post-cessation weight gain might make it a promising agent for treating tobacco addiction, at least in men.
Armitage R, Landis C, Hoffmann R, Lentz M, Watson N, Goldberg J, Buchwald D.	Department of Psychiatry, University of Michigan, Ann Arbor, MI, USA. rosearmi@umich.edu	Power spectral analysis of sleep EEG in twins discordant for chronic fatigue syndrome.	J Psychosom Res. 2009 Jan;66(1):51-7. Epub 2008 Nov 25.	OBJECTIVE: The purpose of the study was to evaluate quantitative sleep electroencephalogram (EEG) frequencies in monozygotic twins discordant for chronic fatigue syndrome. METHODS: Thirteen pairs of female twins underwent polysomnography. During the first night, they adapted to the sleep laboratory, and during the second night, their baseline sleep was assessed. Visual stage scoring was conducted on sleep electroencephalographic records according to standard criteria, and power spectral analysis was used to quantify delta through beta frequency bands, processed in 6-s blocks. Data were averaged across sleep stage within each twin and coded for sleep stage and the presence or absence of chronic fatigue syndrome (CFS). A completely within-subjects repeated measure multivariate analysis of variance evaluated twin pairs by frequency band by sleep stage interactions and simple effects. The relationship between alpha and delta EEG was also assessed across twin pairs. RESULTS: No significant differences in spectral power in any frequency band were found between those with CFS and their nonfatigued cotwins. Phasic alpha activity, coupled with delta was noted in five subjects with CFS but was also present in 4/5 healthy twins, indicating this finding likely reflects genetic influences on the sleep electroencephalogram rather than disease-specific sleep pathology. CONCLUSIONS: The genetic influences on sleep polysomnography and microarchitecture appear to be

				stronger than the disease influence of chronic fatigue syndrome, despite greater subjective sleep complaint among the CFS twins. EEG techniques that focus on short duration events or paradigms that probe sleep regulation may provide a better description of sleep abnormalities in CFS.
Aspler AL, Bolshin C, Vernon SD, Broderick G.	Department of Medicine, Faculty of Medicine and Dentistry, University of Alberta, Edmonton, Alberta, T6G 2H7, Canada. gordon.broderick @ualberta.ca.	Evidence of inflammatory immune signaling in chronic fatigue syndrome: A pilot study of gene expression in peripheral blood.	Behav Brain Funct. 2008 Sep 26;4:44.	ABSTRACT: BACKGROUND: Genomic profiling of peripheral blood reveals altered immunity in chronic fatigue syndrome (CFS) however interpretation remains challenging without immune demographic context. The object of this work is to identify modulation of specific immune functional components and restructuring of co-expression networks characteristic of CFS using the quantitative genomics of peripheral blood. METHODS: Gene sets were constructed a priori for CD4+ T cells, CD8+ T cells, CD19+ B cells, CD14+ monocytes and CD16+ neutrophils from published data. A group of 111 women were classified using empiric case definition (U.S. Centers for Disease Control and Prevention) and unsupervised latent cluster analysis (LCA). Microarray profiles of peripheral blood were analyzed for expression of leukocyte-specific gene sets and characteristic changes in co-expression identified from topological evaluation of linear correlation networks. RESULTS: Median expression for a set of 6 genes preferentially up-regulated in CD19+ B cells was significantly lower in CFS ($p = 0.01$) due mainly to PTPRK and TSPAN3 expression. Although no other gene set was differentially expressed at $p < 0.05$, patterns of co-expression in each group differed markedly. Significant co-expression of CD14+ monocyte with CD16+ neutrophil ($p = 0.01$) and CD19+ B cell sets ($p = 0.00$) characterized CFS and fatigue phenotype groups. Also in CFS was a significant negative correlation between CD8+ and both CD19+ up-regulated ($p = 0.02$) and NK gene sets ($p = 0.08$). These patterns were absent in controls. CONCLUSION: Dissection of blood microarray profiles points to B cell dysfunction with coordinated immune activation supporting persistent inflammation and antibody-mediated NK cell modulation of T cell activity. This has clinical implications as the CD19+ genes identified could provide robust and biologically meaningful basis for the early detection and unambiguous phenotyping of CFS.
Axe EK, Paul Satz, Fawzy I. Fawzy		Cognitive Function and Major Depression in Chronic Fatigue: The Apathy Construct	Journal of Chronic Fatigue Syndrome 2008; 14 (4): 19-38	Objective: The current study examined cognitive function, major depressive disorder (MDD), and apathy construct symptoms in a large multi-site surveillance study of chronic fatigue syndrome conducted by the Centers for Disease Control and Prevention. Method: Subjects underwent neuropsychological testing and were administered the Diagnostic Interview Schedule to establish psychiatric diagnoses. Questions in the Beck Depression Inventory relating to motivation were used to develop an apathy construct. Results: Neuropsychological test results showed impairment in multiple cognitive domains in over 25% of the cohort, and raised proportions of outliers in motor and executive function. Memory complaints were not associated with tests of memory function. The apathy construct rather than MDD was associated with impaired cognition. Conclusions: Impaired cognition in chronic fatigue does not appear to be associated with MDD but rather with endorsement of construct symptoms. Similar associations were reported in medical conditions with known etiologies. These results suggest a potential biological basis for apathy construct symptoms.
Baars EW, Gans S, Ellis EL.	Healthcare & Nutrition Department, Louis Bolk Instituut, Driebergen, The	The effect of hepar magnesium on seasonal fatigue symptoms: a pilot study.	J Altern Complement Med. 2008 May;14(4):395-402.	OBJECTIVES: To evaluate the effect of the anthroposophic drug hepar magnesium D10 intravenously administered on seasonal fatigue symptoms. DESIGN: Time series with two measurements per week, starting before onset of treatment until three measurements after finishing treatment in a regular way. SETTINGS: Six anthroposophic general practitioner practices in the Netherlands. SUBJECTS: Twenty-three (23) patients with seasonal fatigue symptoms. INTERVENTIONS: Hepar magnesium D10

	Netherlands. e.baars@louisbolk.nl			intravenously administered every week. OUTCOME MEASURES: Mean division of 24 hours in categories: sleep, rest, everyday activities, and activities that require a large effort; fatigue-related single questions: unusual emotional response to events, problems with short-term memory, the degree to which fatigue after effort continues for longer than 2 hours, the degree to which people at the end of the day have a complete lack of energy; and the degree to which people are still fit after the evening meal; Multidimensional Fatigue Index: general fatigue, physical fatigue, reduced activity, reduced motivation, and mental fatigue; subjective experiences with regard to the effect of the treatment. RESULTS: (1) No changes in division in 24-hour categories were found; (2) pretreatment versus post-treatment analyses (after 1 and 2.5 weeks, at the end of treatment, and 1.5 weeks after the end of treatment) demonstrated overall large statistically significant differences. Eighteen (18) of 22 patients (82%) who completed the final questionnaire judged that treatment overall had been effective for their fatigue symptoms. Nine (9) patients (41%) judged a strong improvement and 9 patients (41%) a light improvement as a result of the treatment. Four (4) patients reported no change. On average, patients received treatment 4.5 times. CONCLUSIONS: There are clear indications that hepar magnesium D10 intravenously administered can have a positive effect on subsyndromal seasonal affective disorder symptoms of fatigue. A more controlled trial is indicated to study the (long-term) effects of hepar magnesium.
Baetz M, Bowen R.	University of Saskatchewan, Saskatoon, Saskatchewan, Canada. m.baetz@usak.ca	Chronic pain and fatigue: Associations with religion and spirituality.	Pain Res Manag. 2008 Sep-Oct;13(5):383-8.	BACKGROUND: Conditions with chronic, non-life-threatening pain and fatigue remain a challenge to treat, and are associated with high health care use. Understanding psychological and psychosocial contributing and coping factors, and working with patients to modify them, is one goal of management. An individual's spirituality and/or religion may be one such factor that can influence the experience of chronic pain or fatigue. METHODS: The Canadian Community Health Survey (2002) obtained data from 37,000 individuals 15 years of age or older. From these data, four conditions with chronic pain and fatigue were analyzed together -- fibromyalgia, back pain, migraine headaches and chronic fatigue syndrome. Additional data from the survey were used to determine how religion and spirituality affect psychological well-being, as well as the use of various coping methods. RESULTS: Religious persons were less likely to have chronic pain and fatigue, while those who were spiritual but not affiliated with regular worship attendance were more likely to have those conditions. Individuals with chronic pain and fatigue were more likely to use prayer and seek spiritual support as a coping method than the general population. Furthermore, chronic pain and fatigue sufferers who were both religious and spiritual were more likely to have better psychological well-being and use positive coping strategies. INTERPRETATION: Consideration of an individual's spirituality and/or religion, and how it may be used in coping may be an additional component to the overall management of chronic pain and fatigue.
Bains W.	Delta G Ltd, 37 The Moor, Melbourn, Royston, Herts SG8 6ED, UK. william@delta-g.com	Treating Chronic Fatigue states as a disease of the regulation of energy metabolism.	Med Hypotheses. 2008 Oct;71(4):481-8. Epub 2008 Aug 5.	Chronic Fatigue Syndrome is a physiological state in which the patient feels high levels of fatigue without an obvious organic cause, which affects around 1 in 400 people in the developed world. A wide range of causes have been suggested, including immune or hormonal dysfunction, viral or bacterial infection, and psychological somatization. It is likely that several causes are needed to trigger the disease, and that the triggers are different from the mechanisms that maintain fatigue over months or years. Many treatments have been tested for CFS, with very limited success - a programme

				of combined CBT and graded exercise shows the most effect. I suggest that patients with CFS have a reduced ability to increase mitochondrial energy production when exertion requires it, with fewer mitochondria that are each more efficient, and hence nearer to their maximum energy output, than normal. A range of indirect evidence suggests that the renin-angiotensin system stimulates mitochondrial responsiveness and reduces mitochondrial efficiency: chronic under-stimulation of this system could contribute to CFS aetiology. If correct, this means that CFS can be successfully treated with RAS agonists (eg angiotensin mimetics), or adrenergic agonists. It also suggests that there will be a positive link between the use of adrenergic- and RAS-blocking drugs and CFS incidence, and a negative link between adrenergic agonist use and CFS.
Bassi N, Amital D, Amital H, Doria A, Shoenfeld Y.	Department of Rheumatology, University of Padova, Padova, Italy.	Chronic fatigue syndrome: characteristics and possible causes for its pathogenesis.	Isr Med Assoc J. 2008 Jan;10(1):79-82.	Chronic fatigue syndrome is a heterogeneous disorder with unknown pathogenesis and etiology, characterized by disabling fatigue, difficulty in concentration and memory, and concomitant skeletal and muscular pain. Several mechanisms have been suggested to play a role in CFS, such as excessive oxidative stress following exertion, immune imbalance characterized by decreased natural killer cell and macrophage activity, immunoglobulin G subclass deficiencies (IgG1, IgG3) and decreased serum concentrations of complement component. Autoantibodies were also suggested as a possible factor in the pathogenesis of CFS. Recent studies indicate that anti-serotonin, anti-microtubule-associated protein 2 and anti-muscarinic cholinergic receptor 1 may play a role in the pathogenesis of CFS. It has been demonstrated that impairment in vasoactive neuropeptide metabolism may explain the symptoms of CFS.
Bellmann-Weiler R, Schroecksnadel K, Holzer C, Larcher C, Fuchs D, Weiss G.	Department of General Internal Medicine, Clinical Immunology and Infectious Diseases, Innsbruck Medical University, Innsbruck, Austria.	IFN-gamma mediated pathways in patients with fatigue and chronic active Epstein Barr virus-infection.	J Affect Disord. 2008 May;108(1-2):171-6. Epub 2007 Oct 22.	BACKGROUND: Chronic active Epstein Barr virus (EBV)-infection is characterized by mononucleosis like symptoms including fatigue, lymphadenopathy and/or hepatosplenomegaly and serologic evidence for ongoing EBV replication. Interferon-gamma (IFN-gamma) triggers several antiviral mechanisms in target cells including the induction of indoleamine-2,3-dioxygenase (IDO), which degrades the essential amino acid tryptophan to kynurenine. Because tryptophan is a precursor of the neurotransmitter 5-hydroxytryptamine (serotonin), tryptophan depletion by IDO can cause mood disturbances in patients with chronic immune activation. METHODS: This study investigated the tryptophan metabolism in 20 patients with chronic active EBV-infection, who were followed up for 4 to 8 months and in 10 healthy age-matched controls. The clinical suspicion of chronic active EBV infection was verified by the presence of circulating antibodies against EBV early antigen (EA) and virus capsid antigen (VCA). RESULTS: Patients with detectable EBV-DNA had higher serum neopterin ($p<0.01$) and lower tryptophan concentrations ($p=0.01$) than EBV-DNA negative patients. Serum concentrations of neopterin, indicating Th-1 mediated immune activation via IFN-gamma, were positively correlated to enhanced tryptophan degradation ($rs=0.650$, $p<0.001$) in patients, but not in healthy individuals. Patients suffering from more severe symptoms (as assessed by questionnaires) tended to have aggravated tryptophan degradation. CONCLUSION: Our data show that EBV viremia is associated with cell-mediated immune activation and increased tryptophan degradation, which may partly account for the symptoms found in this disorder.
Belotti L, Bigoni F, Pezzoli F, Mosconi G.	USC Medicina del Lavoro, USS Servizio Sanitario	[Chronic fatigue syndrome: from misunderstood	G Ital Med Lav Ergon. 2007 Jul-Sep;29(3	The aim of this paper is to report the case of a Physiotherapist working in a big hospital, affected by Chronic Fatigue Syndrome (CFS). After the diagnosis, made in an High Specialized Center, the Occupational Health Physician, with the cooperation of the Nursing Managing Direction, the Chief of

	Aziendale, Ospedali Riuniti di Bergamo. lbelotti@ospedaliriuniti.bergamo.it	illness to cause of job fitness management problem and of work total disability in a physiotherapist. Case report] [Article in Italian]	Suppl):819-20.	the Department of Rehabilitation and the Physiotherapists Coordinator, had to cope with the job fitness management. Afterwards the patient, in accordance with the Physician of a Trade Union Medical Office and the Occupational Health Physician, tried to obtain the disability pension, that at the end was given by the Medical Commission of the ASL.
Ben-Zvi A, Vernon SD, Broderick G.	Department of Chemical and Materials Engineering, University of Alberta, Edmonton, Alberta, Canada.	Model-based therapeutic correction of hypothalamic-pituitary-adrenal axis dysfunction.	PLoS Comput Biol. 2009 Jan;5(1):e1000273. Epub 2009 Jan 23.	The hypothalamic-pituitary-adrenal (HPA) axis is a major system maintaining body homeostasis by regulating the neuroendocrine and sympathetic nervous systems as well modulating immune function. Recent work has shown that the complex dynamics of this system accommodate several stable steady states, one of which corresponds to the hypocortisol state observed in patients with chronic fatigue syndrome (CFS). At present these dynamics are not formally considered in the development of treatment strategies. Here we use model-based predictive control (MPC) methodology to estimate robust treatment courses for displacing the HPA axis from an abnormal hypocortisol steady state back to a healthy cortisol level. This approach was applied to a recent model of HPA axis dynamics incorporating glucocorticoid receptor kinetics. A candidate treatment that displays robust properties in the face of significant biological variability and measurement uncertainty requires that cortisol be further suppressed for a short period until adrenocorticotropic hormone levels exceed 30% of baseline. Treatment may then be discontinued, and the HPA axis will naturally progress to a stable attractor defined by normal hormone levels. Suppression of biologically available cortisol may be achieved through the use of binding proteins such as CBG and certain metabolizing enzymes, thus offering possible avenues for deployment in a clinical setting. Treatment strategies can therefore be designed that maximally exploit system dynamics to provide a robust response to treatment and ensure a positive outcome over a wide range of conditions. Perhaps most importantly, a treatment course involving further reduction in cortisol, even transient, is quite counterintuitive and challenges the conventional strategy of supplementing cortisol levels, an approach based on steady-state reasoning.
Beqaj SH, Lerner AM, Fitzgerald JT.	Pathgroup Labs, Nashville, TN, USA.	Immunoassay with cytomegalovirus early antigens from gene products p52 and CM2 (UL44 and UL57) detects active infection in patients with chronic fatigue syndrome.	J Clin Pathol. 2008 May;61(5):623-6. Epub 2007 Nov 23.	AIMS: To investigate whether the use of recombinant early antigens for detection of antibodies to human cytomegalovirus (HCMV) gene products CM(2) (UL44, UL57) and p52 (UL44) is specific in the diagnosis and differentiation of active HCMV infection in a subset of patients with chronic fatigue syndrome (CFS), a diagnosis which is often missed by the current ELISA assay that uses crude viral lysate antigen. METHODS: At a single clinic from 1999 to 2001, a total of 4774 serological tests were performed in 1135 patients with patients using two immunoassays, Copalis and ELISA. The Copalis immunoassay utilised HCMV early gene products of UL44 and UL57 recombinant antigens for detection of HCMV IgM antibody, and viral capsid antigen for detection of HCMV IgG antibody. The ELISA immunoassay utilised viral crude lysate as antigen for detection of both HCMV IgG and IgM. RESULTS: 517 patients (45.6%) were positive for HCMV IgG by both assays. Of these, 12 (2.2%) were positive for HCMV(V) IgM serum antibody by HCMV ELISA assay, and 61 (11.8%) were positive for IgM

				HCMV serum antibody by Copalis assay. The Copalis assay that uses HCMV early recombinant gene products CM(2) (UL44, UL57) and p52 (UL44) in comparison with ELISA was 98% specific. CONCLUSIONS: Immunoassays that use early antigen recombinant HCMV CM(2) and p52 are five times more sensitive than HCMV ELISA assay using viral lysate, and are specific in the detection and differentiation of active HCMV infection in a subset of patients with CFS.
Bezerra Fontenele J, Leal LK, Félix FH.		All that shine is not gold: modelling the true relation between orthostatic intolerance, fibromyalgia and chronic fatigue syndromes. Comment on: Clin Auton Res. 2008 Dec;18(6):300-7.	Clin Auton Res. 2008 Dec;18(6):298; author reply 299.	
Bhattacharjee M, Botting CH, Sillanpää MJ.	School of Mathematics and Statistics, University of St Andrews, St Andrews, Fife KY16 9ST, Scotland.	Bayesian biomarker identification based on marker-expression proteomics data.	Genomics. 2008 Dec;92(6):384-92. Epub 2008 Aug 15.	We are studying variable selection in multiple regression models in which molecular markers and/or gene-expression measurements as well as intensity measurements from protein spectra serve as predictors for the outcome variable (i.e., trait or disease state). Finding genetic biomarkers and searching genetic-epidemiological factors can be formulated as a statistical problem of variable selection, in which, from a large set of candidates, a small number of trait-associated predictors are identified. We illustrate our approach by analyzing the data available for chronic fatigue syndrome (CFS). CFS is a complex disease from several aspects, e.g., it is difficult to diagnose and difficult to quantify. To identify biomarkers we used microarray data and SELDI-TOF-based proteomics data. We also analyzed genetic marker information for a large number of SNPs for an overlapping set of individuals. The objectives of the analyses were to identify markers specific to fatigue that are also possibly exclusive to CFS. The use of such models can be motivated, for example, by the search for new biomarkers for the diagnosis and prognosis of cancer and measures of response to therapy. Generally, for this we use Bayesian hierarchical modeling and Markov Chain Monte Carlo computation.
Blazquez A, Ruiz E, Vazquez A, de Sevilla TF, Garcia-Quintana A, Garcia-Quintana J, Alegre J.	Department of Chronic Fatigue Syndrome, Vall Hebron Hospital and Delfos Medical Center, Spain. asikien@yahoo.es	Sexual dysfunction as related to severity of fatigue in women with CFS.	J Sex Marital Ther. 2008 May-Jun;34(3):240-7.	To assess sexual function in women with chronic fatigue syndrome. The study included 27 women, aged 20 to 45 years, with chronic fatigue syndrome (CFS) and 15 healthy female controls. Sexual function was measured with the Golombok Rust Inventory of Sexual Satisfaction (GRISS) questionnaire and five clinical questions. In the patient group, total fatigue impact scale (FIS) score correlated with the GRISS satisfaction (r:-0.471, P < .005), avoidance (r: 0.632, P < .001) and sensuality (r: -0.445, P = .008) subscales. The GRISS satisfaction, avoidance, and sensuality subscale results and the fact of seeing the sexual act as a negative experience correlated with the intensity of fatigue in women with CFS.
Boneva RS, Decker	Chronic Viral	Higher heart rate	Auton Neurosci.	Autonomic nervous system (ANS) dysfunction has been suggested in patients with chronic fatigue

MJ, Maloney EM, Lin JM, Jones JF, Helgason HG, Heim CM, Rye DB, Reeves WC.	Diseases Branch, National Center for Zoonotic, Vector-borne and Enteric Diseases, Centers for Disease Control and Prevention, Atlanta, GA 30329, USA. rboneva@cdc.gov	and reduced heart rate variability persist during sleep in chronic fatigue syndrome: a population-based study.	2007 Dec 30;137(1-2):94-101. Epub 2007 Sep 12.	syndrome (CFS). In this study, we sought to determine whether increased heart rate (HR) and reduced heart rate variability (HRV) parameters observed in CFS patients during wakefulness persist during sleep. To this end, we compared heart rate (HR) and HRV as indicators of ANS function in CFS subjects and non-fatigued (NF) controls in a population-based, case-control study. Thirty subjects with CFS and 38 NF controls, matched for age-, sex- and body mass index, were eligible for analysis. Main outcome measures included mean RR interval (RRI), HR, and HRV parameters derived from overnight ECG. Plasma aldosterone and norepinephrine levels, medicines with cardiovascular effect, and reported physical activity were examined as covariates. General Linear Models were used to assess significance of associations and adjust for potential confounders. Compared to controls, CFS cases had significantly higher mean HR (71.4 vs 64.8 bpm), with a shorter mean RRI [840.4 (85.3) vs 925.4(97.8) ms] ($p<0.0004$, each), and reduced low frequency (LF), very low frequency (VLF), and total power (TP) of HRV ($p<0.02$, all). CFS cases had significantly lower plasma aldosterone ($p<0.05$), and tended to have higher plasma norepinephrine levels. HR correlated weakly with plasma norepinephrine ($r=0.23$, $p=0.05$) and moderately with vitality and fatigue scores ($r=-0.49$ and 0.46, respectively, $p<0.0001$). Limitation in moderate physical activity was strongly associated with increased HR and decreased HRV. Nevertheless, among 42 subjects with similar physical activity limitations, CFS cases still had higher HR (71.8 bpm) than respective controls (64.9 bpm), $p=0.023$, suggesting that reduced physical activity could not fully explain CFS-associated differences in HR and HRV. After adjusting for potential confounders case-control differences in HR and TP remained significant ($p<0.05$). Conclusion: the presence of increased HR and reduced HRV in CFS during sleep coupled with higher norepinephrine levels and lower plasma aldosterone suggest a state of sympathetic ANS predominance and neuroendocrine alterations. Future research on the underlying pathophysiologic mechanisms of the association is needed.
Boone KB.	Center for Forensic Sciences, Alliant University, and Los Angeles Biomedical Institute, Los Angles, CA, USA.	Fixed Belief in Cognitive Dysfunction Despite Normal Neuropsychological Scores: Neurocognitive Hypochondriasis?	Clin Neuropsychol. 2008 Oct 16:1-21. [Epub ahead of print]	A subset of patients who present for neuropsychological testing report dysfunction in daily life activities secondary to cognitive deficits, but are found on formal testing to have no objective abnormalities, raising the possibility of "neurocognitive hypochondriasis." Such a case is presented, and the factors that appear to give rise to this presentation are explored. Cases of hypochondriacal overconcern regarding cognitive function are likely not rare, particularly given research showing there is little correlation between objective report of cognitive dysfunction and actual test scores in such conditions as mild traumatic brain injury, chronic fatigue syndrome, fibromyalgia, toxic mold exposure, and post-polio syndrome.
Boorom KF, Smith H, Nimri L, Viscogliosi E, Spanakos G, Parkar U, Li LH, Zhou XN, Ok UZ, Leelayoova S, Jones MS.	Blastocystis Research Foundation, 5060 SW Philomath Blvd, #202, Corvallis, OR 97333, USA. director@bhomcenter.org.	Oh my aching gut: irritable bowel syndrome, Blastocystis, and asymptomatic infection.	Parasit Vectors. 2008 Oct 21;1(1):40.	ABSTRACT: Blastocystis is a prevalent enteric protozoan that infects a variety of vertebrates. Infection with Blastocystis in humans has been associated with abdominal pain, diarrhea, constipation, fatigue, skin rash, and other symptoms. Researchers using different methods and examining different patient groups have reported asymptomatic infection, acute symptomatic infection, and chronic symptomatic infection. The variation in accounts has lead to disagreements concerning the role of Blastocystis in human disease, and the importance of treating it. A better understanding of the number of species of Blastocystis that can infect humans, along with realization of the limitations of the existing clinical laboratory diagnostic techniques may account for much of the disagreement. The possibility that disagreement was caused by the emergence of particular pathogenic variants of Blastocystis is

				discussed, along with the potential role of Blastocystis infection in irritable bowel syndrome (IBS). Findings are discussed concerning the role of protease-activated receptor-2 in enteric disease which may account for the presence of abdominal pain and diffuse symptoms in Blastocystis infection, even in the absence of fever and endoscopic findings. The availability of better diagnostic techniques and treatments for Blastocystis infection may be of value in understanding chronic gastrointestinal illness of unknown etiology.
Bourrillon A.	Service de pédiatrie générale, hôpital Robert-Debré, 75019 Paris. antoine.bourrillon @rdb.aphp.fr	[Tired children and school] [Article in French]	Rev Prat. 2008 Apr 15;58(7):731-6.	Fatigue is a commonly observed symptom in school environments. Its clinical diagnosis is established based on symptomatology, which varies depending on the age. At school, daily rhythm disorders followed by breakdowns are common causes of school fatigue, requiring adequate corrective measures. Organic causes of school fatigue are uncommon in school environments. They are mostly infectious and suggest in rare occasions a severe condition. Detecting fatigue requires a thorough anamnestic investigation, which most of the time enables to identify the factors responsible for asthenia and suggest correctives measures. Chronic fatigue syndrome affects first and foremost teenagers and its pathophysiological assessment can lead to a better understanding of lasting fatigue in children.
Bramsen I.	Centre of Expertise Participation, Occupation and Health, Rotterdam University, Rotterdam, The Netherlands.	Can CBT substantially change grey matter volume in chronic fatigue syndrome?	Brain. 2008 Aug 29. [Epub ahead of print]	
Brimmer DJ, McCleary KK, Lupton TA, Faryna KM, Hynes K, Reeves WC.	Division of Viral and Rickettsial Diseases, Centers for Disease Control and Prevention, Atlanta, GA, USA. dyv4@cdc.gov	A train-the-trainer education and promotion program: chronic fatigue syndrome--a diagnostic and management challenge.	BMC Med Educ. 2008 Oct 15;8:49.	BACKGROUND: Chronic fatigue syndrome (CFS) is a complicated illness for providers and patients. Fewer than 20% of persons with CFS have been diagnosed and treated. For providers, compounding the issue are the challenges in making a diagnosis due to the lack of a biomedical marker. METHODS: The objective of the CFS diagnosis and management curriculum was to instruct core trainers as to the evaluation, diagnosis, and management of CFS. Over a two year period, 79 primary care physicians, physician assistants, and nurse practitioners from diverse regions in the U.S. participated as core trainers in a two day Train-the-Trainer (TTT) workshop. As core trainers, the workshop participants were expected to show increases in knowledge, self-efficacy, and management skills with the primary goal of conducting secondary presentations. RESULTS: The optimal goal for each core trainer to present secondary training to 50 persons in the health care field was not reached. However, the combined core trainer group successfully reached 2064 primary care providers. Eighty-two percent of core trainers responded "Very good" or "Excellent" in a post-tessurvey of self-efficacy expectation and CFS diagnosis. Data from the Chicago workshops showed significant improvement on the Primary Care Opinion Survey ($p < 0.01$) and on the Relevance and Responsibility Factors of the CAT survey ($p = 0.03$ and $p = 0.04$, respectively). Dallas workshop data show a significant change from pre- to post-test scores on the CFS Knowledge test ($p = 0.001$). Qualitative and process evaluation data revealed that target audience and administrative barriers impacted secondary training feasibility. CONCLUSION: Data show the workshop was successful in meeting the objectives of increasing CFS knowledge and

				raising perceived self-efficacy towards making a diagnosis. The CFS TTT program informed an educational provider project by shifting the format for physicians to grand rounds and continuing medical education design while retaining TTT aspects for nurse practitioners and physicians assistants. Evaluations also indicate that secondary trainings may be more readily employed and accepted if administrative barriers are addressed early in the planning phases.
Buitenhuis J, de Jong PJ, Jaspers JP, Groothoff JW.	Medical Department, Univé Insurance and Department of Social Medicine, University Medical Center Groningen, University of Groningen, the Netherlands. j.buitenhuis@unive.nl	Catastrophizing and causal beliefs in whiplash.	Spine. 2008 Oct 15;33(22):2427-33; discussion 2434.	STUDY DESIGN: Prospective cohort study. OBJECTIVE: This study investigates the role of pain catastrophizing and causal beliefs with regard to severity and persistence of neck complaints after motor vehicle accidents. SUMMARY OF BACKGROUND DATA.: In previous research on low back pain, somatoform disorders and chronic fatigue syndrome, pain catastrophizing and causal beliefs were found to be related to perceived disability and prognosis. Furthermore, it has been argued with respect to whiplash that culturally dependent symptom expectations are responsible for a chronic course. METHODS: Individuals involved in traffic accidents who initiated compensation claim procedures with a Dutch insurance company were sent questionnaires (Q1) containing the Neck Disability Index, the Pain Catastrophizing Scale, and the Causal Beliefs Questionnaire-Whiplash. Of 1252 questionnaires dispatched, 747 (59.7%) were returned. Only car occupants with neck complaints were included in this study (n = 140). Complaints were monitored using additional questionnaires administered 6 (Q2) and 12 months (Q3) after the accident. RESULTS: Pain catastrophizing and causal beliefs were related to the severity of concurrent whiplash disability. The severity of initial complaints was related to the severity and persistence of whiplash complaints. Attributing initial neck complaints to whiplash was found to predict the persistence of disability at 6 and 12 months follow-up, over and above the severity of the initial complaints. CONCLUSION: The results suggest that causal beliefs may play a major role in the perceived disability and course of neck complaints after motor vehicle accidents, whereas pain catastrophizing is predominantly related to concurrent disability.The current findings are consistent with the view that an early conviction that neck complaints are caused by the medico-cultural entity whiplash has a detrimental effect on the course of symptoms.

Busconi BB, DeAngelis N, Guerrero PE.	Department of Orthopedics, U-Mass Medical School, Worcester, MA, USA. BusconiB@ummhc	The proximal biceps tendon: tricks and pearls.	Sports Med Arthrosc. 2008 Sep;16(3):187-94.	The diagnosis and treatment of proximal biceps tendon injuries continue to be a challenge. The difficulty lies on determining if there is isolated biceps pathology versus concomitant rotator cuff tears or instability. Imaging modalities, such as magnetic resonance imaging, continue to provide us with the extra tool to help us confirm our suspicion of additional pathology. Symptomatic biceps tendon tears can undergo debridement, tenotomy, or tenodesis if nonoperative measures fail to provide relief. Reports from performing a biceps tenotomy often give similar functional outcomes compared

	.org			with tenodesis. Cosmetic deformity on the lateral arm may be noted with tenodesis and initial fatigue. Tenodesis may subject the patient to a longer rehabilitation process and increased pain. The decision of which one should be performed lies between the physician and the patient's expectations.

Caro XJ, Winter EF, Dumas AJ.	Division of Rheumatology, David Geffen School of Medicine at UCLA, Los Angeles, CA, USA. xjcaro@earthlink.net	A subset of fibromyalgia patients have findings suggestive of chronic inflammatory demyelinating polyneuropathy and appear to respond to IVIg.	Rheumatology (Oxford). 2008 Feb;47(2):208-11.	OBJECTIVES: The aetiopathogenesis of the fibromyalgia syndrome (FMS) remains unknown. Recent reports, however, suggest that a subgroup of FMS subjects has an immune-mediated disease. Therefore, our primary objective was to study FMS subjects for evidence of an immune-mediated demyelinating polyneuropathy. Our secondary objective was to determine the effects of treating these FMS subjects with the immune modulator, intravenous immunoglobulin (IVIg). METHODS: Fifty-eight FMS subjects, 26 rheumatic non-FMS subjects and 52 non-rheumatic non-FMS subjects were studied. Subjective measures of paraesthesias, weakness, stocking hypaesthesia, pain, fatigue and stiffness were made. Objective measures of tenderness, proximal muscle strength and electrodiagnostic (EDX) evidence of polyneuropathy and demyelination were also made. Eleven other FMS subjects underwent sural nerve biopsy. RESULTS: Paraesthesias, subjective weakness and stocking hypaesthesia were more common in FMS than in rheumatic non-FMS (P < or = 0.0001). Proximal muscle strength was less in FMS than in rheumatic non-FMS (P < or = 0.0001). EDX demonstrated a distal demyelinating polyneuropathy, suggestive of chronic inflammatory demyelinating polyneuropathy (CIDP), in 33% of FMS subjects. No rheumatic non-FMS subject had polyneuropathy (P = 0.005), or demyelination (P = 0.05). Fifteen FMS/CIDP subjects were subsequently treated with IVIg (400 mg/kg each day for 5 days). Pain (P = 0.01), tenderness (P = 0.001) and strength (P = 0.04) improved significantly. Fatigue and stiffness trended towards improvement. CONCLUSIONS: A significant subset of FMS subjects have clinical and EDX findings suggestive of CIDP. IVIg treatment shows promise in treating this subset. These observations have implications for better understanding and treating some FMS patients.
Carville SF, Arendt-Nielsen S, Bliddal H, Blotman F, Branco JC, Buskila D, Da Silva JA, Danneskiold-SamsÃ¸e B, Dincer F, Henriksson C, Henriksson KG, Kosek E, Longley K,	Academic Rheumatology Unit, King's College London, Weston Education Centre, Cutcombe Road, London SE5 9RJ, UK. serena.carville@kcl.ac.uk	EULAR evidence-based recommendations for the management of fibromyalgia syndrome.	Ann Rheum Dis. 2008 Apr;67(4):536-41. Epub 2007 Jul 20.	OBJECTIVE: To develop evidence-based recommendations for the management of fibromyalgia syndrome. METHODS: A multidisciplinary task force was formed representing 11 European countries. The design of the study, including search strategy, participants, interventions, outcome measures, data collection and analytical method, was defined at the outset. A systematic review was undertaken with the keywords "fibromyalgia", "treatment or management" and "trial". Studies were excluded if they did not utilise the American College of Rheumatology classification criteria, were not clinical trials, or included patients with chronic fatigue syndrome or myalgic encephalomyelitis. Primary outcome measures were change in pain assessed by visual analogue scale and fibromyalgia impact questionnaire. The quality of the studies was categorised based on randomisation, blinding and allocation concealment. Only the highest quality studies were used to base recommendations on.

McCarthy GM, Perrot S, Puszczewicz M, Sarzi-Puttini P, Silman A, SpÃ¤th M, Choy EH; EULAR.				When there was insufficient evidence from the literature, a Delphi process was used to provide basis for recommendation. RESULTS: 146 studies were eligible for the review. 39 pharmacological intervention studies and 59 non-pharmacological were included in the final recommendation summary tables once those of a lower quality or with insufficient data were separated. The categories of treatment identified were antidepressants, analgesics, and "other pharmacological" and exercise, cognitive behavioural therapy, education, dietary interventions and "other non-pharmacological". In many studies sample size was small and the quality of the study was insufficient for strong recommendations to be made. CONCLUSIONS: Nine recommendations for the management of fibromyalgia syndrome were developed using a systematic review and expert consensus.
Caseras X, Mataix-Cols D, Rimes KA, Giampietro V, Brammer M, Zelaya F, Chalder T, Godfrey E.	Division of Psychological Medicine and Psychiatry, King's College London, Institute of Psychiatry, London, UK.	The neural correlates of fatigue: an exploratory imaginal fatigue provocation study in chronic fatigue syndrome.	Psychol Med. 2008 Jul;38(7):941-51. Epub 2008 Apr 30.	BACKGROUND: Fatigue is the central symptom in chronic fatigue syndrome (CFS) and yet very little is known about its neural correlates. The aim of this study was to explore the functional brain response, using functional magnetic resonance imaging (fMRI), to the imaginal experience of fatigue in CFS patients and controls.MethodWe compared the blood oxygen level dependent (BOLD) responses of 12 CFS patients and 11 healthy controls to a novel fatigue provocation procedure designed to mimic real-life situations. A non-fatiguing anxiety-provoking condition was also included to control for the non-specific effects of negative affect. RESULTS: During the provocation of fatigue, CFS patients reported feelings of both fatigue and anxiety and, compared to controls, they showed increased activation in the occipito-parietal cortex, posterior cingulate gyrus and parahippocampal gyrus, and decreased activation in dorsolateral and dorsomedial prefrontal cortices. The reverse pattern of findings was observed during the anxiety-provoking scenarios. CONCLUSIONS: The results may suggest that, in CFS patients, the provocation of fatigue is associated with exaggerated emotional responses that patients may have difficulty suppressing. These findings are discussed in relation to the cognitive-behavioural model of CFS.
Cathébras P, Lauwers A.	Service de médecine interne, hôpital Nord, CHU de Saint-Etienne, 42055 Saint-Etienne Cedex 2, France. pascal.cathebras@chu-st-etienne.fr	[Should we make the diagnosis of fibromyalgia?] [Article in French]	Rev Prat. 2009 Jan 20;59(1):25-31.	Fibromyalgia is a functional somatic syndrome characterized by widespread musculoskeletal pain, fatigue, poor sleep, and exercise intolerance, frequently (but inconstantly) associated with psychological distress. Fibromyalgia is a common condition, affecting predominantly middle-aged women, with a chronic course. Fibromaylgia should be differentiated from, and may be associated with, a number of metabolic, rheumatic, neurological or psychiatric conditions. The most plausible pathophysiologic mechanism involves an alteration of pain modulation at the peripheral and central levels of the nervous system ("sensitization"). Psychosocial factors play an important role in precipitating and maintaining symptoms, health care utilization, and disablement. Treatments of fibromyalgia rely mainly on the acknowledgement of pain and distress, patient education, analgesics, balneotherapy and physiotherapy, physical reconditioning (aerobic exercise), and certain antidepressants.
Check JH, Katsoff D, Kaplan H, Liss J, Boimel P.	The University of Medicine and Dentistry of New Jersey, Robert Wood Johnson Medical School at	A disorder of sympathomimetic amines leading to increased vascular permeability may be the etiologic	108: Med Hypotheses. 2008;70(3):671-7. Epub 2007 Aug 31.	There is an evidence that increased capillary permeability in the standing position is related to a deficit in the sympathetic nervous system. The leakage of this fluid leads to various clinical conditions which frequently puzzle the consulting physician because despite the frequency of this condition intelligent physicians and patients are unaware of the cause of their condition. One of the most common manifestations is the inability to lose weight despite proper dieting. A randomized study comparing the efficacy of a diuretic, a converting enzyme inhibitor, spironolactone and a sympathomimetic

	Camden, Cooper Hospital/University Medical Center, Department of Obstetrics and Gynecology, Camden, NJ, United States. laurie@ccivf.com	factor in various treatment refractory health problems in women.		amine on weight loss in diet refractory women found that only the latter in the form of dextroamphetamine sulfate demonstrated significant weight reduction over a six month time span. In fact, the dextroamphetamine sulfate proved effective when given in the next 6 months to the three groups failing to respond for the first 6 months. The diagnosis of a deficit in sympathomimetic amines is established by demonstrating an abnormal clearance of a water load in the erect position and exclusion of other conditions that are associated with an abnormal free water clearance, e.g., hypothyroidism, renal or liver disease or congestive heart failure. The original definition of an abnormal water load test was excretion of <55% of a 1500 ml water load in 6h but we found that <75% defines a greater population who suffer from this problem. There are several conditions that have proven refractory to conventional theory that respond quickly and effectively to sympathomimetic amines. There have been many anecdotal reports of relieving interactable pain syndromes quickly and efficiently with sympathomimetic amine theory, despite failure with a multitude of other therapies. These include interstitial cystitis and pelvic pain that was attributed to endometriosis, gastrointestinal pain including esophagitis and gastroparesis, headaches, joint pain, fibromyalgia, and carpal tunnel syndrome. It is not clear if the improvement in pain is related to a decrease in fluid retention or a direct effect of the sympathomimetic amines on the sympathetic nervous system. Sympathomimetic amine theory has helped other conditions besides pain, e.g., chronic fatigue, vasomotor symptoms in young women not associated with decreased ovarian egg reserve, and chronic urticaria resistant to all other therapies. Thus, these studies strongly suggest that physicians be aware of this condition involving a deficit in the sympathetic nervous system when faced with various enigmatic complaints especially if standard therapy has not proven effective.
Chen GL, Xiao GM, Zheng XL.	Rehabilitation Treatment Center, Gansu Provincial Hospital of TCM, Lanzhou 730050, China. chenguolian1234@163.com	[Observation on therapeutic effect of multiple cupping at back-shu points on chronic fatigue syndrome] [Article in Chinese]	Zhongguo Zhen Jiu. 2008 Jun;28(6):405-7.	OBJECTIVE: To observe therapeutic effect of multiple cupping at back-shu points of zang-and fu-organs on chronic fatigue syndrome. METHODS: One hundred and ninety-one cases were randomly divided into 2 groups. The multiple cupping group (n = 142) were treated with multiple cupping along both sides of the spinal cord, and the acupuncture group (n = 49) were treated with acupuncture at acupoints selected according to TCM syndrome differentiation. Their therapeutic effects were assessed by clinical symptoms and Fatigue Assessment Indexes (FAI). RESULTS: The total effective rate was 97.9% in the multiple cupping group and 79.6% in the acupuncture group with a very significant difference between the two groups (P < 0.01), and after treatment, there was a very significant difference between the two groups in FAI score (P < 0.01). CONCLUSION: Multiple cupping at back-shu points of zang-and fu-organs is an effective method for chronic fatigue syndrome.
Chen R, Liang FX, Moriya J, Yamakawa J, Sumino H, Kanda T, Takahashi T.	Department of General Medicine, Kanazawa Medical University, Ishikawa, Japan.	Chronic fatigue syndrome and the central nervous system.	J Int Med Res. 2008 Sep-Oct;36(5):867-74.	An increasing amount of neuroimaging evidence supports the hypothesis that chronic fatigue syndrome patients have structural or functional abnormalities within the brain. Moreover, some neurotrophic factors, neurotransmitters and cytokines have also been evaluated in order to elucidate the mechanism of abnormal neuropsychic findings in chronic fatigue syndrome. In this review, we suggest that the focal point of chronic fatigue syndrome research should be transferred to the central nervous system.
Chen R, Moriya J, Luo X, Yamakawa JI, Takahashi T,	Department of General Medicine, Kanazawa Medical	Hochu-Ekki-to Combined with Interferon-Gamma	Immunopharmacol Immunotoxicol. 2008 Sep 12:1-15.	The purpose of this study was to evaluate the beneficial effect of Hochu-ekki-to (TJ-41) combined with interferon-gamma (IFNgamma) on daily activity, immunological and neurological alternation in a mouse model of chronic fatigue syndrome (CFS). CFS was induced by 6 times of repeated injection of

Sasaki K, Yoshizaki F.	University, Ishikawa, Japan.	Moderately Enhances Daily Activity of Chronic Fatigue Syndrome Mice by Increasing NK Cell Activity, but not Neuroprotection.	[Epub ahead of print]	Brucella abortus antigen every 2 weeks. Both single TJ-41 and TJ-41 combined with IFNgamma increased running activity and thymus weight of CFS mice, while thicker thymic cortex together with elevation of natural killer cell activity was only found in the combined treatment group. No significant improvement was observed in the atrophic brain and decreased expression level of brain-derived neurotrophic factor and Bcl-2 mRNA in hippocampus in both treatment groups. Our results suggest that TJ-41 combined with IFNgamma might have a protective effect on the marked reduction in the activity in a model of CFS via normalization of host immune responses, but not neuroprotection.
Chen R, Moriya J, Yamakawa JI, Takahashi T, Kanda T.	Department of General Medicine, Kanazawa Medical University, 1-1 Daigaku, Uchinada-machi, Kahoku-gun, Ishikawa 920-0293, Japan. kandat@kanazawa-med.ac.jp.	Traditional Chinese Medicine for Chronic Fatigue Syndrome.	Evid Based Complement Alternat Med. 2008 Feb 27. [Epub ahead of print]	More and more patients have been diagnosed as having chronic fatigue syndrome (CFS) in recent years. Western drug use for this syndrome is often associated with many side-effects and little clinical benefit. As an alternative medicine, traditional Chinese medicine (TCM) has provided some evidences based upon ancient texts and recent studies, not only to offer clinical benefit but also offer insights into their mechanisms of action. It has perceived advantages such as being natural, effective and safe to ameliorate symptoms of CFS such as fatigue, disordered sleep, cognitive handicaps and other complex complaints, although there are some limitations regarding the diagnostic standards and methodology in related clinical or experimental studies. Modern mechanisms of TCM on CFS mainly focus on adjusting immune dysfunction, regulating abnormal activity in the hypothalamic-pituitary-adrenal (HPA) axis and serving as an antioxidant. It is vitally important for the further development to establish standards for 'zheng' of CFS, i.e. the different types of CFS pathogenesis in TCM, to perform randomized and controlled trials of TCM on CFS and to make full use of the latest biological, biochemical, molecular and immunological approaches in the experimental design.
Chen R, Moriya J, Yamakawa JI, Takahashi T, Li Q, Morimoto S, Iwai K, Sumino H, Yamaguchi N, Kanda T.	Department of General Medicine, Kanazawa Medical University, 1-1 Daigaku, Uchinada-machi, Kahoku-gun, Ishikawa, 920-0293, Japan.	Brain Atrophy in a Murine Model of Chronic Fatigue Syndrome and Beneficial Effect of Hochu-ekki-to (TJ-41).	Neurochem Res. 2008 Mar 4. [Epub ahead of print]	Brain-derived neurotrophic factor (BDNF) is associated with the main symptoms of chronic fatigue sydrome (CFS) and neuron apoptosis. Nevertheless, no study has been performed directly to explore the relationship between CFS, BDNF and neuron apoptosis. We induced a CFS model by six injections of killed Brucella abortus antigen in BALB/c mice and treated them with Hochu-ekki-to (TJ-41). Daily running activity, body weight (BW), ratio of cerebral weight to BW (CW/BW) and expression levels of BDNF and Bcl-2 mRNA in the hippocampus were determined. The daily activity and CW/BW decreased significantly in the CFS model. BDNF and Bcl-2 mRNA expression levels in the hippocampus were suppressed in the CFS model and TJ-41 treated mice, while no significant difference was found between them. We improved a murine model to investigate the relationship between CFS and brain dysfunction. In this model, reduced daily activity might have been associated with decreased hippocampal BDNF mRNA expression, hippocampal apoptosis and brain atrophy. TJ-41 increased the daily running activity of the model, which was independent of brain recovery.

Chew-Graham C, Dixon R, Shaw JW, Smyth N, Lovell K, Peters S.	School of Community-Based Medicine, University of Manchester, Manchester, M13 9PL, UK. cchew@manchester.ac.uk.	Practice Nurses' views of their role in the management of Chronic Fatigue Syndrome/Myalagic Encephalitis: a qualitative study.	BMC Nurs. 2009 Jan 22;8:2.	ABSTRACT: BACKGROUND: NICE guidelines suggest that patients with Chronic Fatigue Syndrome/Myalgic Encephalitis (CFS/ME) should be managed in Primary Care. Practice Nurses are increasingly being involved in the management of long-term conditions, so are likely to also have a growing role in managing CFS/ME. However their attitudes to, and experiences of patients with CFS/ME and its management must be explored to understand what barriers may exist in developing their role for this group of patients. The aim of this study was to explore Practice Nurses' understanding and beliefs about CFS/ME and its management. METHODS: Semi-structured interviews with 29 Practice Nurses. Interviews were transcribed verbatim and an iterative approach used to develop themes from the dataset. RESULTS: Practice nurses had limited understanding about CFS/ME which had been largely gained through contact with patients, friends, personal experiences and the media rather than formal training. They had difficulty seeing CFS/ME as a long term condition. They did identify a potential role they could have in management of CFS/ME but devalued their own skills in psychological intervention, and suggested counselling would be an appropriate therapeutic option. They recognised a need for further training and on going supervision from both medical and psychological colleagues. Some viewed the condition as contentious and held pejorative views about CFS/ME. Such scepticism and negative attitudes will be a significant barrier to the management of patients with CFS/ME in primary care. CONCLUSION: The current role of Practice Nurses in the ongoing management of patients with CFS/ME is limited. Practice Nurses have little understanding of the evidence-base for treatment of CFS/ME, particularly psychological therapies, describing management options in terms of advice giving, self-help or counselling. Practice Nurses largely welcomed the potential development of their role in this area, but identified barriers and training needs which must be addressed to enable them to feel confident managing of patients with this condition. Training must begin by addressing negative attitudes to patients with CFS/ME.
Chew-Graham CA, Cahill G, Dowrick C, Wearden A, Peters S.	School of Community-Based Medicine, University of Manchester, Manchester, UK. carolyn.chew-graham@manchester.ac.uk	Using multiple sources of knowledge to reach clinical understanding of chronic fatigue syndrome.	Ann Fam Med. 2008 Jul-Aug;6(4):340-8.	PURPOSE: Chronic fatigue syndrome (CFS), or myalgic encephalitis (ME), is a contentious condition and often a diagnosis of exclusion. Current policy in the United Kingdom recommends management in primary care. We explored how patients with CFS/ME and family physicians understand this condition and how their understanding might affect the primary care consultation. METHODS: We undertook a qualitative study with patients and family physicians from North West England participating in a primary care-based randomized controlled trial (FINE Trial). Data were collected through purposive sampling and in-depth semistructured interviews with 24 patients and 14 family physicians. We analyzed interview transcripts using constant comparison methods. RESULTS: Family physicians access social and cultural knowledge to reach a clinical understanding of CFS/ME and its management. Patients recognize the difficulties family physicians encounter in understanding their symptoms and access similar nonclinical sources of information. We suggest that both patients and physicians use biomedical discourse within the consultation: the physician to maintain the position as an expert, the patient to engage the physician. CONCLUSIONS: Family physicians obtain information about CFS/ME from their nonprofessional world, which they incorporate into their professional realm. Patients and

				physicians describe the use of the discourse of science within consultations about CFS/ME. This form of shared understanding could lead to a positive collaborative interaction. Family physicians need a biomedical, evidence-based knowledge about CFS/ME. There is potential to use the rich knowledge base that patients can bring to consultations in training initiatives directed at family physicians.
Chia JK, Chia AY.	EV Med Research, Lomita, California 90717, USA. evmed@sbcglobal.net	Chronic fatigue syndrome is associated with chronic enterovirus infection of the stomach. Comment in: J Clin Pathol. 2008 Jan;61(1):1-2.	J Clin Pathol. 2008 Jan;61(1):43-8. Epub 2007 Sep 13.	BACKGROUND AND AIMS: The aetiology for chronic fatigue syndrome (CFS) remains elusive although enteroviruses have been implicated as one of the causes by a number of studies. Since most CFS patients have persistent or intermittent gastrointestinal (GI) symptoms, the presence of viral capsid protein 1 (VP1), enterovirus (EV) RNA and culturable virus in the stomach biopsy specimens of patients with CFS was evaluated. METHODS: 165 consecutive patients with CFS underwent upper GI endoscopies and antrum biopsies. Immunoperoxidase staining was performed using EV-specific monoclonal antibody (mAb) or a control mAb specific for cytomegalovirus (CMV). RT-PCR ELISA was performed on RNA extracted from paraffin sections or samples preserved in RNA later. Biopsies from normal stomach and other gastric diseases served as controls. 75 samples were cultured for EV. RESULTS: 135/165 (82%) biopsies stained positive for VP1 within parietal cells, whereas 7/34 (20%) of the controls stained positive (p< or =0.001). CMV mAb failed to stain any of the biopsy specimens. Biopsies taken from six patients at the onset of the CFS/abdominal symptoms, and 2-8 years later showed positive staining in the paired specimens. EV RNA was detected in 9/24 (37%) paraffin-embedded biopsy samples; 1/21 controls had detectable EV RNA (p<0.01); 1/3 patients had detectable EV RNA from two samples taken 4 years apart; 5 patient samples showed transient growth of non-cytopathic enteroviruses. CONCLUSION: Enterovirus VP1, RNA and non-cytopathic viruses were detected in the stomach biopsy specimens of CFS patients with chronic abdominal complaints. A significant subset of CFS patients may have a chronic, disseminated, non-cytolytic form of enteroviral infection, which could be diagnosed by stomach biopsy.
Cho HJ, Bhugra D, Wessely S.	Department of Psychiatry, Federal University of São Paulo, São Paulo, Brazil. h.cho@iop.kcl.ac.uk	'Physical or psychological?'- a comparative study of causal attribution for chronic fatigue in Brazilian and British primary care patients.	Acta Psychiatr Scand. 2008 Jul;118(1):34-41. Epub 2008 May 22.	OBJECTIVE: Causal attribution influences symptom experience, help-seeking behaviour and prognosis in chronic fatigue syndrome. We compared causal attribution of patients with unexplained chronic fatigue (UCF) in Brazil and Britain. METHOD: Primary care attenders in SÃ£o Paulo (n = 3914) and London (n = 2459) were screened for the presence of UCF. Those with UCF (SÃ£o Paulo n = 452; London n = 178) were assessed for causal attribution (physical vs. psychosocial), perceived chronicity (i.e. reported duration of fatigue) and disability. RESULTS: British UCF patients were more likely to attribute their fatigue to physical causes (adjusted odds ratio 1.70, P = 0.037) and perceived their fatigue to be more chronic (adjusted beta 0.15, P = 0.002). There was no significant difference in current disability (adjusted beta -0.01, P = 0.81). CONCLUSION: Despite similar disability levels, UCF patients in different cultural settings presented different attributions and perceptions about their illness. Sociocultural factors may have an important role in shaping illness attribution and perception around chronic fatigue.
Cho HJ, Menezes PR, Bhugra D, Wessely S.	Department of Psychological Medicine, Institute of Psychiatry, King's College	The awareness of chronic fatigue syndrome: a comparative study in Brazil and the	J Psychosom Res. 2008 Apr;64(4):351-5.	OBJECTIVE: While in many Western affluent countries there is widespread awareness of chronic fatigue syndrome (CFS), also known as myalgic encephalomyelitis (ME), little is known about the awareness of CFS/ME in low- and middle-income countries. We compared the awareness of CFS in Brazil and the United Kingdom. METHODS: Recognition and knowledge of CFS were assessed among 120 Brazilian specialist doctors in two major university hospitals using a typical case vignette of CFS.

	London, United Kingdom. h.cho@iop.kcl.ac.uk	United Kingdom.		We also surveyed 3914 and 2435 consecutive attenders in Brazilian and British primary care clinics, respectively, concerning their awareness of CFS. RESULTS: When given a typical case vignette of CFS, only 30.8% [95% confidence interval (CI), 22.7-39.9%] of Brazilian specialist doctors mentioned chronic fatigue or CFS as a possible diagnosis, a proportion substantially lower than that observed in Western affluent countries. Similarly, only 16.2% (95% CI, 15.1-17.4%) of Brazilian primary care attenders were aware of CFS, in contrast to 55.1% (95% CI, 53.1-57.1%) of their British counterparts (P<.001). This difference remained highly significant after controlling for patients' sociodemographic and socioeconomic characteristics (P<.001). CONCLUSIONS: The awareness of CFS was substantially lower in Brazil than the United Kingdom. The observed difference may influence patients' help-seeking behavior and both doctors' and patients' beliefs and attitudes in relation to fatigue-related syndromes. Attempts to promote the awareness of CFS should be considered in Brazil, but careful plans are required to ensure the delivery of sound evidence-based information.
Cho HJ, Menezes PR, Hotopf M, Bhugra D, Wessely S.	Department of Preventive Medicine, University of São Paulo Medical School, University Hospital, University of São Paulo, Brazil. h.cho@iop.kcl.ac.uk	Comparative epidemiology of chronic fatigue syndrome in Brazilian and British primary care: prevalence and recognition.	Br J Psychiatry. 2009 Feb;194(2):117-22.	BACKGROUND: Although fatigue is a ubiquitous symptom across countries, clinical descriptions of chronic fatigue syndrome have arisen from a limited number of high-income countries. This might reflect differences in true prevalence or clinical recognition influenced by sociocultural factors. AIMS: To compare the prevalence, physician recognition and diagnosis of chronic fatigue syndrome in London and São Paulo. METHOD: Primary care patients in London (n=2459) and São Paulo (n=3914) were surveyed for the prevalence of chronic fatigue syndrome. Medical records were reviewed for the physician recognition and diagnosis. RESULTS: The prevalence of chronic fatigue syndrome according to Centers for Disease Control 1994 criteria was comparable in Britain and Brazil: 2.1% v. 1.6% (P=0.20). Medical records review identified 11 diagnosed cases of chronic fatigue syndrome in Britain, but none in Brazil (P<0.001). CONCLUSIONS: The primary care prevalence of chronic fatigue syndrome was similar in two culturally and economically distinct nations. However, doctors are unlikely to recognise and label chronic fatigue syndrome as a discrete disorder in Brazil. The recognition of this illness rather than the illness itself may be culturally induced.
Ciccone DS, Weissman L, Natelson BH.	UMDNJ-New Jersey Medical School, USA. donald.ciccone@va.gov	Chronic fatigue syndrome in male gulf war veterans and civilians: a further test of the single syndrome hypothesis.	J Health Psychol. 2008 May;13(4):529-36.	Different modes of fatigue onset in male Gulf War veterans versus male civilians raise the possibility that chronic fatigue syndrome (CFS) may not be a single disease entity. We addressed this issue by comparing 45 male veterans with CFS to 84 male civilians who satisfied identical case criteria. All were evaluated for fibromyalgia (FM), multiple chemical sensitivity and psychiatric comorbidity. CFS was more likely to present in a sudden flu-like manner in civilians than veterans ($p < .01$) and comorbid FM was more prevalent in civilians ($p < .01$). These findings question the assumption that all patients with CFS suffer from the same underlying disorder.
Clark LV, White PD.		Chronic fatigue syndrome. Comment on: J Rehabil Med. 2008 Apr;40(4):241-7	J Rehabil Med. 2008 Nov;40(10):882-3; author reply 883-5.	
Coaccioli S, Varrassi G, Sabatini C,	Department of Internal Medicine and Rheumatology	Fibromyalgia: nosography and therapeutic	Pain Pract. 2008 May-Jun;8(3):190-201. Epub 2008	Fibromyalgia (FM) is an important cause of morbidity and health expenditure. Severe widespread extra-articular chronic pain, along with nonrestorative sleep, dominates the clinical syndrome. The pathogenesis of FM remains unclear. While dysfunction in serotoninergic neurotransmission is

Marinangeli F, Giuliani M, Puxeddu A.	Unit, Perugia University School of Medicine, Terni, Italy. scoaccioli@tin.it	perspectives.	Mar 27. Comment in: Pain Pract. 2008 May-Jun;8(3):155.	believed to play an important role, several neurologic and immuno-endocrine mechanisms may also be relevant. A theory is advanced based on an inherited imbalance in neuro-vegetative systems resulting from increased sympathetic tone because of a metabolic deficiency in the serotoninergic system that, when exposed to a precipitating event, leads to the development of the clinical manifestations of FM. The importance of both nonpharmacological treatments and multimodal medication management is stressed.
Courjaret J, Schotte CK, Wijnants H, Moorkens G, Cosyns P.	Department of Psychiatry, University Hospital Antwerp, Edegem, Belgium. kim.courjaret@uza.be	Chronic fatigue syndrome and DSM-IV personality disorders.	J Psychosom Res. 2009 Jan;66(1):13-20. Epub 2008 Nov 22.	OBJECTIVE: Personality is an important factor in the research of the chronic fatigue syndrome (CFS). Although some studies report a high rate of personality disorders--around the 40% level--in samples of patients with CFS, the generalizability of these findings can be questioned. The present study evaluates the prevalence of Diagnostic and Statistical Manual for Mental Disorders, Fourth Edition, Text Revision (DSM-IV-TR) personality disorders in a sample of female CFS patients and in two control groups. METHOD: The ADP-IV questionnaire (Assessment of DSM Personality Disorders IV) was used to assess the DSM-IV-TR personality disorders at a dimensional and categorical level in a sample of 50 female CFS patients and in two matched control samples of Flemish civilians (n=50) and psychiatric patients (n=50). RESULTS: The results indicate a striking lack of statistical significant differences between the CFS sample and the Flemish control group at the level of dimensional Trait scores, number of criteria, and prevalence rates of personality disorder diagnoses. Unsurprisingly, higher scores at these levels were obtained within the psychiatric sample. The prevalence of an Axis II disorder was 12% in the Flemish and CFS samples, whereas the psychiatric sample obtained a prevalence of 54%. CONCLUSION: The prominent absence of any significant difference in personality disorder characteristics between the female Flemish general population and the CFS samples seems to suggest only a minor etiological role for personality pathology, as defined by the DSM-IV Axis II, within CFS.
Crawley E, Sterne J.	Bristol University, United Kingdom.	Association between school absence and physical function in paediatric CFS/ME.	Arch Dis Child. 2008 Nov 11. [Epub ahead of print]	OBJECTIVE: To investigate factors associated with school attendance and physical function in paediatric Chronic Fatigue Syndrome/Myalgic Encephalopathy (CFS/ME). DESIGN: Cross sectional study. SETTING: Regional specialist CFS/ME service. Patients: Children and young people aged <18. OUTCOME MEASURES: Self reported school attendance and physical function measured using the physical function subscale of the SF36. METHODS: Linear and logistic regression analysis of data from self completed assessment forms on children attending a regional specialist service between 2004 and 2007. Analyses were done in two groups of children: (1) with a completed Spence Children's Anxiety Scale (SCAS) and (2) with a completed Hospital Anxiety and Depression Scale (HADS). RESULTS: Of 211 children with CFS/ME, 62% attended 40% of school or less. In children with completed SCAS, those with better physical function were more likely to attend school (adjusted OR 1.70, 95% CI 1.36 to 2.13). This was also true for those with completed HADS (adjusted OR 2.05 95% CI 1.4, 3.01). Increasing fatigue and pain and low mood were associated with worse physical function. There was no evidence that anxiety, gender, age at assessment, family history of CFS/ME or time from onset of symptoms to assessment in clinic were associated with school attendance or physical function. Implications: Paediatricians should recognise that reduced school attendance is associated with reduced physical function rather than anxiety. Improving school attendance in children with CFS/ME should focus on evidence-based interventions to improve physical function, particularly concentrating

				on interventions that are likely to reduce pain and fatigue.
Daley M, Morin CM, Leblanc M, Grégoire JP, Savard J, Baillargeon L.	Ecole de Psychologie, Université Laval, Pavillon F.A.S., Quebec, Canada G1K 0A6; Centre d'étude des troubles du sommeil, Centre de recherche Université Laval-Robert Giffard, Quebec, Canada.	Insomnia and its relationship to health-care utilization, work absenteeism, productivity and accidents.	Sleep Med. 2008 Aug 25. [Epub ahead of print]	BACKGROUND AND PURPOSE: To document and provide a micro analysis of the relationship between insomnia and health problems, health-care use, absenteeism, productivity and accidents. PARTICIPANTS AND METHODS: A population-based sample of 953 French-speaking adults from Québec, Canada. Participants were categorized as having insomnia syndrome (SYND) or insomnia symptoms (SYMPT) or as good sleepers (GS). They completed questionnaires on sleep, health, use of health-care services and products, accidents, work absences and reduced work productivity. Data were also obtained from the Québec-government-administered health insurance board on selected variables (e.g., consultations with health-care professionals, diagnoses). RESULTS: There were significantly more individuals in the SYND group relative to the GS group reporting at least one chronic health problem (83% vs. 53%; OR: 2.78) and who had consulted a health-care professional in the past year (81% vs. 60%; OR: 2.8). There were also higher proportions of individuals in the SYND group than in the GS group who had used prescription medications (57% vs. 30.7%; OR: 2.8), most notably to treat insomnia, mood and anxiety disorders, or who had used over-the-counter products (75.6% vs. 62.0%; OR: 1.8) and alcohol as a sleep aid (17.8% vs. 3.9%; OR: 4.6). In terms of daytime function, 25.0% of the SYND had been absent from work relative to 17.1% of GS (OR: 1.7), 40.6% reported having experienced reduced productivity compared to 12.3% of GS (OR: 4.8) and non-motor-vehicle accidents occurred at higher rates in the SYND group (12.5% vs. 6.4% for GS; OR: 2.4). No differences were found for hospitalisations or motor-vehicle accidents. Most of the associations remained significant even after controlling for psychiatric comorbidity. Rates for the SYMPT group were situated between SYND and GS on all major dependent variables. Furthermore, insomnia and fatigue were perceived as contributing significantly to accidents, absences and decreased work productivity, regardless of insomnia status. CONCLUSIONS: This study indicates that insomnia is associated with significant morbidity in terms of health problems and health-care utilization, work absenteeism and reduced productivity, and risk of non-motor-vehicle accidents. Future studies should evaluate whether treating insomnia can reverse this morbidity.
Dalla Libera L, Vescovo G, Volterrani M.	CNR Institute of Neurosciences, Padova, Italy.	Physiological basis for contractile dysfunction in heart failure.	Curr Pharm Des. 2008;14(25):2572-81.	The purpose of this review is to enlighten the mechanisms of skeletal muscle dysfunction in heart failure. The muscle hypothesis suggests that chronic heart failure (CHF) symptoms, dyspnoea and fatigue are due to skeletal muscle alterations. Hyperventilation due to altered ergoreflex seems to be the cause of shortness of breath. Qualitative and quantitative changes occurring in the skeletal muscle, such as muscle wastage and shift from slow to fast fibers type, are likely to be responsible for fatigue. Mechanisms leading to muscle wastage in chronic heart failure, include cytokine-triggered skeletal muscle apoptosis, but also ubiquitin/proteasome and non-ubiquitin-dependent pathways. The regulation of fibre type involves the growth hormone/insulin-like growth factor 1/calcineurin/ transcriptional coactivator PGC1 cascade. The imbalance between protein synthesis and degradation plays an important role. Protein degradation can occur through ubiquitin-dependent and non-ubiquit-independent pathways. Systems controlling ubiquitin/ proteasome activation have been described. These are triggered by tumour necrosis factor and growth hormone/ insulin-like growth factor 1. However, an important role is played by apoptosis. In humans, and experimental models of heart failure, programmed cell death has been found in skeletal muscle and interstitial cells. Apoptosis is

				triggered by tumour necrosis factor and in vitro experiments have shown that it can be induced by its second messenger sphingosine. Apoptosis correlates with the severity of the heart failure syndrome. It involves activation of caspases 3 and 9 and mitochondrial cytochrome c release. Sarcomeric protein oxidation and its consequent contractile impairment can form another cause of skeletal muscle dysfunction in CHF.
Davies S, Crawley E.	Department of Women and Children's Health, Southmead Hospital, Bristol, UK.	Chronic fatigue syndrome in children aged 11 years old and younger.	Arch Dis Child. 2008 May;93(5):419-21. Epub 2008 Jan 11.	Children in primary school can be very disabled by chronic fatigue syndrome or ME (CFS/ME). The clinical presentation in this age group (under 12 years old) is almost identical to that in older children. AIM: To describe children who presented to the Bath paediatric CFS/ME service under the age of 12 years. METHOD: Inventories measuring fatigue, pain, functional disability, anxiety, family history and symptoms were collected prospectively for all children presenting to the Bath CFS/ME service between September 2004 and April 2007. Data from children who presented to the service under the age of 12 are described and compared to those who presented at age 12 or older. RESULTS: 178 children (under the age of 18) were diagnosed as having CFS/ME using the RCPCH criteria out of 216 children assessed. The mean age at assessment for children with CFS/ME was 14.5 years old (SD 2.9). Thirty-two (16%) children were under 12 years at the time of assessment, four children were under 5 years and the youngest child was 2 years old. Children under 12 were very disabled with mean school attendance of just over 40% (average 2 days a week), Chalder fatigue score of 8.29 (CI 7.14 to 9.43 maximum possible score = 11) and pain visual analogue score of 39.7 (possible range 0-100). Comparison with children aged 12 or older showed that both groups were remarkably similar at assessment. Twenty-four out of the 26 children with complete symptom lists would have been diagnosed as having CFS/ME using the stricter adult Centers of Disease Control and prevention (CDC) criteria. CONCLUSION: Disability in the under-12 age group was high, with low levels of school attendance, high levels of fatigue, anxiety, functional disability and pain. The clinical pattern seen is almost identical to that seen in older children, and the majority of children would also be diagnosed as having CFS/ME using the stricter adult definition.

Donders Centre for Cognitive Neuroimaging, Radboud University Nijmegen, Kapittelweg 29, 6500 HB Nijmegen, The Netherlands. florisdelange@gmail.com	Increase in prefrontal cortical volume following cognitive behavioural therapy in patients with chronic fatigue syndrome.	Brain. 2008 Aug;131(Pt 8):2172-80. Epub 2008 Jun 28.	Chronic fatigue syndrome (CFS) is a disabling disorder, characterized by persistent or relapsing fatigue. Recent studies have detected a decrease in cortical grey matter volume in patients with CFS, but it is unclear whether this cerebral atrophy constitutes a cause or a consequence of the disease. Cognitive behavioural therapy (CBT) is an effective behavioural intervention for CFS, which combines a rehabilitative approach of a graded increase in physical activity with a psychological approach that addresses thoughts and beliefs about CFS which may impair recovery. Here, we test the hypothesis that cerebral atrophy may be a reversible state that can ameliorate with successful CBT. We have quantified cerebral structural changes in 22 CFS patients that underwent CBT and 22 healthy control participants. At baseline, CFS patients had significantly lower grey matter volume than healthy control participants. CBT intervention led to a significant improvement in health status, physical activity and cognitive performance. Crucially, CFS patients showed a significant increase in grey matter volume, localized in the lateral prefrontal cortex. This change in cerebral volume was related to improvements in cognitive speed in the CFS patients. Our findings indicate that the cerebral atrophy associated with CFS is partially reversed after effective CBT. This result provides an example of macroscopic cortical plasticity in the adult human brain, demonstrating a surprisingly dynamic relation between behavioural state and cerebral anatomy. Furthermore, our results reveal a possible neurobiological substrate of psychotherapeutic treatment.

Neurological and Psychiatric Sciences Department, Neurophysiopathology of Pain Unit, University of Bari, Bari, Italy.	Fibromyalgia comorbidity in primary headaches.	Cephalalgia. 2008 Dec 15. [Epub ahead of print]	de Tommaso M, Sardaro M, Serpino C, Costantini F, Vecchio E, Pia Prudenzano M, Lamberti P & Livrea P. Fibromyalgia comorbidity in primary headaches. Cephalalgia 2008. London. ISSN 0333-1024Fibromyalgia syndrome (FMS) is a chronic pain condition of unknown aetiology characterized by diffuse pain and tenderness at tender points. The aim of the study was to assess the prevalence and clinical features of FMS in the different forms of primary headaches, in a tertiary headache centre. Primary headache patients (n = 217) were selected and submitted to the Total Tenderness Score, anxiety and depression scales, Migraine Disability Assessment, allodynia questionnaire, Short Form 36 Health Survey and the Medical Outcomes Study-Sleep Scale. In patients with FMS, the Multidimensional Assessment of Fatigue, the Pain Visual Analog Scale, the Manual Tender Point Survey and the Fibromyalgia Impact Questionnaire were employed. FMS was present in 36.4% of patients and prevailed significantly in tension-type headache and in patients with higher headache frequency. Headache frequency, pericranial muscle tenderness, anxiety and sleep inadequacy were especially associated with FMS comorbidity. In the FMS patients, fatigue and pain at tender points were significantly correlated with headache frequency. FMS seems increasingly prevalent with increased headache frequency, for the facilitation of central sensitization phenomena favoured by anxiety and sleep disturbances.
Deary V.	Institute of Health and Society, Newcastle University, Newcastle Upon Tyne, UK. vincent.deary@ncl.ac.uk	A precarious balance: using a self-regulation model to conceptualize and treat chronic fatigue syndrome.	Br J Health Psychol. 2008 May;13(Pt 2):231-6. Epub 2008 Feb 8.	The problem posed by chronic fatigue syndrome (CFS) to the affected individual can be conceptualized, using Leventhal's common sense model, as a health threat to be encoded and coped with accordingly. The current paper adopts an alternative use of self-regulation theory. It is hypothesized that in CFS the health threat is no longer the illness, but anything that threatens to disrupt a precarious accommodation to it. It is argued that attempts at threat regulation may become inadvertently self-defeating, promoting the threats they attempt to diminish. Evidence is presented for homeostatic mechanisms in physiological, neurocognitive and affective domains, and for their potential to become locked in vicious circles. It is further argued that illness attributions, rather than being independent cognitive processes, may be intimately linked with emotional and somatic processes. Damasio's somatic marker hypothesis is used to suggest ways in which the self-regulation of highly interconnected somatic, affective, and cognitive states may be substantially implicated in the maintenance of CFS. This perspective is used to reconsider effective treatment and to suggest new interventions. The self-regulation model is a potentially powerful explanatory framework for the consideration and treatment of CFS and medically unexplained symptoms in general.
Dhir A, Kulkarni SK.	Pharmacology Division, University Institute of Pharmaceutical Sciences, Panjab University, Chandigarh-160014, India.	Venlafaxine reverses chronic fatigue-induced behavioral, biochemical and neurochemical alterations in mice.	Pharmacol Biochem Behav. 2008 Jun;89(4):563-71. Epub 2008 Feb 12.	A state of chronic fatigue was produced in mice by subjecting them to forced swim inside a rectangular jar of specific dimensions everyday for a 6 min session for 15 days. Immobility period was recorded on alternate days. The effect of venlafaxine, a dual reuptake inhibitor of serotonin and norepinephrine was evaluated in this murine model of chronic fatigue. Venlafaxine was administered daily and on the days of testing, it was injected 30 min before forced swim session. On the 16th day i.e. 24 h after the last dose of venlafaxine, various behavioral, biochemical and neurotransmitter estimations in the brain were carried out. There was a significant increase in immobility period in vehicle treated mice on successive days, the maximum immobility score reaching on the 7th day and sustained till 15th day. Behavioral parameters revealed hyperlocomotion, anxiety response, muscle incoordination, hyperalgesia and memory deficit. Biochemical analysis showed a significant increase in

				lipid peroxidation, nitrite and myeloperoxidase levels and a decrease in the reduced glutathione (GSH) levels in brain homogenates. Further, there was a decrease in adrenal ascorbic acid following chronic forced swim. The neurotransmitter estimations in the brain samples revealed a decrease in norepinephrine, serotonin and dopamine levels on chronic exposure to forced swim for 15 days. Daily treatment with venlafaxine (8 and 16 mg/kg, i.p.) for 15 days produced a significant reduction in immobility period and reversed various behavioral, biochemical and neurotransmitter alterations induced by chronic fatigue. Venlafaxine could be of therapeutic potential in the treatment of chronic fatigue.
Dickson A, Toft A, O'Carroll RE.	School of Health and Social Sciences, Napier University, Edinburgh, UK.	Neuropsychological functioning, illness perception, mood and quality of life in chronic fatigue syndrome, autoimmune thyroid disease and healthy participants.	Psychol Med. 2009 Jan 15:1-10. [Epub ahead of print]	BACKGROUND: This study attempted to longitudinally investigate neuropsychological function, illness representations, self-esteem, mood and quality of life (QoL) in individuals with chronic fatigue syndrome (CFS) and compared them with both healthy participants and a clinical comparison group of individuals with autoimmune thyroid disease (AITD).MethodNeuropsychological evaluation was administered at two time points, five weeks apart. Twenty-one individuals with CFS, 20 individuals with AITD and 21 healthy participants were matched for age, pre-morbid intelligence, education level and socio-economic status (SES). All groups also completed measures of illness perceptions, mood, self-esteem and QoL at both time points. RESULTS: The CFS group showed significantly greater impairment on measures of immediate and delayed memory, attention and visuo-constructional ability, and reported significantly higher levels of anxiety and depression. After controlling for the effects of mood, the CFS group still demonstrated significant impairment in attention. The CFS group also reported significantly lower self-reported QoL than the AITD and healthy participants. In terms of illness perceptions, the AITD group believed that their condition would last longer, that they had more treatment control over their condition, and reported less concern than the CFS group. CONCLUSIONS: These results suggest that the primary cognitive impairment in CFS is attention and that this is not secondary to affective status. The lower treatment control perceptions and greater illness concerns that CFS patients report may be causally related to their affective status.
Dietert RR, Dietert JM.	Department of Microbiology and Immunology, College of Veterinary Medicine, Cornell University, Ithaca, NY 14853, USA. rrd1@cornell.edu	Possible role for early-life immune insult including developmental immunotoxicity in chronic fatigue syndrome (CFS) or myalgic encephalomyelitis (ME).	Toxicology. 2008 May 2;247(1):61-72. Epub 2008 Feb 8.	Chronic fatigue syndrome (CFS), also known as myalgic encephalomyelitis (ME) in some countries, is a debilitating disease with a constellation of multi-system dysfunctions primarily involving the neurological, endocrine and immune systems. While substantial information is available concerning the complex dysfunction-associated symptoms of CFS, environmental origins of the disease have yet to be determined. Part of the dilemma in identifying the cause(s) has been the focus on biomarkers (hormones, neurotransmitters, cytokines, infectious agents) that are contemporary with later-life CFS episodes. Yet, recent investigations on the origins of environmental diseases of the neurological, endocrine, reproductive, respiratory and immune systems suggest that early life toxicologic and other insults are pivotal in producing later-life onset of symptoms. As with autism and childhood asthma, CFS can also occur in children where the causes are certainly early-life events. Immune dysfunction is recognized as part of the CFS phenotype but has received comparatively less attention than aberrant neurological or endocrine function. However, recent research results suggest that early life immune insults (ELII) including developmental immunotoxicity (DIT), which is induced by xenobiotics, may offer an important clue to the origin(s) of CFS. The developing immune system is a sensitive and novel target for environmental insult (xenobiotic, infectious agents, stress) with major ramifications for

				postnatal health risks. Additionally, many prenatal and early postnatal neurological lesions associated with postnatal neurobehavioral diseases are now recognized as linked to prenatal immune insult and inflammatory dysregulation. This review considers the potential role of ELII including DIT as an early-life component of later-life CFS.
Dobkin BH.	Department of Neurology, University of California Los Angeles, Los Angeles, CA 90095, USA. bdobkin@mednet.ucla.edu	Fatigue versus activity-dependent fatigability in patients with central or peripheral motor impairments.	Neurorehabil Neural Repair. 2008 Mar-Apr;22(2):105-10.	In the rehabilitation literature, fatigue is a common symptom of patients with any neurological impairment when defined as a subjective lack of physical and mental energy that interferes with usual activities. Some complaints may, however, arise from fatigability , an objective decline in strength as routine use of muscle groups proceeds. By this refined definition of fatigue, exercise or sustained use reduces the ability of muscles to produce force or power, regardless of whether the task can be sustained. Fatigability may be masked clinically because (1) the degree of weakening is not profound, (2) activity-induced weakness rapidly lessens with cessation of exertion, and (3) clinicians rarely test for changes in strength after repetitive movements to objectively entertain the diagnosis. The repetitive movements that induce fatigability during daily activities are an iterative physiological process that depends on changing states induced by activation of spared central and peripheral neurons and axons and compromised muscle. Fatigability may be especially difficult to localize in patients undergoing neurorehabilitation, in part because no finite boundary exists between the central and peripheral components of motor reserve and endurance. At the bedside, however, manual muscle testing before and after repetitive movements could at least put some focus on the presence of fatigability in any patient with motor impairments and related disabilities. Reliable measures of fatigability beyond a careful clinical examination, such as physiological changes monitored by cerebral functional neuroimaging techniques and more standardized central and peripheral electrical and magnetic stimulation paradigms, may help determine the mechanisms of activity-dependent weakening and lead to specific therapies. Testable interventions to increase motor reserve include muscle strengthening and endurance exercises, varying the biomechanical requirements of repetitive muscle contractions, and training-induced neural plasticity or pharmacologic manipulations to enhance synaptic efficacy.
Dorko E, Kalinova Z, Weissova T, Pilipcinec E.	Department of Epidemiology, Faculty of Medicine, Srobarova 2, 041 80 Kosice, Slovak Republic. erikdorco@pobox.sk	Seroprevalence of antibodies to Coxiella burnetii among employees of the Veterinary University in Kosice, eastern Slovakia.	Ann Agric Environ Med. 2008 Jun;15(1):119-24.	Coxiella burnetii is an obligate intracellular pathogen known to be the causative agent of Q fever, a zoonosis with worldwide occurrence. The organism has been found in many wild and domestic animals. Infected animals shed highly stable bacteria in urine, faeces, milk, and through placental and birth fluids. Humans acquire the infection mainly by inhaling infected aerosols, or by ingesting contaminated raw milk or fresh dairy products; tick transmission has been proven but is probably rare. The aim of the present study was to determine the titres of immunoglobulin IgG against phase I and II of C. burnetii, and to evaluate the risk factors that might be associated with exposure to C. burnetii among employees of the Veterinary University. Venous blood was obtained from 92 employees. IgG antibodies were determined by ELISA method modified in our laboratory using whole cells of the Nine Mile C. burnetii strain. The questionnaire was filled out by every subject to obtain epidemiological and clinical date. Phase I antibodies were detected in 35 subjects, i.e. in 38%, and phase II antibodies in 58 subjects, i.e. in 63%. When using the titre > or = 1:800 as a cut-off level, 2 samples were positive for phase I antibodies (2.1%) and 12 for phase II antibodies (13%). Factors predisposing to infection or exposure to C. burnetii included professional orientation and regular contact with farm animals and

				pets. Clinical history of some seropositive subjects revealed substantial problems, such as fever of unknown origin, rheumatic disease, disease of heart, liver, respiratory tract (particularly atypical pneumonia), chronic fatigue syndrome and spontaneous abortion in females. Q fever is a profession-related disease and prevention of its spreading within the risk population groups requires observation of basic safety rules.
Dunleavy M, Bradford A, O'Halloran KD.	Royal College of Surgeons in Ireland, Department of Physiology and Medical Physics. mdunleavy@rcsi.ie	Oxidative stress impairs upper airway muscle endurance in an animal model of sleep-disordered breathing.	Adv Exp Med Biol. 2008;605:458-62.	Obstructive sleep apnoea is characterised by intermittent hypoxia due to recurrent obstructions of the pharyngeal airway during sleep. We have shown that chronic intermittent hypoxia impairs respiratory muscle function and CNS control of upper airway patency. In this study, we tested the hypothesis that disruption of an endogenous antioxidant defence system exacerbates the effects of intermittent hypoxia on upper airway muscle contractile function. Thirty-two male Wistar rats were placed in restrainers with their heads in hoods in which the ambient oxygen concentration could be modified by controlling the gas supply to the hoods. Sixteen rats were exposed to alternating equal periods of hypoxia and normoxia, twice per minute, 8 hours per day for 1 week. The remaining 16 animals were exposed to normoxia continuously under identical experimental conditions. In both groups, half the animals received daily injections of buthionine sulfoxamine (BSO), an inhibitor of the rate-limiting enzyme in glutathione synthesis. The other half received daily vehicle injections. At the end of the 1-week treatment period, the sternohyoid muscles were removed and fatigue characteristics were determined in vitro. Intermittent hypoxia was associated with a decrease in sternohyoid muscle endurance, an effect that was exacerbated by treatment with BSO. In separate experiments, daily treatment with the antioxidant N-acetyl cysteine blocked the deleterious effects of intermittent hypoxia on respiratory muscle function. We suggest that oxidative stress contributes to impaired upper airway muscle endurance in our animal model and that endogenous glutathione may be especially important in limiting free radical-induced muscle dysfunction. Our results may have particular relevance to respiratory disorders associated with recurrent hypoxia, such as the sleep apnoea/hypopnoea syndrome.
Emami MH, Haghdani S, Tavakkoli H, Mahzouni P.	Department of Gastroenterology, Alzahra University Hospital, Isfahan University of Medical Sciences, Isfahan, Iran. mh_emami@med.mui.ac.ir	Endoscopic polypectomy resection of blue rubber bleb nevus lesions in small bowel.	Indian J Gastroenterol. 2008 Jul-Aug;27(4):165-6.	Blue rubber bleb nevus syndrome (BRBNS) is a rare disorder characterized by cutaneous and gastrointestinal (GI) venous malformations. The treatment of BRBNS is primarily supportive and ablative. Ablative therapy involves endoscopic or surgical treatment of GI venous malformations. We describe a 20-year-old woman who had multiple venous malformations all over the GI tract as well as cutaneous lesions. She had suffered from several episodes of melena, chronic anemia and fatigue for 10 years, which were treated temporarily by iron supplementation and blood transfusion. The endoscopic examination of the GI tract and total colonoscopy revealed multiple bluish sessile and polypoid venous malformations 2-3 cm in size throughout the GI tract. Argon plasma coagulation (APC) and polypectomy was done for all gastric and colonic lesions, respectively. Ileoscopy showed a large wide base vascular polypoid lesion at about 70 cm from the ileocecal valve with active bleeding; this was removed by snare polypectomy. One week later, she was discharged in good condition. At about 6 months' follow up she did not report any bleeding attack. Endoscopic polypectomy can be useful in patients with large and polypoid lesions of BRBNs which are not controlled with supportive therapy. Further experience is needed to evaluate the risks versus benefits of this approach.

Exley C, Swarbrick L, Gherardi RK, Authier FJ.	Birchall Centre for Inorganic Chemistry and Materials Science, Keele University, Staffordshire ST5 5BG, UK. c.exley@chem.keele.ac.uk	A role for the body burden of aluminium in vaccine-associated macrophagic myofasciitis and chronic fatigue syndrome.	Med Hypotheses. 2009 Feb;72(2):135-9. Epub 2008 Nov 11.	Macrophagic myofasciitis and chronic fatigue syndrome are severely disabling conditions which may be caused by adverse reactions to aluminium-containing adjuvants in vaccines. While a little is known of disease aetiology both conditions are characterised by an aberrant immune response, have a number of prominent symptoms in common and are coincident in many individuals. Herein, we have described a case of vaccine-associated chronic fatigue syndrome and macrophagic myofasciitis in an individual demonstrating aluminium overload. This is the first report linking the latter with either of these two conditions and the possibility is considered that the coincident aluminium overload contributed significantly to the severity of these conditions in this individual. This case has highlighted potential dangers associated with aluminium-containing adjuvants and we have elucidated a possible mechanism whereby vaccination involving aluminium-containing adjuvants could trigger the cascade of immunological events which are associated with autoimmune conditions including chronic fatigue syndrome and macrophagic myofasciitis.
Eyigor S, Ozdedeli S, Durmaz B.	Ege University Medical Faculty, Department of Physical and Rehabilitation Medicine, Bornova, Izmir, Turkey. eyigor@hotmail.com	The prevalence of generalized soft tissue rheumatic conditions in Turkish medical students.	J Clin Rheumatol. 2008 Apr;14(2):65-8.	OBJECTIVE: To assess the prevalence of generalized soft tissue rheumatism (GSTR) in medical students in Izmir, Turkey. METHODS: Medical students from each grade of Medical School of Ege University, Izmir, Turkey, were evaluated by a survey and physical examination for GSTR including fibromyalgia (FM) syndrome, myofascial pain syndrome (MPS), benign joint hypermobility syndrome (BJHS), and chronic fatigue syndrome. FM Impact Questionnaire was assessed in FM diagnosed students. Short Form-36 (SF-36) was obtained from each student to determine the quality of life. RESULTS: Among the participants (n = 306), 191 were women (62.4%) and 115 were men (37.6%) and mean age was 20.23 +/- 1.56. Fifty-eight students (19%) were diagnosed with a GSTR. The distributions of the diagnoses were: 6 (2%) FM, 21 (6.9%) MPS, 28 (9.2%) BJHS, 1 (0.3%) chronic fatigue syndrome, and 2 students (0.7%) had both BJHS and MPS. Fifty-three (27.7%) women and 5 (4.3%) men were diagnosed with a GSTR ($P < 0.01$). Mean FM Impact Questionnaire score was 50.8 in FM diagnosed students. Physical role, vitality, and mental subscores of SF-36 were significantly lower in the students having a GSTR ($P < 0.05$). CONCLUSION: This is the first study performed in medical students to find out the prevalence of generalized soft tissue rheumatic conditions. Although medical students are under high stress due to hard training, the prevalence of GSTR in medical students was found similar to previous reports in the general population.
Fairhall N, Aggar C, Kurrle SE, Sherrington C, Lord S, Lockwood K, Monaghan N, Cameron ID.	Rehabilitation Studies Unit, Faculty of Medicine, The University of Sydney, Sydney Australia. nfairhall@george.org.au	Frailty Intervention Trial (FIT).	BMC Geriatr. 2008 Oct 13;8:27.	BACKGROUND: Frailty is a term commonly used to describe the condition of an older person who has chronic health problems, has lost functional abilities and is likely to deteriorate further. However, despite its common use, only a small number of studies have attempted to define the syndrome of frailty and measure its prevalence. The criteria Fried and colleagues used to define the frailty syndrome will be used in this study (i.e. weight loss, fatigue, decreased grip strength, slow gait speed, and low physical activity). Previous studies have shown that clinical outcomes for frail older people can be improved using multi-factorial interventions such as comprehensive geriatric assessment, and single interventions such as exercise programs or nutritional supplementation, but no interventions have been developed to specifically reverse the syndrome of frailty.We have developed a

				multidisciplinary intervention that specifically targets frailty as defined by Fried et al. We aim to establish the effects of this intervention on frailty, mobility, hospitalisation and institutionalisation in frail older people. METHODS AND DESIGN: A single centre randomised controlled trial comparing a multidisciplinary intervention with usual care. The intervention will target identified characteristics of frailty, functional limitations, nutritional status, falls risk, psychological issues and management of chronic health conditions. Two hundred and thirty people aged 70 and over who meet the Fried definition of frailty will be recruited from clients of the aged care service of a metropolitan hospital. Participants will be followed for a 12-month period. DISCUSSION: This research is an important step in the examination of specifically targeted frailty interventions. This project will assess whether an intervention specifically targeting frailty can be implemented, and whether it is effective when compared to usual care. If successful, the study will establish a new approach to the treatment of older people at risk of further functional decline and institutionalisation. The strategies to be examined are readily transferable to routine clinical practice and are applicable broadly in the setting of aged care health services. TRIAL REGISTRATION: Australian New Zealand Clinical Trails Registry: ACTRN12608000250336.
Faulkner S, Smith A.	University of Glamorgan, UK. sfaulkne@glam.ac.uk	A longitudinal study of the relationship between psychological distress and recurrence of upper respiratory tract infections in chronic fatigue syndrome.	Br J Health Psychol. 2008 Feb;13(Pt 1):177-86.	OBJECTIVES: Previous research has found that chronic fatigue syndrome (CFS) patients report increased susceptibility to upper respiratory tract illnesses (URTIs) when compared with healthy volunteers. This study aimed to replicate and extend this research by investigating the role of psychological distress (stress and negative mood) in the recurrence of URTIs in CFS patients as well as its role in the recurrence of CFS symptoms. DESIGN: A 15-week diary study. METHODS: Measures of psychological stress, negative mood, recurrence of URTIs and symptoms were recorded each week for a 15-week period. CFS patients (N=21), who had been assessed and diagnosed according to the Oxford criteria, were recruited from the Cardiff Chronic Fatigue Clinic and compared with a matched group of healthy controls (N=18). Frequency of occurrence of infectious illness and the relationship between psychological stress/negative mood and occurrence of illness were assessed. RESULTS: CFS patients reported more URTIs than the controls. Stress scores (and negative mood) were significantly higher in the week prior to the occurrence of URTIs than in weeks when no subsequent illness occurred. High levels of psychological stress also preceded the severity of reported symptoms of fatigue in the CFS group. CONCLUSIONS: CFS patients reported more frequent URTIs than healthy controls and these recurrences were preceded by high levels of psychological stress. High levels of stress were also associated with greater subsequent fatigue. Possible explanations of these results are discussed.
Fawkes-Kirby TM, Wheeler MA, Anton HA, Miller WC, Townson AF, Weeks CA.	School of Rehabilitation Sciences, University of British Columbia, Vancouver, British Columbia, Canada.	Clinical correlates of fatigue in spinal cord injury.	Spinal Cord. 2008 Jan;46(1):21-5. Epub 2007 Apr 3.	STUDY DESIGN: Retrospective chart review. OBJECTIVES: To determine the prevalence of fatigue in an outpatient spinal cord injury population and to examine the clinical variables contributing to that fatigue. SETTING: GF Strong Rehabilitation Centre, Vancouver, British Columbia, Canada. METHODS: Medical charts of 76 individuals admitted to the GF Strong Outpatient SCI Program between December 2004 and December 2005 were reviewed. Data collected included information on clinical characteristics, demographics and Fatigue Severity Scale (FSS) scores. Multivariable analysis was completed to determine the independent association between these variables and fatigue severity. RESULTS: A total of 57% (95% confidence interval (CI)=45-67%) of the sample were found to have fatigue severe enough to interfere with function. People that were admitted for medical reasons; had

				pain, spasticity, incomplete injuries, and/or were on more that one medication with a known side effect of fatigue had significantly higher FSS scores. Multivariable analysis indicated incomplete injury was the only statistically significant predictor of a higher FSS scores; pain approached significance (P=0.07, CI=-0.09, 2.06). Together these variables account for 18% of the variance in FSS scores in this sample. CONCLUSION: Fatigue among individuals with spinal cord injury who are seeking outpatient rehabilitation is very common. The severity of fatigue was greater for individuals with incomplete lesions. Pain was also a potentially important covariate of fatigue. Further research is required to determine what else contributes to fatigue severity beyond these clinical variables as only minimal variance was accounted for in our model.
Findlay SM.	Adolescent Medicine, Department of Pediatrics, McMaster University, Hamilton, Ontario.	The tired teen: A review of the assessment and management of the adolescent with sleepiness and fatigue.	Paediatr Child Health. 2008 Jan;13(1):37-42.	The symptoms of sleepiness and fatigue are frequently encountered when caring for adolescents. Up to 40% of healthy teens experience regular sleepiness, defined as an increased tendency to fall asleep. Fatigue is the perception of low energy following normal activity and is reported by up to 30% of well teens. Chronic fatigue syndrome is an unusual syndrome with severe fatigue accompanied by other physical and neurological symptoms. A thorough assessment is required for all teens with sleepiness and fatigue; however, a treatable underlying medical condition is rarely found. Most fatigue and sleepiness in teens is attributable to lifestyle issues, notably too little time spent sleeping. Physicians are in a position to screen for, assess and manage these common conditions in teens.

Fisher MM, Rose M.	Royal North Shore Hospital of Sydney, St Leonards, NSW 2065, Australia. mfisher@med.usyd.edu.au	Anaesthesia for patients with idiopathic environmental intolerance and chronic fatigue syndrome.	Br J Anaesth. 2008 Oct;101(4):486-91.	BACKGROUND: Idiopathic environmental intolerance syndrome (IEI), formerly known as multiple chemical sensitivity syndrome (MCSS), and chronic fatigue syndrome (CFS) are controversial diseases and there is little information in the literature regarding the appropriate conduct of anaesthesia in such patients. METHODS: We studied 27 patients referred to our anaesthetic allergy clinic with IEI and CFS and performed literature and web searches on anaesthesia in these disorders. RESULTS: The patients had a significant incidence of adverse events related to anaesthesia which were not allergic in nature. The adverse effects usually occurred postoperatively and were self limiting. Patients with IEI and CFS are not at risk of anaphylaxis and there is no scientific evidence that any drug or technique is excessively hazardous. Neither our patients nor the review of the scientific literature supported available web-based recommendations for the anaesthetic management of patients with IEL and CFS. CONCLUSIONS: We suggest that the anaesthetist may be best to use the technique they would use if the patient did not have CFS or IEI but avoid drugs to which there is a history of adverse response. Anaesthesia is likely to be associated with adverse effects in these patients but the effects are not likely to be severe. A series of recommendations for the safe and harmonious conduct of anaesthesia

				in patients with CFS and IEI are provided.
Friedberg F, Sohl S.	Stony Brook University.	Cognitive-behavior therapy in chronic fatigue syndrome: is improvement related to increased physical activity?	J Clin Psychol. 2009 Feb 11;65(4):423-442. [Epub ahead of print]	This multiple case study of cognitive-behavioral treatment (CBT) for chronic fatigue syndrome (CFS) compared self-report and behavioral outcomes. Eleven relatively high-functioning participants with CFS received 6-32 sessions of outpatient graded-activity oriented CBT. Self-report outcomes included measures of fatigue impact, physical function, depression, anxiety, and global change. Behavioral outcomes included actigraphy and the 6-minute walking test. Global change ratings were very much improved (n=2), much improved (n=2), improved (n=5), and no change (n=2). Of those reporting improvement, clinically significant actigraphy increases (n=3) and decreases (n=4) were found, as well as no significant change (n=2). The nature of clinical improvement in CBT trials for high-functioning CFS patients may be more ambiguous than that postulated by the cognitive-behavioral model. (c) 2009 Wiley Periodicals, Inc. J Clin Psychol, 65:1-20, 2009.
Friedberg F, Sohl SJ, Halperin PJ.	Department of Psychiatry and Behavioral Science, Stony Brook University, New York 11794-8790, USA. Fred.Friedberg@stonybrook.edu	Teaching medical students about medically unexplained illnesses: a preliminary study.	Med Teach. 2008;30(6):618-21.	BACKGROUND: This study examined how an interactive seminar focusing on two medically unexplained illnesses, chronic fatigue syndrome (CFS) and fibromyalgia, influenced medical student attitudes toward CFS, a more strongly stigmatized illness. METHODS: Forty-five fourth year medical students attended a 90 minute interactive seminar on the management of medically unexplained illnesses that was exemplified with CFS and fibromyalgia. A modified version of the CFS attitudes test was administered immediately before and after the seminar. RESULTS: Pre-seminar assessment revealed neutral to slightly favorable toward CFS. At the end of the seminar, significantly more favorable attitudes were found toward CFS in general ($t(42) = 2.77$; $P < 0.01$) and for specific items that focused on (1) supporting more CFS research funding ($t(42) = 4.32$; $P < 0.001$; (2) employers providing flexible hours for people with CFS ($t(42) = 3.52$, $P < 0.01$); and (3) viewing CFS as not primarily a psychological disorder ($t(42) = 2.87$, $P < 0.01$). Thus, a relatively brief exposure to factual information on specific medically unexplained illnesses was associated with more favorable attitudes toward CFS in fourth year medical students. CONCLUSION: This type of instruction may lead to potentially more receptive professional attitudes toward providing care to these underserved patients.
Friedberg F, Sohl SJ.	Department of Psychiatry and Behavioral Science, Stony Brook University, Stony Brook, NY 11794-8790, USA. fred.friedberg@stonybrook.edu	Memory for fatigue in chronic fatigue syndrome: the relation between weekly recall and momentary ratings.	Int J Behav Med. 2008 Jan-Mar;15(1):29-33.	BACKGROUND: Understanding how patients with chronic fatigue syndrome (CFS) recall their fatigue is important because fatigue is a core clinical dimension of this poorly understood illness. PURPOSE: This study assessed the associations between momentary fatigue ratings and weekly recall of fatigue in 71 participants with CFS. METHOD: During the three-week data collection period, fatigue intensity was recorded six times a day in electronic diaries. At the end of each week, participants were asked to recall their fatigue intensity for that week. Statistical analyses were done with t-tests and Pearson's and intraclass correlations. RESULTS: Average weekly recall of fatigue intensity was significantly higher than average momentary ratings. Furthermore, moderate to high Pearson's correlations and intraclass correlations (consistency and absolute agreement) between recall and momentary fatigue ratings were found. CONCLUSION: Individuals with CFS recalled consistently higher levels of fatigue in comparison to real-time momentary ratings, yet the level of agreement between the two measures was moderate to high. These findings may have implications for the conduct of office examinations for CFS.
Friedberg F, Sohl	Department of	Longitudinal	J Behav Med. 2008	The purpose of this 2-year prospective study was to compare standard self-report and ecologically-

SJ.	Psychiatry and Behavioral Science Putnam Hall, South Campus, Stony Brook University, Stony Brook, NY, 11794-8790, USA, fred.friedberg@stonybrook.edu.	change in chronic fatigue syndrome: what home-based assessments reveal.	Dec 20. [Epub ahead of print]	based outcome measures in patients with chronic fatigue syndrome (CFS). Standard measures assessed physical function, fatigue impact, psychological variables, and global impression of change ratings. Ecological measures included actigraphy, a structured activity record, and an electronic fatigue/energy diary. Results for this high functioning sample (N = 75) revealed that self-report global improvement was significantly associated with lower momentary fatigue and fatigue impact, and a higher frequency of standing up (at home), but not with actigraphy or psychological variables. However, actigraphy change was significantly correlated with change in self-report physical function. At follow-up, only a small minority (<20%) scored in the healthy adult range for fatigue impact and physical function. The findings suggest that home-based measures of symptom severity and physical functioning may provide evidence of change (or lack of change) that is important for interpreting standard self-report outcomes in CFS.
Fuite J, Vernon SD, Broderick G.	Department of Medicine, Division of Pulmonary Faculty of Medicine and Dentistry, University of Alberta, 2E4.41 Walter Mackenzie Health Sciences Centre, 8440-112 Street, Edmonton, AB, Canada.	Neuroendocrine and immune network re-modeling in chronic fatigue syndrome: an exploratory analysis.	Genomics. 2008 Dec;92(6):393-9. Epub 2008 Oct 1.	This work investigates the significance of changes in association patterns linking indicators of neuroendocrine and immune activity in patients with chronic fatigue syndrome (CFS). Gene sets preferentially expressed in specific immune cell isolates were integrated with neuroendocrine data from a large population-based study. Co-expression patterns linking immune cell activity with hypothalamic-pituitary-adrenal (HPA), thyroidal (HPT) and gonadal (HPG) axis status were computed using mutual information criteria. Networks in control and CFS subjects were compared globally in terms of a weighted graph edit distance. Local re-modeling of node connectivity was quantified by node degree and eigenvector centrality measures. Results indicate statistically significant differences between CFS and control networks determined mainly by re-modeling around pituitary and thyroid nodes as well as an emergent immune sub-network. Findings align with known mechanisms of chronic inflammation and support possible immune-mediated loss of thyroid function in CFS exacerbated by blunted HPA axis responsiveness.
Fulle S, Pietrangelo T, Mancinelli R, Saggini R, Fano G.	Ce.S.I.-Center for Research on Ageing, Università "G. d'Annunzio", Chieti-Pescara, Italy.	Specific correlations between muscle oxidative stress and chronic fatigue syndrome: a working hypothesis.	J Muscle Res Cell Motil. 2007;28(6):355-62. Epub 2008 Feb 15.	Chronic fatigue syndrome (CFS) is a relatively common disorder defined as a status of severe persistent disabling fatigue and subjective unwellness. While the biological basis of the pathology of this disease has recently been confirmed, its pathophysiology remains to be elucidated. Moreover, since the causes of CFS have not been identified, treatment programs are directed at symptom relief, with the ultimate goal of the patient regaining some level of pre-existing function and well-being. Several studies have examined whether CFS is associated with: (i) a range of infectious agents and or immune disturbance; (ii) specific changes of activity in the central or peripheral nervous systems; and (iii) elevated stress periods, which may be associated with the pathology via genetic mechanisms. The role of oxidative stress in CFS is an emerging focus of research due to evidence of its association with some pathological features of this syndrome. New data collectively support the presence of specific critical points in the muscle that are affected by free radicals and in view of these considerations, the possible role of skeletal muscle oxidative imbalance in the genesis of CFS is discussed.
Fuller-Thomson E, Nimigon J.	Department of Family and Community Medicine,	Factors associated with depression among individuals with chronic	Fam Pract. 2008 Dec;25(6):414-22. Epub 2008 Oct 3.	OBJECTIVES: Most previous research regarding chronic fatigue syndrome (CFS) and depression has relied on clinical samples. The current research determined the prevalence and correlates of depression among individuals with CFS in a community sample. METHODS: The nationally representative Canadian Community Health Survey, conducted in 2000/2001, included an unweighted

	University of Toronto, Toronto, Ontario M5S 1A1, Canada. esme.fuller.thomson@utoronto.ca	fatigue syndrome: findings from a nationally representative survey.		sample size of 1045 individuals who reported a diagnosis of CFS and had complete data on depression. Respondents with CFS who were depressed (n = 369) were compared to those who were not depressed (n = 676). Chi-square analyses, t-tests and a logistic regression were conducted. RESULTS: Thirty-six per cent of individuals with CFS were depressed. Among individuals with CFS, depression was associated with lower levels of mastery and self-esteem. In the logistic regression analyses, the odds of depression among individuals with CFS were higher for females, younger respondents, those with lower incomes and food insecurity and those whose activities were limited by pain. Two in five depressed individuals had not consulted with any mental health professional in the preceding year. Twenty-two per cent of depressed respondents had seriously considered suicide in the past year. Individuals with CFS who were depressed were particularly heavy users of family physicians, with an average of 11.1 visits annually (95% confidence interval = 10.7, 11.6). CONCLUSION: It is important for clinicians to assess depression and suicidal ideation among their patients with CFS, particularly among females, those reporting moderate to severe pain, low incomes and inadequate social support.
Gadalla T.	Faculty of Social Work at the University of Toronto.	Association of comorbid mood disorders and chronic illness with disability and quality of life in Ontario, Canada.	Chronic Dis Can. 2008;28(4):148-54.	Mood disorders are more prevalent in individuals with chronic physical illness compared to individuals with no such illness. These disorders amplify the disability associated with the physical condition and adversely affect its course, thus contributing to occupational impairment, disruption in interpersonal and family relationships, poor health and suicide. This study used data collected in the Canadian Community Health Survey, cycle 3.1 (2005) to examine factors associated with comorbid mood disorders and to assess their association with the quality of life of individuals living in Ontario. Results indicate that individuals with chronic fatigue syndrome, fibromyalgia, bowel disorder or stomach or intestinal ulcers had the highest rates of mood disorders. The odds of having a comorbid mood disorder were higher among women, the single, those living in poverty, the Canadian born and those between 30 and 69 years of age. The presence of comorbid mood disorders was significantly associated with short-term disability, requiring help with instrumental daily activities and suicidal ideation. Health care providers are urged to proactively screen chronically ill patients for mood disorders, particularly among the subgroups found to have elevated risk for these disorders.
Gadalla TM.	Faculty of Social Work, University of Toronto, Toronto, Ontario, Canada. tahany.gadalla@utoronto.ca	Disability associated with comorbid anxiety disorders in women with chronic physical illness in Ontario, Canada.	Women Health. 2008;48(1):1-20.	Anxiety disorders are more prevalent in individuals with chronic physical illness compared to individuals with no such illness, and about twice as prevalent in women as in men. This study used data collected in the 2005 Canadian Community Health Survey (21,198 women and 20,478 men) to examine factors associated with comorbid anxiety disorders and to assess the relation of these disorders on short-term disability and suicidal ideation. Comorbid anxiety disorders were more prevalent among women who were young, single, poor, and Canadian-born, and among women with chronic fatigue syndrome; fibromyalgia, bowel disorder or stomach or intestinal ulcers, or bronchitis had the highest rates of anxiety disorders. The presence of comorbid anxiety disorders was significantly associated with short-term disability, requiring help with instrumental daily activities, and suicidal ideation. Our findings underscore the importance of early detection and treatment of anxiety disorders in the physically ill, especially those who also suffer from mood disorders.
Galland BC, Jackson PM, Sayers RM, Taylor	Department of Women's & Children's Health,	A matched case control study of orthostatic	Pediatr Res. 2008 Feb;63(2):196-202.	This study aimed to define cardiovascular and heart rate variability (HRV) changes following head-up tilt (HUT) in children/adolescents with chronic fatigue syndrome (CFS) in comparison to age- and gender-matched controls. Twenty-six children/adolescents with CFS (11-19 y) and controls underwent

BJ.	University of Otago, Dunedin 9015, New Zealand. barbara.galland@otago.ac.nz	intolerance in children/adolescents with chronic fatigue syndrome.		70-degree HUT for a maximum of 30 min, but returned to horizontal earlier at the participant's request with symptoms of orthostatic intolerance (OI) that included lightheadedness. Using electrocardiography and beat-beat finger blood pressure, a positive tilt was defined as OI with 1) neurally mediated hypotension (NMH); bradycardia (HR <75% of baseline), and hypotension [systolic pressure (SysP) drops >25 mm Hg)] or 2) postural orthostatic tachycardia syndrome (POTS); HR increase >30 bpm, or HR >120 bpm (with/without hypotension). Thirteen CFS and five controls exhibited OI generating a sensitivity and specificity for HUT of 50.0% and 80.8%, respectively. POTS without hypotension occurred in seven CFS subjects but no controls. POTS with hypotension and NMH occurred in both. Predominant sympathetic components to HRV on HUT were measured in CFS tilt-positive subjects. In conclusion, CFS subjects were more susceptible to OI than controls, the cardiovascular response predominantly manifest as POTS without hypotension, a response unique to CFS suggesting further investigation is warranted with respect to the pathophysiologic mechanisms involved.
Geisser ME, Strader Donnell C, Petzke F, Gracely RH, Clauw DJ, Williams DA.	Chronic Pain and Fatigue Research Center, Dept. of Internal Medicine, Div. of Rheumatology, Univ. of Michigan, Ann Arbor, MI 48108, USA. mgeisser@med.umich.edu	Comorbid somatic symptoms and functional status in patients with fibromyalgia and chronic fatigue syndrome: sensory amplification as a common mechanism.	Psychosomatics. 2008 May-Jun;49(3):235-42.	BACKGROUND: Somatic symptoms are common in conditions such as fibromyalgia (FM) and chronic fatigue syndrome (CFS). OBJECTIVE: Authors investigated a potential shared pathologic mechanism: a generalized perceptual abnormality where there is heightened responsiveness to varied sensory stimulation, including pain. METHOD: A composite measure of sensory sensitivity was created and compared with measures of somatic symptoms, comorbid psychological disturbances, and self-reported physical functioning in 38 patients with FM and/or CFS. RESULTS: Sensory amplification influenced physical functioning indirectly through pain intensity, and physical symptoms and fatigue also independently contributed to physical functioning. CONCLUSION: Sensory amplification may be an underlying pathophysiologic mechanism in these disorders that is relatively independent of depression and depressive symptoms.
Gilje AM, Söderlund A, Malterud K.	Department of Public Health and Primary Health Care, University of Bergen, Bergen, Norway.	Obstructions for quality care experienced by patients with chronic fatigue syndrome (CFS)--a case study.	Patient Educ Couns. 2008 Oct;73(1):36-41. Epub 2008 May 16. Comment in: Patient Educ Couns. 2008 Oct;73(1):1-2.	OBJECTIVE: To explore obstructions for quality care from experiences by patients suffering from chronic fatigue syndrome (CFS). METHODS: Qualitative case study with data drawn from a group meeting, written answers to a questionnaire and a follow-up meeting. Purposeful sample of 10 women and 2 men of various ages, recruited from a local patient organization, assumed to have a special awareness for quality care. RESULTS: CFS patients said that lack of acknowledgement could be even worse than the symptoms. They wanted their doctors to ask questions, listen to them and take them seriously, instead of behaving degrading. Many participants felt that the doctors psychologized too much, or trivialized the symptoms. Participants described how doctors' lack of knowledge about the condition would lead to long-term uncertainty or maltreatment. Even with doctors who were supportive, it would usually take months and sometimes years until a medical conclusion would be reached, or other disorders were ruled out. Increased physical activity had been recommend, but most of the informants experienced that this made them worse. CONCLUSION: Current medical scepticism and ignorance regarding CFS shapes the context of medical care and the illness experiences of CFS patients, who may feel they neither get a proper assessment nor management. PRACTICE IMPLICATIONS: CFS patients' reports about patronizing attitudes and ignorance among doctors call for development of evidence based strategies and empowerment of patients, acknowledging the patients'

				understanding of symptoms and the complex nature of the disease. The NICE guidelines emphasize the need of patient participation and shared decision-making.
Gimsing P, Hansen M, Knudsen LM, Knoblauch P, Christensen IJ, Ooi CE, Buhl-Jensen P.	Department of Hematology, Finsen Center, University Hospital Rigshospitalet, Copenhagen, Denmark. peter.gimsing@rh.regionh.dk	A phase I clinical trial of the histone deacetylase inhibitor belinostat in patients with advanced hematological neoplasia.	Eur J Haematol. 2008 Sep;81(3):170-6. Epub 2008 May 27.	PURPOSE: To determine the safety, dose-limiting toxicity and maximum tolerated dose (MTD) of the novel hydroxamate histone deacetylase inhibitor belinostat (PXD101) in patients with advanced hematological neoplasms. PATIENTS AND METHODS: Sequential dose-escalating cohorts of three to six patients with hematological malignancies received belinostat administered as a 30-min i.v. infusion on days 1-5 of a 21-d cycle. Experience from a parallel dose-finding study in patients with solid tumors influenced the selection of the final dose. RESULTS: Sixteen patients received belinostat at one of three dose levels: 600 mg/m(2)/d (three patients), 900 mg/m(2)/d (three patients) and 1000 mg/m(2)/d (10 patients), the dose determined to be the MTD in a phase I solid tumor study [Steele et al. (2008) Clin Cancer Res, 14, 804-10]. The most common treatment-related adverse events (all grades) were nausea (50%), vomiting (31%), fatigue (31%) and flushing (31%). No grade 3 or 4 hematological toxicity compared with baseline occurred except one case of grade 3 lymphopenia. There were two related grade 4 adverse events of renal failure observed. Both events occurred in patients with multiple myeloma and had similar characteristics, i.e. an acute episode of decrease in renal function (pre-existing nephropathy in one patient), with a metabolic profile and decrease in tumor burden consistent with tumor lysis syndrome. No other related grade 4 events were noted. The only related grade 3 events noticed in more than one patient were fatigue and neurological symptoms (one patient had status epilepticus in association with uremia and one patient had paresthesia), all other related grade 3 events occurred in single patients. No cardiac events were noted. No complete or partial remissions were noted in these heavily pre-treated (median of four prior regimens) patients. However, five patients, including two patients with diffuse large-cell lymphoma [including one patient with transformed chronic myelocytic leukaemia (CLL)], two patients with CLL and one patient with multiple myeloma, achieved disease stabilization in of two to nine treatment cycles. CONCLUSIONS: Intravenous belinostat at 600, 900 and 1000 mg/m(2)/d is well tolerated by patients with hematological malignancies. The study was carried out in parallel to a similar dose-finding study in patients with solid tumors, in which the MTD was determined to be 1000 mg/m(2)/d days 1-5 in a 21-d cycle. This dose can also be recommended for phase II studies in patients with hematological neoplasms.
Goedendorp MM, Knoop H, Schippers GM, Bleijenberg G.	Expert Centre for Chronic Fatigue, Radboud University Nijmegen Medical Centre, Nijmegen, the Netherlands.	The lifestyle of patients with chronic fatigue syndrome and the effect on fatigue and functional impairments.	J Hum Nutr Diet. 2009 Feb 13. [Epub ahead of print]	Abstract Background: Little is known about the lifestyle of patients with chronic fatigue syndrome (CFS) and its influence on symptoms of CFS. The present study aimed to investigate the lifestyle of patients with CFS, and to assess whether lifestyle factors are related to fatigue and functional impairments. Methods: Two hundred and forty-seven patients fulfilling the Center for Disease Control criteria for CFS were included. Validated questionnaires were used to collect data on lifestyle factors, smoking, intake of alcohol, fat, fibres, fruit and vegetables, body mass index (BMI), fatigue severity and functional impairments. Results: Of the CFS patients, 23% smoked, 32% had an unhealthy BMI, and none had an unhealthy alcohol intake. A majority had an unhealthy food intake: 70% had unhealthy fat, fruit and vegetable intake, and 95% had unhealthy fibre intake. Compared with the general Dutch population, significantly fewer CFS patients were overweight. Significantly more female CFS patients abstained from alcohol, and fewer male CFS patients smoked. Unhealthy lifestyle factors

				were not significantly associated with fatigue severity or functional impairments. Conclusions: CFS patients tend to lead a healthier lifestyle compared to the general Dutch population. However, no relationship was found between lifestyle factors and fatigue severity and functional impairments in CFS.
Griffith JP, Zarrouf FA.	Internal Medicine/Psychiatry Residency Program, West Virginia University, Charleston.	A Systematic Review of Chronic Fatigue Syndrome: Don't Assume It's Depression.	Prim Care Companion J Clin Psychiatry. 2008;10(2):120-8.	Objective: Chronic fatigue syndrome (CFS) is characterized by profound, debilitating fatigue and a combination of several other symptoms resulting in substantial reduction in occupational, personal, social, and educational status. CFS is often misdiagnosed as depression. The objective of this study was to evaluate and discuss different etiologies, approaches, and management strategies of CFS and to present ways to differentiate it from the fatigue symptom of depression.Data Sources: A MEDLINE search was conducted to identify existing information about CFS and depression using the headings chronic fatigue syndrome AND depression. The alternative terms major depressive disorder and mood disorder were also searched in conjunction with the term chronic fatigue syndrome. Additionally, MEDLINE was searched using the term chronic fatigue. All searches were limited to articles published within the last 10 years, in English. A total of 302 articles were identified by these searches. Also, the term chronic fatigue syndrome was searched by itself. This search was limited to articles published within the last 5 years, in English, and resulted in an additional 460 articles. Additional publications were identified by manually searching the reference lists of the articles from both searches.Study Selection and Data Extraction: CFS definitions, etiologies, differential diagnoses (especially depression) and management strategies were extracted, reviewed, and summarized to meet the objectives of this article.Data Synthesis: CFS is underdiagnosed in more than 80% of the people who have it; at the same time, it is often misdiagnosed as depression. Genetic, immunologic, infectious, metabolic, and neurologic etiologies were suggested to explain CFS. A biopsychosocial model was suggested for evaluating, managing, and differentiating CFS from depression.Conclusions: Evaluating and managing chronic fatigue is a challenging situation for physicians, as it is a challenging and difficult condition for patients. A biopsychosocial approach in the evaluation and management is recommended. More studies about CFS manifestations, evaluation, and management are needed.
Grinde B.	National Institute of Public Health, P.O. Box 4404, Nydalen, 0403 Oslo, Norway.	Is chronic fatigue syndrome caused by a rare brain infection of a common, normally benign virus?	Med Hypotheses. 2008;71(2):270-4. Epub 2008 Apr 25.	Chronic fatigue syndrome (CFS) is a disabling disease of unknown aetiology. A variety of factors have been suggested as possible causes. Although the symptoms and clinical findings are heterogeneous, the syndrome is sufficiently distinct, at least in relation to the more obvious cases, that a common explanation seems likely. In this paper, it is proposed that the disease is caused by a ubiquitous, but normally benign virus, e.g., one of the circoviruses. Circoviruses are chronically present in a majority of people, but are rarely tested for diagnostically. Normally these viruses do not penetrate the blood-brain barrier, but exceptions have been reported, and related viruses cause disease in the central nervous system of animals. The flu-like illness that often precedes the onset of CFS may either suppress immune function, causing an increased viremia, and/or lower the blood-brain barrier. In both cases the result may be that a virus already present in the blood enters the brain. It is well known that zoonotic viruses typically are more malignant than viruses with a long history of host-virus evolution. Similarly, a virus reaching an unfamiliar organ may cause particular problems.
Grossi ML, Goldberg MB,	Faculty of Dentistry, Catholic	Irritable bowel syndrome patients	Int J Prosthodont. 2008 May-	PURPOSE: This study aimed to assess the use of neuropsychologic tests as a tool to differentiate, or not, between a nonresponding chronic pain condition of nonmuscular origin, irritable bowel syndrome

Locker D, Tenenbaum HC.	University of Rio Grande do Sul, Brazil. mlgrossi@pucrs.br	versus responding and nonresponding temporomandibular disorder patients: a neuropsychologic profile comparative study.	Jun;21(3):201-9.	(IBS) (n = 20), versus 2 pain conditions of muscular origin, responding (n = 36) and nonresponding (n = 24) temporomandibular disorders. MATERIALS AND METHODS: The neuropsychologic tests used were the simple and multiple-choice reaction-time tests, California Verbal Learning Tests, the Brown-Peterson Consonant Trigram Auditory Memory Test, Sleep Assessment Questionnaire, and Beck Depression Inventory, as well as fatigue and energy level assessments (100-mm visual analog scale). RESULTS: Most of the tests used were capable of significantly differentiating between responding TMD versus IBS patients. Conversely, no statistically significant difference was found between nonresponding TMD versus IBS patients. Overall, the nonresponding TMD and IBS groups did worse in the neuropsychologic assessment than the responding TMD group, with higher memory deficits, levels of depression and fatigue, more sleep disturbances, and lower energy levels. CONCLUSIONS: These data suggested that 2 nonresponding chronic pain conditions of different origins may share similar neuropsychologic test results compared to a responding condition. These findings are consistent with the hypothesis that nonresponding chronic pain disorders, irrespective of peripheral location, may be regulated centrally and have similar neuropsychologic impacts.
Gupta A, Vij G, Sharma S, Tirkey N, Rishi P, Chopra K.	Pharmacology Division, University Institute of Pharmaceutical Sciences, Panjab University, Chandigarh 160014, India.	Curcumin, a polyphenolic antioxidant, attenuates chronic fatigue syndrome in murine water immersion stress model.	Immunobiology. 2009;214(1):33-9. Epub 2008 Jun 17.	Chronic fatigue syndrome, infection and oxidative stress are interrelated in epidemiological case studies. However, data demonstrating scientific validation of epidemiological claims regarding effectiveness of nutritional supplements for chronic fatigue syndrome are lacking. This study is designed to evaluate the effect of natural polyphenol, curcumin, in a mouse model of immunologically induced fatigue, where purified lipopolysaccharide (LPS) and Brucella abortus (BA) antigens were used as immunogens. The assessment of chronic fatigue syndrome was based on chronic water-immersion stress test for 10 min daily for 19 days and the immobility time was taken as the marker of fatigue. Mice challenged with LPS or BA for 19 days showed significant increase in the immobility time and hyperalgesia on day 19, as well as marked increase in serum tumor necrosis factor-alpha (TNF-alpha) levels. Concurrent treatment with curcumin resulted in significantly decreased immobility time as well as hyperalgesia. There was significant attenuation of oxidative stress as well as TNF-alpha levels. These findings strongly suggest that during immunological activation, there is significant increase in oxidative stress and curcumin can be a valuable option in the treatment of chronic fatigue syndrome.
Gur A, Oktayoglu P.	Department of Physical Medicine and Rehabilitation, Medical Faculty, Dicle University, 21280 Diyarbakir, Turkey. alig@dicle.edu.tr	Central nervous system abnormalities in fibromyalgia and chronic fatigue syndrome: new concepts in treatment.	Curr Pharm Des. 2008;14(13):1274-94.	Fibromyalgia (FM) and chronic fatigue syndrome (CFS) are poorly understood disorders that share similar demographic and clinical characteristics. The etiology and pathophysiology of these diseases remain unclear. Because of the similarities between both disorders it was suggested that they share a common pathophysiological mechanisms, namely, central nervous system (CNS) dysfunction. Current hypotheses center on atypical sensory processing in the CNS and dysfunction of skeletal muscle nociception and the hypothalamic-pituitary-adrenal (HPA) axis. Researches suggest that the (CNS) is primarily involved in both disorders in regard to the pain, fatigue and sleep disturbances. Many patients experience difficulty with concentration and memory and many others have mood disturbance, including depression and anxiety. Although fibromyalgia is common and associated with substantial morbidity and disability, there are no US Food and Drug Administration (FDA)-approved treatments except pregabalin. Recent pharmacological treatment studies about fibromyalgia have focused on selective serotonin and norepinephrine (NE) reuptake inhibitors, which enhance serotonin and NE neurotransmission in the descending pain pathways and lack many of the adverse side effects

				associated with tricyclic medications. CFS is a descriptive term used to define a recognisable pattern of symptoms that cannot be attributed to any alternative condition. The symptoms are currently believed to be the result of disturbed brain function. To date, no pharmacological agent has been reliably shown to be effective treatment for CFS. Management strategies are therefore primarily directed at relief of symptoms and minimising impediments to recovery. This chapter presents data demonstrating CFS, abnormal pain processing and autonomic nervous system (ANS) dysfunction in FM and CFS and concludes by reviewing the new concepts in treatments in CFS and FM.
Hadlandsmyth K, Vowles KE.	Bath and Wiltshire Adult Chronic Fatigue Syndrome Service, Royal National Hospital for Rheumatic Diseases, Bath, UK. kehb8c@umsl.edu	Does depression mediate the relation between fatigue severity and disability in chronic fatigue syndrome sufferers?	J Psychosom Res. 2009 Jan;66(1):31-5. Epub 2008 Nov 22.	OBJECTIVE: Chronic fatigue syndrome (CFS) is often associated with significant levels of disability. Although fatigue and depression have been found to be independently related to severity of disability, it is not clear how these three factors are mutually related. The present study sought to address this issue by specifically testing a model of mediation whereby depression was hypothesized to influence relations between fatigue and disability. METHODS: Participants included 90 individuals seeking treatment for CFS at a tertiary care facility. Each provided demographic information and completed standardized measures of depression and fatigue severity, as well as a measure of disability, which assessed difficulties in physical, psychosocial, and independence domains. RESULTS: Analyses indicated that depression and fatigue were positively correlated with one another, as well as all three disability domains. Analyses of mediation indicated that depression completely mediated the relation between fatigue and psychosocial disability and partially mediated the relation between fatigue and the other two disability domains. Indirect effects tests indicated that the inclusion of depression in the statistical models was statistically meaningful. CONCLUSIONS: These results replicate previous findings that fatigue and depression are independently related to disability in those with CFS. A more complex statistical model, however, suggested that depression severity substantially influenced the strength of the relation between fatigue and disability levels across a range of domains, including complete mediation in areas involving psychosocial functioning. These results may aid in clarifying contemporary conceptualizations of CFS and provide guidance in the identification of appropriate treatment targets.
Haig-Ferguson A, Tucker P, Eaton N, Hunt L, Crawley E.	University of Bristol, United Kingdom.	Memory and attention problems in children with CFS/ME.	Arch Dis Child. 2008 Nov 11. [Epub ahead of print]	OBJECTIVE: To understand more about the problems children with CFS/ME experience with their memory and attention, and to test the feasibility of quantitative measurement of both memory and attention. DESIGN: 4 item semi-structured questionnaire and Neuropsychological test battery with 10 psychometric subtests. SETTING: Family home of the child taking part. Patients: 20 children with a diagnosis of CFS/ME and experiencing memory and/or concentration problems were recruited between April and October 2007 from a regional CFS/ME clinical service (Female=13; Average age 13.5yrs; Range 8 - 16 yrs). METHODS: Each child, parent and teacher was asked to describe the child's memory and attention problems. Responses were subject to thematic analysis by two independent researchers. In addition each child completed a battery of 10 tests to measure: Processing speed; Attention; Immediate and Delayed Memory; Working Memory; Executive Function. Raw scores were converted into age-scaled scores and the children's psychometric scores on the 10 tests taken were compared with normative data using t-tests. RESULTS: Children with CFS/ME, their parents and teachers described problems with focussed attention, sustained attention, recall and stress. Children's scores were compared to normative data. Scores for sustained attention (mean 8.1, 95% CI 6.3-9.9),

				switching attention (7.5, 5.5-9.4), divided attention (6.9, 5.5-8.2), auditory learning (8.2, 6.8-9.6) and immediate recall (8.7, 7.3-10.0) appeared lower than the normative mean of 10. CONCLUSIONS: Children with CFS/ME appear to experience problems with attention, which may have adverse implications for verbal memory. These cognitive problems may explain some of the educational difficulties associated with Chronic Fatigue Syndrome.
Hamilton NA, Affleck G, Tennen H, Karlson C, Luxton D, Preacher KJ, Templin JL.	Department of Psychology, University of Kansas, USA. nancyh@ku.edu	Fibromyalgia: the role of sleep in affect and in negative event reactivity and recovery.	Health Psychol. 2008 Jul;27(4):490-7.	OBJECTIVE: Fibromyalgia (FM) syndrome is a chronic pain condition characterized by diffuse muscle pain, increased negative mood, and sleep disturbance. Until recently, sleep disturbance in persons with FM has been modeled as the result of the disease process or its associated pain. The current study examined sleep disturbance (i.e., sleep duration and sleep quality) as a predictor of daily affect, stress reactivity, and stress recovery. DESIGN AND MEASURES: A hybrid of daily diary and ecological momentary assessment methodology was used to evaluate the psychosocial functioning of 89 women with FM. Participants recorded numeric ratings of pain, fatigue, and positive and negative affect 3 times throughout the day for 30 consecutive days. At the end of each day, participants completed daily diary records of positive and negative life events. In addition, participants reported on their sleep duration and sleep quality each morning. RESULTS: After accounting for the effects of positive events, negative events, and pain on daily affect scores, it was found that sleep duration and quality were prospectively related to affect and fatigue. Furthermore, the effects of inadequate sleep on negative affect were cumulative. In addition, an inadequate amount of sleep prevented affective recovery from days with a high number of negative events. CONCLUSIONS: These results lend support to the hypothesis that sleep is a component of allostatic load and has an upstream role in daily functioning. Harvey SB, Wadsworth M, Wessely S, Hotopf M.	Institute of Psychiatry, King's College London, London, UK. s.harvey@iop.kcl.ac.uk	Etiology of chronic fatigue syndrome: testing popular hypotheses using a national birth cohort study.	Psychosom Med. 2008 May;70(4):488-95. Epub 2008 Mar 31.	OBJECTIVE: To review the etiology of chronic fatigue syndrome (CFS) and test hypotheses relating to immune system dysfunction, physical deconditioning, exercise avoidance, and childhood illness experiences, using a large prospective birth cohort. METHODS: A total of 4779 participants from the Medical Research Council's National Survey of Health and Development were prospectively followed for the first 53 years of their life with >20 separate data collections. Information was collected on childhood and parental health, atopic illness, levels of physical activity, fatigue, and participant's weight and height at multiple time points. CFS was identified through self-report during a semistructured interview at age 53 years with additional case notes review. RESULTS: Of 2983 participants assessed at age 53 years, 34 (1.1%, 95% Confidence Interval 0.8-1.5) reported a diagnosis of CFS. Those who reported CFS were no more likely to have suffered from childhood illness or atopy. Increased levels of exercise throughout childhood and early adult life and a lower body mass index were associated with an increased risk of later CFS. Participants who later reported CFS continued to exercise more frequently even after they began to experience early symptoms of fatigue. CONCLUSIONS: Individuals who exercise frequently are more likely to report a diagnosis of CFS in later life. This may be due to the direct effects of this behavior or associated personality factors. Continuing to be active despite increasing fatigue may be a crucial step in the development of CFS.

Häuser W, Akritidou I, Felde E, Klauenberg S, Maier C, Hoffmann A, Köllner V, Hinz A.	Zentrum für Schmerztherapie/Innere Medizin I (Gastroenterologie, Hepatologie, Stoffwechsel- und Infektionskrankheiten, Psychosomatik), Klinikum Saarbrücken gGmbH, Winterberg 1, 66119, Saarbrücken. whaeuser@klinikum-saarbruecken.de	[Steps towards a symptom-based diagnosis of fibromyalgia syndrome. Symptom profiles of patients from different clinical settings] [Article in German]	Z Rheumatol. 2008 Oct;67(6):511-5.	BACKGROUND: A symptom-based diagnosis of fibromyalgia syndrome (FMS) without tender point examination is helpful for primary medical care. We tested whether a symptom-based diagnosis of FMS can be based on the symptoms of musculoskeletal pain and fatigue. METHODS: The most frequent and severe symptoms in FMS patients from four different settings (n= 464 from a self-help organization, n=162 from medical expertise, n= 33 from a private rheumatology practice, n=36 from a tertiary-care pain department) were assessed using the Giessen Subjective Complaints List GBB 24. The most frequent and severe symptoms were assessed and compared to those of a representative German population sample. A k-means cluster analysis was performed to identify sub-groups with and without additional vegetative symptoms within the total sample of FMS patients. RESULTS: The most frequent and severe symptoms in all four sub-samples were low back pain, limb pain and fatigue. The greatest mean differences between FMS patients and the general population were found in the subscales "limb pain" and "fatigue". Cluster analysis identified three sub-groups of patients which were all characterized by severe limb pain and fatigue, as well as varying degrees of vegetative symptoms. SUMMARY: Following the exclusion of inflammatory rheumatoid, endocrinological and neurological diseases, a symptom-based clinical diagnosis of FMS can be based on of the key symptoms of chronic widespread musculoskeletal pain, as well as chronic fatigue.
Häuser W, Bernardy K, Uçeyler N, Sommer C.	Department of Internal Medicine, Klinikum Saarbrücken, Winterberg 1, D-66119 Saarbrücken, Germany. whaeuser@klinikum-saarbruecken.de	Treatment of fibromyalgia syndrome with antidepressants: a meta-analysis.	JAMA. 2009 Jan 14;301(2):198-209.	CONTEXT: Fibromyalgia syndrome (FMS) is a chronic pain disorder associated with multiple debilitating symptoms and high disease-related costs. Effective treatment options are needed. OBJECTIVES: To determine the efficacy of antidepressants in the treatment of FMS by performing a meta-analysis of randomized controlled clinical trials. DATA SOURCES: MEDLINE, PsycINFO, Scopus, and the Cochrane Library databases were searched through August 2008. Reference sections of original studies, meta-analyses, and reviews on antidepressants in FMS were reviewed. STUDY SELECTION: Randomized placebo-controlled trials with tricyclic and tetracyclic antidepressants (TCAs), selective serotonin reuptake inhibitors (SSRIs), serotonin and noradrenaline reuptake inhibitors (SNRIs), and monoamine oxidase inhibitors (MAOIs) were analyzed. DATA EXTRACTION AND DATA SYNTHESIS: Two authors independently extracted data. Effects were summarized using standardized mean differences (SMDs) by a random-effects model. RESULTS: Eighteen randomized controlled trials (median duration, 8 weeks; range, 4-28 weeks) involving 1427 participants were included. Overall, there was strong evidence for an association of antidepressants with reduction in pain (SMD, -0.43; 95% confidence interval [CI], -0.55 to -0.30), fatigue (SMD, -0.13; 95% CI, -0.26 to -0.01), depressed mood (SMD, -0.26; 95% CI, -0.39 to -0.12), and sleep disturbances (SMD, -0.32; 95% CI, -0.46 to -0.18). There was strong evidence for an association of antidepressants with improved health-related quality of life (SMD, -0.31; 95% CI, -0.42 to -0.20). Effect sizes for pain reduction were large for TCAs (SMD, -1.64; 95% CI, -2.57 to -0.71), medium for MAOIs (SMD, -0.54; 95% CI, -1.02 to -0.07), and small for SSRIs (SMD, -0.39; 95% CI, -0.77 to -0.01) and SNRIs (SMD, -0.36; 95% CI, -0.46 to -0.25). CONCLUSION: Antidepressant medications are associated with improvements in pain, depression, fatigue, sleep disturbances, and health-related quality of life in patients with FMS.
Häuser W, Zimmer C, Felde E, Köllner	Zentrum für Schmerztherapie/I	[What are the key symptoms of	Schmerz. 2008 Apr;22(2):176-83.	INTRODUCTION: A new definition of fibromyalgia syndrome (FMS) based on symptoms and without tender points is discussed from a rheumatological viewpoint. METHODS: The German Fibromyalgia

V.	nnere Medizin I (Gastroenterologie, Hepatologie, Stoffwechsel- und Infektionskrankheiten, Psychosomatik), Klinikum Saarbrücken gGmbH, Winterberg 1, 66119, Saarbrücken, Germany. whaeuser@klinikum-saarbruecken.de	fibromyalgia? Results of a survey of the German Fibromyalgia Association] [Article in German]		Association (DFV) developed a questionnaire on potential symptoms in FM based on a list of symptoms established by members of the DFV. The questionnaire was sent to all 3,996 members of the DFV. RESULTS: Of the 753 questionnaires 699 were returned (95% women, most frequent age between 50-60 years) and evaluated. The rank order of the most frequent symptoms (>or=97% of the respondents) was muscle pain with varying locations, low back pain, fatigue, morning stiffness, non-restorative sleep, concentration problems, lack of energy, low productivity and forgetfulness. CONCLUSION: The key symptoms of FM are chronic widespread pain, non-restorative sleep and subjective disabilities. The frequency of general and extra-musculoskeletal symptoms underlines that FMS is more than just a "pain disorder".
Heim C, Nater UM, Maloney E, Boneva R, Jones JF, Reeves WC.	Department of Psychiatry and Behavioral Sciences, Emory University School of Medicine, Woodruff Memorial Research Bldg, Ste 4311, Atlanta, GA 30322, USA. cmheim@emory.edu	Childhood trauma and risk for chronic fatigue syndrome: association with neuroendocrine dysfunction.	Arch Gen Psychiatry. 2009 Jan;66(1):72-80.	CONTEXT: Childhood trauma appears to be a potent risk factor for chronic fatigue syndrome (CFS). Evidence from developmental neuroscience suggests that early experience programs the development of regulatory systems that are implicated in the pathophysiology of CFS, including the hypothalamic-pituitary-adrenal axis. However, the contribution of childhood trauma to neuroendocrine dysfunction in CFS remains obscure. OBJECTIVES: To replicate findings on the relationship between childhood trauma and risk for CFS and to evaluate the association between childhood trauma and neuroendocrine dysfunction in CFS. Design, Setting, and PARTICIPANTS: A case-control study of 113 persons with CFS and 124 well control subjects identified from a general population sample of 19 381 adult residents of Georgia. MAIN OUTCOME MEASURES: Self-reported childhood trauma (sexual, physical, and emotional abuse; emotional and physical neglect), psychopathology (depression, anxiety, and posttraumatic stress disorder), and salivary cortisol response to awakening. RESULTS: Individuals with CFS reported significantly higher levels of childhood trauma and psychopathological symptoms than control subjects. Exposure to childhood trauma was associated with a 6-fold increased risk of CFS. Sexual abuse, emotional abuse, and emotional neglect were most effective in discriminating CFS cases from controls. There was a graded relationship between exposure level and CFS risk. The risk of CFS conveyed by childhood trauma further increased with the presence of posttraumatic stress disorder symptoms. Only individuals with CFS and with childhood trauma exposure, but not individuals with CFS without exposure, exhibited decreased salivary cortisol concentrations after awakening compared with control subjects. CONCLUSIONS: Our results confirm childhood trauma as an important risk factor of CFS. In addition, neuroendocrine dysfunction, a hallmark feature of CFS, appears to be associated with childhood trauma. This possibly reflects a biological correlate of vulnerability due to early developmental insults. Our findings are critical to inform pathophysiological research and to devise targets for the prevention of CFS.
Hickie I,	Brain and Mind	Are chronic fatigue	Aust N Z J	OBJECTIVE: The validity of the diagnosis of chronic fatigue syndrome and related chronic fatigue states

Davenport T, Vernon SD, Nisenbaum R, Reeves WC, Hadzi-Pavlovic D, Lloyd A; International Chronic Fatigue Syndrome Study Group. Collaborators: Bleijenberg G, van der Werf SP, Prins JB, Blenkiron PM, Buchwald D, Smith WR, Edwards R, Lynch S, Kirmayer LJ, Taillefer SS, Lee S, Martin NG, Gillespie NA, McIlvenny S, Sartorius N, Ustun TB, Skapinakis P, Wessely S, Chalder T, Hotopf M, Nimnuan C, Candy B, Darbishire L, Ridsdale L, White PD, Thomas JM, Wilhelm K, Wilson A.	Research Institute, Camperdown, NSW, Australia. ianh@med.usyd.edu.au	and chronic fatigue syndrome valid clinical entities across countries and health-care settings?	Psychiatry. 2009 Jan;43(1):25-35.	remains controversial, particularly in psychiatry. This project utilized international epidemiological and clinical research data to test construct validity across diagnostic categories, health-care settings and countries. Relevant demographic, symptom and diagnostic data were obtained from 33 studies in 21 countries. The subjects had fatigue lasting 1-6 months (prolonged fatigue), or >6 months (chronic fatigue), or met diagnostic criteria for chronic fatigue syndrome. METHOD: Common symptom domains were derived by factor analytic techniques. Mean scores on each symptom factor were compared across diagnostic categories, health-care settings and countries. RESULTS: Data were obtained on 37,724 subjects (n = 20,845 female, 57%), including from population-based studies (n = 15,749, 42%), studies in primary care (n = 19 472, 52%), and secondary or specialist tertiary referral clinics (n = 2503, 7%). The sample included 2013 subjects with chronic fatigue, and 1958 with chronic fatigue syndrome. A five-factor model of the key symptom domains was preferred ('musculoskeletal pain/fatigue', 'neurocognitive difficulties', 'inflammation', 'sleep disturbance/fatigue' and 'mood disturbance') and was comparable across subject groups and settings. Although the core symptom profiles were similar, some differences in symptoms were observed across diagnostic categories, health-care settings and between countries. CONCLUSIONS: The construct validity of chronic fatigue and chronic fatigue syndrome is supported by an empirically derived factor structure from existing international datasets.
Higashimoto T, Baldwin EE, Gold JI, Boles RG.	Division of Medical Genetics and the Saban Research Institute, Childrens Hospital Los Angeles, Los Angeles, California, USA.	Reflex sympathetic dystrophy: complex regional pain syndrome type I in children with mitochondrial disease and maternal inheritance.	Arch Dis Child. 2008 May;93(5):390-7. Epub 2008 Jan 11.	OBJECTIVE: Complex regional pain syndrome type I (CRPS-I), previously known as reflex sympathetic dystrophy (RSD), is an idiopathic condition characterised by localised, abnormally intense and prolonged pain, allodynia and autonomic nervous system changes (ie, swelling, skin colour and temperature changes and altered perspiration) that usually appear following a "noxious" trigger such as trauma or surgery. The objective of this report is to demonstrate that children with CRPS-I can have additional dysautonomic conditions secondary to an underlying maternally inherited mitochondrial disease, an association not previously published. METHODS: Medical records of about 500 patients seen by one paediatric metabolic geneticist were reviewed to identify children meeting established CRPS diagnostic criteria. RESULTS: CRPS-I was present in eight children in seven families, each of which also had additional functional/dysautonomic conditions, the most common (> or = 4 cases per

				condition) being gastrointestinal dysmotility, migraine, cyclic vomiting and chronic fatigue. All seven probands studied met Nijmegen (2002) diagnostic criteria for definite mitochondrial disease on the basis of the clinical signs and symptoms and biochemical analyses. Six of the seven families met our pedigree-based criteria for probable maternal inheritance. CONCLUSION: In one tertiary-care paediatric genetics practice, children meeting the CRPS-I diagnostic criteria frequently had additional autonomic-related conditions secondary to maternally inherited mitochondrial disease, suggesting that mitochondrial DNA sequence variants can predispose children towards the development of CRPS-I and other dysautonomias. CRPS-I should be considered in patients with mitochondrial disease who complain of idiopathic pain. Maternally inherited mitochondrial disease may not be a rare cause of CRPS-I, especially in children who present with other manifestations of dysautonomia.
Hoad A, Spickett G, Elliott J, Newton J.	Northern CFS/ME Clinical Network, Equinox House, Silver Fox Way, Cobalt Business Park, Newcastle upon Tyne.	Postural orthostatic tachycardia syndrome is an under-recognized condition in chronic fatigue syndrome.	QJM. 2008 Dec;101(12):961-5. Epub 2008 Sep 19.	BACKGROUND: It has been suggested that postural orthostatic tachycardia syndrome (POTS) be considered in the differential diagnosis of those with chronic fatigue syndrome/myalgic encephalomyelitis (CFS/ME). Currently, measurement of haemodynamic response to standing is not recommended in the UK NICE CFS/ME guidelines. OBJECTIVES: To determine prevalence of POTS in patients with CFS/ME. DESIGN: Observational cohort study. METHODS: Fifty-nine patients with CFS/ME (Fukuda criteria) and 52 age- and sex-matched controls underwent formal autonomic assessment in the cardiovascular laboratory with continuous heart rate and beat-to-beat blood pressure measurement (Task Force, CNSystems, Graz Austria). Haemodynamic responses to standing over 2 min were measured. POTS was defined as symptoms of orthostatic intolerance associated with an increase in heart rate from the supine to upright position of >30 beats per minute or to a heart rate of >120 beats per minute on standing. RESULTS: Maximum heart rate on standing was significantly higher in the CFS/ME group compared with controls (106 +/- 20 vs. 98 +/- 13; P = 0.02). Of the CFS/ME group, 27% (16/59) had POTS compared with 9% (5) in the control population (P = 0.006). This difference was predominantly related to the increased proportion of those in the CFS/ME group whose heart rate increased to >120 beats per minute on standing (P = 0.0002). Increasing fatigue was associated with increase in heart rate (P = 0.04; r(2) = 0.1). CONCLUSION: POTS is a frequent finding in patients with CFS/ME. We suggest that clinical evaluation of patients with CFS/ME should include response to standing. Studies are needed to determine the optimum intervention strategy to manage POTS in those with CFS/ME.
Hobday RA, Thomas S, O'Donovan A, Murphy M, Pinching AJ.	Infection and Immunity Speciality Group, St Bartholomew's Hospital, West Smithfield, London, UK. rhonahobday@yahoo.co.uk	Dietary intervention in chronic fatigue syndrome.	J Hum Nutr Diet. 2008 Apr;21(2):141-9.	BACKGROUND: Anecdotal reports and books have been published linking an over growth of Candida Albicans with chronic fatigue syndrome (CFS), suggesting dietary change as a treatment option. Little scientific data has been published to validate this controversial theory. This study aims to determine the efficacy of dietary intervention on level of fatigue and quality of life (QoL) in individuals with CFS. METHODS: A 24-week randomized intervention study was conducted with 52 individuals diagnosed with CFS. Patients were randomized to either a low sugar low yeast (LSLY) or healthy eating (HE) dietary interventions. Primary outcome measures were fatigue as measured by the Chalder Fatigue Score and QoL measured by Medical Outcomes Survey Short Form-36. RESULTS: A high drop out rate occurred with 13 participants not completing the final evaluation (7HE/6LSLY). Intention to treat analysis showed no statistically significant differences on primary outcome measurements. CONCLUSION: In this randomized control trial, a LSLY diet appeared to be no more efficacious on

				levels of fatigue or QoL compared to HE. Given the difficulty with dietary compliance experienced by participants, especially in the LSLY group, it would appear HE guidance is a more pragmatic approach than advocating a complicated dietary regime.
Hokama Y, Empey-Campora C, Hara C, Higa N, Siu N, Lau R, Kuribayashi T, Yabusaki K.	Department of Pathology, University of Hawaii-Manoa, Honolulu, HI 96822, USA. yoshitsu@hawaii.edu	Acute phase phospholipids related to the cardiolipin of mitochondria in the sera of patients with chronic fatigue syndrome (CFS), chronic Ciguatera fish poisoning (CCFP), and other diseases attributed to chemicals, Gulf War, and marine toxins.	J Clin Lab Anal. 2008;22(2):99-105.	This study examined 328 CFS sera in a study with 17 CCFP, 8 Gulf War Veterans (GWV), 24 Prostate Cancer (PC), and 52 normal sera in the modified Membrane Immunobead Assay (MIA) procedure for CTX. Three hundred and twenty-eight CFS patients' sera were examined by the modified MIA with purified MAb-CTX and 91.2% gave a titre > or =1:40. 76% of the 17 CCFP sera samples and 100% of the 8 GWV sera samples also had a titre > or =1:40. 92.3% of 52 normal sera showed titres of 1:20 or less, while 4 gave titres of > or =1:40. In addition, 41 sera were examined for Anti-Cardiolipin (aCL) by a commercial ELISA procedure with 87.8% demonstrating IgM, IgM+IgA, or IgM+IgG aCL antibodies. These results showed mostly the IgM aCL antibody alone in the sera samples. In addition, 41 serum samples were examined for aCL, with 37 showing positive for aCL, representing 90.2% positive for the three disease categories examined: CFS, CCFP and GWV. Examination for antiMitochondrial-M2 autoantibody (aM-M2) in 28 patients (CFS (18), CCFP (5), and GWV (5)) was negative for aM-M2. Inhibition analysis with antigens, CTX, CFS "Acute Phase Lipids", commercial Cardiolipin (CL) and 1,2-Dipalmitoyl-sn-Glycero-3-[Phospho-L-Serine] (PS) and antibodies, MAb-CTX and aCL from patients' serum show that the phospholipids in CL and CTX are antigenically indistinguishable with antibodies MAb-CTX and CFS-aCL. Preliminary chemical analyses have shown the lipids to be phospholipids associated with CL of the mitochondria. We designate this "Acute Phase Lipid" comparable to "Acute Phase Proteins" (C-reactive protein (CRP) and Serum Amyloid A (SAA)) in inflammatory conditions. (Copyright) 2008 Wiley-Liss, Inc.
Hollingsworth KG, Newton JL, Taylor R, McDonald C, Palmer JM, Blamire AM, Jones DE.	Newcastle Magnetic Resonance Centre, Newcastle University, Newcastle-upon-Tyne, United Kingdom.	Pilot study of peripheral muscle function in primary biliary cirrhosis: potential implications for fatigue pathogenesis.	Clin Gastroenterol Hepatol. 2008 Sep;6(9):1041-8. Epub 2008 Aug 8.	BACKGROUND & AIMS: Primary biliary cirrhosis (PBC) is characterized in 95% of patients by autoantibody responses directed against the mitochondrial antigen pyruvate dehydrogenase complex (PDC). Although anti-PDC inhibits PDC function in vitro, mitochondrial function in vivo in PBC has not been examined. METHODS:(31)P magnetic resonance spectroscopy was performed in PBC patients (n = 15) and fatigued (chronic fatigue syndrome/myalgic encephalomyelitis, n = 8), cholestatic (primary sclerosing cholangitis [PSC], n = 4), and normal (n = 8) controls to define mitochondrial function and pH regulation in peripheral muscle during exercise at 25% and 35% of maximum voluntary contraction. RESULTS: Normal, chronic fatigue syndrome/myalgic encephalomyelitis, and PSC subjects all showed close correlation between kinetics of adenosine diphosphate (ADP) and phosphocreatine (PCr) recovery after low-impact exercise, reflecting the normal tight regulation of PCr "response" by mitochondria to ADP "drive." This relationship was lost in PBC patients, indicating mitochondrial dysfunction (normal r(2) = 0.78, P < .005; PBC r(2) = 0.007, P = ns). Ratio between PCr and ADP recovery half-times (constant in controls, indicating normal mitochondrial responsivity) was significantly elevated in PBC patients (but not PSC) and was associated with anti-PDC levels. At higher levels of exercise PBC (but not PSC) patients showed excess muscle acidosis, with pH correlating with elevation of PCr/ADP recovery ratio, indicating a link to mitochondrial dysfunction. PBC patients alone also showed significant prolongation of muscle pH recovery time after exercise (unrelated to mitochondrial function), which correlated with clinical fatigue. CONCLUSIONS: PBC patients exhibit a variable degree of muscle mitochondrial dysfunction that manifests as excess acidosis after exercise.

				The extent to which patients can recover rapidly from acidosis appears to determine whether they are clinically fatigued.
Hou R, Moss-Morris R, Bradley BP, Peveler R, Mogg K.	School of Medicine, University of Southampton, Southampton, United Kingdom.	Attentional bias towards health-threat information in chronic fatigue syndrome.	J Psychosom Res. 2008 Jul;65(1):47-50.	OBJECTIVE: To investigate whether individuals with chronic fatigue syndrome (CFS) show an attentional bias towards health-threat information. METHODS: Attentional bias (AB) was assessed in individuals with CFS and healthy controls using a visual probe task which presented health-threat and neutral words and pictures for 500 ms. Self-report questionnaires were used to assess CFS symptoms, depression, anxiety, and social desirability. RESULTS: Compared to a healthy control group, the CFS group showed an enhanced AB towards heath-threat stimuli relative to neutral stimuli. The AB was not influenced by the type of stimulus (pictures vs. words). CONCLUSION: The finding of an AB towards health-threat information in individuals with CFS is supportive of models of CFS which underlie cognitive behavior therapy.
Houdenhove BV, Eede FV, Luyten P.	Department of Liaison Psychiatry, University Hospitals K.U. Leuven, Herestraat 49, B-3000 Leuven, Belgium.	Does hypothalamic-pituitary-adrenal axis hypofunction in chronic fatigue syndrome reflect a 'crash' in the stress system?	Med Hypotheses. 2009 Feb 21. [Epub ahead of print]	The etiopathogenesis of chronic fatigue syndrome (CFS) remains poorly understood. Although neuroendocrine disturbances - and hypothalamic-pituitary-adrenal (HPA) axis hypofunction in particular - have been found in a large proportion of CFS patients, it is not clear whether these disturbances are cause or consequence of the illness. After a review of the available evidence we hypothesize that that HPA axis hypofunction in CFS, conceptualized within a system-biological perspective, primarily reflects a fundamental and persistent dysregulation of the neurobiological stress system. As a result, a disturbed balance between glucocorticoid and inflammatory signaling pathways may give rise to a pathological cytokine-induced sickness response that may be the final common pathway underlying central CFS symptoms, i.e. effort/stress intolerance and pain hypersensitivity. This comprehensive hypothesis on HPA axis hypofunction in CFS may stimulate diagnostic refinement of the illness, inform treatment approaches and suggest directions for future research, particularly focusing on the neuroendocrine-immune interface and possible links between CFS, early and recent life stress, and depression.
Huang Y, Liao XM, Li XX, Song YB.	Southern Medical University, Guangzhou 510515, China.	Clinical observation on the effects of Bo's abdominal acupuncture in 40 cases of chronic fatigue syndrome.	J Tradit Chin Med. 2008 Dec;28(4):264-6.	OBJECTIVE: To observe the curative effect of Bo's abdominal acupuncture on chronic fatigue syndrome (CFS). METHODS: Forty cases with CFS were treated by Bo's abdominal acupuncture at the points for conducting qi back to its origin and 4 points on the abdomen once a day for 2 weeks. Scores for symptoms and scores for fatigue questionnaires were compared before and after treatment. RESULTS: After treatment, the clinical symptoms of patients were differently alleviated, and scores for symptoms, mental condition and neural feeling in questionnaires on fatigue were obviously reduced ($P<0.01$-0.05). CONCLUSION: Bo's abdominal acupuncture has a good curative effect on general disease with complex symptoms, especially on lassitude, anorexia, insomnia, amnesia, diarrhea, and general pain.
Jasiukeviciene L, Vasiliauskas D, Kavoliūniene A, Marcinkeviciene J, Grybauskiene R, Grizas V, Tumyniene V..	Institute of Cardiology, Kaunas University of Medicine, Lithuania. lina.jas@med.kmu.lt	[Evaluation of a chronic fatigue in patients with moderate-to-severe chronic heart failure] [Article in	Medicina (Kaunas). 2008;44(5):366-72.	THE AIM OF THE STUDY: To evaluate the chronic fatigue and its relation to the function of hypothalamus-pituitary-adrenal axis in patients with New York Heart Association (NYHA) functional class III-IV chronic heart failure. MATERIAL AND METHODS: A total of 170 patients with NYHA functional class III-IV chronic heart failure completed MFI-20L, DUFS, and DEFS questionnaires assessing chronic fatigue and underwent echocardiography. Blood cortisol concentration was assessed at 8:00 am and 3:00 pm, and plasma N-terminal brain natriuretic pro-peptide (NT-proBNP) concentration was measured at 8:00 am. Neurohumoral investigations were repeated before

		Lithuanian]		cardiopulmonary exercise test and after it. RESULTS: The results of all questionnaires showed that 100% of patients with NYHA functional class III-IV heart failure complained of chronic fatigue. The level of overall fatigue was 54.5+/-31.5 points; physical fatigue - 56.8+/-24.6 points. Blood cortisol concentration at 8:00 am was normal (410.1+/-175.1 mmol/L) in majority of patients. Decreased concentration was only in four patients (122.4+/-15.5 mmol/L); one of these patients underwent heart transplantation. In the afternoon, blood cortisol concentration was insufficiently decreased (355.6+/-160.3 mmol/L); reaction to a physical stress was attenuated (Delta 92.9 mmol/L). Plasma NT-proBNP concentration was 2188.9+/-1852.2 pg/L; reaction to a physical stress was diminished (Delta 490.3 pg/L). CONCLUSION: All patients with NYHA class III-IV heart failure complained of daily chronic fatigue. Insufficiently decreased blood cortisol concentration in the afternoon showed that in the presence of chronic fatigue in long-term cardiovascular organic disease, disorder of a hypothalamus-pituitary-adrenal axis is involved.
Jason L, Muldowney K, Torres-Harding S.	DePaul University, Chicago, IL, USA.	The Energy Envelope Theory and myalgic encephalomyelitis/ chronic fatigue syndrome.	AAOHN J. 2008 May;56(5):189-95. Erratum in: AAOHN J. 2008 Jul;56(7):288. Muldowney, Kathleen [added]; Torres-Harding, Susan [added].	Individuals with myalgic encephalomyelitis/chronic fatigue syndrome (ME/CFS) have little stamina and endurance, and pose a challenge for nursing professionals. The Energy Envelope Theory, which posits that maintaining expended energy levels consistent with available energy levels may reduce the frequency and severity of symptoms, is particularly useful when working with clients with ME/CFS. Anecdotal support from the client community for this theory supports its use as a management tool for ME/CFS, but little formal research has been done in this area. In this study, a daily energy quotient was established by dividing the expended energy level by the perceived energy level and multiplying by 100. It was predicted that those participants who expended energy beyond their level of perceived energy would have more severe fatigue and symptoms and lower levels of physical and mental functioning. Findings are congruent with the Energy Envelope Theory as they indicated that the daily energy quotient was related to several indices of functioning including depression, anxiety, fatigue, pain, quality of life, and disability. The overall results provide support for a strategy health care professionals can use when working with clients with ME/CFS.
Jason LA, Judith A. Richman		How Science Can Stigmatize: The Case of Chronic Fatigue Syndrome	Journal of Chronic Fatigue Syndrome 2008; 14 (4): 85-103	Objective: This article reviews issues involving the name of an illness, chronic fatigue syndrome (CFS), along with flawed epidemiologic approaches, which may have further contributed to the diagnostic skepticism and stigma that those with CFS encounter. Methods: Patient groups around the world are currently engaged in a major effort to rename this syndrome as either myalgic encephalomyelitis or myalgic encephalopathy, to undo the negative effects of the name previously given to this illness by scientists. Moreover, during the last 15 years, estimated rates of CFS have dramatically increased in both Great Britain and the United States. Results: We suggest that the increases in both the United States and Great Britain are due to a broadening of the case definition to additionally include cases with primary psychiatric conditions. Conclusion: Using a broad or narrow definition of CFS will have crucial influences on CFS epidemiologic findings, on rates of psychiatric comorbidity, and ultimately on the likelihood of finding a biological marker and identified etiology
Jason LA, Susan Torres-Harding Kevin Maher Nadia Reynolds		Baseline Cortisol Levels Predict Treatment Outcomes in	Journal of Chronic Fatigue Syndrome 2008; 14 (4): 39-59	Objective: Understanding how nonpharmacologic interventions differentially affect the subgroups of patients with chronic fatigue syndrome (CFS) might provide insights into the pathophysiology of this illness. In this exploratory study, baseline measures of normal versus abnormal cortisol were compared on a variety of immune markers and other self-report measures. Normal versus abnormal

Molly Brown, Matthew Sorenson, Julie Donalek, Karina Corradi, Mary Fletcher, Tony Lu		Chronic Fatigue Syndrome Nonpharmacologic Clinical Trial		cortisol ratings were used as predictors in a nurse-delivered nonpharmacologic intervention. Methods: Participants diagnosed with CFS were assigned to 6-month nonpharmacologic interventions. Individuals were classified as having abnormal or normal cortisol levels on the basis of scores over the five testing times. Cortisol levels were considered abnormal if they continued to rise, were flat, or were at abnormally low over time. Results: Across interventions, those with abnormal cortisol at the baseline appeared not to improve over time, whereas those with normal baseline cortisol evidenced improvements on a number of immunologic and self-report measures. Conclusion: It appears that, in subgroups of individuals with CFS, baseline cortisol markers are associated with outcome trajectories for nonpharmacologic treatment trials. The implications of these findings are discussed.
Javaras KN, Pope HG, Lalonde JK, Roberts JL, Nillni YI, Laird NM, Bulik CM, Crow SJ, McElroy SL, Walsh BT, Tsuang MT, Rosenthal NR, Hudson JI	Department of Biostatistics, Harvard School of Public Health, Boston, Mass., USA. javaras@wisc.edu	Co-occurrence of binge eating disorder with psychiatric and medical disorders.	J Clin Psychiatry. 2008 Feb;69(2):266-73.	BACKGROUND: Prior studies suggest that certain psychiatric and medical disorders co-occur with binge eating disorder (BED). However, there has been no large, community-based study with diagnoses made by clinician interviewers. We used data from that type of study to assess the co-occurrence of various psychiatric and medical disorders with DSM-IV BED and with subthreshold BED. METHOD: From October 2002 to July 2004, we interviewed 150 probands with BED, 150 probands without BED, and 888 of their first-degree relatives (135 of whom had BED, and 54 of whom met specific partial criteria for BED that we defined as subthreshold BED). Study participants were interviewed using the Structured Clinical Interview for DSM-IV to assess BED and other psychiatric disorders and a supplemental structured interview to assess certain medical disorders; participants also completed a self-report questionnaire, the Bad Things Scale. For each psychiatric and medical disorder, we calculated the age- and sex-adjusted co-occurrence odds ratio: the odds of having that disorder in one's lifetime among individuals with (full or subthreshold) lifetime BED compared to individuals without lifetime BED. We also used subjects' responses to the Bad Things Scale to adjust for adversity over-reporting, a type of response bias that could result in spurious findings of co-occurrence. RESULTS: Full BED co-occurred significantly with bipolar disorder, major depressive disorder, bulimia nervosa but not anorexia nervosa, most anxiety disorders, substance use disorders, body dysmorphic disorder, kleptomania, irritable bowel syndrome, and fibromyalgia. These results changed little after correcting for adversity over-reporting. Subthreshold BED co-occurred significantly with many, but not all, of the significantly co-occurring disorders for full BED. CONCLUSION: BED and, to a lesser degree, subthreshold BED exhibit substantial lifetime co-occurrence with psychiatric and medical disorders.
Jellinger KA.	Vienna, Austria.	Chronic Fatigue Syndrome (CFS/ME), 2nd edn.	Eur J Neurol. 2009 Feb 7. [Epub ahead of print]	PMID: 19220428 [PubMed - as supplied by publisher]
Jhanji V, Beltz J, Vajpayee RB.	Centre for Eye Research Australia, University of Melbourne, Royal Victorian Eye and Ear Hospital,	Contact lens-related acanthamoeba keratitis in a patient with chronic fatigue	Eye Contact Lens. 2008 Nov;34(6):335-6.	PURPOSE: To report a case of contact lens-related Acanthamoeba keratitis associated with improper lens hygiene in a patient with chronic fatigue syndrome (CFS). METHODS: Contact lens-related Acanthamoeba keratitis was diagnosed in a 58-year-old man with a history of CFS. After medical management failed to prevail, a penetrating keratoplasty was performed in the affected eye. RESULTS: There was no recurrence of Acanthamoeba keratitis after surgery. Complete re-epithelialization of the graft was observed with a best-corrected visual acuity of 20/80 in the operated eye at the last follow-

	Melbourne, Australia.	syndrome.		up (3 months). CONCLUSIONS: Our case report highlights the fact that concurrent incapacitating illnesses like CFS may not allow proper care of contact lenses thereby making patients prone to contact lens-related corneal infections.
Jones JF.	Chronic Viral Diseases Branch, Division of Viral and Rickettsial Diseases, National Center for Zoonotic, Vectorborne, and Enteric Diseases, Centers for Disease Control and Prevention, Atlanta, GA 30333, USA. jaj9@cdc.gov	An extended concept of altered self: chronic fatigue and post-infection syndromes.	Psychoneuroendocrinology. 2008 Feb;33(2):119-29. Epub 2007 Dec 26.	Sickness behavior in active infectious diseases is defined here as the responses to cytokines and other mediators of inflammation as well as the adaptability of a pre-existing integrated immunological, psychological, neurological, and philosophical self. These complex behaviors are biologically advantageous to the afflicted individual, but they also impact surrounding individuals. If chronic conditions, such as chronic fatigue syndrome or post-infection fatigue, exhibiting these behaviors follow infection in the absence of ongoing changes in immunological self associated with an active infection or subsequent injury, they are currently considered illness states rather than true diseases. Self-referential recognition (interoception) of bodily processes by the brain and subsequent unconscious and conscious adaptive responses arising in the brain, i.e., in the endocrine system and immune systems, which are initiated during the infection and would normally lead to positive maintenance, may become maladaptive and lead to an "extended altered self state." Exploratory measurements of such alterations using a "top-down" approach such as monitoring responses to appropriate challenges can be obtained using functional brain imaging techniques. Once identified, processes remediable to biological/pharmacologic and/or psychological intervention can be targeted in directed trials.
Jonsson K, Hedelin H.	Research and Development Centre and Department of Urology, Karnsjukhuset, Skovde, Sweden.	Chronic abacterial prostatitis: Living with a troublesome disease affecting many aspects of life.	Scand J Urol Nephrol. 2008;42(6):545-50.	OBJECTIVE: Chronic abacterial prostatitis/chronic pelvic pain syndrome (CP/CPPS) is a disease of yet not clarified aetiology where the symptoms, voiding dysfunction and pelvic pain are difficult to alleviate. The aim of this study is to arrive at an understanding of how it influences the individual afflicted. MATERIALS AND METHODS: Ten men with CP/CPPS were interviewed about their situation. The interviews were transcribed and analysed using a phenomenological perspective. RESULTS: The often severe symptoms influence well-being and a life in more or less constant fear of a relapse is described. A majority manages, despite the problems, to endure and conceal the problems. The situation can, however, become unbearable and force the man to seek solitude or lose his temper. Social isolation and restrictions at work and during recreational activities were thus reported by those more severely afflicted. Confirmation from the healthcare system that the disease is not life threatening and affirmation that they are not unwanted and neglected are essential. CONCLUSIONS: Men with CP/CPPS are mostly able to live a normal life, although it is often difficult and the people around them are rarely given an insight into their world, where their existence is focused on attempts to obtain confirmation, control abrupt mood fluctuations and develop coping strategies. They have much in common with other patient groups afflicted by chronic pain, such as difficulties in performing at work and severe fatigue. More specific for CP/CPPS is the presence of additional symptoms, which individually can severely impair quality of life. Accepting the situation and developing coping strategies are consequently challenges for a man with CP/CPPS.
Jorgensen R.	Mayo Clinic College of Medicine, Rochester,	Chronic fatigue: an evolutionary concept analysis.	J Adv Nurs. 2008 Jul;63(2):199-207.	AIM: This paper is a report of a concept analysis of chronic fatigue. BACKGROUND: Fatigue is a prevalent symptom encompassing both acute and chronic manifestations. It is chronic fatigue that is most problematic because of its duration and impact on life quality. The rise in prevalence of chronic conditions will result in a need to address coexistent symptoms, clarification of which is needed.

	Minnesota, USA. jorgensen.roberta@mayo.edu			Chronic fatigue is one of the most common symptoms in chronic illness. Clarification of the concept and an understanding of its use by discipline are needed. DATA SOURCES: The evolutionary method of concept analysis was used to ascertain the attributes, antecedents, consequences and surrogate terms for chronic fatigue. A review of the literature published between 1966 and 2007 was carried out to determine the contextual use of the concept of chronic fatigue among disciplines. Sources used for this analysis included CINAHL, Medline, PsychINFO and Social Work Abstracts and the search yielded 66 papers. RESULTS: The chronic fatigue experience is associated with a multitude of physical, psychological and social factors. The defining attributes of chronic fatigue are constancy, abnormality, whole-body experience, inexplicability and disabling. The antecedents of chronic fatigue are physical disease, psychopathology, female gender and a history of abuse. Consequences found include social isolation and stigmatization, physical inactivity, psychological disturbances and a reduced quality of life. CONCLUSION: Further research is needed to identify the aetiology of chronic fatigue and to address the social context of living with this disabling symptom.
Joyner MJ, Masuki S.	Dept. of Anesthesiology, Mayo Clinic, 200 First Street SW, Rochester, MN 55905, USA, joyner.michael@mayo.edu	POTS versus deconditioning: the same or different?	Clin Auton Res. 2008 Dec;18(6):300-7. Epub 2008 Aug 12. Comment in: Clin Auton Res. 2008 Dec;18(6):298; author reply 299.	The 2007 Streeten Lecture focused on the idea that physical deconditioning plays a key role in the symptomology and pathophysiology of POTS. Parallels were drawn between the physiological responses to orthostatic stress seen in POTS patients and the physiological responses seen in "normal" humans after prolonged periods of bedrest, deconditioning, or space flight. Additionally, the idea that endurance exercise training might ameliorate some of these symptoms was also advanced. Finally, potential parallels between POTS, chronic fatigue syndrome, and fibromyalgia were also drawn and the potential role of exercise training as a "therapeutic intervention" in all three conditions was raised. The conceptual model for the lecture was that after some "initiating event" chronic deconditioning plays a significant role in the pathophysiology of these conditions, and these physiological changes in conjunction with "somatic hypervigilence" explain many of the complaints that this diverse group of patients have. Additionally, the idea that systematic endurance exercise training might be helpful was advanced, and data supportive of this idea was reviewed. The main conclusion is that the medical community must retain their empathy for patients with unusual conditions but at the same time send a firm but empowering message about physical activity. As always, we must also ask what do the ideas about physical activity and inactivity and the conditions mentioned above not explain?
Kaabia N, Letaief A.	Service de médecine interne et maladies infectieuses, CHU Farhat-Hached, rue Mohamed-Karoui, 4000 Sousse, Tunisie..	[Q fever in Tunisia.] [Article in French]	Pathol Biol (Paris). 2008 Jun 11. [Epub ahead of print]	Q fever is a common zoonosis with almost a worldwide distribution caused by Coxiella burnetii. Farm animals and pets are the main reservoirs of infection and transmission to humans is usually via inhalation of contaminated aerosols. Infection in humans is often asymptomatic, but it can manifest as an acute disease (usually a self-limited flu-like illness, pneumonia or hepatitis) or as a chronic form (mainly endocarditis, but also hepatitis and chronic-fatigue syndrome). In Tunisia, although prevalence of anti-Coxiella burnetii was high among blood donors, Q fever was rarely reported and frequently miss diagnosed by physicians. This study is a review of epidemiological and clinical particularities of Q fever in Tunisia.
Kalaitzakis E, Carlsson E, Josefsson A, Bosaeus I.	Department of Internal Medicine, Sahlgrenska University	Quality of life in short-bowel syndrome: impact of fatigue and	Scand J Gastroenterol. 2008;43(9):1057-65.	OBJECTIVE: Patients with short-bowel syndrome (SBS) have impaired health-related quality of life (QoL). However, comparisons of QoL data with the data on other chronic gastrointestinal diseases are not available. The aim of this study was to assess QoL in SBS patients compared with that in the general population and with patients with inflammatory bowel disease (IBD). The potential relation

	Hospital, Gothenburg, Sweden.	gastrointestinal symptoms.		between fatigue and gastrointestinal symptoms and impaired QoL in these patients was also investigated. MATERIAL AND METHODS: Four validated questionnaires were used to measure aspects of QoL (SF-36), psychological distress (hospital anxiety and depression scale, HAD), fatigue (fatigue impact scale, FIS), and gastrointestinal symptoms (gastrointestinal symptom rating scale, GSRS) in 26/28 patients (93%) attending a SBS clinic (median age 62 years, 15 F/11 M) at a tertiary referral center. Persons from the general population (n=286) as well as patients with IBD (n=41) of similar age and gender distribution as the SBS group acted as controls. RESULTS: SBS patients had significantly lower SF-36 physical and mental component summaries than those in the general population as well as significantly lower SF-36 physical ($p<0.05$) but not mental ($p>0.05$) component summaries compared with those of IBD patients. Fatigue and gastrointestinal symptoms were more severe in SBS patients than in IBD patients ($p>0.05$). The SF-36 physical component summary was independently related to the physical FIS dimension (beta=-0.4, p=0.004), the GSRS eating dysfunction dimension (beta=-0.31, p=0.025), and opiate use (beta=-0.28, p=0.031), regardless of diagnosis (SBS or IBD). CONCLUSIONS: Patients with SBS show poor QoL compared with that in the general population and also impairment of mainly physical health compared with that in patients with IBD. Fatigue and gastrointestinal symptoms are more severe in patients with SBS, which has an impact on QoL.
Kalkman JS, Zwarts MJ, Schillings ML, van Engelen BG, Bleijenberg G.	Department of Medical Psychology, Radboud University Nijmegen Medical Centre, Nijmegen, The Netherlands.	Different types of fatigue in patients with facioscapulohumeral dystrophy, myotonic dystrophy and HMSN-I. Experienced fatigue and physiological fatigue.	Neurol Sci. 2008 Sep;29 Suppl 2:S238-40.	Although fatigue is a common symptom in neuromuscular disorders, little is known about different types of fatigue. Sixty-five FSHD, 79 adult-onset MD and 73 HMSN type I patients were studied. Experienced fatigue was assessed with the CIS-fatigue subscale. Physiological fatigue was measured during a 2-min sustained maximal voluntary contraction of the biceps brachii muscle using the twitch interpolation technique to assess central activation failure (CAF) and peripheral fatigue. Experienced fatigue, CAF and peripheral fatigue appeared to be predominantly separate types of fatigue.
Karlsson I.		[Fatigue syndromes do not belong among depressive and anxiety disorders] [Article in Swedish]	Lakartidningen. 2009 Jan 14-20;106(3):132; author reply 132. Comment on: Lakartidningen. 2008 Nov 19-25;105(47):3393-4.	
Kato K, Sullivan PF, Evengård B, Pedersen NL.	School of Nursing and Rehabilitation, International University of	A population-based twin study of functional somatic	Psychol Med. 2009 Mar;39(3):497-505. Epub 2008 Jun 26.	BACKGROUND: The mechanisms underlying the co-occurrence of the functional somatic syndromes are largely unknown. No empirical study has explicitly examined how genetic and environmental factors influence the co-morbidity of these syndromes. We aimed to examine how the co-morbidity of functional somatic syndromes is influenced by genetic and environmental factors that are in common

	Health and Welfare at Odawara, Kanagawa, Japan.	syndromes.		to the syndromes.MethodA total of 31318 twins in the Swedish Twin Registry aged 41-64 years underwent screening interviews via a computer-assisted telephone system from 1998 to 2002. Four functional somatic syndromes (chronic widespread pain, chronic fatigue, irritable bowel syndrome, and recurrent headache) and two psychiatric disorders (major depression and generalized anxiety disorder) were assessed using structured questions based on standard criteria for each illness in a blinded manner. RESULTS: Multivariate twin analyses revealed that a common pathway model with two latent traits that were shared by the six illnesses fit best to the women's data. One of the two latent traits loaded heavily on the psychiatric disorders, whereas the other trait loaded on all four of the functional somatic syndromes, particularly chronic widespread pain, but not on the psychiatric disorders. All illnesses except the psychiatric disorders were also affected by genetic influences that were specific to each. CONCLUSIONS: The co-occurrence of functional somatic syndromes in women can be best explained by affective and sensory components in common to all these syndromes, as well as by unique influences specific to each of them. The findings clearly suggest a complex view of the multifactorial pathogenesis of these illnesses.

Kawasaki H, Yahata K, Okamoto C, Imamaki H, Seta K, Sugawara A.	Department of Nephrology, National Hospital Organization Kyoto Medical Center, Kyoto, Japan.	[Myasthenia-like syndrome induced by cibenzoline overdose in a patient with chronic kidney disease] [Article in Japanese]	Nippon Jinzo Gakkai Shi. 2008;50(7):942-7.	A female in her late 60s with chronic kidney disease was admitted to the emergency department with complaints of dizziness four days prior to hospitalization. Cibenzoline (300 mg/day) was administered for atrial fibrillation, which was detected in an electrocardiogram. After three days, she experienced blepharoptosis and was admitted for suspected myasthenia gravis. However, the anti-acetylcholine receptor antibody and edrophonium tests were negative. On day four after hospitalization, she suffered from pneumonia with pleural effusion and she was put on a respirator for four days. From day 16 after hospitalization, she had diarrhea and her renal function worsened. At the same time, a gradual aggravation of right blepharoptosis, dull headache, weakness and difficulty in chewing were noted. She experienced dyspnea on day 31 after hospitalization. Chest X-ray film did not show a pneumonia shadow or pleural effusion, and arterial blood gases revealed hypercapnia; she was diagnosed as having CO2 narcosis due to respiratory muscle fatigue and was put on a respirator again. Myasthenia-like syndrome was suspected because of a probable overdose of cibenzoline and administration of cibenzoline was withdrawn. Her condition improved and she was taken off the respirator on day 35 after hospitalization. Repetitive stimulation of 5 Hz was applied to her right facial nerve along with evoked electromyogram(EMG) on days 2 and 11 after discontinuing cibenzoline. On day 2, the EMG showed a waning phenomenon, whereas no such phenomenon was seen on day 11. The blood concentration of cibenzoline immediately after withdrawal was extremely high (2448

				ng/mL). When this drug is administered to a patient with chronic kidney disease, attention must be paid to the indication, dose, and manifestation of the possible side effects.
Kelly M, Gagne R, Newman JD, Olney C, Gualtieri C, Trail D.		Assessment of fibromyalgia & chronic fatigue syndrome: a new protocol designed to determine work capability--chronic pain abilities determination (CPAD).	Ir Med J. 2008 Oct;101(9):277-8.	The objective was to design a protocol to assess work ability in people suffering ill-defined painful and disabling disorders, the outstanding prototype of which is fibromyalgia/chronic fatigue syndrome (FM/CSF).Following an extensive literature search, the mos appropriate components of current methods of assessment of physical and cognitive abilities were incorporated into the protocol, occasionally with appropriate modification to suit the specific requirements of the individual. The initial part of the assessment consists of a standard history taking, principally focusing on the patient's self-reported physical and cognitive abilities and disabilities, as well as the completion of established pain and fatigue scales, and relevant disability questionnaires. Following this, physical and cognitive abilities are objectively assessed on two separate occasions, utilizing computerized hand-held dynamometers, inclinometers, algometers, and force dynamometers. Specific work simulation tests using the industrial standards Methods-Time-Measurement testing are availed of, as is aerobic testing using the Canadian Aerobic Fitness Test (CAFT). Objective computerised neuro-cognitive testing are also utilised as an integral component of the assessment. All results are then subject to specific computerized analysis and compared to normative and standardised work-based databases. The designed system produces reliable, consistent and reproducible results. It also proves capable of detecting any inconsistencies in patient input and results, in addition to being independent of any possible assessor bias. A new protocol has been designed to determine the working capability of individuals who suffer from various chronic disabling conditions, and represents a significant step forward in a difficult but rapidly expanding area of medical practice.
Kerr JR, Burke B, Petty R, Gough J, Fear D, Mattey DL, Axford JS, Dalgleish AG, Nutt DJ.	Department of Cellular and Molecular Medicine, St George's University of London, London, UK. jkerr@sgul.ac.uk	Seven genomic subtypes of chronic fatigue syndrome/myalgic encephalomyelitis: a detailed analysis of gene networks and clinical phenotypes.	J Clin Pathol. 2008 Jun;61(6):730-9. Epub 2007 Dec 5.	AIM: Chronic fatigue syndrome/myalgic encephalomyelitis (CFS/ME) is a multisystem disease, the pathogenesis of which remains undetermined. The authors have recently reported a study of gene expression that identified differential expression of 88 human genes in patients with CFS/ME. Clustering of quantitative PCR (qPCR) data from patients with CFS/ME revealed seven distinct subtypes with distinct differences in Medical Outcomes Survey Short Form-36 scores, clinical phenotypes and severity. METHODS: In this study, for each CFS/ME subtype, those genes whose expression differed significantly from that of normal blood donors were identified, and then gene interactions, disease associations and molecular and cellular functions of those gene sets were determined. Genomic analysis was then related to clinical data for each CFS/ME subtype. RESULTS: Genomic analysis revealed some common (neurological, haematological, cancer) and some distinct (metabolic, endocrine, cardiovascular, immunological, inflammatory) disease associations among the subtypes. Subtypes 1, 2 and 7 were the most severe, and subtype 3 was the mildest. Clinical features of each subtype were as follows: subtype 1 (cognitive, musculoskeletal, sleep, anxiety/depression); subtype 2 (musculoskeletal, pain, anxiety/depression); subtype 3 (mild); subtype 4 (cognitive); subtype 5 (musculoskeletal, gastrointestinal); subtype 6 (postexertional); subtype 7 (pain, infectious, musculoskeletal, sleep, neurological, gastrointestinal, neurocognitive, anxiety/depression). CONCLUSION: It was particularly interesting that in the seven genomically derived subtypes there were distinct clinical syndromes, and that those which were most severe were also those with anxiety/depression, as would be expected in a disease with a biological basis.

Kerr JR, Mattey DL.	Department of Cellular and Molecular Medicine, St. George's University of London, United Kingdom. jkerr@sgul.ac.uk	Preexisting psychological stress predicts acute and chronic fatigue and arthritis following symptomatic parvovirus B19 infection.	Clin Infect Dis. 2008 May 1;46(9):e83-7.	BACKGROUND: Psychological stress is thought to be an important factor in the pathogenesis of chronic fatigue syndrome/myalgic encephalomyelitis (CFS/ME). Therefore, we sought to examine this relationship in the context of parvovirus B19 infection.METHODS: Thirty-nine patients with laboratory-documented acute parvovirus B19 infection were asked to complete questionnaires on negative life events, perceived stress, and negative affect relevant to the time of onset of parvovirus infection and during the preceding 12 months. These scores were combined into an overall stress index, which was then examined for associations with particular parvovirus-associated symptoms at acute infection and during the ensuing 1-3 years. Additional characteristics monitored included presence of parvovirus antibodies and nucleic acid, cortisol level, dehydroepiandrosterone level, autoantibodies, levels of a range of serum cytokines, and human leukocyte antigen class I and II alleles. RESULTS: Stress index was significantly associated with development of fatigue during the acute phase of parvovirus B19 infection and also with chronic fatigue and arthritis occurring 1-3 years following acute parvovirus B19 infection. Logistic regression that included all clinical variables indicated that a high stress index at the time of onset of infection was the primary predictor of CFS/ME 1-3 years following acute parvovirus B19 infection (odds ratio, 25.7; 95% confidence interval, 1.7-121.9; P=.005).CONCLUSIONS: We report a highly significant association between psychological stress and development of acute and chronic fatigue and arthritis several years following laboratory-documented acute parvovirus B19 infection.
Kerr JR, Petty R, Burke B, Gough J, Fear D, Sinclair LI, Mattey DL, Richards SC, Montgomery J, Baldwin DA, Kellam P, Harrison TJ, Griffin GE, Main J, Enlander D, Nutt DJ, Holgate ST.	Department of Cellular & Molecular Medicine, St. George's University of London, London. jkerr@sgul.ac.uk	Gene expression subtypes in patients with chronic fatigue syndrome/myalgic encephalomyelitis.	J Infect Dis. 2008 Apr 15;197(8):1171-84.	Chronic fatigue syndrome/myalgic encephalomyelitis (CFS/ME) is a multisystem disease, the pathogenesis of which remains undetermined. We set out to determine the precise abnormalities of gene expression in the blood of patients with CFS/ME. We analyzed gene expression in peripheral blood from 25 patients with CFS/ME diagnosed according to the Centers for Disease Control and Prevention diagnostic criteria and 50 healthy blood donors, using a microarray with a cutoff fold difference of expression of >or=2.5. Genes showing differential expression were further analyzed in 55 patients with CFS/ME and 75 healthy blood donors, using quantitative polymerase chain reaction. Differential expression was confirmed for 88 genes; 85 were upregulated, and 3 were downregulated. Highly represented functions were hematological disease and function, immunological disease and function, cancer, cell death, immune response, and infection. Clustering of quantitative polymerase chain reaction data from patients with CFS/ME revealed 7 subtypes with distinct differences in Medical Outcomes Survey Short Form-36 scores, clinical phenotypes, and severity.
Kerr JR, Taylor-Robinson D.	Department of Cellular and Molecular Medicine, St. George's University of London, London.	David Arthur John Tyrrell CBE: 19 June 1925 - 2 May 2005.	Biogr Mem Fellows R Soc. 2007;53:349-63.	David Tyrrell is remembered by physicians and scientists principally for his discovery of the common cold viruses and elucidation of their pathogenesis, but also for his work in various other areas, including influenza, bovine spongiform encephalopathy (BSE) and chronic fatigue syndrome (CFS). David possessed a deep humanity, honesty, perseverance and a vision of collaboration as a means of making discoveries that would contribute meaningfully to the alleviation of human suffering. He also had a warmth and a mischievous sense of humour that was frequently directed at bureaucracy, which he thoroughly disliked.

		syndrome/myalgic encephalomyelitis Comment on: J Clin Pathol. 2008 Jan;61(1):43-8.		
Kerr JR.	St. George's University of London, Cranmer Terrace, London SW17 0RE, United Kingdom. jkerr@sgul.ac.uk	Gene profiling of patients with chronic fatigue syndrome/myalgic encephalomyelitis.	Curr Rheumatol Rep. 2008 Dec;10(6):482-91.	Chronic fatigue syndrome/myalgic encephalomyelitis (CFS/ME) is a multisystem disease, the pathogenesis of which remains undetermined. Following two microarray studies, we reported the differential expression of 88 human genes in patients with CFS; 85 of these genes were upregulated and 3 were downregulated. The top functional categories of these 88 genes were hematologic disease and function, immunologic disease and function, cancer, cell death, immune response, and infection. Clustering of quantitative polymerase chain reaction data from CFS/ME patients revealed seven subtypes with distinct differences in Short Form (SF)-36 scores, clinical phenotypes, and severity. Gene signatures in each subtype implicate five human genes as possible targets for specific therapy. Development of a diagnostic test for subtype status is now a priority. The possibility that these subtypes represent individual host responses to particular microbial infections is being investigated and may provide another route to specific therapies for CFS patients.
Kilshaw S.	Department of Anthropology, University College London, 14 Taviton Street, London, UK. s.kilshaw@ucl.ac.uk	Gulf war syndrome: a reaction to psychiatry's invasion of the military?	Cult Med Psychiatry. 2008 Jun;32(2):219-37.	Following the 1991 Gulf War, a number of soldiers who fought there began to complain of various symptoms and disorders, the collection of which came to be known as Gulf War syndrome (GWS). A debate has raged about the nature and cause of this illness, with many suggesting that it is a psychiatric condition. GWS continues to be a contested illness, yet there is no disputing that many Gulf veterans are ill. This article considers the way in which GWS sufferers understand their illness to be physical in nature and the way in which they negotiate and resist psychological theories of their illness. Based on 14 months of ethnographic fieldwork in the United Kingdom, data for this article were collected mainly by in-depth, semistructured interviews with GWS sufferers, their family members, doctors, and scientists, as well as healthy Gulf veterans. A total of 93 informants were interviewed, including 67 UK Gulf veterans, most of whom were ill. The paper argues that despite the increasing presence of psychiatry in military discourse, GWS reveals the way that people are able to transform, negotiate and even negate its power and assumptions.

Kishi A, Struzik ZR, Natelson BH, Togo F, Yamamoto Y.	Graduate School of Education, The University of Tokyo, 7-3-1 Hongo, Bunkyo-	Dynamics of sleep stage transitions in healthy humans and patients with chronic fatigue	Am J Physiol Regul Integr Comp Physiol. 2008 Jun;294(6):R1980-7. Epub 2008 Apr	Physiological and/or pathological implications of the dynamics of sleep stage transitions have not, to date, been investigated. We report detailed duration and transition statistics between sleep stages in healthy subjects and in others with chronic fatigue syndrome (CFS); in addition, we also compare our data with previously published results for rats. Twenty-two healthy females and 22 female patients with CFS, characterized by complaints of unrefreshing sleep, underwent one night of

	ku, Tokyo, Japan.	syndrome.	16.	polysomnographic recording. We find that duration of deep sleep (stages III and IV) follows a power-law probability distribution function; in contrast, stage II sleep durations follow a stretched exponential and stage I, and REM sleep durations follow an exponential function. These stage duration distributions show a gradually increasing departure from the exponential form with increasing depth of sleep toward a power-law type distribution for deep sleep, suggesting increasing complexity of regulation of deeper sleep stages. We also find a substantial number of REM to non-REM sleep transitions in humans, while this transition is reported to be virtually nonexistent in rats. The relative frequency of this REM to non-REM sleep transition is significantly lower in CFS patients than in controls, resulting in a significantly greater relative transition frequency of moving from both REM and stage I sleep to awake. Such an alteration in the transition pattern suggests that the normal continuation of sleep in light or REM sleep is disrupted in CFS. We conclude that dynamic transition analysis of sleep stages is useful for elucidating yet-to-be-determined human sleep regulation mechanisms with pathophysiological implications.
Knoop H, Stulemeijer M, de Jong LW, Fiselier TJ, Bleijenberg G.	Expert Centre Chronic Fatigue, Radboud University, Nijmegen Medical Centre, Postbox 9011, 6525 EC Nijmegen, The Netherlands. j.knoop@nkcv.umcn.nl	Efficacy of cognitive behavioral therapy for adolescents with chronic fatigue syndrome: long-term follow-up of a randomized, controlled trial.	Pediatrics. 2008 Mar;121(3):e619-25.	OBJECTIVES: The purpose of this work was to assess the long-term outcome of adolescents with chronic fatigue syndrome who received cognitive behavioral therapy and to determine the predictive value of fatigue severity and physical impairments of the adolescent and the fatigue severity of the mother at baseline for the outcome of the treatment at follow-up. PATIENTS AND METHODS: Sixty-six adolescent patients with chronic fatigue syndrome who previously participated in a randomized, controlled trial that showed that cognitive behavioral therapy was more effective than a waiting-list condition in reducing fatigue and improving physical functioning were contacted for a follow-up assessment. Fifty participants of the follow-up study had received cognitive behavioral therapy for chronic fatigue syndrome (32 formed the cognitive behavioral therapy group in the original trial, and 18 patients received cognitive behavioral therapy after the waiting period). The remaining 16 patients had refused cognitive behavioral therapy after the waiting period. The main outcome measures were fatigue severity (Checklist Individual Strength), physical functioning (Short-Form General Health Survey), and school attendance. RESULTS: Data were complete for 61 patients at follow-up (cognitive behavioral therapy group: 47 patients; no-treatment group: 14 patients). The mean follow-up time was 2.1 years. There was no significant change in fatigue severity between posttreatment and follow-up in the cognitive behavioral therapy group. There was a significant further increase in physical functioning and school attendance (10% increase). The adolescents in the cognitive behavioral therapy group were significantly less fatigued and significantly less functionally impaired and had higher school attendance at follow-up than those in the no-treatment group. Fatigue severity of the mother was a significant predictor of treatment outcome. CONCLUSIONS: The positive effects of cognitive behavioral therapy in adolescents with chronic fatigue syndrome are sustained after cognitive behavioral therapy. Higher fatigue severity of the mother predicts lower treatment outcome in adolescent patients.
Knoop H, van der Meer JW, Bleijenberg G.	Expert Centre Chronic Fatigue, Radboud University	Guided self-instructions for people with chronic fatigue	Br J Psychiatry. 2008 Oct;193(4):340-1.	A minimal intervention, based on cognitive-behavioural therapy for chronic fatigue syndrome and consisting of self-instructions combined with email contact, was tested in a randomised controlled trial (ISRCTN27293439). A total of 171 patients participated in the trial: 85 were allocated to the intervention condition and 86 to the waiting-list condition. All patients met the Centers for Disease

	Nijmegen Medical Centre, Nijmegen, The Netherlands. j.knoop@nkcv.umcn.nl	syndrome: randomised controlled trial.		Control and Prevention criteria for chronic fatigue syndrome. An intention-to-treat analysis showed a significant decrease in fatigue and disability after self-instruction. The level of disability was negatively correlated with treatment outcome. Guided self-instructions are an effective treatment for patients with relatively less severe chronic fatigue syndrome.
Kong MH, Lee EJ, Lee SY, Cho SJ, Hong YS, Park SB.	Department of Family Practice, Ajou University, Suwon, Korea. MHKong@paran.com	Effect of human placental extract on menopausal symptoms, fatigue, and risk factors for cardiovascular disease in middle-aged Korean women.	Menopause. 2008 Mar-Apr;15(2):296-303.	OBJECTIVE: In Korea, human placental extract (HPE) has recently been used to treat various diseases (chronic liver diseases, menopause syndrome, chronic fatigue, skin pigment diseases, etc.), but evidence-based studies are not yet sufficient. The aim of this study was to examine the effects of HPE on menopausal symptoms, fatigue, and risk factors for cardiovascular disease in middle-aged Korean women in a randomized controlled trial. DESIGN: Korean women, aged 40 to 64 years, with menopausal symptoms and fatigue were recruited as participants. The women were randomly assigned to a placebo group or an HPE group. The HPE group received subcutaneous injections of HPE in the abdomen for 8 weeks, whereas the placebo group received normal saline. Then, the Menopause Rating Scale, and Fatigue Severity Scale, and Visual Analog Scale were administered, and risk factors for cardiovascular disease were assessed. RESULTS: The Menopause Rating Scale total baseline score was not different between the two groups; however, the score of the HPE group decreased significantly at 8 weeks compared with that of the placebo group (P = 0.033). Fatigue Severity Scale and Visual Analog Scale scores of the placebo group did not change, whereas the scores of the HPE group decreased significantly during the study period (Fatigue Severity Scale, P = 0.002; Visual Analog Scale, P = 0.001). The baseline 17beta-estradiol level was not significantly different between the two groups, but the 17beta-estradiol level of the HPE group was significantly increased at 8 weeks compared with that of the placebo group (P = 0.031). No changes in risk factors for cardiovascular disease were observed in either group. CONCLUSIONS: Menopausal symptoms and fatigue in middle-aged Korean women improved after 8 weeks of HPE treatment, whereas risk factors for cardiovascular disease did not change during the study period.

Kos D, Kerckhofs E, Nagels G, D'hooghe MB, Ilsbroukx S.	Vrije Universiteit Brussel, Department of Rehabilitation Research, Brussels, Belgium. Daphne.Kos@vub.ac.be	Origin of fatigue in multiple sclerosis: review of the literature.	Neurorehabil Neural Repair. 2008 Jan-Feb;22(1):91-100. Epub 2007 Apr 4.	Fatigue is one of the most common and most disabling symptoms of multiple sclerosis (MS). Although numerous studies have tried to reveal it, no definite pathogenesis factor behind this fatigue has been identified. Fatigue may be directly related to the disease mechanisms (primary fatigue) or may be secondary to non-disease-specific factors. Primary fatigue may be the result of inflammation, demyelination, or axonal loss. A suggested functional cortical reorganization may result in a higher energy demand in certain brain areas, culminating in an increase of fatigue perception. Higher levels of some immune markers were found in patients with MS-related fatigue, whereas other studies rejected this hypothesis. There may be a disturbance in the neuroendocrine system related to fatigue, but it is not clear whether this is either the result of the interaction with immune activation or the

				trigger of this process. Fatigue may be secondary to sleep problems, which are frequently present in MS and in their turn result from urinary problems, spasms, pain, or anxiety. Pharmacologic treatment of MS (symptoms) may also provoke fatigue. The evidence for reduced activity as a cause of secondary fatigue in MS is inconsistent. Psychological functioning may at least play a role in the persistence of fatigue. Research did not reach consensus about the association of fatigue with clinical or demographic variables, such as age, gender, disability, type of MS, education level, and disease duration. In conclusion, it is more likely to explain fatigue from a multifactor perspective than to ascribe it to one mechanism. The current evidence on the pathogenesis of primary and secondary fatigue in MS is limited by inconsistency in defining specific aspects of the concept fatigue, by the lack of appropriate assessment tools, and by the use of heterogeneous samples. Future research should overcome these limitations and also include longitudinal designs.
Kowalski A, Rebas E, Zylińska L.	Department of Molecular Neurochemistry, Medical University of Lodz, 6/8 Mazowiecka St., 92-215 Lodz, Poland. antek3000@tlen.pl	[Gamma-aminobutyric acid--metabolism and its disorders] [Article in Polish]	Postepy Biochem. 2007;53(4):356-60.	Gamma-aminobutyric acid is a major inhibitory neurotransmitter in the central nervous system. GABA metabolism is dependent on the activity of three enzymes: glutamic acid decarboxylase, GABA-transaminase and succinic semialdehyde dehydrogenase. Decreased activity of these enzymes may cause many neurological syndromes, such as stiff-person syndrome, chronic fatigue syndrome, anxiety disorders and seizures. This article is a review of most important problems related to an impairment of GABA metabolism.
Kumagi T, Heathcote EJ.	Department of Medicine, Toronto Western Hospital (University Health Network/University of Toronto), Toronto, Ontario, Canada. masato_teru@yahoo.co.jp	Primary biliary cirrhosis.	Orphanet J Rare Dis. 2008 Jan 23;3:1.	Primary biliary cirrhosis (PBC) is a chronic and slowly progressive cholestatic liver disease of autoimmune etiology characterized by injury of the intrahepatic bile ducts that may eventually lead to liver failure. Affected individuals are usually in their fifth to seventh decades of life at time of diagnosis, and 90% are women. Annual incidence is estimated between 0.7 and 49 cases per million-population and prevalence between 6.7 and 940 cases per million-population (depending on age and sex). The majority of patients are asymptomatic at diagnosis, however, some patients present with symptoms of fatigue and/or pruritus. Patients may even present with ascites, hepatic encephalopathy and/or esophageal variceal hemorrhage. PBC is associated with other autoimmune diseases such as Sjogren's syndrome, scleroderma, Raynaud's phenomenon and CREST syndrome and is regarded as an organ specific autoimmune disease. Genetic susceptibility as a predisposing factor for PBC has been suggested. Environmental factors may have potential causative role (infection, chemicals, smoking). Diagnosis is based on a combination of clinical features, abnormal liver biochemical pattern in a cholestatic picture persisting for more than six months and presence of detectable antimitochondrial antibodies (AMA) in serum. All AMA negative patients with cholestatic liver disease should be carefully evaluated with cholangiography and liver biopsy. Ursodeoxycholic acid (UDCA) is the only currently known medication that can slow the disease progression. Patients, particularly those who start UDCA treatment at early-stage disease and who respond in terms of improvement of the liver biochemistry, have a good prognosis. Liver transplantation is usually an option for patients with liver failure and the outcome is 70% survival at 7 years. Recently, animal models have been discovered that may provide a new insight into the pathogenesis of this disease and facilitate appreciation for novel treatment in

				PBC.
Kumar A, Garg R, Kumar P.	Pharmacology Division, University Institute of Pharmaceutical Sciences, Panjab University, Chandigarh, 160014, India. kumaruips@yahoo.com	Nitric oxide modulation mediates the protective effect of trazodone in a mouse model of chronic fatigue syndrome.	Pharmacol Rep. 2008 Sep-Oct;60(5):664-72.	The present study was conducted with the aim of elucidating the possible role of nitric oxide (NO) in the neuroprotective effects of trazodone used to treat chronic fatigue syndrome (CFS) in mice. Male albino mice were forced to swim for a six minute session each day for 7 days and the immobility period was recorded every other day. Trazodone (5 mg/kg and 10 mg/kg) was administered each day 30 min before the forced swim test. In addition, L-arginine (100 mg/kg) and L-NAME (5 mg/kg) were administered 15 min before administration of trazodone (5 mg/kg). Various behavioral tests, including locomotor (actophotometer) and anxiety (mirror chamber and plus maze) tests, as well as biochemical parameters (lipid peroxidation, reduced glutathione, catalase, and nitrites) were evaluated on the 8th day. Forced swimming for 7 days caused a chronic fatigue-like condition, anxiety-like behavior, impairments in locomotor activity, and oxidative damage (increased lipid peroxidation and nitrite levels, and depletions in the reduced forms of glutathione and catalase activity) in animals. Pretreatment with L-NAME (5 mg/kg) potentiated the antioxidant effect of trazodone (5 mg/kg). However, L-arginine (100 mg/kg) pretreatment reversed the protective effect of trazodone (5 mg/kg) ($p<0.05$). The present study suggests the possible involvement of NO signaling in the protective effect of trazodone.
Kumar A, Garg R.	Pharmacology Division, University Institute of Pharmaceutical Sciences, Panjab University, Chandigarh 160014, India.	Protective effects of antidepressants against chronic fatigue syndrome - induced behavioral changes and biochemical alterations.	Fundam Clin Pharmacol. 2009 Jan 10. [Epub ahead of print]	Abstract Chronic fatigue syndrome (CFS) is characterized by profound fatigue, which substantially interferes with daily activities. The aim of this study was to explore the protective effects of antidepressants in an animal model of CFS in mice. Male albino mice were forced to swim individually for a period of 6-min session each for 7 days. Imipramine (10 and 20 mg/kg), desipramine (10 and 20 mg/kg) and citalopram (5 and 10 mg/kg) were administered 30 min before forced swimming test on each day. Various behavior tests (immobility time, locomotor activity, anxiety-like behavior by plus maze and mirror chamber) followed by biochemical parameters (lipid peroxidation, reduced glutathione, catalase and nitrite level) were assessed in chronic stressed mice. Chronic forced swimming for 7 days significantly caused increase in immobility period, impairment in locomotor activity, anxiety-like behavior, and oxidative stress (raised lipid peroxidation, nitrite activity and reduced glutathione and catalase activity) as compared with naïve mice ($P < 0.05$). Seven days of pretreatment with imipramine (10 and 20 mg/kg), desipramine (10 and 20 mg/kg), and citalopram (5 and 10 mg/kg) significantly reduced immobility time, improved locomotor activity and anti-anxiety effect (in both plus maze and mirror chamber test), and attenuated oxidative stress in chronic stressed mice as compared with control (chronic fatigues) ($P < 0.05$). These results suggested that these drugs have protective effect and could be used in the management of chronic fatigue like conditions.
Kumar R.	Department of Family Medicine, University of Chicago, Chicago, Illinois 60637, USA. rkumar@medicine.bsd.uchicago.edu	Approved and investigational uses of modafinil : an evidence-based review.	Drugs. 2008;68(13):1803-39.	Modafinil is a wake-promoting agent that is pharmacologically different from other stimulants. It has been investigated in healthy volunteers, and in individuals with clinical disorders associated with excessive sleepiness, fatigue, impaired cognition and other symptoms. This review examines the use of modafinil in clinical practice based on the results of randomized, double-blind, placebo-controlled clinical trials available in the English language in the MEDLINE database. In sleep-deprived individuals, modafinil improves mood, fatigue, sleepiness and cognition to a similar extent as caffeine but has a longer duration of action. Evidence for improved cognition in non-sleep-deprived healthy volunteers is controversial.Modafinil improves excessive sleepiness and illness severity in all three disorders for

				which it has been approved by the US FDA, i.e. narcolepsy, shift-work sleep disorder and obstructive sleep apnoea with residual excessive sleepiness despite optimal use of continuous positive airway pressure (CPAP). However, its effects on safety on the job and on morbidities associated with these disorders have not been ascertained. Continued use of CPAP in obstructive sleep apnoea is essential. Modafinil does not benefit cataplexy.In very small, short-term trials, modafinil improved excessive sleepiness in patients with myotonic dystrophy. It was efficacious in fairly large studies of attention deficit hyperactivity disorder (ADHD) in children and adolescents, and was as efficacious as methylphenidate in a small trial, but has not been approved by the FDA, in part because of its serious dermatological toxicity. In a trial of 21 non-concurrent subjects, with 2-week treatment periods, modafinil was as effective as dexamfetamine in adult ADHD. Modafinil was helpful for depressive symptoms in bipolar disorder in a trial that excluded patients with stimulant-induced mania. A single dose of modafinil may hasten recovery from general anaesthesia after day surgery. A single dose of modafinil improved the ability of emergency room physicians to attend didactic lectures after a night shift, but did not improve their ability to drive home and caused sleep disturbances subsequently.Modafinil had a substantial placebo effect on outcomes such as fatigue, excessive sleepiness and depression in patients with traumatic brain injury, major depressive disorder, schizophrenia, post-polio fatigue and multiple sclerosis; however, it did not provide any benefit greater than placebo.Trials of modafinil for excessive sleepiness in Parkinson's disease, cocaine addiction and cognition in chronic fatigue syndrome provided inconsistent results; all studies had extremely small sample sizes. Modafinil cannot be recommended for these conditions until definitive data become available.Modafinil induces and inhibits several cytochrome P450 isoenzymes and has the potential for interacting with drugs from all classes. The modafinil dose should be reduced in the elderly and in patients with hepatic disease. Caution is needed in patients with severe renal insufficiency because of substantial increases in levels of modafinil acid. Common adverse events with modafinil include insomnia, headache, nausea, nervousness and hypertension. Decreased appetite, weight loss and serious dermatological have been reported with greater frequency in children and adolescents, probably due to the higher doses (based on bodyweight) used. Modafinil may have some abuse/addictive potential although no cases have been reported to date.
Kung WW, Lu PC.	Graduate School of Social Service, Fordham University, New York, New York 10023-7484, USA. kung@fordham.edu	How symptom manifestations affect help seeking for mental health problems among Chinese Americans.	J Nerv Ment Dis. 2008 Jan;196(1):46-54.	This study aims to examine how help-seeking behaviors of Chinese Americans are associated with the types of mental disorder, the tendency to somatize symptoms, social disruptiveness of symptoms, and comorbidity. Based on data from the Chinese American Psychiatric Epidemiological Study, we examined 246 Chinese Americans with a diagnosable major depressive disorder, anxiety disorder, or somatoform disorder, using hierarchical logistic regression analyses. Compared with respondents with somatoform disorder, those with anxiety or depressive disorder were 94% and 87% less likely to seek professional help. The tendency to somatize distress is positively related to soliciting help, especially medical help. Social disruptiveness had a very potent positive association with help seeking whereas comorbidity is nonsignificant when the symptom severity is controlled. The overall picture indicates that somatic expression of distress is a major impetus to help seeking, which happens to concur with the cultural conceptualization and subjective embodied experience of mental disorders among Chinese.

Kuo YH, Tsai WJ, Loke SH, Wu TS, Chiou WF.	National Research Institute of Chinese Medicine, Taipei, Taiwan, ROC.	Astragalus membranaceus flavonoids (AMF) ameliorate chronic fatigue syndrome induced by food intake restriction plus forced swimming.	J Ethnopharmacol. 2009 Feb 25;122(1):28-34. Epub 2008 Dec 6.	AIM OF THE STUDY: Alteration of immune function may be associated with chronic fatigue syndrome (CFS) and this study reveals the immunoregulatory effect of Astragalus membranaceus flavonoids (AMF). MATERIALS AND METHODS: CF rats were induced by food intake restriction plus forced swimming for 6 weeks. RESULTS: An atrophied spleen associated with a significantly decreased spleen/body weight ratio and a reduced spleen cells proliferation was found in CF rats when compared with home cage controls. AMF given orally at 20, 50 and 100mg/kg body weight once a day consecutively for 6 weeks could recover the reduced cell proliferation. A switch to Th1-dominated immune regulation was observed in CF rats as the cultured splenocytes produced more interleukin-2 (IL-2) but less IL-4 when compared with controls. Supplementation with AMF could significantly counteract the aberrant cytokine production and rats received AMF exhibited higher endurance capacity to swim when compared with those without AMF administration. Checking the spectrum signals confirmed that the three major isoflavones contained in AMF were ononin, formononetin, and demethylhomopterocarpin. CONCLUSION: Alterations of immune function may be associated with CFS and the tonic effects of AMF against CF may be attributable to balance the abnormal cytokine level by isoflavones.

Leocani L, Colombo B, Comi G.	Institute of Experimental Neurology Dept. of Neurology, Clinical Neurophysiology, Neurorehabilitation, Univ. Vita-Salute and Scientific Institute San Raffaele, Via Olgettina 60, 20132, Milan, Italy. letizia.leocani@hsr.it	Physiopathology of fatigue in multiple sclerosis.	Neurol Sci. 2008 Sep;29 Suppl 2:S241-3.	Fatigue is an overwhelming sense of tiredness or lack of energy, affecting both mental and physical domains. Fatigue is reported by about 50% of patients with multiple sclerosis (MS), and may be independent from depressed mood or weakness. Recently, the importance of distinguishing between subjective complaint and objective signs of fatigue has been emphasized, since the self-reported increase of subjective cognitive fatigue may not be related to a decline of cognitive performances. There is a general consensus that fatigue in MS is a central phenomenon, related to several factors. Neurophysiological studies revealed an impairment of volitional drive to the descending motor pathways and functional imaging studies indicated a selective involvement of frontal cortex and basal ganglia. Thus, the physiopathology of fatigue may rely on dysfunction of circuits involving thalamus, basal ganglia, and frontal cortex, which, affected by the MS lesions or disturbed in their function by the products of inflammation, could be the substrate of fatigue. The abnormal subjective fatigue observed in MS and perhaps in other neurological disorders could be due to a higher brain working load required to perform a given mental or physical activity, or to an internal overestimation of such load.
Lerner AM, Beqaj SH, Fitzgerald JT.	Department of Medicine, Wayne State University School of Medicine	Validation of the energy index point score to serially measure the	In Vivo. 2008 Nov-Dec;22(6):799-801.	BACKGROUND: A simple quantitative accurate method for assessing the degree of fatigue in patients with chronic fatigue syndrome (CFS) is necessary for physicians and patients. Severity of the disease and recovery can, thus, be assayed. PATIENT AND METHODS: From February 1-27, 2007, fifty-six consecutive CFS patients at a single treatment center were simultaneously evaluated by the patient

	and William Beaumont Hospital, Royal Oak, MI, USA. amartinlerner@yahoo.com	degree of disability in patients with chronic fatigue syndrome.		with the fatigue severity score (FSS), and by consensus of both patient and physician by the energy index (EI) point score. RESULTS: The FSS and EI correlated well, 0.67, p<0.001. CONCLUSION: The El point score is a validated reliable method to assess fatigue in CFS patients.
Li ZC, Zhao Y, Dou ZH, Yu L, Wu H, Zhang FJ.	Department of Infectious Diseases, Beijing Youan Hospital, Capital Medical University, Beijing 100069, China. treatment@chinaaids.cn.	[Clinical features of 66 children with acquired immunodeficienecy syndrome.] [Article in Chinese]	Zhongguo Dang Dai Er Ke Za Zhi. 2009 Feb;11(2):93-5.	OBJECTIVE: To study the clinical features of pediatric acquired immunodeficienecy syndrome(AIDS). METHODS: The epidemiological, clinical and laboratory data of 66 children with AIDS were retrospectively studied. RESULTS: Of the 66 patients, 46 (69.7%) were male and 20 (30.3%) were female, with a mean age of 8.7 years (ranged 2-16 years). The mean age at diagnosis was 7.7 years (ranged 2-15 years). Vertical transmission as the route of infection was documented in 48 cases (72.7%). Fourteen children (21.2%) were infected through blood or blood products. The route of infection could not be identified in 4 cases (6.1%). Body weight loss was noted in 43 cases (65.2%), anemia in 42 cases (63.7%), fever in 40 cases (60.6%), fatigue in 38 cases (57.6%), rash in 31 cases (47.0%), chronic cough in 28 cases (12.1%), chronic diarrhea in 24 cases (36.4%), CNS involvement in 16 cases (24.2%), oral thrush in 13 cases (19.7%), and hepatosplenomegaly in 12 cases (18.2%). Body height of 30 cases (45.4%) and body weight of 26 cases (39.4%) ranked the lower level. The immune system was severely suppressed in 59 cases (89.4%) and moderately suppressed in 7 cases (10.6%). CONCLUSIONS: Vertical transmission remained the most common route of pediatric HIV infection. There were various clinical manifestations in children with AIDS. The immune systems of the majority of children with this disorder were severely suppressed.
Lim JY, Kim KE, Choe G.	Department of Rehabilitation, Seoul National University College of Medicine, Seoul National University Bundang Hospital, Korea.	Myotonic dystrophy mimicking postpolio syndrome in a polio survivor.	Am J Phys Med Rehabil. 2009 Feb;88(2):161-4.	We describe a 38-yr-old polio survivor with newly developed weakness from myotonic dystrophy. He suffered muscle atrophy and weakness in his legs as a result of poliomyelitis at the age of 3 yrs. After a stable interval of about 30 yrs, he felt new weakness and fatigue in his legs. Electromyography revealed generalized myotonic discharges, early recruitment, and findings of chronic denervation in his left leg. Genetic testing was consistent with myotonic dystrophy type 1. A biopsy from the right gastrocnemius revealed findings of both myotonic dystrophy and chronic denervation. This case report shows the importance of considering other uncommon conditions in the differential diagnoses of postpolio syndrome.
Lin E, Hsu SY.	Vita Genomics, Inc., Jung-Shing Road, Wugu Shiang, Taipei, Taiwan. eugene.lin@vitagenomics.com	A Bayesian approach to gene-gene and gene-environment interactions in chronic fatigue syndrome.	Pharmacogenomics. 2009 Jan;10(1):35-42.	INTRODUCTION: In the study of genomics, it is essential to address gene-gene and gene-environment interactions for describing the complex traits that involves disease-related mechanisms. In this work, our goal is to detect gene-gene and gene-environment interactions resulting from the analysis of chronic fatigue syndrome patients' genetic and demographic factors including SNPs, age, gender and BMI. MATERIALS & METHODS: We employed the dataset that was original to the previous study by the Centers for Disease Control and Prevention Chronic Fatigue Syndrome Research Group. To investigate gene-gene and gene-environment interactions, we implemented a Bayesian based method for identifying significant interactions between factors. Here, we employed a two-stage Bayesian variable selection methodology based on Markov Chain Monte Carlo approaches. RESULTS: By applying our Bayesian based approach, NR3C1 was found in the significant two-locus gene-gene effect model, as well as in the significant two-factor gene-environment effect model. Furthermore, a

				significant gene-environment interaction was identified between NR3C1 and gender. These results support the hypothesis that NR3C1 and gender may play a role in biological mechanisms associated with chronic fatigue syndrome. CONCLUSION: We demonstrated that our Bayesian based approach is a promising method to assess the gene-gene and gene-environment interactions in chronic fatigue syndrome patients by using genetic factors, such as SNPs, and demographic factors such as age, gender and BMI.
Lin JM, Brimmer DJ, Boneva RS, Jones JF, Reeves WC. Barriers to healthcare utilization in fatiguing illness: a population-based study in Georgia.	BMC Health Serv Res. 2009 Jan 20;9:13.	ABSTRACT: BACKGROUND: The purpose of this study was to determine the prevalence of barriers to healthcare utilization in persons with fatiguing illness and describe its association with socio-demographics, the number of health conditions, and frequency of healthcare utilization. Furthermore, we sought to identify what types of barriers interfered with healthcare utilization and why they occurred. METHODS: In a cross-sectional population-based survey, 780 subjects, 112 of them with chronic fatigue syndrome (CFS), completed a healthcare utilization questionnaire. Text analysis was used to create the emerging themes from verbatim responses regarding barriers to healthcare utilization. Multiple logistic regression was performed to examine the association between barriers to healthcare utilization and other factors. RESULTS: Forty percent of subjects reported at least one barrier to healthcare utilization. Of 112 subjects with CFS, 55% reported at least one barrier to healthcare utilization. Fatiguing status, reported duration of fatigue, insurance, and BMI were significant risk factors for barriers to healthcare utilization. After adjusting for socio-demographics, medication use, the number of health problems, and frequency of healthcare utilization, fatiguing status remained significantly associated with barriers to healthcare utilization. Subjects with CFS were nearly 4 times more likely to forego needed healthcare during the preceding year than non-fatigued subjects while those with insufficient fatigue (ISF) were nearly 3 times more likely.Three domains emerged from text analysis on barriers to healthcare utilization: 1) accessibility; 2) knowledge-attitudes-beliefs (KABs); and, 3) healthcare system. CFS and reported duration of fatigue were significantly associated with each of these domains. Persons with CFS reported high levels of healthcare utilization barriers for each domain: accessibility (34%), healthcare system (25%), and KABs (19%). In further examination of barrier domains to healthcare utilization, compared to non-fatigued persons adjusted ORs for CFS having "accessibility", "KAB" and "Healthcare System" barrier domains decreased by 40%, 30%, and 19%, respectively. CONCLUSION: Barriers to healthcare utilization pose a significant problem in persons with fatiguing illnesses. Study results suggested two-fold implications: a symptom-targeted model focusing on symptoms associated with fatigue; and an interactive model requiring efforts from patients and providers to improve interactions between them by reducing barriers in accessibility, KABs, and healthcare system.
Lipowsky C, Schorl-Schweikardt BA, Kehl O, Brändle M.	Fachbereich für Endokrinologie und Diabetologie, Departement für Innere Medizin, Kantonsspital St. Gallen.	[19-year-old patient with adrenal cortex insufficiency--only the tip of the iceberg. Polyendocrine	Praxis (Bern 1994). 2008 Jan 23;97(2):77-81.	We report on a 19-year-old woman with polyglandular autoimmune syndrome type II (APS II). She was diagnosed with addison's disease and hypothyroidism due to chronic autoimmune thyroiditis. Her mother had celiac disease and her brohter had diabetes mellitus typ 1. Chronic autoimmune thyroiditis was diagnosed in her mother, subsequently. In patients and their relatives, who have autoimmune disorders, a search for autoimmune polyglandular syndrome is crucial. Consequently, it would be appropriate that the patient and all family members are asked for clinical signs and symptoms of autoimmune disorders. Annual measurement of morning cortisol, TSH and fasting

	christof.lipowsky@kssg.ch	autoimmune syndrome type II (Schmidt syndrome)] [Article in German]		plasma glucose may useful. Screening of affected individuals as well as their first-degree relatives for celiac disease is recommended. Therapy of APS II consists of hormone replacement therapy, but thyroxin replacement may induce life-threatening adrenal failure in a patient with untreated Addison's disease. Thus, in case of doubt hydrocortisone should be given before the thyroxine administration is started.
Lorusso L, Mikhaylova SV, Capelli E, Ferrari D, Ngonga GK, Ricevuti G.	Department of Neurology, Mellino Mellini Hospital, Chiari, Brescia, Italy.	Immunological aspects of chronic fatigue syndrome.	Autoimmun Rev. 2009 Feb;8(4):287-91. Epub 2008 Sep 16.	Chronic fatigue syndrome (CFS) is a specific clinical condition that characterises unexplained disabling fatigue and a combination of non-specific accompanying symptoms for at least 6 months, in the absence of a medical diagnosis that would otherwise explain the clinical presentation. Other common symptoms include headaches, myalgia, arthralgia, and post-exertional malaise; cognitive difficulties, with impaired memory and concentration; unrefreshing sleep; and mood changes. Similar disorders have been described for at least two centuries and have been differently named neurasthenia, post-viral fatigue, myalgic encephalomyelitis and chronic mononucleosis. Recent longitudinal studies suggest that some people affected by chronic fatigue syndrome improve with time but that most remain functionally impaired for several years. The estimated worldwide prevalence of CFS is 0.4-1% and it affects over 800,000 people in the United States and approximately 240,000 patients in the UK. No physical examination signs are specific to CFS and no diagnostic tests identify this syndrome. The pathophysiological mechanism of CFS is unclear. The main hypotheses include altered central nervous system functioning resulting from an abnormal immune response against a common antigen; a neuroendocrine disturbance; cognitive impairment caused by response to infection or other stimuli in sentient people. The current concept is that CFS pathogenesis is a multifactorial condition. Various studies have sought evidence for a disturbance in immunity in people with CFS. An alteration in cytokine profile, a decreased function of natural killer (NK) cells, a presence of autoantibodies and a reduced responses of T cells to mitogens and other specific antigens have been reported. The observed high level of pro-inflammatory cytokines may explain some of the manifestations such as fatigue and flu-like symptoms and influence NK activity. Abnormal activation of the T lymphocyte subsets and a decrease in antibody-dependent cell-mediated cytotoxicity have been described. An increased number of CD8+ cytotoxic T lymphocytes and CD38 and HLA-DR activation markers have been reported, and a decrease in CD11b expression associated with an increased expression of CD28+ T subsets has been observed. This review discusses the immunological aspects of CFS and offers an immunological hypothesis for the disease processes.
Lowry TJ, Pakenham KI.	School of Psychology, University of Queensland, Brisbane, Queensland, Australia.	Health-related quality of life in chronic fatigue syndrome: predictors of physical functioning and psychological distress.	Psychol Health Med. 2008 Mar;13(2):222-38.	This study investigated health-related quality of life (HRQoL; physical functioning and psychological distress) in an Australian chronic fatigue syndrome (CFS) population. The aims of the study were to compare HRQoL in those with CFS to the normal population, and to investigate the extent to which sociodemographic (age, gender, partner status, education), illness-related (illness duration, symptom frequency), and fatigue severity (physical, mental) variables predicted HRQoL. A total of 139 people meeting CFS criteria completed questionnaires. HRQoL was assessed using standardised measures of distress and physical functioning. Compared with norms, those with CFS obtained significantly lower scores on all physical functioning areas, whereas 63% of participants reported clinically significant psychological distress. Hierarchical regression analyses indicated that physical fatigue severity and symptom frequency were the strongest predictors of deficits in physical domain HRQoL. Physical

				HRQoL outcomes were also predicted by mental fatigue severity, older age, and female gender. All predictors were unrelated to psychological distress apart from weak positive associations with physical fatigue and symptom frequency. Results identify a potent set of predictors of HRQoL and show that CFS has a pervasive negative impact on quality of life, particularly physical and psychological functioning.

Maes M, Leunis JC.	MCare4U Outpatient Clinics, Belgium.	Normalization of leaky gut in chronic fatigue syndrome (CFS) is accompanied by a clinical improvement: effects of age, duration of illness and the translocation of LPS from gram-negative bacteria.	Neuro Endocrinol Lett. 2008 Dec;29(6):902-10.	BACKGROUND: There is now evidence that an increased translocation of LPS from gram negative bacteria with subsequent gut-derived inflammation, i.e. induction of systemic inflammation and oxidative & nitrosative stress (IO&NS), is a new pathway in chronic fatigue syndrome (CFS). METHODS: The present study examines the serum concentrations of IgA and IgM to LPS of gram-negative enterobacteria, i.e. Hafnia Alvei; Pseudomonas Aeruginosa, Morganella Morganii, Pseudomonas Putida, Citrobacter Koseri, and Klebsielle Pneumoniae in CFS patients both before and after intake of natural anti-inflammatory and anti-oxidative substances (NAIOSs), such as glutamine, N-acetyl cysteine and zinc, in conjunction with a leaky gut diet during 10-14 months. We measured the above immune variables as well as the Fibromyalgia and Chronic Fatigue Syndrome Rating Scale in 41 patients with CFS before and 10-14 months after intake of NAIOSs. RESULTS: Subchronic intake of those NAIOSs significantly attenuates the initially increased IgA and IgM responses to LPS of gram negative bacteria. Up to 24 patients showed a significant clinical improvement or remission 10-14 months after intake of NAIOSs. A good clinical response is significantly predicted by attenuated IgA and IgM responses to LPS, the younger age of the patients, and a shorter duration of illness (< 5 years). DISCUSSION: The results show that normalization of the IgA and IgM responses to translocated LPS may predict clinical outcome in CFS. The results support the view that a weakened tight junction barrier with subsequent gut-derived inflammation is a novel pathway in CFS and that it is a new target for drug development in CFS. Meanwhile, CFS patients with leaky gut can be treated with specific NAIOSs and a leaky gut diet.
Maes M, Mihaylova I,	MCare4U Outpatient Clinics,	An IgM-mediated immune response	Neuro Endocrinol Lett. 2008	BACKGROUND: It has been shown that chronic fatigue syndrome (CFS) and major depression (MDD) are accompanied by signs of oxidative stress and by a decreased antioxidant status. The aim of the

Kubera M, Leunis JC.	Antwerp, Belgium. crc.mh@telenet.be	directed against nitro-bovine serum albumin (nitro-BSA) in chronic fatigue syndrome (CFS) and major depression: evidence that nitrosative stress is another factor underpinning the comorbidity between major depression and CFS.	Jun;29(3):313-9.	present study was to examine whether CFS and MDD are accompanied by an IgM-mediated immune response directed against nitro-serum bovine albumin (BSA), which is a neoepitope of BSA formed by damage caused by nitrosative stress. AIMS: Toward this end, we examined serum IgM antibodies to nitro-BSA in 13 patients with CFS, 14 subjects with partial CFS, 16 patients with MDD and 11 normal controls. RESULTS: We found that the prevalence and mean values for the serum IgM levels directed against nitro-BSA were significantly greater in patients with partial CFS, CFS and MDD than in normal controls, and significantly greater in CFS than in those with partial CFS and MDD. We found significant and positive correlations between serum IgM levels directed against nitro-BSA and symptoms of the FibroFatigue scale, i.e. aches and pain and muscular tension. There was also a strong positive correlation between serum IgM titers directed against nitro-BSA and an index of increased gut permeability ("leaky gut"), i.e. serum IgM and IgA directed against LPS of different gram-negative enterobacteria. DISCUSSION: The abovementioned results indicate that both CFS and MDD are accompanied by a) an increased gut permeability which has allowed an exaggerated passage of BSA through a compromised epithelial barrier; b) increased nitrosative stress which has induced damage to BSA; and c) an IgM-mediated immune response which is directed against the nitro-BSA neoepitopes. Nitrosative stress is one of the factors underpinning the comorbidity and clinical overlap between CFS and MDD.
Maes M.	Clinical Research Centre of Mental Health (CRC-MH), Antwerp, Belgium. crc.mh@telenet.be	Inflammatory and oxidative and nitrosative stress pathways underpinning chronic fatigue, somatization and psychosomatic symptoms.	Curr Opin Psychiatry. 2009 Jan;22(1):75-83.	PURPOSE OF REVIEW: The aim of this paper is to review recent findings on inflammatory and oxidative and nitrosative stress (IO&NS) pathways in chronic fatigue and somatization disorder. RECENT FINDINGS: Activation of IO&NS pathways is the key phenomenon underpinning chronic fatigue syndrome (CFS): intracellular inflammation, with an increased production of nuclear factor kappa beta (NFkappabeta), cyclo-oxygenase-2 (COX-2) and inducible NO synthase (iNOS); and damage caused by O&NS to membrane fatty acids and functional proteins. These IO&NS pathways are induced by a number of trigger factors, for example psychological stress, strenuous exercise, viral infections and an increased translocation of LPS from gram-bacteria (leaky gut). The 'psychosomatic' symptoms experienced by CFS patients are caused by intracellular inflammation (aches and pain, muscular tension, fatigue, irritability, sadness, and the subjective feeling of infection); damage caused by O&NS (aches and pain, muscular tension and fatigue); and gut-derived inflammation (complaints of irritable bowel). Inflammatory pathways (monocytic activation) are also detected in somatizing disorder. SUMMARY: 'Functional' symptoms, as occurring in CFS and somatization, have a genuine organic cause, that is activation of peripheral and central IO&NS pathways and gut-derived inflammation. The development of new drugs, aimed at treating those disorders, should target these IO&NS pathways.
Magnus P, Brubakk O, Nyland H, Wold BH, Gjessing HK, Brandt I, Eidem T, Nøkleby H, Stene-Larsen G.	Division of Epidemiology, Norwegian Institute of Public Health, Oslo, Norway. per.magnus@fhi.no	Vaccination as teenagers against meningococcal disease and the risk of the chronic fatigue syndrome.	Vaccine. 2009 Jan 1;27(1):23-7. Epub 2008 Nov 5.	The etiology of chronic fatigue syndrome (CFS)/myalgic encephalomyelitis (ME) is unknown. In Norway, a vaccine against Neisseria meningitides group B was administered to teenagers in 1988--1989 in a protection trial. In order to estimate the relative risk of CFS/ME according to vaccine history, we conducted a case-control study in 2007, with 201 cases diagnosed at one of two hospitals and 389 controls. The adjusted odds ratio for CFS/ME was 1.06 (95% CI: 0.67-1.66) for subjects who received the active vaccine contrasted to subjects who did not. Using this design, no statistically significant association between vaccination against meningococcal disease in teenagers and occurrence of CFS/ME could be observed.

Majer M, Welberg LA, Capuron L, Miller AH, Pagnoni G, Reeves WC.	Department of Psychiatry and Behavioral Sciences, Emory University School of Medicine, Atlanta, Georgia, USA.	Neuropsychological performance in persons with chronic fatigue syndrome: results from a population-based study.	Psychosom Med. 2008 Sep;70(7):829-36. Epub 2008 Jul 7.	OBJECTIVE: To examine the neuropsychological function characterized in subjects with chronic fatigue syndrome (CFS) at the same time controlling for relevant confounding factors. CFS is associated with symptoms of neuropsychological dysfunction. Objective measures of neuropsychological performance have yielded inconsistent results possibly due to sample selection bias, diagnostic heterogeneity, comorbid psychiatric disorders, and medication usage. METHOD: CFS subjects (n = 58) and well controls (n = 104) from a population-based sample were evaluated, using standardized symptom severity criteria. Subjects who had major psychiatric disorders or took medications known to influence cognition were excluded. Neuropsychological function was measured using the Cambridge Neuropsychological Test Automated Battery (CANTAB). RESULTS: Compared with controls, CFS subjects exhibited significant decreases in motor speed as measured in the simple and five-choice movement segments of the CANTAB reaction time task. CFS subjects also exhibited alterations in working memory as manifested by a less efficient search strategy on the spatial working memory task, fewer % correct responses on the spatial recognition task, and prolonged latency to a correct response on the pattern recognition task. A significantly higher percentage of CFS subjects versus controls exhibited evidence of neuropsychological impairment (defined by performance 1 standard deviation below the CANTAB normative mean) in tasks of motor speed and spatial working memory. Impairment in CFS subjects versus control subjects ranged from 20% versus 4.8% in five-choice movement time ($p = .002$) to 27.8% versus 10.6% in search strategy on the spatial working memory task ($p = .006$). CONCLUSIONS: These results confirm and quantify alterations in motor speed and working memory in CFS subjects independent of comorbid psychiatric disease and medication usage.
Malaguarnera M, Gargante MP, Cristaldi E, Colonna V, Messano M, Koverech A, Neri S, Vacante M, Cammalleri L, Motta M.	Centro di Ricerca La Grande Senescenza, Università degli Studi di Catania, Via Messina 829, I-95126 Catania, Italy.	Acetyl L-carnitine (ALC) treatment in elderly patients with fatigue.	Arch Gerontol Geriatr. 2008 Mar-Apr;46(2):181-90. Epub 2007 Jul 20.	Fatigue is one of the conditions most frequently complained by the elderly. There are few effective treatment options for patients with chronic fatigue syndrome. To determine the efficacy, tolerability and impact on the fatigue, as well as on cognitive and functional status of elderly subjects with acetyl L-carnitine (ALC), 96 aged subjects (>70 years, range 71-88) were investigated (50 females and 46 males; mean age 76.2+/-7.6 and 78.4+/-6.4 years, respectively). They met four or more of the Holmes major criteria or at least six of Fukuda minor criteria. Fatigue was measured with the Wessely and Powell [Wessely, S., Powell, R., 1989. Fatigue syndromes: a comparison of chronic postviral fatigue with neuromuscular and affective disorders. J. Neurol. Neurosurg. Psychiatry 52, 940-948] scores, with the fatigue severity scale. At the end of the treatment, we observed a decrease of physical fatigue: 6.2 ($p<0.001$), of mental fatigue: 2.8 ($p<0.001$), of severity fatigue: 21.0 ($p<0.001$) and improvements in functional status: 16.1 ($p<0.001$) and cognitive functions: 2.7 ($p<0.001$). By the end of the treatment, significant differences between the two groups were found for the following parameters: muscle pain -27% versus -3% ($p<0.05$); prolonged fatigue after exercise: 51% versus -4% ($p<0.0001$); sleep disorders: 28% versus 4% ($p<0.05$); physical fatigue: 7 versus -0.5 ($p<0.0001$); mental fatigue: -3.3 versus 0.6 ($p<0.0001$); fatigue severity scale: -22.5 versus 1.2 ($p<0.0001$); functional status 17.1 versus 0.6 ($p<0.0001$); mini mental state examination (MMSE) improvements: 3.4 versus 0.5 ($p<0.0001$). Our data show that administering ALC may reduce both physical and mental fatigue in elderly and improves both the cognitive status and physical functions.
Malouff JM, Thorsteinsson EB,	University of New England, Armidale,	Efficacy of cognitive	Clin Psychol Rev. 2008	A meta-analysis of the efficacy of cognitive behavioral therapy (CBT) in treating chronic fatigue included 15 effect sizes for between-group outcome comparisons. Across analyses, which included a

Rooke SE, Bhullar N, Schutte NS.	Australia. jmalouff@une.edu.au	behavioral therapy for chronic fatigue syndrome: a meta-analysis.	Jun;28(5):736-45. Epub 2007 Nov 1.	total of 1371 participants, there was a significant difference, d=0.48, in post-treatment fatigue between participants receiving CBT and those in control conditions. Results indicate that CBT for chronic fatigue syndrome tends to be moderately efficacious. Dropout rates in CBT varied from 0-42%, with a mean of 16%. In the five studies that reported the number of CBT clients who were no longer in the clinical range with regard to fatigue at the latest follow-up, the percentage varied from 33% to 73% of those assigned to CBT, with a mean of 50%. Moderator results suggest directions for future investigations.
Marques A.	Laboratory of Clinical Infectious Diseases, National Institute of Allergy and Infectious Diseases, NIH, Bethesda, MD 20892, USA. amarques@niaid.nih.gov	Chronic Lyme disease: a review.	Infect Dis Clin North Am. 2008 Jun;22(2):341-60, vii-viii.	Studies have shown that most patients diagnosed with chronic Lyme disease either have no objective evidence of previous or current infection with Borrelia burgdorferi or are patients who should be classified as having post-Lyme disease syndrome, which is defined as continuing or relapsing nonspecific symptoms (such as fatigue, musculoskeletal pain, and cognitive complaints) in a patient previously treated for Lyme disease. Despite extensive study, there is currently no clear evidence that post-Lyme disease syndrome is caused by persistent infection with B burgdorferi. Four randomized placebo-controlled studies have shown that antibiotic therapy offers no sustained benefit to patients who have post-Lyme disease syndrome. These studies also showed a substantial placebo effect and a significant risk of treatment-related adverse events. Further research to elucidate the mechanisms underlying persistent symptoms after Lyme disease and controlled trials of new approaches to the treatment and management of these patients are needed.
Martinez-Lavin M, Infante O, Lerma C.	National Institute of Cardiology, Mexico City, Mexico. mmlavin@infosel.net.mx	Hypothesis: the chaos and complexity theory may help our understanding of fibromyalgia and similar maladies.	Semin Arthritis Rheum. 2008 Feb;37(4):260-4. Epub 2007 Jun 14.	BACKGROUND: Modern clinicians are often frustrated by their inability to understand fibromyalgia and similar maladies since these illnesses cannot be explained by the prevailing linear-reductionist medical paradigm. OBJECTIVE: This article proposes that new concepts derived from the Complexity Theory may help understand the pathogenesis of fibromyalgia, chronic fatigue syndrome, and Gulf War syndrome. METHODS: This hypothesis is based on the recent recognition of chaos fractals and complex systems in human physiology. RESULTS: These nonlinear dynamics concepts offer a different perspective to the notion of homeostasis and disease. They propose that the essence of disease is dysfunction and not structural damage. Studies using novel nonlinear instruments have shown that fibromyalgia and similar maladies may be caused by the degraded performance of our main complex adaptive system. This dysfunction explains the multifaceted manifestations of these entities. CONCLUSIONS: To understand and alleviate the suffering associated with these complex illnesses, a paradigm shift from reductionism to holism based on the Complexity Theory is suggested. This shift perceives health as resilient adaptation and some chronic illnesses as rigid dysfunction.
Mathew SJ, Mao X, Keegan KA, Levine SM, Smith EL, Heier LA, Otcheretko V, Coplan JD, Shungu DC.	Department of Psychiatry, Mount Sinai School of Medicine, New York, NY, USA.	Ventricular cerebrospinal fluid lactate is increased in chronic fatigue syndrome compared with generalized anxiety disorder: an in vivo 3.0 T (1)H MRS	NMR Biomed. 2008 Oct 21;22(3):251-258. [Epub ahead of print]	Chronic fatigue syndrome (CFS) is a controversial diagnosis because of the lack of biomarkers for the illness and its symptom overlap with neuropsychiatric, infectious, and rheumatological disorders. We compared lateral ventricular volumes derived from tissue-segmented T(1)-weighted volumetric MRI data and cerebrospinal fluid (CSF) lactate concentrations measured by proton MRS imaging ((1)H MRSI) in 16 subjects with CFS (modified US Centers for Disease Control and Prevention criteria) with those in 14 patients with generalized anxiety disorder (GAD) and in 15 healthy volunteers, matched group-wise for age, sex, body mass index, handedness, and IQ. Mean lateral ventricular lactate concentrations measured by (1)H MRSI in CFS were increased by 297% compared with those in GAD ($P < 0.001$) and by 348% compared with those in healthy volunteers ($P < 0.001$), even after controlling for

		imaging study.		ventricular volume, which did not differ significantly between the groups. Regression analysis revealed that diagnosis accounted for 43% of the variance in ventricular lactate. CFS is associated with significantly raised concentrations of ventricular lactate, potentially consistent with recent evidence of decreased cortical blood flow, secondary mitochondrial dysfunction, and/or oxidative stress abnormalities in the disorder. Meeus M, Nijs J, McGregor N, Meeusen R, De Schutter G, Truijen S, FrÃ©mont M, Van Hoof E, De Meirleir K.	Department of Human Physiology, Faculty of Physical Education and Physiotherapy, Vrije Universiteit Brussel, Belgium.	Unravelling intracellular immune dysfunctions in chronic fatigue syndrome: interactions between protein kinase R activity, RNase L cleavage and elastase activity, and their clinical relevance.	In Vivo. 2008 Jan-Feb;22(1):115-21.	This study examined possible interactions between immunological abnormalities and symptoms in CFS. Sixteen CFS patients filled in a battery of questionnaires, evaluating daily functioning, and underwent venous blood sampling, in order to analyse immunological abnormalities. Ribonuclease (RNase) L cleavage was associated with RNase L activity (rs=0.570; p=0.021), protein kinase R (PKR) (rs=0.716; p=0.002) and elastase activity (rs=0.500; p=0.049). RNase L activity was related to elastase (rs=0.547; p=0.028) and PKR activity (rs=0.625; p=0.010). RNase L activity (rs=0.535; p=0.033), elastase activity (rs=0.585; p=0.017) and RNase L cleavage (rs=0.521; p=0.038) correlated with daily functioning. This study suggests that in CFS patients an increase in elastase activity and subsequent RNase L cleavage is accompanied by increased activity of both the PKR and RNase L enzymes. RNase L and elastase activity are related to daily functioning, thus evidence supporting the clinical importance of these immune dysfunctions in CFS patients was provided.
Meeus M, Nijs J, Van de Wauwer N, Toeback L, Truijen S.	Division of Musculoskeletal Physiotherapy, Department of Health Sciences, University College Antwerp HA, Belgium.	Diffuse noxious inhibitory control is delayed in chronic fatigue syndrome: an experimental study.	Pain. 2008 Oct 15;139(2):439-48. Epub 2008 Jul 9.	Deficient endogenous pain inhibition, e.g. Diffuse noxious inhibitory controls (DNIC), or hormonal abnormalities like hypocortisolism, could be responsible for chronic widespread pain in Chronic Fatigue Syndrome (CFS). Thirty-one CFS-patients with chronic pain and 31 healthy controls were subjected to spatial summation of thermal noxious stimuli by gradual immersion (ascending or descending) of the arm in warm water (46 degrees C). They rated pain intensity every 15s. Every immersion took 2 min, alternated with 5 min rest. Before and after immersion, salivary cortisol was assessed. Overall pain ratings were higher in CFS-patients, but the evolution was not different between patients and controls, during both ascending and descending immersion. Pain intensity and immersed surface were only correlated during the descending session in both patients (r=.334) and controls (r=.346). When comparing the first and the last 15s of every emersion, it was found that pain inhibition starts slower for CFS-patients in comparison to healthy subjects. Both pre- or post-values and cortisol response did not differ between controls and patients. The drop in cortisol was significantly correlated to pain intensity in CFS (r between .357 and .402). In addition to the hyperalgesia in CFS, DNIC react slower to spatial summation of thermal noxious stimuli. We found no evidence for hypocortisolism in CFS, and the cortisol response to nociception was not different in CFS compared to healthy subjects. In conclusion, delayed pain inhibition may play a role in chronic widespread pain in CFS but further research is required.
Metzger K, Frémont M, Roelant C, De Meirleir K.	Protea Biopharma, Z.1-Researchpark 100, 1731 Zellik, Belgium.	Lower frequency of IL-17F sequence variant (His161Arg) in chronic fatigue syndrome patients.	Biochem Biophys Res Commun. 2008 Nov 7;376(1):231-3. Epub 2008 Sep 5.	Chronic fatigue syndrome (CFS) is characterized by immune dysfunctions including chronic immune activation, inflammation, and alteration of cytokine profiles. T helper 17 (Th17) cells belong to a recently identified subset of T helper cells, with crucial regulatory function in inflammatory and autoimmune processes. Th17 cells are implicated in allergic inflammation, intestinal diseases, central nervous system inflammation, disorders that may all contribute to the pathophysiology of CFS. IL-17F

				is one of the pro-inflammatory cytokines secreted by Th17 cells. We investigated the association between CFS and the frequency of rs763780, a C/T genetic polymorphism leading to His161Arg substitution in the IL-17F protein. The His161Arg variant (C allele) antagonizes the pro-inflammatory effects of the wild-type IL-17F. A significantly lower frequency of the C allele was observed in the CFS population, suggesting that the His161Arg variant may confer protection against the disease. These results suggest a role of Th17 cells in the pathogenesis of CFS.
Mini L, Wang-Weigand S, Zhang J.	Takeda Pharmaceuticals North America, Inc., Deerfield, Illinois 60015, USA. lmini@tpna.com	Ramelteon 8 mg/d versus placebo in patients with chronic insomnia: post hoc analysis of a 5-week trial using 50% or greater reduction in latency to persistent sleep as a measure of treatment effect.	Clin Ther. 2008 Jul;30(7):1316-23.	BACKGROUND: Ramelteon is a selective MT1/MT2 melatonin receptor agonist approved by the US Food and Drug Administration for insomnia treatment. OBJECTIVE: The aim of this post hoc analysis was to compare the efficacy and tolerability of ramelteon 8 mg/d versus placebo in adults with chronic insomnia. METHODS: This study analyzed data from a previously published 5-week, randomized, double-blind, placebo-controlled study. Patients aged 18 to 64 years with chronic insomnia were randomly assigned to receive ramelteon 8 or 16 mg/d or placebo QD for 5 weeks. Sleep parameters were evaluated using polysomnography at weeks 1, 3, 5, and 6 (placebo runout). In this post hoc analysis, patients who received ramelteon 8 mg (approved dose) or placebo in the original study were evaluated using a primary end point of a=50% reduction from baseline in latency to persistent sleep (LPS). RESULTS: A total of 270 adults (ramelteon 8 mg, 139 patients, mean age, 38.0 years; placebo, 131 patients, mean age, 39.7 years) met the criteria for inclusion in this analysis. One patient from the original study (ramelteon 8-mg/d group) was excluded from the post hoc analysis based on a lack of evaluable LPS data. Ramelteon was associated with significantly greater proportions of patients who achieved a > or = 50% reduction in LPS compared with placebo at weeks 1 (63.0% vs 39.7%; P < 0.001), 3 (63.0% vs 41.2%; P < 0.001), and 5 (65.9% vs 48.9%; P < 0.005). No rebound insomnia or withdrawal effects were observed. Headache (19.4% and 18.3%), fatigue (9.4% and 2.3%), and somnolence (7.9% and 1.5%) were the most common adverse events. CONCLUSIONS: In this post hoc analysis of data from patients with chronic insomnia, a significantly greater percentage experienced a > or = 50% reduction in LPS with ramelteon 8 mg/d versus placebo. This improvement was evident at week 1 and was sustained through 5 weeks of treatment. Ramelteon 8 mg was well tolerated in this study, with no evidence of withdrawal or rebound insomnia.
Miwa K, Fujita M.	Department of Internal Medicine, Nanto Home and Regional Medical Center, 577 Matsubara, Nanto, Toyama 939-1518, Japan.	Increased oxidative stress suggested by low serum vitamin E concentrations in patients with chronic fatigue syndrome.	Int J Cardiol. 2008 Aug 4. [Epub ahead of print]	Serum alpha-tocopherol concentrations were determined in 50 patients with chronic fatigue syndrome (CFS) and 40 control subjects (Control). Prevalence of each or any coronary risk factor was not significantly different between CFS and Control. CFS had significantly lower alpha-tocopherol concentrations than Control. The concentrations were significantly lower in the subjects with any coronary risk factors than those without in CFS as well as Control. Even among the subjects with any coronary risk factors and also among those without, CFS had significantly lower alpha-tocopherol concentrations than Control. In conclusion, CFS had significantly lower alpha-tocopherol concentrations irrespective of coronary risk factors than Control, suggesting the presence of increased oxidative stress in CFS.
Miwa K, Fujita M.	Division of Internal Medicine, Fukuda General Hospital, Osaka.	Small heart syndrome in patients with chronic fatigue	Clin Cardiol. 2008 Jul;31(7):328-33.	BACKGROUND: Small heart syndrome has previously been reported as neurocirculatory asthenia, associated with a small heart shadow on a chest roentgenogram. This is characterized as weakness or fatigue even after ordinary exertion, palpitation, dyspnea, and fainting, resembling patients with chronic fatigue syndrome (CFS). HYPOTHESIS: Small heart syndrome may be prevalent in patients with

	kmiwa@fukuda-hsp.jp	syndrome.		CFS. METHODS: The study population consisted of 56 patients (<50 y of age) with CFS, and 38 control subjects. Chest roentgenographic, echocardiographic, and physical examinations were performed. RESULTS: Small heart syndrome (cardiothoracic ratio <or= 42%) was significantly more prevalent in the CFS group (61%) than in the control group (24%) (p < 0.01). In CFS patients with a small heart (n = 34), narrow chest (88%), orthostatic dizziness (44%), foot coldness (41%), pretibial pitting edema (32%), r-kidney palpability (47%), and mitral valve prolapse (29%), were all significantly more prevalent than in the control group, and also in the CFS patients without small heart syndrome. Echocardiographic examination demonstrated significantly smaller values of both the left ventricular (LV) end-diastolic dimensions and end-systolic, and stroke volume and cardiac indexes in CFS with a small heart, as compared with control subjects with a normal heart size (42% < cardiothoracic ratio < 50%). CONCLUSIONS: A considerable number of CFS patients have a small heart. Small heart syndrome may contribute to the development of CFS as a constitutional factor predisposing to fatigue, and may be included in the genesis of CFS. Copyright (c) 2008 Wiley Periodicals, Inc.
Moldofsky H.	Faculty of Medicine, University of Toronto, Sleep Disorders Clinic of the Centre for Sleep and Chronobiology, 340 College Street, Suite 580, Toronto, ON MST 3A9, Canada. h.moldofsky@utoronto.ca	The significance of the sleeping-waking brain for the understanding of widespread musculoskeletal pain and fatigue in fibromyalgia syndrome and allied syndromes.	Joint Bone Spine. 2008 Jul;75(4):397-402. Epub 2008 May 5.	The clinical focus of rheumatologists on the widespread pain and numerous tender points in specific anatomic regions in their patients who show no evidence for disease pathology has lead to the characterization of such peripheral symptoms as a specific disorder of the musculoskeletal system, now commonly known as fibromyalgia. This rheumatologic diagnostic entity has resulted in relative inattention to an understanding of their patients' common complaints of unrefreshing sleep, chronic fatigue and psychological distress. Experimental evidence from humans and animal studies indicate that there is an inter-relationship of disturbances in the physiology of the sleeping-waking brain with the widespread musculoskeletal pain, chronic fatigue, and psychological distress in patients with hitherto unexplained pain/fatigue illnesses, e.g., fibromyalgia and chronic fatigue syndromes. The emerging knowledge of the dysfunction of the nervous system in such patients has lead to the study of novel medications that affect neurotransmitter functions, e.g., pregabalin, serotonin/noradrenaline compounds and sodium oxybate that are shown to improve many of the symptoms of such patients.
Molnár G.	BMSZKI Orvosi Krízis Szolgálat, Budapest. mogab@citromail.hu	[Depressive type of drawing test without melancholy] [Article in Hungarian]	Neuropsychopharmacol Hung. 2008 Jun;10(3):159-64.	Depressed patients draw small figures in the left upper corner of sheet in House-Tree-Person (H-T-P) Test. This type of drawing rarely was drawn by patients without melancholic complains. In the Crisis Intervention Department at the Budapest Social Center (Hungary), 5 homeless male patients between 42-67 years of ages were found with depressive type of drawing in the H-T-P Test, but without melancholy. One had alcoholic encephalopathy with mild cognitive disorder, four had alcoholic or vascular types of dementia. Three had severe apathy. One was euphoric, undiscriminating with logorhea, but reported depression without sadness in Beck Depression Inventory. One had retarded thinking. Psycho-organic signs were well demonstrated in demented patients' drawings. Four patients represented human figures without hands, which symbolized helplessness. Apathy frequently was reported to be the only syndrome in psycho-organic, chronic fatigue, burn out syndromes, or even in exhaustive depression and sickness-behaviour, but it could not be classified in ICD-10 or DSM-IV-TR. Apathy, like depression, responded to antidepressive treatments, therefore, this similarity of syndromes could be responsible for our lethargic patients' depressive type of drawings. Furthermore,

				clinically abortive depressions perhaps could be demonstrated only by nonverbal drawing test. Psycho-organic and depressive signs of drawings were reported to be independent of each other, therefore, dementia could not cause our patients' depressive type of drawings. So, H-T-P Drawing Test was a useful nonverbal method of psycho-organic patients' investigation, which demonstrated depression in patients without verbally manifest melancholic illness.
Nancy AL, Shoenfeld Y.	Center for Autoimmune Diseases, Department of Medicine B, Sheba Medical Center, Tel-Hashomer, Israel.	Chronic fatigue syndrome with autoantibodies--the result of an augmented adjuvant effect of hepatitis-B vaccine and silicone implant.	Autoimmun Rev. 2008 Oct;8(1):52-5. Epub 2008 Aug 24.	BACKGROUND: Chronic fatigue syndrome (CFS) that defines by prolonged fatigue and other manifestations, was recently integrated into a spectrum of central sensitivity syndromes including several diseases as fibromylagia. CFS etiology is multi-factorial commonly triggered by infectious agents. Vaccines, induce an immune response similarly to infections, and may trigger just like infections autoimmune diseases, CFS and fibromyalgia. Furthermore vaccines contain an adjuvant which enhances their immune stimulation. CASE PRESENTATION: A 56-year-old woman was diagnosed with CFS accompanied by fibromyalgia, demyelination and autoantibodies. Her illness begun following the 2nd dose of hepatitis-B vaccine, and was aggravated by the 3rd vaccination. She underwent silicone breast implantation 6 years before vaccination with no adverse events. However, between the 2nd and 3rd vaccination she suffered a breast injury with local inflammation. Upon explanation of her breast implants silicone leak was observed. DISCUSSION: Vaccines have been reported to precede CFS mainly following exposure to multiple vaccinations (e.g. the Gulf war syndrome), or as an adverse response to the vaccine adjuvant (e.g. the macrophagic myofasciitis syndrome). Silicone is considered an adjuvant to the immune system, and may induce "the adjuvant disease". Silicone implant, especially silicone leak relationship with autoimmunity and CFS has been the focus of considerable debates. CONCLUSION: Our patient illness started following hepatitis-B vaccine, suggesting that it was caused or accelerated by vaccination. In parallel to vaccination our patient suffered from breast injury, which might represent the time of silicone leak. The exposure to the adjuvant, silicone, might have augmented her immune response to the vaccine. To the best of our knowledge this is the first case of combined adverse effect to vaccine and silicone. Vaccine safety in individuals with silicone implants requires further studies.
Nao S, Adachi Y, Sato S.	Department of Anesthesiology, Intensive Care Unit of University Hospital, Hamamatsu University School of Medicine, Hamamatsu.	[Anesthesia for a patient with Cushing's disease and hepatitis B] [Article in Japanese]	Masui. 2008 Jun;57(6):745-7.	A 34-year-old female patient complaining of general fatigue and liver dysfunction was diagnosed as acute aggravation of chronic hepatitis B. She showed a complication of Cushing's disease and hepatitis was initially treated with lamivudine administration as well as inhibition and supplementation of cortisol, because hypercortisolemia could induce massive liver necrosis with hepatitis. After inducing remission phase, Hardy's operation for pituitary microadenoma was scheduled. Induction and maintenance of anesthesia were achieved by administration of propofol and analgesia was attained by intermittent administration of fentanyl. Liver function was well maintained during perioperative period and no complication concerning anesthesia was observed.
Naschitz JE, Slobodin G, Sharif D, Fields M, Isseroff H, Sabo E, Rosner I.	Department of Internal Medicine A, Bnai Zion Medical Center and Rappaport	Electrocardiographic QT interval and cardiovascular reactivity in fibromyalgia differ	Eur J Intern Med. 2008 May;19(3):187-91. Epub 2007 Nov 19.	BACKGROUND: Fibromyalgia (FM) and chronic fatigue syndrome (CFS) frequently overlap clinically and have been considered variants of one common disorder. We have recently shown that CFS is associated with a short corrected electrocardiographic QT interval (QTc). In the present study, we evaluated whether FM and CFS can be distinguished by QTc. METHODS: The study groups were comprised of women with FM (n=30) and with CFS (n=28). The patients were evaluated with a 10 min

	Family Faculty of Medicine, Technion-Israel Institute of Technology, Haifa, Israel. Naschitz@tx.technion.ac.il	from chronic fatigue syndrome.		supine-30 min head-up tilt test. The electrocardiographic QT interval was corrected for heart rate (HR) according to Fridericia's equation (QTc). In addition, cardiovascular reactivity was assessed based on blood pressure and HR changes and was expressed as the 'hemodynamic instability score' (HIS). RESULTS: The average supine QTc in FM was 417 ms (SD 25) versus 372 ms (SD 22) in CFS (p<0.0001); the supine QTc cut-off <385.7 ms was 79% sensitive and 87% specific for CFS vs. FM. The average QTc at the 10th minute of tilt was 409 ms (SD 18) in FM versus 367 ms (SD 21) in CFS (p<0.0001); the tilt QTc cut-off <383.3 ms was 71% sensitive and 91% specific for CFS vs. FM. The average HIS in FM patients was -3.52 (SD 1.96) versus +3.21 (SD 2.43) in CFS (p<0.0001). CONCLUSION: A relatively short QTc and positive HIS characterize CFS patients and distinguish them from FM patients. These data may support the contention that FM and CFS are separate disorders.
Nater UM, Maloney E, Boneva RS, Gurbaxani BM, Lin JM, Jones JF, Reeves WC, Heim C.	Chronic Viral Diseases Branch, Coordinating Center for Infectious Diseases, Centers for Disease Control and Prevention, Mail Stop A-15, Atlanta, Georgia 30333, USA.	Attenuated morning salivary cortisol concentrations in a population-based study of persons with chronic fatigue syndrome and well controls.	J Clin Endocrinol Metab. 2008 Mar;93(3):703-9. Epub 2007 Dec 26.	CONTEXT: A substantial body of research on the pathophysiology of chronic fatigue syndrome (CFS) has focused on hypothalamic-pituitary-adrenal axis dysregulation. The cortisol awakening response has received particular attention as a marker of hypothalamic-pituitary-adrenal axis dysregulation. OBJECTIVE: The objective of the current study was to evaluate morning salivary cortisol profiles in persons with CFS and well controls identified from the general population. DESIGN AND SETTING: We conducted a case-control study at an outpatient research clinic. CASES AND OTHER PARTICIPANTS: We screened a sample of 19,381 residents of Georgia and identified those with CFS and a matched sample of well controls. Seventy-five medication-free CFS cases and 110 medication-free well controls provided complete sets of saliva samples. MAIN OUTCOME MEASURES: We assessed free cortisol concentrations in saliva collected on a regular workday immediately upon awakening and 30 and 60 min after awakening. RESULTS: There was a significant interaction effect, indicating different profiles of cortisol concentrations over time between groups, with the CFS group showing an attenuated morning cortisol profile. Notably, we observed a sex difference in this effect. Women with CFS exhibited significantly attenuated morning cortisol profiles compared with well women. In contrast, cortisol profiles were similar in men with CFS and male controls. CONCLUSIONS: CFS was associated with an attenuated morning cortisol response, but the effect was limited to women. Our results suggest that a sex difference in hypocortisolism may contribute to increased risk of CFS in women.
Nater UM, Youngblood LS, Jones JF, Unger ER, Miller AH, Reeves WC, Heim C.	Chronic Viral Diseases Branch, Centers for Disease Control and Prevention, Mail Stop A-15, Atlanta, GA 30333, USA.	Alterations in diurnal salivary cortisol rhythm in a population-based sample of cases with chronic fatigue syndrome.	Psychosom Med. 2008 Apr;70(3):298-305. Epub 2008 Mar 31.	OBJECTIVE: To examine diurnal salivary cortisol rhythms and plasma IL-6 concentrations in persons with chronic fatigue syndrome (CFS), persons not fulfilling a diagnosis of CFS (we term them cases with insufficient symptoms or fatigue, ISF) and nonfatigued controls (NF). Previous studies of CFS patients have implicated the hypothalamic-pituitary-adrenal axis and the immune system in the pathophysiology of CFS, although results have been equivocal. METHODS: Twenty-eight people with CFS, 35 persons with ISF, and 39 NF identified from the general population of Wichita, Kansas, were admitted to a research ward for 2 days. Saliva was collected immediately on awakening (6:30 AM), at 08:00 AM, 12 noon, 4:00 PM, 8:00 PM and at bedtime (10:00 PM) and plasma was obtained at 7:30 AM. Salivary cortisol concentrations were assessed using radioimmunoassay, and plasma IL-6 was measured using sandwich enzyme-linked immunosorbent assay. RESULTS: People with CFS demonstrated lower salivary cortisol concentrations in the morning and higher salivary cortisol concentrations in the evening compared with both ISF and NF groups indicating a flattening of the diurnal cortisol profile. Mean plasma IL-6 concentrations were highest in CFS compared with the other

				groups, although these differences were no longer significant after controlling for BMI. Attenuated decline of salivary cortisol concentrations across the day and IL-6 concentration were associated with fatigue symptoms in CFS. CONCLUSIONS: These results suggest an altered diurnal cortisol rhythm and IL-6 concentrations in CFS cases identified from a population-based sample.
Neu D, Hoffmann G, Moutrier R, Verbanck P, Linkowski P, Le Bon O.	University Hospital Brugmann, Sleep Laboratory, Université Libre de Bruxelles (ULB), Brussels, Belgium. daniel.neu@chu-brugmann.be	Are patients with chronic fatigue syndrome just 'tired' or also 'sleepy'?	J Sleep Res. 2008 Dec;17(4):427-31. Epub 2008 Oct 17.	It is presently unclear whether chronic fatigue syndrome (CFS) patients exhibit daytime sleepiness in addition to fatigue. Both, fatigue, such as that seen in CFS patients, and excessive daytime sleepiness, such as in sleep apnea-hypopnea syndrome (SAHS), remain poorly understood. Both daytime conditions are generally related to unrefreshing sleep and show affective symptoms. This study's objective was to contribute to the understanding of the relationship between fatigue and sleepiness in CFS patients not co-morbid for primary sleep or psychiatric disorders. We compared 16 untreated CFS patients (mean age 32.8, all females) with 13 untreated SAHS (mean age 47.7, all females) patients and 12 healthy controls (mean age 32.2, all females). Objective sleepiness was measured using multiple sleep latency tests (MSLT). Subjective sleepiness and fatigue were assessed with the Epworth Sleepiness Scale and the Fatigue Severity Scale, respectively. Mean Sleep Latency (SL) on the MSLT was significantly shorter in SAHS patients than in CFS patients and CFS patients showed significantly shorter mean SL than matched controls but within normal range. Subjective sleepiness was greatest in SAHS patients and subjective fatigue was highest in CFS patients. Affective symptoms showed highest intensities in CFS patients. While higher than the control group on all measures, compared to SAHS, the CFS group had higher subjective fatigue and lower subjective and objective sleepiness. Despite possible overlap in symptoms and signs of both daytime conditions, our data indirectly support the clinical distinction between fatigue and sleepiness.
Neustadt J, Pieczenik SR.	Montana Integrative Medicine, Bozeman, MT 59718, USA. drneustadt@gmail.com	Medication-induced mitochondrial damage and disease.	Mol Nutr Food Res. 2008 Jul;52(7):780-8.	Since the first mitochondrial dysfunction was described in the 1960s, the medicine has advanced in its understanding the role mitochondria play in health and disease. Damage to mitochondria is now understood to play a role in the pathogenesis of a wide range of seemingly unrelated disorders such as schizophrenia, bipolar disease, dementia, Alzheimer's disease, epilepsy, migraine headaches, strokes, neuropathic pain, Parkinson's disease, ataxia, transient ischemic attack, cardiomyopathy, coronary artery disease, chronic fatigue syndrome, fibromyalgia, retinitis pigmentosa, diabetes, hepatitis C, and primary biliary cirrhosis. Medications have now emerged as a major cause of mitochondrial damage, which may explain many adverse effects. All classes of psychotropic drugs have been documented to damage mitochondria, as have stain medications, analgesics such as acetaminophen, and many others. While targeted nutrient therapies using antioxidants or their precursors (e. g., N-acetylcysteine) hold promise for improving mitochondrial function, there are large gaps in our knowledge. The most rational approach is to understand the mechanisms underlying mitochondrial damage for specific medications and attempt to counteract their deleterious effects with nutritional therapies. This article reviews our basic understanding of how mitochondria function and how medications damage mitochondria to create their occasionally fatal adverse effects.
Nicolson GL, Nancy L. Nicolson, Joerg Haier		Chronic Fatigue Syndrome Patients Subsequently Diagnosed with	Journal of Chronic Fatigue Syndrome 2008; 14 (4): 5-17	Objective: We examined the blood of 48 North American chronic fatigue syndrome (CFS) patients subsequently diagnosed with Lyme disease (Borrelia burgdorferi infection) and compared these with 50 North American CFS patients without evidence of Borrelia burgdorferi infections for presence of Mycoplasma species coinfections using forensic polymerase chain reaction. Results: We found that

		Lyme Disease Borrelia burgdorferi: Evidence for Mycoplasma Species Coinfections		68.75% of CFS/Lyme patients show evidence of mycoplasma coinfections (odds ratio [OR] = 41.8; confidence limits [CL] = 11.3–155; and p < .001) compared with controls, whereas 50% of CFS patients without a diagnosis of Lyme disease show Mycoplasma coinfections (OR = 19.0; CL = 5.3–69; and p < .001) compared with controls. Because CFS patients without a diagnosis of Lyme disease have a high prevalence of one of four Mycoplasma species and a majority show evidence of multiple infections, we examined CFS/Lyme patients' blood for various Mycoplasma species. We found that CFS patients with Lyme disease mostly had single species Mycoplasma infections (OR = 31.7; CL = 8.6–116; and p < .001) with a preponderance of Mycoplasma fermentans infections (50% of patients; OR = 59.0; CL = 7.6–460; and p < .001), whereas the most commonly found Mycoplasma species in CFS patients without Lyme disease was Mycoplasma pneumoniae(34% of patients; OR = 14.94; CL = 3.3–69; and p < .001). Conclusions: The results indicate that a subset of CFS patients show evidence of infection with Borrelia burgdorferi, and a large fraction of these patients were also infected with Mycoplasma fermentans and to a lesser degree with other Mycoplasma species.
Nijrolder I, van der Horst H, van der Windt D.	Department of General Practice, EMGO Institute, VU University Medical Centre, Amsterdam, The Netherlands. i.nijrolder@vumc.nl	Prognosis of fatigue. A systematic review.	J Psychosom Res. 2008 Apr;64(4):335-49.	OBJECTIVE: The objective of the study was to summarize evidence on the course and prognostic factors of fatigue in primary care patients and in the community. METHODS: Two reviewers independently screened identified citations, discussed eligible studies, and assessed methodological quality of selected studies. Data concerning study population, duration of follow-up, measurement of fatigue, outcome, and prognostic factors were extracted. Studies with populations selected by a specific disease or postpartum condition were excluded. RESULTS: We selected 21 articles reporting on 11 (partly) primary care cohorts and six community cohorts. Follow-up was up to 1 year in primary care and up to 4 years in the community, and in most studies that presented duration of fatigue, participants were chronically fatigued. Because of wide heterogeneity of studies, a qualitative analysis was performed. Recovery of fatigue varied widely, but no differences were found between settings. Sufficient evidence for an association with recovery was found for lower severity of fatigue, and limited evidence was found for good self-reported health, mental health, and psychological attributions. A major deficit in methodological quality of most studies was a potential bias due to low or selective response or loss to follow-up. CONCLUSION: Most studies on fatigue included patients with long symptom duration at baseline, making it difficult to study prognosis early in the course of fatigue. To provide clear evidence on prognosis in fatigued persons, prognostic studies should use an optimal design including selection of an inception cohort with limited duration of fatigue at baseline, a sufficient sample size, and information on rates and selectivity of response and loss to follow-up.
Nijrolder I, van der Windt DA, van der Horst HE.	Department of General Practice, EMGO Institute, VU University Medical Centre, Amsterdam, The Netherlands. i.nijrolder@vumc.nl	Prognosis of fatigue and functioning in primary care: a 1-year follow-up study.	Ann Fam Med. 2008 Nov-Dec;6(6):519-27.	PURPOSE: Although fatigue is a common presenting symptom in primary care and its course and outcomes often remain unclear, cohort studies among patients seeking care for fatigue are scarce. We therefore aimed to investigate patterns in the course of fatigue and relevant secondary outcomes in a large cohort of patients who sought care for a main symptom of fatigue. METHODS: We performed an observational cohort study in 147 primary care practices. Patients consulting their general practitioner for a new episode of fatigue were sent questionnaires at 1, 4, 8, and 12 months after baseline. We collected measures of fatigue, perceived health and functioning, absenteeism, psychological symptoms, and sleep using the Checklist Individual Strength, the 36-Item Short Form Health Survey, the Four-Dimensional Symptoms Questionnaire, and the Pittsburgh Sleep Questionnaire Inventory.

				Patients were classified into 4 subgroups based on fatigue severity scores over time. We assessed patterns in the course of all outcomes in these subgroups and in the total population, and tested changes over time and differences between subgroups. RESULTS: A total of 642 patients were enrolled in the study. Response rates during follow-up ranged between 82% and 88%. For 75% of the patients, 4 distinct groups could be discerned: 26% of patients had continuously high scores for fatigue, 17% had a fast recovery, 25% had a slow recovery, and 32% initially improved but then had a recurrence of fatigue. Patterns for the secondary outcomes of symptoms and functioning were all similar to the pattern for fatigue within each of the subgroups. CONCLUSIONS: The findings of this study suggest a longitudinal relationship between the severity of fatigue, impaired functioning, psychological symptoms, and poor sleep. Physicians should be aware that a substantial proportion of patients seeking care for fatigue have these additional health and psychosocial problems.
Nijs J, Adriaens J, Schuermans D, Buyl R, Vincken W.	Department of Human Physiology, Faculty of Physical Education and Physiotherapy, Vrije Universiteit, Brussel, Belgium. Jo.Nijs@vub.ac.be	Breathing retraining in patients with chronic fatigue syndrome: a pilot study.	Physiother Theory Pract. 2008 Mar-Apr;24(2):83-94.	The study aimed to 1) examine the point prevalence of asynchronous breathing in chronic fatigue syndrome (CFS) patients; 2) examine whether CFS patients with an asynchronous breathing pattern present with diminished lung function in comparison with CFS patients with a synchronous breathing pattern; and 3) examine whether one session of breathing retraining in CFS patients with an asynchronous breathing pattern is able to improve lung function. Twenty patients fulfilling the diagnostic criteria for CFS were recruited for participation in a pilot controlled clinical trial with repeated measures. Patients presenting with an asynchronous breathing pattern were given 20-30 minutes of breathing retraining. Patients presenting with a synchronous breathing pattern entered the control group and received no intervention. Of the 20 enrolled patients with CFS, 15 presented with a synchronous breathing pattern and the remaining 5 patients (25%) with an asynchronous breathing pattern. Baseline comparison revealed no group differences in demographic features, symptom severity, respiratory muscle strength, or pulmonary function testing data (spirometry). In comparison to no treatment, the session of breathing retraining resulted in an acute (immediately postintervention) decrease in respiratory rate ($p < 0.001$) and an increase in tidal volume ($p < 0.001$). No other respiratory variables responded to the session of breathing retraining. In conclusion, the present study provides preliminary evidence supportive of an asynchronous breathing pattern in a subgroup of CFS patients, and breathing retraining might be useful for improving tidal volume and respiratory rate in CFS patients presenting with an asynchronous breathing motion.
Nijs J, Almond F, De Becker P, Truijen S, Paul L.	Department of Human Physiology, Faculty of Physical Education and Physiotherapy, Vrije Universiteit Brussel, Belgium. j.nijs@ha.be	Can exercise limits prevent post-exertional malaise in chronic fatigue syndrome? An uncontrolled clinical trial.	Clin Rehabil. 2008 May;22(5):426-35.	OBJECTIVE: It was hypothesized that the use of exercise limits prevents symptom increases and worsening of their health status following a walking exercise in people with chronic fatigue syndrome. DESIGN: An uncontrolled clinical trial (semi-experimental design). SETTING: Outpatient clinic of a university department. SUBJECTS: Twenty-four patients with chronic fatigue syndrome. INTERVENTIONS: Subjects undertook a walking test with the two concurrent exercise limits. Each subject walked at an intensity where the maximum heart rate was determined by heart rate corresponding to the respiratory exchange ratio = 1.0 derived from a previous submaximal exercise test and for a duration calculated from how long each patient felt they were able to walk. MAIN OUTCOME MEASURES: The Short Form 36 Health Survey or SF-36, the Chronic Fatigue Syndrome Symptom List, and the Chronic Fatigue Syndrome -Activities and Participation Questionnaire were filled in prior to, immediately after and 24 hours after exercise. RESULTS: The fatigue increase

				observed immediately post-exercise (P= 0.006) returned to pre-exercise levels 24 hours post-exercise. The increase in pain observed immediately post-exercise was retained at 24 hours post-exercise (P=0.03). Fourteen of the 24 subjects experienced a clinically meaningful change in bodily pain (change of SF-36 bodily pain score > or =10); 6 indicated that the exercise bout had slightly worsened their health status, and 2 had a clinically meaningful decrease in vitality (change of SF-36 vitality score > or =20). There was no change in activity limitations/participation restrictions. CONCLUSION: It was shown that the use of exercise limits (limiting both the intensity and duration of exercise) prevents important health status changes following a walking exercise in people with chronic fatigue syndrome, but was unable to prevent short-term symptom increases.
Nijs J, Fremont M.	Vrije Universiteit Brussel, Faculty of Physical Education & Physiotherapy, Department of Human Physiology, Building L, Pleinlaan 2, 1050 Brussels, Belgium. Jo.Nijs@vub.ac.be <Jo.Nijs@vub.ac.be>	Intracellular immune dysfunction in myalgic encephalomyelitis/ chronic fatigue syndrome: state of the art and therapeutic implications.	Expert Opin Ther Targets. 2008 Mar;12(3):281-9.	BACKGROUND: Evidence in support of intracellular immune dysfunctions in people with myalgic encephalomyelitis (ME)/chronic fatigue syndrome (CFS) is accumulating, but few studies have addressed intracellular immunity as a potential therapeutic target. OBJECTIVE: To provide an overview of our present understanding of intracellular immunity in ME/CFS, to relate the intracellular immune dysfunctions to other aspects of the illness like decreased natural killer cell function, the presence of infections and poor exercise performance, and to point to potential therapeutic targets. METHODS: An in-depth review of the scientific literature of intracellular immunity in people with ME/CFS was performed. RESULTS/CONCLUSION: From the scientific literature it is concluded that proteolytic cleavage of the native RNase L enzyme is characteristic of the dysregulation of intracellular immunity in people with ME/CFS, but the origin of the dysregulation is speculative. There is increasing evidence for immune cell apoptosis and upregulation of various aspects of the 2'-5' oligoadenylate (2-5A) synthetase/RNase L pathway in ME/CFS. This review provides the theoretical rationale for conducting studies examining the effectiveness of direct or indirect drug targeting of the 2-5A synthetase/RNase L pathway in ME/CFS patients.
Nijs J, Paul L, Wallman K.	Division of Musculoskeletal Physiotherapy, Department of Health Care Sciences, University College Antwerp, Vrije Universiteit Brussel, Belgium. j.nijs@ha.be	Chronic fatigue syndrome: an approach combining self-management with graded exercise to avoid exacerbations.	J Rehabil Med. 2008 Apr;40(4):241-7. Comment in: J Rehabil Med. 2008 Nov;40(10):882-3; author reply 883-5.	Controversy regarding the aetiology and treatment of patients with chronic fatigue syndrome continues among the medical professions. The Cochrane Collaboration advises practitioners to implement graded exercise therapy for patients with chronic fatigue syndrome using cognitive behavioural principles. Conversely, there is evidence that exercise can exacerbate symptoms in chronic fatigue syndrome, if too-vigorous exercise/activity promotes immune dysfunction, which in turn increases symptoms. When designing and implementing an exercise programme for chronic fatigue syndrome it is important to be aware of both of these seemingly opposing viewpoints in order to deliver a programme with no detrimental effects on the pathophysiology of the condition. Using evidence from both the biological and clinical sciences, this paper explains that graded exercise therapy for people with chronic fatigue syndrome can be undertaken safely with no detrimental effects on the immune system. Exercise programmes should be designed to cater for individual physical capabilities and should take into account the fluctuating nature of symptoms. In line with cognitive behaviourally and graded exercise-based strategies, self-management for people with chronic fatigue syndrome involves encouraging patients to pace their activities and respect their physical and mental limitations, with the ultimate aim of improving their everyday functioning.
Nijs J, Thielemans A.	Department of Human Physiology,	Kinesiophobia and symptomatology in	Psychol Psychother. 2008	OBJECTIVES: The aims of the study were to examine the reliability of the Dutch and French versions of the Tampa scale kinesiophobia (TSK) version chronic fatigue syndrome (CFS), and to examine the

	Vrije Universiteit Brussel, Brussel, Belgium. Jo.Nijs@vub.ac.be	chronic fatigue syndrome: a psychometric study of two questionnaires.	Sep;81(Pt 3):273-83.	reliability and validity of the Dutch and French versions of the CFS symptom list. DESIGN: Repeated-measures design. METHODS: Native Dutch speakers (N=100) and native French (N=48) speakers fulfilling the diagnostic criteria for CFS were asked to list the five most important symptoms and to complete the TSK-CFS, the CFS symptom list, and the Short Form 36 Health Status Survey or SF-36. A modified version of the TSK-CFS and the CFS symptom list was filled in within 24 hours of the first assessment. RESULTS: The French and Dutch version of the TSK-CFS and CFS symptom lists displayed good reliability (ICC>or=.83). The CFS symptom list was internally consistent (Cronbach's alpha>or=.93) and concurrently valid with the SF-36. For the native Dutch and French speakers, respectively, 82 and 78% of the self-reported symptoms matched the content of CFS symptom list. CONCLUSIONS: The results are in support of the psychometric properties of the French and Dutch versions of both the TSK-CFS and the CFS symptom list for assessing kinesiophobia and symptom severity, respectively.
Nijs J, Van de Putte K, Louckx F, Truijen S, De Meirleir K.	Department of Human Physiology, Faculty of Physical Education and Physiotherapy, Vrije Universiteit, Brussels, Belgium. jo.nijs@vub.ac.be	Exercise performance and chronic pain in chronic fatigue syndrome: the role of pain catastrophizing.	Pain Med. 2008 Nov;9(8):1164-72. Epub 2007 Oct 3.	OBJECTIVES: This study aimed to examine the associations between bodily pain, pain catastrophizing, depression, activity limitations/participation restrictions, employment status, and exercise performance in female patients with chronic fatigue syndrome (CFS) who experience widespread pain. DESIGN: Cross-sectional observational study. SETTING: A university-based clinic. PATIENTS: Thirty-six female CFS patients who experienced widespread pain. OUTCOME MEASURES: Patients filled in the Medical Outcomes Short-Form 36 Health Status Survey, the Chronic Fatigue Syndrome Activities and Participation Questionnaire, the Beck Depression Inventory, and the Pain Catastrophizing Scale, and underwent a maximal exercise stress test with continuous monitoring of electrocardiographic and ventilatory parameters. RESULTS: Pain catastrophizing was related to bodily pain (r = -0.70), depression (r = 0.55), activity limitations/participation restrictions (r = 0.68), various aspects of quality of life (r varied between -0.51 and -0.64), and exercise capacity (r varied between -0.41 and -0.61). Based on hierarchical multiple regression analysis, pain catastrophizing accounted for 41% of the variance in bodily pain in female CFS patients who experience chronic widespread musculoskeletal pain. Among the three subscale scores of the Pain Catastrophizing Scale, helplessness and rumination rather than magnification were strongly related to bodily pain. Neither pain catastrophizing nor depression was related to employment status. CONCLUSIONS: These data provide evidence favoring a significant association between pain catastrophizing, bodily pain, exercise performance, and self-reported disability in female patients with CFS who experience widespread pain. Further prospective longitudinal studying of these variables is required.
Ohinata J, Suzuki N, Araki A, Takahashi S, Fujieda K, Tanaka H.	Department of Pediatrics, Asahikawa Medical College, Japan. ohina5p@asahikawa-med.ac.jp	Actigraphic assessment of sleep disorders in children with chronic fatigue syndrome.	Brain Dev. 2008 May;30(5):329-33. Epub 2007 Nov 26.	Children with chronic fatigue syndrome (CFS) often suffer from sleep disorders, which cause many physiological and psychological problems. Understanding sleep characteristics in children with CFS is important for establishing a therapeutic strategy. We conducted an actigraphic study to clarify the problems in sleep/wake rhythm and physical activity in children with CFS. METHODS: Actigraphic recordings were performed for 1-2 weeks in 12 CFS children. The obtained data were compared with those of healthy age-matched children used as the control. RESULTS: Sleep patterns were divided into two groups based on subjects' sleep logs: irregular sleep type and delayed sleep phase type. Compared to the control group, total sleep time was longer and physical activity was lower in both groups of CFS. Continuous sleep for more than 10h was not uncommon in CFS. In the irregular sleep type, impaired daily sleep/wake rhythms and disrupted sleep were observed. CONCLUSION: Using

				actigraphy, we could identify several characteristics of the sleep patterns in CFS children. Actigraphic analysis proved to be useful in detecting sleep/wake problems in children with CFS.
Olson K, Turner AR, Courneya KS, Field C, Man G, Cree M, Hanson J.	Faculty of Nursing, University of Alberta, Edmonton, Alberta, Canada. Karin.olson@ualberta.ca	Possible links between behavioral and physiological indices of tiredness, fatigue, and exhaustion in advanced cancer. Comment in: Support Care Cancer. 2008 Mar;16(3):215-6.	Support Care Cancer. 2008 Mar;16(3):241-9. Epub 2007 Jul 24.	GOALS: In this theoretical paper, we present the Edmonton Fatigue Framework (EFF), a new framework for the study of tiredness, fatigue, and exhaustion in advanced cancer. MATERIALS AND METHODS: The Fatigue Adaptation Model (FAM), the starting point for the EFF, was drawn from a literature review pertaining to fatigue in depression, chronic fatigue syndrome, cancer, shift workers, and athletes published in the Cumulative Index to Nursing and Allied Health Literature (CINAHL), Medical Literature Analysis and Retrieval System Online (MEDLINE), PubMed, PsychINFO, SPORTdiscus, and CancerLit between 1995 and 2004, and from seven qualitative studies conducted by our group. The EFF, an elaboration of the FAM, was constructed after an expansion of our literature review to 2006 and team discussion. The EFF provides new insights into possible links between behavioral and physiological indices of tiredness, fatigue, and exhaustion as they occur in both ill and non-ill states. In this paper, however, we consider only possible links in advanced cancer. CONCLUSIONS: We propose that stressors associated with advanced cancer and its supportive treatment trigger declines in four systems -- cognitive function, sleep quality, nutrition, and muscle endurance -- and that these declines reduce one's ability to adapt. While these systems each likely has its own effect on adaptation, we propose that the most important and serious effects arise from interactions among declines in cognitive function, sleep quality, nutrition, and muscle endurance. CONCLUSIONS: Interventions for fatigue have been limited by a lack of understanding about its etiology. Hypotheses arising from the EFF; suggest a new direction for further study that focuses on interactions among cognitive function, sleep quality, nutrition, and muscle endurance.
Osoba T, Derek Pheby, Selena Gray, Luis Nacul		The Development of an Epidemiological Definition for Myalgic Encephalomyelitis/ Chronic Fatigue Syndrome	Journal of Chronic Fatigue Syndrome 2008; 14 (4): 61-84	An epidemiological case-definition was developed to distinguish myalgic encephalomyelitis/chronic fatigue syndrome from other chronic fatiguing conditions by evaluating the discriminatory potential of different criteria from previous definitions. A two-part model was derived using consensus and discriminant analytic approaches. The optimal discriminators for the first part were severe debilitating fatigue affecting physical and mental functioning, a reduction in activity to less than 50% of the patient's premorbid activity level, and muscle discomfort (sensitivity 92%, specificity 66%). The variables for the second part included a reduction in activity to less than 50% of the patient's premorbid activity, myalgia, generalized muscle weakness, migratory arthralgia, and swollen lymph nodes (sensitivity 77%, specificity 88%).
Pall ML.	School of Molecular Biosciences, Washington State University, Pullman, WA 99164-4234, USA. martin_pall@wsu.edu	Post-radiation syndrome as a NO/ONOO- cycle, chronic fatigue syndrome-like disease.	Med Hypotheses. 2008 Oct;71(4):537-41. Epub 2008 Jul 29.	Post-radiation syndrome is proposed to be chronic fatigue syndrome (CFS) or a chronic fatigue syndrome-like illness, initiated by exposure to ionizing radiation. This view is supported by the nitric oxide/peroxynitrite (NO/ONOO-) cycle mechanism, the putative etiologic mechanism for CFS and related illnesses. Ionizing radiation may initiate illness by increasing nitric oxide levels via increased activity of the transcription factor NF-kappaB and consequent increased synthesis of the inducible nitric oxide synthase. Two types of components of the nitric oxide/peroxynitrite cycle have been studied in post-radiation syndrome patients and shown to be elevated. The symptoms and signs of post-radiation syndrome and its chronicity are similar or identical to those of chronic fatigue syndrome and can be explained as being a consequence of nitric oxide/peroxynitrite cycle etiology.

				While the data available to test this view are limited, it provides for the first time a comprehensive explanation for post-radiation syndrome.
Papadopoulos A, Ebrecht M, Roberts AD, Poon L, Rohleder N, Cleare AJ.	King's College London, Institute of Psychiatry, Section of Neurobiology of Mood Disorders, Division of Psychological Medicine, London SE5 8AF, United Kingdom.	Glucocorticoid receptor mediated negative feedback in chronic fatigue syndrome using the low dose (0.5 mg) dexamethasone suppression test.	J Affect Disord. 2009 Jan;112(1-3):289-94. Epub 2008 Jun 24.	BACKGROUND: Chronic fatigue syndrome (CFS) is associated with hypocortisolism, but it is not yet clear the extent to which enhanced negative feedback may underlie this finding. METHODS: We undertook a low-dose dexamethasone (0.5 mg) suppression test in 18 CFS patients and 20 matched, healthy controls. We measured salivary cortisol levels at 0800 h, 1200 h, 1600 h and 2000 h before and after the administration of 0.5 mg of dexamethasone. RESULTS: Basal cortisol output was raised in this group of CFS patients compared to controls. Overall, the percentage suppression following dexamethasone administration was no different between CFS (mean+/-sem: 80.4+/-4.4%) and controls (76.2+/-4.9 %). However, the sub-group of patients with CFS and comorbid depression (n=9) showed a significant hypersuppression of salivary cortisol in response to dexamethasone (89.0+/-1.9%; $p<0.05$ v controls). LIMITATIONS: The sub-group analysis was on small numbers and should be considered preliminary. Dexamethasone probes only glucocorticoid medicated negative feedback but does not probe mineralocorticoid feedback, the other main physiological feedback mechanism. CONCLUSION: We found partial support for the hypothesis of enhanced negative feedback in CFS but only in patients with comorbid depression and also in the context of a sample of patients with elevated basal cortisol levels, which is an atypical finding in the literature.
Pariante CM. Parrish BP, Zautra AJ, Davis MC.	Department of Psychology, Arizona State University. bparrish@udel.edu	The role of positive and negative interpersonal events on daily fatigue in women with fibromyalgia, rheumatoid arthritis, and osteoarthritis.	Health Psychol. 2008 Nov;27(6):694-702.	OBJECTIVE: The current study tested whether daily interpersonal events predicted fatigue from one day to the next among female chronic pain patients. DESIGN: Self-reported fatigue, daily events, pain, sleep quality, depressive symptoms, and functional health across 30 days were assessed in women with rheumatoid arthritis (RA: n = 89), Osteoarthritis (OA: n = 76), and Fibromyalgia syndrome (FM: n = 90). MAIN OUTCOME MEASURES: Self-report fatigue measured on a 0 to 100 scale and fatigue affect from PANAS-X (Watson & Clark, 1994). RESULTS: Multilevel analyses showed that both higher average levels of and daily increases in negative events predicted more fatigue, whereas daily increases in positive events predicted less fatigue. Across all pain conditions, increases in negative events continued to predict higher fatigue on the following day. Moreover, for participants with FM or RA,

				increases in positive events also predicted increased fatigue the following day. Daily increases in fatigue, in turn, predicted poorer functional health on both the same day and the next day. CONCLUSION: These results indicate that both on average and on a daily basis, interpersonal events influence levels of fatigue beyond common physical and psychological correlates of chronic pain and highlight differences between chronic pain groups.
Patrick Neary J, Roberts AD, Leavins N, Harrison MF, Croll JC, Sexsmith JR.	Faculty of Kinesiology & Health Studies, University of Regina, Regina, SK, Canada. patrick.neary@uregina.ca	Prefrontal cortex oxygenation during incremental exercise in chronic fatigue syndrome.	Clin Physiol Funct Imaging. 2008 Nov;28(6):364-72. Epub 2008 Jul 29.	This study examined the effects of maximal incremental exercise on cerebral oxygenation in chronic fatigue syndrome (CFS) subjects. Furthermore, we tested the hypothesis that CFS subjects have a reduced oxygen delivery to the brain during exercise. Six female CFS and eight control (CON) subjects (similar in height, weight, body mass index and physical activity level) performed an incremental cycle ergometer test to exhaustion, while changes in cerebral oxy-haemoglobin (HbO2), deoxy-haemoglobin (HHb), total blood volume (tHb = HbO2 + HHb) and O2 saturation [tissue oxygenation index (TOI), %)] was monitored in the left prefrontal lobe using a near-infrared spectrophotometer. Heart rate (HR) and rating of perceived exertion (RPE) were recorded at each workload throughout the test. Predicted VO2peak in CFS (1331 +/- 377 ml) subjects was significantly (P < or = 0.05) lower than the CON group (1990 +/- 332 ml), and CFS subjects achieved volitional exhaustion significantly faster (CFS: 351 +/- 224 s; CON: 715 +/- 176 s) at a lower power output (CFS: 100 +/- 39 W; CON: 163 +/- 34 W). CFS subjects also exhibited a significantly lower maximum HR (CFS: 154 +/- 13 bpm; CON: 186 +/- 11 bpm) and consistently reported a higher RPE at the same absolute workload when compared with CON subjects. Prefrontal cortex HbO2, HHb and tHb were significantly lower at maximal exercise in CFS versus CON, as was TOI during exercise and recovery. The CFS subjects exhibited significant exercise intolerance and reduced prefrontal oxygenation and tHb response when compared with CON subjects. These data suggest that the altered cerebral oxygenation and blood volume may contribute to the reduced exercise load in CFS, and supports the contention that CFS, in part, is mediated centrally.
Paul L, Rafferty D, Wood L, Maclaren W.	School of Health & Social Care, Glasgow Caledonian University, Glasgow, UK. L.Paul@clinmed.gla.ac.uk	Gait characteristics of subjects with chronic fatigue syndrome and controls at self-selected and matched velocities.	J Neuroeng Rehabil. 2008 May 27;5:16.	BACKGROUND: Gait abnormalities have been reported in individuals with Chronic Fatigue Syndrome (CFS) however no studies exist to date investigating the kinematics of individuals with CFS in over-ground gait. The aim of this study was to compare the over-ground gait pattern (sagittal kinematics and temporal and spatial) of individuals with CFS and control subjects at their self-selected and at matched velocities. METHODS: Twelve individuals with CFS and 12 matched controls participated in the study. Each subject walked along a 7.2 m walkway three times at each of three velocities: self-selected, relatively slow (0.45 ms-1) and a relatively fast (1.34 ms-1). A motion analysis system was used to investigate the sagittal plane joint kinematics and temporal spatial parameters of gait. RESULTS: At self-selected velocity there were significant differences between the two groups for all the temporal and spatial parameters measured, including gait velocity (P = 0.002). For the kinematic variables the significant differences were related to both ankles during swing and the right ankle during stance. At the relatively slower velocity the kinematic differences were replicated. However, the step distances decreased in the CFS population for the temporal and spatial parameters. When the gait pattern of the individuals with CFS at the relatively fast walking velocity (1.30 +/- 0.24 ms-1) was compared to the control subjects at their self-selected velocity (1.32 +/- 0.15 ms-1) the gait pattern of the two groups was very similar, with the exception of both ankles during swing. CONCLUSION: The self-selected gait velocity and/or pattern of individuals with CFS may be used to monitor the disease

				process or evaluate therapeutic intervention. These differences may be a reflection of the relatively low self-selected gait velocity of individuals with CFS rather than a manifestation of the condition itself.
Perrot S, Dickenson AH, Bennett RM.	Center de la Douleur et Service de Médecine Interne, Hôtel-Dieu, University Paris 5 Descartes, Paris, France. serge.perrot@htd.aphp.fr	Fibromyalgia: harmonizing science with clinical practice considerations.	Pain Pract. 2008 May-Jun;8(3):177-89. Epub 2008 Mar 18. Comment in: Pain Pract. 2008 May-Jun;8(3):155.	This review summarizes the present and emerging knowledge base on the pathophysiology, diagnosis, and management of fibromyalgia. EPIDEMIOLOGY: Fibromyalgia is the most common chronic pain syndrome encountered in general medicine and rheumatology. Historically, contemporary concepts of fibromyalgia have evolved in terms of its clinical description and parallel advances in the understanding of its pathophysiology. PATHOPHYSIOLOGY: A generally accepted paradigm postulates that fibromyalgia is the clinical expression of a rheumatologic disorder in which the associated pain is driven primarily by central sensitization and possibly through changes in several neuronal systems but not necessarily reliant on peripheral processes. MANAGEMENT: Several agents, including serotonin-norepinephrine reuptake inhibitors (ie, duloxetine and milnacipran), opioids (ie, tramadol), and the alpha2-delta ligand pregabalin, which recently received U.S. regulatory approval for the treatment of fibromyalgia, have been evaluated in clinical trials, demonstrating benefit in terms of pain reduction and improvement in core symptoms (ie, fatigue and sleep disturbance). The European League Against Rheumatism has developed updated guidelines for the management of fibromyalgia.
Perrot S.	Service de Médecine Interne et Centre de la Douleur, Hôtel-Dieu, Paris, France. serge.perrot@htd.aphp.fr	Fibromyalgia syndrome: a relevant recent construction of an ancient condition?	Curr Opin Support Palliat Care. 2008 Jun;2(2):122-7.	PURPOSE OF REVIEW: Fibromyalgia is considered the most common chronic pain syndrome. This syndrome is poorly understood and not widely accepted as a distinct clinical entity but an increasing number of pharmacological and nonpharmacological treatments are being developed for its management. RECENT FINDINGS: The clinical description of fibromyalgia is now well established, but controversies on diagnostic criteria are increasing. Pathophysiological studies suggest that fibromyalgia is a painful rheumatic disorder in which pain primarily stems from central sensitization and from other neuronal changes, including alterations in peripheral neuronal systems. Central sensitization may also underlie associated symptoms, including anxiety, sleep disorders, fatigue, and other dysfunctions such as irritable bowel syndrome and bladder instability.Several agents, including serotonin-norepinephrine reuptake inhibitors (duloxetine and milnacipran), weak opioids (tramadol), and anticonvulsants (pregabalin), as well as nonpharmacological approaches, have been recently evaluated in clinical trials, demonstrating benefit in terms of pain reduction and improvement of core symptoms (i.e., fatigue and sleep disturbance). SUMMARY: Despite the fact that pathophysiology and diagnostic criteria remain unclear, the level of scientific data collected on this recently described condition should convince clinicians of the existence of this syndrome, allowing improved management of the many patients suffering from chronic pain.
Pouchain D.	1 ter rue du Midi, 94300 Vincennes.	[Fatigued or depressed?] [Article in French]	Encephale. 2008 Jun;34 Spec No 2:S17-20.	
Presson AP, Sobel EM, Papp JC, Suarez CJ, Whistler T, Rajeevan MS, Vernon SD,	Biostatistics, University of California, Los Angeles, CA, USA. apresson@ucla.ed	Integrated weighted gene co-expression network analysis with an application	BMC Syst Biol. 2008 Nov 6;2:95.	BACKGROUND: Systems biologic approaches such as Weighted Gene Co-expression Network Analysis (WGCNA) can effectively integrate gene expression and trait data to identify pathways and candidate biomarkers. Here we show that the additional inclusion of genetic marker data allows one to characterize network relationships as causal or reactive in a chronic fatigue syndrome (CFS) data set. RESULTS: We combine WGCNA with genetic marker data to identify a disease-related pathway and its

Horvath S.	u	to chronic fatigue syndrome.		causal drivers, an analysis which we refer to as "Integrated WGCNA" or IWGCNA. Specifically, we present the following IWGCNA approach: 1) construct a co-expression network, 2) identify trait-related modules within the network, 3) use a trait-related genetic marker to prioritize genes within the module, 4) apply an integrated gene screening strategy to identify candidate genes and 5) carry out causality testing to verify and/or prioritize results. By applying this strategy to a CFS data set consisting of microarray, SNP and clinical trait data, we identify a module of 299 highly correlated genes that is associated with CFS severity. Our integrated gene screening strategy results in 20 candidate genes. We show that our approach yields biologically interesting genes that function in the same pathway and are causal drivers for their parent module. We use a separate data set to replicate findings and use Ingenuity Pathways Analysis software to functionally annotate the candidate gene pathways. CONCLUSION: We show how WGCNA can be combined with genetic marker data to identify disease-related pathways and the causal drivers within them. The systems genetics approach described here can easily be used to generate testable genetic hypotheses in other complex disease studies.
Price JR, Mitchell E, Tidy E, Hunot V.	Department of Psychiatry, University of Oxford, Warneford Hospital, Headington, Oxford, UK, OX3 7JX. jonathan.price@psych.ox.ac.uk	Cognitive behaviour therapy for chronic fatigue syndrome in adults. Update of: Cochrane Database Syst Rev. 2000;(2):CD001027.	Cochrane Database Syst Rev. 2008 Jul 16;(3):CD001027. Comment in: Evid Based Ment Health. 2009 Feb;12(1):16.	BACKGROUND: Chronic fatigue syndrome (CFS) is a common, debilitating and serious health problem. Cognitive behaviour therapy (CBT) may help to alleviate the symptoms of CFS. OBJECTIVES: To examine the effectiveness and acceptability of CBT for CFS, alone and in combination with other interventions, compared with usual care and other interventions. SEARCH STRATEGY: CCDANCTR-Studies and CCDANCTR-References were searched on 28/3/2008. We conducted supplementary searches of other bibliographic databases. We searched reference lists of retrieved articles and contacted trial authors and experts in the field for information on ongoing/completed trials. SELECTION CRITERIA: Randomised controlled trials involving adults with a primary diagnosis of CFS, assigned to a CBT condition compared with usual care or another intervention, alone or in combination. DATA COLLECTION AND ANALYSIS: Data on patients, interventions and outcomes were extracted by two review authors independently, and risk of bias was assessed for each study. The primary outcome was reduction in fatigue severity, based on a continuous measure of symptom reduction, using the standardised mean difference (SMD), or a dichotomous measure of clinical response, using odds ratios (OR), with 95% confidence intervals (CI). MAIN RESULTS: Fifteen studies (1043 CFS participants) were included in the review. When comparing CBT with usual care (six studies, 373 participants), the difference in fatigue mean scores at post-treatment was highly significant in favour of CBT (SMD -0.39, 95% CI -0.60 to -0.19), with 40% of CBT participants (four studies, 371 participants) showing clinical response in contrast with 26% in usual care (OR 0.47, 95% CI 0.29 to 0.76). Findings at follow-up were inconsistent. For CBT versus other psychological therapies, comprising relaxation, counselling and education/support (four studies, 313 participants), the difference in fatigue mean scores at post-treatment favoured CBT (SMD -0.43, 95% CI -0.65 to -0.20). Findings at follow-up were heterogeneous and inconsistent. Only two studies compared CBT against other interventions and one study compared CBT in combination with other interventions against usual care. AUTHORS' CONCLUSIONS: CBT is effective in reducing the symptoms of fatigue at post-treatment compared with usual care, and may be more effective in reducing fatigue symptoms compared with other psychological therapies. The evidence base at follow-up is limited to a small

				group of studies with inconsistent findings. There is a lack of evidence on the comparative effectiveness of CBT alone or in combination with other treatments, and further studies are required to inform the development of effective treatment programmes for people with CFS.
Priebe S, Fakhoury WK, Henningsen P.	Unit for Social and Community Psychiatry, Barts' and the London School of Medicine, Queen Mary University of London, London, UK. s.priebe@qmul.ac.uk	Functional incapacity and physical and psychological symptoms: how they interconnect in chronic fatigue syndrome.	Psychopathology. 2008;41(6):339-45. Epub 2008 Sep 3.	BACKGROUND: It has been argued that perceived functional incapacity might be a primary characteristic of chronic fatigue syndrome (CFS) and could be explained by physical symptoms. If so, it could be expected to be closely associated with physical, but not psychological symptoms. The study tests this hypothesis. SAMPLING AND METHODS: The sample consisted of 73 patients, with a diagnosis of CFS according to the Oxford criteria, randomly selected from clinics in the Departments of Immunology and Psychiatry at St. Bartholomew's Hospital, London. The degree of fatigue experienced by patients was assessed using the Chalder Fatigue Questionnaire and a visual analogue scale. Self-rated instruments were used to measure physical and social functioning, quality of life, and physical and psychological symptoms. RESULTS: Principal-component analysis of all scale scores revealed 2 distinct components, explaining 53% of the total variance. One component was characterized by psychological symptoms and generic quality of life indicators, whilst the other component was made up of physical symptoms, social and physical functioning and indicators of fatigue. CONCLUSIONS: The findings suggest that perceived functional incapacity is a primary characteristic of CFS, which is manifested and/or explained by physical symptoms. (c) 2008 S. Karger AG, Basel.
Przybyłowski T, Bielicki P, Kumor M, Hildebrand K, Maskey-Warzechowska M, Korczyński P, Chazan R.	Department of Pneumology and Allergology, Warsaw Medical University, Warsaw, Poland. przyb@amwaw.edu.pl	Exercise capacity in patients with obstructive sleep apnea syndrome.	J Physiol Pharmacol. 2007 Nov;58 Suppl 5(Pt 2):563-74.	Obstructive sleep apnea syndrome (OSAS) is a common disease characterized by repetitive partial or complete closure of the upper airway during sleep. Cardiovascular disturbances are the most important complications responsible for increased morbidity and mortality. It is suggested that daytime somnolence, chronic fatigue, and nocturnal hypoxemia may further impair muscle function and decrease exercise fitness. The aim of this study was to evaluate cardiopulmonary response to exercise in OSAS patients. One hundred and eleven middle aged (50.2+/-10 yr), obese (BMI 31.0+/-4.6 kg/m2) patients (109 M, 2F) with severe OSAS (AHI 47.2+/-23.1 h(-1)) were enrolled into the study. OSAS was diagnosed with overnight polysomnography and a symptom-limited cardiopulmonary exercise test was performed on a treadmill using Bruce protocol. The results showed that the most frequent reason for exercise termination were: muscle fatigue and/or dyspnea (66+/-), increase in systolic blood pressure>220 mmHg (20%), ECG abnormalities, and chest pain (6%). Although the mean VO2 peak was within the reference value (29.6+/-6 mlO2/kg/min), in 52 patients (46%) VO2 peak was <84% of predicted. Hypertensive response to exercise was diagnosed in 39 of patients (35%). Patients with severe sleep apnea (AHI40>or=h(-1)) were characterized by higher mean blood pressure at rest, at 25%, 50% of maximal work load, at peak exercise and at post-exercise recovery. Several significant correlations between hemodynamic responses to exercise and sleep apnea severity were also noted. We conclude that exercise tolerance can be limited due to hypertensive response in about 20% of patients. Patients with severe OSAS have exaggerated hemodynamic response to exercise and delayed post-exercise blood pressure recovery. Cardiopulmonary response to exercise seems to be related to sleep apnea severity.
Puetz TW, Flowers SS, O'Connor PJ.	Department of Kinesiology, University of	A randomized controlled trial of the effect of	Psychother Psychosom. 2008;77(3):167-74.	BACKGROUND: There is growing evidence that chronic exercise is a promising intervention for combating feelings of low energy and fatigue. Although groups with well-defined medical conditions (for example cancer and heart disease) or unexplained fatigue syndromes consistently have reported

	Georgia, Athens, GA, USA.	aerobic exercise training on feelings of energy and fatigue in sedentary young adults with persistent fatigue.	Epub 2008 Feb 14.	improved feelings of energy and fatigue after chronic exercise, relatively few exercise training studies have been conducted with people who report persistent fatigue yet neither have a medical condition nor reach diagnostic criteria for an unexplained fatigue syndrome. The purpose of this investigation was to use a randomized controlled design to examine the effects of 6 weeks of chronic exercise training on feelings of energy and fatigue in sedentary, healthy young adults reporting persistent fatigue. METHODS: Thirty-six healthy, young adults who reported persistent feelings of fatigue were randomly assigned to a moderate-intensity exercise, low-intensity exercise or no treatment control group. Participants in each condition then visited the exercise laboratory on 18 occasions over a 6-week period. Exercise laboratory visits occurred 3 days per week. Vigor and fatigue mood state scores were obtained at the beginning of the third exercise session each week for 6 weeks. Aerobic fitness was measured before and after intervention. RESULTS: The effect of 6 weeks of exercise training on feelings of fatigue was dependent on exercise intensity; however, the effect on feelings of energy was similar for both the low- and moderate-intensity conditions. The changes in feelings of energy and fatigue were independent of changes in aerobic fitness. CONCLUSIONS: Six weeks of low and moderate exercise training performed by sedentary adults without a well-defined medical condition or an unexplained fatigue syndrome but reporting persistent feelings of fatigue resulted in similarly beneficial effects on feelings of energy. The effects for symptoms of fatigue were moderated by exercise intensity, and the more favorable outcome was realized with low-intensity exercise. Changes in feelings of energy and fatigue following exercise training were unrelated to changes in aerobic fitness. Copyright (c) 2008 S. Karger AG, Basel.
Raison CL, Lin JM, Reeves WC.	Department of Psychiatry and Behavioral Sciences, Emory University School of Medicine, 1365C Clifton Road, Room 5004, Atlanta, GA 30322, USA. craison@emory.edu	Association of peripheral inflammatory markers with chronic fatigue in a population-based sample.	Brain Behav Immun. 2009 Mar;23(3):327-37. Epub 2008 Dec 11. Comment in: Brain Behav Immun. 2009 Mar;23(3):325-6.	Alterations in the innate immune response may contribute to the pathogenesis of chronic fatigue syndrome (CFS). However, studies have been limited by small sample sizes, use of patients from tertiary care settings, inappropriate selection of controls, and failure to control for confounding demographic, medical and behavioral factors independently associated with immune activity. It is also not known whether specific symptoms account for observed associations between CFS and the innate immune response. To address these limitations, the current study examined plasma concentrations of high-sensitivity c-reactive protein (hs-CRP), white blood cell count (WBC) and a combined inflammation factor in a large population-based sample. Log-transformed mean plasma concentrations of hs-CRP were increased in subjects with CFS (n=102) and in subjects with unwellness symptoms that did not meet diagnostic criteria for CFS (defined as "insufficient fatigue" [ISF]) (n=240) when compared to subjects who were well (n=115). Log transformed WBC was increased in ISF and was increased at a trend level in CFS. The combined inflammation factor was increased in both CFS and ISF. Subjects with CFS and ISF did not differ on any of the inflammation measures. In the entire subject population, the physical component summary score (PCS), but not the mental component summary score (MCS), from the Medical Outcomes Study Short Form-36 (SF-36) was negatively associated with each of the inflammation measures. Depressive symptoms were also associated with increased log hs-CRP. After adjustment for age, sex, race, location of residence, BMI, depressive status and immune-modulating medications, subjects classified as ISF continued to demonstrate increased log hs-CRP, WBC and elevations on the inflammation factor when compared to well controls; however, associations between CFS and log hs-CRP and the inflammation factor were no longer statistically

				significant. After adjustment, PCS score also remained independently associated with each of the inflammation measures. These findings support a role for innate immune activation in unexplained fatigue and unwellness, but do not suggest that immune activation is specific to CFS.
Raszeja-Wyszomirska J, Lawniczak M, Marlicz W, Miezyńska-Kurtycz J, Milkiewicz P.	Pomorska Akademia Medyczna, Samodzielna Pracownia Hepatologii Katedry Gastroenterologii. jorasz@sci.pam.szczecin.pl	[Non-alcoholic fatty liver disease--new view] [Article in Polish]	Pol Merkur Lekarski. 2008 Jun;24(144):568-71.	Non-alcoholic fatty liver disease (NAFLD) covers a wide spectrum of liver pathology--from steatosis alone, through the necroinflammatory disorder of non-alcoholic steatohepatitis (NASH) to cirrhosis and liver cancer. NAFLD/NASH is mostly related with visceral adiposity, obesity, type 2 diabetes melitus (DM t.2) and metabolic syndrome. Pathogenetic concepts of NAFLD include overnutrition and underactivity, insulin resistance (IR) and genetic factor. The prevalence of NAFLD has been estimated to be 17-33% in some countries, NASH may be present in about 1/3 of such cases, while 20-25% of NASH cases could progress to cirrhosis. NAFLD is now recognized as one of the most frequent reason of liver tests elevation without clinical symptoms. Insulin resistance is considering as having a central role in NAFLD pathogenesis. In hepatocytes, IR is related to hyperglycaemia and hyperinsulinaemia, formation of advanced glycation end-products, increased free fatty acids and their metabolites, oxidative stress and altered profiles of adipocytokines. Early stages of fatty liver are clinically silent and include elevation of ALT and GGTP, hyperechogenic liver in USG and/or hepatomegaly. Among clinical symptoms, abdominal discomfort is relatively common as well as chronic fatigue. NAFLD/NASH is not a benign disease, progressive liver biopsy have shown histological progression of fibrosis in 32%, the estimated rate of cirrhosis development is 20% and a liver--related death is 12% over 10 years. No treatment has scientifically proved to ameliorate NAFLD or to avoid its progression. The various therapeutic alternatives are aimed at interfering with the risk factors involved in the pathogenesis of the disorder in order to prevent the progression to end-stage liver disease. The most important therapeutic measure is increasing insulin sensitivity by an attempt to change a lifestyle mostly by dieting and physical activity in order to loose weight. The most used agent is metformin, the others are under controlled trials or their effectiveness is low. NASH is not a common indication for liver transplantation because of the older age distribution of patients and high prevalence of comorbidity, related to metabolic syndrome. Recurence of NASH in the grafted liver is also a relatively frequent complication.
Ravoet C, Mineur P, Robin V, Debusscher L, Bosly A, André M, El Housni H, Soree A, Bron D, Martiat P.	Jules Bordet Institute, Rue Héger-Bordet, 1, 1000 Brussels, Belgium. christophe.ravoet@bordet.be	Farnesyl transferase inhibitor (lonafarnib) in patients with myelodysplastic syndrome or secondary acute myeloid leukaemia: a phase II study.	Ann Hematol. 2008 Nov;87(11):881-5. Epub 2008 Jul 19.	Although an activating mutation of Ras is commonly observed in myelodysplastic syndrome (MDS), the role of Ras in the natural history of MDS remains largely unknown. We prospectively studied efficiency and tolerance of lonafarnib, a compound able to inhibit Ras signalling pathway through an inhibition of farnesyl transferase, in patients with MDS or secondary acute myeloid leukaemia (sAML). Lonafarnib was administered orally at a dose of 200 mg twice daily for three courses of 4 weeks (separated by 1 to 4 weeks without treatment). Sixteen patients were included: FAB/RAEB (n = 10), RAEB-T (n = 2), sAML (n = 2) and chronic myelomonocytic leukaemia (CMML; n = 2); WHO/RAEB-1 (n = 4), RAEB-2 (n = 5), AML (n = 5), CMML (n = 2). Median age was 70 (53-77) years. The karyotype was complex or intermediate in 11 patients, and the International Prognostic Scoring Systems (IPSS) risk groups were low in two patients, INT-1 in one patient, INT-2 in four patients and high in six patients (unknown or not applicable in three patients). Among the 14 patients tested, five had Ras mutations in codons 12, 13 or 61 of N-Ras, K-Ras or H-Ras. One patient was excluded of the analysis for protocol violation, and 15 patients were assessable for tolerance. Gastrointestinal toxicities (diarrhoea, nausea

				and anorexia) and myelosuppression were the major side effects. Other toxicities included infections, fatigue, increase of liver enzymes, arrhythmia and skin rash. One patient died of infection, and the treatment was stopped in one other who developed atrial fibrillation. Doses were reduced in all but one patient treated with more than one course of farnesyl transferase inhibitor. Responses were assessable in 12 patients. A partial response in one sAML patient and a very transient decrease of blast cell count with normalisation of karyotype in one MDS patient were observed. No relation between improvement of marrow parameters and detected Ras mutations was observed. Lonafarnib alone, administered following our schedule, has shown limited activity in patients with MDS or secondary AML. Gastrointestinal and haematological toxicities appear the limiting toxicity in this population of patients.
Regenauer A.	Kompetenzzentrum Medical Research & Underwriting, Münchener Rückversicherungs-Gesellschaft.	[Contentious diseases--a medico-social phenomenon from an insurance medicine perspective] [Article in German]	Versicherungsmedizin. 2008 Mar 1;60(1):3-7.	A group of illnesses that are difficult to assess objectively, comprising such conditions as fibromyalgia, chronic fatigue syndrome, attention-deficit hyperactivity disorder, whiplash injury, and last but not least a multitude of somatoform disorders, has become a growing concern to Western health care systems and insurance industries. Thus far, the medical literature has failed to provide informative overviews of this group, which at first glance admittedly seems to be rather heterogeneous. If at all, the disorders have been grouped together under the term ,,controversial illnesses" to differentiate them from other diseases. The insurance industry - and claims departments, in particular - are increasingly having to deal with this rapidly growing phenomenon, which affects not only life business, but also health, worker's compensation and motor third-party liability. When paying compensation and settling claims, insurers are often left with a feeling that the illness may have been ,,imaginary" or aggravated. Is there a common basis for this new disorder mega-trend - independent of the recognition of the conditions by medical associations? This article aims at providing an overview of the common characteristics of the group of disorders, including a description of the key physical, psychological and social aspects. In particular, it is intended to deepen insurers' understanding of the risks arising from social change. The article also examines the disorder prevalence in Western societies and the possible causes of the significant increase.
Reynolds F, Vivat B, Prior S.	School of Health Sciences and Social Care, Brunel University, Middlesex, UK. frances.reynolds@brunel.ac.uk	Women's experiences of increasing subjective well-being in CFS/ME through leisure-based arts and crafts activities: a qualitative study.	Disabil Rehabil. 2008;30(17):1279-88.	PURPOSE: To understand the meanings of art-making among a group of women living with the occupational constraints and stigma of CFS/ME. The study explored their initial motives for art-making, and then examined how art-making had subsequently influenced their subjective well-being. METHOD: Ten women with CFS/ME were interviewed; three provided lengthy written accounts to the interview questions. FINDINGS: Illness had resulted in devastating occupational and role loss. Participants took many years to make positive lifestyle changes. Art-making was typically discovered once participants had accepted the long-term nature of CFS/ME, accommodated to illness, and reprioritized occupations. Several factors then attracted participants specifically to art-making. It was perceived as manageable within the constraints of ill-health. Participants also tended to be familiar with craft skills; had family members interested in arts and crafts, and some desired a means to express grief and loss. Once established as a leisure activity, art-making increased subjective well-being mainly through providing increased satisfaction in daily life, positive self-image, hope, and contact with the outside world. Participants recommended provision of occupational/recreational counselling earlier in the illness trajectory. CONCLUSIONS: Creative art-making occurred as part of a

				broader acceptance and adjustment process to CFS/ME, and allowed some psychological escape from a circumscribed lifeworld.
Riedl A, Schmidtmann M, Stengel A, Goebel M, Wisser AS, Klapp BF, Mönnikes H.	Division of Hepatology, Gastroenterology, and Endocrinology, Department of Medicine, Charité-University Medical Center, Campus Virchow, Berlin, Germany.	Somatic comorbidities of irritable bowel syndrome: a systematic analysis.	J Psychosom Res. 2008 Jun;64(6):573-82. Epub 2008 Apr 28.	OBJECTIVE: A large number of irritable bowel syndrome (IBS) patients are additionally afflicted with other somatic intestinal and/or extraintestinal comorbidities. The occurrence of one or more comorbidities is correlated with enhanced medical help seeking, worse prognosis, and higher rates of anxiety and depression-all resulting in a reduced quality of life. The aims of this study were, firstly, to review the literature on comorbidities of IBS and to assess gastrointestinal and extraintestinal comorbidities, and, secondly, to evaluate explanatory hypotheses and possible common pathophysiological mechanisms. METHODS: We systematically reviewed the scientific literature in the past 25 years, as cited in MEDLINE. RESULTS: IBS patients present with a twofold increase in somatic comorbidities compared to controls, possibly caused by common pathophysiological mechanisms. Nevertheless, to date, there has been no convincing evidence for a consolidated underlying pathophysiology or somatization. Gastrointestinal disorders, such as functional dyspepsia, gastroesophageal reflux disease, functional constipation, and anal incontinence, occur in almost half of the patients. In a broad variety of extraintestinal comorbidities, fibromyalgia, chronic fatigue syndrome, and chronic pelvic pain are best documented and appear in up to 65%. CONCLUSION: The knowledge and structured assessment of comorbid somatic symptoms might allow to identify subgroups of IBS patients with special characteristics and lead to adaptation of the therapeutic concept.

Rizzieri DA, Feldman E, Dipersio JF, Gabrail N, Stock W, Strair R, Rivera VM, Albitar M, Bedrosian CL, Giles FJ.	Duke University Medical Center, Durham, North Carolina 27710, USA. rizzi003@mc.duke.edu	A phase 2 clinical trial of deforolimus (AP23573, MK-8669), a novel mammalian target of rapamycin inhibitor, in patients with relapsed or refractory hematologic malignancies.	Clin Cancer Res. 2008 May 1;14(9):2756-62.	PURPOSE: Deforolimus (AP23573), a novel non-prodrug rapamycin analogue, inhibits the mammalian target of rapamycin, a downstream effector of the phosphatidylinositol 3-kinase/Akt and nutrient-sensing pathways. A phase 2 trial was conducted to determine the efficacy and safety of single-agent deforolimus in patients with relapsed or refractory hematologic malignancies. EXPERIMENTAL DESIGN: Eligible patients were assigned to one of five disease-specific, parallel cohorts and given 12.5 mg deforolimus as a 30-minute infusion once daily for 5 days every 2 weeks. A Simon two-stage design was used for each cohort. Safety, pharmacokinetics, pharmacodynamics, and antitumor response were assessed. RESULTS: Fifty-five patients received deforolimus as follows: cohort 1 23 acute myelogenous leukemia, two myelodysplastic syndrome and one chronic myelogenous leukemia in nonlymphoid blast phase; cohort 2, one acute lymphocytic leukemia; cohort 3, nine agnogenic myeloid metaplasia; cohort 4, eight chronic lymphocytic leukemia; cohort 5, nine mantle cell lymphoma and two T-cell leukemia/lymphoma. Most patients were heavily pretreated. Of the 52 evaluable patients, partial responses were noted in five (10%), two of seven agnogenic myeloid metaplasia and three of nine mantle cell lymphoma. Hematologic improvement/stable disease was observed in 21 (40%). Common treatment-related adverse events, which were generally mild and

				reversible, were mouth sores, fatigue, nausea, and thrombocytopenia. Decreased levels of phosphorylated 4E-BP1 in 9 of 11 acute myelogenous leukemia/myelodysplastic syndrome patients after therapy showed mammalian target of rapamycin inhibition by deforolimus. CONCLUSIONS: Deforolimus was well-tolerated in patients with heavily pretreated hematologic malignancies, and antitumor activity was observed. Further investigation of deforolimus alone and in combination with other therapeutic agents is warranted in patients with selected hematologic malignancies.

King's College London, Institute of Psychiatry, Department of Psychological Medicine, De Crespigny Park, London SE5 8AF, UK; Chronic Fatigue Syndrome Research and Treatment Unit, Maudsley Hospital, Denmark Hill, London, UK.	Salivary cortisol output before and after cognitive behavioural therapy for chronic fatigue syndrome.	J Affect Disord. 2008 Oct 18. [Epub ahead of print]	BACKGROUND: There is evidence that patients with chronic fatigue syndrome (CFS) have mild hypocortisolism. One theory about the aetiology of this hypocortisolism is that it occurs late in the course of CFS via factors such as inactivity, sleep disturbance, chronic stress and deconditioning. We aimed to determine whether therapy aimed at reversing these factors - cognitive behavioural therapy for CFS - could increase cortisol output in CFS. METHODS: We measured diurnal salivary cortisol output between 0800 and 2000h before and after 15 sessions (or 6 months) of CBT in 41 patients with CDC-defined CFS attending a specialist, tertiary outpatient clinic. RESULTS: There was a significant clinical response to CBT, and a significant rise in salivary cortisol output after CBT. LIMITATIONS: We were unable to control for the passage of time using a non-treated CFS group. CONCLUSIONS: Hypocortisolism in CFS is potentially reversible by CBT. Given previous suggestions that lowered cortisol may be a maintaining factor in CFS, CBT offers a potential way to address this.
Romani A.	Laboratorio Potenziali Evocati, Istituto Neurologico C. Mondino, Via Mondino 2, 27100, Pavia, Italy. alfredo.romani@mondino.it	The treatment of fatigue.	Neurol Sci. 2008 Sep;29 Suppl 2:S247-9.	Fatigue is a psychophysiological state that acts on the subject's motivation to engage in and/or to continue strenuous physical or cognitive activities. In various pathological conditions fatigue seems to lose this homeostatic function and presents itself as a symptom. The pathophysiology of fatigue is complex and includes neurological (central and peripheral) dysfunction, and altered neurotransmitter, cytokine, and hormonal settings. Treatment interventions are generally based on a sequential approach including treatment of comorbid factors, nonpharmacological treatments, and drugs.
Romans S, Cohen M.	Women's College Research Institute, Women's College Hospital, Toronto, Canada. sarah.romans@wchospital.ca	Unexplained and underpowered: the relationship between psychosomatic disorders and interpersonal abuse -- a critical review.	Harv Rev Psychiatry. 2008 Jan-Feb;16(1):35-54.	Although it is commonly accepted that interpersonal violence (IntPV) leads to adverse health consequences, the available data are far from decisive. To test the hypothesized link, the authors devised an evidence-based strategy to determine the data quality in studies purporting to link IntPV and some medically unexplained disorders in women (irritable bowel syndrome, chronic pelvic pain, fibromyalgia/chronic fatigue, and other chronic pain syndromes). English language studies with control groups of unaffected women were assessed for the quality of their methodologies. The number of studies, together with the consistency of their findings in each domain, was collated to determine the overall weight of evidence regarding the link for each condition. The quantity and quality of research in each clinical area proved to be sparse. In general, most research was limited to small, convenience samples, with insufficient attention to the design of control groups and to sample size. The evidence

				currently available regarding irritable bowel syndrome, fibromyalgia/chronic fatigue, chronic pelvic pain, and other chronic pain syndromes does not allow for any firm conclusion regarding their link to IntPV. More research - paying particular regard to the methodological concerns identified here - is required in order to generate any definitive conclusions.

Rudolph T, Larsen JP, Farbu E.	Department of Neurology, Stavanger University Hospital, Stavanger, Norway. mokum99@online.no	The long-term functional status in patients with Guillain-Barré syndrome.	Eur J Neurol. 2008 Dec;15(12):1332-7.	BACKGROUND AND PURPOSE: The purpose of this study was to analyse the long-term impact of Guillain-Barré syndrome (GBS) on quality of life, and the relationship between clinical variables at disease onset and symptoms at follow-up to general health status. METHODS: Forty-two GBS patients were examined at median 6 years after disease onset and were compared with 50 healthy controls. The fatigue severity scale (FSS), visual analogue scale (VAS) for pain, disability rating index (DRI) and medical outcome study 36-item short-form health status scale (SF-36) were applied. Variables at onset and symptoms at follow-up were correlated with outcome measurements in GBS. RESULTS: VAS [2.9 (SD 3.3) vs. 1.5 (SD 1.9); P = 0.01] and DRI [2.5 (SD 2.1) vs. 1.0 (SD 1.5); P < 0.001] were significantly higher in patients with GBS, compared with healthy controls. Decreased physical functioning and general health were found on SF-36. Differences between GBS patients with shorter (<6 years) and longer (> or =6 years) follow-up after onset were not found. CONCLUSIONS: Relatively independent from various variables at onset, patients with GBS seem to have a reduced quality of life and functioning, and the distress seems to have become persistent after the first few years with improvement following the acute disease.
Saiki T, Kawai T, Morita K, Ohta M, Saito T, Rokutan K, Ban N.	Department of General Medicine, Nagoya University Hospital, Nagoya, Japan.	Identification of marker genes for differential diagnosis of chronic fatigue syndrome.	Mol Med. 2008 Sep-Oct;14(9-10):599-607.	Chronic fatigue syndrome (CFS) is a clinically defined condition characterized by long-lasting disabling fatigue. Because of the unknown mechanism underlying this syndrome, there still is no specific biomarker for objective assessment of the pathological fatigue. We have compared gene expression profiles in peripheral blood between 11 drug-free patients with CFS and age- and sex-matched healthy subjects using a custom microarray carrying complementary DNA probes for 1,467 stress-responsive genes. We identified 12 genes whose mRNA levels were changed significantly in CFS patients. Of these 12 genes, quantitative real-time PCR validated the changes in 9 genes encoding granzyme in activated T or natural killer cells (GZMA), energy regulators (ATP5J2, COX5B, and DBI), proteasome subunits (PSMA3 and PSMA4), putative protein kinase c inhibitor (HINT), GTPase (ARHC), and signal transducers and activators of transcription 5A (STAT5A). Next, we performed the same microarray analysis on 3 additional CFS patients and 20 other patients with the chief complaint of long-lasting fatigue related to other disorders (non-CFS patients) and found that the relative mRNA expression of 9 genes classified 79% (11/14) of CFS and 85% (17/20) of the non-CFS patients. Finally, real-time PCR measurements of the levels of the 9 involved mRNAs were done in another group of 18 CFS and 12 non-CFS patients. The expression pattern correctly classified 94% (17/18) of CFS and 92% (11/12) of

				non-CFS patients. Our results suggest that the defined gene cluster (9 genes) may be useful for detecting pathological responses in CFS patients and for differential diagnosis of this syndrome.
Sakudo A, Kato YH, Tajima S, Kuratsune H, Ikuta K. Visible and near-infrared spectral changes in the thumb of patients with chronic fatigue syndrome.	Clin Chim Acta. 2009 Feb 25. [Epub ahead of print]	BACKGROUND: Chronic fatigue syndrome (CFS) patients show a persistent fatigue condition with muscle pain and impairment of concentration, memory, and sleep. Presently, the physiological basis of CFS remains unclear. In this study, spectroscopic differences in the thumb were compared between 103 CFS patients and 122 healthy controls to examine possible changes of levels of oxygenated or deoxygenated hemoglobin. METHODS: Visible and near-infrared (Vis-NIR) spectroscopy was used to examine possible changes in the region of 600-1100 nm. RESULTS: Vis-NIR spectra showed sharp peaks at 694, 970 and 1060 nm and broad peaks in the regions of 740-760 and 830-850 nm. As these peaks are possibly related to oxyhemoglobin, cytochrome c oxidase and water, levels of these factors were compared between the two groups. Statistical analysis of the absorbance of Vis-NIR spectra showed a significant decrease in water content, a significant increase in oxyhemoglobin content, and a significant increase in the oxidation of heme a+a(3) and copper in cytochrome c oxidase in CFS patients. CONCLUSIONS: These changes imply accelerated blood flow and energy metabolism in the thumbs of CFS patients.
Sakudo A, Kuratsune H, Kato YH, Ikuta K.	Department of Virology, Center for Infectious Disease Control, Research Institute for Microbial Diseases, Osaka University, Yamadaoka, Suita, Osaka 565-0871, Japan. sakudo@biken.osaka-u.ac.jp	Secondary structural changes of proteins in fingernails of chronic fatigue syndrome patients from Fourier-transform infrared spectra.	Clin Chim Acta. 2009 Apr;402(1-2):75-8. Epub 2008 Dec 30.	BACKGROUND: Generally, nails can be an index of health, with abnormalities sometimes found under diseased conditions. Fatigue is also supposed to affect the condition of nails. Possible differences in infrared (IR) spectra of nail plates of chronic fatigue syndrome (CFS) patients compared to healthy control subjects were investigated in this study. METHODS: Using an attenuated total reflection (ATR)-Fourier-transform infrared (FTIR) spectrophotometer, spectra in the region of 4000-600 cm(-1) were obtained. The amide I region was then separated by Fourier deconvolution and curve fitting based on the Gauss and Lorentz formula and revealed differences in the secondary structural content of proteins compared to healthy donors. RESULTS: The specific secondary structural pattern commonly observed in nails of male and female CFS patients in the absence and presence of medication indicated a decreased alpha-helix content and increased beta-sheet content, suggesting reduced levels of normal elements of the nail plate. CONCLUSIONS: This provides the first evidence of alterations in the fingernails of CFS patients which could be detected by IR spectroscopy. Possible explanations for the alterations will be discussed.

Scheeres K, Wensing M, Bleijenberg G, Severens JL.	Expert Centre Chronic Fatigue, Radboud University Nijmegen Medical Centre (4628), PO Box 9101, 6500 HB, The Netherlands. k.scheeres@nkcv.umcn.nl	Implementing cognitive behavior therapy for chronic fatigue syndrome in mental health care: a costs and outcomes analysis.	BMC Health Serv Res. 2008 Aug 13;8:175.	BACKGROUND: This study investigated the costs and outcomes of implementing cognitive behavior therapy (CBT) for chronic fatigue syndrome (CFS) in a mental health center (MHC). CBT is an evidence-based treatment for CFS that was scarcely available until now. To investigate the possibilities for wider implementation, a pilot implementation project was set up. METHOD: Costs and effects were evaluated in a non-controlled before- and after study with an eight months time-horizon. Both the costs of performing the treatments and the costs of implementing the treatment program were included in the analysis. The implementation interventions included: informing general practitioners (GPs) and CFS patients, training therapists, and instructing the MHC employees. Given the non-controlled design, cost outcome ratios (CORs) and their acceptability curves were analyzed. Analyses were done from a health care perspective and from a societal perspective. Bootstrap analyses were performed to estimate the uncertainty around the cost and outcome results. RESULTS: 125 CFS patients were included in the study. After treatment 37% had recovered from CFS and the mean gained QALY was 0.03. Costs of patients' health care and productivity losses had decreased significantly. From the societal perspective the implementation led to cost savings and to higher health states for patients, indicating dominancy. From the health care perspective the implementation revealed overall costs of 5.320 euros per recovered patient, with an acceptability curve showing a 100% probability for a positive COR at a willingness to pay threshold of 6.500 euros per recovered patient. CONCLUSION: Implementing CBT for CFS in a MHC appeared to have a favorable cost outcome ratio (COR) from a societal perspective. From a health care perspective the COR depended on how much a recovered CFS patient is being valued. The strength of the evidence was limited by the non-controlled design. The outcomes of this study might facilitate health care providers when confronted with the decision whether or not to adopt CBT for CFS in their institution.
Scheeres K, Wensing M, Knoop H, Bleijenberg G.	Expert Centre Chronic Fatigue, Radboud University Nijmegen Medical Centre, Nijmegen, The Netherlands. k.scheeres@nkcv.u	Implementing cognitive behavioral therapy for chronic fatigue syndrome in a mental health center: a benchmarking	J Consult Clin Psychol. 2008 Feb;76(1):163-71.	OBJECTIVE: This study evaluated the success of implementing cognitive behavioral therapy (CBT) for chronic fatigue syndrome (CFS) in a representative clinical practice setting and compared the patient outcomes with those of previously published randomized controlled trials (RCTs) of CBT for CFS. METHOD: The implementation interventions were the following: spreading information about the new treatment setting to general practitioners and CFS patients; training mental health center (MHC) therapists in CBT for CFS; and organizing changes in the MHC patient workflow. Patient outcomes were documented with validated self-report measures of fatigue and physical functioning before and after treatment. The comparison of the treatment results with RCT results was done following the

	mcn.cl	evaluation.		benchmark strategy. RESULTS: One-hundred forty-three CFS patients were referred to the MHC, of whom 112 started treatment. The implementation was largely successful, but a weak point was the fact that 32% of all referred patients dropped out shortly after or even before starting treatment. Treatment effect sizes were in the range of those found in the benchmark studies. CONCLUSIONS: CBT for CFS can successfully be implemented in an MHC. Treatment results were acceptable, but the relatively large early dropout of patients needs attention.
Scheeres K, Wensing M, Severens H, Adang E, Bleijenberg G.	Expert Centre Chronic Fatigue, Radboud University Nijmegen Medical Centre, Nijmegen, The Netherlands. k.scheeres@nkcv.umcn.nl	Determinants of health care use in chronic fatigue syndrome patients: a cross-sectional study.	J Psychosom Res. 2008 Jul;65(1):39-46. Epub 2008 May 22.	BACKGROUND: Chronic fatigue syndrome (CFS) is associated with a high use of health care services. To reduce the related costs for patients and society, it will be useful to know which factors determine CFS patients' amount of health care use. Little is known, however, about these factors. METHOD: The present study retrospectively performed a cross-sectional analysis to investigate the possible factors determining CFS patients' health care use. A total of 263 CFS patients, derived from two subgroups (149 from tertiary care and 114 from primary/secondary care), participated. Health care use was measured with a questionnaire asking details on consumption over the past 6 months. Fatigue severity and physical functioning were measured with the subscale Experienced Fatigue of the Checklist Individual Strength (CIS-20) and the subscale Physical Functioning of the SF-36, respectively. Multiple regression analysis, T-tests, and chi(2) tests were performed. RESULTS: The regression analysis revealed that, after controlling for patient characteristics (explaining 13%), fatigue factors added 4% predictive value and certain perpetuating factors of fatigue, including focus on bodily symptoms and attributions of fatigue, added another 5%. The analysis of subgroups revealed that, compared to the tertiary care population, fewer patients from primary/secondary care had visited a medical specialist (50% vs. 71%), used antidepressants (16% vs. 25%) and tranquilizers (3% vs. 18%), and had spent a night in hospital (7% vs. 10%). However, overall costs of health care between these subgroups did not differ. CONCLUSIONS: This study showed that illness duration, physical impairment due to fatigue, and psychological perpetuating factors of fatigue do determine the variance in CFS patients' health care use. These results give clear directions for treating CFS patients and managing health care for CFS.
Schmitt L, Faure K.	CHU de Toulouse, Hôpital Casselardit, 31059 Toulouse Cedex 9.	[Discussion] [Article in French]	Encephale. 2008 Jun;34 Spec No 2:S21-3.	
Schnakers C, Majerus S, Goldman S, Boly M, Van Eeckhout P, Gay S, Pellas F, Bartsch V, Peigneux P, Moonen G, Laureys S.	Cyclotron Research Center, University of Liège, Belgium. C.Schnakers@student.ulg.ac.be	Cognitive function in the locked-in syndrome.	J Neurol. 2008 Mar;255(3):323-30. Epub 2008 Mar 20.	OBJECTIVE : The lockedin syndrome (LIS) originates from a ventro-pontine lesion resulting in a complete quadraplegia and anarthria. Classically, communication remains possible by means of spared vertical eye movements and/or blinking. To allow assessing cognitive functions in LIS patients, we propose here a neuropsychological testing based on eye-coded communication. METHODS : Ten chronic LIS survivors were assessed 1 to 6 years after their brain insult.One patient was evaluated subacutely (at 2 months) and retested at 6 and 16 months.Neuropsychological testing encompassed short- and long-term memory, attention, executive functioning, phonological and semantic processing and verbal intelligence. RESULTS : None of the patients showed alterations in verbal intelligence. Impairments in one or several tests were found in five patients. In three of these patients, neuropsychological deficits could be related to additional cortical or thalamic structural brain lesions.

				In the other 2 patients, weakness or signs of fatigue only were observed in one or two cognitive tasks. Repeated measures in a subacute patient with pure brainstem lesion indicate the recovery of good levels of cognition 6 months after injury. CONCLUSION : Results indicate that LIS patients can recover intact cognitive levels in cases of pure brainstem lesions, and that additional brain injuries are most likely responsible for associated cognitive deficits in the LIS. Furthermore, a systematic neuropsychological assessment in LIS patients would allow detecting their cognitive deficits,which will contribute to improve their quality of life and of communication with family and medical caretakers.
Schrijvers D, Van Den Eede F, Maas Y, Cosyns P, Hulstijn W, Sabbe BG.	Collaborative Antwerp Psychiatric Research Institute (CAPRI), Faculty of Medicine, University of Antwerp (UA), Universiteitsplein 1, 2610 Antwerp, Belgium.	Psychomotor functioning in chronic fatigue syndrome and major depressive disorder: A comparative study.	J Affect Disord. 2008 Sep 23. [Epub ahead of print]	BACKGROUND: Studies comparing chronic fatigue syndrome (CFS) and major depressive disorder (MDD) reported similarities as well as differences between the two disorders. However, whereas psychomotor symptoms have been studied extensively in MDD, such research in CFS is more limited. Moreover, the few studies that compared cognitive and motor performance in MDD and CFS yielded inconsistent results. This study hence directly compares fine psychomotor functioning in both syndromes. METHODS: Thirty-eight patients diagnosed with CFS without a current major depressive episode (MDE), 32 MDD patients with a current MDE and 38 healthy controls performed two computerized copying tasks differing in complexity: a line-copying task that mainly requires motor effort and a figure-copying task requiring additional cognitive efforts. All participants were female. A multivariate general linear model was used to compute group differences. RESULT: Overall, both patient groups performed more slowly than the controls. Compared to CFS patients, patients with MDD needed significantly more time to copy the single lines but no such between-group performance difference was observed for the figure reproductions. In this latter copying task, the increasing complexity of the figures resulted in prolonged reaction times for all three participant groups with the effect being larger and the magnitude similar for the two patient groups. LIMITATIONS: All patients were female and most were on psychotropic medication. CONCLUSIONS: Both the MDD and CFS patients tested demonstrated an overall fine motor slowing, with the motor component being more affected in the MDD patients than in the CFS patients while both patient groups showed similar cognitive impairments.

Schutte NS, Malouff JM, Brown RF.	University of New England, Armidale, NSW, Australia. nschutte@une.edu.au	Efficacy of an emotion-focused treatment for prolonged fatigue.	Behav Modif. 2008 Sep;32(5):699-713. Epub 2008 Apr 16.	Previous research findings have suggested a relationship between less adaptive emotional functioning and fatigue. The present study used a research design involving multiple baselines across participants to evaluate the efficacy of a new emotion-focused treatment for prolonged fatigue delivered in a cognitive behavioral therapy framework. The 13 adults participating in the study met the criteria for prolonged fatigue and provided fatigue baselines of 2, 5, or 8 weeks. The results indicated that the treatment was effective, with fatigue severity levels after the initiation of treatment significantly lower than that predicted by baseline patterns, as determined by the split median method of trend estimation. At 3-4 months after treatment, 8 of 11 clients who completed the treatment no longer

				met the criteria for prolonged fatigue.
Schweinhardt P, Sauro KM, Bushnell MC.	Center for Research on Pain, McGill University.	Fibromyalgia: A Disorder of the Brain?	Neuroscientist. 2008 Feb 12. [Epub ahead of print]	This article presents evidence that fibromyalgia patients have alterations in CNS anatomy, physiology, and chemistry that potentially contribute to the symptoms experienced by these patients. There is substantial psychophysical evidence that fibromyalgia patients perceive pain and other noxious stimuli differently than healthy individuals and that normal pain modulatory systems, such as diffuse noxious inhibitory control mechanisms, are compromised in fibromyalgia. Furthermore, functional brain imaging studies revealing enhanced pain-related activations corroborate the patients' reports of increased pain. Neurotransmitter studies show that fibromyalgia patients have abnormalities in dopaminergic, opioidergic, and serotoninergic systems. Finally, studies of brain anatomy show structural differences between the brains of fibromyalgia patients and healthy individuals. The cerebral alterations offer a compelling explanation for the multiple symptoms of fibromyalgia, including widespread pain and affective disturbances. The frequent comorbidity of fibromyalgia with stress-related disorders, such as chronic fatigue, posttraumatic stress disorder, irritable bowel syndrome, and depression, as well as the similarity of many CNS abnormalities, suggests at least a partial common substrate for these disorders. Despite the numerous cerebral alterations, fibromyalgia might not be a primary disorder of the brain but may be a consequence of early life stress or prolonged or severe stress, affecting brain modulatory circuitry of pain and emotions in genetically susceptible individuals.
Seishima M, Mizutani Y, Shibuya Y, Arakawa C.	Department of Dermatology, Ogaki Municipal Hospital, Ogaki City, Japan. marikoseishima@yahoo.co.jp	Chronic fatigue syndrome after human parvovirus B19 infection without persistent viremia.	Dermatology. 2008;216(4):341-6. Epub 2008 Feb 15.	BACKGROUND: It is unclear how often chronic fatigue syndrome (CFS) appears after human parvovirus B19 (B19) infection and whether prolonged B19 viremia or some other factors cause CFS. OBJECTIVES: To determine how often CFS appears after B19 infection and whether prolonged B19 DNA presence, antibody production and persistently reduced complement levels occur in CFS patients after B19 infection. METHODS: Clinical findings were examined in 210 patients after B19 infection, and CH50, C3 and C4 levels were determined. B19 DNA and antibodies to B19 were also tested in 38 patients' sera including 3 with CFS. RESULTS: Serum B19 DNA disappeared after 4-5 months in all 18 patients tested. There are no differences in B19 DNA-positive period between patients with and without persistent symptoms. IgM antibody titers to B19 became reduced after 2 months in all 38 patients. Complement levels persistently decreased in a greater proportion of patients with persistent symptoms. CONCLUSIONS: The present study suggests that we should consider the possibility of CFS after B19 infection and that CFS may be derived from several aspects other than prolonged B19 DNA presence in sera. Silva-Tinoco R, Castillo-Martínez L, Orea-Tejeda A, Orozco-Gutiérrez JJ, Vázquez-Díaz O, Montaño-Hernández P, Flores-Rebollar A, Reza-Albarrán A.	Heart Failure Clinic, Instituto Nacional de Ciencias Médicas y Nutrición "Salvador Zubirán", Mexico City, Mexico.	Developing thyroid disorders is associated with poor prognosis factors in patient with stable chronic heart failure.	Int J Cardiol. 2009 Feb 7. [Epub ahead of print]	We sought to assess the developing of thyroid disorders in forty eight patients with chronic stable heart failure and without thyroid abnormalities during six months follow-up. Thyroid function disorders were observed in 27.1% of the subjects: sick euthyroid syndrome (12.5%), subclinical hypothyroidism (10.4%) and overt hypothyroidism (6.2%). Subjects with higher thyroid stimulating hormone (TSH) levels at the end of the study had more hospitalizations. The developing of altered thyroid profile was related to lower hemoglobin levels, smaller phase angle with bioelectrical impedance method and more fatigue perception by the patients. This abnormal thyroid function behavior on stable chronic heart failure and was observed as part of the disease progress and was associated to worse prognosis factors as lower phase angle and anemia.

Singh BB, Khorsan R, Vinjamury SP.	Medicus Research LLC, Midlothian, Virginia, USA.	Influence of comorbidities on improvement of fibromyalgia symptoms when treated with acupuncture: a short report.	Altern Ther Health Med. 2008 Sep-Oct;14(5):24-5.	BACKGROUND: Fibromyalgia syndrome (FMS) is associated with chronic widespread pain, mood alteration, and disability. A definitive treatment plan has not been identified. The genesis of FMS is unclear and generally occurs in women. PURPOSE: To determine whether patient-identified most disruptive comorbidity (MDC) secondary to FMS may have mediated recovery for individual patients. This is a probative analysis of data from an effectiveness study published in the March 2006 issue of Alternative Therapies in Health and Medicine. (2006;12(2):34-41.) METHODS: The American College ofRheumatology (ACR) criteria for FMS was used in participant selection; 21 participants completed the study. RESULTS: The original outcome study indicated significant changes on standardized measures using specific points and numbers of treatment within an 8-week period. The preliminary data on influence ofMDC on improvement were differential related to self-report MDC by patients. CONCLUSIONS: For all MDCs combined, participants experienced significant improvement at 8 weeks of treatment. Participants with irritable bowel syndrome as their MDC generally had a lower percentage of improvement than other MDC cohort groups. This finding has implications for treatment.
Smith AK, Dimulescu I, Falkenberg VR, Narasimhan S, Heim C, Vernon SD, Rajeevan MS.	Division of Viral and Rickettsial Diseases, National Center for Infectious Diseases, Centers for Disease Control and Prevention, 1600 Clifton Road, MSG41, Atlanta, GA 30333, USA.	Genetic evaluation of the serotonergic system in chronic fatigue syndrome.	Psychoneuroendocrinology. 2008 Feb;33(2):188-97.	Chronic fatigue syndrome (CFS) is a debilitating disorder of unknown etiology with no known lesions, diagnostic markers or therapeutic intervention. The pathophysiology of CFS remains elusive, although abnormalities in the central nervous system (CNS) have been implicated, particularly hyperactivity of the serotonergic (5-hydroxytryptamine; 5-HT) system and hypoactivity of the hypothalamic-pituitary-adrenal (HPA) axis. Since alterations in 5-HT signaling can lead to physiologic and behavioral changes, a genetic evaluation of the 5-HT system was undertaken to identify serotonergic markers associated with CFS and potential mechanisms for CNS abnormality. A total of 77 polymorphisms in genes related to serotonin synthesis (TPH2), signaling (HTR1A, HTR1E, HTR2A, HTR2B, HTR2C, HTR3A, HTR3B, HTR4, HTR5A, HTR6, and HTR7), transport (SLC6A4), and catabolism (MAOA) were examined in 137 clinically evaluated subjects (40 CFS, 55 with insufficient fatigue, and 42 non-fatigued, NF, controls) derived from a population-based CFS surveillance study in Wichita, Kansas. Of the polymorphisms examined, three markers (-1438G/A, C102T, and rs1923884) all located in the 5-HT receptor subtype HTR2A were associated with CFS when compared to NF controls. Additionally, consistent associations were observed between HTR2A variants and quantitative measures of disability and fatigue in all subjects. The most compelling of these associations was with the A allele of -1438G/A (rs6311) which is suggested to have increased promoter activity in functional studies. Further, in silico analysis revealed that the -1438 A allele creates a consensus binding site for Th1/E47, a transcription factor implicated in the development of the nervous system. Electrophoretic mobility shift assay supports allele-specific binding of E47 to the A allele but not the G allele at this locus. These data indicate that sequence variation in HTR2A, potentially resulting in its enhanced activity, may be involved in the pathophysiology of CFS.
Smith AK, Maloney EM, Falkenberg VR, Dimulescu I, Rajeevan MS.	Division of Viral and Rickettsial Diseases, National Center for Zoonotic, Vector-	An angiotensin-1 converting enzyme polymorphism is associated with allostatic load	Psychoneuroendocrinology. 2008 Dec 9. [Epub ahead of print]	Allostatic load (AL) is a theoretical framework that describes the cumulative physiologic effects of adaptation to change or stress throughout the lifespan. AL is operationalized by a composite index of multiple biomarkers. Accordingly, genes, behavior and environment contribute to AL. To determine if individual differences in AL may be influenced by inherent genetic variation, we calculated an allostatic load index (ALI) for 182 Caucasian subjects derived from a population-based study of chronic

	Borne and Enteric Diseases, Centers for Disease Control and Prevention, 1600 Clifton Road, MSG41, Atlanta, GA 30333, USA; Department of Human Genetics, Emory University School of Medicine, Atlanta, GA, USA.	mediated by C-reactive protein, interleukin-6 and cortisol.		fatigue syndrome. Nearly 65% of the subjects in this study sample reported fatiguing illness. ALI was calculated based on 11 measures representing metabolic, cardiovascular, inflammatory, hypothalamic-pituitary-adrenal (HPA) axis and sympathetic nervous system (SNS) activities. Subjects were dichotomized into high (ALI>/=3) or low (ALI<3) AL groups, and the association between high AL and 129 polymorphisms in 32 genes related to the HPA axis, neurotransmission, inflammation, cardiovascular and metabolic functions were evaluated. Polymorphisms in angiotensin-1 converting enzyme (ACE), corticotropin-releasing hormone receptor 1 (CRHR1), and serotonin receptors (HTR3A and HTR4) were associated with AL (p=0.0007-0.0486), but only one polymorphism, rs4968591, in ACE remained significant after correction for multiple comparisons. The T allele of ACE rs4968591 was more common in subjects with high AL (67.5%) than in subjects with low AL (49.3%) (p=0.0007), and this effect appeared independent of age, sex, body mass index and fatigue status. Additionally, high interleukin-6 (IL-6; p(trend)=0.04), and C-reactive protein (CRP; p(trend)=0.01) levels, as well as low urinary cortisol levels in females (p=0.03) were associated with the T allele, which may result in allele-specific binding of the transcription factor, E2F1. Our results suggest a role for ACE in the bidirectional communication between the central nervous and immune systems in response to stress. Further studies will be needed (a) to replicate the association between AL and ACE polymorphisms in population studies designed to differentiate the effects of sex, age and racial/ethnic background, (b) to evaluate the effect of allele-specific binding of E2F1 at rs4968591, and (c) to examine the role of ACE in the co-regulation of CRP, IL-6 and cortisol.
Smits BW, Smeitink JA, van Engelen BG.	Universitair Medisch Centrum St Radboud, Postbus 9101, 6500 HB Nijmegen. b.smits@neuro.umcn.nl	[Mitochondrial diseases; thinking beyond organ specialism necessary] [Article in Dutch]	Ned Tijdschr Geneeskd. 2008 Oct 18;152(42):2275-81. Comment on: Ned Tijdschr Geneeskd. 2008 Oct 18;152(42):2298-301.	Mitochondrial disorders are caused by a defect in intracellular energy production. In general, these are multi-system disorders, predominantly affecting organs with high energy requirements. Due to the fact that mitochondrial disorders are not as rare as is generally assumed, and due to the diversity of symptoms, many different medical specialists will at some time be confronted with these patients. Early recognition ofa mitochondrial disorder reduces patient anxiety and avoids unnecessary ancillary investigations and potentially hazardous treatments. A mitochondrial disease should be considered in the event of dysfunction of more than 2 organ systems or processes with high energy requirements, certainly if there is a positive maternal family history. If fatigue includes exercise-induced muscle pain or muscle weakness, and if muscle pain predominantly occurs during exertion, a mitochondrial disease should be considered. The combination ofdiabetes mellitus and deafness is also a strong indicator of mitochondrial disease. An extensive family history should always be taken. In adults, the most frequently occurring mitochondrial syndromes are chronic progressive external ophthalmoplegia (CPEO), maternally inherited diabetes and deafness syndrome (MIDDS) and Leber's hereditary optic neuropathy. Since much research effort is currently being invested in the development of causal medical treatments, the importance of an early diagnosis is likely to become of increasing importance in the future.
Sohl SJ, Friedberg F.	Psychology Department, Stony Brook University, New York, USA.	Memory for fatigue in chronic fatigue syndrome: relationships to fatigue variability,	Behav Med. 2008 Spring;34(1):29-38.	Fatigue in chronic fatigue syndrome (CFS) is usually assessed with retrospective measures rather than real-time momentary symptom assessments. In this study, the authors hypothesized that in participants with CFS, discrepancies between recalled and momentary fatigue would be related to catastrophizing, anxiety, and depression and to variability of momentary fatigue. They also expected that catastrophizing, anxiety, and depression would be associated with momentary fatigue. The

		catastrophizing, and negative affect.		authors asked 53 adults with CFS to carry electronic diaries for 3 weeks and record their experiences of momentary fatigue. The authors assessed participants' fatigue recall with weekly ratings and administered questionnaires for catastrophizing, depression, and anxiety. Recall discrepancy was significantly related to the variability of momentary fatigue. In addition, catastrophizing, depression, and momentary fatigue were all significantly related to recall discrepancy. Catastrophizing, depression, anxiety, and momentary negative affect were all significantly associated with momentary fatigue. The findings suggest that momentary fatigue in patients with CFS is related to modifiable psychological factors.
Soleo L, Manghisi MS, Panuzzo L, Meliddo G, Lasorsa G, Pesola G, Drago I, Lovreglio P, Urbano ML, Basso A, Ferrara F, Serra R, Gardi S, Savarese MA, Livrea P.	Dipartimento di Medicina Interna e Medicina Pubblica, Sezione di Medicina del Lavoro E.C. Vigliani, Università di Bari, Italy. l.soleo@medlav.uniba.it	[Sleep disorders in cement workers] [Article in Italian]	G Ital Med Lav Ergon. 2008 Jul-Sep;30(3):283-90.	Obstructive Sleep Apnea Syndrome (OSAS) and Excessive Daytime Sleepiness (EDS) are sleep disorders which can increase cardiovascular risk. An health survey was performed on the cement workers to estimate the prevalence of sleep disorders and to investigate occupational, personal and health risk factors that could influence it. A total of 761 male workers, employed at 10 different cement plants of South Italy and Sicily, were examined. All subjects gave informed consent to take part in the survey. The following questionnaires were administered: Berlin Questionnaire to estimate the high risk of OSAS, Epworth Sleepiness Scale for EDS, a questionnaire posing questions about working conditions, personal characteristic, lifestyle, past history of disease and present illness. Statistical analysis was performed with the statistical package SPSS. The prevalence of high risk of OSAS and of EDS resulted respectively in 24.2% and 3.4% of workers. Sleep disorders detected with the two questionnaires were significantly associated. A positive and significant association between OSAS and respectively age, time of employment, BMI, ex-smoker status, neck, waist or hip circumferences, chronic fatigue and arterial hypertension was observed. Subjective variables regarding working conditions (job interest, evaluation oforganization of work and job satisfaction) and alcohol consumption were not associated with the high risk of OSAS. Shift work (2 and 3 shifts) was not associated with the high risk of OSAS. An healthy worker effect was observed for workers who changed from shift work (2 or 3 shifts) to fixed daytime work. For them, this change to fixed daytime work was conditioned by chronic disease like hypertension and obesity. EDS was not dependent, associated or correlated with any of the occupational, personal or pathologic variables investigated in the study. In conclusion the research showed no relationship between working conditions, particularly shift work, and the high risk of OSAS, and the influence of obesity in determining the high risk of OSAS, itself a potential cardiovascular risk factor. The interest of occupational physician has been focused on introducing in health surveillance also measures of health promotion regarding sleep disorders with the aim of preserving health condition in workers.
Sorensen B, Jones JF, Vernon SD, Rajeevan MS.	Division of Viral and Rickettsial Diseases, National Center for Zoonotic, Vector-Borne, and Enteric Diseases, Centers for Disease Control	Transcriptional control of complement activation in an exercise model of chronic fatigue syndrome.	Mol Med. 2009 Jan-Feb;15(1-2):34-42. Epub 2008 Nov 10.	Complement activation resulting in significant increases of C4a split product may be a marker of postexertional malaise in individuals with chronic fatigue syndrome (CFS). This study focused on identification of the transcriptional control that may contribute to the increased C4a in CFS subjects after exercise. We used quantitative reverse-transcription polymerase chain reaction to evaluate differential expression of genes in the classical and lectin pathways in peripheral blood mononuclear cells (PBMCs). Calibrated expression values were normalized to the internal reference gene peptidylpropyl isomerase B (PPIB), the external reference gene ribulose-1,5-bisphosphate carboxylase/oxygenase large subunit (rbcL), or the geometric mean (GM) of the genes ribosomal

	and Prevention, Atlanta, Georgia 30333, United States of America.			protein, large, P0 (RPLP0) and phosphoglycerate kinase 1 (PGK1). All nine genes tested, except mannose-binding lectin 2 (MBL2), were expressed in PBMCs. At 1 hour postexercise, C4, mannan-binding lectin serine protease 2 (MASP2) and ficolin 1 (FCN1) transcripts were detected at higher levels (> or = 2-fold) in at least 50% (4 of 8) of CFS subjects and were detected in 88% (7 of 8) CFS subjects when subjects with overexpression of either C4 or MASP2 were combined. Only an increase in the MASP2 transcript was statistically significant (PPIB, P = 0.001; GM, P = 0.047; rbcL, P = 0.045). This result may be due to the significant but transient downregulation of MASP2 in control subjects (PPIB, P = 0.023; rbcL, P = 0.027). By 6 hours postexercise, MASP2 expression was similar in both groups. In conclusion, lectin pathway responded to exercise differentially in CFS than in control subjects. MASP2 down-regulation may act as an antiinflammatory acute-phase response in healthy subjects, whereas its elevated level may account for increased C4a and inflammation-mediated postexertional malaise in CFS subjects.
Spence VA, Kennedy G, Belch JJ, Hill A, Khan F.	Vascular and Inflammatory Diseases Research Unit, Institute for Cardiovascular Research, Ninewells Hospital and Medical School, University of Dundee, Dundee DD1 9SY, Scotland, UK.	Low-grade inflammation and arterial wave reflection in patients with chronic fatigue syndrome.	Clin Sci (Lond). 2008 Apr;114(8):561-6.	Some of the symptoms reported by people with CFS (chronic fatigue syndrome) are associated with various cardiovascular phenomena. Markers of cardiovascular risk, including inflammation and oxidative stress, have been demonstrated in some patients with CFS, but little is known about the relationship between these and prognostic indicators of cardiovascular risk in this patient group. In the present study, we investigated the relationship between inflammation and oxidative stress and augmentation index, a measure of arterial stiffness, in 41 well-characterized patients with CFS and in 30 healthy subjects. AIx@75 (augmentation index normalized for a heart rate of 75 beats/min) was significantly greater in patients with CFS than in control subjects (22.5+/-1.7 compared with 13.3+/-2.3% respectively; P=0.002). Patients with CFS also had significantly increased levels of CRP (C-reactive protein) (2.58+/-2.91 compared with 1.07+/-2.16 mug/ml respectively; P<0.01) and 8-iso-prostaglandin F(2alpha) isoprostanes (470.7+/-250.9 compared with 331.1+/-97.6 pg/ml respectively; P<0.005). In patients with CFS, AIx@75 correlated significantly with logCRP (r=0.507, P=0.001), isoprostanes (r=0.366, P=0.026), oxidized LDL (low-density lipoprotein) (r=0.333, P=0.039) and systolic blood pressure (r=0.371, P=0.017). In a stepwise multiple regression model, including systolic and diastolic blood pressure, body mass index, CRP, tumour necrosis factor-alpha, interleukin-1, oxidized LDL, high-density lipoprotein-cholesterol levels, isoprostanes, age and gender, AIx@75 was independently associated with logCRP (beta=0.385, P=0.006), age (beta=0.363, P=0.022) and female gender (beta=0.302, P=0.03) in patients with CFS. The combination of increased arterial wave reflection, inflammation and oxidative stress may result in an increased risk of future cardiovascular events. Assessment of arterial wave reflection might be useful for determining cardiovascular risk in this patient group.
Staud R.	Department of Medicine, University of Florida College of Medicine, PO Box 100221, D2-39, Gainesville, FL	Autonomic dysfunction in fibromyalgia syndrome: postural orthostatic tachycardia.	Curr Rheumatol Rep. 2008 Dec;10(6):463-6.	Although fibromyalgia (FM) syndrome is defined by chronic widespread pain and tenderness, additional symptoms, including disabling fatigue and dizziness, are often reported by patients with this chronic illness. Although nonrestorative sleep may play an important role for chronic fatigue in FM, other mechanisms, including dysfunction of the autonomic nervous system (ANS), need to be considered. Many important biological functions, such as heart rate, blood pressure, respirations, and bowel function, are tightly regulated by the ANS. However, dysfunction of the ANS is common in FM and often becomes quite apparent after positional changes from supine to upright. Although such

	32610, USA. staudr@ufl.edu			positional changes sometimes result in syncope, they are more often associated with palpitations and dizziness. Head-up tilt table testing can be used to evaluate autonomic dysfunction and is frequently helpful for the work-up of FM complaints, including fatigue, dizziness, and palpitations. One of the most common events experienced by FM patients during tilt table testing is postural orthostatic tachycardia syndrome, which is defined as a heart rate increase of more than 30 beats per minute after more than 3 minutes of standing upright.
Stubhaug B, Lie SA, Ursin H, Eriksen HR.	Division of Psychiatry, Haukeland University Hospital, N-5021 Bergen, Norway. bjarte.stubhaug@helse-bergen.no	Cognitive-behavioural therapy v. mirtazapine for chronic fatigue and neurasthenia: randomised placebo-controlled trial.	Br J Psychiatry. 2008 Mar;192(3):217-23.	BACKGROUND: Single interventions in chronic fatigue syndrome have shown only limited effectiveness, with few studies of comprehensive treatment programmes. AIMS: To examine the effect of a comprehensive cognitive-behavioural treatment (CCBT) programme compared with placebo-controlled mirtazapine medication in patients with chronic fatigue, and to study the effect of combined medication and CCBT. METHOD: A three-armed randomised clinical trial of mirtazapine, placebo and a CCBT programme was conducted to investigate treatment effect in a patient group (n=72) with chronic fatigue referred to a specialist clinic. The CCBT programme was compared with mirtazapine or placebo therapy for 12 weeks, followed by 12 weeks treatment with a mixed crossover-combination design. Assessments were done at 12 weeks and 24 weeks. RESULTS: By 12 weeks the treatment effect was significantly better in the group initially receiving CCBT, as assessed with the Fatigue Scale (P=0.014) and the Clinical Global Impression Scale (P=0.001). By 24 weeks the treatment group initially receiving CCBT for 12 weeks followed by mirtazapine for 12 weeks showed significant improvement compared with the other treatment groups on the Fatigue Scale (P<0.001) and the Clinical Global Impression Scale (P=0.002). Secondary outcome measures showed overall improvement with no significant difference between treatment groups. CONCLUSIONS: Multimodal interventions may have positive treatment effects in chronic fatigue syndrome. Sequence of interventions seem to be of importance.
Sullivan A, Nord CE, Evengård B.	Division of Clinical Microbiology, F82, Department of Laboratory Medicine, Karolinska University Hospital Huddinge, Karolinska Institutet, SE-14186 Stockholm, Sweden. asa.sullivan@ki.se	Effect of supplement with lactic-acid producing bacteria on fatigue and physical activity in patients with chronic fatigue syndrome.	Nutr J. 2009 Jan 26;8:4.	Disturbances in intestinal microbial ecology and in the immune system of the host have been implicated as a part of the pathogenesis in chronic fatigue syndrome. Probiotic lactic acid producing bacteria have been shown to prevent and alleviate gastrointestinal disturbances and to normalize the cytokine profile which might be of an advantage for patients suffering from chronic fatigue syndrome. The aim of the study was to evaluate the effect of Lactobacillus paracasei ssp. paracasei F19, Lactobacillus acidophilus NCFB 1748 and Bifidobacterium lactis Bb12 on fatigue and physical activity in CFS patients. Fifteen patients fulfilling the criteria set by international researchers in the field at the US Centre for Disease Control and Prevention in 1994 for chronic fatigue syndrome, were included in the study. The patients had high fatigue severity scores and high disability scores. During the first two weeks baseline observations without treatment were assessed, succeeded by four weeks of intake of a probiotic product and a four-week follow-up period. The fatigue, health and physical activity was assessed by the use of the Visual Analogue Scales and the SF-12 Health Survey. Faecal samples were collected and the normal microflora was analysed. Neurocognitive functions improved during the study period while there were no significant changes in fatigue and physical activity scores. No major changes occurred in the gastrointestinal microflora. At the end of the study 6 of 15 patients reported that they had improved according to the assessment described. The findings in this study that improvement of health is possible to achieve should encourage further studies with interventions with

				probiotics in patients with CFS.
Swoboda DA.	City University of New York, USA. dswoboda@york.cuny.edu	Negotiating the diagnostic uncertainty of contested illnesses: physician practices and paradigms.	Health (London). 2008 Oct;12(4):453-78.	In the absence of scientific consensus about contested illnesses such as Chronic Fatigue Syndrome (CFS), Multiple Chemical Sensitivities (MCS), and Gulf War Syndrome (GWS), physicians must make sense of competing accounts and develop practices for patient evaluation. A survey of 800 United States physicians examined physician propensity to diagnose CFS, MCS, and GWS, and the factors shaping clinical decision making. Results indicate that a substantial portion of physicians, including nonexperts, are diagnosing CFS, MCS, and GWS. Diagnosing physicians manage the uncertainty associated with these illnesses by using strategies that enhance bounded rationality and aid in thinking beyond current disease models. Strategies include consulting ancillary information sources, conducting analytically informed testing, and considering physiological explanations of causation. By relying on these practices and paradigms, physicians fit CFS, MCS, and GWS into an explanatory system that makes them credible and understandable to them, their patients, and the medical community. Findings suggest that physicians employ rational decision making for diagnosing contested illnesses, creating a blueprint of how illnesses lacking conclusive pathogenic and etiological explanations can be diagnosed. Findings also suggest that patients with contested illnesses might benefit from working with physicians who use these diagnostic strategies, since they help manage the complexity and ambiguity of the contested illness diagnostic process and aid in diagnosis. In addition, findings provide a window into how emerging illnesses get diagnosed in the absence of medical and scientific consensus, and suggest that diagnosing physicians advance the legitimacy of controversial illnesses by constructing the means for their diagnosis.

ter Wolbeek M, van Doornen LJ, Kavelaars A, Heijnen CJ.	Laboratory of Psychoneuroimmunology, University Medical Center Utrecht, 3508 AB Utrecht, The Netherlands.	Predictors of persistent and new-onset fatigue in adolescent girls.	Pediatrics. 2008 Mar;121(3):e449-57.	OBJECTIVE: The purpose of this study was to investigate the stability of fatigue in adolescents and to explore whether psychological, somatic, and lifestyle factors are involved in the onset and persistence of fatigue during adolescence. METHODS: In this longitudinal study, a total of 653 adolescent girls (aged 14.40 +/- 1.45 years) who previously participated in an epidemiological study filled out questionnaires 6 (T2) and 12 (T3) months after the initial assessment (T1). Fatigue severity, depression, anxiety, and chronic fatigue syndrome-related symptoms were assessed. We determined the prevalence of severely fatigued cases at T2 and T3 and evaluated whether persistently fatigued participants initially differed from nonfatigued participants and participants with transient fatigue. We examined which factors predicted the development of new-onset fatigue and investigated whether changes in fatigue covaried with changes in other complaints and changes in lifestyle. RESULTS: Of all participants who were severely fatigued at T1, 25.7% were persistently fatigued throughout the study. Persistently fatigued participants had higher levels of depression and anxiety at the beginning of the study, were less physically active, and slept shorter. New-onset fatigue was predicted by depression, less physical activity, and more nightlife activities. Interestingly, new onset was not predicted by initial levels of fatigue. Persistently fatigued participants did not differ in initial fatigue severity from short-term fatigued patients. A decrease in fatigue severity was associated with a decrease in depression,

				anxiety, and chronic fatigue syndrome-related symptoms and, to a lesser extent, with an increase in physical activity and sleep duration. CONCLUSIONS: The stability of severe fatigue among adolescents is substantial. The involvement in the onset and persistence of fatigue suggests that both preventive and therapeutic strategies with respect to fatigue treatment in adolescents should concentrate on emotional well-being. Moreover, adolescents at risk should be stimulated to spend more time on physical activities and to sleep longer.
ter Wolbeek M, van Doornen LJ, Schedlowski M, Janssen OE, Kavelaars A, Heijnen CJ.	Laboratory of Psychoneuroimmunology, University Medical Center Utrecht, The Netherlands.	Glucocorticoid sensitivity of immune cells in severely fatigued adolescent girls: a longitudinal study.	Psychoneuroendocrinology. 2008 Apr;33(3):375-85. Epub 2008 Jan 31.	Fatigue during adolescence is associated with somatic and psychological complaints that resemble the pattern of symptoms described for chronic fatigue syndrome (CFS). Studies in CFS and other stress-related syndromes suggested a dysfunction of the interactions between the hypothalamic-pituitary-adrenal axis (HPA-axis) and the immune system, i.e. a changed glucocorticoid (GC) receptor sensitivity of immune cells, to exist. Here we investigated whether severely fatigued girls from a healthy population have altered cortisol production and immune cell sensitivity for the synthetic GC, dexamethasone (DEX). In a longitudinal design, we examined ex vivo DEX sensitivity of monocytes and of T-cell mitogen-induced responses of severely fatigued (N=65) and non-fatigued girls (N=60). Fatigued girls reported more severe comorbid complaints than non-fatigued participants across three measurements during 1 year (T1: spring, T2: autumn, T3: spring) and had higher plasma cortisol levels throughout the study. DEX sensitivity of T-cell mitogen-induced responses showed seasonal variation with increased sensitivity in autumn compared to spring. No systematic variation of monocyte glucocorticoid receptor (GR) sensitivity was observed. Significant rank correlations of DEX sensitivity of T-cell mitogen-induced responses between the three assessments during the year suggest a stable trait of immune function. Groups did not differ in DEX sensitivity on any of the read outs. However, in a persistently fatigued subgroup, sensitivity to DEX was significantly reduced on the level of interferon (IFN)-gamma production. These results show that although fatigued participants had severe (comorbid) complaints, only in the case when symptoms persisted, altered GC sensitivity of immune cells was observed.
Thambirajah AA, Sleigh K, Stiver HG, Chow AW.	Department of Biochemistry and Microbiology,University of Victoria, Victoria, Canada.	Differential heat shock protein responses to strenuous standardized exercise in chronic fatigue syndrome patients and matched healthy controls.	Clin Invest Med. 2008 Dec 1;31(6):E319-27.	PURPOSE: Since physical exertion is known to exacerbate the symptoms of chronic fatigue syndrome (CFS) and metabolic changes and including oxidative stress can modulate heat shock protein (HSP) expression responses, we sought to determine whether HSP expression is altered in CFS patients before and after exercise. Heat shock proteins (HSPs) in peripheral blood mononuclear cells (PBMC) were examined from 6 chronic fatigue syndrome (CFS) patients and 7 controls before and after a standardized treadmill exercise. Basal hsp27 was significantly higher among CFS patients compared to controls, and decreased immediately post-exercise, remaining below basal levels even at 7 days. A similar pattern was observed for HSP60, which gradually decreased in CFS patients but increased in controls post-exercise. These findings suggest an abnormal adaptive response to oxidative stress in CFS, and raise the possibility that HSP profiling may provide a more objective biologic marker for this illness. METHODS: HSP27, HSP60, HSP70 and HSP90 expression from 6 CFS patients and 7 age- and sex-matched controls were examined by western blot analysis of peripheral blood mononuclear cells immediately before, after, and at 1 day and 7 days following a standardized treadmill exercise. RESULTS: Basal HSP27 was higher among CFS patients than in controls (0.54 +/- 0.13 vs. 0.19 +/- 0.06, mean +/- SEM; $P < 0.01$). In addition, these levels in CFS patients decreased immediately post-exercise

				(0.25 +/- 0.09; P < 0.05) and remained below basal levels at day 1 post-exercises (0.18 +/- 0.05; P < 0.05). P < 0.05). This declining expression of HSP27 during the post-exercise period among CFS patients was confirmed by one-way ANOVA analysis with repeated measures (P < 0.05). In contrast, HSP27 levels remained relatively constant following exercise among control subjects. Similar patterns of declining HSP levels in CFS patients were also observed for HSP60 (0.94 +/- 0.40 vs. 1.32 +/- 0.46; P < 0.05), and for HSP90 (0.34 +/- 0.09 vs. 0.49 +/- 0.10; P < 0.05) at day 7 post-exercise compared with basal levels, respectively. In contrast, HSP60 levels in control subjects increased at day 1 (1.09 +/- 0.27) and day 7 (1.24 +/- 0.50) post-exercise compared to corresponding levels immediately post-exercise (0.55 +/- 0.06) (P < 0.05, respectively). CONCLUSION: These preliminary findings suggest an abnormal or defective adaptive response to oxidative stress in CFS, and raise the possibility that HSP profiling may provide a more objective biologic marker for this illness.
Thompson EA, Mathie RT, Baitson ES, Barron SJ, Berkovitz SR, Brands M, Fisher P, Kirby TM, Leckridge RW, Mercer SW, Nielsen HJ, Ratsey DH, Reilly D, Roniger H, Whitmarsh TE.	Bristol Homeopathic Hospital, Bristol, UK. elizabeth.thompson@ubht.nhs.uk	Towards standard setting for patient-reported outcomes in the NHS homeopathic hospitals.	Homeopathy. 2008 Jul;97(3):114-21.	INTRODUCTION: We report findings from a pilot data collection study within a programme of quality assurance, improvement and development across all five homeopathic hospitals in the UK National Health Service (NHS). AIMS: (1) To pilot the collection of clinical data in the homeopathic hospital outpatient setting, recording patient-reported outcome since first appointment; (2) to sample the range of medical complaints that secondary-care doctors treat using homeopathy, and thus identify the nature and complexity of complaints most frequently treated nationally; (3) to present a cross section of outcome scores by appointment number, including that for the most frequently treated medical complaints; (4) to explore approaches to standard setting for homeopathic practice outcome in patients treated at the homeopathic hospitals. METHODS: A total of 51 medical practitioners took part in data collection over a 4-week period. Consecutive patient appointments were recorded under the headings: (1) date of first appointment in the current series; (2) appointment number; (3) age of patient; (4) sex of patient; (5) main medical complaint being treated; (6) whether other main medical complaint(s); (7) patient-reported change in health, using Outcome Related to Impact on Daily Living (ORIDL) and its derivative, the ORIDL Profile Score (ORIDL-PS; range, -4 to +4, where a score <or=-2 or >or=+2 indicates an effect on the quality of a patient's daily life); (8) receipt of other complementary medicine for their main medical complaint. RESULTS: The distribution of patient age was bimodal: main peak, 49 years; secondary peak, 6 years. Male:female ratio was 1:3.5. Data were recorded on a total of 1797 individual patients: 195 first appointments, 1602 follow-ups (FUs). Size of clinical service and proportion of patients who attended more than six visits varied between hospitals. A total of 235 different medical complaints were reported. The 30 most commonly treated complaints were (in decreasing order of frequency): eczema; chronic fatigue syndrome (CFS); menopausal disorder; osteoarthritis; depression; breast cancer; rheumatoid arthritis; asthma; anxiety; irritable bowel syndrome; multiple sclerosis; psoriasis; allergy (unspecified); fibromyalgia; migraine; premenstrual syndrome; chronic rhinitis; headache; vitiligo; seasonal allergic rhinitis; chronic intractable pain; insomnia; ulcerative colitis; acne; psoriatic arthropathy; urticaria; ovarian cancer; attention-deficit hyperactivity disorder (ADHD); epilepsy; sinusitis. The proportion of patients with important co-morbidity was higher in those seen after visit 6 (56.9%) compared with those seen up to and including that point (40.7%; P<0.001). The proportion of FU patients reporting ORIDL-PS>or=+2 (improvement affecting daily living) increased overall with appointment number: 34.5% of patients at visit 2 and

				59.3% of patients at visit 6, for example. Amongst the four most frequently treated complaints, the proportion of patients that reported ORIDL-PS>or=+2 at visit numbers greater than 6 varied between 59.3% (CFS) and 73.3% (menopausal disorder). CONCLUSIONS: We have successfully piloted a process of national clinical data collection using patient-reported outcome in homeopathic hospital outpatients, identifying a wide range and complexity of medical complaints treated in that setting. After a series of homeopathy appointments, a high proportion of patients, often representing "effectiveness gaps" for conventional medical treatment, reported improvement in health affecting their daily living. These pilot findings are informing our developing programme of standard setting for homeopathic care in the hospital outpatient context.
Togo F, Natelson BH, Cherniack NS, FitzGibbons J, Garcon C, Rapoport DM.	Pain and Fatigue Study Center, Department of Neurosciences, University of Medicine and Dentistry of New Jersey-New Jersey Medical School, 30 Bergen Street, Newark, NJ 07103, USA. tougou@p.u-tokyo.ac.jp	Sleep structure and sleepiness in chronic fatigue syndrome with or without coexisting fibromyalgia.	Arthritis Res Ther. 2008;10(3):R56. Epub 2008 May 13.	INTRODUCTION: We evaluated polysomnograms of chronic fatigue syndrome (CFS) patients with and without fibromyalgia to determine whether patients in either group had elevated rates of sleep-disturbed breathing (obstructive sleep apnea or upper airway resistance syndrome) or periodic leg movement disorder. We also determined whether feelings of unrefreshing sleep were associated with differences in sleep architecture from normal. METHODS: We compared sleep structures and subjective scores on visual analog scales for sleepiness and fatigue in CFS patients with or without coexisting fibromyalgia (n = 12 and 14, respectively) with 26 healthy subjects. None had current major depressive disorder, and all were studied at the same menstrual phase. RESULTS: CFS patients had significant differences in polysomnograpic findings from healthy controls and felt sleepier and more fatigued than controls after a night's sleep. CFS patients as a group had less total sleep time, lower sleep efficiency, and less rapid eye movement sleep than controls. A possible explanation for the unrefreshing quality of sleep in CFS patients was revealed by stratification of patients into those who reported more or less sleepiness after a night's sleep (a.m. sleepier or a.m. less sleepy, respectively). Those in the sleepier group reported that sleep did not improve their symptoms and had poorer sleep efficiencies and shorter runs of sleep than both controls and patients in the less sleepy group; patients in the less sleepy group reported reduced fatigue and pain after sleep and had relatively normal sleep structures. This difference in sleep effects was due primarily to a decrease in the length of periods of uninterrupted sleep in the a.m. sleepier group. CONCLUSION: CFS patients had significant differences in polysomnographic findings from healthy controls and felt sleepier and more fatigued than controls after a night's sleep. This difference was due neither to diagnosable sleep disorders nor to coexisting fibromyalgia but primarily to a decrease in the length of periods of uninterrupted sleep in the patients with more sleepiness in the morning than on the night before. This sleep disruption may explain the overwhelming fatigue, report of unrefreshing sleep, and pain in this subgroup of patients.
Travers MK, Lawler J.	Faculty of Nursing & Midwifery, University of Sydney, Australia. mtravers@nursing.usyd.edu.au	Self within a climate of contention: Experiences of chronic fatigue syndrome.	Soc Sci Med. 2008 Jan;66(2):315-26. Epub 2007 Oct 24.	Chronic fatigue syndrome (CFS) is a contested condition associated with scepticism and dispute. This qualitative project examines the illness experiences, and specifically the experiences of self, for people affected with CFS living in Australia. Using grounded theory methods, theory related to the process of self-renewal and adaptation associated with CFS is explicated. Narratives were derived from semi-structured interviews with 19 adults, including 3 people recovered from CFS. Analysis generated the narrative of the struggling self seeking renewal that defined the illness experience of CFS. The struggling self articulated the negative effects to self and personhood associated with CFS, defined as the violation of self, and the consequent efforts of participants to manage symptoms and decrease

				their violation by use of what was termed the Guardian Response and the Reconstructing Response. The Guardian Response provided protection and self-reclamation. The Reconstructing Response fostered self-renewal and meaning. The struggling self occurred within a climate of threats, and it was these threats which provided the catalyst for violation and the responses. Under different conditions the relative strengths of violation, guardianship or reconstruction fluctuated, and it was these fluctuations that presented the participants with the ongoing struggle of CFS.
Turk Charles S, Gatz M, Kato K, Pedersen NL.	Department of Psychology, University of California, Irvine, CA 92697-7085, USA. scharles@uci.edu	Physical health 25 years later: the predictive ability of neuroticism.	Health Psychol. 2008 May;27(3):369-78.	OBJECTIVE: Neuroticism, a personality trait related to distress and emotional stability, is often correlated with physical symptoms and disease presence. Theorists have posited that chronic emotional instability creates physiological changes detrimental to health, yet most findings are based on cross-sectional analyses. The objective of the current study was to examine neuroticism assessed in 1973 and the likelihood of reporting physical conditions 25 years later. DESIGN: Participants included 21676 adult twins (n = 8143 intact twin pairs) ranging from 15 to 47 years old in 1973 who were assessed again between 1998 and 2002. MAIN OUTCOME MEASURES: Thirteen physical conditions, including chronic fatigue syndrome, ulcers, and coronary heart disease, were selected based on their prior theoretical and empirical links to personality traits. RESULTS: Results indicate that the likelihood of having a physical condition is related to higher levels of prior neuroticism, with some associations attenuated when controlling for familial similarity. CONCLUSION: Familial influences are most pronounced for conditions most related to systemic pain, suggesting genetic pathways between neuroticism and these pain experiences.
Uçeyler N, Offenbächer M, Petzke F, Häuser W, Sommer C.	Department of Neurology, University of Würzburg Germany.	New treatment options for fibromyalgia: critical appraisal of duloxetine.	Neuropsychiatr Dis Treat. 2008 Jun;4(3):525-9.	Fibromyalgia syndrome (FMS) is a chronic condition characterized by widespread pain, tender points, fatigue, and sleep disturbance. FMS leads to high disability levels, poor quality of life, and extensive use of medical care. Effective pharmacological treatment options are rare, and treatment effects are often of limited duration. Duloxetine is a new selective serotonin and norepinephrine reuptake inhibitor that is licensed for the treatment of pain in diabetic neuropathy. So far two randomized, placebo-controlled trials have investigated the short-term safety and efficacy of duloxetine 60 mg/day and 120 mg/day in patients suffering from FMS over a period of 12 weeks. Both dosages were superior to placebo in pain relief, and improvement in quality of life and depressive symptoms. The analgesic effect was largely independent of the antidepressant action of duloxetine. The higher dose of 120 mg/day further reduced the tender point count and elevated the tender point pain thresholds. Only mild to moderate adverse effects were reported. Duloxetine 60 mg/day and 120 mg/day has proven to be beneficial in the treatment of FMS symptoms. As true for other antidepressants further studies are needed to assess the long-term efficacy and safety of duloxetine as an additional pharmacological treatment option in FMS.
Ulvestad E.	Department of Microbiology and Immunology, Haukeland University Hospital, and The Gade Institute,	Chronic fatigue syndrome defies the mind-body-schism of medicine : New perspectives on a multiple realisable	Med Health Care Philos. 2008 Feb 21. [Epub ahead of print]	The article maintains that chronic fatigue syndrome can be properly understood only by taking an integrated perspective in which evolutionary, developmental and ecological aspects are considered. The integrative approach, supplemented by a complexity theory and psychoneuroimmunological research, is capable of explaining why there are so few structural aberrations to be found in chronic fatigue syndrome and why specific treatment is so difficult to establish. A major outcome of the investigation, that all individuals with chronic fatigue syndrome are diseased in their own way, emphasises the need to study the development of personalised life histories. It also highlights an

	University of Bergen, Armauer Hansen Building, Bergen, 5021, Norway, elling.ulvestad@helse-bergen.no.	developmental systems disorder.		ethical dimension; personalised disease defies essentialist thinking on patient management. Another major outcome, which follows from the developmental systems perspective, is the dissolution of ontological mind-body dualism. This in turn allows for a methodological complementation of the biological and phenomenological approaches to knowledge. New research strategies that may help to resolve chronic fatigue syndrome, grounded in the revised perspective on individual development, are suggested.
Valdizán Usón JR, Idiazábal Alecha MA..	Servicio de Neurofisiología Clínica, Hospital Universitario Miguel Servet, Paseo Isabel la Católica 1-3, E-50009 Zaragoza, Spain. jrvaldizan@auna.com	Diagnostic and treatment challenges of chronic fatigue syndrome: role of immediate-release methylphenidate.	Expert Rev Neurother. 2008 Jun;8(6):917-27.	Chronic fatigue syndrome (CFS) is a distinct entity belonging to the group of persistent fatigue that can be challenging to diagnose and to treat. It is characterized by a combination of prolonged fatigue, other nonspecific somatic manifestations and neuropsychological symptoms, including difficulties with concentration, short-term memory and thinking, as well as impaired attention and slowed processing speed. Neurostimulants increasing dopamine and norepinephrine activity, such as bupropion, dextroamphetamine and recently immediate-release methylphenidate have been advocated to improve neurocognitive deficits. The use of immediate-release methylphenidate in CFS has been shown in one small study. Using the positive results of this study and the well-known beneficial effects of the drug on a range of similar cognitive symptoms in attention-deficit/hyperactivity disorder, this perspective addresses CFS and other related disorders and provides a discussion on the potential promising role of methylphenidate in the therapeutic armamentarium of CFS.
van Alfen N, van der Werf SP, van Engelen BG.	Department of Neurology, Neuromuscular Centre Nijmegen, Donders Center for Neuroscience, Radboud University Nijmegen Medical Centre, Nijmegen, The Netherlands. n.vanalfen@neuro.umcn.nl	Long-term pain, fatigue, and impairment in neuralgic amyotrophy.	Arch Phys Med Rehabil. 2009 Mar;90(3):435-9.	OBJECTIVES: Recently, it has become clear that neuralgic amyotrophy (NA; idiopathic and hereditary brachial plexus neuropathy) has a less optimistic prognosis than usually assumed. To optimize treatment and management of these patients, one needs to know the residual symptoms and impairments they suffer. Therefore, the objective of this study was to describe the prevalence of pain, psychologic symptoms, fatigue, functional status, and quality of life in patients with NA. SETTING: Neurology outpatient department of an academic teaching hospital. PARTICIPANTS: NA patients (N=89) were studied, and clinical details were recorded. Self-report data were on average collected 2 years after the onset of the last NA episode. MAIN OUTCOME MEASURES: Pain was assessed with the McGill Pain Questionnaire, fatigue with the Checklist Individual Strength, and psychologic distress with the Symptom Checklist 90. Functional status and handicap were assessed with the modified Rankin Scale and Medical Outcomes Study 36-Item Short-Form Health Survey. RESULTS: Pain was usually localized in the right shoulder and upper arm, matching the clinical predilection site for paresis in NA. About a quarter to a third of the patients reported significant long-term pain and fatigue, and half to two thirds still experienced impairments in daily life. Over one third of the individual patients suffered from severe fatigue. The group did not fulfill the criteria of chronic fatigue or major psychologic distress. There was no correlation of pain or fatigue with the level of residual paresis on a Medical Research Council scale, but patients with a comorbid condition fared worse than patients without. CONCLUSIONS: A significant number of NA patients suffer from persistent pain and fatigue, leading to impairment. Symptoms were not correlated with psychologic distress. This makes it likely that they are caused by residual shoulder or arm dysfunction but not as part of a chronic pain or fatigue syndrome in these patients.

Van Houdenhove B, Luyten P.	Dienst Liaisonpsychiatrie, UZ Gasthuisberg, Herestraat 49, B-3000 Leuven, Belgium. boudewijn.vanhoudenhove@uz.kuleuven.ac.be	Customizing treatment of chronic fatigue syndrome and fibromyalgia: the role of perpetuating factors.	Psychosomatics. 2008 Nov-Dec;49(6):470-7.	BACKGROUND: Syndromes characterized by chronic, medically unexplained fatigue, effort- and stress-intolerance, and widespread pain are highly prevalent in medicine. RESULTS: In chronic fatigue syndrome (CFS) and fibromyalgia (FM), various perpetuating factors may impair patients' quality of life and functioning and impede recovery. Although cognitive-behavioral and graded-exercise therapy are evidence-based treatments, the effectiveness and acceptability of therapeutic interventions in CFS/FM may largely depend on a customized approach taking the heterogeneity of perpetuating factors into account. CONCLUSION: Further research should clarify the aim and outcome of different treatment strategies in CFS/FM, as well as the underlying mechanisms of change, including those facilitating neurobiological recovery.
van Ittersum MW, van Wilgen CP, Hilberdink WK, Groothoff JW, van der Schans CP.	Hanze University Groningen, University of Applied Sciences, Center for Research and Development in Health Care and in Nursing, Groningen, The Netherlands. m.w.van.ittersum@pl.hanze.nl	Illness perceptions in patients with fibromyalgia.	Patient Educ Couns. 2009 Jan;74(1):53-60. Epub 2008 Sep 23.	OBJECTIVE: Former studies in chronic diseases showed the importance of patients' beliefs and perceptions. The Revised Illness Perception Questionnaire was developed to assess these illness perceptions. Our goal was to investigate psychometric properties of the IPQ-R for Fibromyalgia Dutch language version (IPQ-R FM-Dlv) and to describe illness perceptions of participants with FM. METHODS: 196 patients completed the IPQ-R FM-Dlv. Internal consistency, domain structure and inter domain correlations were calculated and compared to the IPQ-R English language version. Scores were compared with chronic fatigue syndrome (CFS), rheumatoid arthritis (RA), and coronary heart disease (CHD). RESULTS: Most psychometric properties were comparable to those of the original IPQ-R. Participants showed a lack of understanding of their illness, expected their FM to be chronic and to have a lot of negative consequences on functioning. In 17 out of 24 domains significant differences were found between FM and CFS, RA, and CHD patients. CONCLUSION: The IPQ-R FM-Dlv showed acceptable psychometric properties, although some aspects need closer examination. Illness perceptions of FM patients on the Dutch questionnaire were non-comparable to CFS, RA, and CHD patients on the English questionnaire. PRACTICE IMPLICATIONS: The IPQ-R FM-Dlv can be used to assess illness perceptions of Dutch FM patients.
Van Oudenhove L, Vandenberghe J, Geeraerts B, Vos R, Persoons P, Fischler B,	Department of Pathophysiology, Gastroenterology Section, University of Leuven &	Determinants of symptoms in functional dyspepsia: gastric sensorimotor	Gut. 2008 Dec;57(12):1666-73. Epub 2008 Jul 14. Comment in: Gut. 2008	BACKGROUND: Gastric sensorimotor dysfunction, psychosocial factors and somatisation are all implicated in symptom generation in functional dyspepsia (FD). AIM: To determine the relative contribution of each of these factors to overall dyspeptic symptom severity and weight loss in FD. METHODS: In 201 consecutive tertiary care patients with FD (mean age 40.1 (SD 12.6) years), gastric sensorimotor function was studied using barostat (sensitivity, compliance and accommodation).

Demyttenaere K, Tack J.	University Hospital Gasthuisberg, Leuven, Belgium.	function, psychosocial factors or somatisation?	Dec;57(12):1642-3.	Psychosocial factors (depression and anxiety disorders, positive and negative affect, perceived stress, alexithymia and history of abuse), somatisation and co-morbid irritable bowel syndrome (IBS) and chronic fatigue symptoms were assessed using self-report questionnaires. Variables were correlated with dyspepsia symptom severity (DSS) and weight loss. Hierarchical multiple linear regression was used to identify determinants of DSS and weight loss. RESULTS: Multiple linear regression identified the following determinants of DSS: gastric sensitivity (beta = 0.77, p = 0.25), depression (beta = 0.12, p = 0.06) and somatisation (beta = 0.48, p<0.0001) (controlling for age and occupation, R(2) = 0.29, p<0.0001). The effect of depression on DSS is partially mediated by somatisation. Gastric sensitivity (beta = 2.87, p = 0.08), history of childhood sexual abuse (beta = 9.37, p = 0.0006), depression (beta = 0.19, p = 0.24) and somatisation (beta = 0.67, p = 0.01) are independent determinants of weight loss (controlling for gender and occupation, R(2) = 0.42, p<0.0001). The effect of depression on weight loss is fully mediated by somatisation. CONCLUSION: Symptom severity and weight loss in FD are determined by psychosocial factors (depression, abuse history) and somatisation, and only to a lesser extent by gastric sensorimotor function. The importance of psychosocial factors and somatisation compared to gastric sensorimotor function is most pronounced in hypersensitive patients.
van Wilgen CP, Dijkstra PU, Versteegen GJ, Fleuren MJ, Stewart R, van Wijhe M.	Pain Centre, Department of Anesthesiology, University Medical Centre Groningen, University of Groningen, Groningen, The Netherlands. c.p.van.wilgen@sport.umcg.nl	Chronic pain and severe disuse syndrome: long-term outcome of an inpatient multidisciplinary cognitive behavioural programme.	J Rehabil Med. 2009 Feb;41(3):122-8.	OBJECTIVE: Patients with chronic pain and severe disuse syndrome have pain with physiological, psychological and social adaptations. The duration and severity of complaints, combined with previously failed treatments, makes them unsuitable for treatment in primary care. DESIGN: A prospective waiting list controlled study. PATIENTS: A total of 32 patients with chronic pain for at least one year and severe disuse syndrome were included in an inpatient multidisciplinary cognitive behavioural treatment. METHODS: Patients were assessed before the waiting list period, before the clinical phase, after the clinical phase and after follow-ups of 6 months and one year. The visual analogue scale for pain and fatigue were assessed. Muscle strength of the arms and legs, arm endurance and a 6-minute walking test were used to assess physical outcome. The Symptom Checklist-90, RAND-36, pain cognition list and the Tampa scale for kinesiophobia were used to assess psychological outcome. RESULTS: Long-term significant (p < 0.001) improvements were found for pain, fatigue, walking distance, muscle strength, anxiety, depression, somatization, negative self-efficacy, and catastrophizing in the intervention period. CONCLUSION: An inpatient multidisciplinary cognitive behavioural programme is beneficial for patients with chronic pain and a severe disuse syndrome.
Vasiliauskas D, Kavoliūniene A, Jasiukeviciene L, Grizas V, Statkeviciene A, Leimoniene L, Tumyniene V, Kubilius R.	Institute of Cardiology, Kaunas University of Medicine, Sukileliu 17, 50161 Kaunas, Lithuania. donatas@kmu.lt	[Impact of a long-term complex rehabilitation on chronic fatigue and cardiorespiratory parameters in patients with chronic heart failure] [Article in Lithuanian]	Medicina (Kaunas). 2008;44(12):911-21.	The aim of the study was to evaluate the impact of a long-term rehabilitation on chronic fatigue and cardiorespiratory parameters in patients with chronic heart failure. MATERIAL AND METHODS: One hundred seventy patients with class III-IV (NYHA) chronic heart failure were examined. The study population was divided into two groups: long-term rehabilitation group and control group. They underwent cardiopulmonary exercise test and completed questionnaires on chronic fatigue (MFI-20L, DUFS, and DEFS). Measurements were repeated 3 and 6 months after long-term complex rehabilitation. RESULTS: According to the data of MFI-20L, DUFS, and DEFS questionnaires, 170 patients (100%) with class III-IV (NYHA) chronic heart failure complained of fatigue. Overall daily fatigue was 56.8+/-28.5 points on a 100-point scale, and after 6-month rehabilitation, this parameter was statistically significantly reduced on all scales (P<0.05). Physical fatigue and self-care improved in controls. Cardiopulmonary exercise test showed that parameters of hyperventilation, ventilatory

				equivalents, and pCO2 were significantly improved in rehabilitation group after 6 months as compared to baseline data (P<0.05), but not in the control group. CONCLUSION: Patients with class III-IV (NYHA) chronic heart failure experience chronic fatigue, which reduces their motivation and self-care abilities. Long-term complex rehabilitation programs improve all parameters of chronic fatigue, respiratory efficiency, and prognostic indicator of chronic heart failure--ventilatory equivalent for carbon dioxide.
Veldman J, Van Houdenhove B, Verguts J.	Department of Obstetrics and Gynaecology, University Hospital Gasthuisberg, Catholic University Leuven, Herestraat 49, 3000, Louvain, Belgium.	Chronic fatigue syndrome: a hormonal origin? A rare case of dysmenorrhea membranacea.	Arch Gynecol Obstet. 2008 Sep 12. [Epub ahead of print]	BACKGROUND: Membranous dysmenorrhea is a rare entity involving expulsion of fragments of endometrium retaining the shape of the uterus. The condition is often linked to high progesterone levels. An association with a chronic fatigue syndrome was never described. CASE: A 44-year-old woman with a chronic fatigue syndrome (CFS), presented with membranous dysmenorrhea after taking an oral contraceptive pill containing ethinylestradiol 0.02 mg and desogestrel 0.15 mg for 3 months in a continuous regimen as treatment for dysfunctional bleeding. Oral contraception was discontinued and she resumed normal menstruations. Remarkably, she mentioned complete disappearance of the CFS since expulsion of the tissue and started working again. CONCLUSION: The occurrence of membranous dysmenorrhea with a dissolving chronic fatigue syndrome is very rare and was never described before. This case suggests a hormonal dysfunction as a possible cause of chronic fatigue syndrome. A review of the literature on membranous dysmenorrhea is presented.
Viaene M, Vermeir G, Godderis L.	Department of Occupational, Environmental and Insurance Medicine, Catholic University of Leuven, UZ St. Rafaël, Kapucijnenvoer 35-5th floor, 3000 Leuven, Belgium; Expertise Centre of Neurotoxicology and Neuropsychology, Governmental Psychiatric Hospital, Dr. Sanodreef 4, 2440 Geel, Belgium.	Sleep disturbances and occupational exposure to solvents.	Sleep Med Rev. 2009 Feb 5. [Epub ahead of print]	A solvent can be defined as "a liquid that has the ability to dissolve, suspend or extract other materials, without chemical change to the material or solvent". Numerous chemical or technical processes rely on these specific properties of organic solvents in industry. Occupational exposure to solvents is not rare and some activities may cause substantial exposure to these substances in the workforce. Short-term or acute exposures cause a prenarcotic syndrome, and long lasting exposure conditions have been associated with various neurological and neuropsychiatric disorders, e.g., anosmia, hearing loss, colour vision dysfunctions, peripheral polyneuropathy and depression, but most significantly with the gradual development of an irreversible toxic encephalopathy. For the last 3 decades reports and epidemiological studies have been published reporting sleep disturbances among other complaints, related to long-term exposure to these compounds. In addition, the question has been posed if solvents can be the cause of a sleep apnoea syndrome in exposed workers, or on the contrary, if these workers are misdiagnosed and 'common' sleep apnoea syndromes are the cause of their chronic symptoms of fatigue and memory and attentional disturbances.
Viner RM, Clark C, Taylor SJ, Bhui K, Klineberg E, Head J, Booy R,	General and Adolescent Paediatrics Unit, Institute of Child	Longitudinal risk factors for persistent fatigue in adolescents.	Arch Pediatr Adolesc Med. 2008 May;162(5):469-75.	OBJECTIVE: To examine whether sedentary behavior, obesity, smoking, and depression are risk factors for persistent fatigue in adolescents. DESIGN: Longitudinal population-based survey. SETTING: Twenty-eight randomly selected schools in east London, England, in 2001 and 2003. PARTICIPANTS: A total of 1880 adolescents (49% male; 81% nonwhite British) aged 11 to 12 years and 13 to 14 years in 2000.

Stansfeld SA.	Health, University College London, England. r.viner@ich.ucl.ac.uk			INTERVENTION: Confidential questionnaires completed in class. MAIN OUTCOME MEASURES: Persistent fatigue (extreme tiredness twice weekly or more often in the previous month at both surveys), sedentary behavior, physical activity, depressive symptoms, body mass index, and smoking. RESULTS: Severe fatigue was reported in 11% of participants aged 11 to 14 years and 17% of participants aged 13 to 16 years. Eighty-four participants (4%) reported persistent fatigue. Across both surveys, only 3 pupils reported chronic fatigue syndrome. In multivariate logistic regression, risk of persistent fatigue was independently associated with being sedentary for more than 4 hours per day (odds ratio = 1.6; 95% confidence interval, 1.1-2.3; P = .01), being physically active (odds ratio = 1.5; 95% confidence interval, 1.1-2.3; P = .004), and depressive symptoms (odds ratio = 2.0; 95% confidence interval, 1.5-2.7; P < .001) in the first survey, after adjustment for age, sex, and socioeconomic status. Obesity and smoking were not associated with fatigue. CONCLUSIONS: Persistent fatigue is common. Being highly sedentary or highly active independently increased the risk of persistent fatigue, suggesting that divergence in either direction from healthy levels of activity increases the risk for persistent fatigue. Mental health is important in the etiology of persistent fatigue. To help define effective preventive strategies, further work is needed on the mechanisms by which these factors contribute to fatigue.
Walach H, Bosch H, Lewith G, Naumann J, Schwarzer B, Falk S, Kohls N, Haraldsson E, Wiesendanger H, Nordmann A, Tomasson H, Prescott P, Bucher HC.	Samueli Institute, European Office, School of Social Sciences, University of Northampton, Northampton, UK. harald.walach@northampton.ac.uk	Effectiveness of distant healing for patients with chronic fatigue syndrome: a randomised controlled partially blinded trial (EUHEALS).	Psychother Psychosom. 2008;77(3):158-66. Epub 2008 Feb 14.	BACKGROUND: Distant healing, a form of spiritual healing, is widely used for many conditions but little is known about its effectiveness. METHODS: In order to evaluate distant healing in patients with a stable chronic condition, we randomised 409 patients with chronic fatigue syndrome (CFS) from 14 private practices for environmental medicine in Germany and Austria in a two by two factorial design to immediate versus deferred (waiting for 6 months) distant healing. Half the patients were blinded and half knew their treatment allocation. Patients were treated for 6 months and allocated to groups of 3 healers from a pool of 462 healers in 21 European countries with different healing traditions. Change in Mental Health Component Summary (MHCS) score (SF-36) was the primary outcome and Physical Health Component Summary score (PHCS) the secondary outcome. RESULTS: This trial population had very low quality of life and symptom scores at entry. There were no differences over 6 months in post-treatment MHCS scores between the treated and untreated groups. There was a non-significant outcome (p = 0.11) for healing with PHCS (1.11; 95% CI -0.255 to 2.473 at 6 months) and a significant effect (p = 0.027) for blinding; patients who were unblinded became worse during the trial (-1.544; 95% CI -2.913 to -0.176). We found no relevant interaction for blinding among treated patients in MHCS and PHCS. Expectation of treatment and duration of CFS added significantly to the model. CONCLUSIONS: In patients with CFS, distant healing appears to have no statistically significant effect on mental and physical health but the expectation of improvement did improve outcome. Wang T, Zhang Q, Xue X, Yeung A.	Department of TCM Diagnostics, Preclinical College, Beijing University of Chinese Medicine, Beijing,	A systematic review of acupuncture and moxibustion treatment for chronic fatigue	Am J Chin Med. 2008;36(1):1-24.	Studies on the treatment of chronic fatigue syndrome (CFS) with acupuncture and moxibustion in China were reviewed. All studies concluded the treatments were effective, with response rates ranging from 78.95% to 100%. However, the qualities of the studies were generally poor, and none of them used a RCT design. The common acupoints/sites used in the treatment of CFS, which may reflect the collective experience of acupuncturists in China based on Traditional Chinese Medicine theories can be used to evaluate the effectiveness of acupuncture for the treatment of CFS in future studies

	China 100029, China. tianfangwang@hotmail.com	syndrome in China.		using more scientifically rigorous study designs.
Wang TF, Xue XL.	Department of TCM Diagnostics, Beijing University of Chinese Medicine, Beijing. tianfangwang2000@yahoo.com.cn	[Sub-health state and chronic fatigue syndrome] [Article in Chinese]	Zhongguo Zhong Xi Yi Jie He Za Zhi. 2008 Jan;28(1):77-9.	This paper points out that the sub-health state is not equal to chronic fatigue syndrome (CFS) on basis of elaborating the concept and category of sub-health. And the present understanding on concepts of fatigue, chronic fatigue and CFS, as well as the diagnosis criteria and differential diagnosis of CFS are discussed systematically.
Warren JW, Howard FM, Cross RK, Good JL, Weissman MM, Wesselmann U, Langenberg P, Greenberg P, Clauw DJ.	Department of Medicine, Epidemiology and Preventive Medicine, and Neurology, University of Maryland School of Medicine, Baltimore, Maryland, USA.	Antecedent nonbladder syndromes in case-control study of interstitial cystitis/painful bladder syndrome.	Urology. 2009 Jan;73(1):52-7. Epub 2008 Nov 8.	OBJECTIVES: Probing for clues to the pathogenesis of interstitial cystitis/painful bladder syndrome (IC/PBS), we sought antecedent nonbladder syndromes that distinguished incident IC/PBS cases from matched controls. METHODS: Female incident IC/PBS cases were recruited nationally, and their IC/PBS onset date (index date) was established. The controls were recruited by national random digit dialing and matched to the cases by sex, age, region, and interval between the (assigned) index date and interview. The prevalence of 24 nonbladder syndromes before the index date was assessed, 7 by multiple methods. RESULTS: The cases with IC/PBS had greater antecedent prevalence of 11 syndromes, and 243 of 313 cases (78%) vs 145 of 313 controls (45%) had multiple syndromes (P < .001). Fibromyalgia-chronic widespread pain (FM-CWP), chronic fatigue syndrome, sicca syndrome, and irritable bowel syndrome were associated with each other by pairwise and factor analyses using numerous assumptions. Cases with FM-CWP, chronic fatigue syndrome, sicca syndrome, and/or irritable bowel syndrome (n = 141, 45%) were more likely to have other syndromes (ie, migraine, chronic pelvic pain, depression, and allergy). Three other syndrome clusters were identified; each was associated with this FM-CWP cluster. CONCLUSIONS: Eleven antecedent syndromes were more often diagnosed in those with IC/PBS, and most syndromes appeared in clusters. The most prominent cluster comprised FM-CWP, chronic fatigue syndrome, sicca syndrome, and irritable bowel syndrome; most of the other syndromes and identified clusters were associated with it. Among the hypotheses generated was that some patients with IC/PBS have a systemic syndrome and not one confined to the bladder.
Watanabe N, Stewart R, Jenkins R, Bhugra DK, Furukawa TA.	Department of Psychiatry and Cognitive-Behavioral Medicine, Nagoya City University Graduate School of Medical Sciences, Nagoya, Japan. noriow@med.nago	The epidemiology of chronic fatigue, physical illness, and symptoms of common mental disorders: a cross-sectional survey from the second British National Survey of	J Psychosom Res. 2008 Apr;64(4):357-62.	OBJECTIVE: The study aimed to describe the prevalence of chronic fatigue in the general population and to investigate the extent to which its association with physical illness was independent of other symptoms of common mental disorders. METHODS: Data from the second British National Survey of Psychiatric Morbidity (2000) were analyzed. The survey covered people aged 16 to 74 years living in private households. Chronic fatigue (significant reported fatigue lasting 6 months or more) was ascertained using the revised Clinical Interview Schedule. Information on reported physical illness and sociodemographic factors was considered. Psychiatric symptoms were also assessed using the revised Clinical Interview Schedule. RESULTS: The prevalence of chronic fatigue was 15.0%, and this showed a significant association with the number of reported physical illnesses (odds ratio [OR] per reported illness, 1.79; 95% confidence interval, 1.68-1.90). It was higher in midlife, in women, in participants

	ya-cu.ac.jp	Psychiatric Morbidity.		with less skilled occupations, and in those with lower educational attainment. Chronic fatigue was strongly associated with the presence of depressive symptoms (OR, 5.37), anxiety-related symptoms (OR, 4.66), and with sleep complaints (OR, 4.41). After adjustment for all sociodemographic and psychiatric factors, the number of reported physical illnesses was less strongly but still significantly associated with chronic fatigue (OR, 1.51; 1.39-1.63). CONCLUSION: Physical illness is strongly associated with chronic fatigue. Symptoms of common mental disorders are also associated with chronic fatigue, but the association between physical illness and chronic fatigue is evident even after adjusting for psychiatric symptoms. The assessment of physically ill people should include chronic fatigue and psychiatric symptoms.
Whitehouse CR, Boullata J, McCauley LA.	Adult Health/Gerontology Nurse Practitioner Program, School of Nursing, University of Pennsylvania, Philadelphia, PA, USA.	The potential toxicity of artificial sweeteners.	AAOHN J. 2008 Jun;56(6):251-9; quiz 260-1.	Since their discovery, the safety of artificial sweeteners has been controversial. Artificial sweeteners provide the sweetness of sugar without the calories. As public health attention has turned to reversing the obesity epidemic in the United States, more individuals of all ages are choosing to use these products. These choices may be beneficial for those who cannot tolerate sugar in their diets (e.g., diabetics). However, scientists disagree about the relationships between sweeteners and lymphomas, leukemias, cancers of the bladder and brain, chronic fatigue syndrome, Parkinson's disease, Alzheimer's disease, multiple sclerosis, autism, and systemic lupus. Recently these substances have received increased attention due to their effects on glucose regulation. Occupational health nurses need accurate and timely information to counsel individuals regarding the use of these substances. This article provides an overview of types of artificial sweeteners, sweetener history, chemical structure, biological fate, physiological effects, published animal and human studies, and current standards and regulations.
Winceslaus SJ, Pinching AJ, Harris A, Ankrett V, Mark.	Department of GU Medicine, Culverden Suite, Kent & Sussex Hospital, Mount Ephraim, Tunbridge Wells, Kent TN4 8AT, UK. joseph.winceslaus@mtw-tr.nhs.uk	HIV diagnosis: why and how do we miss important clues?	Sex Transm Infect. 2008 Apr;84(2):101-2.	Research has found that a significant proportion of patients diagnosed late with HIV infection had been in contact with healthcare professionals in the preceding year with symptoms attributable to HIV. We report a unique case of late HIV diagnosis missed when seen by a number of specialists and discuss whether with better communication the diagnosis could have been alerted earlier.
Wyller VB, Barbieri R, Thaulow E, Saul JP.	Department of Pediatrics, Rikshospitalet-Radiumhospitalet Medical Center, Oslo, Norway. brwylle@online.no	Enhanced vagal withdrawal during mild orthostatic stress in adolescents with chronic fatigue.	Ann Noninvasive Electrocardiol. 2008 Jan;13(1):67-73.	BACKGROUND: Hemodynamic abnormalities have been documented in the chronic fatigue syndrome (CFS), indicating functional disturbances of the autonomic nervous system responsible for cardiovascular regulation. The aim of this study was to investigate autonomic heart rate control during mild orthostatic stress in adolescents with CFS. METHODS: A total of 14 CFS patients and 56 healthy controls having equal distribution of age and gender underwent lower body negative pressure (LBNP) of horizontal line 20 mmHg. The RR interval (RRI) was recorded continuously, and spectral power densities were computed in the low-frequency (LF) band (0.04-0.15 Hz) and the high-frequency (HF) band (0.15-0.50 Hz) from segments of 120-second length, using an autoregressive algorithm. In addition, the time-domain indices SDNN, pNN50, and r-MSSD were computed. RESULTS: At rest, CFS

				had lower RRI than controls (P < 0.05), but indices of variability were similar in the two groups. During LBNP, compared to controls, CFS patients had lower normalized and absolute HF power and r-MSSD (P < 0.05), and higher RRI (P < 0.001), normalized LF power and LF/HF (P < 0.05). CONCLUSIONS: During mild orthostatic stress, adolescents with CFS appear to have enhanced vagal withdrawal, leading to a sympathetic predominance of heart rate control compared to controls. Possible underlying mechanisms include hypovolemia and abnormalities of reflex mechanisms.
Wyller VB, Eriksen HR, Malterud K.		Can sustained arousal explain the Chronic Fatigue Syndrome?	Behav Brain Funct. 2009 Feb 23;5(1):10. [Epub ahead of print]	ABSTRACT: We present an integrative model of disease mechanisms in the Chronic Fatigue Syndrome (CFS), unifying empirical findings from different research traditions. Based upon the Cognitive activation theory of stress (CATS), we argue that new data on cardiovascular and thermoregulatory regulation indicate a state of permanent arousal responses - sustained arousal - in this condition. We suggest that sustained arousal can originate from different precipitating factors (infections, psychosocial challenges) interacting with predisposing factors (genetic traits, personality) and learned expectancies (classical and operant conditioning). Furthermore, sustained arousal may explain documented alterations by establishing vicious circles within immunology (Th2 (humoral) vs Th1 (cellular) predominance), endocrinology (attenuated HPA axis), skeletal muscle function (attenuated cortical activation, increased oxidative stress) and cognition (impaired memory and information processing). Finally, we propose a causal link between sustained arousal and the experience of fatigue. The model of sustained arousal embraces all main findings concerning CFS disease mechanisms within one theoretical framework.
Wyller VB, Saul JP, WallÃ¸e L, Thaulow E.	Department of Pediatrics, Rikshospitalet-Radiumhospitalet Medical Center, 0027 Oslo, Norway. brwylle@online.no	Sympathetic cardiovascular control during orthostatic stress and isometric exercise in adolescent chronic fatigue syndrome.	Eur J Appl Physiol. 2008 Apr;102(6):623-32. Epub 2007 Dec 8.	The chronic fatigue syndrome (CFS) has been shown to be associated with orthostatic intolerance and cardiovascular dysregulation. We investigated the cardiovascular responses to combined orthostatic stress and isometric exercise in adolescents with CFS. We included a consecutive sample of 15 adolescents 12-18 years old with CFS diagnosed according to a thorough and standardized set of investigations, and a volunteer sample of 56 healthy control subjects of equal sex and age distribution. Heart rate, systolic, mean and diastolic blood pressure, stroke index, and total peripheral resistance index were non-invasively recorded during lower body negative pressure (LBNP) combined with two consecutive periods of handgrip. In addition, we measured baseline plasma catecholamines, and recorded symptoms. At rest, CFS patients had higher heart rate, diastolic blood pressure, plasma norepinephrine (P < 0.01), mean blood pressure and plasma epinephrine (P < 0.05) than controls. During LBNP, CFS patients had a greater increase in heart rate, diastolic blood pressure, mean blood pressure (P < 0.05) and total peripheral resistance index (n.s.) than controls. During handgrip, CFS patients had a smaller increase in heart rate, diastolic blood pressure (P < 0.05), mean blood pressure and total peripheral resistance index (n.s.) than controls. Our results indicate that adolescents with CFS have increased sympathetic activity at rest with exaggerated cardiovascular response to orthostatic stress, but attenuated cardiovascular response when performing isometric exercise during orthostatic stress. This suggests that CFS might be causally related to sympathetic dysfunction.
Zoppi M, Maresca M.	Dipartimento di Medicina Interna, Sezione di Reumatologia,	Symptoms accompanying fibromyalgia.	Reumatismo. 2008 Jul-Sep;60(3):217-20.	OBJECTIVE: The objective of the study was to investigate the relationship between spontaneous and provoked pain in fibromyalgia and to evaluate the frequency of disturbances associated with muscle pain, including some disturbances which are not usually considered as typical symptoms associated with pain in fibromyalgia. METHODS: In sixty-seven patients with fibromyalgia the severity of

	Università degli Studi di Firenze, Firenze. m.zoppi@dmi.unifi.it			spontaneous pain was assessed by a visual analogue scale and the severity of provoked pain by an original method, which includes the evaluation of the number of tender points and the evaluation of the intensity of provoked pain. The method used to assess the severity of provoked pain is more sensitive than other methods currently used. The occurrence of accompanying symptoms was also evaluated. The investigation included the occurrence of paresthesias of the upper limbs, hemorrhoids and epistaxis, which are not usually considered as typical symptoms associated with fibromyalgia. RESULTS: No significant correlation was observed between the severity of spontaneous and provoked pain. The following disturbances were more frequent in the examined patients than in general population: headache, chronic fatigue, sleep disorders, irritable bowel syndrome, restless legs syndrome, paresthesias in the upper limbs, hemorrhoids and epistaxis. CONCLUSIONS: Spontaneous and provoked pain should be considered two independent clinical features of fibromyalgia. Paresthesias in the upper limbs, hemorrhoids and epistaxis should be considered as typical symptoms associated with fibromyalgia. Hemorrhoids and epistaxis are frequently due to a diathesis characterized by laxity of connective tissues and fibromyalgia could be a consequence of such a diathesis.
Zwarts MJ, Bleijenberg G, van Engelen BG.	University Medical Centre Nijmegen, Institute of Neurology, 920 Department of Clinical Neurophysiology, PO Box 9101, 6500 HB Nijmegen, The Netherlands. M.Zwarts@neuro.umcn.nl	Clinical neurophysiology of fatigue.	Clin Neurophysiol. 2008 Jan;119(1):2-10. Epub 2007 Nov 26.	Fatigue is a multidimensional concept covering both physiological and psychological aspects. Chronic fatigue is a typical symptom of diseases such as cancer, multiple sclerosis (MS), Parkinson's disease (PD) and cerebrovascular disorders but is also presented by people in whom no defined somatic disease has been established. If certain criteria are met, chronic fatigue syndrome can be diagnosed. The 4-item Abbreviated Fatigue Questionnaire allows the extent of the experienced fatigue to be assessed with a high degree of reliability and validity. Physiological fatigue has been well defined and originates in both the peripheral and central nervous system. The condition can be assessed by combining force and surface-EMG measurements (including frequency analyses and muscle-fibre conduction estimations), twitch interpolation, magnetic stimulation of the motor cortex and analysis of changes in the readiness potential. Fatigue is a well-known phenomenon in both central and peripheral neurological disorders. Examples of the former conditions are multiple sclerosis, Parkinson's disease and stroke. Although it seems to be a universal symptom of many brain disorders, the unique characteristics of the concomitant fatigue also point to a specific relationship with several of these syndromes. As regards neuromuscular disorders, fatigue has been reported in patients with post-polio syndrome, myasthenia gravis, Guillain-BarrÃ© syndrome, facioscapulohumeral dystrophy, myotonic dystrophy and hereditary motor and sensory neuropathy type-I. More than 60% of all neuromuscular patients suffer from severe fatigue, a prevalence resembling that of patients with MS. Except for several rare myopathies with specific metabolic derangements leading to exercise-induced muscle fatigue, most studies have not identified a prominent peripheral cause for the fatigue in this population. In contrast, the central activation of the diseased neuromuscular system is generally found to be suboptimal. The reliability of the psychological and clinical neurophysiological assessment techniques available today allows a multidisciplinary approach to fatigue in neurological patients, which may contribute to the elucidation of the pathophysiological mechanisms of chronic fatigue, with the ultimate goal to develop tailored treatments for fatigue in neurological patients. The present report discusses the different manifestations of fatigue and the available tools to assess peripheral

				and central fatigue.

Agarwal AK, Garg R, Ritch A, Sarkar P.	City Hospital, Birmingham, UK. anilabliuk@yahoo.co.uk	Postural orthostatic tachycardia syndrome.	Postgrad Med J. 2007 Jul;83(981):478-80.	Postural orthostatic tachycardia syndrome (POTS) is an autonomic disturbance which has become better understood in recent years. It is now thought to encompass a group of disorders that have similar clinical features, such as orthostatic intolerance, but individual distinguishing parameters--for example, blood pressure and pulse rate. The clinical picture, diagnosis, and management of POTS are discussed.
Ahboucha S, Pomier-Layrargues G, Vincent C, Hassoun Z, Tamaz R, Baker G, Butterworth RF.	Neuroscience Research Unit, CHUM—Hôpital Saint-Luc, 1058 St.-Denis, Montreal, Quebec 2X 3J4, Canada.	Reduced plasma dehydroepiandrosterone sulfate levels are significantly correlated with fatigue severity in patients with primary biliary cirrhosis.	Neurochem Int. 2007 Jun 19 [Epub ahead of print]	Fatigue is a common debilitating complication of primary biliary cirrhosis (PBC), the pathophysiologic mechanism of which is poorly understood. Recently, the neuroactive steroid dehydroepinadrosterone sulfate (DHEAS) was reported to be implicated in Chronic Fatigue Syndrome in the absence of liver disease. The present study was undertaken to analyse fatigue scores and their relationship with disease severity and circulating levels of DHEAS as well as its precursors DHEA and pregnenolone in PBC patients with (n=15) or without fatigue (n=10) compared to control subjects (n=11). Fatigue was assessed using the fatigue impact scale (FIS) including cognitive, physical and psychosocial subclasses. Steroids were measured by radioimmunoassay or gas chromatography/mass spectrometry. Plasma concentrations of DHEAS were significantly reduced in PBC patients with fatigue as compared to controls, while those of its precursors DHEA and pregnenolone remained within the control range. Plasma levels of DHEAS in PBC patients were significantly correlated with fatigue severity as reflected by total FIS scores including total (rp=-0.42; p=0.018), as well as the cognitive (rp=-0.37; p=0.03), physical (rp=-0.48; p=0.006) and psychosocial (rp=-0.35; p=0.04) subclasses of fatigue scores. No correlation of fatigue scores was observed with indices of liver function. These findings suggest that reduced levels of the neurosteroid DHEAS may contribute to fatigue in patients with PBC; substitutive therapy using DHEAS or its precursor DHEA could be beneficial in the management of fatigue in patients with low levels of DHEAS.
Ahmed M. Abdel-Khalek		Chronic Fatigue Syndrome and Its Association with Obsession Compulsion Among a Non-Clinical Sample Using Questionnaires	Journal of Chronic Fatigue Syndrome 2007; 14(3):	The present study investigated the possible association between the Chronic Fatigue Syndrome (CFS) and obsession compulsion (OC). A non-clinical sample of 427 volunteer Kuwaiti male and female college students was recruited. Their ages ranged from 17 to 40 years. They completed the Arabic Scale of CFS (ASCFS) and the Arabic Scale of Obsession Compulsion (ASOC). Both have good reliability and validity. Females had significantly higher mean score on the ASCFS than did their male counterparts. All the intercorrelations between the 20 items as well as the total score of the ASCFS were statistically significant ($p < 0.01$) with the total ASOC score in males and females. It was concluded that there is an obsessive compulsive element in CFS, and both disorders share specific common elements.
Amato MP, De Stefano N.		Longitudinal follow-up of "benign" multiple sclerosis at 20 years.	Neurology. 2007 Aug 28;69(9):938; author reply 938-9. Comment on: Neurology. 2007 Feb 13;68(7):496-500.	

Aminzadeh KK, Etminan M.	Center for Clinical Epidemiology and Evaluation, Vancouver Hospital, Vancouver, Canada.	Dental amalgam and multiple sclerosis: a systematic review and meta-analysis.	J Public Health Dent. 2007 Winter;67(1):64-6.	OBJECTIVES: Amalgam restorations have long been controversial due to their mercury content. Allegations that the mercury may be linked to nervous disorders such as Alzheimer's, chronic fatigue syndrome, and multiple sclerosis (MS) have fueled the calls for the removal of amalgam restorations from dentists' armamentarium. To explore and quantify the association between amalgam restorations and MS we have conducted a systematic review and meta-analysis of the literature. METHODS: A systematic search in Medline (from 1966 to April 2006), EMBASE (2006, Week 16), and the Cochrane library (Issue 2, 2006) for English-language articles meeting specific definitions of MS and amalgam exposure was conducted. Studies were also identified using the references of retrieved articles. Studies were independently reviewed by two authors and disagreements were resolved by consensus. Studies were selected based on an a priori of defined criteria. Odds ratios (ORs) or relative risks were pooled using the random effects model. Heterogeneity was assessed using Q statistics. RESULTS: The pooled OR for the risk of MS among amalgam users was consistent, with a slight, nonstatistically significant increase between amalgam use and risk of MS. CONCLUSION: Future studies that take into consideration the amalgam restoration size and surface area along with the duration of exposure are needed in order to definitively rule out any link between amalgam and MS.
Amsterdam JD, Shults J, Rutherford N.	Depression Research Unit, Department of Psychiatry, University of Pennsylvania School of Medicine, Philadelphia, PA, United States.	Open-label study of s-citalopram therapy of chronic fatigue syndrome and co-morbid major depressive disorder.	Prog Neuropsychopharmacol Biol Psychiatry. 2008 Jan 1;32(1):100-6. Epub 2007 Aug 3.	OBJECTIVE: Chronic fatigue syndrome (CFS) is a debilitating disorder with prominent symptoms of malaise, fatigue, myalgia, arthralgia, and impaired concentration. The symptoms of CFS may often overlap those of Major Depressive Disorder (MDD). Treatment of CFS has generally been disappointing. We hypothesized that s-citalopram therapy may improve the symptoms of both disorders in CFS patients with co-morbid depression. METHODS: 16 patients received s-citalopram 10 mg to 20 mg daily for up to 12 weeks. Outcome measures of CFS included the Chalder Fatigue Questionnaire (CFQ), the multi-dimensional Fatigue Impact Scale (FIS), the CFS symptom rating (CFS-SR) 100 mm visual analogue scale, and the clinical global impressions severity (CGI/S) and change (CGI/C) ratings. Secondary outcomes of MDD included the Hamilton Depression Rating (HAM-D), Beck Depression Inventory (BDI), and the CGI/S and CGI/C ratings of MDD. RESULTS: We observed reductions in the mean CFQ score ($p<0.0005$), FIS score ($p<0.0005$), and CGI/S ($p<0.0005$) and CGI/C ($p<0.0005$) ratings over time. There was a significant improvement in 5 of the 8 CFS-SR symptoms: post-exertion malaise ($p=0.001$), headaches ($p<0.0005$), un-refreshing sleep ($p<0.0005$), and impaired memory and concentration ($p<0.0005$). There was also a reduction in mean HAM-D ($p<0.0005$), BDI ($p<0.0005$), CGI/S ($p=0.001$) and CGI/C ($p<0.0005$) ratings of MDD. LIMITATIONS: The sample size was limited and the study design was not double-blind or placebo controlled. CONCLUSION: We observed a significant reduction in both CFS and co-morbid MDD symptom severity ratings, and improvement in 5 of 8 core somatic symptoms of CFS during s-citalopram therapy.
Andersen Mette Marie, Henrik Permin, Frank Albrecht		Nine-Year Follow-Up of Danish Chronic Fatigue Syndrome (CFS) Patients Impact on Health, Social, Vocational, and	Journal of Chronic Fatigue Syndrome 2007; 14(2): 7-23	Objective: To determine quality of life (QOL) and health in Danish CFS patients 9 years after diagnosis. Methods: Thirty-four adults with CFS responded to questions regarding QOL at diagnosis, and again 5 and 9 years later. At 9-year followup patients also responded to questions regarding health, fatigue, use of Health Care system, alcohol and exercise. Results: Two patients (6%) had recovered and 3 patients (10%) had received secondary diagnoses. Overall, there was no improvement, except with depression/anxiety. The order of severity among disabilities remained the same. Work had the highest disability score, followed by post-exertional malaise. Patients slept and

		Personal Lives		rested 13.6 hours a day (mean). Self-reported physical health correlated with hours sleeping and resting. Rheumatic symptoms dominated the health symptoms. Alcohol consumption was low, and the use of the Health Care system was modest. Conclusion: After 9 years QOL was the same as at diagnosis, only mental health had improved.
Appel S, Chapman J, Shoenfeld Y.	Department of Neurology, Sheba Medical Center, Tel Hashomer, Israel.	Infection and vaccination in chronic fatigue syndrome: myth or reality?	Autoimmunity. 2007 Feb;40(1):48-53.	Chronic fatigue syndrome (CFS) is characterized by severe disabling fatigue lasting for more than 6 months associated with physical and mental disturbances such as headache, arthralgia, myalgia, memory impairment, sore throat and tender lymph nodes. The exact pathogenesis is still unknown. Several models were proposed to explain its etiology including chronic infection, endocrine dysfunction, autonomic imbalance, depression, decreased immunity states and an aberrant reaction to infection. No convincing evidence was found to support any of the suggested pathogenic mechanisms. The current concept is that CFS pathogenesis is a multi factorial condition in which an infective agent cause an aberrant immune response characterized by a shift to Th-2 dominant response. When the response fails to be switched-off, a chronic immune activation occurs and clinically expressed as the symptomatology of CFS. Vaccinations are used in order to stimulate the immune system to induce a persistent immunity against the favorable antigens. Several syndromes that contain chronic fatigue as one of their symptoms, such as "Gulf war syndrome" and macrophagic myofasciitis were related to vaccinations. Can vaccinations induce the aberrant immune response of CFS? Little is known about this issue. There are some reports on CFS occurring after vaccination, but few prospective and retrospective studies failed to find such an association. A working group of the Canadian Laboratory Center for Disease Control (LCDC) that was founded in order to examine the suspected association between CFS and vaccinations concluded that there is no evidence that relates CFS to vaccination. Further studies are requested to examine this issue since it is very conceivable that if infection can lead to CFS, vaccination may also lead to it in the same immune-mediated pathogenesis.
Armitage R, Landis C, Hoffmann R, Lentz M, Watson NF, Goldberg J, Buchwald D.	Department of Psychiatry, University of Michigan, Ann Arbor, MI 48105, USA. rosearmi@med.umich.edu	The impact of a 4-hour sleep delay on slow wave activity in twins discordant for chronic fatigue syndrome.	Sleep. 2007 May 1;30(5):657-62.	OBJECTIVES: Chronic fatigue syndrome (CFS) has been associated with altered amounts of slow wave sleep, which could reflect reduced delta electroencephalograph (EEG) activity and impaired sleep regulation. To evaluate this hypothesis, we examined the response to a sleep regulatory challenge in CFS. DESIGN: The first of 3 consecutive nights of study served as laboratory adaptation. Baseline sleep was assessed on the second night. On the third night, bedtime was delayed by 4 hours, followed by recovery sleep. Total available sleep time was held constant on all nights. SETTING: A research sleep laboratory. PARTICIPANTS: 13 pairs of monozygotic twins discordant for CFS. INTERVENTIONS: N/A. MEASUREMENTS AND RESULTS: Power spectral analysis quantified slow wave activity (SWA) in the 0.5-3.9 Hz band in successive NREM periods (stage 2, 3, or 4) on each night. To ensure comparability, analyses were restricted to the first 4 NREM periods on each night. Data were coded for NREM period and twin pair. Repeated-measures analysis of variance (ANOVA) contrasted sleep delay effects across NREM periods between twin pairs. A second ANOVA calculated the SWA in each NREM period in recovery sleep relative to baseline SWA. The 2 groups of twins were similar on baseline SWA power. After sleep delay, CFS twins exhibited significantly less SWA power in the first NREM period of recovery sleep and accumulated a smaller percentage of SWA in the first NREM period than their co-

				twins. CONCLUSIONS: CFS is associated with a blunted SWA response to sleep challenge, suggesting that the basic sleep drive and homeostatic response are impaired.
Arnold LD, Bachmann GA, Rosen R, Rhoads GG.	Department of Epidemiology, School of Public Health, University of Medicine and Dentistry of New Jersey, Piscataway, NJ, USA.	Assessment of vulvodynia symptoms in a sample of US women: a prevalence survey with a nested case control study.	Am J Obstet Gynecol. 2007 Feb;196(2):128.e1-6.	OBJECTIVE: Vulvodynia is a chronic pain syndrome of unknown origin with scant data on frequency. This study assessed the prevalence of vulvodynia symptoms in a sample of US women and compared health characteristics of symptomatic and asymptomatic women. STUDY DESIGN: A phone survey contacted 2127 US households to identify 100 symptomatic women, who were matched on age and time zone to 325 asymptomatic controls. Odds ratios (ORs) and logistic regression were used to model associations between pain, medical conditions, and health care utilization variables. RESULTS: Current vulvar pain of at least 6 months duration was reported by 3.8% of respondents, with a 9.9% lifetime prevalence. Forty-five percent of women with pain reported an adverse effect on their sexual life and 27% an adverse effect on their lifestyle. Cases more frequently reported repeated urinary tract infections (OR, 6.15; 95% CI, 3.51-10.77) and yeast infections (OR, 4.24; 95% CI, 2.47-7.28). Associations existed with chronic fatigue syndrome (OR, 2.78; 95% CI, 1.33-6.19), fibromyalgia (OR, 2.15; 95% CI, 1.06-4.36), depression (OR, 2.99; 95% CI, 1.87-4.80), and irritable bowel syndrome (OR, 1.86; 95% CI, 1.07-3.23). CONCLUSION: Lifetime chronic vulvar pain was less prevalent in this national sample of women than previous data suggest and was correlated with several comorbid chronic medical conditions and substantial reduction in self-reported quality of life.

Balon R.	Department of Psychiatry and Behavioral Neurosciences Wayne State University School of Medicine, Detroit, Mich., USA. rbalon@wayne.ed	Reflections on relevance: the fields of psychosomatics and psychotherapy in 2006.	Psychother Psychosom. 2007;76(4):203-12.	This article reviews several areas of new and interesting development in the fields of psychosomatics and psychotherapy published in the literature during 2006. These areas are: (1) cardiovascular illness and its interplay with depression; (2) risks and predisposing factors in the areas of mental illness and physical illness; (3) new developments in chronic fatigue syndrome, and (4) new or newly explored/modified (psycho)therapies, especially cognitive-behavioral therapy. In addition, an important area of conflict of interest in psychiatry in particular and in biomedical science in general is discussed, as this issue has reached prominence in the biomedical literature. Ban N, Saiki T, Ko G, Kuwahata A	. Department of General Medicine, Nagoya University School of Medicine	[Clinical features of chronic fatigue syndrome--symptoms] [Article in Japanese]	Nippon Rinsho. 2007 Jun;65(6):1011-5.	. Chronic fatigue syndrome (CFS) is a clinically defined condition characterized by long-lasting disabling fatigue, resulting in severe impairment in daily functioning and associated symptoms such as memory and concentration difficulties, muscle aches, sleep disturbances, and headache. Common symptoms encountered in CFS patients were reviewed and top 10 common symptoms were described in detail with special reference to the particular features of each symptom helpful to diagnose CFS
Bennett B, Goldstein D, Friedlander M, Hickie I, Lloyd A.	Department of Medical Oncology, Prince of Wales Hospital, Sydney, Australia. Barbara.Bennett@sesiahs.health.nsw.gov.au	The experience of cancer-related fatigue and chronic fatigue syndrome: a qualitative and comparative study.	J Pain Symptom Manage. 2007 Aug;34(2):126-35. Epub 2007 Jun 4.	Cancer-related fatigue (CRF) is a common and disabling symptom complex reported by survivors. This study aimed to better understand the manifestations of CRF in women treated for breast cancer, and to compare them with those of women diagnosed with chronic fatigue syndrome (CFS). Women with CRF persisting 6 months after treatment for early stage breast cancer, and women with CFS participated in separate, audiotaped focus groups. Transcripts of the sessions were analyzed using the NUD*IST software, and interpreted using grounded theory. Twenty-eight women participated, 16 with CRF and 12 with CFS. Analysis of transcripts from both groups revealed a similar core set of symptoms, featuring fatigue, neurocognitive difficulties, and mood disturbances. Women with CFS reported additional symptoms including musculoskeletal pain and influenza-like manifestations. Both groups suffered disabling behavioral consequences of the symptom complex. Qualitatively, CRF appears closely related to CFS. These findings raise the emergent hypothesis of a conserved neurobehavioral symptom complex, which results from diverse triggering insults.
Beqaj SH, Lerner AM, Fitzgerald JT.	Pathgroup Labs, Nashville, TN, United States.	Immunoassay with cytomegalovirus early antigens from gene products p52 and CM2 (UL44 and UL57) detect active infection in patients with chronic fatigue syndrome.	J Clin Pathol. 2007 Dec 5 [Epub ahead of print]	AIMS: The purpose of this study is to demonstrate that the use of recombinant early antigens for detection of antibodies to cytomegalovirus (HCMV) gene products CM2 (UL44, UL57) and p52 (UL44) is specific in the diagnosis and differentiation of active HCMV infection in a subset of patients with chronic fatigue syndrome (CFS) which is often missed by the current ELISA assay that uses crude viral lysate antigen. METHODS: At a single clinic from 1999 - 2001 a total of 4,774 serologic tests were performed in 1135 CFS patients using two immunoassays; Copalis immunoassay and ELISA immunoassay. The Copalis immunoassay utilized HCMV Early gene products of UL44 and UL57 recombinant antigens for detection of HCMV IgM antibody, and viral capsid antigen for detection of HCMV IgG antibody. The ELISA immunoassay utilized viral crude lysate as antigen for detection of both HCMV IgG and IgM. RESULTS: Of the total, 1135 CFS patients, 517 patients (45.6%) were positive for HCMV IgG by both HCMV IgG by both assays. Of these, twelve CFS patients (2.2%) were positive for HCMV(V) IgM serum antibody by HCMV ELISA assay, and 61 CFS patients (11.8%) were positive for IgM HCMV serum antibody by Copalis assays. The Copalis assay that uses HCMV early recombinant gene products CM2 (UL44, UL57) and p52 (UL44) in comparison with ELISA was 98% specific. CONCLUSIONS: Immunoassays that use Early Antigen recombinant HCMV CM2 and p52 are five times more sensitive than HCMV ELISA assay using viral lysate and are specific in the detection and differentiation of active HCMV infection in a subset of CFS patients.
Bisbal C, Silverman RH.	IGH UPR CNRS 1142, 141 rue de la Cardonille, 34396 Montpellier, France.	Diverse functions of RNase L and implications in pathology.	Biochimie. 2007 Jun-Jul;89(6-7):789-98. Epub 2007 Feb 20.	The endoribonuclease L (RNase L) is the effector of the 2-5A system, a major enzymatic pathway involved in the molecular mechanism of interferons (IFNs). RNase L is a very unusual nuclease with a complex mechanism of regulation. It is a latent enzyme, expressed in nearly every mammalian cell type. Its activation requires its binding to a small oligonucleotide, 2-5A. 2-5A is a series of unique 5'-triphosphorylated oligoadenylates with 2'-5' phosphodiester bonds. By regulating viral and cellular

	catherine.bisbal@igh.cnrs.fr			RNA expression, RNase L plays an important role in the antiviral and antiproliferative activities of IFN and contributes to innate immunity and cell metabolism. The 2-5A/RNase L pathway is implicated in mediating apoptosis in response to viral infections and to several types of external stimuli. Several recent studies have suggested that RNase L could have a role in cancer biology and evidence of a tumor suppressor function of RNase L has emerged from studies on the genetics of hereditary prostate cancer.
Bogaerts K, Hubin M, Van Diest I, De Peuter S, Van Houdenhove B, Van Wambeke P, Crombez G, Van den Bergh O.	Research Group on Health Psychology, Department of Psychology, University of Leuven, Tiensestraat 102, 3000 Leuven, Belgium.	Hyperventilation in patients with chronic fatigue syndrome: the role of coping strategies.	Behav Res Ther. 2007 Nov;45(11):2679-90. Epub 2007 Jul 20.	Hyperventilation has been suggested as a concomitant and possible maintaining factor that may contribute to the symptom pattern of chronic fatigue syndrome (CFS). Because patients accepting the illness and trying to live with it seem to have a better prognosis than patients chronically fighting it, we investigated breathing behavior during different coping response sets towards the illness in patients with CFS (N=30, CDC criteria). Patients imagined a relaxation script (baseline), a script describing a coping response of hostile resistance, and a script depicting acceptance of the illness and its (future) consequences. During each imagery trial, end-tidal PCO2 (Handheld Capnograph, Oridion) was measured. After each trial, patients filled out a symptom checklist. Results showed low resting values of PetCO2 overall, while only imagery of hostile resistance triggered a decrease and deficient recovery of PetCO2. Also, more hyperventilation complaints and complaints of other origin were reported during hostile resistance imagery compared with acceptance and relaxation. In conclusion, hostile resistance seems to trigger both physiological and symptom perception processes contributing to the clinical picture of CFS.
Boiko AN, Batysheva TT, Matvievskaya OV, Manevich TM, Gusev EI.	Department of Neurology and Neurosurgery, Russian State Medical University.	Characteristics of the formation of chronic fatigue syndrome and approaches to its treatment in young patients with focal brain damage.	Neurosci Behav Physiol. 2007 Mar;37(3):221-8.	Chronic fatigue is among the manifestations of focal brain lesions. It is most often encountered in multiple sclerosis (MS) and patients with the sequelae of traumatic, inflammatory, and vascular brain damage (encephalopathies). The aim of the present work was to study the mechanisms of formation of this syndrome in 50 patients with focal brain lesions of different origins (in the inactive stage) and to assess the possibility of correcting it using the combined agent Fezam (2 capsules t.i.d. for one month), which contains piracetam and cinarrizine. In patients with encephalopathies, chronic fatigue syndrome was directly associated with the severity of depression. Patients with MS showed changes in the value-sense sphere. Neuropsychological testing showed that the psychological and personality components played a greater role in the origins of chronic fatigue in patients with encephalopathies than in those with MS. Fezam significantly decreased the severity of chronic fatigue, particularly in patients with MS; in the second group (non-MS patients) this was accompanied by a decrease in the severity of depression. Mild side effects (in six patients--12%) consisted generally of sleep disturbances. These results indicate that Fezam should be used in the treatment of chronic fatigue in patients with focal brain lesions; in encephalopathies it should be combined with psychoactive agents.
Boimel P, Check JH, Katsoff D.	Albert Enstein College of Medicine of Yeshiva University, Bronx, NY, USA.	Sympathomimetic amine therapy may improve refractory gastroparesis similar to its effect on chronic pelvic pain--case report.	Clin Exp Obstet Gynecol. 2007;34(3):185-7.	PURPOSE: To determine if treatment with sympathomimetic amines can effectively treat gastroparesis that was refractory to other medical therapy. METHODS: After failing a water load test, a 29-year-old female was treated with 20 mg/day of dextroamphetamine sulfate. RESULTS: After several weeks of therapy she noted that most of her symptoms of gastroparesis subsided and she has remained symptom free for eight months. CONCLUSIONS: Similar to its beneficial effect on chronic pelvic pain of both bladder and non bladder origin, refractory weight gain, esophageal pain, chronic fatigue syndrome, headaches and vasomotor symptoms, sympathomimetic amine therapy can also effectively

				treat gastroparesis refractory to other medical therapies at least in some cases.
Boneva RS, Decker MJ, Maloney EM, Lin JM, Jones JF, Helgason HG, Heim CM, Rye DB, Reeves WC.	Chronic Viral Diseases Branch, National Center for Zoonotic, Vector-borne and Enteric Diseases, Centers for Disease Control and Prevention, Atlanta, GA 30329, USA. rboneva@cdc.gov	Higher heart rate and reduced heart rate variability persist during sleep in chronic fatigue syndrome: a population-based study.	Auton Neurosci. 2007 Dec 30;137(1-2):94-101. Epub 2007 Sep 12.	Autonomic nervous system (ANS) dysfunction has been suggested in patients with chronic fatigue syndrome (CFS). In this study, we sought to determine whether increased heart rate (HR) and reduced heart rate variability (HRV) parameters observed in CFS patients during wakefulness persist during sleep. To this end, we compared heart rate (HR) and HRV as indicators of ANS function in CFS subjects and non-fatigued (NF) controls in a population-based, case-control study. Thirty subjects with CFS and 38 NF controls, matched for age-, sex- and body mass index, were eligible for analysis. Main outcome measures included mean RR interval (RRI), HR, and HRV parameters derived from overnight ECG. Plasma aldosterone and norepinephrine levels, medicines with cardiovascular effect, and reported physical activity were examined as covariates. General Linear Models were used to assess significance of associations and adjust for potential confounders. Compared to controls, CFS cases had significantly higher mean HR (71.4 vs 64.8 bpm), with a shorter mean RRI [840.4 (85.3) vs 925.4(97.8) ms] ($p<0.0004$, each), and reduced low frequency (LF), very low frequency (VLF), and total power (TP) of HRV ($p<0.02$, all). CFS cases had significantly lower plasma aldosterone ($p<0.05$), and tended to have higher plasma norepinephrine levels. HR correlated weakly with plasma norepinephrine ($r=0.23$, $p=0.05$) and moderately with vitality and fatigue scores ($r=-0.49$ and 0.46, respectively, $p<0.0001$). Limitation in moderate physical activity was strongly associated with increased HR and decreased HRV. Nevertheless, among 42 subjects with similar physical activity limitations, CFS cases still had higher HR (71.8 bpm) than respective controls (64.9 bpm), $p=0.023$, suggesting that reduced physical activity could not fully explain CFS-associated differences in HR and HRV. After adjusting for potential confounders case-control differences in HR and TP remained significant ($p<0.05$). Conclusion: the presence of increased HR and reduced HRV in CFS during sleep coupled with higher norepinephrine levels and lower plasma aldosterone suggest a state of sympathetic ANS predominance and neuroendocrine alterations. Future research on the underlying pathophysiologic mechanisms of the association is needed.
Britton S.		[Burnout in Greene-land] [Article in Swedish]	Lakartidningen. 2007 Aug 29-Sep 4;104(35):2446-7.	
Brown MM, Jason LA.	Department of Psychology, DePaul University, Center for Community Research, Chicago, IL, USA. mbrown59@depaul.edu.	Functioning in individuals with chronic fatigue syndrome: increased impairment with co-occurring multiple chemical sensitivity and fibromyalgia.	Dyn Med. 2007 Jul 30;6:9.	
Brown MM, Jason LA.	Department of Psychology, DePaul	Functioning in individuals with	Dyn Med. 2007 May 31;6:6.	BACKGROUND: Chronic fatigue syndrome (CFS), multiple chemical sensitivity (MCS), and fibromyalgia (FM) commonly co-occur. Some propose that CFS, MCS, and FM are manifestations of the same illness

	University, Center for Community Research, Chicago, IL, USA. mbrown59@depaul.edu	chronic fatigue syndrome: increased impairment with co-occurring multiple chemical sensitivity and fibromyalgia.		based on high rates of co-occurrence and overlapping diagnostic criteria. This study seeks to differentiate these diagnoses by comparing individuals with one or more illness on functioning, psychiatric comorbidity, coping style, and in vivo physical measures. METHODS: Participants included 114 men and women who met criteria for CFS. FM was diagnosed during a physical examination, and MCS was assessed using a questionnaire. Participants were divided into four groups: CFS alone, CFS-MCS, CFS-FM, and CFS-MCS-FM. Self-report measures, a psychiatric interview, and in vivo physical measures were given. RESULTS: 43.9% met criteria for CFS alone, 23.7% met criteria for CFS-MCS, 15.8% met criteria for CFS-FM, and 16.7% met criteria for CFS-MCS-FM. The CFS-MCS-FM group was more disabled than the CFS alone group on measures of physical functioning, general health, and bodily pain. In vivo measures did not differ, but the CFS-MCS-FM group rated exertion higher than the CFS alone group. CONCLUSION: Individuals with CFS alone were the highest functioning group across several domains, such as disability, depression, and severity of symptoms. Participants with three diagnoses experienced the greatest amount of disability. While substantial co-occurrence of these illnesses was found, this study provides evidence that having more than one illness exacerbates one's disability beyond CFS alone.
Brown RJ.		Introduction to the special issue on medically unexplained symptoms: background and future directions.	Clin Psychol Rev. 2007 Oct;27(7):769-80. Epub 2007 Jul 17.	This special issue is devoted to the topic of medically unexplained symptoms (MUS), a heterogeneous group of conditions characterized by persistent physical symptoms that cannot be explained by medical illness or injury. Although psychological factors have long been regarded as central to these problems, patients with MUS have typically been managed within medical settings and referrals to mental health services have been relatively rare. In recent years, however, interest in the psychological nature and treatment of MUS has expanded, culminating in the development of tailored psychological interventions for these conditions. This, coupled with the increasing willingness of practitioners to diagnose conditions such as chronic fatigue syndrome, fibromyalgia and irritable bowel syndrome, has led to an increase in the number of patients who are referred for psychological treatment. At present, however, many psychological therapists are unfamiliar with the literature on MUS. With this in mind, this special issue presents a series of papers that provide an overview of what is known about the nature, aetiology and treatment of medically unexplained illness. This introductory paper provides general information about the clinical presentation, diagnosis, classification, terminology and epidemiology of MUS in adults, and concludes with an examination of important areas for future development in the field. Subsequent papers address the psychological mechanisms [Deary, V., Chalder, T., & Sharpe, M. (2007-this issue). The cognitive behavioural model of medically unexplained symptoms: A theoretical and empirical review. Clinical Psychology Review; Iverson, A., Chalder, T., & Wessely, S. (2007-this issue). Gulf war illness: Lessons from medically unexplained illness. Clinical Psychology Review; Rief, W., & Broadbent, E. (2007-this issue). Explaining medically unexplained symptoms: Models and mechanisms. Clinical Psychology Review; Roelofs, K., & Spinhoven, P. (2007-this issue). Trauma and medically unexplained symptoms: Towards an integration of cognitive and neuro-biological accounts. Clinical Psychology Review] and management [Deary, V., Chalder, T., & Sharpe, M. (2007-this issue). The cognitive behavioural model of medically unexplained symptoms: A theoretical and empirical review. Clinical Psychology Review] of these conditions. A separate overview of the literature on MUS in children and adolescents is provided by Eminson

				[Eminson, J. (2007-this issue). Medically unexplained symptoms in children and adolescents. Clinical Psychology Review].
Cameron B, Galbraith S, Zhang Y, Davenport T, Vollmer-Conna U, Wakefield D, Hickie I, Dunsmuir W, Whistler T, Vernon S, Reeves WC, Lloyd AR; Dubbo Infection Outcomes Study.	School of Medical Sciences, University of New South Wales, Sydney, Australia	Gene expression correlates of postinfective fatigue syndrome after infectious mononucleosis	J Infect Dis. 2007 Jul 1;196(1):56-66. Epub 2007 May 24. Comment in: J Infect Dis. 2007 Jul 1;196(1):4-5.	BACKGROUND: Infectious mononucleosis (IM) commonly triggers a protracted postinfective fatigue syndrome (PIFS) of unknown pathogenesis. METHODS: Seven subjects with PIFS with 6 or more months of disabling symptoms and 8 matched control subjects who had recovered promptly from documented IM were studied. The expression of 30,000 genes was examined in the peripheral blood by microarray analysis in 65 longitudinally collected samples. Gene expression patterns associated with PIFS were sought by correlation with symptom factor scores. RESULTS: Differential expression of 733 genes was identified when samples collected early during the illness and at the late (recovered) time point were compared. Of these genes, 234 were found to be significantly correlated with the reported severity of the fatigue symptom factor, and 180 were found to be correlated with the musculoskeletal pain symptom factor. Validation by analysis of the longitudinal expression pattern revealed 35 genes for which changes in expression were consistent with the illness course. These genes included several that are involved in signal transduction pathways, metal ion binding, and ion channel activity. CONCLUSIONS: Gene expression correlates of the cardinal symptoms of PIFS after IM have been identified. Further studies of these gene products may help to elucidate the pathogenesis of PIFS.
Capuron L, Pagnoni G, Demetrashvili MF, Lawson DH, Fornwalt FB, Woolwine B, Berns GS, Nemeroff CB, Miller AH	Department of Psychiatry and Behavioral Sciences, Emory University School of Medicine, Atlanta, GA 30322, USA.	Basal ganglia hypermetabolism and symptoms of fatigue during interferon-alpha therapy.	Neuropsychopharmacology. 2007 Nov;32(11):2384-92. Epub 2007 Feb 28.	Interferon (IFN)-alpha is a cytokine of the innate immune response that is well known for inducing behavioral alterations and has been used to study effects of cytokines on the nervous system. Limited data, however, are available on the sites of action of IFN-alpha within the brain and their relationship with specific IFN-alpha-induced symptoms. Using a longitudinal design, whole-brain metabolic activity as assessed by fluorine-18-labeled fluorodeoxyglucose uptake and positron emission tomography was examined before and 4 weeks after IFN-alpha administration in patients with malignant melanoma. Changes in metabolic activity in relevant brain regions were then correlated with IFN-alpha-induced behavioral changes. IFN-alpha administration was associated with widespread bilateral increases in glucose metabolism in subcortical regions including the basal ganglia and cerebellum. Decreases in dorsal prefrontal cortex glucose metabolism were also observed. Prominent IFN-alpha-induced behavioral changes included lassitude, inability to feel, and fatigue. Correlational analyses revealed that self-reported fatigue (specifically as assessed by the 'energy' subscale of the Visual Analog Scale of Fatigue) was associated with increased glucose metabolism in the left nucleus accumbens and putamen. These data indicate that IFN-alpha as well as other cytokines of the innate immune response may target basal ganglia nuclei, thereby contributing to fatigue-related symptoms in medically ill patients.
Carpenter J, Hutchings A, Raine R, Sanderson C	Department of Epidemiology and Population Health, London School of Hygiene & Tropical Medicine, Keppel Street, London, UK.	An experimental study of the influence of individual participant characteristics on formal consensus	Technol Assess Health Care. 2007 Winter;23(1):108-15.	OBJECTIVES: The aim of this study was to examine the influence of participants' characteristics on the results produced by formal consensus methods. METHODS: The approach was an experimental study of 346 participants in 20 groups rating the appropriateness of four mental health interventions for the treatment of chronic fatigue syndrome, irritable bowel syndrome, and chronic back pain. There were four factors in the design: systematic literature review provided or not, decisions made under realistic or "ideal" resource assumptions, clinically mixed (general practitioners and mental health professionals) or homogenous group (general practitioners only), convened or mail-only group. A

	james.carpenter@lshtm.ac.uk	development		group's rating was defined as the median of participants' ratings. The influence of participants' characteristics (age, sex, and specialty) was examined using multilevel models. RESULTS: The largest differences were between the GPs and mental health professionals, both in their initial ratings of the different interventions, and in how much they altered their ratings between rounds. There were smaller but statistically significant (p<.05) differences between specialty and age groups in initial ratings for the treatment (by whatever means) of different conditions, and for certain conditions women increased their ratings more than men. Women rated intervention more favorably when assuming "ideal" rather than realistic levels of resources, but men did not. CONCLUSIONS: Our findings support the practice of treating professional specialty as an important determinant of the results in consensus panels.
Carville SF, Arendt-Nielsen S, Bliddal H, Blotman F, Branco JC, Buskila D, Da Silva JA, Danneskiold-Samsøe B, Dincer F, Henriksson C, Henriksson K, Kosek E, Longley K, McCarthy GM, Perrot S, Puszczewicz MJ, Sarzi-Puttini P, Silman A, Späth M, Choy EH.	King's College London, United Kingdom.	EULAR evidence based recommendations for the management of fibromyalgia syndrome.	Ann Rheum Dis. 2007 Oct 3 [Epub ahead of print]	OBJECTIVE: To develop evidence based recommendations for the management of fibromyalgia syndrome (FMS). METHODS: A multidisciplinary task force was formed representing eleven European Countries. The design of the study including search strategy, participants, interventions, outcome measures, data collection and analytical method was defined at the outset. A systematic review was undertaken with the keywords 'fibromyalgia', 'treatment or management' and 'trial'. Studies were excluded if they did not utilise the ACR classification criteria, were not clinical trials, or included patients with chronic fatigue syndrome or myalgic encephalomyelitis. Primary outcome measures were change in pain assessed by visual analogue scale (VAS) and fibromyalgia impact questionnaire (FIQ). The quality of the studies was categorised based on randomisation, blinding and allocation concealment. Only the highest quality studies were used to base recommendations on. When there was insufficient evidence from the literature, a Delphi process was used to provide basis for recommendation. RESULTS: One hundred and forty six studies were eligible for the review. Thirty nine pharmacologic intervention studies and 59 non-pharmacologic were included in the final recommendation summary tables once those of a lower quality or with insufficient data were separated. The categories of treatment identified were antidepressants, analgesics, and 'other pharmacological' and exercise, cognitive behavioural therapy, education, dietary interventions and 'other non-pharmacological'. In many studies sample size was small and the quality of the study was insufficient for strong recommendations to be made. CONCLUSION: Nine recommendations for the management of FMS were developed using a systematic review and expert consensus.
Chapenko S, Krumina A, Kozireva S, Nora Z, Sultanova A, Viksna L, Murovska M.	August Kirchenstein Institute of Microbiology and Virology, Riga Stradins University, Ratsupites St.1, Riga, LV-1067, Latvia. modra@latnet.lv	Activation of human herpesviruses 6 and 7 in patients with chronic fatigue syndrome.	J Clin Virol. 2006 Dec;37 Suppl 1:S47-51.	BACKGROUND: Human herpesvirus 6 (HHV-6) and 7 (HHV-7) have been suggested as possible triggering agents for chronic fatigue syndrome (CFS). OBJECTIVES: To determine the possible association of HHV-6 and HHV-7 infections with CFS. STUDY DESIGN: The prevalence of latent/persistent and active viral infections by nPCR, characteristic of HHV-6 variants using restriction endonuclease analysis and changes of lymphocyte subsets in peripheral blood by laser flow-cytometry in 17 CFS patients was examined. In addition, 12 patients with unexplained chronic fatigue and 20 blood donors (BD) were studied. RESULTS: No difference in prevalence of latent/persistent single viral infections between the patients and BD was found but dual infection rate was significantly higher in CFS patients. Active HHV-6 and dual (HHV-6 + HHV-7) infections were detected in CFS patients only and frequency of HHV-7 reactivation was also significantly higher in these patients. HHV-6 variant B was predominant in CFS patients (12/13). The changes of immunological parameters in CFS patients

				with active dual infection were characterized by significant decrease of CD3+ and CD4+ T cells, significant increase of CD95+ cells and decrease of CD4+/CD8+ ratio. CONCLUSIONS: HHV-6 and HHV-7 may be involved in the pathogenesis of CFS and reactivation of both viruses may provoke changes in the phenotype of circulating lymphocytes.
Chia JK, Chia AY.	EV Med Research, Lomita, California 90717, USA. evmed@sbcglobal.net	Chronic fatigue syndrome is associated with chronic enterovirus infection of the stomach.	J Clin Pathol. 2008 Jan;61(1):43-8. Epub 2007 Sep 13. Comment in: J Clin Pathol. 2008 Jan;61(1):1-2.	BACKGROUND AND AIMS: The aetiology for chronic fatigue syndrome (CFS) remains elusive although enteroviruses have been implicated as one of the causes by a number of studies. Since most CFS patients have persistent or intermittent gastrointestinal (GI) symptoms, the presence of viral capsid protein 1 (VP1), enterovirus (EV) RNA and culturable virus in the stomach biopsy specimens of patients with CFS was evaluated. METHODS: 165 consecutive patients with CFS underwent upper GI endoscopies and antrum biopsies. Immunoperoxidase staining was performed using EV-specific monoclonal antibody (mAb) or a control mAb specific for cytomegalovirus (CMV). RT-PCR ELISA was performed on RNA extracted from paraffin sections or samples preserved in RNA later. Biopsies from normal stomach and other gastric diseases served as controls. 75 samples were cultured for EV. RESULTS: 135/165 (82%) biopsies stained positive for VP1 within parietal cells, whereas 7/34 (20%) of the controls stained positive (p< or =0.001). CMV mAb failed to stain any of the biopsy specimens. Biopsies taken from six patients at the onset of the CFS/abdominal symptoms, and 2-8 years later showed positive staining in the paired specimens. EV RNA was detected in 9/24 (37%) paraffin-embedded biopsy samples; 1/21 controls had detectable EV RNA (p<0.01); 1/3 patients had detectable EV RNA from two samples taken 4 years apart; 5 patient samples showed transient growth of non-cytopathic enteroviruses. CONCLUSION: Enterovirus VP1, RNA and non-cytopathic viruses were detected in the stomach biopsy specimens of CFS patients with chronic abdominal complaints. A significant subset of CFS patients may have a chronic, disseminated, non-cytolytic form of enteroviral infection, which could be diagnosed by stomach biopsy.
Ciccolella Margaret, Staci R. Stevens, Christopher R. Snell, Mark Van Ness		Legal and Scientific Considerations of the Exercise Stress Test	Journal of Chronic Fatigue Syndrome 2007; 14(2): 61-75	This article examines the legal and scientific bases on which an exercise stress test can provide medically acceptable evidence of disability for the Chronic Fatigue Syndrome (CFS) patient. To qualify for disability benefits, a claimant must establish the existence of a serious medically determinable impairment (MDI) that causes the inability to work. The single stress test has been used to objectively establish whether a claimant can engage in "substantial gainful employment" and is an important determinant of the award or denial of benefits. A review of case law indicates problems associated with a single test protocol that may be remedied by a "test-retest" protocol. The results of a preliminary study employing this approach indicate that the test-retest protocol addresses problems inherent in a single test and therefore provides an assessment of CFS related disability consistent with both medical and legal considerations.
Claypoole KH, Noonan C, Mahurin RK, Goldberg J, Erickson T, Buchwald D.	Department of Psychology, University of Hawaii, Honolulu, HI, USA.	A twin study of cognitive function in chronic fatigue syndrome: the effects of sudden illness onset.	Neuropsychology. 2007 Jul;21(4):507-13.	Variable reports of neuropsychological deficits in individuals with chronic fatigue syndrome (CFS) may, in part, be attributable to methodological limitations. In this study, these limitations were addressed by controlling for genetic and environmental influences and by assessing the effects of comorbid depression and mode of illness onset. Specifically, the researchers conducted a co-twin control study of 22 pairs of monozygotic twins, in which 1 twin met strict criteria for CFS and the co-twin was healthy. Twins underwent a structured psychiatric interview and comprehensive neuropsychological assessment evaluating 6 cognitive domains. Results indicated that twin groups had similar intellectual

				and visual memory functioning, but fatigued twins exhibited decreases in motor functions (p = .05), speed of information processing (p = .02), verbal memory (p = .02), and executive functioning (p = .01). Major depression did not affect neuropsychological functioning among fatigued twins, although twins with sudden illness onset demonstrated slowed information processing compared with those with gradual onset (p = .01). Sudden onset CFS was associated with reduced speed of information processing. If confirmed, these findings suggest the need to distinguish illness onset in future CFS studies and may have implications for treatment, cognitive rehabilitation, and disability determination.
Cook DB, O'Connor PJ, Lange G, Steffener J.	Department of Veterans Affairs-William S. Middleton Memorial Veterans Hospital, Madison, WI 53706, USA. dcook@education.wisc.edu	Functional neuroimaging correlates of mental fatigue induced by cognition among chronic fatigue syndrome patients and controls.	Neuroimage. 2007 May 15;36(1):108-22. Epub 2007 Mar 3.	The neural mechanisms underlying feelings of fatigue are poorly understood. The primary purpose of the study was to use functional magnetic resonance imaging (fMRI) to determine the association between feelings of mental fatigue and blood oxygen level dependent (BOLD) brain responses during a mentally fatiguing cognitive task. Healthy, non-fatigued controls and chronic fatigue syndrome (CFS) patients were included to determine the influence of chronic levels of fatigue on brain responses. We hypothesized that mental fatigue would be significantly related to brain activity during a fatiguing cognitive task but not during either a non-fatiguing motor (finger tapping) or cognitive (auditory monitoring) task. Patients (n=9) and controls (n=11) completed a finger tapping task, a simple auditory monitoring task and a challenging working memory task, designed to induce mental fatigue, while undergoing fMRI. Fatigue was measured prior to scanning and following each task during fMRI data collection. Results showed that mental fatigue was significantly related to brain activity during the fatiguing cognitive task but not the finger tapping or simple auditory monitoring tasks. Significant (p< or =0.005) positive relationships were found for cerebellar, temporal, cingulate and frontal regions. A significant (p=0.001) negative relationship was found for the left posterior parietal cortex. CFS participants did not differ from controls for either finger tapping or auditory monitoring tasks, but exhibited significantly greater activity in several cortical and subcortical regions during the fatiguing cognitive task. Our results suggest an association between subjective feelings of mental fatigue and brain responses during fatiguing cognition.

Crofford LJ.	Center for the Advancement of Women's Health, University of Kentucky, USA. lcrofford@uky.edu	Violence, stress, and somatic syndromes.	Trauma Violence Abuse. 2007 Jul;8(3):299-313.	Syndromes characterized by pain, fatigue, mood disorder, cognitive dysfunction, and sleep disturbance have been referred to as stress-related somatic disorders by virtue of the observation that onset and exacerbation of symptoms occur with stress. These syndromes include but are not limited to fibromyalgia, chronic fatigue syndrome, temporomandibular disorder, and irritable bowel syndrome. As with most chronic illnesses, genetic susceptibility and lifetime environmental exposures play a role in creating vulnerability to disease. Cumulative lifetime stress has been associated with a number of physiologic changes in the brain and body that reflect dysregulated hormonal and autonomic activity. Exposure to the stressor of violence is likely to create a state of vulnerability for the stress-related somatic syndromes and also to contribute to symptom expression and severity. Understanding the relationship between violence, stress, and somatic syndromes will help in clarifying the consequences of violence exposure to long-term health and health-related quality of life.
Davies SM, Crawley EM.	Gloucester Royal Hospital, United Kingdom.	Chronic fatigue syndrome in children aged 11 years old and younger.	Arch Dis Child. 2008 Jan 11 [Epub ahead of print]	AIM: To describe children who presented to the Bath paediatric CFS/ME service under the age of 12. Method: Inventories measuring fatigue, pain, functional disability, anxiety, family history and symptoms were collected prospectively for all children presenting to the Bath CFS/ME service between September 2004 and April 2007. Data from children who presented to the service under the age of 12 were described and compared to those who presented at age 12 or older. RESULTS: 178 children (under the age of 18) were diagnosed as having CFS/ME using the RCPCH criteria out of 216 children assessed. The mean age at assessment for children with CFS/ME was 14.5 years old (SD 2.9). 32 (16%) children were under 12 years old at the time of assessment, four children were under 5 years old and the youngest child was 2 years old. Children under 12 were very disabled with mean school attendance of just over 40% (average 2 days a week), Chalder Fatigue score of 8.29 (CI 7.14 -9.43 maximum possible score=11) and pain visual analogue score of 39.7 (possible range 0-100). Comparison with the children aged 12 or older showed that both groups were remarkably similar at assessment. 24/26 children with complete symptom lists, would have been diagnosed as having CFS/ME using the stricter adult CDC criteria. CONCLUSION: Disability in the under 12 age group was high, with low levels of school attendance, high level of fatigue, anxiety, functional disability and pain. The clinical pattern seen is almost identical to that seen in older children and the majority of children would also be diagnosed as having CFS/ME using the stricter adult definition.
Deary V, Chalder T, Sharpe M.	Institute of Health and Society, University of Newcastle, 21 Claremont Place, Newcastle Upon Tyne NE2 4AA, UK. vincent.deary@ncl.ac.uk	The cognitive behavioural model of medically unexplained symptoms: a theoretical and empirical review.	Clin Psychol Rev. 2007 Oct;27(7):781-97. Epub 2007 Jul 17.	The article is a narrative review of the theoretical standing and empirical evidence for the cognitive behavioural model of medically unexplained symptoms (MUS) in general and for chronic fatigue syndrome (CFS) and irritable bowel syndrome (IBS) in particular. A literature search of Medline and Psychinfo from 1966 to the present day was conducted using MUS and related terms as search terms. All relevant articles were reviewed. The search was then limited in stages, by cognitive behavioural therapy (CBT), condition, treatment and type of trial. Evidence was found for genetic, neurological, psychophysiological, immunological, personality, attentional, attributional, affective, behavioural, social and inter-personal factors in the onset and maintenance of MUS. The evidence for the contribution of individual factors, and their autopoietic interaction in MUS (as hypothesised by the

				cognitive behavioural model) is examined. The evidence from the treatment trials of cognitive behavioural therapy for MUS, CFS and IBS is reviewed as an experimental test of the cognitive behavioural models. We conclude that a broadly conceptualized cognitive behavioural model of MUS suggests a novel and plausible mechanism of symptom generation and has heuristic value. We offer suggestions for further research.
Díaz-Caneja Greciano A, Rodríguez Sosa JT, Aguilera Albesa S, Sánchez-Carpintero R, Soutullo Esperón C.	Unidad de Psiquiatría Infantil y Adolescente, Departamento de Psiquiatría y Psicología Médica, Clínica Universitaria, Universidad de Navarra, España. adiazcaneja@hotmail.com	[Chronic fatigue syndrome in a 15-year-old girl] [Article in Spanish]	An Pediatr (Barc). 2007 Jul;67(1):74-7.	Fatigue and lack of energy are frequent symptoms in children and adolescents. A diagnosis of chronic fatigue syndrome should be considered in children and adolescents who complain of chronic fatigue associated with other symptoms without a demonstrable physical cause. Lack of knowledge about this syndrome and late diagnosis may have a negative impact on the normal development of affected children and adolescents. Treatment should be based on a rehabilitation program with cognitive behavioral therapy and a gradual increase in activities.
Donnelly DL, Rockland RH, Reisman SS, Quigley KS.	New Jersey Inst. of Technol., Newark, NJ, USA.	Continuous measurement of BRSI in chronic fatigue syndrome.	Conf Proc IEEE Eng Med Biol Soc. 2004;2:906-8.	This paper discusses the development of a system to measure continuous cardiac baroreceptor measurement during a 45-minute 70-degree head-up tilt (HUT) of five groups of subjects suffering the following: chronic fatigue syndrome (CFS), CFS with fibromyalgia (CFS-FM), CFS with postural orthostatic tachycardia syndrome (CFS-POTS), controls with POTS (CON-POTS), and controls (CON). The duration of the test was 56-minutes, which included a five-minute supine baseline, a 45-minute HUT and a six-minute recovery period. The system was developed in LabView, and can provide a comparative time analyses of weighted BRSI averages. Baroreflex effectiveness index (BEI) was also investigated over the course of lags 0, 1 and 2 as well as an assessment of overall BEI performance between groups.
Edwards CR, Thompson AR, Blair A.	Barnsley Primary Care Trust, UK. catherine.edwards@barnsleypct.nhs.uk	An 'overwhelming illness': women's experiences of learning to live with chronic fatigue syndrome/myalgic encephalomyelitis.	J Health Psychol. 2007 Mar;12(2):203-14.	The processes through which people learn to live with CFS/ME are poorly understood and have not been rigorously explored within the literature. Semi-structured interviews were conducted with eight women and analysed using interpretative phenomenological analysis. Participants initially described being 'overwhelmed' by CFS/ME. Attempts at seeking help were unsatisfactory and participants described feeling let down and disbelieved. Participants reacted to this by identifying types of 'self-help' and assertively taking more responsibility for their illness and its treatment. Acquiring social support and greater knowledge were key mediating factors in the emergence of control and acceptance. The relevance of the themes to existing research and the implications for clinical practice are considered.
Ellen A. Schur, Carolyn Noonan, Dedra S. Buchwald		Prospective Study of Body Mass Index, Weight Change, and Fatigue in Acute	Journal of Chronic Fatigue Syndrome 2007; 14(3):	Objective: To examine the influence of body mass index (BMI) and weight change on fatigue severity and failure to recover in individuals with acute infectious mononucleosis. Methods: We prospectively studied 148 individuals presenting with a positive monospot test. We obtained measured weights and vitality subscale scores from the Short Form-36 Health Survey (SF-36) at the index visit and at 6 months. Results: The mean age of the participants was 21 years and 24% were overweight or obese.

		Infectious Mononucleosis		During acute illness, overweight and obese participants had an adjusted odds ratio for low vitality scores of 2.9 (confidence interval 1.2-7.1) compared to normal weight subjects. Neither index BMI nor 6-month weight gain was significantly associated with prolonged fatigue or failure to recover. Conclusion: Overweight and obese patients with acute infectious mononucleosis are more likely to experience severe fatigue. In contrast, neither baseline weight nor weight gain appear to impede recovery.
Emmert-Streib F.	Stowers Institute for Medical Research, Kansas City, Missouri 64110, USA. fes@stowers-institute.org	The chronic fatigue syndrome: a comparative pathway analysis.	J Comput Biol. 2007 Sep;14(7):961-72.	In this paper, we introduce a method to detect pathological pathways of a disease. We aim to identify biological processes rather than single genes affected by the chronic fatigue syndrome (CFS). So far, CFS has neither diagnostic clinical signals nor abnormalities that could be diagnosed by laboratory examinations. It is also unclear if the CFS represents one disease or can be subdivided in different categories. We use information from clinical trials, the gene ontology (GO) database as well as gene expression data to identify undirected dependency graphs (UDGs) representing biological processes according to the GO database. The structural comparison of UDGs of sick versus non-sick patients allows us to make predictions about the modification of pathways due to pathogenesis.
Endresen GK.	Department of Rheumatology, The National Hospital Rikshospitalet, Forskningsvn. 2, Block B, 0027 Oslo, Norway. gerhard.endresen @rikshospitalet.no	Fibromyalgia: a rheumatologic diagnosis?	Rheumatol Int. 2007 Sep;27(11):999-1004. Epub 2007 Jul 20.	Fibromyalgia (FM) is a medically unexplained or functional somatic syndrome (FSS). The two classification criteria are chronic widespread pain (CWP) and the finding of 11/18 tender points (TP). FM overlaps and co-occurs with other FSSs, and auxiliary symptoms that are not included in the criteria may be clues to other FSSs. About ten FSSs include chronic fatigue syndrome, myofascial pain syndromes and irritable bowel syndrome. TP do not reflect demonstrable pathology, and are locations where everyone is generally more tender. In FM they are more tender than normal due to lowered pain threshold. High TP counts are associated with the extent of distress or unspecific somatic symptoms in the absence of chronic pain. TP lack validity and should be excluded. CWP and distress are outside the domain of rheumatology, and abnormal mechanisms in FM relate to the central nervous system, as compared to "peripheral" mechanisms studied in rheumatology. FM should not be considered as a rheumatologic condition but rather as part of a broader spectre of FSSs. Patients with FSSs should be considered and treated together across medical specialities by general physicians in primary health care.
Eva Libman, Laura Creti, Dorrie Rizzo, Melanie Jastremski, Sally Bailes, Catherine S. Fichten		Descriptors of Fatigue in Chronic Fatigue Syndrome	Journal of Chronic Fatigue Syndrome 2007; 14(3):	Objective: To explore how individuals with chronic fatigue syndrome (CFS) describe their fatigue experience and examine how this differs from descriptions of fatigue in healthy controls. Methods: 52 individuals with CFS and 27 controls listed words that described their fatigue. These words were grouped into 18 categories. Results: Individuals with CFS used more categories to describe their fatigue and more descriptors within each category. The most popular category used by both groups was energy depletion/physical weakness. CFS participants also experienced their fatigue as limiting their ability to function, frustrating, permanent/ persistent, out of their control, depressing, and pervading all aspects of their lives. Controls reported that when they experienced fatigue, it was temporary, and they felt unmotivated, sleepy, and comfortable. Conclusion: Themultidimensional descriptive pattern characterizing the fatigue of individuals with CFS differs dramatically from the experienced fatigue of healthy individuals, suggesting their "language of fatigue" has a distinctive quality. Keywords: Fatigue, chronic fatigue syndrome, measure

Evengård B, Gräns H, Wahlund E, Nord CE.	Division of Clinical Microbiology, Department of Laboratory Medicine, Karolinska Institutet, Karolinska University Hospital Huddinge, Stockholm, Sweden.	Increased number of Candida albicans in the faecal microflora of chronic fatigue syndrome patients during the acute phase of illness.	Scand J Gastroenterol. 2007 Sep 18;:1-2 [Epub ahead of print]	
Faulkner S, Smith A.		A longitudinal study of the relationship between psychological distress and recurrence of upper respiratory tract infections in chronic fatigue syndrome.	Br J Health Psychol. 2006 Dec 18 [Epub ahead of print]	ObjectivesPrevious research has found that chronic fatigue syndrome (CFS) patients report increased susceptibility to upper respiratory tract illnesses (URTIs) when compared with healthy volunteers. This study aimed to replicate and extend this research by investigating the role of psychological distress (stress and negative mood) in the recurrence of URTIs in CFS patients as well as its role in the recurrence of CFS symptoms.DesignA 15-week diary study.MethodsMeasures of psychological stress, negative mood, recurrence of URTIs and symptoms were recorded each week for a 15-week period. CFS patients (N=21), who had been assessed and diagnosed according to the Oxford criteria, were recruited from the Cardiff Chronic Fatigue Clinic and compared with a matched group of healthy controls (N=18). Frequency of occurrence of infectious illness and the relationship between psychological stress/negative mood and occurrence of illness were assessed.ResultsCFS patients reported more URTIs than the controls. Stress scores (and negative mood) were significantly higher in the week prior to the occurrence of URTIs than in weeks when no subsequent illness occurred. High levels of psychological stress also preceded the severity of reported symptoms of fatigue in the CFS group.ConclusionsCFS patients reported more frequent URTIs than healthy controls and these recurrences were preceded by high levels of psychological stress. High levels of stress were also associated with greater subsequent fatigue. Possible explanations of these results are discussed.
Friedberg F, Quick J.	Stony Brook University, Stony Brook, NY 11794-8790, USA. fred.friedberg@stonybrook.edu	Alexithymia in chronic fatigue syndrome: associations with momentary, recall, and retrospective measures of somatic complaints and emotions.	Psychosom Med. 2007 Jan;69(1):54-60.	OBJECTIVE: The relationship between alexithymia and real-time momentary symptom assessments has not been reported. This cross-sectional study hypothesized that alexithymia would be a predictor of somatic symptoms using three different types of symptom measurement (momentary, recall, and retrospective) in the medically unexplained illness of chronic fatigue syndrome (CFS). In addition, it was hypothesized that negative affect would be a significant mediator of the relationship between alexithymia and somatic symptoms. Finally, the relation of alexithymia to physical illness attribution (a CFS illness predictor) was explored. METHODS: Participants were 111 adults with CFS. Alexithymia was assessed with the Toronto Alexithymia Scale. Momentary ratings of current symptoms and affect were recorded in electronic diaries carried for 3 weeks. Weekly recall of these momentary reports was also recorded. Retrospective measures included 6-month ratings of fatigue and pain, the Fatigue Severity Scale, the Brief Pain Inventory-Short Form, a CFS symptom measure, the Beck Depression Inventory-II, the Beck Anxiety Inventory, and an illness attribution rating. RESULTS: Partial correlations, controlling

				for age and sex, yielded no significant associations between general or specific forms of alexithymia and momentary ratings of fatigue or pain. On the other hand, a significant association, partially mediated by anxiety scores, was found between a specific form of alexithymia and a retrospective pain measure. Finally, physical illness attribution was not significantly associated with alexithymia. CONCLUSION: Based on assessments of real-time and retrospectively measured symptoms, these data provided only modest support for the alexithymia construct as a predictor of somatic symptoms in people with CFS.
Friedberg F, Sohl S, Schmeizer B.	Department of Psychiatry and Behavioral Medicine, Stony Brook University, NY 11794-8790, USA. fred.friedberg@stonybrook.edu	Publication trends in chronic fatigue syndrome: comparisons with fibromyalgia and fatigue: 1995-2004.	J Psychosom Res. 2007 Aug;63(2):143-6.	OBJECTIVE: In order to identify publishing patterns in chronic fatigue syndrome (CFS), we compared the annual number of peer review articles for CFS, fibromyalgia (FM), and non-CFS fatigue over a recent decade (1995-2004). METHOD: Citations were drawn from Ovid/Medline, PsychInfo, and the Journal of Chronic Fatigue Syndrome for peer review articles focusing on CFS, FM, and fatigue for each year of the decade ending in 2004. Statistics included chi-square, tests for differences in proportions, and regression-based curve estimation. RESULTS: The frequency of CFS peer review articles did not significantly change from the first half to the second half of the decade (1995-2004). By comparison, the output of both FM and fatigue articles significantly increased (P<.0001). A quadratic model (inverted U shape; P<.02) best fit the data for CFS annual publication frequency. By comparison, exponential models best fit the data for both FM (P<.0001) and fatigue (P<.0001) citations. The highest percentage of citations (15-16%) for both CFS and FM fell within the domains of diagnosis, physiopathology, and psychology. For fatigue, almost one third (31.4%) of the citations were focused on etiology, while psychology (11.5%) and physiopathology (10.4%) articles were the next most cited. Based on first-author affiliation, CFS articles were most likely to originate in the United States (37.7%), England (31.4%), and the Netherlands (4.9%). CONCLUSION: The output of CFS peer review articles has not increased over the past decade, while the number of FM and fatigue articles has increased substantially.
Galland BC, Jackson PM, Sayers RM, Taylor BJ.	Department of Women's & Children's Health, University of Otago, Dunedin 9015, New Zealand.	A Matched Case Control Study of Orthostatic Intolerance in Children/Adolescents With Chronic Fatigue Syndrome.	Pediatr Res. 2008 Feb;63(2):196-202.	This study aimed to define cardiovascular and heart rate variability (HRV) changes following head-up tilt (HUT) in children/adolescents with chronic fatigue syndrome (CFS) in comparison to age- and gender-matched controls. Twenty-six children/adolescents with CFS (11-19 y) and controls underwent 70-degree HUT for a maximum of 30 min, but returned to horizontal earlier at the participant's request with symptoms of orthostatic intolerance (OI) that included lightheadedness. Using electrocardiography and beat-beat finger blood pressure, a positive tilt was defined as OI with 1) neurally mediated hypotension (NMH); bradycardia (HR <75% of baseline), and hypotension [systolic pressure (SysP) drops >25 mm Hg)] or 2) postural orthostatic tachycardia syndrome (POTS); HR increase >30 bpm, or HR >120 bpm (with/without hypotension). Thirteen CFS and five controls exhibited OI generating a sensitivity and specificity for HUT of 50.0% and 80.8%, respectively. POTS without hypotension occurred in seven CFS subjects but no controls. POTS with hypotension and NMH occurred in both. Predominant sympathetic components to HRV on HUT were measured in CFS tilt-positive subjects. In conclusion, CFS subjects were more susceptible to OI than controls, the cardiovascular response predominantly manifest as POTS without hypotension, a response unique to CFS suggesting further investigation is warranted with respect to the pathophysiologic mechanisms involved. ABBREVIATIONS::

Gielissen MF, Knoop H, Servaes P, Kalkman JS, Huibers MJ, Verhagen S, Bleijenberg G.	Expert Centre Chronic Fatigue Nijmegen, Radboud University, Nijmegen Medical Centre, The Netherlands. m.gielissen@nkcv.umcn.nl	Differences in the experience of fatigue in patients and healthy controls: patients' descriptions.	Health Qual Life Outcomes. 2007 Jul 2;5:36.	BACKGROUND: The primary objective was to develop an adjective checklist, the Fatigue Quality List (FQL), aimed at assessing different perceptions of fatigue. METHODS: 961 participants filled out the FQL (28 adjectives). A component and confirmatory factor analyses were performed and psychometric properties were evaluated. Differences on factor scores between different patients' groups were investigated and pre- and post treatment scores were compared in demonstrating change of perceptions after treatment of fatigue. RESULTS: Four independent factors were found with adequate psychometric properties. Different perceptions were found between the patients' groups. Patients who were recovered after treatment for fatigue showed similar scores on the factors as healthy controls. CONCLUSION: The FQL appears to be a promising tool in measuring different perceptions of fatigue, which can be especially interesting for clinical practice.
Gilula MF.	President and Director, Life Energies Research Institute, 2510 Inagua Avenue, Miami, FL 33133, USA. mgilula@mindspring.com	Cranial electrotherapy stimulation and fibromyalgia.	Expert Rev Med Devices. 2007 Jul;4(4):489-95.	Cranial electrotherapy stimulation (CES) is a well-documented neuroelectrical modality that has been proven effective in some good studies of fibromyalgia (FM) patients. CES is no panacea but, for some FM patients, the modality can be valuable. This article discusses aspects of both CES and FM and how they relate to the individual with the condition. FM frequently has many comorbidities such as anxiety, depression, insomnia and a great variety of different rheumatologic and neurological symptoms that often resemble multiple sclerosis, dysautonomias, chronic fatigue syndrome and others. However, despite long-standing criteria from the American College of Rheumatology for FM, some physicians believe there is probably no single homogeneous condition that can be labeled as FM. Whether it is a disease, a syndrome or something else, sufferers feel like they are living one disaster after another. Active self-involvement in care usually enhances the therapeutic results of various treatments and also improves the patient's sense of being in control of the condition. D-ribose supplementation may prove to significantly enhance energy, sleep, mental clarity, pain control and well-being in FM patients. A form of evoked potential biofeedback, the EPFX, is a powerful stress reduction technique which assesses the chief stressors and risk factors for illness that can impede the FM patient's built-in healing abilities. Future healthcare will likely expand the diagnostic criteria of FM and/or illuminate a group of related conditions and the ways in which the conditions relate to each other. Future medicine for FM and related conditions may increasingly involve multimodality treatment that features CES as one significant part of the therapeutic regimen. Future medicine may also include CES as an invaluable, cost-effective add-on to many facets of clinical pharmacology and medical therapeutics.
Glover DS, Brown GP, Fairburn CG, Shafran R.	Royal Holloway University of London, UK.	A preliminary evaluation of cognitive-behaviour therapy for clinical perfectionism: a case series.	Br J Clin Psychol. 2007 Mar;46(Pt 1):85-94.	OBJECTIVE: The construct of 'clinical perfectionism' has been developed in response to criticisms that other approaches have failed to yield advances in the treatment of the type of self-oriented perfectionism that poses a clinical problem. The primary aim of this study was to conduct a preliminary investigation into the efficacy of a theory-driven, cognitive-behavioural intervention for 'clinical perfectionism'. DESIGN: A multiple baseline single case series design was used. METHOD: A specific, 10-session cognitive-behavioural intervention to address clinical perfectionism in eating disorders was adapted to allow its use in nine patients referred with a range of axis I disorders and clinical perfectionism. RESULTS: The intervention led to clinically significant improvements in self-referential perfectionism from pretreatment to follow-up for six of the nine participants on two perfectionism measures and for three of the nine participants on the measure of clinical

				perfectionism. Statistically significant improvements from pre- to post-intervention for the group as a whole were found on all three measures. The improvements were maintained at follow-up. CONCLUSIONS: The finding that clinical perfectionism is improved in the majority of participants is particularly encouraging given that perfectionism has traditionally been viewed as a personality characteristic resistant to change. These preliminary findings warrant replication in a larger study.
Godfrey E, Chalder T, Ridsdale L, Seed P, Ogden J.	Department of Psychology, Institute of Psychiatry, Kings College London, UK. emma.l.godfrey@kcl.ac.uk	Investigating the active ingredients of cognitive behaviour therapy and counselling for patients with chronic fatigue in primary care: developing a new process measure to assess treatment fidelity and predict outcome.	Br J Clin Psychol. 2007 Sep;46(Pt 3):253-72.	OBJECTIVES: To develop a brief measure of the therapy process and use it to examine which therapeutic ingredients were associated with outcome in a sample of patients from a randomized controlled trial (RCT) of cognitive behaviour therapy (CBT) versus counselling for patients with chronic fatigue in primary care. It was hypothesized that the two therapies would be clearly distinguishable and that in terms of process variables, the therapeutic alliance would be important in predicting outcome. DESIGN: The data for this study were collected alongside a RCT in primary care and included audiotaped therapy sessions. These tapes were assessed by two independent raters using a newly devised measure in order to evaluate therapy process and its relationship with outcome. METHODS: Tapes from 71 patients participating in the RCT were assessed to form the basis of the process analysis. Outcome was self-reported fatigue symptoms at 6 months follow-up. Data reduction was achieved via a principal component analysis (PCA). Factors were entered into a multiple regression analysis to produce a final model of predictors of outcome. RESULTS: The process measure showed that although the treatments could be distinguished, there was some overlap between them. The key predictor of a good fatigue outcome was emotional processing, including the expression, acknowledgement and acceptance of emotional distress. CONCLUSION: A new process measure was developed successfully which now warrants further testing. It was able to assess treatment adherence and unpack, and distinguish the common factor which predicted outcome across therapy modalities. The findings lend preliminary support to the view that the specific techniques associated with particular 'brand names' of therapy are not necessarily the 'active ingredients' that help patient's change within the primary care setting. Emotional processing predicted outcome for patients with chronic fatigue and therefore future research might explore this in more depth, in order to understand better how it can be facilitated.
Goudsmit EM.		Chronic fatigue syndrome	J R Soc Med. 2007 Jan;100(1):7. Comment on: J R Soc Med. 2006 Oct;99(10):506-20	
Guo J.	Hospital of Chengdu Jiuxing Company of Textile Group, Chengdu 610053, China.	Chronic fatigue syndrome treated by acupuncture and moxibustion in combination with psychological approaches in 310 cases.	J Tradit Chin Med. 2007 Jun;27(2):92-5.	OBJECTIVE: To observe clinical therapeutic effect of acupuncture and moxibustion combined with a psychological approach on chronic fatigue syndrome (CFS). METHODS: The treatment was given by acupuncture plus moxibustion combined with a psychological approach based on differentiation of symptoms and signs in 310 cases. RESULTS: Of 310 cases observed, 275 cases (88.7%) were clinically cured, 28 cases (9%) improved, and 7 cases (2.3%) failed. CONCLUSION: Acupuncture plus moxibustion combined with a psychological approach is an effective therapy for CFS.

Gupta S, Aslakson E, Gurbaxani BM, Vernon SD.	Division of Viral and Rickettsial Diseases, National Center for Zoonotic, Vector-Borne, and Enteric Diseases, Centers for Disease Control and Prevention, Atlanta, Georgia 30333, USA. shaktig@gmail.com	Inclusion of the glucocorticoid receptor in a hypothalamic pituitary adrenal axis model reveals bistability.	Theor Biol Med Model. 2007 Feb 14;4:8.	BACKGROUND: The body's primary stress management system is the hypothalamic pituitary adrenal (HPA) axis. The HPA axis responds to physical and mental challenge to maintain homeostasis in part by controlling the body's cortisol level. Dysregulation of the HPA axis is implicated in numerous stress-related diseases. RESULTS: We developed a structured model of the HPA axis that includes the glucocorticoid receptor (GR). This model incorporates nonlinear kinetics of pituitary GR synthesis. The nonlinear effect arises from the fact that GR homodimerizes after cortisol activation and induces its own synthesis in the pituitary. This homodimerization makes possible two stable steady states (low and high) and one unstable state of cortisol production resulting in bistability of the HPA axis. In this model, low GR concentration represents the normal steady state, and high GR concentration represents a dysregulated steady state. A short stress in the normal steady state produces a small perturbation in the GR concentration that quickly returns to normal levels. Long, repeated stress produces persistent and high GR concentration that does not return to baseline forcing the HPA axis to an alternate steady state. One consequence of increased steady state GR is reduced steady state cortisol, which has been observed in some stress related disorders such as Chronic Fatigue Syndrome (CFS). CONCLUSION: Inclusion of pituitary GR expression resulted in a biologically plausible model of HPA axis bistability and hypocortisolism. High GR concentration enhanced cortisol negative feedback on the hypothalamus and forced the HPA axis into an alternative, low cortisol state. This model can be used to explore mechanisms underlying disorders of the HPA axis.

Hakariya Y, Kuratsune H.	Department of Virology, Center for Infectious Disease Control, Research Institute for Microbial Diseases, Osaka University.	[Chronic fatigue syndrome: biochemical examination of blood] [Article in Japanese]	Nippon Rinsho. 2007 Jun;65(6):1071-6.	Though patients with chronic fatigue syndrome (CFS) have lots of complaints, abnormal findings cannot be detected by biochemical screening tests. However, some specialized blood tests have revealed neuroendocrine immune axis abnormalities, which is closely associated with each other. Recent studies indicate that CFS can be understood as a special condition based on abnormality of the psycho-neuro-endocrino-immunological system, with the distinguishing feature of CFS seeming to be the secondary brain dysfunction caused by several cytokines and/or autoantibodies. In this paper, we summarize these abnormalities found in CFS and show the neuro-molecular mechanism leading to chronic fatigue.
Hanna Grans, Birgetta Evengard, Peter Nilsson		Transcriptome Analysis of Peripheral Blood Mononuclear Cells from Patients with Chronic Fatigue Syndrome	Journal of Chronic Fatigue Syndrome 2007; 14(3):	Objective: Chronic fatigue syndrome (CFS) is an illness defined by unexplained disabling fatigue lasting longer than six months, together with at least four out of eight specified symptoms. The etiology and pathophysiology of CFS are to a large degree unknown. Since much remains unclear about CFS we wanted to investigate transcript expression levels in peripheral blood mononuclear cells to identify genes that are involved in CFS. Method: Transcript expression profiles for 20 CFS patients were compared with 14 healthy controls using microarray technology. Results were verified with real-time PCR. Results: We have identified significantly differentially expressed genes comparing a female CFS patient subgroup with gradual illness onset and no previously documented infection with female healthy controls. We have also created a list of genes with indicated, but not verified, expression differences from comparisons between other subgroups and healthy controls. These genes are

				candidates for further study of potential involvement in CFS. Conclusion: Our results stress the necessity of subgrouping the heterogeneous CFS patient cohort. The mRNA expression differences identified here may be causal factors for the illness or symptoms observed in these patients, or a result of altered functions of other cellular components involved in the illness. The role of these genes in the CFS pathology needs further investigation.
Harvey SB, Wadsworth M, Wessely S, Hotopf M.	Department of Psychological Medicine, Institute of Psychiatry, Kings College London, London, UK.	The relationship between prior psychiatric disorder and chronic fatigue: evidence from a national birth cohort study.	Psychol Med. 2007 Nov 2;:1-8 [Epub ahead of print]	BACKGROUND: Increased rates of psychiatric disorder have previously been reported in those diagnosed with chronic fatigue syndrome (CFS) or myalgic encephalomyelitis (ME), although the direction of causation in this relationship has not been established. We aimed to test the hypothesis that individuals with self-reported CFS/ME have increased levels of psychiatric disorder prior to the onset of their fatigue symptoms.MethodA total of 5362 participants were prospectively followed with various measures of personality, psychiatric disorder and fatigue levels collected over the first 43 years of their life. CFS/ME was identified through self-report during a semi-structured interview at age 53 years. RESULTS: Thirty-four (1.1%) of the 3035 subjects assessed at age 53 years reported a diagnosis of CFS/ME. CFS/ME was more common among females, but there was no association between CFS/ME and either social class, social mobility or educational level. Those with psychiatric illness between the ages of 15 and 36 years were more likely to report CFS/ME later in life with an odds ratio (OR, adjusted for sex) of 2.65 [95% confidence interval (CI) 1.26-5.57, p=0.01]. Increased levels of psychiatric illness, in particular depression and anxiety, were present prior to the occurrence of fatigue symptoms. There was a dose-response relationship between the severity of psychiatric symptoms and the likelihood of later CFS/ME. Personality factors were not associated with a self-reported diagnosis of CFS/ME. CONCLUSIONS: This temporal, dose-response relationship suggests that psychiatric disorders, or shared risk factors for psychiatric disorders, are likely to have an aetiological role in some cases of CFS/ME.
Hashimoto N.	Center for Medical Education and Information.	[History of chronic fatigue syndrome] [Article in Japanese]	Nippon Rinsho. 2007 Jun;65(6):975-82.	Chronic fatigue syndrome (CFS) is not a new disease. Similar morbidities have been known as different names since past several centuries. For example, neurasthenia, epidemic neuromyasthenia, myalgic encephalomyelitis, Akureyri disease, Royal Free disease, chronic EBV disease, post-viral fatigue syndrome etc. Much of the recent interest in CFS was generated by incidence of infection-like outbreak at Lake Tahoe in Nevada. The Center for Disease Control (USA) realized that correlation was poor between those patients who had virologic evidence of EBV infection and those who had the symptoms of chronic fatigue. This is a review of the history of CFS. (1) Historical perspectives in chronic fatigue cases in past old period, (2) Post-viral infectious fatigue and chronic fatigue (myalgic encephalomyelitis), (3) Recent trend of CFS studies and its clinical similar situation. Finally, I would like to state that we intend to draw up a new diagnostic guideline for CFS in Japan.
Heim ME, v d Malsburg ML, Niklas A.	Sonnenberg-Klinik, Bad Sooden-Allendorf, Germany. heim@sonnenberg-klinik.de <heim@sonnenber	Randomized controlled trial of a structured training program in breast cancer patients with tumor-related chronic fatigue.	Onkologie. 2007 Sep;30(8-9):429-34. Epub 2007 Sep 7.	BACKGROUND: Cancer-related fatigue is the most disabling symptom experienced by breast cancer patients following the cancer treatment. The positive effects of physical activity in the rehabilitation of breast cancer patients are documented in several studies. In a randomized controlled study the effects of a structured physical training program on fatigue and health-related quality of life were evaluated. PATIENTS AND METHODS: 63 breast cancer patients with cancer-related chronic fatigue were randomized at the beginning of the inpatient rehabilitation. The control group received the standard complex rehabilitation program, the intervention group a structured physical training program and

	g-klinik.de>			additional muscle strength and aerobic exercises. The effects of the treatment were evaluated by questionnaires at the start of rehabilitation (t1), end of rehabilitation (t2), and 3 months after t2 (t3). Isometric muscle strength and aerobic capacity were evaluated at t1 and t2. RESULTS: There was an improvement of muscle strength at the end of rehabilitation for both groups. The increase from t1 to t2 was significantly higher for the training group. The scores for global quality of life, physical well-being, and functionality increased from t1 to t2, but further improvement in the follow-up (t3) was only observed in the training group. The cancer-related fatigue was significantly reduced in the training group from t1 to t3, however, not in the control group. CONCLUSIONS: Structured physical training programs initiated during inpatient rehabilitation and continuously practiced in the time thereafter can improve symptoms of chronic fatigue and quality of life in breast cancer patients.
Hempel S, Chambers D, Bagnall AM, Forbes C.	Centre for Reviews and Dissemination, University of York, York, UK.	Risk factors for chronic fatigue syndrome/myalgic encephalomyelitis: a systematic scoping review of multiple predictor studies.	Psychol Med. 2007 Sep 25;:1-12 [Epub ahead of print]	BACKGROUND: The aetiology of chronic fatigue syndrome/myalgic encephalomyelitis (CFS/ME) is still unknown. The identification of risk factors for CFS/ME is of great importance to practitioners.MethodA systematic scoping review was conducted to locate studies that analysed risk factors for CFS/ME using multiple predictors. We searched for published and unpublished literature in 11 electronic databases, reference lists of retrieved articles and guideline stakeholder submissions in conjunction with the development of a forthcoming national UK guideline. Risk factors and findings were extracted in a concise tabular overview and studies synthesized narratively. RESULTS: Eleven studies were identified that met inclusion criteria: two case-control studies, four cohort studies, three studies combining a cohort with a case-control study design, one case-control and twin study and one cross-sectional survey. The studies looked at a variety of demographic, medical, psychological, social and environmental factors to predict the development of CFS/ME. The existing body of evidence is characterized by factors that were analysed in several studies but without replication of a significant association in more than two studies, and by studies demonstrating significant associations of specific factors that were not assessed in other studies. None of the identified factors appear suitable for the timely identification of patients at risk of developing CFS/ME within clinical practice. CONCLUSIONS: Various potential risk factors for the development of CFS/ME have been assessed but definitive evidence that appears meaningful for clinicians is lacking.
Henningsen P, Zipfel S, Herzog W.	Department of Psychosomatic Medicine and Psychotherapy, University Hospital, Technical University of Munich, Langerstrasse 3, 81675 Munich, Germany. p.henningsen@tum.de	Management of functional somatic syndromes.	Lancet. 2007 Mar 17;369(9565):946-55. Comment in: Lancet. 2007 May 19;369(9574):1691-2.	Although functional somatic syndromes (FSS) show substantial overlap, treatment research is mostly confined to single syndromes, with a lack of valid and generally accepted diagnostic criteria across medical specialties. Here, we review management for the full variety of FSS, drawn from systematic reviews and meta-analyses since 2001, and give recommendations for a stepped care approach that differentiates between uncomplicated and complicated FSS. Non-pharmacological treatments involving active participation of patients, such as exercise and psychotherapy, seem to be more effective than those that involve passive physical measures, including injections and operations. Pharmacological agents with CNS action seem to be more consistently effective than drugs aiming at restoration of peripheral physiological dysfunction. A balance between biomedical, organ-oriented, and cognitive interpersonal approaches is most appropriate at this truly psychosomatic interface. In view of the iatrogenic component in the maintenance of FSS, doctor-centred interventions and close observation of the doctor-patient relationship are of particular importance.

Hinton DE, Hinton L, Tran M, Nguyen M, Nguyen L, Hsia C, Pollack MH.	Harvard Medical School. devon_hinton@hms.harvard.edu.	Orthostatic panic attacks among vietnamese refugees.	Transcult Psychiatry. 2007 Dec;44(4):515-44.	Viewed historically and cross-culturally, orthostatic-induced dizziness, i.e., dizziness caused by standing up from a sitting or a lying position, forms a key aspect of many syndromes: irritable heart (American Civil War), effort syndrome (World War I and World War II), chronic fatigue syndrome (contemporary USA), Gulf War syndrome (contemporary USA), and orthostatic dysregulation (contemporary Japan). Among Vietnamese refugees attending a psychiatric clinic, this study documents a high rate of orthostatic panic (OP), as well as certain processes seemingly generating these panic attacks, viz., flashbacks and culturally specific catastrophic cognitions. Case examples are used to demonstrate OP's phenomenology and relevance to clinical care. To illustrate the mechanisms producing OP, we adduce the multiplex model of panic generation. Culturally appropriate care of Vietnamese refugees should include assessment and treatment of OP.

Ismail K, Kent K, Sherwood R, Hull L, Seed P, David AS, Wessely S.	Department of Psychological Medicine, Institute of Psychiatry, King's College London, London, UK.	Chronic fatigue syndrome and related disorders in UK veterans of the Gulf War 1990-1991: results from a two-phase cohort study.	Psychol Med. 2007 Sep 25;:1-9 [Epub ahead of print]	BACKGROUND: The aim was to determine the prevalence of chronic fatigue syndrome (CFS), chronic fatigue and fibromyalgia in UK military personnel after the Gulf War 1990-1991.MethodA two-phase cohort study was used. Three randomly selected subsamples identified from a population-based cross-sectional postal survey of over 10 000 current and ex-service UK military personnel (Gulf veterans were those deployed to the Gulf War 1990-1991; non-Gulf veterans were Bosnia peacekeepers 1992-1997 and those on active duty during the Gulf War 1990-1991 but not deployed) were recruited. Their disability status was assessed using the Short Form 36 physical functioning scale; Gulf veterans who reported physical disability (n=111) were compared with non-Gulf (n=133) veterans who reported similar levels of physical disability. Screening for known medical and psychiatric conditions was conducted to exclude medical explanations for disability and symptomatic distress. Standardised criteria for CFS, chronic fatigue and fibromyalgia were used. RESULTS: Disabled Gulf veterans were more likely to be overweight, have elevated gamma-glutamyl transferase levels and screen positive for hypertension. There were no other clinically significant differences in clinical markers for medically

				explainable conditions. Disabled Gulf veterans were more likely than similarly disabled Bosnia and Era veterans (adjusted odds ratio 7.8, 95% confidence interval 2.5-24.5) to meet the criteria for CFS. Rates for other medically unexplained conditions were not significantly increased. CONCLUSIONS: Symptoms in keeping with CFS account for a significant part of the symptomatic distress in Gulf veterans.
Jansen NW, Huibers MJ, van Amelsvoort LG, Kant I.	Capaciteitsgroep Epidemiologie van de Universiteit Maastricht. Nicole.Jansen@epid.unimaas.nl	[Aetiology of prolonged fatigue among workers. An overview of findings from the Maastricht Cohort Study] [Article in Dutch]	Comment in: Tijdschr Psychiatr. 2007;49(8):555-7.	BACKGROUND: Considerable attention is being given to prolonged fatigue among workers because it occurs so frequently and is alleged to have serious consequences. AIM: To present an overview of the magnitude, causes and consequences of prolonged fatigue in the workplace with a view to preventing its occurrence. METHOD: On the basis of of the articles written as part of the Maastricht Cohort Study we present an overview of this study, a prospective cohort study (n=12,140) that covered a period of 4 years. results Prolonged fatigue seems to occur frequently among workers. Risk factors in the aetiology of prolonged fatigue were found in subjective and objective work-related factors, as well as in factors related to the health and private situation of the employee. CONCLUSION: The assumed multifactorial aetiology of prolonged fatigue was confirmed by means of prospective analyses in the Maastricht Cohort Study. The observed risk factors can be applied as tools for the development of effective preventive measures against prolonged fatigue.

Jedlicka F, Elbl L, Vásová I, Tomásková I, Vorlícek J, Spinar J.	Interní kardiologická klinika Lékarské fakulty MU a FN Brno. fjedlicka@fnbrno.cz	[Chronic fatigue syndrome in cancer patients. Diagnostic and treatment options] [Article in Czech]	Vnitr Lek. 2007 Sep;53(9):979-85. Comment in: Vnitr Lek. 2007 Sep;53(9):930.	Fatigue is the most frequent symptom accompanying a cancer disease and its treatment according to the visual analogue scale. Fatigue is reported by as many as 100% of patients in the course of cancer treatment and still by 40 to 70% of patients one year after the treatment has finished. This symptom has become known under the designation of "cancer-related fatigue" in the English language literature on the subject. The knowledge of the causes and mechanisms of fatigue is relatively limited. Based on practical guidelines, an algorithm has been used to detect, evaluate and influence by treatment the syndrome of fatigue caused by a cancer disease. Research in the field has been focused on both pharmacological and non-pharmacological approach. The highest efficiency in the treatment of fatigue syndrome has been recorded for the treatment of anaemia with erythropoietin, while aerobic exercise programmes have proven to be most efficient among the behavioural measures. In spite of a dramatically growing interest in the above problem in the past decade, a number of issues continue unresolved with respect to chronic fatigue syndrome related to a cancer disease or to its treatment. Based on their own experience and on the relevant literature, the authors deal with issues of chronic fatigue syndrome and the options for its diagnosing and treatment in patients undergoing cancer treatment.
Jerjes WK, Taylor NF, Wood PJ, Cleare AJ.	Department of Clinical Biochemistry,	Enhanced feedback sensitivity to	Psychoneuroendocrinology. 2007 Feb;32(2):192-8.	OBJECTIVE: Enhancement of negative feedback control of the HPA axis in patients with chronic fatigue syndrome (CFS) has been reported using the low dose dexamethasone suppression test. We have developed the use of prednisolone (5mg) as a more physiologically appropriate alternative to

	Guy's, King's and St Thomas' School of Medicine, Bessemer Road, London SE5 9RS, UK. w_jerjes@yahoo.co.uk	prednisolone in chronic fatigue syndrome.	Epub 2007 Feb 5.	dexamethasone in the investigation of mild degrees of glucocorticoid resistance or supersensitivity. The objective of the study was to use this test to look for alterations in negative feedback control of the HPA axis in CFS patients. METHODS: Fifteen patients with CFS were recruited after fulfilling strict criteria including the absence of comorbid psychiatric diagnosis. They collected urine between 0900 and 1800h and saliva at 0900h pre-prednisolone. At midnight, they took prednisolone (5mg) orally and then collected urine and saliva at the same intervals the following day. RESULTS: Salivary cortisol was lower in CFS subjects pre-prednisolone than controls. Urinary cortisol metabolites were lower in CFS subjects pre-prednisolone, but did not reach significance. Both measures were significantly lower in CFS subjects post-dose. Mean percentage suppression of both salivary cortisol and urinary cortisol metabolites was significantly higher in CFS compared to controls. CONCLUSION: There is enhanced sensitivity of the HPA axis to negative feedback in CFS as demonstrated using the prednisolone suppression test. This provides further evidence of alterations in the control of the HPA axis in patients with established CFS.
Johansson S, Ytterberg C, Claesson IM, Lindberg J, Hillert J, Andersson M, Widén Holmqvist L, von Koch L.	Division of Neurology, Dept. of Clinical Neuroscience, Karolinska Institutet, Karolinska University Hospital Huddinge, SE-141 86 Stockholm, Sweden. sverker.johansson@ki.se	High concurrent presence of disability in multiple sclerosis. Associations with perceived health.	J Neurol. 2007 Jun;254(6):767-73. Epub 2007 Apr 2.	OBJECTIVES : (1) To explore functioning and concurrent presence of disabilities - concerning cognition, manual dexterity, walking, energy, mood, activities of daily living (ADL), and social/lifestyle activities - in persons with multiple sclerosis (PwMS) cared for at an outpatient MS clinic. 2) To describe the PwMS' perceived physical and psychological impact and associations with the same disabilities. MATERIAL/METHODS : A descriptive cross-sectional study was carried out in 219 PwMS at the MS Centre, Karolinska University Hospital. Logistic regression employing proportional odds models was used to identify the associations of the disabilities with the perceived physical and psychological impact. RESULTS : In this sample the distribution with regard to disease severity as per Expanded Disability Status Scale was; mild 59.5%, moderate 17% and severe 23.5%. Despite the high proportion with mild disease severity disability regarding cognition was found in 49%, manual dexterity 76%, walking 43%, energy 67%, mood 29%, ADL 44% and social/lifestyle activities in 48%. Two or more disabilities were found in 80%, 24 % had six or seven disabilities. Disability regarding energy, mood, walking, manual dexterity and ADL was significantly associated with increase in the perceived physical impact, whereas disability in energy and mood was significantly associated with increase in the perceived psychological impact. CONCLUSIONS : The presence of several concurrent disabilities, some significantly associated with high perceived physical and psychological impact, in the majority of PwMS in outpatient clinics highlights the importance to identify disabilities, in particular fatigue and depressed mood, in order to supply health care interventions aiming to improve the life situation of PwMS.
Jones JF, Maloney EM, Boneva RS, Jones AB, Reeves WC.	Division of Viral and Rickettsial Diseases, Coordinating Center for Infectious Diseases, Centers for Disease Control	Complementary and alternative medical therapy utilization by people with chronic fatiguing illnesses in the United States.	BMC Complement Altern Med. 2007 Apr 25;7:12.	BACKGROUND: Chronic fatiguing illnesses, including chronic fatigue syndrome (CFS), pose a diagnostic and therapeutic challenge. Previous clinical reports addressed the utilization of health care provided to patients with CFS by a variety of practitioners with other than allopathic training, but did not examine the spectrum of complementary and alternative medicine (CAM) therapies used. This study was designed to measure CAM therapy use by persons with fatiguing illnesses in the United States population. METHODS: During a random-digit dialing survey to estimate the prevalence of CFS-like illness in urban and rural populations from different geographic regions of the United States, we queried the utilization of CAM including manipulation or body-based therapies, alternative medical

	and Prevention, Atlanta, GA 30333, USA. jaj9@cdc.gov			systems, mind-body, biologically-based, and energy modalities. RESULTS: Four hundred forty fatigued and 444 non-fatigued persons from 2,728 households completed screening. Fatigued subjects included 53 persons with prolonged fatigue, 338 with chronic fatigue, and 49 with CFS-like illness. Mind-body therapy (primarily personal prayer and prayer by others) was the most frequently used CAM across all groups. Among women, there was a significant trend of increasing overall CAM use across all subgroups (p-trend = 0.003). All categories of CAM use were associated with significantly poorer physical health scores, and all but one (alternative medicine systems) were associated with significantly poorer mental health scores. People with CFS-like illness were significantly more likely to use body-based therapy (chiropractic and massage) than non-fatigued participants (OR = 2.52, CI = 1.32, 4.82). Use of body-based therapies increased significantly in a linear trend across subgroups of non-fatigued, prolonged fatigued, chronic fatigued, and CFS-like subjects (p-trend = 0.002). People with chronic fatigue were also significantly more likely to use body-based therapy (OR = 1.52, CI = 1.07, 2.16) and mind-body (excluding prayer) therapy than non-fatigued participants (OR = 1.73, CI = 1.20 - 2.48). CONCLUSION: Utilization of CAM was common in fatiguing illnesses, and was largely accounted for by the presence of underlying conditions and poor physical and mental health. Compared to non-fatigued persons, those with CFS-like illness or chronic fatigue were most likely to use body-based and mind-body therapies. These observations have important implications for provider education programs and development of intervention strategies for CFS.
Jones JF.	Chronic Viral Diseases Branch, Division of Viral and Rickettsial Diseases, National Center for Zoonotic, Vectorborne, and Enteric Diseases, Centers for Disease Control and Prevention, Atlanta, GA 30333, USA.	An extended concept of altered self: Chronic fatigue and post-infection syndromes.	Psychoneuroendocrinology. 2007 Dec 24 [Epub ahead of print]	Sickness behavior in active infectious diseases is defined here as the responses to cytokines and other mediators of inflammation as well as the adaptability of a pre-existing integrated immunological, psychological, neurological, and philosophical self. These complex behaviors are biologically advantageous to the afflicted individual, but they also impact surrounding individuals. If chronic conditions, such as chronic fatigue syndrome or post-infection fatigue, exhibiting these behaviors follow infection in the absence of ongoing changes in immunological self associated with an active infection or subsequent injury, they are currently considered illness states rather than true diseases. Self-referential recognition (interoception) of bodily processes by the brain and subsequent unconscious and conscious adaptive responses arising in the brain, i.e., in the endocrine system and immune systems, which are initiated during the infection and would normally lead to positive maintenance, may become maladaptive and lead to an "extended altered self state." Exploratory measurements of such alterations using a "top-down" approach such as monitoring responses to appropriate challenges can be obtained using functional brain imaging techniques. Once identified, processes remediable to biological/pharmacologic and/or psychological intervention can be targeted in directed trials.
Jubeau M, Zory R, Gondin J, Martin A, Maffiuletti NA.	Laboratory INSERM U887, Faculty of Sport Sciences, University of Burgundy, BP 27877, 21078	Effect of electrostimulation training-detraining on neuromuscular fatigue mechanisms.	Neurosci Lett. 2007 Aug 31;424(1):41-6. Epub 2007 Aug 1.	The aim of this study was to evaluate the effects of neuromuscular electrical stimulation (NMES) training and subsequent detraining on neuromuscular fatigue mechanisms. Ten young healthy men completed one NMES fatigue protocol before and after a NMES training program of 4 weeks and again after 4 weeks of detraining. Muscle fatigue (maximal voluntary torque loss), central fatigue (activation failure), and peripheral fatigue (transmission failure and contractile failure) of the plantar flexor muscles were assessed by using a series of electrically evoked and voluntary contractions with concomitant electromyographic and torque recordings. At baseline, maximal voluntary torque

	Dijon, France. Marc.Jubeau@u-bourgogne.fr			decreased significantly with fatigue (P<0.001), due to both activation and transmission failure. After detraining, maximal voluntary torque loss was significantly reduced (P<0.05). In the same way, the relative decrease in muscle activation after training and detraining was significantly lower compared to baseline values (P<0.05). Short-term NMES training-detraining of the plantar flexor muscles significantly reduced the muscle fatigue associated to one single NMES exercise session. This was mainly attributable to a reduction in activation failure, i.e., lower central fatigue, probably as a result of subject's accommodation to pain and discomfort during NMES.
Juruena MF, Cleare AJ.	Seção de Neurobiologia dos Transtornos de Humor, Instituto de Psiquiatria, King's College, Universidade de Londres, UK. M.Juruena@iop.kcl.ac.uk	[Overlap between atypical depression, seasonal affective disorder and chronic fatigue syndrome] [Article in Portuguese]	Rev Bras Psiquiatr. 2007 May;29 Suppl 1:S19-26.	OBJECTIVE: We reviewed previous studies that have described an association between abnormal functioning of the hypothalamic-pituitary-adrenal axis and depression. In addition to melancholic depression, a spectrum of conditions may be associated with increased and prolonged activation of the hypothalamic-pituitary-adrenal axis. In contrast another group of states is characterized by hypoactivation of the stress system, rather than sustained activation, in which chronically reduced secretion of corticotropin releasing factor may result in pathological hypoarousal and an enhanced hypothalamic-pituitary-adrenal negative feedback. Patients with atypical depression, seasonal affective disorder and chronic fatigue syndrome fall in this category. METHOD: The literature data on the overlap between the key-words were reviewed, summarized and discussed. RESULTS: Many studies suggest that these conditions themselves overlap biologically, showing hypofunction of central corticotropin releasing factor neuronal systems. CONCLUSIONS: Therefore, in the real world of clinical practice, patients often present in a grey area between classical idiopathic fatigue and early chronic atypical depression and/or seasonal depression. This underscores the potential common biological links underpinning common symptom clusters not only between depression (atypical and seasonal) and chronic fatigue syndrome, but also other conditions characterized by the hypothalamic-pituitary-adrenal axis mainly diminished the corticotropin realising factor activity.
Kanaan RA, Lepine JP, Wessely SC.	King's College London, Department of Psychological Medicine, Institute of Psychiatry, London, UK.	The association or otherwise of the functional somatic syndromes.	Psychosom Med. 2007 Dec;69(9):855-9.	OBJECTIVE: To review the evidence for overlap in the phenomenology of the Functional Somatic Syndromes (FSS). The FSS show considerable comorbidity, leading some to suggest they may be aspects of the same disorder. METHODS: We conducted a selective review of peer-reviewed articles on the co-occurrence of FSS symptoms and diagnoses. RESULTS: Considerable evidence of overlap was found at the level of symptoms, diagnostic criteria, and clinical diagnoses made. CONCLUSIONS: Phenomenological commonalities support a close relationship between the FSS, although differences remain in other domains. Whether the FSS may best be considered the same or different will depend on the pragmatics of diagnosis.
Kant I, Jansen NW, van Amelsvoort LG, Huibers MJ.	Capaciteitsgroep Epidemiologie van de Universiteit Maastricht. IJ.Kant@epid.unimaas.nl	[Course, consequences and treatment of prolonged fatigue among workers: an overview of findings from the Maastricht Cohort Study] [Article in	Tijdschr Psychiatr. 2007;49(8):547-54. Comment in: Tijdschr Psychiatr. 2007;49(8):555-7.	summary background Although prolonged fatigue is a common complaint among workers, relatively little is known about its course and consequences. AIM: To present an overview of the course, consequences and treatment of prolonged fatigue in the work force. METHOD: We present an overview of the findings from the Maastricht Cohort Study, which was a prospective cohort (n=12.140) that covered a period of 4 years. results Fatigue runs an unfavourable course. In many workers symptoms of fatigue are present for a long time, and in some workers the symptoms even develop into those of chronic fatigue syndrome. The consequences of prolonged fatigue are also serious and are manifested in various ways: sick leave, work disability, accidents, immunological effects and reduction in work participation. A brief cognitive behaviour therapy administered by general

		Dutch]		practitioners to employees with prolonged fatigue proved ineffective. CONCLUSION: The severe consequences of prolonged fatigue and the current lack of effective therapies underline the importance of preventing the development of fatigue complaints, for which the Maastricht Cohort Study may provide the basic tools.
Karceski S.		Early Parkinson disease and depression.	Neurology. 2007 Jul 24;69(4):E2-3. Comment on: Neurology. 2007 Jul 24;69(4):342-7.	
Kasatkin DS, Spirin NN.	Yaroslavl State Medical Academy.	Possible mechanisms of the formation of chronic fatigue syndrome in the clinical picture of multiple sclerosis.	Neurosci Behav Physiol. 2007 Mar;37(3):215-9.	A frequent manifestation of multiple sclerosis (MS) is chronic fatigue syndrome, which can be defined as a subjective decrease in the level of physical and/or mental energy. Chronic fatigue syndrome can be divided into asthenia (fatigue at rest), pathological fatigability (fatigue on physical loading), and fatigue on the background of deterioration of other symptoms (exacerbation of MS). There are both central and peripheral mechanisms for the formation of fatigue. The combination of fatigue and affective disturbances, especially depression and sleep disorders (insomnia, restless legs syndrome) is common in MS and may provide evidence that they share common mechanisms--decreases in the activity of the serotoninergic and noradrenergic systems. An important component in the formation of chronic fatigue syndrome consists of endocrine and autoimmune factors, the latter having a greater effect on asthenia than on pathological fatigue. Further studies of the pathogenetic mechanisms of the formation of asthenia and pathological fatigue and clarification of their differential diagnostic signs should allow not only a better understanding of the nature of this syndrome, but also better selection of individual treatment.
Kawai T, Rokutan K.	Department of Stress Science, Institute of Health Biosciences, The University of Tokushima Graduate School.	[Identification and application of marker genes for differential diagnosis of chronic fatigue syndrome] [Article in Japanese]	Nippon Rinsho. 2007 Jun;65(6):1029-33.	Chronic fatigue syndrome (CFS) is a complex disease and has no laboratory biomarkers, which makes diagnosis of CFS difficult. Several research groups challenged to identify genes specific for CFS; however, there are no overlaps between studies. The U.S. Centers for Disease Control and Prevention reported remarkable gene expression profiles of a large scale cohort study recruited 227 people. Reported genes were mostly different from the previously reported genes, again featuring the complexity of CFS. Separately, we identified 9 genes that were significantly and differentially expressed between CFS patients and healthy subjects using an original microarray. The changes in expression of 9 genes were confirmed by quantitative PCR. We also demonstrated the usefulness of 9 genes for differential diagnosis of CFS.
Kent Holtorf		Diagnosis and Treatment of Hypothalamic-Pituitary-Adrenal (HPA) Axis Dysfunction in Patients with Chronic Fatigue Syndrome (CFS)	Journal of Chronic Fatigue Syndrome 2007; 14(3):	There is controversy regarding the incidence and significance of hypothalamic-pituitaryadrenal (HPA) axis dysfunction in chronic fatigue syndrome (CFS) and fibromyalgia (FM). Studies that utilize central acting stimulation tests, including CRH, IST, d-fenfluramine, ipsapirone, IL-6 and metyrapone testing, have demonstrated that HPA axis dysfunction of central origin is present in a majority of these patients. However, ACTH stimulation tests and baseline cortisol testing lack the sensitivity to detect this central dysfunction and have resulted in controversy and confusion regarding the incidence of HPA axis dysfunction in these conditions and the appropriateness of treatment. While both CFS and FM patients are shown to have central HPA dysfunction, the dysfunction in CFS appears to be at the pituitaryhypothalamic level while the dysfunction in FM is more related to dysfunction at the

		and Fibromyalgia (FM)		hypothalamic and supra-hypothalamic levels. Because treatment with low physiologic doses of cortisol (< 15 mg) has been shown to be safe and effective and routine dynamic ACTH testing does not appear to have significant diagnostic sensitivity, it is reasonable to give a therapeutic trial of physiologic doses of cortisol to the majority of patients with CFS and FM, especially to those who have symptoms that are consistent with adrenal dysfunction, have low blood pressure or have baseline cortisol levels in the low or low-normal range.
Kerr J, Burke B, Petty R, Gough J, Fear D, David M, Axford J, Dalgleish A, Nutt D.	St George's University of London, United Kingdom.	Seven genomic subtypes of Chronic Fatigue Syndrome / Myalgic Encephalomyelitis (CFS/ME): a detailed analysis of gene networks and clinical phenotypes.	J Clin Pathol. 2007 Dec 5 [Epub ahead of print]	Chronic Fatigue Syndrome / myalgic encephalomyelitis (CFS/ME) is a multisystem disease, the pathogenesis of which remains undetermined. We have recently reported a study of gene expression which identified differential expression of 88 human genes in patients with CFS/ME. Clustering of QPCR data from CFS/ME patients revealed 7 distinct subtypes with distinct differences in SF-36 scores, clinical phenotypes and severity. In this study, for each CFS/ME subtype, we determined those genes whose expression differed significantly from that of normal blood donors, and then determined gene interactions, disease associations and molecular and cellular functions of those gene sets. Genomic analysis was then related to clinical data for each CFS/ME subtype. Genomic analysis revealed some common (neurological, cancer, immunological, inflammatory, haematological) and some distinct (metabolic, endocrine, dermatological, cardiovascular, connective tissue) disease associations among the subtypes. Subtypes 1, 2 and 7 were the most severe, and subtype 3 was the mildest. Clinical features of each subtype were as follows: subtype 1 (cognitive, musculoskeletal, sleep, anxiety / depression); subtype 2 (musculoskeletal, pain, anxiety / depression); subtype 3 (mild); subtype 4 (cognitive); subtype 5 (musculoskeletal, gastrointestinal); subtype 6 (postexertional); subtype 7 (pain, infectious, musculoskeletal, sleep, neurological, gastrointestinal, neurocognitive, anxiety / depression). It is particularly interesting that in these genomically derived subtypes, there were distinct clinical syndromes and that those which were most severe were also those with anxiety / depression, as would be expected in a disease with a biological basis.

Ulvestad E.	samfunnsmedisinske fag Universitetet i Tromsø. anlui-k@online.no	and complex disease--an integrated perspective] [Article in Norwegian]	Laegeforen. 2007 Dec 13;127(24):3228-31.	growing challenge. Valid biomedical models of etiology, pathogenesis, treatment and prognosis are inadequate for understanding these diseases. The article discusses current knowledge about the impact of stress on the immune-, hormonal - and central nervous systems, and integrates this knowledge with a phenomenological understanding of the body in an attempt to explain the complex chronic fatigue syndrome. The medical significance of the individual's biography is highlighted, and the inadequacy of statistically grounded biomedical research when aiming to understand complex disease is presented. By regarding human beings as persons who experience bodily and who both create and convey meaning, we claim to have transgressed the mind-body-dichotomy in complex disease development. The dichotomy converges in the living body.
Klimas NG, Koneru AO.	University of Miami Miller School of Medicine, 1201 NW 16th Street, VA Medical Center, 200 BMRC, 6th Floor, Miami, FL 33125, USA. nancy.klimas@va.gov	Chronic fatigue syndrome: inflammation, immune function, and neuroendocrine interactions.	Curr Rheumatol Rep. 2007 Dec;9(6):482-7.	Investigations into the underlying cause of chronic fatigue syndrome have advanced the field considerably in the past year. Gene microarray data have led to a better understanding of pathogenesis. Recent research has evaluated genetic signatures, described biologic subgroups, and suggested potential targeted treatments. Acute viral infection studies found that initial infection severity was the single best predictor of persistent fatigue. Genomic studies showed that persistent cases express Epstein Barr virus-specific genes and demonstrate abnormalities of mitochondrial function. Studies of immune dysfunction extended observations of natural killer cytotoxic cell dysfunction of the cytotoxic T cell through quantitative evaluation of intracellular perforins and granzymes. Other research has focused on a subgroup of patients with reactivated viral infection. These advances should result in targeted therapies that impact immune function, hypothalamic-pituitary-adrenal axis regulation, and persistent viral reactivation.
Knoop H, Bleijenberg G, Gielissen MF, van der Meer JW, White PD.	Expert Centre Chronic Fatigue, Radboud University Nijmegen Medical Centre, Nijmegen, The Netherlands. j.knoop@nkcv.umcn.nl	Is a full recovery possible after cognitive behavioural therapy for chronic fatigue syndrome?	Psychother Psychosom. 2007;76(3):171-6.	BACKGROUND: Cognitive behavioural therapy (CBT) for chronic fatigue syndrome (CFS) leads to a decrease in symptoms and disabilities. There is controversy about the nature of the change following treatment; some suggest that patients improve by learning to adapt to a chronic condition, others think that recovery is possible. The objective of this study was to find out whether recovery from CFS is possible after CBT. METHODS: The outcome of a cohort of 96 patients treated for CFS with CBT was studied. The definition of recovery was based on the absence of the criteria for CFS set up by the Center for Disease Control (CDC), but also took into account the perception of the patients' fatigue and their own health. Data from healthy population norms were used in calculating conservative thresholds for recovery. RESULTS: After treatment, 69% of the patients no longer met the CDC criteria for CFS. The percentage of recovered patients depended on the criteria used for recovery. Using the most comprehensive definition of recovery, 23% of the patients fully recovered. Fewer patients with a co-morbid medical condition recovered. CONCLUSION: Significant improvement following CBT is probable and a full recovery is possible. Sharing this information with patients can raise the expectations of the treatment, which may enhance outcomes without raising false hopes. Copyright 2007 S. Karger AG, Basel.
Knoop H, Prins JB, Stulemeijer M, van der Meer JW, Bleijenberg G.	Expert Centre Chronic Fatigue, Radboud University Nijmegen Medical	The effect of cognitive behaviour therapy for chronic fatigue syndrome on self-	J Neurol Neurosurg Psychiatry. 2007 Apr;78(4):434-6.	BACKGROUND: Patients with chronic fatigue syndrome (CFS) often have concentration and memory problems. Neuropsychological test performance is impaired in at least a subgroup of patients with CFS. Cognitive behavioural therapy (CBT) for CFS leads to a reduction in fatigue and disabilities. AIM: To test the hypothesis that CBT results in a reduction of self-reported cognitive impairment and in an improved neuropsychological test performance. METHODS: Data of two previous randomised

	Centre, P O Box 9011, 6525 EC Nijmegen, The Netherlands. j.knoop@nkcv.umcn.nl	reported cognitive impairments and neuropsychological test performance.		controlled trials were used. One study compared CBT for adult patients with CFS, with two control conditions. The second study compared CBT for adolescent patients with a waiting list condition. Self-reported cognitive impairment was assessed with questionnaires. Information speed was measured with simple and choice reaction time tasks. Adults also completed the symbol digit-modalities task, a measure of complex attentional function. RESULTS: In both studies, the level of self-reported cognitive impairment decreased significantly more after CBT than in the control conditions. Neuropsychological test performance did not improve. CONCLUSIONS: CBT leads to a reduction in self-reported cognitive impairment, but not to improved neuropsychological test performance. The findings of this study support the idea that the distorted perception of cognitive processes is more central to CFS than actual cognitive performance.
Knoop H, Stulemeijer M, Prins JB, van der Meer JW, Bleijenberg G.	Expert Centre Chronic Fatigue, Radboud University Nijmegen Medical Centre, Post Box 9011, 6525 EC Nijmegen, The Netherlands. j.knoop@nkcv.umcn.nl	Is cognitive behaviour therapy for chronic fatigue syndrome also effective for pain symptoms?	Behav Res Ther. 2007 Sep;45(9):2034-43. Epub 2007 Mar 14.	Patients with chronic fatigue syndrome (CFS) frequently report chronic pain symptoms. Cognitive behavioural therapy (CBT) for CFS results in a reduction of fatigue, but is not aimed at pain symptoms. In this study, we tested the hypothesis that a successful treatment of CFS can also lead to a reduction of pain. The second objective was to explore possible mechanisms of changes in pain. The third objective was to assess the predictive value of pain for treatment outcome. Data from two previous CBT studies were used, one of adult CFS patients (n=96) and one of adolescent CFS patients (n=32). Pain severity was assessed with a daily self-observation list at baseline and post-treatment. The location of pain in adults was assessed with the McGill Pain Questionnaire (MPQ). Patients were divided into recovered and non-recovered groups. Recovery was defined as reaching a post-treatment level of fatigue within normal range. Recovered adult and adolescent CFS patients reported a significant reduction of pain severity compared to non-recovered patients. Recovered adult patients also had fewer pain locations following treatment. The decrease in fatigue predicted the change in pain severity. In adult patients, a higher pain severity at baseline was associated with a negative treatment outcome.
Kobelt A, Grosch E, Wasmus A, Ehlebracht-König I, Schwarze M, Krähling M, Gutenbrunner C.	Deutsche Rentenversicherung Braunschweig-Hannover, Arztlicher Dienst, Lange Weihe 2, 30880 Laatzen. axel.kobelt@drv.bsh.de	[Is it possible to predict approval of medical rehabilitation by the extent of fatigue and subjective need for rehabilitation? Development, results and acceptance of a short screening] [Article in German]	Rehabilitation (Stuttg). 2007 Feb;46(1):33-40.	OBJECTIVES: In earlier studies the lack of correlation between subjective need for rehabilitation of the applicant and the medically determined objective need for rehabilitation was reported again and again. The correlation between fatigue and subjective need for rehabilitation was not yet examined so far. Nevertheless fatigue is not defined sufficiently in the ICD, so interactions between chronic fatigue and somatic diseases are not taken into account appropriately. The following questions are considered: How high is the degree of chronic fatigue in insurees applying for rehabilitation? Is there a correlation between degree of fatigue and need for rehabilitation? Is it possible to predict approval of medical rehabilitation by fatigue and need for rehabilitation? How will insurees accept a screening accompanying their application for rehabilitation? METHOD: The study is based on data of 500 (response rate 85.6%) insurees of the pension insurance Braunschweig-Hannover, who had applied for medical rehabilitation between 1/2004 and 3/2004. The screening instrument included: scales on functional activity, mobility, social support, coping (IRES), the Chalder Fatigue Scale, SCL 14, Items concerning need for rehabilitation. As statistical methods t-, chi (2)-test, correlations, covariance-analysis and regression analysis are used. RESULTS: 70.2% of the patients claiming rehabilitation reported relevant clinical symptoms of chronic fatigue. There were no differences in age, work status, motivation, or expectations of returning to work, but differences in sex. Patients with chronic fatigue

				met more citeria of need for rehabilitation. But the approval of medical rehabilitation could not be predicted by fatigue and need for rehabilitation. Nevertheless the acceptance of the screening was high in the insurees. CONCLUSIONS: Patients with chronic fatigue met more criteria of need for rehabilitation. But the approval of medical rehabilitation could not be predicted by fatigue and need for rehabilitation. We assume that the reduction of activity and participation is associated with the degree of fatigue. It is discussed that the information an investigator may derive from a screening which is accepted by the insurees claiming medical rehabilitation will complete the collected clinical documents in a meaningful manner.
Kogelnik AM, Loomis K, Hoegh-Petersen M, Rosso F, Hischier C, Montoya JG.	Stanford University School of Medicine, Stanford, CA, USA.	Use of valganciclovir in patients with elevated antibody titers against Human Herpesvirus-6 (HHV-6) and Epstein-Barr Virus (EBV) who were experiencing central nervous system dysfunction including long-standing fatigue.	J Clin Virol. 2006 Dec;37 Suppl 1:S33-8.	BACKGROUND: Twelve patients with long-standing symptoms of central nervous system (CNS) dysfunction were found to have elevated antibody titres to human herpesvirus-6 (HHV-6) and Epstein-Barr virus (EBV). All patients had four or more of the following neurocognitive symptoms: impaired cognitive functioning, slowed processing speed, sleep disturbance, short-term memory deficit, fatigue and symptoms consistent with depression. OBJECTIVES: We sought to determine whether elevated antibodies to EBV and HHV-6 indicated chronic viral activation in patients with CNS dysfunction and if their symptoms could be improved by suppressing viral activity with oral valganciclovir. STUDY DESIGN: Patients with high IgG antibody titers against HHV-6 and EBV who were suffering from central nervous system dysfunction and debilitating fatigue for more than one year (median 3 years, range 1-8 years) were treated with 6 months of valganciclovir in an open label study. RESULTS: Nine out of 12 (75%) patients experienced near resolution of their symptoms, allowing them all to return to the workforce or full time activites. In the nine patients with a symptomatic response to treatment, EBV VCA IgG titers dropped from 1:2560 to 1:640 ($p = 0.008$) and HHV-6 IgG titers dropped from a median value of 1:1280 to 1:320 ($p = 0.271$). Clinically significant hematological toxicity or serious adverse events were not observed among the 12 patients. CONCLUSION: These preliminary clinical and laboratory observations merit additional studies to establish whether this clinical response is mediated by an antiviral effect of the drug, indirectly via immunomodulation or by placebo effect.
Komaroff AL.	Division of General Medicine, Department of Medicine, Brigham and Women's Hospital, Harvard Medical School, 10 Shattuck Street, Suite 602, Boston, MA 02115, USA. komaroff@hms.harvard.edu	Is human herpesvirus-6 a trigger for chronic fatigue syndrome?	J Clin Virol. 2006 Dec;37 Suppl 1:S39-46.	Chronic fatigue syndrome (CFS) is an illness currently defined entirely by a combination of non-specific symptoms. Despite this subjective definition, CFS is associated with objective underlying biological abnormalities, particularly involving the nervous system and immune system. Most studies have found that active infection with human herpesvirus-6 (HHV-6)--a neurotropic, gliotropic and immunotropic virus--is present more often in patients with CFS than in healthy control and disease comparison subjects, yet it is not found in all patients at the time of testing. Moreover, HHV-6 has been associated with many of the neurological and immunological findings in patients with CFS. Finally, CFS, multiple sclerosis and seizure disorders share some clinical and laboratory features and, like CFS, the latter two disorders also are being associated increasingly with active HHV-6 infection. Therefore, it is plausible that active infection with HHV-6 may trigger and perpetuate CFS in a subset of patients.
Kondo K.	Department of Virology, The Jikei University School	[Chronic fatigue syndrome and herpesvirus	Nippon Rinsho. 2007 Jun;65(6):1043-8.	Human herpesvirus 6(HHV-6) and human herpesvirus 7(HHV-7) establish life-long latency, reactivate frequently, and are shed in saliva. To identify the factor(s) of their reactivation, we have studied the association with the reactivation and fatigue. Reactivation was examined for viral DNA by real-time

	of Medicine.	reactivation] [Article in Japanese]		PCR method. As a result, healthy adults shed the reactivated HHV-6 in the saliva during work -induced fatigue, and the copy number of HHV-6 DNA was reduced after holidays. However, no significant HHV-6 DNA increase was observed in chronic fatigue syndrome (CFS) patients. In contrast, increase of HHV-7 reactivation was observed both in the case of work-induced fatigue and CFS. These findings suggest that the amount of HHV-6 and HHV-7 reactivation can be an objective biomarker for fatigue.
Kumano-go T, Adachi H, Sugita Y.	Osaka University Health Care Center.	[Sleep disturbance in chronic fatigue syndrome] [Article in Japanese]	Nippon Rinsho. 2007 Jun;65(6):1017-22.	Attempts to elucidate the complex pathophysiology of chronic fatigue syndrome (CFS) must consider subjective and objective sleep. Several reports of CFS showed the high rate of sleep disturbance such as insomnia, hypersomnia, circadian rhythm sleep disorder, sleep apnea/hypopnea syndrome and so on. To analyze pulse wave continuously in sleep of CFS patients by laser blood flowmeter, we set base line component (0.01-0.08 Hz) and pulse wave component(0.70-1.50 Hz). Results of FFT analysis indicate that the CFS can have at least three subtypes of pulse dynamics in sleep. There probably are different types of illnesses now contained within the CFS construct, in which identifying subtypes of sleep disturbance can be one important key.
Kumor K, Pierzchała K.	Z Katedry i Kliniki Neurologii w Zabrzu Slaskiej Akademii Medycznej w Katowicach. kum2@poczta.onet.pl	[The problem of fatigue in neurological disorders] [Article in Polish]	Wiad Lek. 2006;59(9-10):685-91.	Fatigue or piercing feeling of weakness, lack of strength and energy or total exhaustion is a common complaint of patients with neurological disorders. From 40 to over 90 per cent of individuals with multiple sclerosis, Parkinson disease, amyotrophic lateral sclerosis, neuroboreliosis, post polio syndrome or stroke confirm its experience. It is not infrequently numbered among most disabling complaints. A separate entity, with fatigue as a cardinal sign, is a chronic fatigue syndrome, a disorder, though controversial, more and more frequently diagnosed. Fatigue ought to be discriminated from fatigability, paresis, somnolence and, first of all depression which commonly coexists in chronic disorders. The assessment is almost entirely based on self-estimate scales filled in by a patient. Attainable results of neuroimaging, electrophysiological, polisomnographic, vegetative, psychological and biochemical surveys have not allowed yet to define the pathogenesis of fatigue. The treatment basis consists of behavioral therapy, psychotherapy and a proper treatment of the basic disease.
Kuo DZ, Cheng TL, Rowe PC.	Maple Avenue Pediatrics, Fair Lawn, New Jersey, USA. dkuo5@jhmi.edu	Successful use of a primary care practice-specialty collaboration in the care of an adolescent with chronic fatigue syndrome.	Pediatrics. 2007 Dec;120(6):e1536-9.	We report on the successful collaborative care of an adolescent with chronic fatigue syndrome between a primary care pediatrician and an academic chronic fatigue syndrome specialist located in different cities. Regular telephone and e-mail communication and clearly defined patient-care roles allowed for timely management of symptoms and marked clinical improvement. We discuss ways to improve the collaboration of primary care and subspecialty physicians for patients with chronic fatigue syndrome and children with special health care needs.
Kuratsune H.	Faculty of Health Science for Welfare, Kansai University of Welfare Sciences.	[Overview of chronic fatigue syndrome focusing on prevalence and diagnostic criteria] [Article in Japanese]	Nippon Rinsho. 2007 Jun;65(6):983-90.	Chronic fatigue syndrome (CFS) is an operational concept proposed by Centers for Disease Control and Prevention to clarify the unknown etiology of the syndrome characterized by the sensation of abnormally prolonged fatigue. Lots of investigators reported various abnormalities such as virus infection, immune abnormalities, HPA axis abnormalities, metabolic abnormalities, etc., but there are a few abnormalities common to vast majority cases of CFS. Therefore, lots of people as well as medical doctors are still skeptical about the presence of CFS. However, recent studies reveal that CFS can be understood to be a special condition based on the abnormality of neuroendocrine-immunologic system caused by the psycho-social stress and some genetic components. Under these conditions, a

				reactivation of various kinds of herpes virus infections and/or chronic infections might occur as a result of immune dysfunction, causing the abnormal production of several cytokines. A distinctive feature of CFS is thought to be the secondary brain dysfunction caused by the abnormal production of several cytokines. In this paper, I show the overview of CFS focusing around prevalence, economic impact and diagnostic criteria in Japan.
Langelaan M, de Boer MR, van Nispen RM, Wouters B, Moll AC, van Rens GH.	Department of Ophthalmology, VU University Medical Center, Amsterdam, and Elkerliek Hospital, Helmond, The Netherlands. maaikelangelaan@visio.org	Impact of visual impairment on quality of life: a comparison with quality of life in the general population and with other chronic conditions.	Ophthalmic Epidemiol. 2007 May-Jun;14(3):119-26.	PURPOSE: Subjective evaluation of health-related quality of life (HRQoL) and health status is recognized as an important tool in the assessment and treatment of visually impaired patients. The aims of this study are to describe the generic HRQoL and health status of visually impaired patients and to compare the HRQoL of visually impaired patients with that of both the general population of the Netherlands and patients with other chronic conditions. METHODS: 128 persons attending a rehabilitation centre for visually impaired adults completed the EuroQol questionnaire (EQ-5D). These patients' EQ-5D scores were compared with EQ-5D norms of the Dutch population and of patients with other chronic conditions; both sets of data were taken from the literature. RESULTS: The average EQ-5Dindex score of the total study population was 0.73 (SD 0.22). Visually impaired patients reported more problems on every dimension of the EQ-5D than the general Dutch population. Only stroke patients and patients with chronic fatigue syndrome and reported more problems on every dimension of the EQ-5D than visually impaired patients. CONCLUSIONS: Visual impairment has a substantial impact on the quality of life; compared with other chronic conditions, it seems to affect the HRQoL, spoiling the quality of life more than diabetes type II, coronary syndrome, and hearing impairments, but less than stroke, multiple sclerosis, chronic fatigue syndrome, major depressive disorder, and severe mental illness.
Larun L, Malterud K.	Norwegian Knowledge Centre for the Health Services, Norway. lillebeth.larun@kunnskapssenteret.no	Identity and coping experiences in Chronic Fatigue Syndrome: a synthesis of qualitative studies.	Patient Educ Couns. 2007 Dec;69(1-3):20-8. Epub 2007 Aug 14.	OBJECTIVE: To provide insight into patients' and doctors' experiences with CFS. METHODS: We compiled available qualitative studies and applied meta-ethnography to identify and translate across the studies. Analysis provided second-order interpretation of the original findings and developed third-order constructs from a line of arguments. RESULTS: Twenty qualitative studies on CFS experiences were identified. Symptom experiences and the responses from significant others could jeopardise the patients' senses of identity. They felt severely ill, yet blamed and dismissed. Patients' beliefs and causal attributions oppose the doctor's understanding of the condition. For the patient, getting a diagnosis and knowing more was necessary for recovery. Doctors were reluctant towards the diagnosis, and struggle to maintain professional authority. For patients, experience of discreditation could lead to withdrawal and behavioural disengagement. CONCLUSION: The identities of CFS patients are challenged when the legitimacy of their illness is questioned. This significant burden adds to a loss of previously established identity and makes the patient more vulnerable than just suffering from the symptoms. CFS patients work hard to cope with their condition by knowing more, keeping a distance to protect themselves and learning more about their limits. PRACTICE IMPLICATIONS: Doctors can support patients' coping by supporting the strong sides of the patients instead of casting doubt upon them.
Le Bon Olivier MD, PhD, Daniel Neu MD, Filomena		HUParadoxical Nrems Distribution in "Pure" Chronic	Journal of Chronic Fatigue Syndrome 2007; 14(2): 45-59	Objective: The chronic fatigue syndrome (CFS) is a debated clinical entity, not presently associated with specific sleep abnormalities. However, higher levels of deep sleep and/or lower levels of light sleep have been reported in several all-night polysomnography studies in CFS patients. This

Valente PhD, Paul		Fatigue PAtients A Comparison With Sleep Apnea-Hypopnea Patients and Healthy Control Subjects UH		distribution of Non-Rapid Eye Movement Sleep (NREMS) contrasts with what would be expected if sleep was interrupted by microawakenings, such as in sleep apneas or periodic limb movements, where more light sleep and less deep sleep are commonly observed. This "paradoxical" distribution of NREMS could represent a characteristic feature of chronic fatigue and deserved to be investigated. Methods: A retrospective comparison of the NREMS distribution was performed between 28 "pure" Chronic Fatigue Syndrome patients (without primary sleep or psychiatric disorders), 27 Apneic-Hypopneic patients and 27 Healthy Controls. Results: Data showed CFS patients to have a higher stage 4/stage 2 or stage 4/light sleep ratios than the other two conditions. Conclusion: This sleep pattern is closer to what is observed in cases of infections than to what is seen after sleep fragmentation by primary sleep or in psychiatric disorders. Such a particular sleep pattern could provide insights into the pathophysiology of fatigue.
Ledina D, Bradarić N, Milas I, Ivić I, Brncić N, Kuzmicić N.	Department of Infectious Diseases, Split University Hospital, Split, Croatia. dledina@krizine.kbsplit.hr	Chronic fatigue syndrome after Q fever.	Med Sci Monit. 2007 Jul;13(7):CS88-92.	BACKGROUND: Q fever is a common and acute but rare chronic zoonosis caused by Coxiella burnetii. Its acute form manifests as atypical pneumonia, flu-like syndrome, or hepatitis. Some authors observed symptoms of chronic fatigue in a small number of patients after the acute phase of Q fever; in many cases serological assay confirmed the activity of Coxiella burnetii infection. The effect of antibiotic therapy on post-Q-fever fatigue syndrome has not been studied in south-east Europe thus far. CASE REPORTS: Three patients are presented with post-Q-fever fatigue syndrome. All fulfilled the CDC criteria for chronic fatigue syndrome. IgA antibodies to phase I of the growth cycle of Coxiella burnetii were positive in two patients and negative in one. Two patients were treated with doxycycline for two weeks in the acute phase of illness and one with a combination of erythromycin and gentamycin. After 4-12 months they developed post-Q-fever fatigue syndrome and were treated with intracellular active antibiotics (fluoroquinolones and tetracycline) for 3-12 months. Efficacy of the treatment was observed in two patients, but in one patient the results were not encouraging. CONCLUSIONS: These results suggest the possibility of the involvement of Coxiella burnetii infection in the evolution of chronic fatigue syndrome. This is the first report on post-Q-fever fatigue syndrome in Mediterranean countries. Evidence of IgA antibodies to phase I of the growth cycle of Coxiella burnetii is not a prerequisite for establishing a diagnosis of CFS. The recommendation of antibiotic treatment in post-Q-fever fatigue syndrome requires further investigation.
Leiblum S, Seehuus M, Goldmeier D, Brown C.	UNDNJ-Robert Wood Johnson Medical School-Psychiatry, Piscataway, NJ 08854, USA. leiblum@umdnj.edu	Psychological, medical, and pharmacological correlates of persistent genital arousal disorder.	J Sex Med. 2007 Sep;4(5):1358-66. Epub 2007 Aug 2.	INTRODUCTION: Little is known about the etiology or medical/psychological correlates of persistent genital arousal disorder (PGAD). AIM: The aims of this article were (i) to replicate the findings of earlier research identifying two subtypes of women with persistent arousal-those who meet all features of the condition and are at least moderately distressed, and those who meet only some features and are less distressed; and (ii) to identify the medical, psychological and/or pharmacological correlates of the condition. METHOD: A comprehensive web-based survey of persistent genital arousal (PGA) was posted on several Internet websites. Of the 156 women who completed the survey, 76 met all five features qualifying for a persistent genital arousal disorder (PGAD) group, and 48 met only some features (non-PGAD group). MAIN OUTCOME MEASURES: The main outcome measures were endorsement of diagnostic signs of depression, anxiety, obsessive-compulsive disorder, and panic attack as well as medical illnesses and pharmacological preparations. RESULTS: Compared to non-PGA subjects, women with PGA were significantly more likely to be depressed (55% vs. 38%) and to report
