				panic attacks (31.6% vs. 14.6%). They were more anxious and more likely to monitor their physical sensations. Both groups reported high rates of childhood and adult sexual abuse, although the PGA women reported a higher prevalence of sexual victimization. They were significantly more likely to endorse negative feelings about their genital sensations and also more likely to complain of chronic fatigue syndrome than women without the condition (10% vs. 0%). There were no significant relationships with pharmacologic agents and symptoms. CONCLUSIONS: Women who met all the criteria of PGAD were more likely than women who only met some of the criteria to report depression, anxiety, panic attacks, and certain obsessive-compulsive symptoms such as monitoring their physical sensations. It is hypothesized that for a subset of women, psychological factors, namely anxiety, reinforce exacerbate and maintain PGAD.
Lerdal A, Celius EG, Krupp L, Dahl AA.	Department of Health, Buskerud University College, Drammen, Norway. Anners.Lerdal@hibu.no	A prospective study of patterns of fatigue in multiple sclerosis.	Eur J Neurol. 2007 Dec;14(12):1338-43. Epub 2007 Sep 26.	We sought to identify clinical characteristics and socio-demographic variables associated with longitudinal patterns of fatigue in multiple sclerosis (MS) patients. A questionnaire including the Fatigue Severity Scale (FSS) was mailed to a community sample of 502 MS patients three times 1 year apart. Three patterns of fatigue were defined: persistent fatigue (PF) (mean FSS score > or = 5 at all time-points), sporadic fatigue (SF) (mean FSS score > or = 5 at one or two time-points) and no fatigue (mean FSS score < 5 at all time-points). Among the 267 (53%) patients who responded at all time-points, 101 [38%, 95% confidence intervals (CI) 32-44] had persistent, 98 (37%, 95% CI 31-43) sporadic and 68 (25%, 95% CI 20-31) no fatigue. Persistent and sporadic fatigue were more common in patients with, increased neurological impairment (P < 0.001), primary progressive MS (P = 0.01), insomnia (P < 0.001), heat sensitivity (P < 0.001), sudden-onset fatigue (P < 0.001) or mood disturbance (P < 0.001) compared with patients without fatigue. Multivariable analysis showed that depression (PF P = 0.02, SF P < 0.001), heat sensitivity (PF P = 0.04, SF P = 0.02) and physical impairment (PF P = 0.004, SF P = 0.01) were associated with both sporadic and persistent fatigue. About 75% of the patients had persistent or sporadic fatigue over a 2 years observation period. Multivariable analyses confirmed a significant association between levels of depression, physical impairment and persistent fatigue.
Lerner AM, Beqaj SH, Deeter RG, Fitzgerald JT.	Department of Medicine, William Beaumont Hospital, Royal Oak, MI, USA. amartinlerner@yahoo.com	Valacyclovir treatment in Epstein-Barr virus subset chronic fatigue syndrome: thirty-six months follow-up.	In Vivo. 2007 Sep-Oct;21(5):707-13.	BACKGROUND: We hypothesized that subset classification of Epstein-Barr virus (EBV) in chronic fatigue syndrome (CFS) is required. At first, a blinded-random placebo-controlled trial of valacyclovir in EBV CFS subset was performed (Group 1), and this EBV subset was followed for thirty-six months (Group 2). Patients were given valacyclovir at 14.3 mg/kg every 6 hours. The validated Energy Index (EI) point score assessing physical functional capacity, Holter monitor, multigated (radionuclide) MUGA rest/stress ventriculographic examination, EBV serum IgM viral capsid antibodies (VCA), and EBV early antigen diffuse (EA) were followed. After six-months, Group 1 CFS patients receiving valacyclovir experienced an increased mean least square EI point score +1.12 units (122 kcal/day), while the placebo cohort increased +0.42 EI units (65 kcal/day). EI point scores at Group 2 increased progressively. Sinus tachycardias decreased and abnormal cardiac wall motion improved. Serum antibody titers to EBV VCA IgM decreased. Patients resumed normal activities.
Linde A.	Abteilung für Psychosomatik, Bereich Medizin, Universitätsspital	[Chronic fatigue syndrome--a functional somatic syndrome] [Article	Ther Umsch. 2007 Oct;64(10):567-74.	Chronic fatigue can be categorized as a functional somatic syndrome (fss), because there are findings of typical preconditions, trigger mechanisms and maintaining conditions. With relevance for therapy it makes sense to see it as an medical-psychiatric interface-disorder Subsyndromal short episodes of chronic fatigue are many more frequent as three or six month during clearly diagnosed episodes of

	Basel. alinde@uhbs.ch	in German]		"neurasthenia" or "chronic fatigue syndrome". Their descriptions are very similar and obvious those means the same matter. For original aetiological assumptions it wasn't any evidence. But there are findings of charcteristical patterns of changed neurhumeral and immunological interactions for the chronic fatigue syndrome, common for fss. Especially changes of HPA-Axis and its interactions with other systems of functional regulation. Another importent fact are increased senzitation in neuronal and neurocognitive regulation. Increased critical appraisal of somatic funtions and dysfunctional coping strategies are maintaining factors at least. Patterns of dysfuntional coping are not a problem of patients alone. There are also experiences, that some doctors shows the same dysfunctional somatizing management of fss in general and especially for chronic fatigue. In fact, a single and specific cause of chronic fatigue doesn't exist. But the above-mentioned facts allows a starting point for a more successful treatment. There are reviews that shows a good evidence for therapeutic procedures wich are calling for acticvity by patients, such cognitive behavioral therapy and graduated activation. Antidepressants, especialy SSRI, are helpful with a small evidence. They can be used to increase treatment effects. There is no evidence for therapies without patients activation.
Lu Tony V. Susan R. Torres-Harding, Leonard A Jason		HUThe Effectiveness of Early Educational Intervention in Improving Future Physicians' Attitudes Regarding CFS/FM UH	Journal of Chronic Fatigue Syndrome 2007; 14(2): 25-30	Objective: To assess the effects of an early educational intervention program's ability to alter the perceptions and attitudes of future physicians regarding chronic fatigue syndrome/fibromyalgia (CFS/FM), improve their understanding and acceptance of these diseases, make them feel more comfortable in diagnosing and treating patients. Method: Third-year medical students were surveyed before and after an educational intervention program. The three questions posed to the students in the survey were: (1) How comfortable do you feel you are in diagnosing and treating patients with CFS /FM?, (2) Do you consider CFS/FM legitimate illnesses?, and (3) Do you want to treat patients with CFS/FM? Results: The educational intervention program helped about half of the future physicians feel comfortable in diagnosing and treating patients with CFS/FM and improved by over 25% their willingness to treat patients with CFS. Conclusion: An educational intervention program appeared to improve future physicians' understanding and appreciation of CFS/FM, made them feel more comfortable diagnosing and treating these diseases, and increased their willingness to treat patients with CFS/FM.
Maes M, Coucke F, Leunis JC.	MCare4U Outpatient Clinics, Belgium. crc.mh@telenet.be	Normalization of the increased translocation of endotoxin from gram negative enterobacteria (leaky gut) is accompanied by a remission of chronic fatigue syndrome.	Neuro Endocrinol Lett. 2007 Dec;28(6):739-44.	There is now evidence that chronic fatigue syndrome (CFS) is accompanied by an increased translocation of endotoxins from gram-negative enterobacteria through the gut wall, as demonstrated by increased prevalences and median values for serum IgM and IgA against the endotoxins of gram-negative enterobacteria. This condition can also be described as increased gut permeability or leaky gut and indicates intestinal mucosal dysfunction (IMD). Here we report a case of a 13 year old girl with CFS who showed very high values for serum IgM against the LPS of some enterobacteria and signs of oxidative and nitrosative stress, activation of the inflammatory response system, and IgG3 subclass deficiency. Upon treatment with specific antioxidants and a "leaky gut diet", which both aim to treat increased gut permeability, and immunoglobins intravenously, the increased translocation of the LPS of gram negative enterobacteria normalized and this normalization was accompanied by a complete remission of the CFS symptoms.
Maes M, Mihaylova I,	MCare4U Outpatient Clinics,	Not in the mind of neurasthenic	Neuro Endocrinol Lett. 2007	There is now some evidence that chronic fatigue syndrome is accompanied by an activation of the inflammatory response system and by increased oxidative and nitrosative stress. Nuclear factor kappa

Bosmans E.	Olmenlaan 9, 2610 Wilrijk, Belgium. crc.mh@telenet.be	lazybones but in the cell nucleus: patients with chronic fatigue syndrome have increased production of nuclear factor kappa beta.	Aug;28(4):456-62.	beta (NFkappabeta) is the major upstream, intracellular mechanism which regulates inflammatory and oxidative stress mediators. In order to examine the role of NFkappabeta in the pathophysiology of CFS, this study examines the production of NFkappabeta p50 in unstimulated, 10 ng/mL TNF-alpha (tumor necrosis factor alpha) and 50 ng/mL PMA (phorbolmyristate acetate) stimulated peripheral blood lymphocytes of 18 unmedicated patients with CFS and 18 age-sex matched controls. The unstimulated (F=19.4, df=1/34, p=0.0002), TNF-alpha-(F=14.0, df=1/34, p=0.0009) and PMA-(F=7.9, df=1/34, p=0.008) stimulated production of NFkappabeta were significantly higher in CFS patients than in controls. There were significant and positive correlations between the production of NFkappabeta and the severity of illness as measured with the FibroFatigue scale and with symptoms, such as aches and pain, muscular tension, fatigue, irritability, sadness, and the subjective feeling of infection. The results show that an intracellular inflammatory response in the white blood cells plays an important role in the pathophysiology of CFS and that previous findings on increased oxidative stress and inflammation in CFS may be attributed to an increased production of NFkappabeta. The results suggest that the symptoms of CFS, such as fatigue, muscular tension, depressive symptoms and the feeling of infection reflect a genuine inflammatory response in those patients. It is suggested that CFS patients should be treated with antioxidants, which inhibit the production of NFkappabeta, such as curcumin, N-Acetyl-Cysteine, quercitin, silimarin, lipoic acid and omega-3 fatty acids.
Maes M, Mihaylova I, Kubera M, Bosmans E.	MCare4U Outpatient Clinics, Olmenlaan 9, 2610 Wilrijk, Belgium. crc.mh@telenet.be	Not in the mind but in the cell: increased production of cyclo-oxygenase-2 and inducible NO synthase in chronic fatigue syndrome.	Neuro Endocrinol Lett. 2007 Aug;28(4):463-9.	Chronic fatigue syndrome (CFS) is a medically unexplained disorder, characterized by profound fatigue, infectious, rheumatological and neuropsychiatric symptoms. There is, however, some evidence that CFS is accompanied by signs of increased oxidative stress and inflammation in the peripheral blood. This paper examines the role of the inducible enzymes cyclo-oxygenase (COX-2) and inducible NO synthase (iNOS) in the pathophysiology of CFS. Toward this end we examined the production of COX-2 and iNOS by peripheral blood lymphocytes (PBMC) in 18 CFS patients and 18 normal volunteers and examined the relationships between those inflammatory markers and the severity of illness as measured by means of the FibroFatigue scale and the production of the transcription factor nuclear factor kappa beta (NFkappabeta). We found that the production of COX-2 and iNOS was significantly higher in CFS patients than in normal controls. There were significant and positive intercorrelations between COX-2, iNOS and NFkappabeta and between COX-2 and iNOS, on the one hand, and the severity of illness, on the other. The production of COX-2 and iNOS by PBMCs was significantly related to aches and pain, muscular tension, fatigue, concentration difficulties, failing memory, sadness and a subjective experience of infection. The results suggest that a) an intracellular inflammatory response in the white blood cells plays an important role in the pathophysiology of CFS; b) the inflammatory response in CFS is driven by the transcription factor NFkappabeta; c) symptoms, such as fatigue, pain, cognitive defects and the subjective feeling of infection, indicates the presence of a genuine inflammatory response in CFS patients; and d) CFS patients may be treated with substances that inhibit the production of COX-2 and iNOS.
Maes M, Mihaylova I, Leunis JC.	MCare4U Outpatient Clinics, Belgium. crc.mh@telenet.be	Increased serum IgM antibodies directed against phosphatidyl	Neuro Endocrinol Lett. 2007 Dec;28(6):861-7.	Major depression and chronic fatigue syndrome (CFS) are accompanied by signs of oxidative and nitrosative stress (O&NS) and an inflammatory response. Phosphatidyl inositol (Pi) is thought to play a role in depression. The aim of the present study is to examine whether depression and CFS are characterized by an IgM-mediated immune response directed against Pi. Toward this end, this study

		inositol (Pi) in chronic fatigue syndrome (CFS) and major depression: evidence that an IgM-mediated immune response against Pi is one factor underpinning the comorbidity between both CFS and depression.		examines the serum IgM antibodies directed against Pi in 14 patients with major depression, 14 patients with CFS, 14 subjects with partial CFS, and in 11 normal controls. We found that the prevalence and mean value for the serum IgM levels directed against Pi were significantly greater in patients with major depression and CFS than in normal controls and patients with partial CFS. There were significant and positive correlations between serum IgM levels directed against Pi and two symptoms of the FibroFatigue Scale, i.e. fatigue and depression. The results show that an IgM-related immune response directed against Pi may occur in both depression and CFS and may play a role in the pathophysiology of the key symptom of CFS and major depression. It is suggested that the above disorders in Pi result from increased O&NS in both depression and CFS. Autoanti-Pi antibodies may have biological effects, for example, by changing inositol 1,4,5-triphosphate (IP3), phosphatidylinositol-4,5-bisphosphate (PIP2), diacylglycerol and phosphatidylinositol-3,4,5-triphosphate (PIP3) production, thus interfering with intracellular signalling processes. Future research in major depression and CFS should focus on the functional consequences of the immune responses directed against Pi.
Majer M, Jones JF, Unger ER, Solomon Youngblood L, Decker MJ, Gurbaxani B, Heim C, Reeves WC.		Perception versus polysomnographic assessment of sleep in CFS and non-fatigued control subjects: results from a population-based study.	BMC Neurol. 2007 Dec 5;7(1):40 [Epub ahead of print]	ABSTRACT: BACKGROUND: Complaints of unrefreshing sleep are a prominent component of chronic fatigue syndrome (CFS); yet, polysomnographic studies have not consistently documented sleep abnormalities in CFS patients. We conducted this study to determine whether alterations in objective sleep characteristics are associated with subjective measures of poor sleep quality in persons with CFS. METHODS: We examined the relationship between perceived sleep quality and polysomnographic measures of nighttime and daytime sleep in 35 people with CFS and 40 non-fatigued control subjects, identified from the general population of Wichita, Kansas and defined by empiric criteria. Perceived sleep quality and daytime sleepiness were assessed using clinical sleep questionnaires. Objective sleep characteristics were assessed by nocturnal polysomnography and daytime multiple sleep latency testing. RESULTS: Participants with CFS reported unrefreshing sleep and problems sleeping during the preceding month significantly more often than did non-fatigued controls. Participants with CFS also rated their quality of sleep during the overnight sleep study as significantly worse than did control subjects. Control subjects reported significantly longer sleep onset latency than latency to fall asleep as measured by PSG and MSLT. There were no significant differences in sleep pathology or architecture between subjects with CFS and control subjects. CONCLUSION: People with CFS reported sleep problems significantly more often than control subjects. Yet, when measured these parameters and sleep architecture did not differ between the two subject groups. A unique finding requiring further study is that control, but not CFS subjects, significantly over reported sleep latency suggesting CFS subjects may have an increased appreciation of sleep behaviour that may contribute to their perceived sleep problems.
Malaguarnera M, Gargante MP, Cristaldi E, Colonna V, Messano M, Koverech A, Neri	Centro di Ricerca "La Grande Senescenza", Università degli Studi di Catania, Via Messina 829, I-	Acetyl l-carnitine (ALC) treatment in elderly patients with fatigue.	Arch Gerontol Geriatr. 2007 Jul 19 [Epub ahead of print]	Fatigue is one of the conditions most frequently complained by the elderly. There are few effective treatment options for patients with chronic fatigue syndrome. To determine the efficacy, tolerability and impact on the fatigue, as well as on cognitive and functional status of elderly subjects with acetyl l-carnitine (ALC), 96 aged subjects (>70 years, range 71-88) were investigated (50 females and 46 males; mean age 76.2+/-7.6 and 78.4+/-6.4 years, respectively). They met four or more of the Holmes major criteria or at least six of Fukuda minor criteria. Fatigue was measured with the Wessely and

S, Vacante M, Cammalleri L, Motta M.	95126 Catania, Italy.			Powell [Wessely, S., Powell, R., 1989. Fatigue syndromes: a comparison of chronic postviral fatigue with neuromuscular and affective disorders. J. Neurol. Neurosurg. Psychiatry 52, 940-948] scores, with the fatigue severity scale. At the end of the treatment, we observed a decrease of physical fatigue: 6.2 ($p<0.001$), of mental fatigue: 2.8 ($p<0.001$), of severity fatigue: 21.0 ($p<0.001$) and improvements in functional status: 16.1 ($p<0.001$) and cognitive functions: 2.7 ($p<0.001$). By the end of the treatment, significant differences between the two groups were found for the following parameters: muscle pain -27% versus -3% ($p<0.05$); prolonged fatigue after exercise: 51% versus -4% ($p<0.0001$); sleep disorders: 28% versus 4% ($p<0.05$); physical fatigue: 7 versus -0.5 ($p<0.0001$); mental fatigue: -3.3 versus 0.6 ($p<0.0001$); fatigue severity scale: -22.5 versus 1.2 ($p<0.0001$); functional status 17.1 versus 0.6 ($p<0.0001$); mini mental state examination (MMSE) improvements: 3.4 versus 0.5 ($p<0.0001$). Our data show that administering ALC may reduce both physical and mental fatigue in elderly and improves both the cognitive status and physical functions.
Malouff JM, Thorsteinsson EB, Rooke SE, Bhullar N, Schutte NS.	University of New England, Armidale, Australia.	Efficacy of cognitive behavioral therapy for chronic fatigue syndrome: A meta-analysis.	Clin Psychol Rev. 2007 Nov 1 [Epub ahead of print]	A meta-analysis of the efficacy of cognitive behavioral therapy (CBT) in treating chronic fatigue included 15 effect sizes for between-group outcome comparisons. Across analyses, which included a total of 1371 participants, there was a significant difference, d=0.48, in post-treatment fatigue between participants receiving CBT and those in control conditions. Results indicate that CBT for chronic fatigue syndrome tends to be moderately efficacious. Dropout rates in CBT varied from 0-42%, with a mean of 16%. In the five studies that reported the number of CBT clients who were no longer in the clinical range with regard to fatigue at the latest follow-up, the percentage varied from 33% to 73% of those assigned to CBT, with a mean of 50%. Moderator results suggest directions for future investigations.
Maquet D, Demoulin C, Croisier JL, Crielaard JM.	Department of Motricity Sciences, University of Liege, ISEPK, B21, allée des sports 4, 4000 Liege, Belgium. D.Maquet@ulg.ac.be	Benefits of physical training in fibromyalgia and related syndromes. [Article in English, French]	Ann Readapt Med Phys. 2007 Jul;50(6):363-8, 356-62. Epub 2007 Apr 13.	OBJECTIVE: To review the published information on physical training for fibromyalgia (FM) and related syndromes. METHODS: A search of Medline literature (via Ovid and PubMed) with the following keywords: FM, chronic fatigue syndrome, therapy, rehabilitation, aerobic, exercise, and cognitive behavioral therapy. The reference lists of articles were examined for additional related articles. RESULTS: Several studies investigated the benefits of graded exercise therapy for patients with FM or related syndromes. Although some systematic reviews have not established an unequivocal benefit of physical training, most authors report a benefit for patients with chronic pain or fatigue. Ideally, such a therapy should be a part of multidisciplinary program. Muscular rehabilitation is reserved for preventing the deconditioning syndrome often reported in patients and the vicious cycle of pain, avoidance and inactivity behaviors, or even kinesiophobia, deconditioning, incapacity and psychological distress. CONCLUSION: This review emphasizes the relevance of graded physical training for treating FM and related syndromes. The development of rehabilitation centers, with experts able to propose a relevant therapy to patients with chronic pain or fatigue, should help alleviate this public health problem.
Martin A, Chalder T, Rief W, Braehler E.	Section for Clinical Psychology and Psychotherapy, Philipps University, Marburg,	The relationship between chronic fatigue and somatization syndrome: a	J Psychosom Res. 2007 Aug;63(2):147-56.	OBJECTIVE: The objective of this study was to assess the prevalence of chronic fatigue (CF) and its association with somatization syndrome [Somatization Syndrome Index (SSI) 4/6: >/=4 somatoform symptoms in men, 6 in women] in the general population. METHODS: A representative sample of the German population (N=2412) completed a fatigue questionnaire and a screening instrument for current somatoform symptoms (Screening for Somatoform Symptoms 7). RESULTS: The prevalence

	Germany. martin@staff.uni-marburg.de	general population survey.		rate of CF was 6.1% (n=147). Females were affected significantly more often as compared with males (7% vs. 5.1%). The mean number of somatoform symptoms was higher in CF cases than in control subjects without CF (11 vs. 2; P<.001). Seventy-two percent of the subjects with CF fulfilled the SSI4/6 criterion for somatization syndrome. Quality of life (EUROHIS-QOL and 8-item Short-Form Health Survey) and well-being (5-item WHO Well-Being Index) were markedly decreased in CF and SSI4/6. The results of regression analyses suggest that fatigue and somatization severity had a similar impact on quality of life. CONCLUSIONS: The results suggest that CF is relevant in the general population. Its substantial overlap with somatization syndrome supports the hypothesis that the two syndromes are only partially different manifestations of the same underlying processes.
Martinez-Lavin M, Infante O, Lerma C.	National Institute of Cardiology, Mexico City, Mexico.	Hypothesis: The Chaos and Complexity Theory May Help our Understanding of Fibromyalgia and Similar Maladies.	Semin Arthritis Rheum. 2008 Feb;37(4):260-4. Epub 2007 Jun 14.	BACKGROUND: Modern clinicians are often frustrated by their inability to understand fibromyalgia and similar maladies since these illnesses cannot be explained by the prevailing linear-reductionist medical paradigm. OBJECTIVE: This article proposes that new concepts derived from the Complexity Theory may help understand the pathogenesis of fibromyalgia, chronic fatigue syndrome, and Gulf War syndrome. METHODS: This hypothesis is based on the recent recognition of chaos fractals and complex systems in human physiology. RESULTS: These nonlinear dynamics concepts offer a different perspective to the notion of homeostasis and disease. They propose that the essence of disease is dysfunction and not structural damage. Studies using novel nonlinear instruments have shown that fibromyalgia and similar maladies may be caused by the degraded performance of our main complex adaptive system. This dysfunction explains the multifaceted manifestations of these entities. CONCLUSIONS: To understand and alleviate the suffering associated with these complex illnesses, a paradigm shift from reductionism to holism based on the Complexity Theory is suggested. This shift perceives health as resilient adaptation and some chronic illnesses as rigid dysfunction.
Masuda A, Munemoto T, Tei C.	Masuda Clinic.	[A new treatment: thermal therapy for chronic fatigue syndrome] [Article in Japanese	Nippon Rinsho. 2007 Jun;65(6):1093-8.	Thermal therapy using far-infrared ray dry sauna was performed for patients with chronic fatigue syndrome (CFS). Symptoms such as fatigue, pain, and low-grade fever were dramatically improved on two patients. And prednisolone administration was discontinued and became socially rehabilitated 6 months after discharge. On other 11 patients with CFS, physical symptoms such as fatigue and pain improved, too. Furthermore, we reported that repeated thermal therapy had relaxation effect and diminishes appetite loss and subjective complaints in mildly depressed patients. These results suggest that repeated thermal therapy may be a promising method for the treatment of CFS.
Mihaylova I, DeRuyter M, Rummens JL, Bosmans E, Maes M.	MCare4U Outpatient Clinics, Olmenlaan 9, 2610 Wilrijk, Belgium. crc.mh@telenet.be	Decreased expression of CD69 in chronic fatigue syndrome in relation to inflammatory markers: evidence for a severe disorder in the early activation of T lymphocytes and	Neuro Endocrinol Lett. 2007 Aug;28(4):477-83.	There is some evidence that patients with chronic fatigue syndrome (CFS) suffer from immune abnormalities, such as immune activation and decreased immune cell responsivity upon polyclonal stimili. This study was designed to evaluate lymphocyte activation in CFS by using a CD69 expression assay. CD69 acts as a costimulatory molecule for T- and natural killer (NK) cell activation. We collected whole blood from CFS patients, who met CDC criteria, and healthy volunteers. The blood samples were stimulated with mitogens during 18 h and the levels of activated T and NK cells expressing CD69 were measured on a Coulter Epics flow cytometer using a three color immunofluorescence staining protocol. The expression of the CD69 activation marker on T cells (CD3+, CD3+CD4+, and CD3+CD8+) and on NK cells (CD45+CD56+) was significantly lower in CFS patients than in healthy subjects. These differences were significant to the extent that a significant diagnostic performance was obtained, i.e. the area under the ROC curve was around 89%. No differences either in the number of leukocytes or

		natural killer cells.		in the number or percentage of lymphocytes, i.e. CD3, CD4, CD8 and CD19, could be found between CFS patients and the controls. Patients with CFS show defects in T- and NK cell activation. Since induction of CD69 surface expression is dependent on the activation of the protein kinase C (PKC) activation pathway, it is suggested that in CFS there is a disorder in the early activation of the immune system involving PKC.
Miike T.	Department of Child Development, Faculty of Medical and Pharmaceutical Sciences, Kumamoto University Graduate School.	[Childhood chronic fatigue syndrome] [Article in Japanese]	Nippon Rinsho. 2007 Jun;65(6):1099-104.	Chronic fatigue syndrome in childhood and adolescents(CCFS) is a complex and debilitation with severe morbidity and confusion. It is common condition with up to 3-5% of children and adolescents showing strange fatigue and confusion for more than 30 days. In this condition, four major symptoms are important: sleep disorders, easy fatigability, disturbed learning and memorization and immunological problems. Routine laboratory studies are similar to adult CFS, although abnormalities can be seen on serum pyruvic acid level, OGTT pattern, deep body temperature rhythm, hormonal secretion rhythm, and cerebral blood flow. For a diagnosis of CCFS, a research group supported by Japanese ministry of health, labor and welfare developed CCFS case definition on 2004. Treatment focused to correct disrupted circadian rhythms and supply of energy.
Mirkin D, Murphy-Barron C, Iwasaki K.	Milliman, Inc, New York, NY 10119, USA. david.mirkin@milliman.com	Actuarial analysis of private payer administrative claims data for women with endometriosis.	J Manag Care Pharm. 2007 Apr;13(3):262-72.	BACKGROUND: Endometriosis is a painful, chronic disease affecting 5.5 million women and girls in the United States and Canada and millions more worldwide. The usual age range of women diagnosed with endometriosis is 20 to 45 years. Endometriosis has an estimated prevalence of 10% among women of reproductive age, although estimates of prevalence vary greatly. Endometriosis is the most common gynecological cause of chronic pelvic pain, but published information on its associated medical care costs is scarce. OBJECTIVE: The aim of this study was to determine (1) the prevalence of endometriosis in the United States, (2) the amount of health care services used by women coded with endometriosis in a commercial medical claims database during 1999 to 2003, and (3) the endometriosis-related costs for 2003, the most recent data available at the time the study was performed. METHODS: This study was a retrospective review of administrative data for commercial payers, which included enrollment, eligibility, and claims payment data contained in the Medstat Marketscan database for approximately 4 million commercial insurance members. All claims and membership data were extracted for each woman aged 18 to 55 years who had at least 1 medical or hospital claim with a diagnosis code for endometriosis (International Classification of Diseases, Ninth Revision, Clinical Modification [ICD-9-CM] codes 617.00-617.99) for 1999 through 2003. Claims data from 1999 through 2003 were used to determine prevalence and health care resource utilization (i.e., annual admission rate, annual surgical rate, distribution of endometriosis-related surgeries, and prevalence of comorbid conditions). The cost analysis was based on claims from 2003 only. Cost was defined as the payer-allowed charge, which equals the net payer cost plus member cost share. RESULTS: The prevalence of women with medical claims (inpatient and/or outpatient) containing ICD-9-CM codes for endometriosis was 1.1% for the age band of 30 to 39 years and 0.7% over the entire age span of 18 to 55 years. The medical costs per patient per month (PPPM) for women with endometriosis were 63% greater ($706 PPPM) than those of the average woman per member per month ($433) in 2003; inpatient hospital costs accounted for 32% of total direct medical costs. Between 1999 and 2003, these women with endometriosis who were identified by either inpatient

				and/or outpatient claims had high rates of hospital admission (53% for any reason; 38% for an endometriosis-related reason) and a high annual surgical procedure rate (64%). Additionally, women with endometriosis frequently suffered from comorbid conditions, and these conditions were associated with greater PPPM costs of 15% to 50% for women with an endometriosis diagnosis code, depending on the condition. Interstitial cystitis was associated with 50% greater cost ($1,061 PPPM); depression, 41% ($997 PPPM); migraine, 40% ($988 PPPM); irritable bowel syndrome, 34% ($943 PPPM); chronic fatigue syndrome, 29% ($913 PPPM); abdominal pain, 20% ($846 PPPM); and infertility, 15% ($813 PPPM). CONCLUSIONS: Women with endometriosis have a high hospital admission rate and surgical procedure rate and a high incidence of comorbid conditions. Consequently, these women incur total medical costs that are, on average, 63% higher than medical costs for the average woman in a commercially insured group.
Miwa S, Takikawa O.	Department of Cellular Pharmacology, Hokkaido University Graduate School of Medicine.	[Chronic fatigue syndrome and neurotransmitters] [Article in Japanese	Nippon Rinsho. 2007 Jun;65(6):1005-10.	Chronic fatigue syndrome (CFS) is an idiopathic illness characterized by persistent fatigue, which could be caused by a variety of etiologic factors including viral infection, abnormal production of cytokines and abnormal acylcarnitine metabolism. Recent studies suggest that CFS is closely associated with attenuation of central synaptic transmission mediated by neurotransmitters such as serotonin and glutamate. Attenuation of serotonin neurotransmission can be caused by increased expression of serotonin transporter, which results either from viral infection and subsequent production of interferon--alpha or from abnormal promoter for serotonin transporter gene. Other neurotransmitter systems may be also involved in CFS mediated by abnormal acylcarnitine metabolism and autoantibodies for neurotransmitter receptors. In this review, we focus recent data on CFS in terms of neurotransmitters.
Murakami M.	Department of Psychosomatic Internal Medicine, Nihon University Itabashi Hospital.	[Considerations for the treatment of chronic fatigue syndrome] [Article in Japanese]	Nippon Rinsho. 2007 Jun;65(6):1089-92.	The etiology of chronic fatigue syndrome(CFS) is still unknown and under active discussion, but involvement of psychosocial factors appear to be essential for the onset and clinical course of CFS. As CFS patients complain of many stress-related physical and psychological symptom, it is important to understand the CFS from psychosomatic point of view. Not only for the pharmaceutical treatment, attentive consideration is required for treatment of exhaustion of body and mind of CFS patients. Use of anti-depressants or oriental herb medicine is often effective to relieve the anxiety and depressive condition. Furthermore to augment the self-healing potential, psychosomatic approach is important to modify the life style and behavioral characteristics.
Mutter J, Naumann J, Guethlin C.	Institute for Environmental Medicine and Hospital Epidemiology, Freiburg i.Br., Deutschland. joachim.mutter@uniklinik-freiburg.de	Elimination of xenobiotics in a female patient with fibromyalgia, chronic fatigue, and trunk obesity.	Forsch Komplement Med (2006). 2007 Feb;14(1):39-44. Epub 2007 Mar 6.	We describe the case of a 28-year-old woman, who had been suffering for more than 5 years from severe fatigue, myofascial pain, obstipation, obesity of trunk, abdominal striae, oedema, tinnitus, folliculitis, and facial swelling. The patient also showed a secondary adrenocortical insufficiency. From the anamnesis we assumed that environmental factors could account for the symptoms. The therapy consisted of dietary advise, chelating agents, supplements, and acupuncture. Under this therapy the patient became completely symptom-free. No such case has ever been reported before. We report mainly on the CAM diagnostic and therapeutic procedures, which are discussed together with the assumed pathogenetic factors.
Narita M, Narita N.	'Graduate School of Medicine, Mie	[Genetic background of	Nippon Rinsho. 2007	Although previous twin and family studies have suggested the involvement of genetic factor(s) in the pathogenesis of chronic fatigue syndrome (CFS), responsible gene for CFS was not known. We have

	University.	chronic fatigue syndrome] [Article in Japanese]	Jun;65(6):997-1002.	recently reported the association of serotonin transporter gene polymorphism in CFS. A significant increase of longer (L and XL) alleic variants was found in the CFS patients compared to the controls. Compared to S allele, the L allele is believed to retain higher transcriptional activity, which causes decreased concentration of serotonin in the extracellular space, namely, active serotonin in CFS. These results thus support the serotonin hypothesis in the pathogenesis of CFS.
Natelson BH, Intriligator R, Cherniack NS, Chandler HK, Stewart JM.	Department of Neurosciences, UMDNJ-New Jersey Medical School, Newark NJ, USA. natelson@njneuromed.org	Hypocapnia is a biological marker for orthostatic intolerance in some patients with chronic fatigue syndrome.	Dyn Med. 2007 Jan 30;6:2.	CONTEXT: Patients with chronic fatigue syndrome and those with orthostatic intolerance share many symptoms, yet questions exist as to whether CFS patients have physiological evidence of orthostatic intolerance. OBJECTIVE: To determine if some CFS patients have increased rates of orthostatic hypotension, hypertension, tachycardia, or hypocapnia relative to age-matched controls. DESIGN: Assess blood pressure, heart rate, respiratory rate, end tidal CO2 and visual analog scales for orthostatic symptoms when supine and when standing for 8 minutes without moving legs. SETTING: Referral practice and research center. PARTICIPANTS: 60 women and 15 men with CFS and 36 women and 4 men serving as age matched controls with analyses confined to 62 patients and 35 controls showing either normal orthostatic testing or a physiological abnormal test. MAIN OUTCOME MEASURES: Orthostatic tachycardia; orthostatic hypotension; orthostatic hypertension; orthostatic hypocapnia or combinations thereof. RESULTS: CFS patients had higher rates of abnormal tests than controls (53% vs 20%, $p < .002$), but rates of orthostatic tachycardia, orthostatic hypotension, and orthostatic hypertension did not differ significantly between patients and controls (11.3% vs 5.7%, 6.5% vs 2.9%, 19.4% vs 11.4%, respectively). In contrast, rates of orthostatic hypocapnia were significantly higher in CFS than in controls (20.6% vs 2.9%, $p < .02$). This CFS group reported significantly more feelings of illness and shortness of breath than either controls or CFS patients with normal physiological tests. CONCLUSION: A substantial number of CFS patients have orthostatic intolerance in the form of orthostatic hypocapnia. This allows subgrouping of patients with CFS and thus reduces patient pool heterogeneity engendered by use of a clinical case definition.
Nater UM, Maloney E, Boneva RS, Gurbaxani BM, Lin JM, Jones JF, Reeves WC, Heim C.	Chronic Viral Diseases Branch, Coordinating Center for Infectious Diseases, Centers for Disease Control & Prevention, Atlanta, GA; Department of Psychiatry & Behavioral Sciences, Emory University School of Medicine, Atlanta, GA;	Attenuated Morning Salivary Cortisol Concentrations in a Population-based Study of Persons with Chronic Fatigue Syndrome and Well Controls.	J Clin Endocrinol Metab. 2007 Dec 26 [Epub ahead of print]	Context A substantial body of research on the pathophysiology of chronic fatigue syndrome (CFS) has focused on hypothalamic-pituitary-adrenal (HPA) axis dysregulation. The cortisol awakening response has received particular attention as a marker of HPA axis dysregulation. Objective The objective of the current study was to evaluate morning salivary cortisol profiles in persons with CFS and well controls identified from the general population. Design Case-control study. Setting This study was conducted at an outpatient research clinic. Cases and Other Participants We screened a sample of 19,381 residents of Georgia and identified those with CFS and a matched sample of well controls. Seventy-five medication-free CFS cases and 110 medication-free well controls provided complete sets of saliva samples. Main Outcome Measures Free cortisol concentrations in saliva collected on a regular workday, immediately upon awakening, 30 minutes and 60 minutes after awakening. Results There was a significant interaction effect, indicating different profiles of cortisol concentrations over time between groups, with the CFS group showing an attenuated morning cortisol profile. Notably, we observed a sex difference in this effect. Women with CFS exhibited significantly attenuated morning cortisol profiles compared with well women. In contrast, cortisol profiles were similar in men with CFS and male controls. Conclusions CFS was associated with an attenuated morning cortisol response but the effect was limited to women. Our results suggest that a sex difference in hypocortisolism may

	Department of Electrical and Computer Engineering, Georgia Institute of Technology, Atlanta, GA.			contribute to increased risk of CFS in women.

Neu D, Mairesse O, Hoffmann G, Dris A, Lambrecht LJ, Linkowski P, Verbanck P, Le Bon O.	Sleep Laboratory, Department of Psychiatry, University Hospital Brugmann, Brussels, Belgium. daniel.neu@skynet.be	Sleep quality perception in the chronic fatigue syndrome: correlations with sleep efficiency, affective symptoms and intensity of fatigue.	Neuropsychobiology. 2007;56(1):40-6. Epub 2007 Nov 6.	BACKGROUND/AIMS: One of the core symptoms of the chronic fatigue syndrome (CFS) is unrefreshing sleep and a subjective sensation of poor sleep quality. Whether this perception can be expressed, in a standardized questionnaire as the Pittsburgh Sleep Quality Index (PSQI), has to our knowledge never been documented in CFS. Furthermore, correlations of subjective fatigue, PSQI, affective symptoms and objective parameters such as sleep efficiency are poorly described in the literature. METHODS: Using a cross-sectional paradigm, we studied subjective measures like PSQI, Fatigue Severity Scale scores and intensity of affective symptoms rated by the Hamilton Depression and Anxiety scales as well as objective sleep quality parameters measured by polysomnography of 28 'pure' (no primary sleep and no psychiatric disorders) CFS patients compared to age- and gender-matched healthy controls. RESULTS: The PSQI showed significantly poorer subjective sleep quality in CFS patients than in healthy controls. In contrast, objective sleep quality parameters, like the Sleep Efficiency Index (SEI) or the amount of slow-wave sleep did not differ significantly. Subjective sleep quality showed a correlation trend with severity of fatigue and was not correlated with the intensity of affective symptoms in CFS. CONCLUSION: Our findings indicate that a sleep quality misperception exists in CFS or that potential nocturnal neurophysiological disturbances involved in the nonrecovering sensation in CFS are not expressed by sleep variables such as the SEI or sleep stage distributions and proportions. Newton JL, Okonkwo O, Sutcliffe K, Seth A, Shin J, Jones DE.	Fatigue Interest group and Liver Research Group, Institute for Cellular Medicine, University of Newcastle, Newcastle, UK. julia.newton@nuth.nhs.uk	Symptoms of autonomic dysfunction in chronic fatigue syndrome.	QJM. 2007 Aug;100(8):519-26. Epub 2007 Jul 7.	BACKGROUND: Chronic fatigue syndrome (CFS) is common and its cause is unknown. AIM: To study the prevalence of autonomic dysfunction in CFS, and to develop diagnostic criteria. DESIGN: Cross-sectional study with independent derivation and validation phases. METHODS: Symptoms of autonomic dysfunction were assessed using the Composite Autonomic Symptom Scale (COMPASS). Fatigue was assessed using the Fatigue Impact Scale (FIS). Subjects were studied in two groups: phase 1 (derivation phase), 40 CFS patients and 40 age- and sex-matched controls; phase 2 (validation phase), 30 CFS patients, 37 normal controls and 60 patients with primary biliary cirrhosis. RESULTS: Symptoms of autonomic dysfunction were strongly and reproducibly associated with the presence of CFS or primary biliary cirrhosis (PBC), and correlated with severity of fatigue. Total COMPASS score >32.5 was identified in phase 1 as a diagnostic criterion for autonomic dysfunction in CFS patients, and

				was shown in phase 2 to have a positive predictive value of 0.96 (95%CI 0.86-0.99) and a negative predictive value of 0.84 (0.70-0.93) for the diagnosis of CFS. DISCUSSION: Autonomic dysfunction is strongly associated with fatigue in some, but not all, CFS and PBC patients. We postulate the existence of a 'cross-cutting' aetiological process of dysautonomia-associated fatigue (DAF). COMPASS >32.5 is a valid diagnostic criterion for autonomic dysfunction in CFS and PBC, and can be used to identify patients for targeted intervention studies.
Niblett SH, King KE, Dunstan RH, Clifton-Bligh P, Hoskin LA, Roberts TK, Fulcher GR, McGregor NR, Dunsmore JC, Butt HL, Klineberg I, Rothkirch TB.	Environmental and Pathogenic Microbiology Laboratory, School of Environmental and Life Sciences, The University of Newcastle, Callaghan, NSW 2308, Australia.	Hematologic and urinary excretion anomalies in patients with chronic fatigue syndrome.	Exp Biol Med (Maywood). 2007 Sep;232(8):1041-9.	Patients with chronic fatigue syndrome (CFS) have a broad and variable spectrum of signs and symptoms with variable onsets. This report outlines the results of a single-blind, cross-sectional research project that extensively investigated a large cohort of 100 CFS patients and 82 non fatigued control subjects with the aim of performing a case-control evaluation of alterations in standard blood parameters and urinary amino and organic acid excretion profiles. Blood biochemistry and full blood counts were unremarkable and fell within normal laboratory ranges. However, the case-control comparison of the blood cell data revealed that CFS patients had a significant decrease in red cell distribution width and increases in mean platelet volume, neutrophil counts, and the neutrophil-lymphocyte ratio. Evaluation of the urine excretion parameters also revealed a number of anomalies. The overnight urine output and rate of amino acid excretion were both reduced in the CFS group ($P < 0.01$). Significant decreases in the urinary excretion of asparagine ($P < 0.0001$), phenylalanine ($P < 0.003$), the branch chain amino acids ($P < 0.005$), and succinic acid ($P < 0.0001$), as well as increases in 3-methylhistidine ($P < 0.05$) and tyrosine ($P < 0.05$) were observed. It was concluded that the urinary excretion and blood parameters data supported the hypothesis that alterations in physiologic homeostasis exist in CFS patients.
Nijs J, Demol S, Wallman K.	Department of Human Physiology, Faculty of Physical Education & Physiotherapy, Vrije Universiteit, Brussels, Belgium. Jo.Nijs@vub.ac.be	Can submaximal exercise variables predict peak exercise performance in women with chronic fatigue syndrome?	Arch Med Res. 2007 Apr;38(3):350-3. Epub 2007 Jan 30.	This study aimed at examining whether physiological exercise variables at the submaximal level, defined as 75% of the age-predicted target heart rate, are able to predict peak exercise performance in women with chronic fatigue syndrome (CFS) (n=222). Subjects performed a bicycle ergometric test against a graded increase in workload until exhaustion with continuous monitoring of electrocardiographic and ventilatory variables. Oxygen uptake at the submaximal level (VO2SUBMAX) correlated strongly with peak oxygen uptake (VO2PEAK) (r=0.70). For the prediction of VO2PEAK, linear regression analysis determined the line of best fit as: VO2PEAK=0.95xVO2SUBMAX+372.3. Using this equation, the mean error in the prediction was 14.6+/-11.2% (range 0.1-63.7%). It is concluded that the prediction of VO2PEAK based on VO2SUBMAX might be useful for analyzing group differences or treatment effects but not for individual (clinical) purposes.
Nishikai M.	National Hospital Organization Tokyo Medical Center.	[Antinuclear antibodies in patients with chronic fatigue syndrome] [Article in Japanese]	Nippon Rinsho. 2007 Jun;65(6):1067-70.	Significance of antinuclear antibodies (ANA) in the patients with chronic fatigue syndrome (CFS) was reviewed. When indirect immunofluorescence with the HEp-2 cells as the substrates was used, prevalence of the positive ANA was reportedly 15-25%. The ANA titers were low and the immunofluorescent staining patterns were heterogeneous. One group in the USA reported that 'nuclear envelope staining pattern' was found in more than 50% of the patients with CFS. This results, however, have not been confirmed by any other research groups. Clinical significance of the positive ANA in the CFS patients resides in differential diagnoses of systemic lupus erythematosus and other diffuse connective tissue diseases. Recently, several ANAs specific to CFS have been described. We reported anti-68/48kD protein antibodies utilizing SDS-PAGE/ immunoblot method. These

				autoantibodies were found in 13% of 114 CFS patients and 0% in healthy subjects ($p < 0.05$). Hypersomnia and difficulty in concentration were found more frequently in the CFS patients with this specific autoantibody.
Njoku MG, Jason LA, Torres-Harding SR.	DePaul University, Chicago, IL 60614, USA. nmgloria@depaul.edu	The prevalence of chronic fatigue syndrome in Nigeria.	J Health Psychol. 2007 May;12(3):461-74.	The present study found adult rates of chronic fatigue syndrome (CFS) in Nigeria that were somewhat higher than rates from community-based CFS epidemiologic studies in the USA. The rates of chronic fatigue for both adults and children were also higher than in existing community-based studies. It is possible that the presence of several fatiguing illnesses such as malaria and typhoid, the lack of adequate healthcare resources and poverty in Nigeria, place individuals at greater risk for fatigue and its syndromes. There is a need for more epidemiologic studies on the prevalence and sociodemographic characteristics of CFS in developing countries.
Nogué S, Fernández-Solá J, Rovira E, Montori E, Fernández-Huerta JM, Munné P.	Unidades de Toxicología y de Fatiga Crónica, Hospital Clínic, IDIBAPS, Universidad de Barcelona, Barcelona, España. SNOGUE@clinic.ub.es	[Multiple chemical sensitivity: study of 52 cases[Article in Spanish]]	Med Clin (Barc). 2007 Jun 16;129(3):96-8; quiz 99. Comment in: Med Clin (Barc). 2007 Jun 16;129(3):94-5.	BACKGROUND AND OBJECTIVE: Multiple chemical sensitivity (MCS) is characterized by a loss of tolerance to various environmental chemicals. The objective of this study was to describe patients with MCS seen in our hospital. PATIENTS AND METHOD: Patients consecutively seen by the Toxicology and Chronic Fatigue Units who presented symptoms of MCS were included. The diagnosis was clinical. All patients completed the Quick Environmental Exposure and Sensitivity Inventory (QEESI) questionnaire. RESULTS: Fifty-two patients were included. The average age (standard deviation) was 47.2 (7.6) years, and 46 (88%) were females. The origin of the syndrome was related to occupational exposure to various chemical agents in 31 cases (59.6%), including occupational accidents in 14 patients (fumigation of the workplace with insecticides). In 20 patients (38.5%), the syndrome could not be associated with any toxic exposure and was considered a manifestation of chronic fatigue syndrome. The QEESI showed mean scores of 72.9 (18.6) on the chemical inhalant intolerance scale, 45.5 (20.6) on the other intolerances scale, 69.8 (20.6) on the symptom severity scale, 4.4 (1.8) on the masking index and 66.6 (21.7) on the life impact scale. All patients were followed up for a minimum of 12 months, and during this period they remained stable with no deaths. CONCLUSIONS: MCS normally affects middle-aged women. It is frequently triggered by exposure to chemical agents, especially insecticides. An association with chronic fatigue syndrome is common. The prognosis is good but the patients' quality of life is seriously affected.
Nunez Juarez Montserrat, Esther Nunez Juarez, Jose Luis Del Val Garcia, Jose Manuel Fernandez Huerta, Cayetano Alegre de Miguel, Maria Bonet Llorach, Daniel Roig, Esther Gomez Gil, Teresa Godas Sieso, Joaquim		HUHealth-Related Quality of Life in Chronic Fatigue Syndrome versus Rheumatoid Arthritis as Control Group UH	Journal of Chronic Fatigue Syndrome 2007; 14(2): 31-43	The objectives of this study were (1) evaluate health-related quality of life (HRQL) in patients with chronic fatigue syndrome (CFS); (2) to compare the HRQL of these patients with that of rheumatoid arthritis (RA) patients and healthy Spanish reference population values (RPV); and (3) to identify the influence of sociodemographic and clinical variables on HRQL in CFS patients. We included 216 outpatients: 94 females/14 males (age 42.9 ± 9.9 years) with CFS and 94 females/14 males with RA (age 42.9 ± 9.9 years). We used a cross-sectional, observational design. Sociodemographic data, comorbidities, pain (VAS) and global functional status were determined. HRQL was measured by the SF-36 and HAQ questionnaires. CFS patients had worse scores than RA patients in all SF36 dimensions except emotional role ($p < 0.01$). Both CFS and RA patients had worse scores in all SF36 dimensions than RPV. In CFS patients, pain negatively influenced HRQL ($p < 0.05$) except for physical role, social function and emotional role. Global functional status negatively influenced HRQL ($p < 0.05$) except for bodily pain, general health and mental health. Comorbidities worsened scores for physical and social functions and mental health. In conclusion, HRQL was worse in patients with CFS than in those with

Fernandez Sola				RA. Both CFS and RA patients had worse HRQL compared with RPV. Comorbidities, pain and global functional status influenced HRQL in CFS patients. Standardised HRQL instruments are of value in determining the quality of life in these patients.

Ohinata J, Suzuki N, Araki A, Takahashi S, Fujieda K, Tanaka H.	Department of Pediatrics, Asahikawa Medical College, Japan.	Actigraphic assessment of sleep disorders in children with chronic fatigue syndrome.	Brain Dev. 2007 Nov 19 [Epub ahead of print]	Children with chronic fatigue syndrome (CFS) often suffer from sleep disorders, which cause many physiological and psychological problems. Understanding sleep characteristics in children with CFS is important for establishing a therapeutic strategy. We conducted an actigraphic study to clarify the problems in sleep/wake rhythm and physical activity in children with CFS. Methods. Actigraphic recordings were performed for 1-2 weeks in 12 CFS children. The obtained data were compared with those of healthy age-matched children used as the control. Results. Sleep patterns were divided into two groups based on subjects' sleep logs: irregular sleep type and delayed sleep phase type. Compared to the control group, total sleep time was longer and physical activity was lower in both groups of CFS. Continuous sleep for more than 10h was not uncommon in CFS. In the irregular sleep type, impaired daily sleep/wake rhythms and disrupted sleep were observed. Conclusion. Using actigraphy, we could identify several characteristics of the sleep patterns in CFS children. Actigraphic analysis proved to be useful in detecting sleep/wake problems in children with CFS.
Ojima K, Watanabe N, Narita N, Narita M.	Graduate School Human Sciences, University of Tsukuba, Ibaraki, Japan. narita_m@doc.medic.mie-u.ac.jp.	Temporomandibular disorder is associated with a serotonin transporter gene polymorphism in the Japanese population.	Biopsychosoc Med. 2007 Jan 10;1:3.	ABSTRACT: AIMS: Recent genetic studies have linked serotonin-related genetic polymorphisms with diverse disorders characterized by functional somatic symptoms, including chronic fatigue syndrome, irritable bowel syndrome, and premenstrual dysphoric disorder. METHODS: We investigated three serotonin-related genetic polymorphisms by screening genomic DNA of 36 temporomandibular disorder (TMD) patients. RESULTS: A significant increase of longer alleles (l and xl) was found in the TMD patients compared to the controls both by the genotype-wise and the allele-wise analyses (both $p < 0.01$ by chi2 test and Fisher's exact test). CONCLUSION: Genetic factors that involve the serotonergic system may play a role in the pathogenesis of TMD.
Oki J, Okubo J.	Department of Pediatrics, Asahikawa Kosei Hospital.	[Usefulness of growth chart in children and adolescents with chronic fatigue syndrome] [Article in Japanese]	Nippon Rinsho. 2007 Jun;65(6):1113-9.	We presented three sheets of growth chart in children with chronic fatigue syndrome. The growth chart in 14-year-old boy (patient 1) showed decreased weight gain because of too much exercise. After that he complained nausea, abdominal pain, sleep disturbance and debilitating fatigue. The growth chart in 12-year-old girl (patient 2) revealed increased weight gain because of overeating due to the divorce of her parents. She developed syncope, sleep disturbance, and fatigue during overeating. The growth chart in 13-year-old girl (patient 3) showed decreased weight gain after she developed lymph node enlargement. We diagnosed her as autoimmune fatigue syndrome because of persistent positive antinuclear antibody. Although growth chart will not be able to detect childhood

				chronic fatigue syndrome prospectively, the chart may be useful for detecting some life events in these children.
Olson K, Turner AR, Courneya KS, Field C, Man G, Cree M, Hanson J.	Faculty of Nursing, University of Alberta, Edmonton, Alberta, Canada.	Possible links between behavioral and physiological indices of tiredness, fatigue, and exhaustion in advanced cancer.	Support Care Cancer. 2007 Jul 24 [Epub ahead of print]	GOALS: In this theoretical paper, we present the Edmonton Fatigue Framework (EFF), a new framework for the study of tiredness, fatigue, and exhaustion in advanced cancer. MATERIALS AND METHODS: The Fatigue Adaptation Model (FAM), the starting point for the EFF, was drawn from a literature review pertaining to fatigue in depression, chronic fatigue syndrome, cancer, shift workers, and athletes published in the Cumulative Index to Nursing and Allied Health Literature (CINAHL), Medical Literature Analysis and Retrieval System Online (MEDLINE), PubMed, PsychINFO, SPORTdiscus, and CancerLit between 1995 and 2004, and from seven qualitative studies conducted by our group. The EFF, an elaboration of the FAM, was constructed after an expansion of our literature review to 2006 and team discussion. The EFF provides new insights into possible links between behavioral and physiological indices of tiredness, fatigue, and exhaustion as they occur in both ill and non-ill states. In this paper, however, we consider only possible links in advanced cancer. CONCLUSIONS: We propose that stressors associated with advanced cancer and its supportive treatment trigger declines in four systems-cognitive function, sleep quality, nutrition, and muscle endurance-and that these declines reduce one's ability to adapt. While these systems each likely has its own effect on adaptation, we propose that the most important and serious effects arise from interactions among declines in cognitive function, sleep quality, nutrition, and muscle endurance. CONCLUSIONS: Interventions for fatigue have been limited by a lack of understanding about its etiology. Hypotheses arising from the EFF; suggest a new direction for further study that focuses on interactions among cognitive function, sleep quality, nutrition, and muscle endurance.
Ondo WG, Sethi KD, Kricorian G.	Baylor College of Medicine, Department of Neurology, 6550 Fannin, Houston, TX 77030, USA. wondo@bcm.tmc.edu	Selegiline orally disintegrating tablets in patients with Parkinson disease and "wearing off" symptoms.	Clin Neuropharmacol. 2007 Sep-Oct;30(5):295-300. Comment in: Clin Neuropharmacol. 2007 Sep-Oct;30(5):301-4. Clin Neuropharmacol. 2007 Sep-Oct;30(5):305-7	BACKGROUND: Selegiline orally disintegrating tablet (ODT; Zelapar) is a selective monoamine oxidase B inhibitor developed as an adjunct to levodopa (LD) for Parkinson disease. Most patients on long-term LD therapy eventually experience deterioration at the end of the LD dosing interval, with predictable "wearing off" and "on-off" fluctuations. METHODS: We conducted a 12-week, double-blind, placebo-controlled, parallel-design trial of selegiline ODT. The primary efficacy point was reduction in the percentage of average daily "off" time. Secondary measures included reductions in daily off hours and total daily off time, Clinical Global Impressions-Improvement (CGI-I), and Patient Global Impression-Improvement (PGI-I). Patients on LD received selegiline ODT (1.25 mg/d for 6 weeks, then 2.5 mg/d for 6 weeks) or placebo. Safety and tolerability were measured. RESULTS: The intent-to-treat population included 98 patients receiving selegiline ODT and 50 patients receiving placebo. Combined efficacy results for weeks 10 and 12 revealed an 11.6% reduction in percentage of daily off time for selegiline ODT versus a 9.8% reduction for placebo (NS). PGI-I detected a statistically significant difference between treatment groups in favor of selegiline ODT (P = 0.02), whereas CGI-I detected a strong trend toward improvement (P = 0.06). Selegiline ODT was safe and well tolerated. CONCLUSIONS: This study showed no significant difference in improvement in percentage of off time with selegiline ODT versus placebo. Some clinical impressions (e.g., PGI-I, CGI-I) improved. This result contrasts with an identically designed study that showed a significant improvement in off time with selegiline ODT. A combined analysis of both studies suggested overall efficacy.
Osipenko MF,		[Cirrhotic	Klin Med (Mosk).	Modern studies have shown that hepatic cirrhosis (HC) is accompanied by moderate cardiac

Bikbulatova EA.		cardiomyopathy] [Article in Russian]	2007;85(9):80-3.	dysfunction. The character and degree of these changes do not depend on the etiology of HC and manifest by an increased ventricular wall thickness and diastolic dysfunction, which deteriorate with ascite and physical labor, as well as basal hyperdynamic systolic dysfunction with pathologic response to physical stress. The latter decreases physical tolerance, which contributes to the development of chronic fatigue syndrome and lowered working ability in HC patients. Cardiovascular changes get reversed in 6 to 12 months after hepatic transplantation.
Page WF.	Medical Follow-up Agency, Institute of Medicine, 500 Fifth Street NW, Washington, DC 20001, USA. wpage@nas.edu	Update on the NAS-NRC Twin Registry	Twin Res Hum Genet. 2006 Dec;9(6):985-7	The National Academy of Sciences-National Research Council (NAS-NRC) Twin Registry is one of the oldest, national population-based twin registries in the United States. It consists of 15,924 white male twin pairs born in the years 1917 to 1927 (inclusive), both of whom served in the armed forces, mostly during World War II. This article updates activity in this registry since the earlier 2002 article in Twin Research. The results of clinically based studies on dementia, Parkinson's disease, age-related macular degeneration, and primary osteoarthritis were published, as well as articles based on previously collected questionnaire data on chronic fatigue syndrome, functional limitations, and healthy aging. In addition, risk factor studies are being planned to merge clinical data with earlier collected risk factor data from questionnaires. Examination data from the subset of National Heart, Lung, and Blood Institute (NHLBI) twins resulted in a number of articles, including the relationship of endogenous sex hormones to coronary heart disease and morphological changes in aging brain structures. The NEO Five-Factor Personality Inventory (a paper-and-pencil self-administered questionnaire) has been fielded for the first time. A push to consolidate the various data holdings of the registry is being made.
Pall ML.	School of Molecular Biosciences, Washington State University, Pullman, WA 99164-4234, USA. martin_pall@wsu.edu	Nitric oxide synthase partial uncoupling as a key switching mechanism for the NO/ONOO- cycle.	Med Hypotheses. 2007;69(4):821-5. Epub 2007 Apr 19.	Short-term stressors, capable of increasing nitric oxide levels, act to initiate cases of illnesses including chronic fatigue syndrome, multiple chemical sensitivity, fibromyalgia and posttraumatic stress disorder. These stressors, acting primarily through the nitric oxide product, peroxynitrite, are thought to initiate a complex vicious cycle mechanism, known as the NO/ONOO- cycle that is responsible for chronic illness. The complexity of the NO/ONOO- cycle raises the question as to whether the mechanism that switches on this cycle is this complex cycle itself or whether a simpler mechanism is the primary switch. It is proposed here that the switch involves a combination of two variable switches, the increase of nitric oxide synthase (NOS) activity and the partial uncoupling of the NOS activity, with uncoupling caused by a tetrahydrobiopterin (BH4) deficiency. NOS uncoupling causes the NOS enzymes to produce superoxide, the other precursor of peroxynitrite, in place of nitric oxide. Thus partial uncoupling will cause NOS proteins to act like peroxynitrite synthases, leading, in turn to increased NF-kappaB activity. Peroxynitrite is known to oxidize BH4, and consequently partial uncoupling may initiate a vicious cycle, propagating the partial uncoupling over time. The combination of high NOS activity and BH4 depletion will lead to a potential vicious cycle that may be expected to switch on the larger NO/ONOO- cycle, thus producing the symptoms and signs of chronic illness. The role of peroxynitrite in the NO/ONOO- cycle also implies that such uncoupling is part of the chronic phase cycle mechanism such that agents that lower uncoupling will be useful in treatment.

Paralikar V, Sarmukaddam S, Agashe M, Weiss MG.	Maharashtra Institute of Mental Health, Pune, India. vasudeop@vsnl.com	Diagnostic concordance of neurasthenia spectrum disorders in Pune, India.	Soc Psychiatry Psychiatr Epidemiol. 2007 Jul;42(7):561-72. Epub 2007 May 2.	BACKGROUND: Clinically significant fatigue or weakness is a common but understudied clinical problem in India. The applicability and relevance of Western clinical criteria in this setting are not studied. Alternative criteria sets used in different clinical contexts suggest a range of conditions constituting neurasthenia spectrum disorders (NSDs). We therefore aimed to determine frequency of patients with these complaints in four specialty outpatient clinics of an urban general hospital. We compared the concordance of four diagnostic criteria sets of fatigue disorders among the same patients. METHODS: Patients from the clinics of Psychiatry, Medicine, Dermatology, and Ayurved were screened for clinically significant fatigue or weakness and assessed for CFS, ICD-10 neurasthenia, DSM-IV draft criteria for neurasthenia, and CCMD-2 neurasthenia. RESULTS: For 352 patients, sensitivity of CDC criteria for CFS (13.4%) was poorest. CFS was most frequent in the Medicine clinic. CCMD-2 criteria were the most frequently met (77.6%) with no significant difference across clinics. Two-way concordance of neurasthenia categories was no better than fair (< or =0.4) and few patients (8.0%) met criteria for all four categories. DISCUSSION: Four NSD criteria sets identified different clinical subgroups. CFS, considering fatigue and ignoring weakness, was least relevant for identifying NSD patients in these clinics. Poor concordance among the four diagnostic systems studied indicates the need for reviewing the nosology of these disorders. Focus on clinical significance alone is likely to avoid the discordant confusion arising from cross-cultural differences.
Park J, Knudson S.	Health Statistics Division, Statistics Canada, Ottawa, Ontario. Jungwee.Park@statcan.ca	Medically unexplained physical symptoms.	Health Rep. 2007 Feb;18(1):43-7.	
Perrin RN.	The Perrin Clinic, 11 St John St, Manchester, Greater Manchester, M3 4DW, UK. rayperrin@btconnect.com	Lymphatic drainage of the neuraxis in chronic fatigue syndrome: a hypothetical model for the cranial rhythmic impulse.	J Am Osteopath Assoc. 2007 Jun;107(6):218-24.	The cranial rhythmic impulse is a palpable, rhythmic fluctuation believed to be synchronous with the primary respiratory mechanism. The precise physiologic mechanism of the cranial rhythmic impulse is not fully understood. Based on traditional and current views of the cranial rhythmic impulse, animal studies, and clinical findings in patients with chronic fatigue syndrome, the author argues that the cranial rhythmic impulse is the rhythm produced by a combination of cerebrospinal fluid drainage from the neuraxis (brain and spinal cord) and pulsations of central lymphatic drainage induced by the sympathetic nervous system. In addition, evidence is provided to demonstrate that a disturbed, palpable, and visible neurolymphatic process leads to chronic fatigue syndrome. This process may also explain the pathophysiologic mechanisms leading to other disease states. Finally, the author's proposed manual treatment protocol for patients with chronic fatigue syndrome is described.
Pieczenik SR, Neustadt J.	drneustadt@gmail.com	Mitochondrial dysfunction and molecular pathways of	Exp Mol Pathol. 2007 Aug;83(1):84-92. Epub 2007 Jan 18.	Since the first mitochondrial dysfunction was described in the 1960s, the medicine has advanced in its understanding the role mitochondria play in health, disease, and aging. A wide range of seemingly unrelated disorders, such as schizophrenia, bipolar disease, dementia, Alzheimer's disease, epilepsy, migraine headaches, strokes, neuropathic pain, Parkinson's disease, ataxia, transient ischemic attack,

		disease		cardiomyopathy, coronary artery disease, chronic fatigue syndrome, fibromyalgia, retinitis pigmentosa, diabetes, hepatitis C, and primary biliary cirrhosis, have underlying pathophysiological mechanisms in common, namely reactive oxygen species (ROS) production, the accumulation of mitochondrial DNA (mtDNA) damage, resulting in mitochondrial dysfunction. Antioxidant therapies hold promise for improving mitochondrial performance. Physicians seeking systematic treatments for their patients might consider testing urinary organic acids to determine how best to treat them. If in the next 50 years advances in mitochondrial treatments match the immense increase in knowledge about mitochondrial function that has occurred in the last 50 years, mitochondrial diseases and dysfunction will largely be a medical triumph.
Pohar SL, Jones CA, Warren S, Turpin KV, Warren K.	Institute of Health Economics, Faculty of Rehabilitation Medicine, Edmonton, Alberta, Canada.	Health status and health care utilization of multiple sclerosis in Canada.	Can J Neurol Sci. 2007 May;34(2):167-74. Comment in: Can J Neurol Sci. 2007 May;34(2):120.	BACKGROUND: Persons with multiple sclerosis (MS) represent a small segment of the population, but given the progression of the disease, they experience substantial physical, psychosocial and economic burdens. OBJECTIVE: The primary aim was to compare demographic characteristics, health status, health behaviours, health care resource utilization and access to health care of the community dwelling populations with and without MS. METHODS: Cross-sectional survey using data from the Canadian Community Health Survey (CCHS 1.1). Adjusted analyses were performed to assess differences between persons with MS and the general population, after controlling for age and sex. Normalized sampling weights and bootstrap variance estimates were used. RESULTS: Respondents with MS were 7.6 times (95% CI: 5.4, 10.7) more likely to have health-related quality of life scores that reflected severe impairment than respondents without MS. Respondents with MS were 12.2 times (95% CI: 8.6, 17.2) to rate their health as 'poor' or 'fair' than the general population. Urinary incontinence and chronic fatigue syndrome were 18.7 times (95% CI: 12.5, 28.2) and 21.9 times (95% CI: 11.9, 40.3), more likely to be reported by respondents with MS than those without. Differences between the two populations also existed in terms of health care resource utilization and access and health behaviours. CONCLUSION: Large discrepancies in health status and health care utilization existed between persons with MS who reside in the community and the general population according to all indicators used. Health care needs of persons with MS were also not met.
Rees RJ, Bellon ML.	Disability Studies, School of Medicine, Flinders University, Adelaide, Australia. rees1@iinet.net.au	Post concussion syndrome ebb and flow: longitudinal effects and management.	NeuroRehabilitation. 2007;22(3):229-42.	This research identified persistent post concussion symptoms (PCS) in a group of 20 adult subjects. PCS generally lasted for two years with a mean of 3.35 years. Typical symptoms included physical and cognitive fatigue, depressive behaviors, sensitivity to noise, social withdrawal, irritability, concentration and problem solving difficulties, loss of libido and much difficulty making decisions at even the simplest strategic level. They represented a hard core group for whom the original symptoms persisted well beyond the 6~month period. Participants identified their PCS according to sensory, somatic affective and cognitive items immediately following their trauma (01) and two years later (02). Counseling and psychotherapy intervention took place between 01 and 02. Items on the PCS schedules and the Beck Depression Inventory (II) demonstrated significant decline in the presence of overall symptoms most noticeably in reduction of agitation, irritability and suicidal wishes. However, subjects throughout generally experienced the feeling that they were being punished which equated with behaviors comparable with learned helplessness. The PCS group considered themselves to be different people after trauma. They had different goals, changing lifestyle, relationships and employment and were more often in a dependent state. Comparability with other conditions such as

				PTSD and chronic fatigue syndrome (CFS) was demonstrated by individuals who experienced persistent and invasive post concussion symptoms.
Reeves WC, Jones JF, Maloney E, Heim C, Hoaglin DC, Boneva RS, Morrissey M, Devlin R.	Chronic Viral Diseases Branch, Coordinating Center for Infectious Diseases, Centers for Disease Control and Prevention, Atlanta, GA, USA. wcr1@cdc.gov	Prevalence of chronic fatigue syndrome in metropolitan, urban, and rural Georgia.	Popul Health Metr. 2007 Jun 8;5:5. Comment in: Popul Health Metr. 2007;5:6.	BACKGROUND: Chronic fatigue syndrome (CFS) is a debilitating illness with no known cause or effective therapy. Population-based epidemiologic data on CFS prevalence are critical to put CFS in a realistic context for public health officials and others responsible for allocating resources. METHODS: Based on a random-digit dialing survey we ascertained CFS cases and controls to estimate the prevalence of CFS in metropolitan, urban, and rural populations of Georgia. This report focuses on the 5,623 of 19,381 respondents ages 18 to 59 years old. Fatigued (2,438), randomly selected unwell not fatigued (1,429) and randomly selected well (1,756) respondents completed telephone questionnaires concerning fatigue, other symptoms, and medical history. Subsets of those identified by interview as having CFS-like illness (292), chronic unwellness which was not CFS-like (268 - randomly selected), and well subjects (223, matched to those with CFS-like illness on sex, race, and age) completed a clinical evaluation. RESULTS: We estimated that 2.54% of persons 18 to 59 years of age suffered from CFS. There were no significant differences in prevalence of CFS between metropolitan, urban or rural populations or between white and black residents of the three regions. However, there were significant differences in female-to-male ratios of prevalence across the strata (metropolitan female: male 11.2 : 1, urban 1.7 : 1, rural 0.8 : 1). CONCLUSION: We estimated that 2.54% of the Georgia population suffers from CFS, which is 6- to 10-fold higher than previous population-based estimates in other geographic areas. These differences may reflect broader screening criteria and differences in the application of the case definition. However, we cannot exclude the possibility that CFS prevalence may be higher in Georgia than other areas where it has been measured. Although the study did not identify differences in overall prevalence between metropolitan, urban, and rural Georgia populations, it did suggest the need for additional stratified analyses by geographic strata.
Rimes KA, Goodman R, Hotopf M, Wessely S, Meltzer H, Chalder T.	King's College London, Institute of Psychiatry, Section of General Hospital Psychiatry, Weston Education Centre, Cutcombe Rd, London SE5 9RJ, United Kingdom. K.Rimes@iop.kcl.ac.uk	Incidence, prognosis, and risk factors for fatigue and chronic fatigue syndrome in adolescents: a prospective community study.	Pediatrics. 2007 Mar;119(3):e603-9.	OBJECTIVE: The objective of this study was to describe the incidence, prevalence, risk factors, and prognosis of fatigue, chronic fatigue, and chronic fatigue syndrome in 11- to 15-year-olds. METHODS: A random general population sample (n = 842) of British adolescents and their parents were assessed at baseline and 4 to 6 months later. The main outcomes were fatigue, chronic fatigue, and chronic fatigue syndrome, operationally defined. RESULTS: The incidence over 4 to 6 months was 30.3% for fatigue, 1.1% for chronic fatigue, and 0.5% for chronic fatigue syndrome. The point prevalence was 34.1% and 38.1% for fatigue, 0.4% and 1.1% for chronic fatigue, and 0.1% and 0.5% for chronic fatigue syndrome at time 1 and time 2, respectively. Of participants who were fatigued at time 1, 53% remained fatigued at time 2. The 3 cases of chronic fatigue and 1 case of chronic fatigue syndrome at time 1 had recovered by time 2. Higher risk for development of chronic fatigue at time 2 was associated with time 1 anxiety or depression, conduct disorder, and maternal distress; in multivariate analysis, baseline anxiety or depression remained a significant predictor of chronic fatigue. Increased risk for development of fatigue at time 2 was associated with time 1 anxiety or depression, conduct disorder, and older age; in multivariate analyses, these factors and female gender all were significant predictors of fatigue. CONCLUSIONS: The incidence rates for chronic fatigue and chronic fatigue syndrome in this adolescent sample were relatively high, but the prognosis for these conditions was good. This prospective study provides evidence for an association between emotional/behavioral

				problems and subsequent onset of fatigue/chronic fatigue.

Joseph_Roscoe@URMC.Rochester.edu	Cancer-related fatigue and sleep disorders.	Oncologist. 2007;12 Suppl 1:35-42.	Sleep disorders, such as difficulty falling asleep, problems maintaining sleep, poor sleep efficiency, early awakening, and excessive daytime sleepiness, are prevalent in patients with cancer. Such problems can become chronic in some patients, persisting for many months or years after completion of cancer therapy. For patients with cancer, sleep is potentially affected by a variety of factors, including the biochemical changes associated with the process of neoplastic growth and anticancer treatments, and symptoms that frequently accompany cancer, such as pain, fatigue, and depression.Fatigue is highly prevalent and persistent in patients with cancer and cancer survivors. Although cancer-related fatigue and cancer-related sleep disorders are distinct, a strong interrelationship exists between these symptoms, and a strong possibility exists that they may be reciprocally related. The majority of studies that have assessed both sleep and fatigue in patients with cancer provide evidence supporting a strong correlation between cancer-related fatigue and various sleep parameters, including poor sleep quality, disrupted initiation and maintenance of sleep, nighttime awakening, restless sleep, and excessive daytime sleepiness.This paper reviews the data from these studies with a view toward suggesting further research that could advance our scientific understanding both of potential interrelationships between sleep disturbance and cancer-related fatigue and of clinical interventions to help with both fatigue and sleep disturbance.Disclosure of potential conflicts of interest is found at the end of this article.

Ryan JL, Carroll JK, Ryan EP, Mustian KM, Fiscella K, Morrow GR.	Department of Radiation Oncology, University of Rochester School of Medicine and Dentistry, James P Wilmot Cancer Center, Rochester, NY 14642, USA. Julie_Ryan@urmc.rochester.edu	Mechanisms of cancer-related fatigue.	Oncologist. 2007;12 Suppl 1:22-34.	Cancer-related fatigue (CRF) is one of the most prevalent symptoms patients with cancer experience, both during and after treatment. CRF is pervasive and affects patients' quality of life considerably. It is important, therefore, to understand the underlying pathophysiology of CRF in order to develop useful strategies for prevention and treatment. At present, the etiology of CRF is poorly understood and the relative contributions of the neoplastic disease, various forms of cancer therapy, and comorbid conditions (e.g., anemia, cachexia, sleep disorders, depression) remain unclear. In any individual, the etiology of CRF probably involves the dysregulation of several physiological and biochemical systems. Mechanisms proposed as underlying CRF include 5-HT neurotransmitter dysregulation, vagal afferent activation, alterations in muscle and ATP metabolism, hypothalamic-pituitary-adrenal axis dysfunction, circadian rhythm disruption, and cytokine dysregulation. Currently, these hypotheses are largely based on evidence from other conditions in which fatigue is a characteristic, in particular chronic fatigue syndrome and exercise-induced fatigue. The mechanisms that lead to fatigue in these conditions provide a theoretical basis for future research into the complex etiology of this distressing and debilitating symptom. An understanding of relevant mechanisms may offer potential routes for its prevention and treatment in patients with cancer.Disclosure of potential conflicts of interest is found at the end of this article.
Sairenji T, Nagata K.	Division of Biosignaling, Department of Biomedical Sciences, School of Life Science, Faculty of Medicine, Tottori University.	[Viral infections in chronic fatigue syndrome] [Article in Japanese	Nippon Rinsho. 2007 Jun;65(6):991-6.	Chronic fatigue syndrome (CFS) is a heterogeneous illness in which patients can have different, overlapping signs and symptoms. No single underlying cause has been established for all CFS patients. Epidemiological studies reveal that a flu-like sickness precedes the onset in the majority of cases. The major hypothesis of the pathogenesis of CFS is that infectious agents such as viruses, may trigger and lead to chronic activation of the immune system with abnormal regulation of cytokine production. Many studies have been performed to identify the possible microbial triggers and to understand the epidemiological microbial agents. We have summarized the recent progressive literature of virus, rickettsia, and mycoplasma implicated in the pathogenesis of CFS.
Sakudo A, Kuratsune H, Hakariya Y, Kobayashi T, Ikuta K.	Department of Virology, Research Institute for Microbial Diseases, Osaka University.	[Spectroscopic diagnosis of chronic fatigue syndrome by multivariate analysis of visible and near-infrared spectra] [Article in	Nippon Rinsho. 2007 Jun;65(6):1051-6.	We have recently evaluated the possibility of visible and near-infrared (Vis-NIR) spectroscopy for diagnosis of chronic fatigue syndrome(CFS). Vis-NIR spectra in the 600-1,100 nm region for sera from CFS patients and healthy donors were subjected to principal component analysis (PCA) and soft independent modeling of class analogy (SIMCA) to develop multivariate models to discriminate between CFS patients and healthy donors. The PCA and SIMCA model predicted successful prediction of the masked samples. Furthermore, taking advantage of Vis-NIR spectroscopy to enable noninvasive analysis, our preliminary results have shown that SIMCA model from Vis-NIR spectra of thumb has achieved 70-80% correct determinations. In this review, we will introduce the potential of the Vis-NIR

		Japanese]		spectroscopy for CFS diagnosis.
Samer Koutoubi, John W. Cartmell, Mark Kestin, Geoffrey Lecovin		Protein Nutrition in Fibromyalgia	Journal of Chronic Fatigue Syndrome 2007; 14(3):	Background: Fibromyalgia (FM) is a soft-tissue disease of unknown origin. It causes soft-tissue pain and stiffness, often with chronic fatigue, disrupted sleep, headaches and irritable bowel. Fibromyalgia affects an estimated six million Americans of which 80 to 90 percent are female. Objective: To determine whether dietary intake of protein, Tryptophan, and Branched Chain Amino Acids (BCAA) meet Dietary Reference Intake (DRI) recommendations, and whether there is a difference in animal and vegetable protein intake in subjects with FM compared to healthy controls. Methods: Thirty subjects with FM and an equal number of controls completed a Food Frequency Questionnaire (FFQ) regarding dietary intake over the previous month. The FFQs were then computer analyzed to determine dietary intake. Results: Protein intake of all subjects was more than adequate to meet DRI recommendations and there was no significant difference in intake of protein, BCAA, Tryptophan, animal or vegetable protein. Subjects with FM had significantly higher body weight and Body Mass Index (BMI) than controls, and reported having a higher incidence of Irritable Bowel Syndrome (IBS) symptoms than controls. Conclusion: There was no significant difference in dietary intake of protein, Tryptophan, BCAA, or amounts of animal or vegetable protein in FM subjects compared to healthy controls. Significant differences in body weight and BMI in FM subjects might be related to less physical activity or possibly to malabsorption problems associated with IBS. Malabsorption related to IBS might increase the potential for protein malnutrition, FM, and associated symptoms like chronic fatigue.
Sanders P, Korf J.	University Centre of Psychiatry, University of Groningen, Groningen, The Netherlands.	Neuroaetiology of chronic fatigue syndrome: An overview.	World J Biol Psychiatry. 2007 May 8;:1-7 [Epub ahead of print]	Chronic fatigue syndrome (CFS) is now recognized as a medial disorder. In contrast to recent related reports, the present review focuses primarily on aetiological aspects of CFS. Four major hypotheses are reviewed. (1) Although CFS is often associated with viral infection, the presence of viruses has as yet not consistently been detected. (2) It is not clear whether anomalies of the HPA axis often observed in CFS, are cause or the consequences of the disorder. (3) Immune dysfunction as the cause of CFS is thus far the weakest hypothesis. (4) The psychiatric and psychosocial hypothesis denies the existence of CFS as a disease entity. Accordingly, the fatigue symptoms are assumed to be the consequence of other (somatic) diseases. Other possible causes of CFS are oxidative stress and genetic predisposition. In CFS cognitive behavioural therapy is most commonly used. This therapy, however, appears to be ineffective in many patients. The suggested causes of CFS and the divergent reactions to therapy may be explained by the lack of recognition of subgroups. Identification of subtypes may lead to more effective therapeutic interventions.
Scheeres K, Wensing M, Mes C, Bleijenberg G.	Expert Centre Chronic Fatigue, Radboud University Nijmegen Medical Centre, The Netherlands. K.Scheeres@nkcv.	The impact of informational interventions about cognitive behavioral therapy for chronic fatigue syndrome on GPs referral behavior.	Patient Educ Couns. 2007 Sep;68(1):29-32. Epub 2007 May 22.	OBJECTIVE: This study investigated the impact of an informational intervention among general practitioners (GPs) about a new treatment with cognitive behavioral therapy (CBT) for chronic fatigue syndrome (CFS) in a mental health center (MHC). The outcome measures concerned GPs knowledge and attitudes towards CFS and their actual referrals of CFS patients to this new treatment setting. METHODS: Three hundred and one GPs, who all had received written information about CFS four times, and who partly had also visited an informational group session, completed a short questionnaire survey on CFS knowledge and attitudes. Referral data were obtained from the mental health center. RESULTS: During 16 months 22% of all GPs in the concerning region had referred at

	umcn.nl			least one CFS patient. Concerning knowledge and attitude, the survey results showed that 70% of the GPs had remembered the intervention's main message, namely the new treatment possibility. These informed GPs reported better knowledge and more positive attitudes towards CFS than the non-informed GPs, who had not seen and read the intervention's information. CONCLUSION: This study showed that disseminating written materials can be a useful method for stimulating GPs to refer CFS patients for CBT. PRACTICE IMPLICATIONS: In future implementation projects concerning CBT for CFS (or other 'new' treatments for a disputed illness) in a MHC or other institution, the informational intervention evaluated here can be a suitable and efficient method to inform GPs and let them refer patients.
Schur E, Afari N, Goldberg J, Buchwald D, Sullivan PF.	Department of Medicine, University of Washington School of Medicine, Seattle,Washington, USA. ellschur@washington.edu	Twin analyses of fatigue.	Twin Res Hum Genet. 2007 Oct;10(5):729-33.	Prolonged fatigue equal to or greater than 1 month duration and chronic fatigue equal to or greater than 6 months duration are both commonly seen in clinical practice, yet little is known about the etiology or epidemiology of either symptom. Chronic fatigue syndrome (CFS), while rarer, presents similar challenges in determining cause and epidemiology. Twin studies can be useful in elucidating genetic and environmental influences on fatigue and CFS. The goal of this article was to use biometrical structural equation twin modeling to examine genetic and environmental influences on fatigue, and to investigate whether these influences varied by gender. A total of 1042 monozygotic (MZ) twin pairs and 828 dizygotic (DZ) twin pairs who had completed the University of Washington Twin Registry survey were assessed for three fatigue-related variables: prolonged fatigue, chronic fatigue, and CFS. Structural equation twin modeling was used to determine the relative contributions of additive genetic effects, shared environmental effects, and individual-specific environmental effects to the 3 fatigue conditions. In women, tetrachoric correlations were similar for MZ and DZ pairs for prolonged and chronic fatigue, but not for CFS. In men, however, the correlations for prolonged and chronic fatigue were higher in MZ pairs than in DZ pairs. About half the variance for both prolonged and chronic fatigue in males was due to genetic effects, and half due to individual-specific environmental effects. For females, most variance was due to individual environmental effects.
Schur EA, Afari N, Furberg H, Olarte M, Goldberg J, Sullivan PF, Buchwald D.	Department of Medicine, University of Washington School of Medicine, Seattle, WA, USA. ellschur@u.washington.edu	Feeling bad in more ways than one: comorbidity patterns of medically unexplained and psychiatric conditions.	J Gen Intern Med. 2007 Jun;22(6):818-21.	BACKGROUND: Considerable overlap in symptoms and disease comorbidity has been noted among medically unexplained and psychiatric conditions seen in the primary care setting, such as chronic fatigue syndrome, low back pain, irritable bowel syndrome, chronic tension headache, fibromyalgia, temporomandibular joint disorder, major depression, panic attacks, and posttraumatic stress disorder. OBJECTIVE: To examine interrelationships among these 9 conditions. DESIGN: Using data from a cross-sectional survey, we described associations and used latent class analysis to investigate complex interrelationships. PARTICIPANTS: 3,982 twins from the University of Washington Twin Registry. MEASUREMENTS: Twins self-reported a doctor's diagnosis of the conditions. RESULTS: Comorbidity among these 9 conditions far exceeded chance expectations; 31 of 36 associations were significant. Latent class analysis yielded a 4-class solution. Class I (2% prevalence) had high frequencies of each of the 9 conditions. Class II (8% prevalence) had high proportions of multiple psychiatric diagnoses. Class III (17% prevalence) participants reported high proportions of depression, low back pain, and headache. Participants in class IV (73% prevalence) were generally healthy. Class I participants had the poorest markers of health status. CONCLUSIONS: These results support theories suggesting that medically unexplained conditions share a common etiology. Understanding patterns of comorbidity

				can help clinicians care for challenging patients.

Shevchuk NA.	Molecular Radiobiology Section, the Department of Radiation Oncology, Virginia Commonwealth University School of Medicine, 401 College St, Richmond, VA 23298, USA. nshevchuk@comcast.net.	Possible use of repeated cold stress for reducing fatigue in chronic fatigue syndrome: a hypothesis.	Behav Brain Funct. 2007 Oct 24;3:55.	ABSTRACT: BACKGROUND: Physiological fatigue can be defined as a reduction in the force output and/or energy-generating capacity of skeletal muscle after exertion, which may manifest itself as an inability to continue exercise or usual activities at the same intensity. A typical example of a fatigue-related disorder is chronic fatigue syndrome (CFS), a disabling condition of unknown etiology and with uncertain therapeutic options. Recent advances in elucidating pathophysiology of this disorder revealed hypofunction of the hypothalamic-pituitary-adrenal axis and that fatigue in CFS patients appears to be associated with reduced motor neurotransmission in the central nervous system (CNS) and to a smaller extent with increased fatigability of skeletal muscle. There is also some limited evidence that CFS patients may have excessive serotonergic activity in the brain and low opioid tone. PRESENTATION OF THE HYPOTHESIS: This work hypothesizes that repeated cold stress may reduce fatigue in CFS because brief exposure to cold may transiently reverse some physiological changes associated with this illness. For example, exposure to cold can activate components of the reticular activating system such as raphe nuclei and locus ceruleus, which can result in activation of behavior and increased capacity of the CNS to recruit motoneurons. Cold stress has also been shown to reduce the level of serotonin in most regions of the brain (except brainstem), which would be consistent with reduced fatigue according to animal models of exercise-related fatigue. Finally, exposure to cold increases metabolic rate and transiently activates the hypothalamic-pituitary-adrenal axis as evidenced by a temporary increase in the plasma levels of adrenocorticotropic hormone, beta-endorphin and a modest increase in cortisol. The increased opioid tone and high metabolic rate could diminish fatigue by reducing muscle pain and accelerating recovery of fatigued muscle, respectively. TESTING THE HYPOTHESIS: To test the hypothesis, a treatment is proposed that consists of adapted cold showers (20 degrees Celsius, 3 minutes, preceded by a 5-minute gradual adaptation to make the procedure more comfortable) used twice daily. IMPLICATIONS OF THE HYPOTHESIS: If testing supports the proposed hypothesis, this could advance our understanding of the mechanisms of fatigue in CFS.
Shin JI, Lee JS.		Can chronic fatigue symptoms associated with nutcracker phenomenon be treated with aspirin?	Med Hypotheses. 2007;69(3):704-5. Epub 2007 Feb 27. Comment on: Med Hypotheses. 2007;68(6):1318-27.	
Shinchuk LM, Holick MF.	Spaulding Rehabilitation Hospital, Boston,	Vitamin d and rehabilitation: improving	Nutr Clin Pract. 2007 Jun;22(3):297-304.	Vitamin D inadequacy is pandemic among rehabilitation patients in both inpatient and outpatient settings. Male and female patients of all ages and ethnic backgrounds are affected. Vitamin D deficiency causes osteopenia, precipitates and exacerbates osteoporosis, causes the painful bone

	MA, USA.	functional outcomes.	Erratum in: Nutr Clin Pract. 2007 Aug;22(4):table of contents. Shinchuk, Leonid [corrected to Shinchuk, Leonid M].	disease osteomalacia, and worsens proximal muscle strength and postural sway. Vitamin D inadequacy can be prevented by sensible sun exposure and adequate dietary intake with supplementation. Vitamin D status is determined by measurement of serum 25-hydroxyvitamin D. The recommended healthful serum level is between 30 and 60 ng/mL. 25-Hydroxyvitamin D levels of >30 ng/mL are sufficient to suppress parathyroid hormone production and to maximize the efficiency of dietary calcium absorption from the small intestine. This can be accomplished by ingesting 1000 IU of vitamin D(3) per day, or by taking 50,000 IU of vitamin D(2) every 2 weeks. Vitamin D toxicity is observed when 25-hydroxyvitamin D levels exceed 150 ng/mL. Identification and treatment of vitamin D deficiency reduces the risk of vertebral and nonvertebral fractures by improving bone health and musculoskeletal function. Vitamin D deficiency and osteomalacia should be considered in the differential diagnosis of patients with musculoskeletal pain, fibromyalgia, chronic fatigue syndrome, or myositis. There is a need for better education of health professionals and the general public regarding the optimization of vitamin D status in the care of rehabilitation patients.
Sleigh KM, Danforth DG, Hall RT, Fleming JA, Stiver HG.	Division of Infectious Disease, Department of Medicine;	Double-blind, randomized study of the effects of influenza vaccination on the specific antibody response and clinical course of patients with chronic fatigue syndrome.	Can J Infect Dis. 2000 Sep;11(5):267-73.	OBJECTIVE: To determine whether influenza immunization is associated with early side effects, a deleterious impact on the illness course and depressed antibody response in patients with chronic fatigue syndrome (CFS). DESIGN: Prospective, randomized, double-blind, placebo controlled trial. CFS patients and healthy volunteers filled out a questionnaire on immunization side effects and had hemagglutination-inhibiting (HI) antibody titres measured pre- and three weeks after immunization. CFS patients completed symptom and function questionnaires before and during the six-week, postimmunization period. SETTING: Ambulatory care. POPULATION STUDIED: Convenience sample of 40 CFS patients fulfilling the Centers for Disease Control and Prevention criteria and 21 demographically matched healthy volunteers. INTERVENTIONS: CFS patients were randomly selected to receive commercially available whole virus influenza vaccine (n=19) or an injection of saline placebo (n=21). Healthy volunteers received vaccine only. MAIN RESULTS: As a group, immunized CFS patients had lower geometric mean HI antibody rises than healthy volunteers (P<0.001). However, there was no difference in the rates of fourfold titre rises, and immunization did achieve a probably protective titre (1:32 or greater) in most CFS patients. No difference could be detected between immunized and placebo CFS patients in immunization side effects, although CFS patients as a group reported four times as many side effects as healthy volunteers. Further, in the six weeks following immunization, placebo and immunized CFS patients did not demonstrate any differences in terms of functioning, symptom severity and sleep disturbance. CONCLUSIONS: In patients with CFS, influenza immunization is safe, not associated with any excess early reactions, and stimulates an immunizing response comparable with that of healthy volunteers.
Smith AK, Dimulescu I, Falkenberg VR, Narasimhan S, Heim C, Vernon SD, Rajeevan MS.	Division of Viral and Rickettsial Diseases, National Center for Infectious Diseases, Centers for Disease Control	Genetic evaluation of the serotonergic system in chronic fatigue syndrome.	Psychoneuroendocrinology. 2007 Dec 11 [Epub ahead of print]	Chronic fatigue syndrome (CFS) is a debilitating disorder of unknown etiology with no known lesions, diagnostic markers or therapeutic intervention. The pathophysiology of CFS remains elusive, although abnormalities in the central nervous system (CNS) have been implicated, particularly hyperactivity of the serotonergic (5-hydroxytryptamine; 5-HT) system and hypoactivity of the hypothalamic-pituitary-adrenal (HPA) axis. Since alterations in 5-HT signaling can lead to physiologic and behavioral changes, a genetic evaluation of the 5-HT system was undertaken to identify serotonergic markers associated with CFS and potential mechanisms for CNS abnormality. A total of 77 polymorphisms in genes related

	and Prevention, 1600 Clifton Road, MSG41, Atlanta, GA 30333, USA.			to serotonin synthesis (TPH2), signaling (HTR1A, HTR1E, HTR2A, HTR2B, HTR2C, HTR3A, HTR3B, HTR4, HTR5A, HTR6, and HTR7), transport (SLC6A4), and catabolism (MAOA) were examined in 137 clinically evaluated subjects (40 CFS, 55 with insufficient fatigue, and 42 non-fatigued, NF, controls) derived from a population-based CFS surveillance study in Wichita, Kansas. Of the polymorphisms examined, three markers (-1438G/A, C102T, and rs1923884) all located in the 5-HT receptor subtype HTR2A were associated with CFS when compared to NF controls. Additionally, consistent associations were observed between HTR2A variants and quantitative measures of disability and fatigue in all subjects. The most compelling of these associations was with the A allele of -1438G/A (rs6311) which is suggested to have increased promoter activity in functional studies. Further, in silico analysis revealed that the -1438 A allele creates a consensus binding site for Th1/E47, a transcription factor implicated in the development of the nervous system. Electrophoretic mobility shift assay supports allele-specific binding of E47 to the A allele but not the G allele at this locus. These data indicate that sequence variation in HTR2A, potentially resulting in its enhanced activity, may be involved in the pathophysiology of CFS.
Spain LA, Tubridy N, Kilpatrick TJ, Adams SJ, Holmes AC.	Department of Neurology, Royal Melbourne Hospital, Parkville, Vic., Australia.	Illness perception and health-related quality of life in multiple sclerosis.	Acta Neurol Scand. 2007 Nov;116(5):293-9. Epub 2007 Sep 11.	AIMS - A number of physical and psychological factors have been shown to affect health-related quality of life (HRQoL) in patients with multiple sclerosis (MS). Among these, the role of illness perceptions has not been established as an independent factor. This study, the first of its kind in an Australian population, aimed to use a large sample to determine the relative importance of individual factors to each domain of HRQoL, in particular the role of illness perception. MATERIALS AND METHODS - 580 patients with confirmed MS were assessed cross sectionally in a designated research clinic to determine the relative impact of physical factors (illness severity, duration, age, fatigue and pain) and psychological factors (mood, cognition and illness representations) on each domain of the SF-36. RESULTS - Categorical regression analysis showed that a combination of physical and psychological factors predicted 38-71% of variance in HRQoL. Illness perception was shown to have an independent effect on HRQoL in MS. The Extended Disability Status Scale was a significant determinant in all domains except for mental health. Depression was less prevalent than anxiety, but had a greater effect on function. CONCLUSION - Illness perception is an independent factor contributing to HRQoL in people with MS. Individual domains of HRQoL are associated with different patterns of physical and psychological factors. In the domains of role and social function, activities most highly valued by patients with MS, depression, anxiety, fatigue and illness perceptions are key determinants, all of which have the potential to be improved through specific interventions.
Spence VA, Kennedy G, Belch JJ, Hill A, Khan F.		Low grade inflammation and arterial wave reflection in patients with chronic fatigue syndrome.	Clin Sci (Lond). 2007 Nov 21 [Epub ahead of print]	Some of the symptoms reported by people with chronic fatigue syndrome (CFS) are associated with various cardiovascular phenomena. Markers of cardiovascular risk, including inflammation and oxidative stress, have been demonstrated in some CFS patients but little is known about the relationship of these and prognostic indicators of cardiovascular risk in this patient group. We sought to investigate the relationship between inflammation and oxidative stress and augmentation index, a measure of arterial stiffness, in 41 well characterised CFS patients and in 30 healthy subjects. The augmentation index, normalised for a heart rate of 75 beats per minute (AIx@75), was significantly greater in CFS patients than in control subjects (22.5 +/- 1.7 versus 13.3 +/- 2.3%, P=0.002). CFS patients also had significantly increased levels of C-reactive protein (2.58 +/- 2.91 versus 1.07 +/- 2.16

				g/mL, P<0.01) and 8-iso-prostaglandin F 2alpha isoprostanes (470.7 +/- 250.9 versus 331.1 +/- 97.6 pg/mL, P<0.005). In CFS patients, AIx@75 significantly correlated with log C-reactive protein (r=0.507, P=0.001), isoprostanes (r=0.366, P=0.026), oxidised LDL (r=0.333, P=0.039) and systolic blood pressure (r=0.371, P=0.017). In a stepwise multiple regression model, (including systolic and diastolic blood pressure, body mass index, C-reactive protein, TNFalpha, IL-1, oxidised LDL, HDL cholesterol levels, isoprostanes, age and gender), AIx@75 was independently associated with log CRP (beta=0.385, P=0.006), age (beta=0.363, P=0.022), and female gender (beta=0.302, P=0.03) in CFS patients. The combination of increased arterial wave reflection, inflammation and oxidative stress may result in an increased risk of future cardiovascular events. Assessment of arterial wave reflection might be useful for determining cardiovascular risk in this patient group.
Stenlund T, Ahlgren C, Lindahl B, Burell G, Knutsson A, Stegmayr B, Birgander LS.	Department of Public Health and Clinical Medicine, Umeå University, Sweden. therese.stenlund@vll.se	Patients with burnout in relation to gender and a general population.	Scand J Public Health. 2007;35(5):516-23.	AIMS: The aims of this study were to describe gender differences in patients with burnout and compare these patients with a general population with respect to physical, psychosocial and work variables. METHODS: Data were collected from a total of 136 patients (96 women and 40 men, 41.6 +/- 7.4 years), diagnosed with stress-related disease and burnout at the Stress Clinic, University Hospital of Umeå. Data on burnout, physical, psychosocial and work characteristics were compared with similar data from a geographical and age-matched population based survey, the 2004 Northern Sweden MONICA study. The survey sample included a total of 573 participants (283 women and 290 men, 40.7 +/- 8.5 years). RESULTS: Women with burnout reported a higher rate of impaired awakening, lower job control, greater proportion of unpaid work and worked to a greater extent "with people" compared to men. Men with burnout had a more restricted social network and reported working more overtime than women. Patients with burnout reported a higher rate of unemployment, a more restricted social network and higher work demands compared to a general population. Women with burnout reported less emotional support, a more sedentary work situation, high job strain and worked to a greater extent "with people" than women from the general population. CONCLUSIONS: There are some differences in working conditions and social network between women and men with burnout. Patients with burnout differ from a general population regarding individual and social factors as well as work-related factors.
Tackenberg B, Himmerich H, Wellek A, Oertel WH, Sommer N.	Philipps Universität Marburg und Universitäts-klinikum Giessen. tackenbb@med.uni-marburg.de	[Advances in the treatment of multiple sclerosis?] [Article in German]	MMW Fortschr Med. 2007 May 21;149 Suppl 2:51-5.	The natural course of multiple sclerosis (MS) is probably more favourable than previously assumed years ago. Since the introduction of interferons in Germany, the establishment and further development of new diagnostic criteria (McDonald criteria), the causal and symptomatic treatment possibilities and initiation of therapy early in the course of the disease have led to a considerable change in the treatment of MS. MS attacks are usually treated with the intravenous administration of high-dosed steroids. When the attack symptoms do not sufficiently subside, plasmapheresis can be considered. For long-term treatment of MS, beta interferon, glatirameracetate and natalizumab are available as basic causal therapy and natalizumab and mitoxantrone are available for escalation therapy. Frequently occurring spasticity, chronic fatigue syndrome, depression, cognitive disturbances, incontinence, pain, ataxia and sexual disorders must be treated symptomatically. Overall, the outpatient treatment of MS is complex and should be carried out with close cooperation between the family doctor, neurological practices and outpatient departments specialized in treating MS.
Tajima S,	Fatigue Clinical	[Estimation of	Nippon Rinsho.	OBJECTIVES: In this study, we try to estimate the fatigue state using actigraphy and R-R interval power

Kuratsune H, Yamaguti K, Takahashi A, Takashima S, Watanabe Y, Nishizawa Y.	Center, Osaka City University Graduate School of Medicine.	fatigue state in patient with CFS using actigraph and R-R interval power spectrum analysis] [Article in Japanese]	2007 Jun;65(6):1057-64.	spectrum analysis. RESULTS: Actigraphy analysis showed that mean awake activity was decreased and duration of sleep was prolonged in patients with chronic fatigue syndrome (CFS), significantly ($p < 0.001$). Both of sleep episodes in wake period and wake episodes in sleep period were significantly increased in CFS patients in comparison with healthy volunteers ($p < 0.001$) In autonomic nerve analysis, sleep/awake ratio of high frequency component was significantly decreased in patients with CFS ($p < 0.05$). CONCLUSION: The quality of sleep in patients with CFS was decreased because of increase of wake episodes in sleep period. Also the lack of parasympathetic activation during sleep period might be associated with the deterioration of sleep quality in patients with CFS.
Takken T, Henneken T, van de Putte E, Helders P, Engelbert R.	Pediatric Physical Therapy and Exercise Physiology, UMC Utrecht, Utrecht, Netherlands. t.takken@umcutrecht.nl	Exercise testing in children and adolescents with chronic fatigue syndrome.	Int J Sports Med. 2007 Jul;28(7):580-4. Epub 2007 Mar 15.	The objective of this study was to evaluate exercise capacity in children and adolescents diagnosed with Chronic Fatigue Syndrome (CFS). We examined 20 patients (12 girls and 8 boys; mean age 14.9 +/- 3.7 years) diagnosed with CFS. Exercise capacity was measured using a maximal exercise test on a bicycle ergometer and an expired gas analysis system. Fatigue was assessed using a questionnaire and a daily activity diary was used to describe activities for three days. Z-scores were calculated using age- and sex-matched reference values. Z-scores in children and adolescents with CFS were - 0.33 +/- 1.0 ($p = 0.17$) for peak oxygen uptake, - 1.13 +/- 1.41 ($p = 0.002$) for relative peak oxygen uptake [ml/kg/min] and - 0.93 +/- 1.29 ($p = 0.07$) for maximal work load. Both heart rate and blood pressure at peak performance were significantly reduced compared to reference values. Fatigue levels were significantly positively associated with age and negatively with blood pressure at peak exercise ($p < 0.05$). In conclusion maximum exercise testing was feasible in young people with CFS. Maximal exercise capacity was only reduced in a minority of the patients and was related to current physical activity levels.
Tanaka H.	Department of Pediatrics, Osaka Medical College.	[Autonomic function and child chronic fatigue syndrome] [Article in Japanese	Nippon Rinsho. 2007 Jun;65(6):1105-12.	It is postulated that child chronic fatigue syndrome (CFS) involves the autonomic nervous system, although the precise mechanism has not been clearly indicated. This paper reviews recent reports focusing the role of the autonomic nervous system which plays in CFS. Many of the method for measuring autonomic function have appeared in the clinical setting in parallel with advancing computer technology, but these are limited when applied in children. In these blood pressure and heart rate changes during orthostatic stress and these variability are favorably used. As a result, one third of children with CFS showed abnormal cardiovascular adjustment during posture change (orthostatic dysregulation: OD) which is characterized by instantaneous orhthostatic hypotension, postural tachycardia or neurally-mediated syncope. Most of the studies using power spectral analysis of heart rate variability showed sympathetic activation, however no consistent finding has been obtained. In conclusion, autonomic function might be partly involved in CFS such as OD, but its priority in causing CFS is unclear.
Tanriverdi F, Karaca Z, Unluhizarci K, Kelestimur F.	Department of Endocrinology, Medical School, Erciyes University, Kayseri, Turkey.	The hypothalamo-pituitary-adrenal axis in chronic fatigue syndrome and fibromyalgia syndrome.	Stress. 2007 Mar;10(1):13-25.	The hypothalamo-pituitary-adrenal (HPA) axis plays a major role in the regulation of responses to stress. Human stress-related disorders such as chronic fatigue syndrome (CFS), fibromyalgia syndrome (FMS), chronic pelvic pain and post-traumatic stress disorder are characterized by alterations in HPA axis activity. However, the role of the HPA axis alterations in these stress-related disorders is not clear. Most studies have shown that the HPA axis is underactive in the stress-related disorders, but contradictory results have also been reported, which may be due to the patients selected for the study, the methods used for the investigation of the HPA axis, the stage of the syndrome when the

				tests have been done and the interpretation of the results. There is no structural abnormality in the endocrine organs which comprise the HPA axis, thus it seems that hypocortisolemia found in the patients with stress-related disorder is functional. It may be also an adaptive response of the body to chronic stress. In this review, tests used in the assessment of HPA axis function and the HPA axis alterations found in CFS and FMS are discussed in detail.
Ter Wolbeek M, van Doornen LJ, Coffeng LE, Kavelaars A, Heijnen CJ.	Laboratory of Psychoneuroimmunology, University Medical Center Utrecht, Office KC03.068.0, P.O. Box 85090, 3508 AB, Utrecht, The Netherlands.	Cortisol and severe fatigue: a longitudinal study in adolescent girls.	Psychoneuroendocrinology. 2007 Feb;32(2):171-82. Epub 2007 Feb 6.	Fatigue is a common complaint among adolescents, especially in girls, and is associated with high rates of school absenteeism. Severe fatigue is often accompanied by psychological and physical symptoms. In the chronic fatigue syndrome (CFS) functioning of the hypothalamic-pituitary-adrenal (HPA)-axis has previously been found to be altered. The aim of the present study was to investigate whether cortisol production is deviant in fatigued adolescent girls from the general population and to study longitudinal changes in fatigue in association with possible changes in HPA-axis functioning. In the cross-sectional part of the study the cortisol response to awakening (CAR) and to a low-dose oral dexamethasone were examined in a group of fatigued adolescent girls (n=87) in comparison to a non-fatigued control group (n=77). Questionnaires regarding fatigue, depression, anxiety, sleep quality, somatic symptoms and CFS-related symptoms were filled out. Follow up measurements were performed after 6 and 12 months. While the fatigued and non-fatigued group differed remarkably on all symptom self-reports, no differences between groups in CAR and response to dexamethasone were observed. Girls in the fatigued group remained fatigued over time and reported high levels of other psychological and physical symptoms during the whole year of the study. The CAR varied between time points but correlated non-systematically with situational characteristics or symptom reports. We conclude that trait-like fatigue, as measured in a sample of adolescent girls from a high school population, is not reflected in a dysregulation as assessed on the level of salivary cortisol after awakening.
ter Wolbeek M, van Doornen LJ, Kavelaars A, van de Putte EM, Schedlowski M, Heijnen CJ.	Laboratory of Psychoneuroimmunology, University Medical Center Utrecht, 3508 AB Utrecht, The Netherlands.	Longitudinal analysis of pro- and anti-inflammatory cytokine production in severely fatigued adolescents.	Brain Behav Immun. 2007 Nov;21(8):1063-74. Epub 2007 Jun 1.	In the adolescent population, fatigue is associated with somatic complaints, unrefreshing sleep, cognitive disturbances and symptoms of depression and anxiety. This pattern of symptoms resembles the one described in chronic fatigue syndrome (CFS). Since immunological alterations have been reported in CFS patients, we wondered whether also severely fatigued girls from a healthy population would show comparable alterations in psychological and immunological parameters. We tested this hypothesis in a longitudinal design, allowing a reliable assessment of the participants' characteristic immune status. Groups of severely fatigued (N=67) and non-fatigued (N=61) participants were selected. Severely fatigued girls reported more depressive symptoms, anxiety, reduced sleep quality, and somatic and CFS-related symptoms than non-fatigued participants across three measurements during one year (T1: spring, T2: autumn, T3: spring). In contrast, no group differences in mitogen-induced cytokine production or T-cell proliferation in vitro or in leukocyte subset counts were observed. Although absolute cytokine production and cell counts were affected by seasonal variation, the within-subject values, relatively to the rest of the participants, were fairly stable. Data from a small group of CFS patients (N=11) showed similarities in self-reported complaints between CFS patients and fatigued participants. Interestingly, CFS patients showed a distinct immune profile when compared to the severely fatigued or non-fatigued participants, i.e. increased levels of anti-inflammatory cytokines (IL-10, decreased IFN-gamma/IL-10 ratio) and reduced levels of pro-inflammatory cytokines (IL-6, TNF-

				alpha) over all three time points analyzed. These results show that, although overlap in symptomatology between the general population and patients with CFS was observed, only CFS patients show a skewing of the cytokine balance towards an anti-inflammatory profile.
Thanawala Sachi, Renee R. Taylor		Service Utilization, Barriers to Service Access, and Coping in Adults with Chronic Fatigue Syndrome	Journal of Chronic Fatigue Syndrome 2007; 14(1): 5 - 21	Objective: In a sample of 47 adults with CFS, we aimed to describe patterns of service utilization, identify barriers to service access, and explore the relationship between service utilization and coping styles. Method: A questionnaire assessing service utilization frequency and barriers to service access was administered to a sample of 47 individuals with CFS. The Illness Management Questionnaire was used to assess relationships between coping styles and service utilization. Results: A Cochran's Q test of homogeneity revealed that medical and CFS self-help services were most frequently used and rehabilitation services were least frequently used. In terms of service accessibility, 80.9% of participants reported at least one barrier. Lack of financial (including insurance) resources and lack of knowledge about service availability were the two most frequently reported. In terms of coping styles, symptom focusing was positively associated with use of CFS self-help services and with use of in-home services and social service agencies. Information seeking was negatively associated with use of in-home and social service agencies and with use of mental health services. Conclusion: These findings can be used by health-care professionals and advocacy-based organizations to develop programs focused on mass education campaigns for health-care providers, increase knowledge of service availability among individuals with CFS, and to understand relationships between certain types of coping styles and service preferences.
The GK, Bleijenberg G, van der Meer JW.	Department of General Internal Medicine, Nijmegen Expert Centre Chronic Fatigue, Radboud University Nijmegen Medical Centre, Nijmegen, The Netherlands. g.the@aig.umcn.nl	The effect of acclydine in chronic fatigue syndrome: a randomized controlled trial.	PLoS Clin Trials. 2007 May 18;2(5):e19.	OBJECTIVES: It is unclear whether insulin-like growth factor (IGF) function is involved in the pathophysiology of chronic fatigue syndrome (CFS). Unpublished data and reports in patient organization newsletters suggest that Acclydine, a food supplement, could be effective in the treatment of CFS by increasing biologically active IGF1 levels. Here we aimed to measure the IGF1 and IGF binding protein (IGFBP) 3 status of CFS patients compared to age- and gender-matched neighborhood controls, and to assess the effect of Acclydine on fatigue severity, functional impairment, and biologically active IGF1 level (IGFBP3/IGF1 ratio). DESIGN: A randomized, placebo-controlled, double-blind clinical trial. SETTING: Radboud University Nijmegen Medical Centre, The Netherlands. PARTICIPANTS: Fifty-seven adult patients who fulfilled the US Centers for Disease Control and Prevention criteria for CFS. IGF status of 22 CFS patients was compared to that of 22 healthy age- and gender-matched neighborhood control individuals. INTERVENTION: Acclydine or placebo for 14 wk. OUTCOME MEASURES: Outcomes were fatigue severity (Checklist Individual Strength, subscale fatigue severity [CIS-fatigue]), functional impairment (Sickness Impact Profile-8 [SIP-8]), and biologically active IGF1 serum concentrations. Analyses were on an intention-to-treat basis. RESULTS: There was no difference in IGF status in 22 CFS patients compared to healthy age- and gender-matched control individuals. Treatment with Acclydine did not result in significant differences compared with the placebo group on any of the outcome measures: CIS-fatigue +1.1 (95% CI -4.4 to +6.5, p = 0.70), SIP-8 +59.1 (95% CI -201.7 to +319.8, p = 0.65), and IGFBP3/IGF1 ratio -0.5 (95% CI -2.8 to +1.7, p = 0.63). CONCLUSION: We found no differences in IGF1 status in CFS patients compared to healthy matched neighborhood controls. In addition, the results of this clinical trial do not demonstrate any benefit of Acclydine over placebo in the treatment of CFS.

Tietjen GE, Bushnell CD, Herial NA, Utley C, White L, Hafeez F.	Department of Neurology, University of Toledo Medical Center, Health Science Campus, 3120 Glendale Avenue, Toledo, OH 43614, USA.	Endometriosis is associated with prevalence of comorbid conditions in migraine.	Headache. 2007 Jul-Aug;47(7):1069-78.	OBJECTIVE: To examine the headache characteristics of women with migraine and endometriosis (EM), and differences in the prevalence of comorbid conditions between female migraineurs with EM, without EM and nonheadache controls. BACKGROUND: Migraine and EM are common conditions in women of reproductive age, and both are influenced by ovarian hormones. The comorbidity of migraine and EM is newly recognized, but reasons for the association are uncertain. METHODS: This is a cross-sectional study of female headache outpatients and healthy controls conducted at University of Toledo and Duke University in 2005 and 2006. After a headache specialist determined headache frequency and diagnosis (based on criteria of the second International Classification of Headache Disorders), patients completed a self-administered electronic survey with information on demographics, headache-related disability, menstrual disorders, premenstrual dysphoric disorder (PMDD), vascular event risk, and comorbid conditions, including irritable bowel syndrome (IBS), fibromyalgia (FM), chronic fatigue syndrome (CFS), interstitial cystitis (IC), depression, and anxiety. RESULTS: Study enrolled 171 women with migraine and 104 controls. EM was reported more commonly in migraineurs than in controls (22% vs 9.6%, P < .01). Frequency of chronic headache was higher in migraineurs with EM compared to without EM (P= .002) and median headache-related disability scores were also higher in the EM group (P= .025). Symptoms of PMDD were more common in migraineurs, but frequency did not differ by EM status. Migraineurs with EM reported more menorrhagia, dysmenorrhea, and infertility compared to the migraine cohort without EM and to controls. Depression, anxiety, IBS, FM, CFS, and IC were more common in migraine with EM group than in controls. Anxiety (OR = 2.2, 95% CI 1.0-4.7), IC (OR = 10.6, 95% CI 1.9-56.5), and CFS (OR = 3.6, 95% CI 1.1-11.5) were more common in migraine with EM group, than in the cohort with migraine without EM. CONCLUSION: Prevalence of EM is higher in women with migraine than in nonheadache controls. Migraineurs with EM have more frequent and disabling headaches, and are more likely to have other comorbid conditions affecting mood and pain, compared to migraineurs without EM.
Tietjen GE, Herial NA, Hardgrove J, Utley C, White L.	Department of Neurology, The University of Toledo College of Medicine, Toledo, OH 43614, USA.	Migraine comorbidity constellations.	Headache. 2007 Jun;47(6):857-65. Comment in: Headache. 2007 Jun;47(6):876-7.	OBJECTIVES: To identify distinct constellations of comorbid disorders occurring in migraineurs, and to examine differences in demographics, headache profiles, and psychosocial features between the comorbidity constellations. METHODS: This is a retrospective electronic chart review of consecutive new female outpatients diagnosed with migraine (n = 223) using International Classification of Headache Disorders (ICHD)-II criteria. Questionnaire collected information on comorbid diagnoses, current depression, somatic symptoms, psychosocial stressors, and antidepressant use, social and abuse history. Cluster analysis, based on nonheadache disorders, was performed and differences between the resulting groups were examined. RESULTS: We identified 3 groups. Group 1 (n = 55) was defined by hypertension, hyperlipidemia, diabetes mellitus, and hypothyroidism; Group 2 (n = 83) by depression, anxiety, and fibromyalgia; Group 3 (n = 85) by the absence of defining comorbidities. Group 1 had more males (22% vs 5% vs 12%, P < .05), was older (median years: 52 vs 36 vs 32, P < .01), and had later age of headache onset (median years: 22 vs 16 vs 18, P < .05). Group 2 had the greatest disability (P < .05), and the lowest quality of life (P < .001). Persons in Group 2 more commonly reported sexual abuse (OR = 2.7, 95% CI: 1.1 to 6.5), physical abuse (OR = 2.5, 95% CI: 1.2 to 5.1), and emotional abuse (OR = 4.3, 95% CI: 1.9 to 8.9). CONCLUSION: Within a headache clinic population, we identified 3 different migraine comorbidity constellations, with differing headache and psychosocial

				profiles, suggesting heterogeneity of genetic and environmental factors. This may have implications for diagnosis and disease management.
Tjørve E, Tjørve KM, Olsen JO, Senum R, Oftebro H.	Lillehammer University College, 2626 Lillehammer, Norway. even.tjorve@hil.no	On commonness and rarity of thyroid hormone resistance: a discussion based on mechanisms of reduced sensitivity in peripheral tissues.	Med Hypotheses. 2007;69(4):913-21. Epub 2007 Mar 26.	Reduced sensitivity to thyroid hormone (TH) in peripheral tissues can occur as defects in TH transport into the cell, intracellular TH metabolism, cytosolic mechanisms, TH entry into the nucleus, thyroxin receptors (TRs) and receptor binding, transcription and post-transcriptional mechanisms. Current literature reveals an extensive list of mutations, drugs, toxins, metabolites and autoimmune antibodies that may impair TH action in the cell, but such impairment may not be picked up by assays of TH and TSH in blood plasma. Substances may induce tissue specific resistance to thyroid hormone (RTH), e.g. by affecting numbers of different TR isoforms. Recent literature also indicates mechanisms by which different conditions, for example, chronic fatigue syndrome (CFS), chronic renal failure (CRF) and nonthyroidal illness, can be accompanied by acquired RTH caused by inhibition of TH metabolism, cell uptake, TR binding and transcription. This prompts us to reassess commonness and rarity of congenital vs. acquired RTH. We hypothesise that observed clinical symptoms of hypothyroidism in chemically euthyroid patients are typically caused by changes in hormonal systems, autoimmune antibodies, metabolites or other substances in the body, leading to reduced sensitivity to TH in peripheral tissues. These changes may be a by-product of other processes and a reversible biological response in the body, and may also result in chronic acquired RTH. Antibodies may prove to be the most common cause of chronic reduction in TH sensitivity. It is argued that the acquired form of RTH, caused by endogenous and exogenous sources, may indeed be more common than the congenital, as in insulin resistance. If acquired RTH exists, then it may not be picked up by blood assays of TH and TSH. An appropriate test to assess TH action in peripheral tissues is therefore greatly desired.
Tomoda A.	Department of Child Developmental Sociology, Faculty of Medical and Pharmaceutical Sciences, Kumamoto University.	[School phobia and childhood chronic fatigue syndrome (CCFS)] [Article in Japanese]	Nippon Rinsho. 2007 Jun;65(6):1121-33.	Chronic fatigue occurring in previously healthy children and adolescents is a vexing problem encountered by pediatric practitioners and the impact of fatigue in youngsters should not be underestimated. In its severe form, it is often associated with mood disorders. Findings in children and adolescent cases suggest that severe unexplained fatigue might precede the development of fatigue-related illness, such as childhood chronic fatigue syndrome (CCFS). This is a disabling condition characterized by severe disabling fatigue and a combination of symptoms, the prominent features being self-reported impairments in concentration and short-term memory, sleep disturbances and autonomic symptoms that cannot be explained by medical or psychiatric illness. We have encountered such patients with these complaints; their major symptoms include: general fatigue, fever, headache (not migraine), and memory disturbance. From our clinical experience, we have inferred that patients with CCFS might experience changes in brain function levels, which induce an autonomic imbalance and engender symptoms such as general fatigue, higher-order level cognitive dysfunction, and memory disturbance.
Torpy DJ, Ho JT.	Endocrine and Metabolic Unit, and the Hanson Institute, Royal Adelaide Hospital, Adelaide, South	Corticosteroid-binding globulin gene polymorphisms: clinical implications and	Clin Endocrinol (Oxf). 2007 Aug;67(2):161-7. Epub 2007 Jun 4.	Corticosteroid-binding globulin (CBG) binds cortisol with high affinity, facilitating transport of cortisol in blood, although tissue-specific CBG-cortisol interactions have long been postulated. There are three heritable, human CBG gene mutations that can reduce CBG-cortisol binding affinity and/or reduce circulating CBG levels. In some families, fatigue and low blood pressure have been associated with affinity altering or CBG level reducing mutations. The limited numbers of reports raise the possibility of ascertainment bias as many cases presented with features suggesting cortisol deficiency. The recent

	Australia, Australia. dtorpy@mail.rah.sa.gov.au	links to idiopathic chronic fatigue disorders.		description of a genetically CBG-deficient mouse listed fatigue, manifest as reduced activity levels, as part of the phenotype, which also included immune aberrations. Severe CBG mutations may produce fatigue, but one study suggests that these are a rare cause of idiopathic fatigue. A mechanism for the effect of CBG mutations on fatigue is not readily apparent because free cortisol levels are normal, although we speculate that CBG may have an effect on cortisol-brain transport.
Travers MK, Lawler J.	Faculty of Nursing & Midwifery, University of Sydney, Australia.	Self within a climate of contention: Experiences of chronic fatigue syndrome.	Soc Sci Med. 2008 Jan;66(2):315-26. Epub 2007 Oct 24.	Chronic fatigue syndrome (CFS) is a contested condition associated with scepticism and dispute. This qualitative project examines the illness experiences, and specifically the experiences of self, for people affected with CFS living in Australia. Using grounded theory methods, theory related to the process of self-renewal and adaptation associated with CFS is explicated. Narratives were derived from semi-structured interviews with 19 adults, including 3 people recovered from CFS. Analysis generated the narrative of the struggling self seeking renewal that defined the illness experience of CFS. The struggling self articulated the negative effects to self and personhood associated with CFS, defined as the violation of self, and the consequent efforts of participants to manage symptoms and decrease their violation by use of what was termed the Guardian Response and the Reconstructing Response. The Guardian Response provided protection and self-reclamation. The Reconstructing Response fostered self-renewal and meaning. The struggling self occurred within a climate of threats, and it was these threats which provided the catalyst for violation and the responses. Under different conditions the relative strengths of violation, guardianship or reconstruction fluctuated, and it was these fluctuations that presented the participants with the ongoing struggle of CFS.
Ullrich PM, Afari N, Jacobsen C, Goldberg J, Buchwald D.	Department of Rehabilitation Medicine, University of Washington, Seattle, WA 98104, USA. pullrich@u.washington.edu	Cold pressor pain sensitivity in monozygotic twins discordant for chronic fatigue syndrome.	Pain Med. 2007 Apr;8(3):216-22.	OBJECTIVE: Individuals with chronic fatigue syndrome (CFS) experience many pain symptoms. The present study examined whether pain and fatigue ratings and pain threshold and tolerance levels for cold pain differed between twins with CFS and their cotwins without CFS. DESIGN: Cotwin control design to assess cold pain sensitivity, pain, and fatigue in monozygotic twins discordant for CFS. PATIENTS AND SETTING: Fifteen monozygotic twin pairs discordant for CFS recruited from the volunteer Chronic Fatigue Twin Registry at the University of Washington. RESULTS: Although cold pain threshold and tolerance levels were slightly lower in twins with CFS than their cotwins without CFS, these differences failed to reach statistical significance. Subjective ratings of pain and fatigue at multiple time points during the experimental protocol among twins with CFS were significantly higher than ratings of pain ($P = 0.003$) and fatigue ($P < 0.001$) by their cotwins without CFS. CONCLUSIONS: These results, while preliminary, highlight the perceptual and cognitive components to the pain experience in CFS. Future studies should focus on examining the heritability of pain sensitivity and the underlying mechanisms involved in the perception of pain sensitivity in CFS.
van de Glind G, de Vries M, Rodenburg R, Hol F, Smeitink J, Morava E.	Department of Pediatrics, Nijmegen Centre for Mitochondrial Disorders, Radboud University Nijmegen Medical	Resting muscle pain as the first clinical symptom in children carrying the MTTK A8344G mutation.	Eur J Paediatr Neurol. 2007 Jul;11(4):243-6. Epub 2007 Feb 12.	The characteristic clinical presentation, especially the appearance of muscle symptoms, is quite unique in children carrying the mtA8344G mutation. The diagnosis of MERRF syndrome is seldom made in the pediatric age. Fatigue is a common finding in children of pubertal age. Fatigue in combination with recurrent resting muscle pain occurs frequently in the initial phase of various hereditary muscle disorders and in several autoimmune, endocrine and metabolic syndromes. In the absence of obvious biochemical/metabolic abnormalities and in the lack of neurological symptoms the complaints are frequently labelled as fibromyalgia or chronic fatigue syndrome. In patients with behavioural or psychiatric abnormalities one might even start to question the organic etiology of the

	Centre, 6500 HB Nijmegen, The Netherlands.			complaints. We describe a family carrying the classic MTTK mutation with a variable degree of heteroplasmy, presenting in childhood as isolated recurrent muscle pain as the first symptom of the disease.
van de Putte EM, Engelbert RH, Kuis W, Kimpen JL, Uiterwaal CS.	Department of Pediatrics, Wilhelmina Children's Hospital, University Medical Center Utrecht; The Netherlands. e.vandeputte@umcutrecht.nl	Alexithymia in adolescents with chronic fatigue syndrome.	J Psychosom Res. 2007 Oct;63(4):377-80.	BACKGROUND: Alexithymia is postulated as an important factor in the development of medically unexplained physical symptoms. Chronic fatigue syndrome (CFS) is presently medically unexplained. The aim of this study was to investigate whether the prevalence of alexithymia was higher in adolescents with CFS compared to healthy adolescents. Comorbidity such as anxiety and depression were analyzed as possible confounding factors. Secondly, alexithymia was investigated as a prognostic factor for the recovery of CFS. METHODS: A cross-sectional study was performed among 40 adolescent outpatients diagnosed with CFS and 36 healthy controls. The 20-item Toronto Alexithymia Scale was used to assess all participants for alexithymia. Additionally, all participants completed a number of questionnaires regarding fatigue (Checklist Individual Strength), somatic complaints (Checklist Somatization Inventory), depression (Children's Depression Inventory), and trait anxiety (Spielberger State Trait Anxiety Questionnaire). A follow-up study was performed among the CFS adolescents 1 1/2 years after the initial assessment. RESULTS: CFS adolescents scored higher only on the subscale identifying feelings of the TAS-20 [mean difference after adjustment for depression and anxiety 2.8 (95% CI: 0.6; 4.9]. Twelve CFS adolescents (30%) fulfilled criteria for alexithymia. This subgroup was characterized by higher scores for depression and anxiety and equal scores for fatigue and somatic complaints. At follow-up, no differences in recovery were established between the alexithymic and nonalexithymic CFS adolescents. CONCLUSIONS: Alexithymia neither appears to be a unique correlate of CFS nor to be a prognostic factor for recovery of the CFS illness.
Van Den Eede F, Moorkens G, Hulstijn W, Van Houdenhove B, Cosyns P, Sabbe BG, Claes SJ.	Department of Molecular Genetics VIB8, Flanders Interuniversity Institute for Biotechnology, University of Antwerp, Antwerp, Belgium.	Combined dexamethasone/corticotropin-releasing factor test in chronic fatigue syndrome.	Psychol Med. 2007 Sep 6;:1-11 [Epub ahead of print]	BACKGROUND: Studies of hypothalamic-pituitary-adrenal (HPA) axis function in chronic fatigue syndrome (CFS) point to hypofunction, although there are negative reports. Suggested mechanisms include a reduced hypothalamic or supra-hypothalamic stimulus to the HPA axis and enhanced sensitivity to the negative feedback of glucocorticoids. The aim of the current study was to investigate HPA axis function in CFS with the dexamethasone/corticotropin-releasing factor (Dex/CRF) test, in analogy with research in affective disorders.MethodThirty-four well-characterized female CFS patients and 25 healthy control subjects participated in the low-dose Dex/CRF test. Current major depressive episode was an exclusion criterion. History of early-life stress (ELS) was assessed with the Structured Trauma Interview. RESULTS: Salivary cortisol responses after 0.5 mg Dex were lower in CFS patients than in controls (before 100 mug CRF, p=0.038; after 100 mug CRF, p=0.015). A secondary analysis revealed an influence of early-life stress and of oestrogen intake. After removal of the 10 participants who were taking an oral oestrogen, patients without a history of ELS showed lower cortisol responses than patients with ELS and controls (before CRF, p=0.005; after CRF, p=0.008). CONCLUSIONS: CFS is globally associated with reduced cortisol responses in the combined low-dose Dex/CRF test, but this effect is only clearly present in CFS patients without a history of ELS. This study provides further support for an enhanced glucocorticoid negative feedback and/or a reduced central HPA axis drive in CFS. Furthermore, it demonstrates that ELS is an important variable to consider in CFS research.
Van Den Eede F, Moorkens G, Van	Department of Psychiatry,	Hypothalamic-pituitary-adrenal	Neuropsychobiology.	There is evidence for a hypofunction of the hypothalamic-pituitary-adrenal (HPA) axis in a proportion of the patients with chronic fatigue syndrome (CFS), despite the negative studies and methodological

Houdenhove B, Cosyns P, Claes SJ.	University Hospital Antwerp, Edegem, Belgium. filip.van.den.eede@uza.be	axis function in chronic fatigue syndrome.	2007;55(2):112-20. Epub 2007 Jun 27.	difficulties. In this review, we focus on challenge studies and on the role of the HPA axis in the pathogenesis of CFS. Mild hypocortisolism, blunted adrenocorticotropin response to stressors and enhanced negative feedback sensitivity to glucocorticoids are the main findings. Several underlying mechanisms have been proposed. Currently, it is a matter of debate whether these disturbances have a primary role in the pathogenesis of CFS. However, even if the HPA axis dysfunctions are secondary to other factors, they are probably a relevant factor in symptom propagation in CFS.
van Geelen SM, Sinnema G, Hermans HJ, Kuis W.	Department of Psychology, Wilhelmina Children's Hospital, University Medical Center Utrecht, The Netherlands.	Personality and chronic fatigue syndrome: methodological and conceptual issues.	Clin Psychol Rev. 2007 Dec;27(8):885-903. Epub 2007 Jan 27.	Among clinical psychologists, consulting physicians, scientific researchers and society in general an image has emerged of patients with chronic fatigue syndrome (CFS) as perfectionist, conscientious, hardworking, somewhat neurotic and introverted individuals with high personal standards, a great desire to be socially accepted and with a history of continuously pushing themselves past their limits. The aim of this article is to (a) give a concise review of the main recent studies on personality and CFS, (b) address the major methodological problems in the study of personality in CFS and (c) discuss some of the conceptual assumptions that seem to limit the research on personality and CFS. The results of the reviewed studies range from no evidence of major differences between the personalities of patients with CFS and controls, to evidence of severe psychopathology and personality disorder in patients with CFS. Although personality seems to play a role in CFS, it is difficult to draw general conclusions on the relation between personality and CFS. It is argued that this is partially due to the diversity and heterogeneity in study methods, patient populations, control groups and CFS case definitions. Personality should be regarded as an important factor to be studied in CFS. However, additional studies are needed, not focusing exclusively on personality disorder, or personality considered on a general trait level. In recent developments in personality research, the continually evolving life narrative that makes sense of, and gives direction to, an individual's life is also regarded as an important aspect of personality. New insights into personality and CFS might be gained by systematically studying the self-narratives of patients with the syndrome.
Van Hoof E, De Becker P, Lapp C, Cluydts R, De Meirleir K.	Department of Human Physiology, Vrije Universiteit, Brussels, Belgium. Van.Hoof@vub.ac.be	Defining the occurrence and influence of alpha-delta sleep in chronic fatigue syndrome.	Am J Med Sci. 2007 Feb;333(2):78-84.	BACKGROUND: Patients with chronic fatigue syndrome (CFS) present a disordered sleep pattern and frequently undergo polysomnography to exclude a primary sleep disorder. Such studies have shown reduced sleep efficiency, a reduction of deep sleep, prolonged sleep initiation, and alpha-wave intrusion during deep sleep. Deregulation of the 2-5A synthetase/RNase L antiviral pathway and a potential acquired channelopathy are also found in a subset of CFS patients and could lead to sleep disturbances. This article compiles a large sleep study database on CFS patients and correlates these data with a limited number of immune parameters as it has been thought that RNase L could be associated with these sleep disturbances. METHODS: Forty-eight patients who fulfilled 1994 Centers for Disease Control and Prevention criteria for CFS underwent extensive medical evaluation, routine laboratory testing, and a structured psychiatric interview. Subjects then completed a complaint checklist and a two-night polysomnographic investigation. RNase L analysis was performed by gel electrophoresis using a radiolabeled 2',5'-oligoadenylate trimer. Basic descriptive statistical parameters were calculated. RESULTS: Patients experienced a prolonged sleep latency, showed a low sleep efficiency index, and had a low percentage of slow wave sleep. The present alpha-delta intrusion correlated with anxiety; no correlations appeared, however, between alpha-delta sleep and immunologic parameters, including RNase L. CONCLUSIONS: The main findings are 1) validation of

				sleep latency problems and other sleep disturbances as already suggested by several authors; 2) alpha-delta intrusion seems associated with anxiety; and 3) elevated RNase L did not correlate with alpha-delta sleep.
Van Hootegem H.	henk.van.hootegem@skynet.be	Can homeopathy learn something from psychoanalysis?	Homeopathy. 2007 Apr;96(2):108-12.	This paper attempts to demonstrate how some insights from psychoanalysis can be useful in homeopathic treatment. I discuss three concepts: I illustrate these concepts with the case of a 23-year-old woman with chronic fatigue syndrome. (1) The working alliance: comparing medical alliance with a psychodynamic alliance. (2) The dream-function: serious somatic disorders can be the result of a blocked dream function, the restoration of the capacity to dream may lead to the disappearance of these disorders, homeopathy can help in this process. (3) The transgenerational influence: some traumatic, concealed events from the lives of ancestors can influence their descendants.
Van Houdenhove B, Verheyen L, Pardaens K, Luyten P, Van Wambeke P.	Faculty of Medicine. boudewijn.vanhoudenhove@uz.kuleuven.ac.be.	Rehabilitation of decreased motor performance in patients with chronic fatigue syndrome: should we treat low effort capacity or reduced effort tolerance?	Clin Rehabil. 2007 Dec;21(12):1121-42.	Aim: The aetiology, pathophysiology, diagnostic delineation and treatment of chronic fatigue syndrome (CFS) remain a matter of debate. Here some aspects of the debate are elucidated, with a particular focus on the patients' decreased motor performance.Hypothesis: The pathophysiological basis of decreased motor performance in CFS may, theoretically, involve three components: (1) a peripheral energetic deficit (impaired oxidative metabolism and/or physical deconditioning); (2) a central perceptual disturbance (higher effort sense or increased ;interoception'); and (3) a fundamental failure of the neurobiological stress system, leading to an abnormal ;sickness response'. It is proposed that the first two components may lead to low effort capacity, while the third component may lead to reduced effort tolerance. Although there is evidence for low effort capacity influencing symptoms and functional limitations in CFS, it is assumed that reduced effort tolerance might be the primary disturbance in CFS.Diagnostic implications: Distinguishing low effort capacity and reduced effort tolerance may contribute to a refinement of current diagnostic criteria of CFS and the identification of subgroups.Therapeutic implications: The above-mentioned distinction may make it possible to formulate a rationale for an effective implementation and adequate outcome evaluation of rehabilitation strategies in CFS.Research implications: This new heuristic framework may inform future research aimed at disentangling the complex determination of impaired motor performance in CFS, as well as studies aimed at customizing treatment to different subtypes of patients.
Van Ness Mark, Christopher R. Snell, Staci R. Stevens		HUDiminished Cardiopulmonary Capacity During Post-Exertional Malaise UH	Journal of Chronic Fatigue Syndrome 2007; 14(2): 77-85	Reduced functional capacity and post-exertional malaise following physical activity are hallmark symptoms of Chronic Fatigue Syndrome (CFS). That these symptoms are often delayed may explain the equivocal results for clinical cardiopulmonary exercise testing with CFS patients. The reproducibility of VO2max in healthy subjects is well documented. This may not be the case with CFS due to delayed recovery symptoms. Purpose: To compare results from repeated exercise tests as indicators of post-exertional malaise in CFS. Methods: Peak oxygen consumption (VO2 peak), percentage of predicted peak heart rate (HR%), and VO2 at anaerobic threshold (AT), were compared between six CFS patients and six control subjects for two maximal exercise tests separated by 24 hours. Results: Multivariate analysis showed no significant differences between control and CFS, respectively, for test 1: VO2 peak (28.4 ± 7.2 ml/ kg/min; 26.2 ± 4.9 ml/kg/min), AT (17.5 ± 4.8 ml/kg/min; 15.0 ± 4.9 ml/ kg/min) or HR% (87.0 ± 25.4%; 94.8 ± 8.8%). However, for test 2 the CFS patients achieved significantly lower values for both VO2peak (28.9 ± 8.0 ml/kg/min; 20.5 ± 1.8 ml/kg/min, p = 0.031) and AT (18.0 ± 5.2 ml/kg/min; 11.0 ± 3.4 ml/kg/min, p = 0.021). HR% was not

				significantly different (97.6 ± 27.2%; 87.8 ± 9.3%, p = 0.07). A follow-up classification analysis differentiated between CFS patients and controls with an overall accuracy of 92%. Conclusion: In the absence of a second exercise test, the lack of any significant differences for the first test would appear to suggest no functional impairment in CFS patients. However, the results from the second test indicate the presence of a CFS related post-exertional malaise. It might be concluded then that a single exercise test is insufficient to demonstrate functional impairment in CFS patients. A second test may be necessary to document the atypical recovery response and protracted malaise unique to CFS
Vanheule S, Vandenbergen J, Desmet M, Rosseel Y, Insleghers R.	Faculty of Psychology and Educational Sciences, Department of Psychoanalysis and Clinical Consulting, Ghent University, Belgium. stijn.Vanheule@UGent.be	Alexithymia and core conflictual relationship themes: a study in a chronically fatigued primary care population.	Int J Psychiatry Med. 2007;37(1):87-98.	OBJECTIVE: Clinical studies have indicated that concomitant to problems with affect regulation interpersonal problems can be observed in alexithymic patients. We test whether this is the case, and determine a parsimonious set of typical relationship themes. METHOD: Relationship themes were assessed by means of the Core Conflictual Relationship Theme (CCRT) method. This method examines transference patterns, and was applied to clinical interview data collected from a sample (n = 30) of chronically fatigued primary care patients. Alexithymia was assessed by means of a score on the 20-item Toronto Alexithymia Scale. The data were analyzed by means of the leaps and bounds regression algorithm for selecting optimal subsets of indicators, and by bootstrapping to determine 95% confidence intervals. RESULTS: Alexithymia can be meaningfully explained by typical relationship themes. A set of two wishes and one response of the self to the other that is most representative of alexithymia was mapped. The wishes demonstrate that the more alexithymic someone is, the less likely it is that this person wishes to be helped by others and the less likely it is that he/she interacts with others in order to feel good about him/herself. The selected response of the self indicates that it is typical of alexithymia that interactions with others do not result in good or happy feelings. CONCLUSION: Linking alexithymia to typical relationship themes is valid. Limitations of the study are indicated.

Vollmer-Conna U, Cameron B, Hadzi-Pavlovic D, Singletary K, Davenport T, Vernon S, Reeves WC, Hickie I, Wakefield D, Lloyd AR; Dubbo Infective Outcomes Study Group.	School of Psychiatry, University of New South Wales, Sydney University, Sydney, Australia. ute@unsw.edu.au	Postinfective fatigue syndrome is not associated with altered cytokine production.	Clin Infect Dis. 2007 Sep 15;45(6):732-5. Epub 2007 Aug 6.	Peripheral blood specimens and clinical data were obtained over a 12-month period from subjects in the Dubbo Infection Outcomes Study to examine cytokine production in postinfective fatigue syndrome. Ex vivo production of 8 cytokines was examined in 22 case patients and in 42 control subjects who recovered promptly. No significant differences were found. Ongoing production of the cytokines examined does not play a role in postinfective fatigue syndrome.

Von Heuft G, Schneider G, Klaiberg A, Brähler E.	Klinik und Poliklinik für Psychosomatik und Psychotherapie, Universitätsklinikum Münster. heuftge@mednet.uni-muenster.de	[Bombed out--psychic and psychosomatic long term consequences of World War II for the cohort born until 1945 in the year 2004] [Article in German]	Z Psychosom Med Psychother. 2007;53(3):228-43.	OBJECTIVES: In a population-based study the hypothesis was pursued as to what extent psychiatric consequences of specific war experiences of the cohort born up to 1945, exemplified through the fate of those bombed out during World War II, can be proven. METHODS: A representative sample of 2552 participants (1206 men and 1346 women) with an age range from 14 to 92 years were questioned using the random-route-technique by an opinion research institute. The subsample of the cohort born until 1945 was comprised of 776 participants (30.4 % of the complete sample), of whom 375 were men (48.3 %) and 401 women. RESULTS: 161 participants (20.7 % of the cohort born until 1945) had been bombed out (66 men and 95 women). Comparing those who had been bombed out to those who had not been did not show any significant differences concerning their age, their place of residence (Eastern vs. Western Germany), marital status, education level or income level. From a gender perspective women had been bombed out more frequently ($p < .05$). Four predictors rendered in a multiple regression analysis significant contributions for the prediction of negative body functioning: age, having been bombed out, low income level and low education level (9 % of the variance could be explained). CONCLUSIONS: The results show the necessity for a new approach to the long-term consequences of severe strain and traumata concerning psychopathology of older people. For this purpose the concept of ambivalence must be further developed.
Wallman KE, Sacco P.	School of Human Movement & Exercise Science, The University of Western Australia, Crawley, Western Australia. kwallman@cyllene.uwa.edu.au	Sense of effort during a fatiguing exercise protocol in chronic fatigue syndrome.	Res Sports Med. 2007 Jan-Mar;15(1):47-59.	The purpose of this study was to determine whether chronic fatigue syndrome (CFS) subjects would produce greater force production in their matching limb during a fatiguing contralateral limb-matching task of the elbow flexors, compared with healthy, matched controls. Eight CFS subjects and 8 healthy, matched control subjects participated in a fatiguing task that consisted of intermittent submaximal contractions (30% maximal voluntary contraction) of the nondominant arm performed over a 45 min duration. Each minute, the subject attempted to match the force of the nondominant arm with their dominant arm (without visual feedback for the dominant arm). Results showed that average matching force and ratings of perceived effort values were significantly higher in the CFS group during the fatiguing task ($P = 0.04$, $P = 0.02$, respectively). This study demonstrated objectively that CFS subjects experienced a greater sense of effort in the elbow flexors while performing a fatiguing task.

White PD, Sharpe MC, Chalder T, DeCesare JC, Walwyn R; PACE trial group.	Department of Psychological Medicine, Queen Mary School of Medicine and Dentistry, St Bartholomew's Hospital, London, UK. p.d.white@qmul.ac.uk <p.d.white@qmul.ac.uk>	Protocol for the PACE trial: a randomised controlled trial of adaptive pacing, cognitive behaviour therapy, and graded exercise, as supplements to standardised specialist medical care versus standardised specialist medical	BMC Neurol. 2007 Mar 8;7:6.	BACKGROUND: Chronic fatigue syndrome (CFS, also called myalgic encephalomyelitis /encephalopathy or ME) is a debilitating condition with no known cause or cure. Improvement may occur with medical care and additional therapies of pacing, cognitive behavioural therapy and graded exercise therapy. The latter two therapies have been found to be efficacious in small trials, but patient organisations surveys have reported adverse effects. Although pacing has been advocated by patient organisations, it lacks empirical support. Specialist medical care is commonly provided but its efficacy when given alone is not established. This trial compares the efficacy of the additional therapies when added to specialist medical care against specialist medical care alone. METHODS: 600 patients, who meet operationalised diagnostic criteria for CFS, will be recruited from secondary care into a randomised trial of four treatments, stratified by current co morbid depressive episode and different CFS/ME criteria. The four treatments are standardised specialist medical care either given alone, or with adaptive pacing therapy or cognitive behaviour therapy or graded exercise therapy. Supplementary therapies will involve fourteen sessions over 23 weeks and a booster session at 36 weeks. Outcome will be assessed at 12, 24, and 52 weeks after randomisation. Two primary outcomes of self-rated fatigue and physical function will assess differential effects of each treatment on these measures.

		care alone for patients with the chronic fatigue syndrome/myalgic encephalomyelitis or encephalopathy.		Secondary outcomes include adverse events and reactions, subjective measures of symptoms, mood, sleep and function and objective measures of physical activity, fitness, cost-effectiveness and cost-utility. The primary analysis will be based on intention to treat and will use logistic regression models to compare treatments. Secondary outcomes will be analysed by repeated measures analysis of variance with a linear mixed model. All analyses will allow for stratification factors. Mediators and moderators will be explored using multiple linear and logistic regression techniques with interactive terms, with the sample split into two to allow validation of the initial models. Economic analyses will incorporate sensitivity measures. DISCUSSION: The results of the trial will provide information about the benefits and adverse effects of these treatments, their cost-effectiveness and cost-utility, the process of clinical improvement and the predictors of efficacy.

Wyller VB, Due R, Saul JP, Amlie JP, Thaulow E.	Department of Pediatrics, Rikshospitalet-Radiumhospitalet Medical Centre, and Department of Physiology, University of Oslo,	Usefulness of an abnormal cardiovascular response during low-grade head-up tilt-test for discriminating adolescents with	Am J Cardiol. 2007 Apr 1;99(7):997-1001. Epub 2007 Feb 16.	Hemodynamic dysfunction is documented in chronic fatigue syndrome (CFS). This study was conducted to investigate cardiovascular responses to orthostatic stress in adolescents with CFS, using a novel procedure for tilt-table testing. A total of 27 adolescents with CFS and 33 healthy control subjects with equal age and gender distribution underwent 15 minutes of 20 degrees head-up tilt testing. Heart rate, systolic blood pressure (BP), mean BP, diastolic BP, stroke index, total peripheral resistance index, end-diastolic volume index, and acceleration index were continuously and noninvasively recorded. At rest, patients with CFS had higher total peripheral resistance index values ($p<0.01$) and lower stroke index and end-diastolic volume index values ($p<0.05$) than controls. During

	Oslo, Norway. brwylle@online.no	chronic fatigue from healthy controls.		20 degrees head-up tilt testing, patients with CFS had greater increases in heart rate, diastolic BP (p<0.001), mean BP (p<0.01), and total peripheral resistance index (p<0.05) than controls and greater decreases in stroke index (p<0.05). Syncope or near syncope was not observed. In conclusion, this study found that adolescents with CFS have significant abnormalities of cardiovascular regulation in response to mild orthostatic stress, differentiating them from healthy controls.
Wyller VB, Godang K, Mørkrid L, Saul JP, Thaulow E, Walløe L.	Department of Pediatrics, Rikshospitalet-Radiumhospitalet Medical Center, N-0027 Oslo, Norway. brwylle@online.no	Abnormal thermoregulatory responses in adolescents with chronic fatigue syndrome: relation to clinical symptoms.	Pediatrics. 2007 Jul;120(1):e129-37.	OBJECTIVES: Chronic fatigue syndrome is a common and disabling disease of unknown etiology. Accumulating evidence indicates dysfunction of the autonomic nervous system. To further explore the pathophysiology of chronic fatigue syndrome, we investigated thermoregulatory responses dependent on catecholaminergic effector systems in adolescent patients with chronic fatigue syndrome. PATIENTS AND METHODS: A consecutive sample of 15 patients with chronic fatigue syndrome aged 12 to 18 years and a volunteer sample of 57 healthy control subjects of equal gender and age distribution were included. Plasma catecholamines and metanephrines were measured before and after strong cooling of 1 hand. Acral skin blood flow, tympanic temperature, heart rate, and mean blood pressure were measured during moderate cooling of 1 hand. In addition, clinical symptoms indicative of thermoregulatory disturbances were recorded. RESULTS: Patients with chronic fatigue syndrome reported significantly more shivering, sweating, sudden change of skin color, and feeling unusually warm. At baseline, patients with chronic fatigue syndrome had higher levels of norepinephrine, heart rate, epinephrine, and tympanic temperature than control subjects. During cooling of 1 hand, acral skin blood flow was less reduced, vasoconstrictor events occurred at lower temperatures, and tympanic temperature decreased more in patients with chronic fatigue syndrome compared with control subjects. Catecholamines increased and metanephrines decreased similarly in the 2 groups. CONCLUSIONS: Adolescent patients with chronic fatigue syndrome have abnormal catecholaminergic-dependent thermoregulatory responses both at rest and during local skin cooling, supporting a hypothesis of sympathetic dysfunction and possibly explaining important clinical symptoms.
Wyller VB, Saul JP, Amlie JP, Thaulow E.	Department of Pediatrics, Rikshospitalet-Radiumhospitalet Medical Centre, Oslo, and Department of Pysiology, University of Oslo, Oslo, Norway. brwylle@online.no	Sympathetic predominance of cardiovascular regulation during mild orthostatic stress in adolescents with chronic fatigue.	Clin Physiol Funct Imaging. 2007 Jul;27(4):231-8.	Haemodynamic abnormalities have been documented in the chronic fatigue syndrome (CFS), indicating functional disturbances of the autonomic nervous system responsible for cardiovascular control. This study was designed to explore the pathophysiology in adolescent CFS-patients by analysing RR-interval (RRI) variability and diastolic blood pressure (DBP) variability during mild orthostatic stress, using an algorithm which accounts for non-stationary biosignals. A total of 27 adolescents with CFS and 33 healthy control subjects having equal age- and sex distribution underwent 15 min of 20 degrees head-up tilt (HUT). The spectral power densities of RRI and DBP were computed in the low-frequency (LF) band (0.04-0.15 Hz) and the high-frequency (HF) band (0.15-0.4 Hz) using an adaptive autoregressive algorithm to obtain a time-varying spectrum. RMSSD, a time domain index of RRI variability, was also computed. At rest, all indices of variability were similar in the two groups. During tilt, CFS patients had a larger increase in the LF/HF ratio (P<or=0.001) and normalized LF power of RRI (P<or=0.01), and a larger decrease in normalized HF power (P<or=0.01) of RRI than controls. CFS patients also had trends towards a larger decrease in absolute HF power of RRI and a larger increase in normalized LF power of DBP. These findings suggest that adolescents with CFS have sympathetic predominance of cardiovascular regulation during very mild orthostatic stress. Possible underlying mechanisms are moderate hypovolemia, abnormalities of reflex control or

				physical de-conditioning.
Wyller VB, Saul JP, Walløe L, Thaulow E.	Department of Pediatrics, Rikshospitalet-Radiumhospitalet Medical Center, 0027, Oslo, Norway.	Sympathetic cardiovascular control during orthostatic stress and isometric exercise in adolescent chronic fatigue syndrome.	Eur J Appl Physiol. 2007 Dec 8 [Epub ahead of print]	The chronic fatigue syndrome (CFS) has been shown to be associated with orthostatic intolerance and cardiovascular dysregulation. We investigated the cardiovascular responses to combined orthostatic stress and isometric exercise in adolescents with CFS. We included a consecutive sample of 15 adolescents 12-18 years old with CFS diagnosed according to a thorough and standardized set of investigations, and a volunteer sample of 56 healthy control subjects of equal sex and age distribution. Heart rate, systolic, mean and diastolic blood pressure, stroke index, and total peripheral resistance index were non-invasively recorded during lower body negative pressure (LBNP) combined with two consecutive periods of handgrip. In addition, we measured baseline plasma catecholamines, and recorded symptoms. At rest, CFS patients had higher heart rate, diastolic blood pressure, plasma norepinephrine ($P < 0.01$), mean blood pressure and plasma epinephrine ($P < 0.05$) than controls. During LBNP, CFS patients had a greater increase in heart rate, diastolic blood pressure, mean blood pressure ($P < 0.05$) and total peripheral resistance index (n.s.) than controls. During handgrip, CFS patients had a smaller increase in heart rate, diastolic blood pressure ($P < 0.05$), mean blood pressure and total peripheral resistance index (n.s.) than controls. Our results indicate that adolescents with CFS have increased sympathetic activity at rest with exaggerated cardiovascular response to orthostatic stress, but attenuated cardiovascular response when performing isometric exercise during orthostatic stress. This suggests that CFS might be causally related to sympathetic dysfunction.
Wyller VB, Thaulow E, Amlie JP.	Department of Pediatrics, Rikshospitalet-Radiumhospitalet Medical Centre, Oslo, Norway. brwylle@online.no	Treatment of chronic fatigue and orthostatic intolerance with propranolol.	J Pediatr. 2007 Jun;150(6):654-5.	We describe the effect of propranolol in an adolescent with chronic fatigue syndrome and orthostatic intolerance. Our observations suggest that the head-up tilt-test and beta-blocker treatment might be considered in patients with chronic fatigue syndrome and that enhanced sympathetic nervous activity might be part of the underlying pathophysiology.
Wyller VB.	Department of Pediatrics, Rikshospitalet-Radiumhospitalet Medical Centre, Oslo, Norway. brwylle@online.no	The chronic fatigue syndrome--an update.	Acta Neurol Scand Suppl. 2007;187:7-14.	BACKGROUND: In this article, current scientific knowledge on the chronic fatigue syndrome (CFS) is reviewed. The US case definition of CFS (the CDC-definition) is most widespread in research and clinical practice. Estimates of prevalence vary from 0.2% to above 2%. The female-male ratio is approximately 3:1. CLINICAL FEATURES: Severe fatigue is the dominating complaint; it is worsened from exertions and not substantially relieved by rest. In addition, the patients might have a varying combination of accompanying symptoms. Clinical evaluation should be based upon standardized guidelines, including an assessment of functional impairments. PATHOPHYSIOLOGY: The pathophysiology should be interpreted within a biopsychosocial framework. Present knowledge suggests that certain genetic polymorphisms and personality traits might be regarded as predisposing factors, some infections and severe psychosocial stress constitute precipitating factors, whereas disturbances of immunity, skeletal muscle, cognitive abilities, endocrine control and cardiovascular homeostasis are possible perpetuating factors. TREATMENT: Cognitive behavioural therapy and graded exercise therapy are of proven value in randomized controlled trials. Several pharmaceutical measures have been explored and found to have no beneficial effect. Most patients might expect long-term improvement, but full recovery is rare; however, the prognosis is better among adolescents.

Yamadera W, Itoh H.	Department of Psychiatry, Jikei University School of Medicine.	[Overview of psychiatric therapy for chronic fatigue syndrome] [Article in Japanese]	Nippon Rinsho. 2007 Jun;65(6):1082-6.	Chronic fatigue syndrome (CFS) is recognized as a special condition based on abnormality of psycho-neuro-endocrine-immunological system, which is caused by several cytokines and autoantibodies. For CFS diagnosis, it is required to exclude psychiatric diseases which could cause chronic fatigue. On the other hand, recent studies proved the effectiveness cognitive behavioral therapy(CBT) for CFS. Distorted cognition relevant to CFS includes the characteristics such as over adaptation, perfectionism, avoidance and so on. In the CBT for CFS, it is important to quit seeking physical causes, to accept the pathological state as it is, to monitor daily activity and recognize the cognitive and behavioral patterns which might prolong fatigue, to maintain a constant activity level and to make planned increases in activity.
Yamaguti K.	Department of Physiology, Graduate School of Medicine, Osaka City University.	[Evaluation of fatigue by using acceleration plethysmography] [Article in Japanese	Nippon Rinsho. 2007 Jun;65(6):1034-42.	We evaluated the fatigue of patients with chronic fatigue syndrome by using acceleration plethysmography. The changes in the acceleration plethysmography were relatively dominant in the sympathetic nervous system from the viewpoint of the autonomic nervous system, and the fluctuation in the time-series data of the acceleration plethysmography was decreased from the viewpoint of chaos or complexity system. We found the relation between the level of fatigue and the changes in acceleration plethysmography. Therefore, the acceleration plethysmography might be useful for the evaluation of fatigue.
Yao F, Ji Q, Zhao Y, Feng JL.	College of Acupuncture and Massage, Shanghai University of TCM, Shanghai 201203, China. yaofei@tuina.com.cn	[Observation on therapeutic effect of point pressure combined with massage on chronic fatigue syndrome] [Article in Chinese]	Zhongguo Zhen Jiu. 2007 Nov;27(11):819-20.	OBJECTIVE: To search for an effective therapy for chronic fatigue syndrome (CFS). METHODS: Eighty-five cases of CFS were treated with massage and pressing of Back-shu points, combined with pressing acupoints on the head. The therapeutic effect was observed. RESULTS: After treatment of 3 courses, 26 cases were markedly effective, 52 cases were effective, and 7 cases were ineffective, with a total effective rate of 91.8% and a markedly effective rate of 30.6%. CONCLUSION: Pressing acupoints and massage can effectively improve clinical symptoms of the patient with chronic fatigue syndrome.
Yao R.	College of Traditional Chinese Medicine of Hong Kong University, China.	The thoughts and methods for clinical research on acupuncture treatment of chronic fatigue syndrome.	J Tradit Chin Med. 2007 Sep;27(3):163-5.	The general situation of chronic fatigue syndrome (CFS) and the criteria for its diagnosis are discussed, and it is put forward that making qi and blood of the zang-fu organs balanced is the key to acupuncture treatment of the disease. Such aspects as case selection, point selection and therapeutic assessment are also discussed in the present paper.
Yiu YM, Ng SM, Tsui YL, Chan YL.	School of Chinese Medicine, University of Hong Kong, China. yoyo@hku.hk	[A clinical trial of acupuncture for treating chronic fatigue syndrome in Hong Kong] [Article in Chinese]	Zhong Xi Yi Jie He Xue Bao. 2007 Nov;5(6):630-3.	OBJECTIVE: To evaluate the efficacy of acupuncture in treating chronic fatigue syndrome (CFS) in Hong Kong. METHODS: A single-blinded, randomized controlled trial design was adopted. Participants meeting inclusion criteria were randomly assigned to a treatment and a control group according to 1:1 ratio, resulting in an effective sample size of 99, with 50 and 49 patients in treatment and control group respectively. The same set of acupuncture points, which were selected according to traditional Chinese medicine theories, was applied in both groups, while conventional needle acupuncture was applied in treatment group and sham acupuncture (without skin penetration) was applied in control group. Schedule of treatment was the same in both groups, i.e. twice a week for 4 weeks. Key outcome measures were Chalder's Fatigue Scale, diagnostic criteria for CFS of the US's Centre for

				Disease Control and SF-12 health-related quality of life (HQOL) questionnaire. Adverse events, if any, were recorded. RESULTS: Improvements in physical and mental fatigue and HQOL in both groups were observed, but the improvements in treatment group were significantly bigger than in control group (P<0.01 or P<0.05). No adverse events occurred. CONCLUSION: Acupuncture is a safe, effective treatment for CFS.
Yokoyama T, Lisi TL, Moore SA, Sluka KA.	Physical Therapy and Rehabilitation Science Graduate Program, Department of Pathology, Pain Research Program, University of Iowa, Iowa City, Iowa 52242, USA.	Muscle fatigue increases the probability of developing hyperalgesia in mice.	J Pain. 2007 Sep;8(9):692-9. Epub 2007 Jul 12.	Chronic muscle pain is a major clinical problem that is often associated with fatigue. Conversely, chronic fatigue conditions are commonly associated with muscle pain. We tested the hypothesis that muscle fatigue enhances hyperalgesia associated with injection of acidic saline into muscle. We evaluated mechanical sensitivity of the paw (von Frey) in mice after 2 intramuscular injections of saline (20 microL; pH 4, pH 5, pH 6, pH 7.2) in a fatigue and a control group. To induce fatigue, mice were run for 2 h/day for 2 days prior to the first injection and 2 h/day for 2 days prior to the second injection. Muscle lactate, pCO(2), pO(2), creatinine kinase, phosphate, and histology were examined after the fatigue task and compared to a control group. Grip force was significantly decreased after 2 h of running indicating fatigue. The fatigue task did not induce muscle damage as there was no difference in muscle lactate, pCO(2), pO(2), creatinine kinase, phosphate, or histology. The fatigue task altered the dose-response relationship to intramuscular acidic saline injections. Mechanical hyperalgesia was observed in both fatigue and control groups after intramuscular injection of pH 4.0, but only the fatigue group after injection of pH 5. Neither the fatigue nor the control group developed hyperalgesia in response to intramuscular injection of pH 6 or pH 7.2. In conclusion, fatigue modified the susceptibility of mice to acid injection of pH 5.0 to result in mechanical hyperalgesia after 2 injections of pH 5.0. The fatigue task did not produce measurable changes in the muscle tissue suggesting a central mechanism mediating the enhancement of hyperalgesia. PERSPECTIVE: These data therefore show that muscle fatigue can enhance the likelihood that one develops pain to a mild insult. Clinically, this could relate to the development of pain from such conditions as repetitive strain injury, and may relate to the interrelationship between chronic pain and fatigue.
Yoshihara K, Kubo C.	Department of Psychosomatic Medicine, Graduate School of Medical Sciences, Kyushu University.	[Overview of medical treatment and management of chronic fatigue syndrome] [Article in Japanese	Nippon Rinsho. 2007 Jun;65(6):1077-81.	A tailor-made management plan that includes various combinations of non-pharmacologic and pharmacologic therapy for patients with chronic fatigue syndrome (CFS) is important. We present an overview of four aspects of our medical treatment and management for CFS: introduction of our medical management system, summary of our management strategy, non-pharmacologic therapy, and pharmacologic therapy; according to foreign guidelines and the latest studies. The main non-pharmacologic therapies for CFS are rehabilitation and lifestyle guidance. Using a graded exercise therapy, we have constructed a broad management strategy for CFS. Herein we introduce our graded exercise therapy. If the symptoms continue despite careful management of the program by the physician, consultation with a psychiatrist or psychosomatic medicine specialist is necessary.
Yoshiuchi K, Cook DB, Ohashi K, Kumano H, Kuboki T, Yamamoto Y, Natelson BH.	Department of Neurosciences, University of Medicine and Dentistry of New Jersey - New Jersey	A real-time assessment of the effect of exercise in chronic fatigue syndrome.	Physiol Behav. 2007 Dec 5;92(5):963-8. Epub 2007 Jul 25.	Patients with chronic fatigue syndrome (CFS) report substantial symptom worsening after exercise. However, the time course over which this develops has not been explored. Therefore, the objective of this study was to investigate the influence of exercise on subjective symptoms and on cognitive function in CFS patients in natural settings using a computerized ecological momentary assessment method, which allowed us to track the effects of exercise within and across days. Subjects were 9 female patients with CFS and 9 healthy women. A watch-type computer was used to collect real-time

	Medical School, United States. kyoshiuc-tky@umin.ac.jp			data on physical and psychological symptoms and cognitive function for 1week before and 2weeks after a maximal exercise test. For each variable, we investigated temporal changes after exercise using multilevel modeling. Following exercise, physical symptoms did get worse but not until a five-day delay in CFS patients. Despite this, there was no difference in the temporal pattern of changes in psychological symptoms or in cognitive function after exercise between CFS patients and controls. In conclusion, physical symptoms worsened after several days delay in patients with CFS following exercise while psychological symptoms or cognitive function did not change after exercise.
Yoshiuchi K.	Department of Psychosomatic Medicine, The University of Tokyo.	[Psychological symptoms in chronic fatigue syndrome] [Article in Japanese]	Nippon Rinsho. 2007 Jun;65(6):1023-7.	Patients with chronic fatigue syndrome (CFS) frequently complain of psychological symptoms including depression, anxiety, and neuropsychological impairment. In addition, patients with CFS have been reported to be more likely to have psychiatric diseases such as major depressive disorder, panic disorder, generalized anxiety disorder, and personality disorder. In the present review article, psychological symptoms and psychiatric comorbidity in CFS patients were introduced. In addition, differentiation between CFS and psychiatric disorders were discussed, because there have been few studies on comorbidity and differentiation between CFS and undifferentiated somatoform disorder although there has been heated debate about the existence of CFS itself.
Young JL, Redmond JC.	Rochester Center for Behavioral Medicine, Rochester Hills, MI. judithcredmond@aol.com	Fibromylagia, chronic fatigue, and adult attention deficit hyperactivity disorder in the adult: a case study.	Psychopharmacol Bull. 2007;40(1):118-26.	Adult attention deficit hyperactivity disorder (ADHD) may share common features with fibromyalgia syndrome (FMS) and chronic fatigue syndrome (CFS). In an outpatient psychiatric clinic, a number of adult patients who presented primarily with symptoms of ADHD, predominately inattentive type, also reported unexplained fatigue, widespread musculoskeletal pain or a pre-existing diagnosis of CFS or FMS. As expected, ADHD pharmacotherapy usually attenuated the core ADHD symptoms of inattention, distractibility, hyperactivity, and impulsivity. Less expected was the observation that some patients also reported amelioration of pain and fatigue symptoms. The utility of ADHD medications in FMS and CFS states may be their innate arousal and enhanced filtering properties. This model supposes that FMS and CFS are central processing problems rather than peripheral disorders of muscles and joints.
Yunus MB.	Section of Rheumatology, The University of Illinois College of Medicine at Peoria, One Illini Drive, Peoria, IL 61605, USA.	Fibromyalgia and overlapping disorders: the unifying concept of central sensitivity syndromes.	Semin Arthritis Rheum. 2007 Jun;36(6):339-56. Epub 2007 Mar 13.	OBJECTIVES: To discuss fibromyalgia syndrome (FMS) and overlapping conditions, eg, irritable bowel syndrome, headaches, and chronic fatigue syndrome, within the concept of central sensitivity syndromes (CSS). METHODS: A critical overview of the literature and incorporation of the author's own views. RESULTS: The concept of CSS seems viable. It is based on mutual associations among the CSS conditions as well as the evidence for central sensitization (CS) among several CSS members. However, such evidence is weak or not available in other members at this time, requiring further studies. The biology of CSS is based on neuroendocrine aberrations, including CS, that interact with psychosocial factors to cause a number of symptoms. CONCLUSIONS: CSS is an important new concept that embraces the biopsychosocial model of disease. Further critical studies are warranted to fully test this concept. However, it seems to have important significance for new directions for research and patient care involving physician and patient education. Each patient, irrespective of diagnosis, should be treated as an individual considering both the biological and psychosocial contributions to his or her symptoms and suffering.
Zuckerman AJ.	WHO Collaborating Centre for	Safety of hepatitis B vaccines.	Travel Med Infect Dis. 2004	Although concerns about vaccine safety have increased, true adverse reactions associated with hepatitis B vaccines are few, apart from minor symptoms at the site of injection and occasionally

	Reference and Research on Viral Diseases, Royal Free and University College Medical School, Rowland Hill Street, London NW3 2PF, UK.		May;2(2):81-4.	systemic reactions. There is no evidence of an association with hepatitis B vaccination and Sudden Infant Death Syndrome, Multiple Sclerosis and the Chronic Fatigue Syndrome. Hepatitis B vaccines are safe and essential for the prevention of this important and common infection.
Zwarts MJ, Bleijenberg G, van Engelen BG.	University Medical Centre Nijmegen, Institute of Neurology, 920 Department of Clinical Neurophysiology, PO Box 9101, 6500 HB Nijmegen, The Netherlands; Neuromuscular Centre Nijmegen, Department of Neurology, Radboud University Nijmegen Medical Centre, Nijmegen, The Netherlands.	Clinical neurophysiology of fatigue.	Clin Neurophysiol. 2008 Jan;119(1):2-10. Epub 2007 Nov 26.	Fatigue is a multidimensional concept covering both physiological and psychological aspects. Chronic fatigue is a typical symptom of diseases such as cancer, multiple sclerosis (MS), Parkinson's disease (PD) and cerebrovascular disorders but is also presented by people in whom no defined somatic disease has been established. If certain criteria are met, chronic fatigue syndrome can be diagnosed. The 4-item Abbreviated Fatigue Questionnaire allows the extent of the experienced fatigue to be assessed with a high degree of reliability and validity. Physiological fatigue has been well defined and originates in both the peripheral and central nervous system. The condition can be assessed by combining force and surface-EMG measurements (including frequency analyses and muscle-fibre conduction estimations), twitch interpolation, magnetic stimulation of the motor cortex and analysis of changes in the readiness potential. Fatigue is a well-known phenomenon in both central and peripheral neurological disorders. Examples of the former conditions are multiple sclerosis, Parkinson's disease and stroke. Although it seems to be a universal symptom of many brain disorders, the unique characteristics of the concomitant fatigue also point to a specific relationship with several of these syndromes. As regards neuromuscular disorders, fatigue has been reported in patients with post-polio syndrome, myasthenia gravis, Guillain-Barré syndrome, facioscapulohumeral dystrophy, myotonic dystrophy and hereditary motor and sensory neuropathy type-I. More than 60% of all neuromuscular patients suffer from severe fatigue, a prevalence resembling that of patients with MS. Except for several rare myopathies with specific metabolic derangements leading to exercise-induced muscle fatigue, most studies have not identified a prominent peripheral cause for the fatigue in this population. In contrast, the central activation of the diseased neuromuscular system is generally found to be suboptimal. The reliability of the psychological and clinical neurophysiological assessment techniques available today allows a multidisciplinary approach to fatigue in neurological patients, which may contribute to the elucidation of the pathophysiological mechanisms of chronic fatigue, with the ultimate goal to develop tailored treatments for fatigue in neurological patients. The present report discusses the different manifestations of fatigue and the available tools to assess peripheral and central fatigue.

Ablin JN, Shoenfeld Y, Buskila D.	Department of Rheumatology, Tel-Aviv Sourasky Medical Center and Sackler Faculty of Medicine, Tel-Aviv University, 6 Weizman St., 64239 Tel-Aviv, Israel.	Fibromyalgia, infection and vaccination: Two more parts in the etiological puzzle.	J Autoimmun. 2006 Nov;27(3):145-52. Epub 2006 Oct 30.	As the pathogenesis of fibromyalgia continues to raise debate, multiple putative triggers have been implicated. The current review summarizes the available data linking fibromyalgia to either infection or vaccination. Multiple infectious agents have been associated with the development of either full-blown fibromyalgia (e.g. hepatits C), or with symptom complexes extensively overlapping with that syndrome (e.g. chronic Lyme disease). The cases of Lyme disease, mycoplasma, hepatits C and HIV are detailed. Despite the described associations, no evidence is available demonstrating the utility of antibiotic or anti-viral treatment in the management of fibromyalgia. Possible mechanistic links between fibromyalgia and HIV are reviewed. Associations have been described between various vaccinations and symptom complexes including fibromyalgia and chronic fatigue syndrome. The case of Gulf War syndrome, a functional multisystem entity sharing many clinical characteristics with fibromyalgia is discussed, with emphasis on the possibility of association with administration of multiple vaccinations during deployment in the Persian Gulf and the interaction with stress and trauma. Based on this example a model is proposed, wherein vaccinations function as co-triggers for the development of functional disorders including fibromyalgia, in conjunction with additional contributing factors.
Arnold Llamosas PA, Arrizabalaga Clemente P, Bonet Agusti M, de la Fuente Brull X.	Inmunologia y Medicina Interna, Servicio de Reumatologia, Centro Internacional Medicina Avanzada (CIMA), Servei Acreditat Cat Salut, Barcelona, Spain.	[Multiple chemical sensitivity in sick-building syndrome] [Article in Spanish]	Med Clin (Barc). 2006 May 27;126(20):774-8.	The sick building syndrome includes irritation of the eyes and the respiratory tract neurotoxicity affectation and skin problems, which can occur in individuals under improperly ventilated buildings. Poor air quality, as shown in CO2 atmospheric levels of more than 1,000 ppm, results in a pathological exposure to biological and chemical products. We present a work-related case of multiple chemical hypersensitivity from a dialysis unit that had no air renewal. This person, who was summitted to continuous exposure despite having taken corrective measures in the ventilation, developed chronic fatigue syndrome. An acoustic voice observation alerted of the case which led to the analysis of the environmental conditions which confirmed the relationship between multiple chemical hypersensitivity and chronic fatigue syndrome. This case stresses the neglected fact that all health service centres pose a high risk of chemical exposure and that there exists a lack of rigoroursness in putting in practice scientific medical knowledge.
Aslakson E, Vollmer-Conna U, White PD.	Centers for Disease Control and Prevention, Division of Viral and Rickettsial Diseases, National Center for Infectious Diseases, Atlanta, GA 30333, USA. EAslakson@cdc.gov	The validity of an empirical delineation of heterogeneity in chronic unexplained fatigue.	Pharmacogenomics. 2006 Apr;7(3):365-73.	OBJECTIVES: To validate a latent class structure derived empirically from a clinical data set obtained from persons with chronic medically unexplained fatigue. METHODS: The strategies utilized in this validation study included: recalculating latent class analysis (LCA) results varying random seeds and the number of initial random starting sets; recalculating LCA results by substituting alternate variables to demonstrate a robust solution; determining the statistical significance of between-class differences on disability, fatigue and demographic measures omitted from the data set used for LCA; cross-classifying class membership using established Centers for Disease Control and Prevention (CDC) research criteria for chronic fatigue syndrome (CFS) to compare the relative proportions of subjects designated CFS, chronic fatigue (not CFS) or healthy controls captured by the latent classes. RESULTS: Recalculation of results and substitution of variables for low-loading variables demonstrated a robust LCA result. Highly significant between-class differences were confirmed between Class 2 (well) and those interpreted as ill/fatigued. Analysis of between-class differences for the fatigue groups revealed

				significant differences for all disability and fatigue variables, but with equivalent levels of reported activity and reduction in motivation. Cross-classification against established CDC criteria demonstrated that 89% of subjects constituting Class 2 (well) were indeed nonfatigued controls. A general tendency for grouping CFS cases in the multiple symptomatic classes was noted. CONCLUSION: This study established reasonably good validity for an empirically-derived latent class solution reflecting considerable heterogeneity among subjects with medically unexplained chronic fatigue. This work strengthens the growing understanding of CFS as a heterogeneous entity comprised of several conditions with different underlying pathophysiological mechanisms.
Authier FJ, Gherardi RK.	Centre de Reference pour Maladies Neuromusculaires Garches-Necker-Mondor-Hendaye (GNMH), Hopital Henri-Mondor, AP-HP, Creteil. francois-jerome.authier@hmn.aphp.fr	[Muscular complications of human immunodeficiency virus (HIV) infection in the era of effective anti-retroviral therapy] [Article in French]	Rev Neurol (Paris). 2006 Jan;162(1):71-81.	Introduction of highly active antiretroviral therapy (HAART) has dramatically modified the natural history of HIV disease, but lengthening the survival of HIV-infected individuals has been associated with an increasing prevalence of iatrogenic conditions. Muscular complications of HIV infection are classified as follows: (1) HIV-associated myopathies and related conditions including polymyositis, inclusion-body myositis, nemaline myopathy, diffuse infiltrative lymphocytosis syndrome (DILS), HIV-wasting syndrome, vasculitis, myasthenic syndromes, and chronic fatigue; (2) iatrogenic conditions including mitochondrial myopathies, HIV-associated lipodystrophy syndrome, and immune restoration syndrome; (3) opportunistic infections and tumor infiltrations of skeletal muscle; and (4) rhabdomyolysis. These features are described in the present review.
Axelrod FB, Chelimsky GG, Weese-Mayer DE.	Dysautonomia Treatment and Evaluation Center, Department of Pediatrics and Neurology, New York University School of Medicine, 530 First Ave, Suite 9Q, New York, New York 10016, USA. felicia.axelrod@med.nyu.edu	Pediatric autonomic disorders.	Pediatrics. 2006 Jul;118(1):309-21.	The scope of pediatric autonomic disorders is not well recognized. The goal of this review is to increase awareness of the expanding spectrum of pediatric autonomic disorders by providing an overview of the autonomic nervous system, including the roles of its various components and its pervasive influence, as well as its intimate relationship with sensory function. To illustrate further the breadth and complexities of autonomic dysfunction, some pediatric disorders are described, concentrating on those that present at birth or appear in early childhood.
Bailes S, Libman E, Baltzan M, Amsel R, Schondorf R, Fichten CS.	SMBD-Jewish General Hospital, Montreal, Canada. sally.bailes@mail.mcgill.ca	Brief and distinct empirical sleepiness and fatigue scales.	J Psychosom Res. 2006 Jun;60(6):605-13.	OBJECTIVE: Sleepiness and fatigue are conceptually distinct but pervasively confounded in research, measurement instruments, clinical settings, and everyday spoken language. The purpose of the present study was to construct two scales that represent unconfounded measures of sleepiness and fatigue, using widely used questionnaires. METHOD: Four questionnaires purporting to measure sleepiness [Stanford Sleepiness Scale (SSS); Epworth Sleepiness Scale (ESS)] or fatigue [Fatigue Severity Scale (FSS); Chalder Fatigue Scale (CFS)] were administered, as well as a battery measuring

				sleep, psychological, and health functioning variables, to three samples: 19 individuals with chronic fatigue syndrome, 14 with narcolepsy, and 11 normal control subjects. RESULTS: Analyses revealed two distinct sets of items (six sleepiness and three fatigue items) that were combined into two scales. These newly formed scales are only minimally correlated and represent separate constructs that have reasonably distinctive patterns of association. Findings were replicated and validated in a sample of 128 older individuals complaining of daytime sleepiness and/or fatigue. CONCLUSIONS: We conclude that (a) it is possible to derive empirically distinct sleepiness and fatigue scales from existing, commonly used self-report instruments, (b) the Empirical Sleepiness Scale is limited to the experience of daytime sleep tendency, while (c) the Empirical Fatigue Scale is associated more broadly with insomnia, psychological maladjustment, and poorer perceived health function. The important clinical implication of the new Empirical Sleepiness and Fatigue Scales is in the ability to identify "sleepiness which is not fatigue," a construct closely related to primary sleep disorders, such as sleep apnea/hypopnea syndrome, for which there is both available and effective treatment.
Barat M, Dehail P, de Seze M.	Unite de Reeducation Neurologique, Universite Victor-Segalen Bordeaux-II et Federation des Neurosciences Cliniques, CHU de Bordeaux, 146, rue Leo-Saignat, 33076 Bordeaux cedex, France. michel.barat@chu-bordeaux.fr	Fatigue after spinal cord injury. [Article in English, French]	Ann Readapt Med Phys. 2006 Jul;49(6):277-82, 365-9. Epub 2006 Apr 25.	OBJECTIVES: To identify variables increasing fatigue following spinal cord injury (SCI) and their functional consequences. METHODS: A search of the Medline and Reedoc databases with the keywords SCI, fatigue, intrinsic muscular fatigue, chronic fatigue, aging, training, electrostimulation, quality of life and the same words in French. RESULTS: Two kinds of fatigue are identified following SCI. Intrinsic fatigue in muscles totally or partially paralysed at the level of or below the spinal cord lesion; this peripheral fatigue is due to denervation, total or partial loss of motoneurons, or histological and metabolical changes in muscle; it is well-defined by electrophysiological technology; spasticity and spasms have little influence on its development; it is reversible in part with long term electrostimulation, but at this time, electroneuroprosthetic techniques do not reduce the excessive energetic cost to stand up and walk. Chronic fatigue appears in the long term following SCI; it is linked with aging, physiological, and psychological deconditioning; some data point to chronic fatigue after SCI similar to post-polio syndrome and chronic fatigue syndrome, which may explain the central nature of the fatigue; training programs could be useful in delaying this chronic fatigue and as a consequence, increasing the latent quality of life. CONCLUSION: Muscular intrinsic fatigue after SCI is always of a peripherical nature in muscles partially or totally paralysed. Chronic fatigue during aging greatly decreases quality of life. Both intrinsic and chronic fatigue could be anticipated by electrostimulation technique on the one hand and long term training on the other.
Barbado Hernandez FJ, Gomez Cerezo J, Lopez Rodriguez M, Vazquez Rodriguez JJ.	Servicio de Medicina Interna, Hospital Universitario La Paz, Universidad Autonoma, Madrid. Bates MN.	Division of Environmental Health Sciences, School of Public Health, 140 Warren Hall, University of California, Berkeley, CA 94720-7360, USA. m_bates@berkeley.edu	Mercury amalgam dental fillings: an epidemiologic assessment.	Int J Hyg Environ Health. 2006 Jul;209(4):309-16. Epub 2006 Jan 30.	Dental amalgam fillings containing approximately 50% mercury have been used for almost 200 years and have been controversial for almost the same time. Allegations of effects caused by amalgams have involved many diseases. Recent evidence that small amounts of mercury are continuously released from amalgam fillings has fuelled the controversy. This is a comprehensive review of the epidemiologic evidence for the safety of dental amalgam fillings, with an emphasis on methodological issues and identifying gaps in the literature. Studies show little evidence of effects on general chronic disease incidence or mortality. Limited evidence exists for an association with multiple sclerosis, but few studies on either Alzheimer's or Parkinson's diseases. The preponderance of evidence suggests no renal effects and that ill-defined symptom complexes, including chronic fatigue syndrome, are not caused by amalgams. There is little direct evidence that can be used to assess reproductive hazards. Overall, few relevant epidemiologic studies are available. Most prior assessments of possible amalgam health effects have been based on comparisons of dental mercury exposures with occupational exposures causing harm. However, the amalgam-exposed population contains a broader, possibly more susceptible, spectrum of people. Common limitations of population-based studies of dental amalgam effects include inadequate longitudinal exposure assessment and negative confounding by better access to dental care in higher socioeconomic groups. Better designed studies are needed, particularly for investigation of neurodegenerative diseases and effects on infants and children.
Bell SD, Van Hoof E.		Guidelines for the Diagnosis of Pediatric Chronic Fatigue Syndrome: Things Parents Need to Know This	Journal of Chronic Fatigue Syndrome 2006;13(2/3): 79-88	In this special issue of the Journal of Chronic Fatigue Syndrome, chronic fatigue syndrome (CFS) in children and adolescents is specifically addressed. It is a topic long overdue. It is my sincere hope that the criteria presented here will begin a process of rigorous clinical testing and refinement so that pediatricians and other medical providers will come to have a reliable and accepted way of making the diagnosis of ME/CFS in a person under 18 years of age. This short review is meant for parents and other caregivers as a brief summary of the guidelines that may be of value. The primary role of these guidelines is to present a strict and rigorous definition that can be tried and tested. This summary is to make the process of diagnosis somewhat easier for parents and caregivers alike until the testing process is completed. Therefore, for more detailed symptom description and exclusionary illness description, I would refer the reader to the primary article. Professional caregivers and clinicians may offer this article available to inform parents with a child or/ adolescent suffering from CFS.
Blockmans D, Persoons P, Van Houdenhove B, Bobbaers H.	Department of Internal Medicine, University Hospital Gasthuisberg, Leuven, Belgium. daniel.blockmans@uz.kuleuven.ac.be	Does methylphenidate reduce the symptoms of chronic fatigue syndrome?	Am J Med. 2006 Feb;119(2):167.e23-30.	PURPOSE: Chronic fatigue syndrome is a clinical entity consisting of prolonged and debilitating fatigue in which concentration disturbances are very frequent. Until now, no medical treatment has shown any efficacy. The objectives of this study were to investigate the short-term effects of methylphenidate, an amphetamine derivative, on fatigue, concentration disturbances, and quality of life. SUBJECTS AND METHODS: A double-blind randomized placebo-controlled crossover study was conducted in 60 patients who fulfilled the 1994 Centers for Disease Control criteria for chronic fatigue syndrome and had concentration difficulties. Patients were enrolled between March 2003 and March 2004 at the outpatient department of a university hospital referral center for chronic fatigue syndrome patients. Random assignment to 4 weeks treatment with methylphenidate 2 x 10 mg/day, followed by 4 weeks of placebo treatment, or 4 weeks of placebo treatment, followed by methylphenidate treatment. Fatigue and concentration were measured with a Checklist Individual

				Strength (CIS) and a Visual Analogue Scale (VAS). RESULTS: Fatigue scores fell significantly during methylphenidate intake in comparison with baseline (mean difference: -0.7, P = .010 for VAS; mean difference: -11.8, P <.0001 for CIS) and in comparison with placebo (mean difference: -1.0, P = .001 for VAS; mean difference: -9.7, P <.0001 for CIS). Concentration disturbances, measured with a VAS improved significantly under methylphenidate treatment compared with baseline (mean difference: -1.3, P <.0001) and compared with placebo (mean difference: -1.1, P <.0001). A clinical significant effect (> or =33% improvement or CIS < or =76) on fatigue was achieved in 17% of patients, who were considered responders; on concentration in 22% of patients. CONCLUSIONS: Methylphenidate at a dose of 2 x 10 mg/day is significantly better than placebo in relieving fatigue and concentration disturbances in a minority of chronic fatigue syndrome patients. Further studies are needed to investigate the long-term effects of this treatment.
Bond PA, Dinan TG.		Antibodies to Herpes Simplex Types 1 and 2 in Chronic Fatigue Syndrome	Journal of Chronic Fatigue Syndrome 2006;13(1): 35-40	Background. It has been suggested that Herpes simplex virus (HSV) could play a role in the aetiology of chronic fatigue syndrome (CFS). An immune system that has been compromised, could account for HSV reactivating or infecting for the first time, and also being insufficiently under control in the body. Another consequence of inadequate control could be that several strains of HSV could simultaneously infect the body. Objectives. To look for the presence of antibodies to HSV-1 and HSV-2 in patients with CSF and in controls. The presence of antibodies to both types of HSV could reflect infection by multiple strains of HSV. Methods. Antibodies to HSV-1 and HSV-2 were measured in sera from 27 CSF patients and 26 ageand sex-matched controls. CFS was diagnosed using the CDC criteria. Results. More CFS patients had antibodies to HSV-1, HSV-2 and both types simultaneously, than did the controls (all p < .019). Conclusions. More CFS patients have antibodies to both HSV-1 and HSV-2 than do controls. The possibility that multiple strains could
Broderick G, Craddock RC, Whistler T, Taylor R, Klimas N, Unger ER.	University of Alberta, Institute for Biomolecular Design, Edmonton, Alberta, T6G 2H7, Canada. gordon.broderick @ualberta.ca	Identifying illness parameters in fatiguing syndromes using classical projection methods.	Pharmacogenomics. 2006 Apr;7(3):407-19.	OBJECTIVES: To examine the potential of multivariate projection methods in identifying common patterns of change in clinical and gene expression data that capture the illness state of subjects with unexplained fatigue and nonfatigued control participants. METHODS: Data for 111 female subjects was examined. A total of 59 indicators, including multidimensional fatigue inventory (MFI), medical outcome Short Form 36 (SF-36), Centers for Disease Control and Prevention (CDC) symptom inventory and cognitive response described illness. Partial least squares (PLS) was used to construct two feature spaces: one describing the symptom space from gene expression in peripheral blood mononuclear cells (PBMC) and one based on 117 clinical variables. Multiplicative scatter correction followed by quantile normalization was applied for trend removal and range adjustment of microarray data. Microarray quality was assessed using mean Pearson correlation between samples. Benjamini-Hochberg multiple testing criteria served to identify significantly expressed probes. RESULTS: A single common trend in 59 symptom constructs isolates of nonfatigued subjects from the overall group. This segregation is supported by two co-regulation patterns representing 10% of the overall microarray variation. Of the 39 principal contributors, the 17 probes annotated related to basic cellular processes involved in cell signaling, ion transport and immune system function. The single most influential gene was sestrin 1 (SESN1), supporting recent evidence of oxidative stress involvement in chronic fatigue syndrome (CFS). Dominant variables in the clinical feature space described heart rate variability (HRV) during sleep. Potassium and free thyroxine (T4) also figure prominently. CONCLUSION: Combining

				multiple symptom, gene or clinical variables into composite features provides better discrimination of the illness state than even the most influential variable used alone. Although the exact mechanism is unclear, results suggest a common link between oxidative stress, immune system dysfunction and potassium imbalance in CFS patients leading to impaired sympatho-vagal balance strongly reflected in abnormal HRV.
Brooks JK, Francis LA.	Department of Diagnostic Sciences and Pathology, Baltimore College of Dental Surgery, Dental School, University of Maryland, Baltimore, MD 21201, USA. Oralpath5@aol.com	Postural orthostatic tachycardia syndrome: Dental treatment considerations.	J Am Dent Assoc. 2006 Apr;137(4):488-93.	BACKGROUND: Postural orthostatic tachycardia syndrome (POTS) is a chronic, relatively common autonomic disorder typically affecting younger females. It is distinguished by a dramatic increase in heart rate on the assumption of an upright posture from the supine position. METHODS: The authors provide an overview of the demographics, clinical assessment, diagnostic features, differential diagnoses, pathogeneses and medical treatment of patients with POTS, with an emphasis on the clinical treatment of the dental patient affected by the syndrome. CONCLUSION: Patients frequently exhibit symptoms of lightheadedness, fatigue, palpitations and syncope. Patients with POTS may have Ehlers-Danlos syndrome, mitral valve prolapse, chronic fatigue syndrome or, rarely, the Brugada syndrome. Despite widespread dissemination of information regarding POTS in the medical literature, scant information on it has appeared in dental publications. PRACTICE IMPLICATIONS: Dentists need to be familiar with the clinical features of POTS and be prepared to treat patients at risk of developing syncope.

Capuron L, Welberg L, Heim C, Wagner D, Solomon L, Papanicolaou DA, Craddock RC, Miller AH, Reeves WC.	Department of Psychiatry and Behavioral Sciences, Emory University School of Medicine, Atlanta, GA, USA.	Cognitive dysfunction relates to subjective report of mental fatigue in patients with chronic fatigue syndrome.	Neuropsychopharmacology. 2006 Aug;31(8):1777-84. Epub 2006 Jan 4.	Patients with chronic fatigue syndrome (CFS) frequently complain of cognitive dysfunction. However, evidence of cognitive impairment in CFS patients has been found in some, but not other, studies. This heterogeneity in findings may stem from the relative presence of mental fatigue in the patient populations examined. The present study assessed this possibility in a population-based sample of CFS patients. In all, 43 patients with CFS defined by the criteria of the 1994 research case definition using measurements recommended by the 2003 International CFS Study Group, and 53 age-, sex-, and race/ethnicity-matched nonfatigued subjects were included in the study. Mental fatigue was assessed using the mental fatigue subscale of the multidimensional fatigue inventory. Cognitive function was evaluated using an automated battery of computerized tests (Cambridge neuropsychological test automated battery (CANTAB)) that assessed psychomotor function, planning and problem-solving abilities, and memory and attentional performance. CFS patients with significant complaints of mental

				fatigue (score of mental fatigue 2 standard deviations above the mean of nonfatigued subjects) exhibited significant impairment in the spatial working memory and sustained attention (rapid visual information processing) tasks when compared to CFS patients with low complaints of mental fatigue and nonfatigued subjects. In CFS patients with significant mental fatigue, sustained attention performance was impaired only in the final stages of the test, indicating greater cognitive fatigability in these patients. CFS patients with low mental fatigue displayed performance comparable to nonfatigued subjects on all tests of the CANTAB battery. These findings show strong concordance between subjective complaints of mental fatigue and objective measurement of cognitive impairment in CFS patients and suggest that mental fatigue is an important component of CFS-related cognitive dysfunction.
Carlo-Stella N, Badulli C, De Silvestri A, Bazzichi L, Martinetti M, Lorusso L, Bombardieri S, Salvaneschi L, Cuccia M.	Immunogenetics Laboratory, Dept. of Genetics and Microbiology, University of Pavia, Italy. nickics@ipvgen.unipv.it	A first study of cytokine genomic polymorphisms in CFS: Positive association of TNF-857 and IFNgamma 874 rare alleles.	Clin Exp Rheumatol. 2006 Mar-Apr;24(2):179-82.	OBJECTIVE: In the past two years we have developed a biological bank of genomic DNA, cDNA, serum and red blood cells of Italian patients with certified CFS from the two Italian referral centers for the syndrome. Recent studies have shown an imbalance in cytokine production in disease states similar to Chronic Fatigue Syndrome (CFS), such as sickness behavior, both in animals and in humans. However we notice that serum cytokine concentrations are often inconstant and degrade rapidly. With this in mind, we investigated cytokine gene polymorphisms in 80 Italian patients with CFS in order to ascertain whether in this group of patients it is possible to describe a genetic predisposition to an inflammatory response. METHODS: We analyzed the promoter polymorphisms of IL-10, IL-6 and the IFNgamma 874 T/A polymorphism in intron 1 with a PCR-SSP method (Cytogen One Lambda Inc. Canoga Park, CA, U.S.A) in 54 patients and TNF-308 G/A and -857 C/T promoter polymorphisms with a PCR-RFLP method (in 54 and 80 patients respectively). RESULTS: There is a highly significant increase of TNF -857 TT and CT genotypes (p = 0.002) among patients with respect to controls and a significant decrease of IFN gamma low producers (A/A) (p = 0.04) among patients with respect to controls. CONCLUSIONS: We hypothesize that CFS patients can have a genetic predisposition to an immunomodulatory response of an inflammatory nature probably secondary to one or more environmental insults of unknown nature.
Carmel L, Efroni S, White PD, Aslakson E, Vollmer-Conna U, Rajeevan MS.	National Center for Biotechnology Information, National Library of Medicine, National Institutes of Health, Bethesda, Maryland, USA.	Gene expression profile of empirically delineated classes of unexplained chronic fatigue.	Pharmacogenomics. 2006 Apr;7(3):375-86.	OBJECTIVES: To identify the underlying gene expression profiles of unexplained chronic fatigue subjects classified into five or six class solutions by principal component (PCA) and latent class analyses (LCA). METHODS: Microarray expression data were available for 15,315 genes and 111 female subjects enrolled from a population-based study on chronic fatigue syndrome. Algorithms were developed to assign gene scores and threshold values that signified the contribution of each gene to discriminate the multiclasses in each LCA solution. Unsupervised dimensionality reduction was first used to remove noise or otherwise uninformative gene combinations, followed by supervised dimensionality reduction to isolate gene combinations that best separate the classes. RESULTS: The authors' gene score and threshold algorithms identified 32 and 26 genes capable of discriminating the five and six multiclass solutions, respectively. Pair-wise comparisons suggested that some genes (zinc finger protein 350 [ZNF350], solute carrier family 1, member 6 [SLC1A6], F-box protein 7 [FBX07] and vacuole 14 protein homolog [VAC14]) distinguished most classes of fatigued subjects from healthy subjects, whereas others (patched homolog 2 [PTCH2] and T-cell leukemia/lymphoma [TCL1A]) differentiated specific fatigue classes. CONCLUSION: A computational approach was developed for

				general use to identify discriminatory genes in any multiclass problem. Using this approach, differences in gene expression were found to discriminate some classes of unexplained chronic fatigue, particularly one termed interoception.
Caseras X, Mataix-Cols D, Giampietro V, Rimes KA, Brammer M, Zelaya F, Chalder T, Godfrey EL.	Unitat de Psicologia Medica, Institut de Neurociencies, Universitat Autonoma de Barcelona, Barcelona, Spain. x.caseras@iop.kcl.ac.uk	Probing the working memory system in chronic fatigue syndrome: a functional magnetic resonance imaging study using the n-back task.	Psychosom Med. 2006 Nov-Dec;68(6):947-55. Epub 2006 Nov 1.	OBJECTIVE: Up to 90% of patients with chronic fatigue syndrome (CFS) report substantial cognitive difficulties. However, objective evidence supporting these claims is inconsistent. The present functional magnetic resonance imaging study examined the neural correlates of working memory in patients with CFS compared with controls. METHODS: Seventeen patients with CFS and 12 healthy control subjects were scanned while performing a parametric version of the n-back task (0-, 1-, 2-, and 3-back). RESULTS: Both groups performed comparably well and activated the verbal working memory network during all task levels. However, during the 1-back condition, patients with CFS showed greater activation than control subjects in medial prefrontal regions, including the anterior cingulate gyrus. Conversely, on the more challenging conditions, patients with CFS demonstrated reduced activation in dorsolateral prefrontal and parietal cortices. Furthermore, on the 2- and 3-back conditions, patients but not control subjects significantly activated a large cluster in the right inferior/medial temporal cortex. Trend analyses of task load demonstrated statistically significant differences in brain activation between the two groups as the demands of the task increased. CONCLUSIONS: These results suggest that patients with CFS show both quantitative and qualitative differences in activation of the working memory network compared with healthy control subjects. It remains to be determined whether these findings stay stable after successful treatment.
Chalmers RA, Jones MG, Goodwin CS, Amjad S.	St George's Hospital Medical School, Cranmer Terrace, London SW17 0RE, UK. rachalmers@cimoa.org.uk	CFSUM1 and CFSUM2 in urine from patients with chronic fatigue syndrome are methodological artefacts.	Clin Chim Acta. 2006 Feb;364(1-2):148-58. Epub 2005 Aug 10.	McGregor et al. reported increased levels of an unidentified urinary compound (CFSUM1) in patients with chronic fatigue syndrome (CFS), with reduced excretion of another unidentified compound (CFSUM2), and suggested the possibility of chemical or metabolic 'markers' for CFS. The identity of CFSUM1 as reported was erroneous and the identities of these compounds have remained unknown until now. Urine samples were obtained from 30 patients with ME/CFS, 30 age- and sex-matched healthy controls, 20 control patients with depression and 22 control patients with rheumatoid arthritis. Samples were prepared using the published methods of McGregor et al. to produce heptafluorobutyryl-isobutyl derivatives of urinary metabolites. Alternative preparations utilised isopropyl, n-butyl and trifluoroacetyl derivatives. These were separated and identified using gas chromatography-mass spectrometry. CFSUM2 was identified as being partially derivatised [isobutyl ester-mono-heptafluorobutyryl (HFB)] serine. CFSUM1 was identified as partially derivatised pyroglutamic acid, being the isobutyl ester without formation of a HFB derivative. Both CFSUM1 and CFSUM2 are artefacts of the sample preparation procedure and previously reported quantitative abnormalities of CFSUM1 and CFSUM2 in urine from patients with ME/CFS are also artefactual. Pyroglutamic acid may be of primarily dietary origin. The methods used cannot provide reliable qualitative or quantitative data on urinary metabolites. No clinical or biochemical significance can be drawn between these compounds in ME/CFS or any other clinical conditions.
Chambers D, Bagnall AM, Hempel S, Forbes C.	Centre for Reviews and Dissemination, University of York, York YO10 5DD,	Interventions for the treatment, management and rehabilitation of	J R Soc Med. 2006 Oct;99(10):506-20.	OBJECTIVES: To determine whether any particular intervention or combination of interventions is effective in the treatment, management and rehabilitation of adults and children with a diagnosis of chronic fatigue syndrome / myalgic encephalomyelitis (CFS/ME). DESIGN: Substantive update of a systematic review published in 2002. Randomized (RCTs) and non-randomized controlled trials of any

	UK. dc510@york.ac.uk	patients with chronic fatigue syndrome/myalgic encephalomyelitis: an updated systematic review.		intervention or combination of interventions were eligible for inclusion. Study participants could be adults or children with a diagnosis of CFS/ME based on any criteria. We searched eleven electronic databases, reference lists of articles and reviews, and textbooks on CFS/ME. Additional references were sought by contact with experts. RESULTS: Seventy studies met the inclusion criteria. Studies on behavioural, immunological, pharmacological and complementary therapies, nutritional supplements and miscellaneous other interventions were identified. Graded exercise therapy and cognitive behaviour therapy appeared to reduce symptoms and improve function based on evidence from RCTs. For most other interventions, evidence of effectiveness was inconclusive and some interventions were associated with significant adverse effects. CONCLUSIONS: Over the last five years, there has been a marked increase in the size and quality of the evidence base on interventions for CFS/ME. Some behavioural interventions have shown promising results in reducing the symptoms of CFS/ME and improving physical functioning. There is a need for research to define the characteristics of patients who would benefit from specific interventions and to develop clinically relevant objective outcome measures.
Chapenko S, Krumina A, Kozireva S, Nora Z, Sultanova A, Viksna L, Murovska M.	August Kirchenstein Institute of Microbiology and Virology, Riga Stradins University, Ratsupites St.1, Riga, LV-1067, Latvia.	Activation of human herpesviruses 6 and 7 in patients with chronic fatigue syndrome.	J Clin Virol. 2006 Dec;37 Suppl 1:S47-51.	BACKGROUND: Human herpesvirus 6 (HHV-6) and 7 (HHV-7) have been suggested as possible triggering agents for chronic fatigue syndrome (CFS). OBJECTIVES: To determine the possible association of HHV-6 and HHV-7 infections with CFS. STUDY DESIGN: The prevalence of latent/persistent and active viral infections by nPCR, characteristic of HHV-6 variants using restriction endonuclease analysis and changes of lymphocyte subsets in peripheral blood by laser flow-cytometry in 17 CFS patients was examined. In addition, 12 patients with unexplained chronic fatigue and 20 blood donors (BD) were studied. RESULTS: No difference in prevalence of latent/persistent single viral infections between the patients and BD was found but dual infection rate was significantly higher in CFS patients. Active HHV-6 and dual (HHV-6 + HHV-7) infections were detected in CFS patients only and frequency of HHV-7 reactivation was also significantly higher in these patients. HHV-6 variant B was predominant in CFS patients (12/13). The changes of immunological parameters in CFS patients with active dual infection were characterized by significant decrease of CD3+ and CD4+ T cells, significant increase of CD95+ cells and decrease of CD4+/CD8+ ratio. CONCLUSIONS: HHV-6 and HHV-7 may be involved in the pathogenesis of CFS and reactivation of both viruses may provoke changes in the phenotype of circulating lymphocytes.
Chaudhuri A.	Essex Centre for Neurological Sciences, Oldchurch Hospital, Romford, Essex.	Diagnosing chronic fatigue.	Practitioner. 2006 Oct;250(1687):33-4, 37.	Review
Cho HJ, Skowera A, Cleare A, Wessely S.	Department of Psychological Medicine, Institute of Psychiatry, King's College	Chronic fatigue syndrome: an update focusing on phenomenology and	Curr Opin Psychiatry. 2006 Jan;19(1):67-73.	PURPOSE OF REVIEW: Chronic fatigue syndrome is a controversial condition especially concerning its clinical definition and aetiopathogenesis. Most recent research progress has been made in phenomenology and pathophysiology and we focused our review on these two areas. RECENT FINDINGS: The phenomenology research supports the notion of a discrete fatigue syndrome which can be distinguished from depression and anxiety. The current case definition, however, may need an

	London, London, UK. h.cho@iop.kcl.ac.uk	pathophysiology.		improvement based on empirical data. Recent advances in understanding the pathophysiology of chronic fatigue syndrome continue to demonstrate the involvement of the central nervous system. Hyperserotonergic state and hypoactivity of the hypothalamic-pituitary-adrenal axis constitute other findings, but the question of whether these alterations are a cause or consequence of chronic fatigue syndrome still remains unanswered. Immune system involvement in the pathogenesis seems certain but the findings on the specific mechanisms are still inconsistent. Genetic studies provide some evidence of the syndrome being a partly genetic condition, but environmental effects seem to be still predominant and identification of specific genes is still at a very early stage. SUMMARY: The recent findings suggest that further research is needed in improving the current case definition; investigating overlaps and boundaries among various functional somatic syndromes; answering the question of whether the pathophysiologic findings are a cause or consequence; and elucidating the involvement of the central nervous system, immune system and genetic factors.
Cook DB, Nagelkirk PR, Poluri A, Mores J, Natelson BH.	University of Wisconsin, Madison, WI 53706, USA. dcook@education.wisc.edu	The influence of aerobic fitness and fibromyalgia on cardiorespiratory and perceptual responses to exercise in patients with chronic fatigue syndrome.	Arthritis Rheum. 2006 Oct;54(10):3351-62.	OBJECTIVE: To investigate cardiorespiratory and perceptual responses to exercise in patients with chronic fatigue syndrome (CFS), accounting for comorbid fibromyalgia (FM) and controlling for aerobic fitness. METHODS: Twenty-nine patients with CFS only, 23 patients with CFS plus FM, and 32 controls completed an incremental bicycle test to exhaustion. Cardiorespiratory and perceptual responses were measured. Results were determined for the entire sample and for 18 subjects from each group matched for peak oxygen consumption. RESULTS: In the overall sample, there were no significant differences in cardiorespiratory parameters between the CFS only group and the controls. However, the CFS plus FM group exhibited lower ventilation, lower end-tidal CO2, and higher ventilatory equivalent of carbon dioxide compared with controls, and slower increases in heart rate compared with both patients with CFS only and controls. Peak oxygen consumption, ventilation, and workload were lower in the CFS plus FM group. Subjects in both the CFS only group and the CFS plus FM group rated exercise as more effortful than did controls. Patients with CFS plus FM rated exercise as significantly more painful than did patients with CFS only or controls. In the subgroups matched for aerobic fitness, there were no significant differences among the groups for any measured cardiorespiratory response, but perceptual differences in the CFS plus FM group remained. CONCLUSION: With matching for aerobic fitness, cardiorespiratory responses to exercise in patients with CFS only and CFS plus FM are not different from those in sedentary healthy subjects. While CFS patients with comorbid FM perceive exercise as more effortful and painful than do controls, those with CFS alone do not. These results suggest that aerobic fitness and a concurrent diagnosis of FM are likely explanations for currently conflicting data and challenge ideas implicating metabolic disease in the pathogenesis of CFS.
Craddock RC, Taylor R, Broderick G, Whistler T, Klimas N, Unger ER.	Centers for Disease Control and Prevention, Viral Exanthems and Herpesvirus Branch, Atlanta, GA 30333, USA.	Exploration of statistical dependence between illness parameters using the entropy correlation	Pharmacogenomics. 2006 Apr;7(3):421-8.	The entropy correlation coefficient (ECC) is a useful tool for measuring statistical dependence between variables. We employed this tool to search for pairs of variables that correlated in the chronic fatigue syndrome (CFS) Computational Challenge dataset. Highly related variables are candidates for data reduction, and novel relationships could lead to hypotheses regarding the pathogenesis of CFS. METHODS: Data for 130 female participants in the Wichita (KS, USA) clinical study [1] was coded into numerical values. Metric data was grouped using Gaussian mixture models; the number of groups was chosen using Bayesian information content. The pair-wise correlation

	cmi5@cdc.gov	coefficient.		between all variables was computed using the ECC. Significance was estimated from 1000 iterations of a permutation test and a threshold of 0.01 was used to identify significantly correlated variables. RESULTS: The five dimensions of multidimensional fatigue inventory (MFI) were all highly correlated with each other. Seven Short Form (SF)-36 measures, four CFS case-defining symptoms and the Zung self-rating depression scale all correlated with all MFI dimensions. No physiological variables correlate with more than one MFI dimension. MFI, SF-36, CDC symptom inventory, the Zung self-rating depression scale and three Cambridge Neuropsychological Test Automated Battery (CANTAB) measures are highly correlated with CFS disease status. DISCUSSION: Correlations between the five dimensions of MFI are expected since they are measured from the same instrument. The relationship between MFI and Zung depression index has been previously reported. MFI, SF-36, and Centers for Disease Control and Prevention (CDC) symptom inventory are used to classify CFS; it is not surprising that they are correlated with disease status. Only one of the three CANTAB measures that correlate with disease status has been previously found, indicating the ECC identifies relationships not found with other statistical tools. CONCLUSION: The ECC is a useful tool for measuring statistical dependence between variables in clinical and laboratory datasets. The ECC needs to be further studied to gain a better understanding of its meaning for clinical data.
Crawley E.		Chronic fatigue syndrome in young people: the spectrum and the myths.	Br J Hosp Med (Lond). 2006 Sep;67(9):452-3.	Editorial
Demitrack MA.	Neuronetics, Inc., One Great Valley Parkway, Suite 2, Malvern, Pennsylvania 19355, USA. mdemitrack@neuronetics.com	Clinical methodology and its implications for the study of therapeutic interventions for chronic fatigue syndrome: a commentary.	Pharmacogenomics. 2006 Apr;7(3):521-8.	Chronic fatigue syndrome (CFS) is a complex, multisymptom illness of unknown etiology. A variety of operational case definitions based on symptom report have been developed that share some common clinical features. Patients often come to clinical presentation after months or, more typically, years of symptomatic distress. Comorbid presentation with psychiatric illnesses has been noted. Due to these fundamental issues, the impact of patient selection and the specification of the methods of outcome assessment loom large in therapeutic studies of CFS. While a substantial body of research has focused on increasing our understanding of the basic pathobiology of CFS, there have been comparatively fewer studies that have addressed the problems of patient characterization and outcome assessment. The role of clinical methodology in the study of the therapeutics of CFS is not trivial, and may confound our understanding of pragmatic recommendations for treatment.
Devanur LD, Kerr JR.	Chronic Fatigue Syndrome (CFS) Group, Department of Cellular & Molecular Medicine, St. George's University of	Chronic fatigue syndrome.	J Clin Virol. 2006 Nov;37(3):139-50. Epub 2006 Sep 15.	Chronic fatigue syndrome (CFS) is thought to have a worldwide prevalence of 0.4-1% with approximately 240,000 patients in the UK. Diagnosis is based on clinical criteria and critically depends on exclusion of other physical and psychiatric diseases. Studies of pathogenesis have revealed immune system abnormalities and chronic immune activation, dysfunction of the hypothalamic-pituitary-adrenal (HPA) axis, brain abnormalities, evidence of emotional stress (comprising host aspects) and evidence of exogenous insults, for example, various microbial infections (Epstein-Barr virus, enteroviruses, parvovirus B19, Coxiella burnetii and Chlamydia pneumoniae), vaccinations and exposure to organophosphate chemicals and other toxins (comprising environmental aspects). Emotional stress appears to be very important as it reduces the ability of the immune system to clear

	London, Cranmer Terrace, London SW17 0RE, United Kingdom.			infections, it's presence has been shown to determine whether or not an individual develops symptoms upon virus infection, and it leads to activation of the HPA axis. But, emotional stress is distinct from depression, the presence of which precludes a diagnosis of CFS. There is no specific treatment for CFS other than the much underutilised approach of specific treatment of virus infections. Current priorities are to understand the molecular pathogenesis of disease in terms of human and virus gene expression, to develop a diagnostic test based on protein biomarkers, and to develop specific curative treatments.
Dumit J.	Program in Science, Technology & Society, Massachusetts Institute of Technology, E51-296D MIT, Cambridge, MA 02139-4307, USA. dumit@mit.edu	Illnesses you have to fight to get: facts as forces in uncertain, emergent illnesses.	Soc Sci Med. 2006 Feb;62(3):577-90. Epub 2005 Aug 8.	Chronic fatigue syndrome and multiple chemical sensitivity are two clusters of illnesses that are pervaded by medical, social and political uncertainty. This article examines how facts are talked about and experienced in struggles over these emergent, contested illnesses in the US. Based principally on a large archive of internet newsgroup postings, and also on fieldwork and on published debates, it finds that (1) sufferers describe their experiences of being denied healthcare and legitimacy through bureaucratic categories of exclusion as dependent upon their lack of biological facts; (2) institutions manage these exclusions rhetorically through exploiting the open-endedness of science to deny efficacy to new facts; (3) collective patient action responds by archiving the systematic nature of these exclusions and developing counter-tactics. The result is the maintenance of these very expensive struggles for all involved.
Dyer C.		GMC must consider case against paediatricians who suspected parents of fabricating child's illness.	BMJ. 2006 May 13;332(7550):1110 .	
Engel CC.	Department of Psychiatry, F. Edward Hebert School of Medicine of Uniformed Services University of Health Sciences, Bethesda, MD 20814-4799, USA. cengel@usuhs.mil	Explanatory and pragmatic perspectives regarding idiopathic physical symptoms and related syndromes.	CNS Spectr. 2006 Mar;11(3):225-32.	In recent years, research-methods literature mainly addressing controlled clinical trials has arisen regarding explanatory and pragmatic treatment trials. Explanatory trials tend to examine causal mechanisms and questions of efficacy and value internal validity (creating optimal study conditions) over generalizability (using study results to understand treatment effects in real-life patient populations). In contrast, pragmatic trials value "external relevance" (generalizability) of study results over "internal elegance" so that clinicians and health policymakers can better understand how treatments might impact their patients and policies. This review draws inspiration from these contrasting explanatory and pragmatic perspectives and develops them for clinical and research pertaining to idiopathic physical symptoms and related syndromes (eg, somatization disorder, chronic fatigue syndrome, multiple chemical sensitivities, irritable bowel syndrome). Explanatory and pragmatic perspectives are used to examine these idiopathies with regard to causation, case definition, labels, and treatment. It is concluded that idiopathic symptom syndromes are fundamentally pragmatic clinical and research challenges. For epidemiologic and methodologic reasons, the complex explanations for these syndromes remain largely elusive. Even so, scientific and clinical pragmatism offers the opportunity to reduce disagreement between competing medical

				disciplines and between clinicians and affected patients with regard to irreconcilable etiologic questions and to remain evidence-based in the care of patients.
Fang H, Xie Q, Boneva R, Fostel J, Perkins R, Tong W.	Z-Tech Corporation at NCTR, Division of Bioinformatics, 3900 NCTR Road, Jefferson, AR 72079, USA.	Gene expression profile exploration of a large dataset on chronic fatigue syndrome.	Pharmacogenomics. 2006 Apr;7(3):429-40.	OBJECTIVE: To gain understanding of the molecular basis of chronic fatigue syndrome (CFS) through gene expression analysis using a large microarray data set in conjunction with clinically administrated questionnaires. METHOD: Data from the Wichita (KS, USA) CFS Surveillance Study was used, comprising 167 participants with two self-report questionnaires (multidimensional fatigue inventory [MFI] and Zung depression scale [Zung]), microarray data, empiric classification, and others. Microarray data was analyzed using bioinformatics tools from ArrayTrack. RESULTS: Correspondence analysis was applied to the MFI questionnaire to select the 23 samples having either the most or the least fatigue, and to the Zung questionnaire to select the 26 samples having either the most or least depression; ten samples were common, resulting in a total of 39 samples. The MFI and Zung-based CFS/non-CFS (NF) classifications on the 39 samples were consistent with the empiric classification. Two differentially-expressed gene lists were determined, 188 fatigue-related genes and 164 depression-related genes, which shared 24 common genes and involved 11 common pathways. Principal component analysis based on 24 genes clearly separates 39 samples with respect to their likelihood to be CFS. Most of the 24 genes are not previously reported for CFS, yet their functions are consistent with the prevailing model of CFS, such as immune response, apoptosis, ion channel activity, signal transduction, cell-cell signaling, regulation of cell growth and neuronal activity. Hierarchical cluster analysis was performed based on 24 genes to classify 128 (=167-39) unassigned samples. Several of the 11 identified common pathways are supported by earlier findings for CFS, such as cytokine-cytokine receptor interaction and neuroactive ligand-receptor interaction. Importantly, most of the 11 common pathways are interrelated, suggesting complex biological mechanisms associated with CFS. CONCLUSION: Bioinformatics is critical in this study to select definitive sample groups, analyze gene expression data and gain insight into biological mechanisms. The 24 identified common genes and 11 common pathways could be important in future studies of CFS at the molecular level.

Fostel J, Boneva R, Lloyd A.	National Center for Toxicogenomics, NIEHS MD F1-05, 111 Alexander Drive, PO Box 12233, Research Triangle Park, NC	Exploration of the gene expression correlates of chronic unexplained fatigue using factor analysis.	Pharmacogenomics. 2006 Apr;7(3):441-54.	OBJECTIVE: To identify biomarkers of chronic fatigue syndrome (CFS) and related disorders through analysis of microarray data, pathology test results and self-report symptom profiles. METHOD: To empirically derive the symptom domains of the illnesses, factor analysis was performed on responses to self-report questionnaires (multidimensional fatigue inventory, Centers for Disease Control and Prevention (CDC) symptom inventory and Zung depression scale) before validation with independent datasets. Gene expression patterns that distinguished subjects across each factor dimension were then sought. RESULTS: A four-factor solution was favored, featuring 'fatigue' and 'mood disturbance'

	27709-2233, USA. fostel@niehs.nih.gov			factors. Scores on these factors correlated with measures of disability on the Short Form (SF)-36. A total of 57 genes that distinguished subjects along each factor dimension were identified, although the separation was significant only for subjects beyond the extreme (15th and 85th) percentiles of severity. Clustering of laboratory parameters with expression of these genes revealed associations with serum measurements of pH, electrolytes, glucose, urea, creatinine, and liver enzymes (aspartate amino transferase [AST] and alanine amino transferase [AST]); as well as hematocrit and white cell count. CONCLUSION: CFS is a complex syndrome that cannot simply be associated with changes in individual laboratory tests or expression levels of individual genes. No clear association with gene expression and individual symptom domains was found. However, analysis of such multifacetted datasets is likely to be an important means to elucidate the pathogenesis of CFS.
Frémont M, Freya Vaeyens, C. Vincent Herst, Kenny De Meirleir, Patrick Englebienne		Antiviral Pathway Deregulation of Chronic Fatigue Syndrome Induces Nitric Oxide Production in Immune Cells that Precludes a Resolution of the Inflammatory Response	Journal of Chronic Fatigue Syndrome 2006; 13(4): 19-30	Chronic fatigue syndrome (CFS) is a poorly defined medical condition diagnosed by exclusion, which, besides severe chronic fatigue as the hallmark symptom, involves inflammatory and immune activation stigma. Although viral infections are not systematically found in CFS patients, the type I interferon antiviral pathway has been repeatedly shown to be activated in peripheral blood mononuclear cells (PBMC) of the most afflicted patients. An abnormal truncated form of ribonuclease L (37-kDa RNase L) is also found in the PBMC of CFS patients and this protein has been proposed as a biological marker for CFS. Recently, the levels of this abnormal protein have been significantly correlated to the extent of inflammatory symptoms displayed by CFS patients. We report here that active double-stranded RNA-dependent kinase (PKR) is expressed and activated in parallel to the presence of the 37-kDa RNase L and to an increase in nitric oxide production by immune cells. However, PKR upregulation results also in a significant increase followed by a decrease in caspase 3 activity for the samples containing the highest levels of 37-kDa RNase L. This caspase 3 downregulation does not result from increased expression of the anti-apoptotic proteins Bcl-2 and Bcl-XL. These results therefore suggest that chronic inflammation due to excess nitric oxide production plays a role in CFS and that the normal resolution of the inflammatory process by NF-KB activation and apoptotic induction is impaired. These observations draw new directions for the therapeutic approach of CFS.

Antiviral Pathway Deregulation of Chronic Fatigue Syndrome Induces Nitric Oxide Production in Immune Cells That Precludes a Resolution of the Inflammatory Response	Journal of Chronic Fatigue Syndrome 2006;13(4):	No abstract available at September 2006
Garcia-Campayo J, Pascual A, Alda M,	Department of Psychiatry, Miguel	The Spanish version of the	Gen Hosp Psychiatry. 2006	OBJECTIVE: To examine some of the psychometric properties of the Spanish version of the FibroFatigue Scale (FFS). METHODS: FFS was administered to 120 patients diagnosed with fibromyalgia

Marzo J, Magallon R, Fortes S.	Servet University Hospital and University of Zaragoza Faculty of Medicine, Avenida Isabel La Catolica, s/n 50.009 Zaragoza, Spain. jgarcamp@arrakis.es	FibroFatigue Scale: validation of a questionnaire for the observer's assessment of fibromyalgia and chronic fatigue syndrome.	Mar-Apr;28(2):154-60.	and chronic fatigue syndrome. Internal consistency was evaluated by using Cronbach's alpha, test-retest reliability with weighted kappa and construct validity by correlations among FFS, the Fibromyalgia Impact Questionnaire (FIQ), the EuroQol 5D (EQ-5D) and the Hospital Anxiety and Depression Scale (HADS). The interrater reliability was tested using analysis of variance with patients and raters as independent factors. RESULTS: Internal consistency (alpha) was .88, test-retest reliability was .91, and interrater reliability was .93. Significant correlations were obtained between overall FFS and the FIQ (.55, P<.01), the EQ-5D (-.48, P<.01) and the HADS depression subscale (.25, P<.01), but not with the HADS anxiety subscale. CONCLUSION: These results support the reliability and validity of the data obtained with the Spanish version of the FSS.
Geisser ME, Gracely RH, Giesecke T, Petzke FW, Williams DA, Clauw DJ.	Chronic Pain and Fatigue Research Center, Department of Internal Medicine, Division of Rheumatology, University of Michigan, Ann Arbor, MI, United States; Department of Physical Medicine and Rehabilitation, University of Michigan Health System, 325 E. Eisenhower Parkway, Ann Arbor, MI 48108, United States.	The association between experimental and clinical pain measures among persons with fibromyalgia and chronic fatigue syndrome.	Eur J Pain. 2006 Mar 16; [Epub ahead of print]	Evoked or experimental pain is often used as a model for the study of clinical pain, yet there are little data regarding the relationship between the two. In addition, there are few data regarding the types of stimuli and stimulus intensities that are most closely related to clinical pain. In this study, 36 subjects with fibromyalgia (FM), chronic fatigue syndrome (CFS), or both syndromes were administered measures of clinical pain and underwent a dolorimetry evaluation. Subjects also underwent experimental pain testing utilizing heat and pressure stimulation. Stimulation levels evoking low, moderate and high sensory intensity, and comparable levels of unpleasantness, were determined for both types of stimuli using random staircase methods. Clinical pain was assessed using visual analogue ratings and the short form of the McGill Pain Questionnaire (MPQ). Ratings of heat pain sensation were not significantly associated with clinical pain ratings, with the exception of unpleasantness ratings at high stimulus intensities. Pain threshold and tolerance as assessed by dolorimetry were significantly associated with average measures of clinical pain. Both intensity and unpleasantness ratings of pressure delivered using random staircase methods were significantly associated with clinical pain at low, moderate and high levels, and the strength of the association was greater at increasingly noxious stimulus intensities. These findings suggest that random pressure stimulation as an experimental pain model in these populations more closely reflects the clinical pain for these conditions. These findings merit consideration when designing experimental studies of clinical pain associated with FM and CFS.

Gibson I.	House of Commons, United Kingdom.	A new look at Chronic Fatigue Syndrome / Myalgic Encephalomyelitis (CFS/ME).	J Clin Pathol. 2006 Aug 25; [Epub ahead of print]	It has been three years since the Chief Medical Office reported on CFS/ME and the time has come for a thorough investigation by an All Party Group drawn from the House of Commons and the House of Lords. We have received many written submissions and are engaged in taking oral evidence in 2-hour sessions, which we open to the public as well as interested groups. The group has received a fantastic response to its requests for written evidence over the last few months. Questions that arise for a government response are the lack of provision and support for CFS/ME patients, the issue of the clinical definition of CFS/ME, the need for a diagnostic test for CFS/ME, effectiveness of the NICE guidelines, and criteria used to decide which treatments are best for patients with CFS/ME.
Glass JM.	University of Michigan, Institute for Social Research and Department of Psychiatry, 426 Thompson Street, Room 5256, Ann Arbor, MI 48106-1248, USA. jglass@umich.edu	Cognitive dysfunction in fibromyalgia and chronic fatigue syndrome: new trends and future directions.	Curr Rheumatol Rep. 2006 Dec;8(6):425-9.	Fibromyalgia (FM) and chronic fatigue syndrome (CFS) patients often have memory and cognitive complaints. Objective cognitive testing demonstrates long-term and working memory impairments. In addition, CFS patients have slow information-processing, and FM patients have impaired control of attention, perhaps due to chronic pain. Neuroimaging studies demonstrate cerebral abnormalities and a pattern of increased neural recruitment during cognitive tasks. Future work should focus on the specific neurocognitive systems involved in cognitive dysfunction in each syndrome.
Goertzel BN, Pennachin C, de Souza Coelho L, Gurbaxani B, Maloney EM, Jones JF.	Virginia Tech, National Capital Region, Arlington, VA, USA. ben@goertzel.org	Combinations of single nucleotide polymorphisms in neuroendocrine effector and receptor genes predict chronic fatigue syndrome.	Pharmacogenomics. 2006 Apr;7(3):475-83.	OBJECTIVE: This paper asks whether the presence of chronic fatigue syndrome (CFS) can be more accurately predicted from single nucleotide polymorphism (SNP) profiles than would occur by chance. METHODS: Specifically, given SNP profiles for 43 CFS patients, together with 58 controls, we used an enumerative search to identify an ensemble of conjunctive rules that predict whether a patient has CFS. RESULTS: The accuracy of the rules reached 76.3%, with the highest accuracy rules yielding 49 true negatives, 15 false negatives, 28 true positives and nine false positives (odds ratio [OR] 8.94, $p < 0.0001$). Analysis of the SNPs used most frequently in the overall ensemble of rules gave rise to a list of 'most important SNPs', which was not identical to the list of 'most differentiating SNPs' that one would calculate via studying each SNP independently. The top three genes containing the SNPs accounting for the highest accumulated importances were neuronal tryptophan hydroxylase (TPH2), catechol-O-methyltransferase (COMT) and nuclear receptor subfamily 3, group C, member 1 glucocorticoid receptor (NR3C1). CONCLUSION: The fact that only 28 out of several million possible SNPs predict whether a person has CFS with 76% accuracy indicates that CFS has a genetic component that may help to explain some aspects of the illness.
Goertzel BN, Pennachin C, de Souza Coelho L, Maloney EM, Jones JF, Gurbaxani B.	Virginia Tech, National Capital Region, Arlington, Virginia, USA. ben@goertzel.org	Allostatic load is associated with symptoms in chronic fatigue syndrome patients.	Pharmacogenomics. 2006 Apr;7(3):485-94.	OBJECTIVES: To further explore the relationship between chronic fatigue syndrome (CFS) and allostatic load (AL), we conducted a computational analysis involving 43 patients with CFS and 60 nonfatigued, healthy controls (NF) enrolled in a population-based case-control study in Wichita (KS, USA). We used traditional biostatistical methods to measure the association of high AL to standardized measures of physical and mental functioning, disability, fatigue and general symptom severity. We also used nonlinear regression technology embedded in machine learning algorithms to

				learn equations predicting various CFS symptoms based on the individual components of the allostatic load index (ALI). METHODS: An ALI was computed for all study participants using available laboratory and clinical data on metabolic, cardiovascular and hypothalamic-pituitary-adrenal (HPA) axis factors. Physical and mental functioning/impairment was measured using the Medical Outcomes Study 36-item Short Form Health Survey (SF-36); current fatigue was measured using the 20-item multidimensional fatigue inventory (MFI); frequency and intensity of symptoms was measured using the 19-item symptom inventory (SI). Genetic programming, a nonlinear regression technique, was used to learn an ensemble of different predictive equations rather just than a single one. Statistical analysis was based on the calculation of the percentage of equations in the ensemble that utilized each input variable, producing a measure of the 'utility' of the variable for the predictive problem at hand. Traditional biostatistics methods include the median and Wilcoxon tests for comparing the median levels of subscale scores obtained on the SF-36, the MFI and the SI summary score. RESULTS: Among CFS patients, but not controls, a high level of AL was significantly associated with lower median values (indicating worse health) of bodily pain, physical functioning and general symptom frequency/intensity. Using genetic programming, the ALI was determined to be a better predictor of these three health measures than any subcombination of ALI components among cases, but not controls.
Goodwin GM.	Oxford University, Warneford Hospital, United Kingdom. guy.goodwin@psychiatry.oxford.ac.uk	Depression and associated physical diseases and symptoms.	Dialogues Clin Neurosci. 2006;8(2):259-65.	Depression can occur in association with virtually all the other psychiatric and physical diagnoses. Physical illness increases the risk of developing severe depressive illness. There are two broadly different mechanisms. The most obvious has a psychological or cognitive mechanism. Thus, the illness may provide the life event or chronic difficulty that triggers a depressive episode in a vulnerable individual. Secondly, more specific associations appear to exist between depression and particular physical disorders. These may turn out to be of particular etiological interest. The best examples are probably stroke and cardiovascular disease. Finally, major depression, but especially minor depression, dysthymia, and depressive symptoms merge with other manifestations of human distress with which patients present to their doctors. Such somatic presentations test the conventional distinction between physical and mental disorder and are a perennial source of controversy.
Gottfries CG, Hager O, Regland B, Zachrisson O.		Long-Term Treatment with a Staphylococcus Toxoid Vaccine in Patients with Fibromyalgia and Chronic Fatigue Syndrome	Journal of Chronic Fatigue Syndrome 2006;13(4):	No abstract available at September 2006
Gottfries CG, Ove Häger, Björn Regland, Olof Zachrisson		Long-Term Treatment with a Staphylococcus Toxoid Vaccine in Patients with	Journal of Chronic Fatigue Syndrome 2006; 13(4): 31-43	One hundred and sixty patients with fibromyalgia and chronic fatigue syndrome, who were on a continuous treatment with a Staphylococcus vaccine, were followed during one year with repeated consultation visits. The patients had participated in controlled studies and been on continuous treatment with the vaccine for 22 ±10 months before inclusion into this follow-up study. They were treated with 1 mL of the vaccine subcutaneously every third to fourth week. Adverse events were few.

		Fibromyalgia and Chronic Fatigue Syndrome		The adherence to the treatment was very good. Over a period of one year, 8% withdrew, and in only 5%, the withdrawal was due to insufficient clinical effect. Only in two cases where the patients were allergic to the preservative of the vaccine, the side effects caused the withdrawal of the treatment. Ratings with scales (CPRS-15 and FibroFatigue) showed improvement from start of treatment and also further improvement during the follow-up year. In view of the natural history for these disorders the result is of interest.
Grans H, Nilsson M, Dahlman-Wright K, Evengard B.	Karolinska Institutet, Sweden.	Reduced levels of oestrogen receptor {beta} mRNA in Swedish patients with chronic fatigue syndrome.	J Clin Pathol. 2006 May 26; [Epub ahead of print]	BACKGROUND: Chronic fatigue syndrome (CFS) is an illness with unknown aetiology and pathophysiology. The sex difference observed for CFS indicates a role for oestrogen and oestrogen receptors (ERs) for disease development. Furthermore, an immuno-mediated pathogenesis has been suggested for CFS which provides an additional connection to oestrogen, which display immunomodular functions. AIMS: The aim of this study was to investigate a possible association of ER mRNAs and two ERbeta single nucleotide polymorphisms (SNPs) with CFS. METHODS: Messenger RNA levels of ERalpha, ERbetawt and ERbetacx were investigated in peripheral blood mononuclear cells (PBMCs) from 30 CFS patients and 36 healthy controls by quantitative real-time PCR. Two ERbeta SNPs were scored in the same material. RESULTS: The CFS patient group showed significantly lower mRNA expression levels of ERbetawt compared with the healthy control group. No differences were observed for ERalpha or ERbetacx between patients and controls. There were no significant differences in frequency for the investigated ERbeta SNPs between cases and controls. CONCLUSIONS: The reduced ERbetawt expression levels observed in this study is consistent with an immune-mediated pathogenesis of CFS. Additionally, the observation that ERbetawt expression is decreased in CFS could provide an entry point to identify interesting, potentially disease causing, candidate molecules for further study. A possible connection between oestrogen, ERs and CFS should be further evaluated.
Greenberg S, Frid M.	Cardiac Rehabilitation and Prevention Unit, Tel Aviv Medical Center, Israel. shaigr@zahav.net.il	[Chronic fatigue syndrome--exercise and physical activity] [Article in Hebrew]	Harefuah. 2006 Apr;145(4):276-80, 318.	One of the major symptoms of chronic fatigue syndrome (CFS) is reduced exercise and functional capacity and increased fatigue symptoms following physical effort. A review of the literature indicates that patients that suffer from CFS are characterized by: low aerobic capacity, higher heart rate during sub-maximal exercise, higher subjective effort prescription, reduced muscle strength, and prolonged recovery period. Although several symptoms are a result of lack of physical activity, several mechanisms were suggested to explain those symptoms: pathological heart rate control, reduced aerobic metabolic capacity, reduced blood supply to the working muscles and nerve system dysfunction. Participating in guided exercise programs was found to be the most effective treatment in improving exercise and functional capacity, reducing fatigue syndromes and improving patients' daily function.
Greenfield JR, Samaras K.	Department of Endocrinology, St Vincent's Hospital and St Vincent's Clinic and the Garvan Institute of Medical Research,	Evaluation of pituitary function in the fatigued patient: a review of 59 cases.	38: Eur J Endocrinol. 2006 Jan;154(1):147-57.	OBJECTIVE: The aim of this study was to review the results of dynamic pituitary testing in patients presenting with fatigue. METHODS: We reviewed clinical histories and insulin tolerance test (ITT) results of 59 patients who presented with fatigue and other symptoms of glucocorticoid insufficiency over a 4-year period. All patients referred for ITT had an early-morning cortisol level of <400 nM and a low or normal ACTH level. RESULTS: Peak cortisol and GH responses following insulin-induced hypoglycaemia were normal in only seven patients (12%). Median age of the remaining 52 patients was 47 years (range, 17-67 years); all but five were female. Common presenting symptoms were

	Sydney, Australia.			neuroglycopaenia (n = 47), depression (n = 37), arthralgia and myalgia (n = 28), weight gain (n = 25), weight loss (n = 9), postural dizziness (n = 15) and headaches (n = 13). Other medical history included autoimmune disease (n = 20; particularly Hashimoto's thyroiditis, Graves' disease and coeliac disease), postpartum (n = 8) and gastrointestinal (n = 2) haemorrhage and hyperprolactinaemia (n = 13). 31 subjects had peak cortisol levels of <500 nM (suggestive of ACTH deficiency; 18 of whom had levels < 400 nM) and a further six had indeterminate results (500-550 nM). The remaining 15 subjects had normal cortisol responses (median 654 nM; range, 553-1062 nM) but had low GH levels following hypoglycaemic stimulation (5.9 mU/l; 3-11.6 mU/l). CONCLUSION: Our results suggest that patients presenting with fatigue and symptoms suggestive of hypocortisolism should be considered for screening for secondary adrenal insufficiency, particularly in the presence of autoimmune disease or a history of postpartum or gastrointestinal haemorrhage. Whether physiological glucocorticoid replacement improves symptoms in this patient group is yet to be established.
Guilleminault C, Poyares D, Rosa A, Kirisoglu C, Almeida T, Lopes MC.	Stanford University Sleep Disorders Clinic, 401 Quarry road, suite 3301, Stanford, CA 94305, USA. cguil@stanford.edu	Chronic fatigue, unrefreshing sleep and nocturnal polysomnography.	Sleep Med. 2006 Sep;7(6):513-20. Epub 2006 Aug 24.	BACKGROUND AND PURPOSE: To investigate the complaint of unrefreshing sleep with study of sleep electroencephalogram (EEG) in patients with chronic fatigue. PATIENTS AND METHODS: Fourteen successively seen patients (mean age: 41.1 9.8) who complained of chronic fatigue but denied sleepiness and agreed to participate were compared to 14 controls (33.6+/-10.2 years) who were monitored during sleep recorded in parallel. After performing conventional sleep scoring we applied Fast Fourier Transformation (FFT) for the delta 1, delta 2, theta, alpha, sigma 1, sigma 2, beta EEG frequency bands. The presence of non-rapid eye movement (NREM) sleep instability was studied with calculation of cyclic alternating pattern (CAP) rate. Two-way analysis of variance (ANOVA) was performed to analyze FFT results and Mann-Whitney U-test to compare CAP rate in both groups of subjects. RESULTS: Slow wave sleep (SWS) percentage and sleep efficiency were lower, but there was a significant increase in delta 1 (slow delta) relative power in the chronic fatigue group when compared to normals (P<0.01). All the other frequency bands were proportionally and significantly decreased compared to controls. CAP rate was also significantly greater in subjects with chronic fatigue than in normals (P=0.04). An increase in respiratory effort and nasal flow limitation were noted with chronic fatigue. CONCLUSIONS: The complaints of chronic fatigue and unrefreshing sleep were associated with an abnormal CAP rate, with increase in slow delta power spectrum, affirming the presence of an abnormal sleep progression and NREM sleep instability. These specific patterns were related to subtle, undiagnosed sleep-disordered breathing.
Gurbaxani BM, Jones JF, Goertzel BN, Maloney EM.	1Centers for Disease Control and Prevention, 600 Clifton Road, MS A-15, Atlanta, GA 30333, USA. buw8@cdc.gov	Linear data mining the Wichita clinical matrix suggests sleep and allostatic load involvement in chronic fatigue syndrome.	Pharmacogenomics. 2006 Apr;7(3):455-65.	OBJECTIVES: To provide a mathematical introduction to the Wichita (KS, USA) clinical dataset, which is all of the nongenetic data (no microarray or single nucleotide polymorphism data) from the 2-day clinical evaluation, and show the preliminary findings and limitations, of popular, matrix algebra-based data mining techniques. METHODS: An initial matrix of 440 variables by 227 human subjects was reduced to 183 variables by 164 subjects. Variables were excluded that strongly correlated with chronic fatigue syndrome (CFS) case classification by design (for example, the multidimensional fatigue inventory [MFI] data), that were otherwise self reporting in nature and also tended to correlate strongly with CFS classification, or were sparse or nonvarying between case and control. Subjects were excluded if they did not clearly fall into well-defined CFS classifications, had comorbid depression with melancholic features, or other medical or psychiatric exclusions. The popular data

				mining techniques, principle components analysis (PCA) and linear discriminant analysis (LDA), were used to determine how well the data separated into groups. Two different feature selection methods helped identify the most discriminating parameters. RESULTS: Although purely biological features (variables) were found to separate CFS cases from controls, including many allostatic load and sleep-related variables, most parameters were not statistically significant individually. However, biological correlates of CFS, such as heart rate and heart rate variability, require further investigation. CONCLUSIONS: Feature selection of a limited number of variables from the purely biological dataset produced better separation between groups than a PCA of the entire dataset. Feature selection highlighted the importance of many of the allostatic load variables studied in more detail by Maloney and colleagues in this issue [1] , as well as some sleep-related variables. Nonetheless, matrix linear algebra-based data mining approaches appeared to be of limited utility when compared with more sophisticated nonlinear analyses on richer data types, such as those found in Maloney and colleagues [1] and Goertzel and colleagues [2] in this issue.

Hannestad U, Theodorsson E, Evengard B.	Faculty of Health Science, Division of Clinical Chemistry, Linkoping University, SE-581 85 Linkoping, Sweden.	beta-Alanine and gamma-aminobutyric acid in chronic fatigue syndrome.	Clin Chim Acta. 2006 Jul 14; [Epub ahead of print]	BACKGROUND: Due to the occurrence of sleep disturbances and fatigue in chronic fatigue syndrome (CFS), an investigation was performed to examine if there is an abnormal excretion of gamma-aminobutyric acid (GABA) and/or its structural analogue beta-alanine in the urine from CFS patients. Both GABA and beta-alanine are inhibitory neurotransmitters in the mammalian central nervous system. METHODS: The 24 h urine excretion of GABA and beta-alanine was determined by isotope dilution gas chromatography mass spectrometry in 33 CFS patients and 43 healthy controls. The degree of symptoms in both patients and controls was measured by grading of three typical CFS symptoms using a Visual Analogue Scale. RESULTS: Men had a significantly higher excretion of both beta-alanine and GABA than women. Comparing CFS patients with healthy controls showed no significant difference in excretion of neither beta-alanine nor GABA. No correlation was found

				between the excretion of beta-alanine or GABA and any of the three characteristic CFS symptoms measured. However, two female and two male CFS patients excreted considerably higher amounts of beta-alanine in their 24 h urine samples than control subjects. CONCLUSIONS: Increased excretion of beta-alanine was found in a subgroup of CFS patients, indicating that there may be a link between CFS and beta-alanine in some CFS patients.

Heesen C, Nawrath L, Reich C, Bauer N, Schulz KH, Gold SM.	Department of Neurology, University Hospital Eppendorf, Martinistrasse 52, D-20246 Hamburg, Germany. heesen@uke.uni-hamburg.de	Fatigue in multiple sclerosis: an example of cytokine mediated sickness behaviour?	J Neurol Neurosurg Psychiatry. 2006 Jan;77(1):34-9. Comment in: J Neurol Neurosurg Psychiatry. 2006 Jan;77(1):2-3.	BACKGROUND: Fatigue is a major complaint of multiple sclerosis (MS) patients. However, little is known about its pathophysiological mechanisms. Evidence from chronic fatigue syndrome and studies on sickness behaviour suggest that immune and neuroendocrine factors may play a causative role in the development of fatigue. METHODS: We compared whole blood stimulatory capacity for pro- (TNFalpha, IFNgamma) and anti-inflammatory cytokines (IL-10) as well as hypothalamo-pituitary-adrenal (HPA) axis function in 15 MS patients with marked fatigue and 15 patients without fatigue as determined by the Fatigue Severity Scale (FSS). RESULTS: Proinflammatory cytokines were significantly higher (TNFalpha: 478.9 v 228.2 pg/ml, p = 0.01; IFNgamma: 57.6 v 27.8 pg/ml; p = 0.01) in MS patients with fatigue. Furthermore, TNFalpha values significantly correlated with daytime sleepiness as measured by the Epworth Sleepiness Scale (r = 0.64, p = 0.001). Controlling for disease activity (as measured by the Cambridge Multiple Sclerosis Basic Score), disease duration, Expanded Disability Status Scale, and depression further increased the correlation of cytokine production and fatigue. HPA axis activity was not related to fatigue but was modestly correlated with cognitive impairment. CONCLUSION: Our data suggest that fatigue in MS is at least partially mediated through activation of proinflammatory cytokines. In line with earlier findings, HPA axis dysfunction seems not to be relevant in MS fatigue pathogenesis but appears to be linked to cognitive impairment. Our findings suggest that increased levels of inflammatory cytokines may be involved in MS fatigue. Investigation of cytokine profiles may increase the understanding of fatigue pathogenesis in MS.
Heim C, Wagner D, Maloney E, Papanicolaou DA, Solomon L, Jones JF, Unger ER, Reeves WC.	Viral Exanthems and Herpesvirus Branch, Division of Viral and Rickettsial Diseases, National Center for Infectious Diseases, Centers for Disease Control and Prevention, Atlanta, GA 30322, USA.	Early adverse experience and risk for chronic fatigue syndrome: results from a population-based study.	Arch Gen Psychiatry. 2006 Nov;63(11):1258-66.	CONTEXT: Chronic fatigue syndrome (CFS) is an important public health problem. The causes of CFS are unknown and effective prevention strategies remain elusive. A growing literature suggests that early adverse experience increases the risk for a range of negative health outcomes, including fatiguing illnesses. Identification of developmental risk factors for CFS is critical to inform pathophysiological research and devise targets for primary prevention. OBJECTIVE: To examine the relationship between early adverse experience and risk for CFS in a population-based sample of clinically confirmed CFS cases and nonfatigued control subjects. DESIGN, SETTING, AND PARTICIPANTS: A case-control study of 43 cases with current CFS and 60 nonfatigued controls identified from a general population sample of 56 146 adult residents from Wichita, Kan. MAIN OUTCOME MEASURES: Self-reported childhood trauma (sexual, physical, and emotional abuse and emotional and physical neglect) and psychopathology (depression, anxiety, and posttraumatic stress disorder) by CFS status. RESULTS: The CFS cases reported significantly higher levels of childhood trauma and psychopathology compared with the controls. Exposure to childhood trauma was

	cmheim@emory.edu			associated with a 3- to 8-fold increased risk for CFS across different trauma types. There was a graded relationship between the degree of trauma exposure and CFS risk. Childhood trauma was associated with greater CFS symptom severity and with symptoms of depression, anxiety, and posttraumatic stress disorder. The risk for CFS conveyed by childhood trauma increased with the presence of concurrent psychopathology. CONCLUSIONS: This study provides evidence of increased levels of multiple types of childhood trauma in a population-based sample of clinically confirmed CFS cases compared with nonfatigued controls. Our results suggest that childhood trauma is an important risk factor for CFS. This risk was in part associated with altered emotional state. Studies scrutinizing the psychological and neurobiological mechanisms that translate childhood adversity into CFS risk may provide direct targets for the early prevention of CFS.
Hickie I, Davenport T, Wakefield D, Vollmer-Conna U, Cameron B, Vernon SD, Reeves WC, Lloyd A; Dubbo Infection Outcomes Study Group.	Brain and Mind Research Institute, Sydney University, Sydney, NSW 2050, Australia.	Post-infective and chronic fatigue syndromes precipitated by viral and non-viral pathogens: prospective cohort study.	BMJ. 2006 Sep 16;333(7568):575. Epub 2006 Sep 1.	OBJECTIVE: To delineate the risk factors, symptom patterns, and longitudinal course of prolonged illnesses after a variety of acute infections. DESIGN: Prospective cohort study following patients from the time of acute infection with Epstein-Barr virus (glandular fever), Coxiella burnetii (Q fever), or Ross River virus (epidemic polyarthritis). SETTING: The region surrounding the township of Dubbo in rural Australia, encompassing a 200 km geographical radius and 104,400 residents. PARTICIPANTS: 253 patients enrolled and followed at regular intervals over 12 months by self report, structured interview, and clinical assessment. OUTCOME MEASURES: Detailed medical, psychiatric, and laboratory evaluations at six months to apply diagnostic criteria for chronic fatigue syndrome. Premorbid and intercurrent illness characteristics recorded to define risk factors for chronic fatigue syndrome. Self reported illness phenotypes compared between infective groups. RESULTS: Prolonged illness characterised by disabling fatigue, musculoskeletal pain, neurocognitive difficulties, and mood disturbance was evident in 29 (12%) of 253 participants at six months, of whom 28 (11%) met the diagnostic criteria for chronic fatigue syndrome. This post-infective fatigue syndrome phenotype was stereotyped and occurred at a similar incidence after each infection. The syndrome was predicted largely by the severity of the acute illness rather than by demographic, psychological, or microbiological factors. CONCLUSIONS: A relatively uniform post-infective fatigue syndrome persists in a significant minority of patients for six months or more after clinical infection with several different viral and non-viral micro-organisms. Post-infective fatigue syndrome is a valid illness model for investigating one pathophysiological pathway to chronic fatigue syndrome.
Hines CH, Leonard A. Jason, Susan R. Torres-Harding		Reliability of a Chronic Fatigue Syndrome Questionnaire	Journal of Chronic Fatigue Syndrome 2006; 13(4): 45-71	Background: A diagnostic instrument, the CFS Questionnaire, was developed for clinicians and researchers to administer to their patients as a screening instrument for CFS. The CFS Questionnaire is comprehensive, covering the inclusionary and exclusionary self-report criteria of the current U.S. case definition (Fukuda et al. 199). The instrument also assesses past and current activity levels, and symptoms of post-exertional malaise to ensure these items are adequately assessed. Objectives: The goal of the present study was to evaluate the diagnostic reliability of an experimental measure for assessing chronic fatigue syndrome (CFS). Methods: This instrument was administered to 15 persons with CFS, 15 persons with major depressive disorder (MDD), and 15 controls. Using the Fukuda et al. (1994) diagnostic criteria, raters independently reviewed participants' CFS Questionnaire responses and rated whether each study participant met criteria for chronic fatigue syndrome. Results: This instrument demonstrated good inter-rater reliability. Further, this instrument demonstrated adequate

				classification accuracy, with a 9.3 positive likelihood ratio and a .08 negative likelihood ratio. Overall, the CFS Questionnaire demonstrated good test-retest reliability, with intra-class correlation coefficients and kappa coefficients at .70 or higher for most items. Lower test-retest reliability coefficients were found for some items assessing temporal symptoms or items requiring an estimate of time. Conclusion: The present study suggests that the CFS Questionnaire is a reliable diagnostic tool. Use of the CFS Questionnaire should promote higher levels of diagnostic reliability because it allows for accurate classification of individuals with CFS
Horng-Shiuann Wu HS, Mengel MB.		Unexplained Prolonged Fatigue in Primary Care	Journal of Chronic Fatigue Syndrome 2006;13(1): 15-34	Background: Unexplained prolonged fatigue (UPF) is one of the most common complaints in primary care. UPF is difficult to manage because of its nonspecific nature and unknown mechanism. UPF frequently frustrates health care professionals and has negative impacts on the physician-patient relationship. Although it is nonfatal, fatigueassociated functional impairments and economic consequences are substantial, negatively impacting patients' quality of life. Objectives: To evaluate current knowledge development of UPF and to help focus the direction of future investigations. Methods: A literature review was undertaken with the MEDLINE databases chosen as the primary electronic resources to retrieve the literature. Results: Current understanding of UPF is limited. Lack of consistent scientific language is a major problem. There is no consensus about the case definition of UPF even for the most widely studied chronic fatigue syndrome (CFS). Various sets of classification have been developed, each with similar but not identical criteria. Clinicians are dubious about perceiving fatigue as a clinical entity and ignore the diagnosis criteria. Many more patients are excluded than included from the current classifications and lack appropriate evaluation and treatment. The predisposing factors are not well established with the exception of being female and relatively young. Laboratory testing and immune and endocrine abnormalities are inconsistent in determining the causes. Psychological and social factors play an important but inconclusive role in mediating fatigue status. Conclusions: The high prevalence, persistence, and disability-associated consequences of UPF warrant more attention. Further investigations of the symptoms, psychosocial-based symptom experiences, and a search for effective management are needed. Keywords: Unexplained fatigue, prolonged fatigue, primary care

Huibers MJ, Leone SS, Kant IJ, Knottnerus JA.	Department of Medical, Clinical and Experimental Psychology, Maastricht University, Maastricht, Netherlands.	Chronic fatigue syndrome-like caseness as a predictor of work status in fatigued employees on sick leave: four year follow up study.	Occup Environ Med. 2006 Aug;63(8):570-2. Epub 2006 May 12.	OBJECTIVE: To assess whether CFS-like caseness (meeting the criteria for chronic fatigue syndrome (CFS)) predicts work status in the long term. METHODS: Prospective study in a sample of fatigued employees absent from work. Data were collected at baseline and four years later, and included CFS-like caseness and work status (inactive work status and full work incapacity). RESULTS: CFS-like cases at baseline were three times more likely to be unable to work at follow up than fatigued employees who did not meet CFS criteria at baseline (ORs 3-3.3). These associations grew even stronger when demographic and clinical confounders were controlled for (ORs 3.4-4.4). CONCLUSION: A CFS-like status (compared to non-CFS fatigue) proved to be a strong predictor of an inactive work status and

	m.huibers@dmkep.unimaas.nl			full work incapacity in the long term. Since little is known about effective interventions that prevent absenteeism and work incapacity or facilitate return to work in subjects with chronic fatigue, there is a great need for powerful early interventions that restore or preserve the ability to work, especially for workers who meet criteria for CFS.
Huibers MJ, Wessely S.	Department of Medical, Clinical & Experimental Psychology, Maastricht University, The Netherlands. m.huibers@dmkep.unimaas.nl	The act of diagnosis: pros and cons of labelling chronic fatigue syndrome.	Psychol Med. 2006 Jul;36(7):895-900. Epub 2006 Jan 10.	BACKGROUND: One of the many controversies surrounding chronic fatigue syndrome (CFS) is the possible impact of the diagnostic label: is it disabling or enabling? In this paper, we discuss the pros and cons of labelling CFS. METHOD: A narrative synthesis of the literature. RESULTS: Diagnosed CFS patients have a worse prognosis than fatigue syndrome patients without such a label. The ways in which CFS patients perceive themselves, label their symptoms and appraise stressors may perpetuate or exacerbate their symptoms, a process that involves psychological, psychosocial and cultural factors. Labels can also lead to conflicts with doctors who fear diagnosis might lead to worse outcomes. However, on the other hand, finding a label that fits one's condition can provide meaning, emotional relief and recognition, whilst the denial of the diagnosis of CFS in those who have already reached their own conclusion can be very counter productive. The act of diagnosis therefore seems to be a trade-off between empowerment, illness validation and group support, contrasted with the risk of diagnosis as self-fulfilling prophecy of non-recovery. CONCLUSIONS: The answer to the question of 'to label or not to label' may turn out to depend not on the label, but on what that label implies. It is acceptable and often beneficial to make diagnoses such as CFS, provided that this is the beginning, and not the end, of the therapeutic encounter.
Hunsaker DH, Riffenburgh RH.	Department of Otolaryngology, Naval Medical Center San Diego, San Diego, California 92109, USA. tripwest@earthlink.net	Snoring significance in patients undergoing home sleep studies.	Otolaryngol Head Neck Surg. 2006 May;134(5):756-60.	OBJECTIVE: To analyze the impact of snoring, independent of obstructive sleep apnea syndrome on patients referred for home sleep studies and to report a new technology for the reporting of snoring, using sophisticated sound collection and noise-canceling technology. STUDY DESIGN AND SETTING: A retrospective statistical review of consecutive anonymous data compiled from questionnaires and digital data of snoring loudness and duration measured at the upper lip during unattended home sleep studies in 4,860 patients referred for snoring and sleep-disturbed breathing. RESULTS: A strong relationship exists between a history of snoring and complaints of daytime sleepiness (80%), obesity (73%), and chronic fatigue (78%) (all yield P<0.001). By contrast, only 42% to 48% of patients without these symptoms complain of snoring. In 3 multiple-regression analyses, the percent of time snoring, average loudness, and peak loudness are all significantly predicted by the apnea hypopnea index (all P<0.003), body mass index (all P<0.001), and age (P=0.014). Daytime sleepiness was strongly predicted by percent time snoring (P=0.014), weakly by average loudness (P=0.046), and not at all by peak loudness (P=0.303). CONCLUSION: By using a pair of microphones placed at the upper lip, one that samples breath sounds and the other ambient sound and artifact noise, the NovaSOM QSG measures snoring while canceling ambient noise. The clinical impact of snoring on the patient as well as the bed partner, independent of obstructive sleep apnea syndrome, is an unrecognized factor in sleep-disturbed breathing. SIGNIFICANCE: Measurable criteria to define snoring are suggested. Snoring loudness is not measured in most laboratory Polysomnograms. EBM rating: B-3b.
Hyland ME, Sodergren SC, Lewith GT.	School of Psychology, University of	Chronic fatigue syndrome: the role of positivity to	J Health Psychol. 2006 Sep;11(5):731-41.	Fifty-three chronic fatigue syndrome patients treated at a complementary medical centre were assessed over 12 months. Measures included the Chalder Fatigue scale, the General Health Questionnaire (GHQ) and positivity in illness (Silver Lining Questionnaire, SLQ). The SLQ measured at 6

	Plymouth, Plymouth, UK. mhyland@plymouth.ac.uk	illness in chronic fatigue syndrome patients.		and 9 months predicted (p < .01) mental (but not physical) fatigue at 12 months independently of current mental fatigue, initial mental fatigue, duration since diagnosis and time between start of treatment and entry to the study. The GHQ did not predict fatigue at any time point. The results suggest that a caring therapeutic intervention increases positive interpretations of illness prior to improvements in mental fatigue, but that positivity does not play a causal role in the reduction of fatigue.
Hyland ME, Sodergren SC, Lewith GT.	University of Plymouth, UK. mhyland@plymouth.ac.uk.	Chronic fatigue syndrome: the role of positivity to illness in chronic fatigue syndrome patients.	J Health Psychol. 2006 Sep;11(5):731-41.	Fifty-three chronic fatigue syndrome patients treated at a complementary medical centre were assessed over 12 months. Measures included the Chalder Fatigue scale, the General Health Questionnaire (GHQ) and positivity in illness (Silver Lining Questionnaire, SLQ). The SLQ measured at 6 and 9 months predicted (p < .01) mental (but not physical) fatigue at 12 months independently of current mental fatigue, initial mental fatigue, duration since diagnosis and time between start of treatment and entry to the study. The GHQ did not predict fatigue at any time point. The results suggest that a caring therapeutic intervention increases positive interpretations of illness prior to improvements in mental fatigue, but that positivity does not play a causal role in the reduction of fatigue.
Hyland ME, Whalley B.		Chronic fatigue syndrome.	Comment on: Lancet. 2006 Jan 28;367(9507):346-55. Lancet. 2006 May 13;367(9522):1573-4; author reply 1575.	
Iasiukiavichene L, Vasiliauskas D.		[Chronic fatigue syndrome in cardiology neurohumoral changes] [Article in Russian]	Kardiologiia. 2006;46(1):58-64.	Chronic fatigue markedly worsens quality of life of cardiological patients. Chronic fatigue and chronic fatigue syndrome are neuro-immuno-endocrine disorders which manifest as moderate and severe even invalidizing fatigue with psychosomatic symptoms. External and internal stress such as psychological stress, stress after major surgery and trauma, depressive states, inadequate physical exercise, chronic heart failure, chronic viral infection, oncologic diseases, -- can promote development of chronic fatigue. Immune and hypothalamic-pituitary-adrenal (HPA) axis abnormalities were found to be associated with this condition. Measurement of plasma cortisol concentration is used as basic characteristic of HPA axis function. Measures aimed at detection of chronic fatigue in cardiological patients and its appropriate management should supplement programs of integrated rehabilitation in order to improve quality of life and facilitate return to work.
Ismail K, Lewis G.	Department of Psychological Medicine, Institute of Psychiatry, King's College London, Weston Education Centre,	Multi-symptom illnesses, unexplained illness and Gulf War Syndrome.	Philos Trans R Soc Lond B Biol Sci. 2006 Apr 29;361(1468):543-51.	Explanatory models for the increased prevalence of ill health in Gulf veterans compared to those not deployed to the Gulf War 1990-1991 remain elusive. This article addresses whether multi-symptom reporting in Gulf veterans are types of medically unexplained symptoms and whether the alleged Gulf War Syndrome is best understood as a medically unexplained syndrome. A review of the epidemiological studies, overwhelmingly cross-sectional, describing ill health was conducted including those that used factor analysis to search for underlying or latent clinical constructs. The overwhelming evidence was that symptoms in Gulf veterans were either in keeping with currently defined psychiatric

	UK. k.ismail@iop.kcl.ac.uk			disorders such as depression and anxiety or were medically unexplained. The application of factor analysis methods had varied widely with a risk of over interpretation in some studies and limiting the validity of their findings. We concluded that ill health in Gulf veterans and the alleged Gulf War Syndrome is best understood within the medically unexplained symptoms and syndromes constructs. The cause of increased reporting in Gulf veterans are still not clear and requires further inquiry into the interaction between sociological factors and symptomatic distress.
Ito N, Nagai T, Yabe T, Nunome S, Hanawa T, Yamada H.	Kitasato Institute for Life Sciences, Kitasato University, 5-9-1 Shirokane, Minato-ku, Tokyo 108-8641, Japan.	Antidepressant-like activity of a Kampo (Japanese herbal) medicine, Koso-san (Xiang-Su-San), and its mode of action via the hypothalamic-pituitary-adrenal axis.	Phytomedicine. 2006 Nov;13(9-10):658-67. Epub 2006 Mar 3.	Koso-san (Xiang-Su-San in Chinese), a Kampo (Japanese herbal) medicine, is used clinically in East Asia for the treatment of depression-like symptoms associated with the initial stage of the common cold, allergic urticaria due to food ingestion, irritable bowel syndrome, chronic fatigue syndrome, insomnia, and autonomic imbalance. However, the antidepressant-like activity of Koso-san has never been evaluated scientifically. In this study, ddY mice subjected to a combination of forced swimming and chronic mild stresses were termed depression-like model mice. The degree of the depression-like state was measured by the animal's duration of immobility using the forced swimming test (FST). Oral administration of Koso-san (1.0 g/kg/body wt./day, 9 days) significantly shortened the duration of immobility of the depression-like model mice in the FST; however, locomotor activity was not affected. Hyperactivity of the hypothalamic-pituitary-adrenal (HPA) axis plays an important role in the pathophysiology of depression. Levels of corticotropin-releasing hormone mRNA expression in the hypothalamus and proopiomelanocortin mRNA expression in the pituitary were significantly increased, and glucocorticoid receptor protein expression in the hypothalamus paraventricular nucleus was downregulated in the depression-like model mice. However, Koso-san ameliorated these alterations to the normal conditions. The results of this study suggest that Koso-san shows the antidepressant-like effect through suppressing the hyperactivity of the HPA axis in depression-like model mice.
Jackson JL, O'Malley PG, Kroenke K.	Department of Medicine, Uniformed Services University of Health Sciences, Bethesda, MD 20814, USA. jejackson@usuhs.mil	Antidepressants and cognitive-behavioral therapy for symptom syndromes.	CNS Spectr. 2006 Mar;11(3):212-22.	Somatic symptoms are common in primary care and clinicians often prescribe antidepressants as adjunctive therapy. There are many possible reasons why this may work, including treating comorbid depression or anxiety, inhibition of ascending pain pathways, inhibition of prefrontal cortical areas that are responsible for "attention" to noxious stimuli, and the direct effects of the medications on the syndrome. There are good theoretical reasons why antidepressants with balanced norepinephrine and serotonin effects may be more effective than those that act predominantly on one pathway, though head-to-head comparisons are lacking. For the 11 painful syndromes review in this article, cognitive-behavioral therapy is most consistently demonstrated to be effective, with various antidepressants having more or less randomized controlled data supporting or refuting effectiveness. This article reviews the randomized controlled trial data for the use of antidepressant and cognitive-behavior therapy for 11 somatic syndromes: irritable bowel syndrome, chronic back pain, headache, fibromyalgia, chronic fatigue syndrome, tinnitus, menopausal symptoms, chronic facial pain, noncardiac chest pain, interstitial cystitis, and chronic pelvic pain. For some syndromes, the data for or against treatment effectiveness is relatively robust, for many, however, the data, one way or the other is scanty.
Janal MN, Ciccone DS, Natelson BH.	Fatigue Research Center and	Sub-typing CFS patients on the	Biol Psychol. 2006 Aug;73(2):124-31.	The diagnosis of chronic fatigue syndrome (CFS), an illness characterized by medically unexplained fatigue, depends on a clinical case definition representing one or more pathophysiological

	Department of Psychiatry, New Jersey Medical School, BHSB-F1522, Box 1709, University of Medicine and Dentistry of New Jersey, Newark, NJ 07101, United States.	basis of 'minor' symptoms.	Epub 2006 Feb 10.	mechanisms. To prepare for studies of these mechanisms, this study sought to identify subtypes of CFS. In 161 women meeting 1994 criteria for CFS, principal components analysis of the 10 'minor' symptoms of CFS produced three factors interpreted to indicate musculoskeletal, infectious and neurological subtypes. Extreme scores on one or more of these factors characterized about 2/3 of the sample. Those characterized by the neurological factor were at increased risk of reduced scores on cognitive tests requiring attention, working memory, long-term memory or rapid performance. In addition, the neurological subtype was associated with reduced levels of function. Those characterized by the musculoskeletal factor were at increased risk for the diagnosis of fibromyalgia (chronic widespread pain and mechanical allodynia) and reduced physical function. Those characterized by the infectious factor were less likely to evidence co-occurring fibromyalgia, and showed lesser risk of functional impairment. The prevalence of disability was increased in those with the highest scores on any of the subtypes, as well as in those with high scores on multiple factors. Depression and anxiety, while frequently present, were not more prevalent in any particular subtype, and did not increase with the severity of specific symptom reports. Results suggest that subtypes of CFS may be identified from reports of the minor diagnostic symptoms, and that these subtypes demonstrate construct validity.
Jason LA, Bell DS, Row J, Van Hoof EL, Jordan K, Lapp C, Gurwitt A, Miike T, Torres-Harding S, De Meirleir K.		A Pediatric Case Definition for Myalgic Encephalomyelitis and Chronic Fatigue Syndrome	Journal of Chronic Fatigue Syndrome 2006;13(2/3): 1-44	For a diagnosis chronic fatigue syndrome (CFS), most researchers use criteria that were developed by Fukuda et al. (1994), with modifications suggested by Reeves et al. (2003). However, this case definition was established for adults rather than children. A Canadian Case Definition (ME/CFS; Myalgic Encephalomyelitis/CFS) has recently been developed, with more specific inclusion criteria (Carruthers et al., 2003). Again, the primary aim of this case definition is to diagnose adult CFS. A significant problem in the literature is the lack of both a pediatric definition of ME/CFS and a reliable instrument to assess it. These deficiencies can lead to criterion variance problems resulting in studies labeling children with a wide variety of symptoms as having ME/CFS. Subsequently, comparisons between articles become more difficult, decreasing the possibility of conducting a meta-analysis. This article presents recommendations developed by the International Association of Chronic Fatigue Syndrome Pediatric Case Definition Working group for a ME/CFS pediatric case definition. It is hoped that this pediatric case definition will lead to more appropriate identification of children and adolescents with ME/CFS.
Jason LA, Corradi K, Gress S, Williams S, Torres-Harding S.	DePaul University, Chicago, IL 60614, USA. Ljason@depaul.edu	Causes of death among patients with chronic fatigue syndrome.	Health Care Women Int. 2006 Aug;27(7):615-26.	Chronic fatigue syndrome (CFS) is a debilitating illness affecting thousands of individuals. At the present time, there are few studies that have investigated causes of death for those with this syndrome. The authors analyzed a memorial list tabulated by the National CFIDS Foundation of 166 deceased individuals who had had CFS. There were approximately three times more women than men on the list. The three most prevalent causes of death were heart failure, suicide, and cancer, which accounted for 59.6% of all deaths. The mean age of those who died from cancer and suicide was 47.8 and 39.3 years, respectively, which is considerably younger than those who died from cancer and suicide in the general population. The implications of these findings are discussed.
Jerjes WK, Peters TJ, Taylor NF, Wood PJ, Wessely	Department of Clinical Biochemistry,	Diurnal excretion of urinary cortisol, cortisone, and	J Psychosom Res. 2006 Feb;60(2):145-53.	OBJECTIVE: The aim of this study was to obtain comprehensive information on basal hypothalamic-pituitary-adrenal (HPA) axis activity in chronic fatigue syndrome (CFS) patients who were not affected by medication or comorbid psychiatric disorder likely to influence the HPA axis. METHOD: Steroid

S, Cleare AJ.	Guy's, King's and St Thomas' School of Medicine, Bessemer Road, SE5 9RS London, UK. jerjes@kcl.ac.uk	cortisol metabolites in chronic fatigue syndrome.	Comment in: J Psychosom Res. 2006 Jun;60(6):627-8; author reply 629.	analysis of urine collections from 0600 to 2100 h at 3-h intervals in CFS patients and in controls. RESULTS: Urinary free cortisol and cortisone concentrations showed a significant normal diurnal rhythm, but levels were lower across the cycle in CFS. In contrast, while urinary cortisol metabolites also showed a normal diurnal rhythm, levels were not significantly different between the CFS and controls at any time. Derived metabolite ratios were similar in both groups. CONCLUSION: This study provides further evidence for reduced basal HPA axis function in patients with CFS, based on lower free cortisol and cortisone levels, but this is not corroborated by cortisol metabolite data. The difference between these measures cannot be explained by an altered timing of the diurnal rhythm.
Jerjes WK, Taylor NF, Peters TJ, Wessely S, Cleare AJ.	Department of Clinical Biochemistry, Guy's, King's and St. Thomas' School of Medicine, King's College London, UK. walid.jerjes@kcl.ac.uk	Urinary cortisol and cortisol metabolite excretion in chronic fatigue syndrome.	Psychosom Med. 2006 Jul-Aug;68(4):578-82.	OBJECTIVES: Reduced basal hypothalamic-pituitary-adrenal (HPA) axis output in chronic fatigue syndrome (CFS) has been inferred from low cortisol levels in blood, saliva, and urine in some studies. Because > 95% of cortisol is metabolized before excretion, we assessed cortisol output by assay of both cortisol metabolites and free cortisol in 24-hour urine collections and also investigated sex differences in these between CFS and control groups. METHOD: We calculated total urinary cortisol metabolites (TCM) and cortisol metabolite ratios from individual steroid data in 40 patients (20 males and 20 females) with CFS who were free of medication or comorbid psychiatric disorder likely to influence the HPA axis. Results were compared with those of 40 healthy volunteers (20 males and 20 females) well matched for age and body mass index. Data for free cortisol was obtained on 28 of the patients and 27 of the controls. RESULTS: The mean of TCM and cortisol metabolite ratios was not significantly different between patients and controls for either sex ($p > .05$ for all parameters). Previously established sex differences were confirmed in our controls and were found to be similar in CFS for TCM and the ratios 11OH/11OXO, 5alpha/5beta THF, and 20OH/20OXO (see text) ($p < .005$, $p < .05$, $p < .05$, and $p < .005$, respectively). Urinary free cortisol values were numerically (but not statistically) lower in patients with CFS than controls, and correlated inversely with fatigue levels in patients. CONCLUSION: The finding of normal urinary cortisol metabolite excretion in patients with CFS is at variance with earlier reports that CFS is a hypocortisolemic state. If serum and saliva cortisol levels are lower in CFS, this would suggest that metabolic clearance of cortisol is faster in patients with CFS than controls. This study also demonstrates that sex differences must be taken into account when interpreting results in patients with CFS.
Jones G, Godlee F.		Chronic Fatigue Syndrome: Editorial Bias in the British Medical Journal. Letter	Journal of Chronic Fatigue Syndrome 2006;13(1): 69-70	
Jonker K, van Hemert AM.	Parnassiagroep-PsyQ, afd Somatiek en Psyche, Den Haag.	[Treatment of patients with the chronic-fatigue syndrome] [Article in Dutch]	Ned Tijdschr Geneeskd. 2006 Sep 23;150(38):2067-8. Comment on: Ned Tijdschr Geneeskd. 2006 Sep	In the last few years, the chronic-fatigue syndrome has been recognised as an important health problem. In a recent report, the Health Council of the Netherlands suggested that the capacity for treatment be increased. Cognitive behavioural therapy and graded exercise training are treatment options of first choice. A recently published, uncontrolled evaluation of a Dutch clinical rehabilitation programme based partly on these methods proved to be successful. Unfortunately, due to the uncontrolled character of the study, it remains unclear which elements in the treatment were responsible for the success. Which patients should be included in a costly clinical rehabilitation

			23;150(38):2088-94.	programme also remains unclear. More in general, there is room for empirical studies of treatment allocation, not in the least because of the frequently occurring comorbidity. Good progress has been made in the treatment of the chronic-fatigue syndrome, but we are still far removed from evidence-based, stepped care, treatment programmes.

Katafuchi T, Kondo T, Take S, Yoshimura M.	Department of Integrative Physiology, Graduate School of Medical Sciences, Kyushu University, Fukuoka, 812-8582, Japan. kataf@physiol.med.kyushu-u.ac.jp	Brain cytokines and the 5-HT system during poly I:C-induced fatigue.	Ann N Y Acad Sci. 2006 Nov;1088:230-7.	Fatigue is evoked not only by peripheral factors, such as muscle fatigue, but also by the central nervous system (CNS). For example, it is generally known that the feeling of fatigue is greatly influenced by psychological aspects, such as motivation. However, little is known about the central mechanisms of fatigue. The clinical symptoms of chronic fatigue syndrome (CFS) are shown to include disorders in neuroendocrine, autonomic, and immune systems. On the other hand, it has been demonstrated that cytokines produced in the brain play significant roles in neural-immune interactions through their various central actions, including hypothalamo-pituitary and sympathetic activation, as well as immunosuppression. In this article, using the immunologically induced fatigue model, which was achieved by intraperitoneal (i.p.) injection of synthetic double-stranded RNAs, polyriboinosinic: polyribocytidylic acid (poly I:C) in rats, we show an involvement of brain interferon-alpha (IFN-alpha) and serotonin (5-HT) transporter (5-HTT) in the central mechanisms of fatigue. In the poly I:C-induced fatigue rats, expression of IFN-alpha and 5-HTT increased, while extracellular concentration of 5-HT in the medial prefrontal cortex decreased, probably on account of the enhanced expression of 5-HTT. Since the poly I:C-induced reduction of the running wheel activity was attenuated by a 5-HT(1A) receptor agonist, but not by 5-HT(2), 5-HT(3), or dopamine D(3) receptor agonists, it is suggested that the decrease in 5-HT actions on 5-HT(1A) receptors may at least partly contribute to the poly I:C-induced fatigue.
Kato K, Sullivan PF, Evengard B, Pedersen NL.	Department of Medical Epidemiology and Biostatistics, Karolinska University Hospital	Premorbid predictors of chronic fatigue.	Arch Gen Psychiatry. 2006 Nov;63(11):1267-72.	CONTEXT: Chronic fatigue syndrome is a disabling problem characterized by persistent fatigue lasting at least 6 months with a number of ancillary symptoms. Although the etiology of chronic fatiguing illness is unknown, some evidence suggests that stress may confer increased risk for development of the disorder. Moreover, subjects with chronic fatiguing illness may have distinctive personality traits, although this finding could reflect confounding by other mechanisms. OBJECTIVE: To assess the prospective association of premorbid self-reported stress and personality with chronic fatigue-like

	Huddinge, Karolinska Institutet, Stockholm, Sweden.			illness. DESIGN: Prospective nested case-control study in a population-based sample. SETTING: General community. PARTICIPANTS: From the Swedish Twin Registry, 19,192 twins born between January 1, 1935, and December 31, 1958. MAIN OUTCOME MEASURES: Information about current chronic fatiguing illnesses was obtained from computer-assisted telephone interviews conducted between 1998 and 2002. Self-reported stress (based on a single question) and personality scales (emotional instability and extraversion in the Eysenck Personality Inventory) were measured from 1972 to 1973 by a mailed questionnaire. Relative risks were estimated with case-control analyses (matched for age and sex) and co-twin control analyses (comparing discordant pairs). RESULTS: Higher emotional instability and self-reported stress in the premorbid period were associated with higher risk for chronic fatigue-like illness in matched case-control analyses (odds ratios, 1.72 and 1.64, respectively). In co-twin control analyses, relative risk of emotional instability decreased to 1.02 whereas that of stress increased considerably to 5.81. There was no association between extraversion and fatigue. CONCLUSIONS: Elevated premorbid stress is a significant risk factor for chronic fatigue-like illness, the effect of which may be buffered by genetic influences. Emotional instability assessed 25 years earlier is associated with chronic fatigue through genetic mechanisms contributing to both personality style and expression of the disorder. These findings suggest plausible mechanisms for chronic fatiguing illness.
Kato K, Sullivan PF, Evengard B, Pedersen NL.	Department of Medical Epidemiology and Biostatistics, Karolinska Institutet, SE-171 77 Stockholm, Sweden. Kenji.Kato@ki.se	Chronic widespread pain and its comorbidities: a population-based study.	Arch Intern Med. 2006 Aug 14-28;166(15):1649-54.	BACKGROUND: Chronic widespread pain (CWP), the cardinal symptom of fibromyalgia, is prevalent and co-occurs with numerous symptom-based conditions such as chronic fatigue syndrome, joint pain, headache, irritable bowel syndrome, and psychiatric disorders. Few studies have examined the comorbidities of CWP in the general population. Furthermore, little is known about the importance of familial (genetic and family environmental) factors in the etiology of co-occurrence. METHODS: Data were obtained from 44 897 individuals in the Swedish Twin Registry via computer-assisted telephone interview from 1998 through 2002 (age >/=42 years; 73.2% response rate). Screening for CWP was based on the American College of Rheumatology criteria without clinical evaluation. Measures for comorbidities were based on standard criteria when available. Odds ratios (ORs) were calculated in case-control and co-twin control designs to assess the effect of familial confounding in the associations. RESULTS: Considerable co-occurrences were found in CWP cases for chronic fatigue (OR, 23.53; 95% confidence interval [CI], 19.67-28.16), joint pain (OR, 7.41; 95% CI, 6.70-8.21), depressive symptoms (OR, 5.26; 95% CI, 4.75-5.82), and irritable bowel syndrome (OR, 5.17; 95% CI, 4.55-5.88). In co-twin control analyses, ORs were no longer significant for psychiatric disorders, whereas they decreased but remained significant for most other comorbidities. No changes in ORs were observed for headache. CONCLUSIONS: Associations between CWP and most comorbidities are mediated by unmeasured genetic and family environmental factors in the general population. The extent of mediation via familial factors is likely to be disorder specific.
Kaufman FR, Goodnick PJ		Depression, Chronic Fatigue Syndrome, and Fibromyalgia: An Update	Journal of Chronic Fatigue Syndrome 2006; 13(4): 83-112	Centers for Disease Control criteria for chronic fatigue syndrome (CFS) specifically recognize that patients can have both CFS and depression. The clinician's challenge is to judge for each individual patient whether the complaint of fatigue is primarily depression, physical illness, such as CFS, or a combination of both. This review differentiates CFS and fibromyalgia, discussed as "chronic fatigue syndrome and related immune deficiency syndromes" (CFIDS), from depression in terms of physical

				signs, symptoms, biological parameters, brain imaging, immunology, and treatment. The review focuses on practical applications of research findings with a further focus on future ability to show clear biologic separation and specific treatment. When depressive symptoms exist with those of CFS, accurate differentiation can usually be accomplished by focusing on diagnostic criteria. Presence of multiple physical signs and symptoms of CFIDS may be of great value. In terms of laboratory testing, a single helpful test may be measuring the plasma cortisol, which is usually high in depression and low in CFS. Future research should focus on the combination of plasma cortisol with an index of serotonin function, which is high in CFIDS and low in depression. Additional research should focus on neuroimaging and immune differentiation. Combination of multiple tests should result in a significant and clinically useful separation between CFIDS and major depressive disorder (MDD). In treating patients with significant depression or MDD with CFIDS, one should think of the noradrenergic approach using bupropion or low-dose tricyclic antidepressants in combination with a selective serotonin reuptake inhibitor, especially sertraline, to aid improvement of global, pain, and immunologic parameters. Alternatively, serotonin norepinephrine reuptake inhibitors (venlafaxine and duloxetine) should be considered. Future treatment research should focus on larger placebo-controlled, double-blind trials of these and other antidepressants as well as the evaluation of psychostimulants, electroconvulsive therapy (ECT) and repetitive transcranial magnetic stimulation (rTMS).

Kelsall H, Sim M, McKenzie D, Forbes A, Leder K, Glass D, Ikin J, McFarlane A.	Department of Epidemiology and Preventive Medicine, Monash University, Melbourne, Victoria, Australia. helen.kelsall@med.monash.edu.au	Medically evaluated psychological and physical health of Australian Gulf War veterans with chronic fatigue.	J Psychosom Res. 2006 Jun;60(6):575-84.	OBJECTIVE: The aim of this study was to evaluate fatigue in Australian Gulf War veterans and a military comparison group according to the 1994 chronic fatigue syndrome (CFS) definition and investigate the relation with exposures. METHODS: Comprehensive medical, psychological and reported exposure assessments of 1,456 veterans and 1,588 comparison group in a cross-sectional study. RESULTS: More Gulf War veterans had fatigue at all levels than did the military comparison group. The findings may be at least partly explained as an "active-deployment effect." The odds ratios increased with increasing clinical evaluation of the nature of the fatigue, even after adjustment for current psychiatric disorders in addition to other possible confounding factors. CONCLUSION: Medically unexplained chronic fatigue was more common, but not more disabling, in veterans than in the comparison group, but veterans with unexplained chronic fatigue had poorer health than veterans without. Within both populations, CFS is uncommon and at a similar level to the general community.
Kennedy G, Norris G, Spence V, McLaren M, Belch JJ.	Vascular Diseases Research Unit, University Department of Medicine, Ninewells Hospital	Is chronic fatigue syndrome associated with platelet activation?	Blood Coagul Fibrinolysis. 2006 Mar;17(2):89-92.	Chronic fatigue syndrome (CFS) is a debilitating condition that has no known aetiology or pathophysiology. Recent investigations by other workers have suggested that individuals with CFS may have a hypercoagulable state. This study investigated various aspects of platelet activation and function in 17 patients with CFS and in 16 age-matched and sex-matched healthy controls. Platelet aggregation, platelet volume and coagulation tests were performed. Platelet aggregation was investigated by means of the photometric changes using citrated platelet-rich plasma, whole blood

	& Medical School, Dundee, UK. g.y.kennedy@dundee.ac.uk			aggregation was calculated as the percentage fall in single platelet counts and the coagulation tests were performed on an automatic microcentrifugal analyser.A trend was observed for the patients to have lower aggregation results and a reduced mean platelet volume. However, this only reached statistical significance for one result; the rate of the aggregation slope by 1.0 microg/ml collagen [CFS patients, 18 (9-28) versus controls, 32.5 (19-36); Mann-Whitney U test, P = 0.029]. No significant differences were found for any of the measurements of coagulation.These results are in contrast to previously reported findings. However, due to the heterogeneous nature of the disease, and the resulting lifestyles of the patients, caution should be taken when comparing one group of patients with another. Nevertheless, we certainly found no evidence of increased platelet activation or of a hypercoagulable state in patients with CFS and, on the basis of these results, anti-platelet or anti-coagulant therapy is not warranted.
Kerr JR, Christian P, Hodgetts A, Langford PR, Devanur LD, Petty R, Burke B, Sinclair LI, Richards SC, Montgomery J, McDermott C, Harrison TJ, Kellam P, Nutt DJ, Holgate ST.	St George's University of London, United Kingdom.	Current research priorities in Chronic Fatigue Syndrome / Myalgic Encephalomyelitis (CFS/ME): disease mechanisms, a diagnostic test and specific treatments.	J Clin Pathol. 2006 Aug 25; [Epub ahead of print]	Chronic fatigue syndrome (CFS) is an illness characterised by disabling fatigue of at least 6 months duration which is accompanied by various rheumatological, infectious and neuropsychiatric symptoms. A collaborative study group has been formed in order to address the current areas for development in CFS research, namely, to develop an understanding of the molecular pathogenesis of CFS, to develop a diagnostic test, and to develop specific and curative treatments. Various groups have studied the gene expression in peripheral blood of CFS patients and of those studies which have been confirmed using polymerase chain reaction (PCR), it is clear that the most predominant functional theme is that of immunity and defense. However, we do not yet know the precise gene signature and metabolic pathways involved. Currently, this is being addressed using a microarray representing 47,000 human genes and variants, massive parallel signature sequencing (MPSS) and real-time PCR. It will be important to ensure that once a gene signature has been identified, that it is specific to CFS and does not occur in other diseases and infections. A diagnostic test is being developed using Surface-Enhanced, Laser-Desorption and Ionisation - Time of Flight (SELDI-TOF) mass spectrometry following a pilot study in which putative biomarkers were identified. And, finally, clinical trials are being planned; novel treatments which we believe are important to trial in CFS patients are interferon-a and one of the anti-tumour necrosis factor-a drugs.
Kodama M, Kodama T.	Kodama Research Institute of Preventive Medicine, 50-5 Chiyogaoka, Chikusaku, Nagoya 464-0005, Japan.	Four problems with the clinical control of interstitial pneumonia, or chronic fatigue syndrome, using the megadose vitamin C infusion system with dehydroepiandrosterone-cortisol annex.	In Vivo. 2006 Mar-Apr;20(2):285-91.	Since 1996 in our clinic, the regular practice of megadose vitamin C infusion with dehydroepiandrosterone-cortisol annex and the continuous intake of erythromycin and chloramphenicol have been found useful for the clinical control of the autoimmune disease interstitial pneumonia, also known as chronic fatigue syndrome. The long-term use of these two systems for the treatment of the autoimmune disease has led to the emergence of four problems of theoretical or practical importance, as described below: i) Should maintenance of the above core treatments be continued for prophylactic purposes in the absence of acute signs of pneumonia? Evidence indicated that their use was essential to arrest the dynamic activity of an intrapulmonary bacterial colony in the immunodeficient host, and that the 5-year survival rate of interstitial pneumonia patients would have been worse without the prophylactic practice of the 2 treatments. ii) Evidence was presented to suggest that the activity of the intrapulmonary bacterial colony was becoming less responsive because of the emergence of a drug-resistent mutant bacterium. The introduction of new antibiotics (kanamycin) was found to improve the acute signs of pneumonia. iii) The bone marrow function of

				one male patient with interstitial pneumonia was found to decline during the observation period of 9 years. It was speculated that his bone marrow, like his lungs, was in the course of fibrosis. iv) One female patient was diagnosed with breast cancer in the course of interstitial pneumonia treatment--an example indicating that the persistence of an autoimmune disease in an elderly subject might be associated with the emergence of malignancy. Dehydroepiandrosterone was shown to promote the recovery of hepatic function in the course of cancer chemotherapy with cyclophosphamide. The beneficial effect of the adrenal androgen was dose-dependent. The significance of this finding is discussed in the light of the steroid carcinogenesis concept. The reasoning behind the view that interstitial pneumonia and chronic fatigue syndrome are one disease is also discussed.
Komaroff AL, Jacobson S, Ablashi DV, Yamanishi K.	Harvard Medical School, Boston, MA, USA.	Highlights from 5th International Conference on HHV-6 and -7.	Herpes. 2006 Nov;13(3):81-2.	This article reports on key presentations at the 5th International Conference on Human Herpesvirus (HHV)-6 and -7, organized by the HHV-6 Foundation. New assays for HHV-6 and -7 promise to be more accurate and better able to distinguish between HHV-6A and B or differentiate active from latent infection. Nevertheless, more research is needed to enhance the sensitivity and specificity of these assays. Cellular receptors for both HHV-6 and -7 have been identified. Both viruses have in vitro tropism for neurons and dendritic cells of the central nervous system (CNS), and their role in producing CNS disease in the immunocompromised (particularly transplant recipients and the HIV-infected) is well established. HHV-6 may enhance the progression of simian immunodeficiency virus in monkeys, as suggested by in vivo data. In immunocompetent children and adults, HHV-6 and/or -7 may play a role in triggering and perpetuating several diseases of the nervous system, namely encephalitis, multiple sclerosis, chronic fatigue syndrome and epilepsy.
Komaroff AL.	Division of General Medicine, Department of Medicine, Brigham and Women's Hospital, Harvard Medical School, 10 Shattuck Street, Suite 602, Boston, MA 02115, USA.	Is human herpesvirus-6 a trigger for chronic fatigue syndrome?	J Clin Virol. 2006 Dec;37 Suppl 1:S39-46.	Chronic fatigue syndrome (CFS) is an illness currently defined entirely by a combination of non-specific symptoms. Despite this subjective definition, CFS is associated with objective underlying biological abnormalities, particularly involving the nervous system and immune system. Most studies have found that active infection with human herpesvirus-6 (HHV-6) - a neurotropic, gliotropic and immunotropic virus - is present more often in patients with CFS than in healthy control and disease comparison subjects, yet it is not found in all patients at the time of testing. Moreover, HHV-6 has been associated with many of the neurological and immunological findings in patients with CFS. Finally, CFS, multiple sclerosis and seizure disorders share some clinical and laboratory features and, like CFS, the latter two disorders also are being associated increasingly with active HHV-6 infection. Therefore, it is plausible that active infection with HHV-6 may trigger and perpetuate CFS in a subset of patients.

Department of Epidemiology, Maastricht University, Maastricht, The Netherlands. stephanie.leone@epid.unimaas.nl	Long-term efficacy of cognitive-behavioral therapy by general practitioners for fatigue: a 4-year follow-up study.	J Psychosom Res. 2006 Nov;61(5):601-7.	OBJECTIVE: In an earlier study, we found that cognitive-behavioral therapy (CBT) delivered by general practitioners (GPs) for fatigue among employees on sick leave was not effective after 12 months. In this study we aim to assess the long-term efficacy of CBT by GPs for fatigue. It was hypothesized that the intervention could prevent deterioration as well as relapse of fatigue complaints and relapse into absenteeism in the long term. METHODS: Patients who participated in the original randomized controlled trial were followed up 4 years later. Fatigue and absenteeism were the main outcomes. RESULTS: Fatigue and absenteeism were high in the intervention and control groups at the 4-year follow-up. There was no significant difference between the intervention group and the control group on fatigue and absenteeism. The intervention group however tended toward less-favorable outcomes as compared with the control group. CONCLUSIONS: Like that of chronic fatigue syndrome, the prognosis of less-advanced fatigue is rather poor. CBT delivered by GPs is not effective in the long term.
Leone SS, Huibers MJ, Kant I, Van Schayck CP, Bleijenberg G, Andre Knottnerus J.	Department of Epidemiology, Maastricht University, The Netherlands. Stephanie.Leone@epid.unimaas.nl	Long-term predictors of outcome in fatigued employees on sick leave: a 4-year follow-up study.	Psychol Med. 2006 Sep;36(9):1293-300. Epub 2006 Jun 6.	BACKGROUND: Persistent fatigue is strongly associated with functional status and can lead to absenteeism and work disability. Despite several prognostic studies on chronic fatigue, little attention has been paid to occupational outcomes. METHOD: A total of 127 fatigued employees on sick leave were followed-up after 4 years to determine long-term predictors of work disability, fatigue caseness and chronic fatigue syndrome (CFS)-like caseness. Measures included fatigue, physical functioning, illness attributions, psychological problems and emotional exhaustion. RESULTS: Thirty-three participants (26%) were receiving work disability benefits at the 4-year follow-up. Older age and lower levels of physical functioning predicted work disability. Weaker psychological attributions and lower levels of physical functioning were predictors of fatigue caseness. CFS-like caseness was predicted by

				female gender and lower levels of physical functioning. Self-reported physical functioning remained a strong and statistically significant determinant of work disability [odds ratio (OR) 0.45, 95% confidence interval (CI) 0.24-0.87] and CFS-like caseness (OR 0.20, 95% CI 0.09-0.43) after controlling for confounders. CONCLUSIONS: This study suggests that physical functioning plays an important role in the persistence of fatigue complaints and work disability in employees on sick leave. The course of fatigue is a complex process, and exploring temporal relationships between fatigue, functional status and work status in future research could provide valuable information for the improvement of fatigue management.

S-Lin2@northwestern.edu	Improved prediction of treatment response using microarrays and existing biological knowledge.	Pharmacogenomics. 2006 Apr;7(3):495-501.	A desired application for microarrays in the clinic is to predict treatment response from an often diverse patient population. We present a method for analyzing microarray data that is predicated on biological pathway and function knowledge as opposed to a purely data-driven initial analysis. From an analysis perspective, this methodology takes advantage of information that is available across genes on a single array, as well as differences in those patterns across measurements. By using biological knowledge in the initial analysis, the accuracy and robustness of microarray profile classification is enhanced, especially when low numbers of samples are available. For clinical studies, particularly Phase I or I/II studies, this technique is exceptionally advantageous.
Lincoln AE, Helmer DA, Schneiderman AI, Li M, Copeland HL, Prisco MK, Wallin MT, Kang HK, Natelson BH.	War-Related Illness and Injury Study Center, Washington DC Veterans Affairs Medical Center, 50 Irving Street, NW, Washington, DC 20422, USA.	The war-related illness and injury study centers: a resource for deployment-related health concerns.	Mil Med. 2006 Jul;171(7):577-85.	Combat veterans often return from deployment having experienced a wide range of exposures, symptoms, and medical conditions. The Department of Veterans Affairs established war-related illness and injury study centers to serve combat veterans with unexplained illnesses. We report the exposures, clinical status, and utilization of 53 combat veterans who participated in the National Referral Program (NRP) from January 2002 until March 2004. Participants were primarily male (81%) and served in the Persian Gulf War (79%). Common diagnoses were chronic fatigue syndrome (n = 23, 43%), neurotic depression (n = 21, 40%), and post-traumatic stress disorder (n = 20, 38%). Self-reported exposures related to weaponry, disease prophylaxis, environmental hazards, stress, and poor hygiene. A small increase in mean SF-36V mental component scores (2.8 points, p = 0.009) and use of rehabilitation therapies (1.6 additional visits, p = 0.018) followed the NRP referral. The small gain in mental function suggests that the NRP may benefit combat veterans with long and complex medical histories.

Lundell K, Qazi S, Eddy L, Uckun FM.	Parker Hughes Institute and Parker Hughes Clinics, St. Paul, MN 55113, USA.	Clinical activity of folinic acid in patients with chronic fatigue syndrome.	Arzneimittelforschung. 2006;56(6):399-404.	A high incidence of severe B-cell immunodeficiency and chronic reactivated Epstein-Barr virus (EBV) infection in patients with chronic fatigue syndrome (CFS) is reported herein. Of the 58 patients evaluated, 100% had evidence of prior EBV exposure and 72% had evidence for reactivated EBV infection. Notably, 94% of CFS patients had B-cell immunodeficiency with a marked depletion of their CD19+IgM+ mature B-lymphocyte population. A remarkable 81% of CFS patients experienced subjective improvement of their symptoms after treatment with folinic acid (CAS 58-05-9, leucovorin). The findings provide unprecedented evidence that CFS frequently is a folinic acid responsive clinical entity accompanied by B-cell immunodeficiency and inappropriate antibody responses to EBV.
Madhavan G, Stewart JM, McLeod KJ.	Department of Orthopaedics, School of Medicine, Health Sciences Center, State University of New York, Stony Brook, USA. guru@binghamton.edu	Cardiovascular systemic regulation by plantar surface stimulation.	Biomed Instrum Technol. 2006 Jan-Feb;40(1):78-84.	The decreased blood pressure and flow rates associated with orthostasis have been implicated in the etiology of numerous clinical conditions, including deep vein thrombosis, chronic fatigue syndrome, and more recently osteoporosis. Here, we investigate the potential of low-magnitude vibration, applied at the plantar surface, to inhibit the cardiovascular responses of adult women to the orthostatic stress associated with quiet sitting. METHODS: Thirty healthy women, aged 22-82 years, were exposed to a plantar-based vibration immediately after taking a seated position. Seven stimulus frequencies (0, 15, 22, 44, 60, 90, and 120 Hz, all at 0.2g) were tested on each subject, and cardiovascular responses were followed for 20 minutes. Each subject experienced only a single test frequency on any day. Pre- and poststimulus blood pressures and continuous electrocardiogram results were obtained, from which mean arterial pressure (MAP) and heart rate variability (HRV) were calculated. RESULTS: In the per-protocol study population (n = 25), 20 minutes of quiet sitting was associated with an average depression of 8.95 mm Hg in systolic pressure and of 1.9 mm Hg in diastolic blood pressure, corresponding to an average decrease in MAP of 5.15 mm Hg. These orthostasis-based changes in blood pressure were significantly reduced by exposure to plantar vibration, in a frequency-dependent manner, with essentially complete suppression of the drop in MAP achieved with plantar stimulation at 44 Hz (P < or = . 01). In the orthostatically hypotensive subpopulation (n = 15), both the 9.3-mm Hg depression in MAP and the decline in HRV were eliminated by exposure to plantar vibrations in the 40- to 60-Hz range (P = .01 and P = .03, respectively). These results are consistent with the hypothesis that the plantar vibration may be stimulating type IIA muscle fiber activity in the leg, which is critical for effective skeletal muscle pumping in the absence of locomotion. CONCLUSIONS: Our findings lead us to suggest that noninvasive, low-level, plantar-based vibration in the regime of 30-60 Hz can significantly inhibit the effects of the orthostatic stress of quiet sitting on the cardiovascular system.
Maes M, Mihaylova I, De Ruyter M.	M-Care4U Outpatient Clinics, Olmenlaan 9, 2610 Antwerp-Wilrijk, Belgium. crc.mh@telenet.be	Lower serum zinc in Chronic Fatigue Syndrome (CFS): relationships to immune dysfunctions and relevance for the oxidative stress status in CFS.	J Affect Disord. 2006 Feb;90(2-3):141-7. Epub 2005 Dec 9.	The present study examines serum zinc concentrations in patients with chronic fatigue syndrome (CFS) versus normal volunteers. Serum zinc levels were determined by means of an atomic absorption method. We found that serum zinc was significantly lower in the CFS patients than in the normal controls. There was a trend toward a significant negative correlation between serum zinc and the severity of CFS and there was a significant and negative correlation between serum zinc and the subjective experience of infection. We found that serum zinc was significantly and negatively correlated to the increase in the alpha2 protein fraction and positively correlated to decreases in the expression of mitogen-induced CD69+ (a T cell activation marker) on CD3+ as well as CD3+CD8+ T cells. These results show that CFS is accompanied by a low serum zinc status and that the latter is

				related to signs of inflammation and defects in early T cell activation pathways. Since zinc is a strong anti-oxidant, the present results further support the findings that CFS is accompanied by increased oxidative stress. The results of these reports suggest that some patients with CFS should be treated with specific antioxidants, including zinc supplements.
Maes M, Mihaylova I, Leunis JC.	MCare4U Outpatient Clinics, Antwerp, Belgium.	Chronic fatigue syndrome is accompanied by an IgM-related immune response directed against neopitopes formed by oxidative or nitrosative damage to lipids and proteins.	Neuro Endocrinol Lett. 2006 Oct;27(5):615-21.	There is now some evidence that chronic fatigue syndrome (CFS) is accompanied by signs of oxidative stress and by a decreased antioxidant status. The aim of the present study was to examine whether CFS is accompanied by an immune response to neoepitopes of a variety of modified lipids and proteins indicating damage caused by oxidative and nitrosative stress. Toward this end we examined serum antibodies to fatty acids (oleic, palmitic and myristic acid), by-products of lipid peroxidation, i.e. azelaic acid and malondialdehyde (MDA), acetylcholine, S-farnesyl-L-cysteine, and N-oxide modified amino-acids in 14 patients with CFS, 14 subjects with partial CFS and 11 normal controls. We found that the prevalences and mean values for the serum IgM levels directed against oleic, palmitic and myristic acid, MDA, azelaic acid, S-farnesyl-L-cysteine, and the N-oxide derivates, nitro-tyrosine, nitro-phenylalanine, nitro-arginine, nitro-tryptophan, and nitro-cysteinyl were significantly greater in CFS patients than in normal controls, whereas patients with partial CFS took up an intermediate position. There were significant and positive correlations between the serum IgM levels directed against fatty acids, MDA and azelaic acid and the above N-oxide-derivates and the severity of illness (as measured by the FibroFatigue scale) and symptoms, such as aches and pain, muscular tension and fatigue. The results show that CFS is characterized by an IgM-related immune response directed against disrupted lipid membrane components, by-products of lipid peroxidation, S-farnesyl-L-cysteine, and NO-modified amino-acids, which are normally not detected by the immune system but due to oxidative and nitrosative damage have become immunogenic.

Maloney EM, Gurbaxani BM, Jones JF, de Souza Coelho L, Pennachin C, Goertzel BN.	Centers for Disease Control and Prevention, 1600 Clifton Road, MS A-15, Atlanta, GA 30333, USA. evm3@cdc.gov	Chronic fatigue syndrome and high allostatic load.	Pharmacogenomics. 2006 Apr;7(3):467-73.	STUDY POPULATION: We examined the relationship between chronic fatigue syndrome (CFS) and allostatic load in a population-based, case-control study of 43 CFS patients and 60 nonfatigued, healthy controls from Wichita, KS, USA. METHODS: An allostatic load index was computed for all study participants using available laboratory and clinical data, according to a standard algorithm for allostatic load. Logistic regression analysis was used to compute odds ratios (ORs) as estimates of relative risk in models that included adjustment for matching factors and education; 95% confidence intervals (CIs) were computed to estimate the precision of the ORs. RESULTS: CFS patients were 1.9-times more likely to have a high allostatic load index than controls (95% CI = 0.75, 4.75) after adjusting for education level, in addition to matching factors. The strength of this association increased in a linear trend across categories of low, medium and high levels of allostatic load (p = 0.06). CONCLUSION: CFS was associated with a high level of allostatic load. The three allostatic load components that best discriminated cases from controls were waist:hip ratio, aldosterone and urinary

				cortisol.
Maoz D, Shoenfeld Y.		[Chronic fatigue syndrome] [Article in Hebrew]	Harefuah. 2006 Apr;145(4):272-5, 319, 318.	BACKGROUND: Chronic fatigue syndrome (CFS) is characterized by severe fatigue and other non-specific symptoms. It causes disturbance of normal function. Uncertainty about etiology and the appropriate treatment, combined with high prevalence of psychiatric comorbidity, cause a problem in the perception of the disease by the patient, physician and society. OBJECTIVES: This review recapitulates the updated information regarding CFS. It addresses the following aspects: definitions, diagnosis, demographic figures, etiology and treatment options. Since much about CFS is yet to be known, a large amount of work has recently been performed on this subject. Current perceptions, as recognized today, are also presented. METHODS: A literature search was performed using Medline. RESULTS: Accurate diagnosis of CFS patients is low despite the disabling fatigue. CFS patients present certain demographic characteristics and the illness etiology is as yet unclear. Nonetheless, many possible directions exist with inconclusive evidence about certain suspected causes. There are no treatment guidelines available. Different treatment approaches were investigated without consensus on the results. CONCLUSIONS: CFS is an illness that should be taken seriously by the medical establishment. Conscious awareness of the malady might reduce rates of undiagnosed patients. The different etiologic factors showing some degree of involvement in CFS, might suggest that this syndrome is a multi-factorial condition. Despite the fact that there is no distinct undisputed treatment, there are 2 treatments (cognitive behavioral therapy and graded exercise therapy) that might be effective.
Maquet D, Demoulin C, Crielaard JM.	Departement des Sciences de la Motricite, Unite de Medecine Physique et Kinesitherapie-Readaptation, Universite de Liege, CHU Sart-Tilman, ISEPK, Belgique. D.Maquet@ulg.ac.be	Chronic fatigue syndrome: a systematic review. [Article in English, French]	Ann Readapt Med Phys. 2006 Jul;49(6):337-47, 418-27. Epub 2006 Apr 19.	OBJECTIVE: A systematic review of the literature about chronic fatigue syndrome (CFS). METHODS: A search of the Medline database (via Ovid and PubMed) with the key words chronic fatigue syndrome, diagnosis, classification, epidemiology, etiology, physiopathology, metabolism, microbiology, immunology, virology, psychology, drug therapy, rehabilitation, and therapy. The reference lists of each article were examined for additional related articles. RESULTS: CFS was defined in 1988 by the US Centes for Disease Control and Prevention. The prevalence of chronic fatigue syndrome has ranged from 0.2% to 0.7% in the general population. In 1994, the definition of CFS was revised by Fukuda et al. Despite various research in several topics (e.g. infection, immune systems, neuroendocrinology, autonomic activity, neuromuscular involvement), the pathophysiology remains unknown. CONCLUSION: CFS, with its various major clinical and functional impacts, should be associated with a "biopsychosocial model". Progressive muscular rehabilitation, combined with behavioral and cognitive treatment, is an essential part of therapy.
Margutti P, Delunardo F, Ortona E.	Dipartimento di Malattie Infettive, Parassitarie e Immunomediate, Istituto Superiore di Sanita, Rome, Italy. ortona@iss.it.	Autoantibodies associated with psychiatric disorders.	Curr Neurovasc Res. 2006 May;3(2):149-57.	Growing evidence suggests that autoantibodies to neuronal or endothelial targets in psychiatric disorders exist and may be pathogenic. This review describes and discusses the possible role of autoantibodies related to the psychiatric manifestations in autoimmune diseases, autoantibodies related to the psychiatric disorders present in post-streptococcal diseases, celiac disease, chronic fatigue syndrome and substance abuse, and autoantibodies related to schizophrenia and autism, disorders now considered of autoimmune origin.

McCue P, Buchanan T, Martin CR.	Department of Psychology, Northumbria University, UK.	Screening for psychological distress using internet administration of the Hospital Anxiety and Depression Scale (HADS) in individuals with chronic fatigue syndrome.	Br J Clin Psychol. 2006 Nov;45(Pt 4):483-98.	OBJECTIVES: To investigate the factor structure and internal consistency of the Hospital Anxiety and Depression Scale (HADS) in individuals with Chronic Fatigue Syndrome (CFS) using an Internet administered version of the instrument. DESIGN: Between subjects. METHOD: Confirmatory factor analysis (CFA) and internal consistency analysis of the HADS was used to determine the psychometric characteristics of the instrument in individuals with CFS and a control group with data captured via an Internet data collection protocol. RESULTS: CFA revealed that a 3-factor solution offered the most parsimonious account of the data. Internal consistency estimations of the anxiety and depression subscales were found to be acceptable for both groups. The CFS group was found to have significantly higher HADS-assessed anxiety and depression scores compared with controls, however, there was also evidence found that Internet administration of the instrument may inflate HADS subscale scores as an artifact of testing medium. CONCLUSIONS: The HADS is suitable for use for screening individuals with CFS in terms of the factor structure of the instrument, however, clinicians should be aware that this instrument assesses 3 domains of affective disturbance rather than 2 as is interpreted within the current HADS anxiety and depression subscale scoring system. Researchers need also be aware that Internet administration of negative affective state measures such as the HADS is likely to inflate scores and need to ensure that comparisons between clinical groups are made with control group data gathered using the same collection methodology.
McCully KK, Malucelli E, Iotti S.	Department of Kinesiology, University of Georgia, Athens GA 30602. mccully@uga.edu.	Increase of free Mg2+ in the skeletal muscle of chronic fatigue syndrome patients.	Dyn Med. 2006 Jan 11;5:1.	ABSTRACT : In a previous study we evaluated muscle blood flow and muscle metabolism in patients diagnosed with chronic fatigue syndrome (CFS). To better understand muscle metabolism in CFS, we re-evaluated our data to calculate free Magnesium levels in skeletal muscle. Magnesium is an essential cofactor in a number of cell processes. A total of 20 CFS patients and 11 controls were evaluated. Phosphorus magnetic resonance spectroscopy from the medial gastrocnemius muscle was used to calculate free Mg2+ from the concentrations and chemical shifts of Pi, PCr, and beta ATP peaks. CFS patients had higher magnesium levels in their muscles relative to controls (0.47 + 0.07 vs 0.36 + 0.06 mM, $P < 0.01$), although there was no difference in the rate of phosphocreatine recovery in these subjects, as reported earlier. This finding was not associated with abnormal oxidative metabolism as measured by the rate of recovery of phosphocreatine after exercise. In summary, calculation of free Mg2+ levels from previous data showed CFS patients had higher resting free Mg2+ levels compared to sedentary controls.
McDermott C, Richards SC, Thomas PW, Montgomery J, Lewith G.	University of Southampton, UK. crm202@soton.ac.uk	A placebo-controlled, double-blind, randomized controlled trial of a natural killer cell stimulant (BioBran MGN-3) in chronic fatigue syndrome.	QJM. 2006 Jul;99(7):461-8. Epub 2006 Jun 29.	BACKGROUND: Previous research has suggested that natural killer (NK) cell activity may be reduced in patients with chronic fatigue syndrome (CFS). AIM: To evaluate the effectiveness of a putative NK cell stimulant, BioBran MGN-3, in reducing fatigue in CFS patients. DESIGN: Randomized, double-blind, placebo-controlled trial. METHODS: We recruited 71 patients with CFS (according to the Centers for Disease Control 1994 criteria) attending an out-patient specialist CFS service. Participants were given oral BioBran MGN-3 for 8 weeks (2 g three times per day) or placebo equivalent. The primary outcome measure was the Chalder physical fatigue score. Self-reported fatigue measures, self-assessment of improvement, change in key symptoms, quality of life, anxiety and depression measures were also included. RESULTS: Data were complete in 64/71 patients. Both groups showed marked improvement over the study duration, but without significant differences. Mean improvement in the Chalder fatigue score (physical scale) was 0.3 (95%CI -2.6 to 3.2) lower in the BioBran group. DISCUSSION: The findings

				do not support a specific therapeutic effect for BioBran in CFS. The improvement showed by both groups over time highlights the importance of placebo controls when evaluating interventions in CFS.
McIntyre RS, Konarski JZ, Soczynska JK, Wilkins K, Panjwani G, Bouffard B, Bottas A, Kennedy SH.	Department of Psychiatry, University of Toronto, Ontario, Canada. roger.mcintyre@uhn.on.ca	Medical comorbidity in bipolar disorder: implications for functional outcomes and health service utilization.	Psychiatr Serv. 2006 Aug;57(8):1140-4.	OBJECTIVE: This is the first cross-national population-based investigation exploring the prevalence and functional implications of comorbid general medical disorders in bipolar disorder. METHODS: Data were extracted from the Canadian Community Health Survey (N = 36,984). Analyses were conducted to ascertain the prevalence and prognostic implications of predetermined comorbid general medical disorders among persons who screened positive for a lifetime manic episode (indicative of a diagnosis of bipolar disorder). Within the subpopulation of people who screened positive for a manic episode, the effect of medical comorbidity on employment, functional role, psychiatric care, and medication use was examined. RESULTS: When the data were weighted to be representative of the household population of the ten provinces in 2002, an estimated 2.4 percent of respondents screened positive for a lifetime manic episode. Rates of chronic fatigue syndrome, migraine, asthma, chronic bronchitis, multiple chemical sensitivities, hypertension, and gastric ulcer were significantly higher in the bipolar disorder group (all $p < .05$). Chronic medical disorders were associated with a more severe course of bipolar disorder, increased household and work maladjustment, receipt of disability payments, reduced employment, and more frequent medical service utilization. CONCLUSIONS: Comorbid medical disorders in bipolar disorder are associated with several indices of harmful dysfunction, decrements in functional outcomes, and increased utilization of medical services.
McLean SA, Williams DA, Stein PK, Harris RE, Lyden AK, Whalen G, Park KM, Liberzon I, Sen A, Gracely RH, Baraniuk JN, Clauw DJ.	Department of Emergency Medicine, University of Michigan Medical Center, Ann Arbor, MI, USA. samclean@umich.edu	Cerebrospinal fluid corticotropin-releasing factor concentration is associated with pain but not fatigue symptoms in patients with fibromyalgia.	Neuropsychopharmacology. 2006 Dec;31(12):2776-82. Epub 2006 Aug 23.	Previous studies have identified stress system dysregulation in fibromyalgia (FM) patients; such dysregulation may be involved in the generation and/or maintenance of pain and other symptoms. Corticotropin-releasing factor (CRF) is the principal known central nervous system mediator of the stress response; however, to date no studies have examined cerebrospinal fluid (CSF) CRF levels in patients with FM. The relationship between CSF CRF level, heart rate variability (HRV), and pain, fatigue, and depressive symptoms was examined in patients with FM. Among participants (n=26), CSF CRF levels were associated with sensory pain symptoms ($r=0.574$, $p=0.003$) and affective pain symptoms ($r=0.497$, $p=0.011$), but not fatigue symptoms. Increased HRV was also strongly associated with increased CSF CRF and FM pain. In multivariate analyses adjusting for age, sex, and depressive symptoms, the association between CSF CRF and sensory pain symptoms ($t=2.54$, $p=0.027$) persisted. Women with FM who reported a history of physical or sexual abuse had lower CSF CRF levels than women who did not report such a history. CSF CRF levels are associated with both pain symptoms and variation in autonomic function in FM. Differences in CSF CRF levels among women with and without a self-reported history of physical or sexual abuse suggest that subgroups of FM patients may exist with different neurobiological characteristics. Further studies are needed to better understand the nature of the association between CSF CRF and pain symptoms in FM.
Meeus M, Nijs J, Meirleir KD.	Division of Musculoskeletal Physiotherapy, Higher Institute of Physiotherapy, Department of	Chronic musculoskeletal pain in patients with the chronic fatigue syndrome: A systematic	Eur J Pain. 2006 Jul 12; [Epub ahead of print]	BACKGROUND: In addition to debilitating fatigue the majority of patients with chronic fatigue syndrome (CFS) experience chronic widespread pain. AIMS: Conducting a systematic review to critically assess the existing knowledge on chronic pain in CFS. We focussed on the definition, the prevalence and incidence, the aetiology, the relevance and the therapy strategy for chronic musculoskeletal pain and post-exertional pain in CFS. METHODS: To identify relevant articles, we searched eight medical search engines. The search terms "chronic fatigue syndrome" AND "pain",

	Health Care Sciences, Hogeschool Antwerpen (HA), Van Aertselaerstraat 31, 2170 Merksem, Belgium; Department of Human Physiology, Faculty of Physical Education and Physiotherapy, Vrije Universiteit Brussel (VUB), Belgium.	review.		"nociception", "arthralgia" and "myalgia", were used to identify articles concerning pain in CFS. Included articles were reviewed by two blinded researchers. RESULTS: Twenty-five articles and two abstract were identified and selected for further appraisal. Only 11 search results focussed on musculoskeletal pain in CFS patients. Regarding the standardized review of the articles, a 96% agreement between the researchers was observed. There is no consensus in defining chronic widespread pain in CFS, and although there is little or no strong proof for the exact prevalence, chronic pain is strongly disabling in CFS. Aetiological theories are proposed (sleep abnormalities, tryptophan, parovirus-B, hormonal and brain abnormalities and central sensitisation) and a reduction of pain threshold after exercise has been shown. Furthermore depression seemed not related to pain in CFS and a staphylococcus toxoid vaccine caused no significant pain reduction. CONCLUSIONS: The results from the systematic review highlight the clinical importance of chronic pain in CFS, but only few studies addressing the aetiology or treatment of chronic pain in CFS are currently available.
Meeus M, Nijs J.	Department of Human Physiology, Faculty of Physical Education and Physiotherapy, Vrije Universiteit Brussel (VUB), Brussel, Belgium.	Central sensitization: a biopsychosocial explanation for chronic widespread pain in patients with fibromyalgia and chronic fatigue syndrome.	Clin Rheumatol. 2006 Nov 18; [Epub ahead of print]	In addition to the debilitating fatigue, the majority of patients with chronic fatigue syndrome (CFS) experience chronic widespread pain. These pain complaints show the greatest overlap between CFS and fibromyalgia (FM). Although the literature provides evidence for central sensitization as cause for the musculoskeletal pain in FM, in CFS this evidence is currently lacking, despite the observed similarities in both diseases. The knowledge concerning the physiological mechanism of central sensitization, the pathophysiology and the pain processing in FM, and the knowledge on the pathophysiology of CFS lead to the hypothesis that central sensitization is also responsible for the sustaining pain complaints in CFS. This hypothesis is based on the hyperalgesia and allodynia reported in CFS, on the elevated concentrations of nitric oxide presented in the blood of CFS patients, on the typical personality styles seen in CFS and on the brain abnormalities shown on brain images. To examine the present hypothesis more research is required. Further investigations could use similar protocols to those already used in studies on pain in FM like, for example, studies on temporal summation, spatial summation, the role of psychosocial aspects in chronic pain, etc.
Michielsen HJ, Van Houdenhove B, Leirs I, Vandenbroeck A, Onghena P.	Department of Psychology and Health, Tilburg University, Tilburg, The Netherlands.	Depression, attribution style and self-esteem in chronic fatigue syndrome and fibromyalgia patients: is there a link?	Clin Rheumatol. 2006 Mar;25(2):183-8. Epub 2005 Jul 12.	The aims of the present study were to compare a single diagnosis (chronic fatigue syndrome, CFS) and a double diagnosis (CFS + fibromyalgia, CFS+FM) group regarding depression, attribution style and self-esteem as well as to examine whether attribution style is a mediator in the relationship between self-esteem and depression. Eighty-five patients (CFS: 47, CFS+FM: 38) completed questionnaires on attribution style, self-esteem and depression. The single and double diagnosis groups tended to differ slightly, but the differences were never statistically significant. In addition, only one condition was met of the four conditions mentioned by Baron and Kenny to establish that mediation exists between two variables. In conclusion, an external attribution style does not protect the CFS or CFS+FM patients with a low self-esteem from depression. The prevalence rate of depression was high in both patient samples, of which clinicians should be aware.

Mommersteeg PM, Heijnen CJ, Verbraak MJ, van Doornen LJ.	Department of Health Psychology, Utrecht University, P.O. Box 80.140, 3508 TC Utrecht, The Netherlands. p.mommersteeg@fss.uu.nl	Clinical burnout is not reflected in the cortisol awakening response, the day-curve or the response to a low-dose dexamethasone suppression test.	Psychoneuroendocrinology. 2006 Feb;31(2):216-25. Epub 2005 Sep 16.	Burnout is presumed to be the result of chronic stress, and chronic stress is known to affect the HPA-axis. To date, studies on HPA-axis functioning in burnout have showed inconsistent results. In the present study, a large sample (n=74) of clinically diagnosed burnout individuals, mostly on sick-leave, were included and compared with 35 healthy controls. Salivary cortisol was sampled on 2 days to determine the cortisol awakening response (CAR) and the day-curve. In addition, the dexamethasone suppression test (DST) was applied to assess the feedback efficacy of the HPA-axis. There were no differences observed in the CAR, day-curve or CAR after DST in the burnout group as compared to a healthy control group. Burnout shows overlap in symptoms with chronic fatigue syndrome (CFS) and depression. Therefore, differential changes in HPA-axis functioning that resemble the hypo-functioning of the HPA-axis in CFS, or rather the hyper-functioning of the HPA-axis in depression, might have obscured the findings. However, no effect of fatigue or depressive mood on HPA-axis functioning was found in the burnout group. We concluded that HPA-axis functioning in clinically diagnosed burnout participants as tested in the present study, seems to be normal.
Moss-Morris R, Spence M.	School of Psychology, University of Southampton, Highfield, Southampton, SO17 1BJ, United Kingdom. R.E.Moss-Morris@soton.ac.uk	To "lump" or to "split" the functional somatic syndromes: can infectious and emotional risk factors differentiate between the onset of chronic fatigue syndrome and irritable bowel syndrome?	Psychosom Med. 2006 May-Jun;68(3):463-9.	OBJECTIVES: Recent academic debate has centered on whether functional somatic syndromes should be defined as separate entities or as one syndrome. The aim of this study was to investigate whether there may be significant differences in the etiology or precipitating factors associated with two common functional syndromes, irritable bowel syndrome (IBS) and chronic fatigue syndrome (CFS). METHODS: We prospectively studied 592 patients with an acute episode of Campylobacter gastroenteritis and 243 with an acute episode of infectious mononucleosis who had no previous history of CFS or IBS. At the time of infection, patients completed a baseline questionnaire that measured their levels of distress using the Hospital Anxiety and Depression scale. At 3- and 6-month follow-up, they completed questionnaires to determine whether they met published diagnostic criteria for chronic fatigue (CF), CFS, and/or IBS. RESULTS: The odds of developing IBS were significantly greater post-Campylobacter than post-infectious mononucleosis at both 3- (odds ratio, 3.45 [95% confidence interval (CI), 1.75-6.67]) and 6- (2.22 [95% CI, 1.11-6.67]) month follow-up. In contrast, the odds for developing CF/CFS were significantly greater after infectious mononucleosis than after Campylobacter at 3 (2.77 [95% CI, 1.08-7.11]) but not 6 (1.48 [95% CI, 0.62-3.55]) months postinfection. Anxiety and depression were the strongest predictors of CF/CFS, whereas the nature of the infection was the strongest predictor of IBS. CONCLUSIONS: These results support the argument to distinguish between postinfectious IBS and CFS. The nature of the precipitating infection appears to be important, and premorbid levels of distress appear to be more strongly associated with CFS than IBS, particularly levels of depression.
Naschitz J, Fields M, Isseroff H, Sharif D, Sabo E,	Department of Internal Medicine A, Bnai Zion	Shortened QT interval: a distinctive feature	J Electrocardiol. 2006 Oct;39(4):389-94.	PURPOSE: Because autonomic nervous functioning is frequently abnormal in chronic fatigue syndrome (CFS), we examined whether the corrected QT interval (QTc) in CFS differs from QTc in other populations. METHODS: The QTc was calculated at the end of 10 minutes of recumbence and the end

Rosner I.	Medical Center and Rappaport Family Faculty of Medicine, Technion-Israel Institute of Technology, P.O. Box 4940, Haifa 31048, Israel. naschitz@tx.technion.ac.il	of the dysautonomia of chronic fatigue syndrome.	Epub 2006 Feb 28.	of 10 minutes of head-up tilt. In a pilot study, groups of 15 subjects, CFS, and controls, matched for age and sex, were investigated. In a second phase of the study, the QTc was measured in larger groups of CFS (n = 30) and control patients (n = 96) not matched for demographic features. RESULTS: In the pilot study, the average supine QTc in CFS was 0.371 +/- 0.02 seconds and QTc on tilt, 0.385 +/- 0.02 seconds, significantly shorter than in controls (P = .0002 and .0003, respectively). Results of phase II confirmed this data. CONCLUSIONS: Relative short QTc intervals are features of the CFS-related dysautonomia. The significance of this finding is discussed.
Naschitz JE, Mussafia-Priselac R, Kovalev Y, Zaigraykin N, Slobodin G, Elias N, Rosner I.	Department of Internal Medicine A, the Bnai-Zion Medical Center and Bruce Rappaport Faculty of Medicine, Technion-Israel Institute of Technology, Haifa, Israel. Naschitz@tx.technion.ac.il	Patterns of hypocapnia on tilt in patients with fibromyalgia, chronic fatigue syndrome, nonspecific dizziness, and neurally mediated syncope.	Am J Med Sci. 2006 Jun;331(6):295-303.	OBJECTIVES: To assess whether head-up tilt-induced hyperventilation is seen more often in patients with chronic fatigue syndrome (CFS), fibromyalgia, dizziness, or neurally mediated syncope (NMS) as compared to healthy subjects or those with familial Mediterranean fever (FMF). PATIENTS AND METHODS: A total of 585 patients were assessed with a 10-minute supine, 30-minute head-up tilt test combined with capnography. Experimental groups included CFS (n = 90), non-CFS fatigue (n = 50), fibromyalgia (n = 70), nonspecific dizziness (n = 75), and NMS (n =160); control groups were FMF (n = 90) and healthy (n = 50). Hypocapnia, the objective measure of hyperventilation, was diagnosed when end-tidal pressure of CO2 (PETCO2) less than 30 mm Hg was recorded consecutively for 10 minutes or longer. When tilting was discontinued because of syncope, one PETCO2 measurement of 25 or less was accepted as hyperventilation. RESULTS: Hypocapnia was diagnosed on tilt test in 9% to 27% of patients with fibromyalgia, CFS, dizziness, and NMS versus 0% to 2% of control subjects. Three patterns of hypocapnia were recognized: supine hypocapnia (n = 14), sustained hypocapnia on tilt (n = 76), and mixed hypotensive-hypocapnic events (n = 80). Hypocapnia associated with postural tachycardia syndrome (POTS) occurred in 8 of 41 patients. CONCLUSIONS: Hyperventilation appears to be the major abnormal response to postural challenge in sustained hypocapnia but possibly merely an epiphenomenon in hypotensive-hypocapnic events. Our study does not support an essential role for hypocapnia in NMS or in postural symptoms associated with POTS. Because unrecognized hypocapnia is common in CFS, fibromyalgia, and nonspecific dizziness, capnography should be a part of the evaluation of patients with such conditions.
Nater UM, Wagner D, Solomon L, Jones JF, Unger ER, Papanicolaou DA, Reeves WC, Heim C.	Viral Exanthems and Herpesvirus Branch, Division of Viral and Rickettsial Diseases, National Center for Infectious Diseases, Centers for Disease Control	Coping styles in people with chronic fatigue syndrome identified from the general population of Wichita, KS.	J Psychosom Res. 2006 Jun;60(6):567-73.	OBJECTIVE: Studies of primary and tertiary care patients suggest that maladaptive coping styles contribute to the pathogenesis and maintenance of chronic fatigue syndrome (CFS). We assessed coping styles in persons with unexplained fatigue and nonfatigued controls in a population-based study. METHODS: We enrolled 43 subjects meeting the 1994 Research Case Definition of CFS, matching them with 61 subjects with chronic unexplained fatigue who did not meet criteria for CFS [we term them insufficient symptoms or fatigue (ISF)] and 60 non-ill (NI) controls. Coping styles and clinical features of CFS were assessed using standard rating scales. RESULTS: Subjects with CFS and ISF reported significantly more escape-avoiding behavior than NI controls. There were no differences between the CFS and ISF subjects. Among participants with CFS, escape-avoiding behavior was associated with fatigue severity, pain, and disability. CONCLUSIONS: We demonstrate significantly

	and Prevention, Atlanta, GA, USA.			higher reporting of maladaptive coping in a population-based sample of people with CFS and other unexplained fatiguing illnesses defined by reproducible standardized clinical empirical means in comparison to NI controls.
Nicolson GL, Ellithorpe R.		Lipid Replacement and Antioxidant Nutritional Therapy for Restoring Mitochondrial Function and Reducing Fatigue in Chronic Fatigue Syndrome and Other Fatiguing Illnesses	Journal of Chronic Fatigue Syndrome 2006;13(1): 57-68	Evidence in the literature indicates that diminished mitochondrial function through loss of efficiency in the electron transport chain caused by oxidation occurs during aging and in fatiguing illnesses. Lipid Replacement Therapy (LRT) administered as a nutritional supplement with antioxidants can prevent oxidative membrane damage, and LRT can be used to restore mitochondrial and other cellular membrane functions via delivery of undamaged replacement lipids to cellular organelles. Recent clinical trials using patients with chronic fatigue have shown the benefit of LRT plus antioxidants in restoring mitochondrial electron transport function and reducing moderate to severe chronic fatigue. These studies indicate the benefits of LRT plus antioxidants in reducing fatigue and preventing loss of mitochondrial function, most likely by protecting mitochondrial and other cellular membranes from oxidative and other damage and removing damaged lipids by lipid replacement. In one clinical study we determined if mitochondrial function is reduced in subjects with mild to severe chronic fatigue, and if this can be reversed with NT Factor(r), a nutritional supplement that replaces damaged cellular lipids. With the use of the Piper Fatigue Scale, there was a significant time-dependent reduction in overall fatigue in moderately or severely fatigued subjects while on the dietary supplement for 4-8 weeks. Analysis of mitochrondrial function indicated that four and eight weeks of the dietary supplement in moderately or severely fatigued subjects significantly increased mitochondrial function. Similarly, chronic fatigue syndrome patients administered antioxidants plus LRT also show reductions in fatigue. The results indicate that LRT plus antioxidants can significantly reduce moderate to severe chronic fatigue and restore mitochondrial function. Dietary use of unoxidized membrane lipids plus antioxidants is recommended for patients with moderate to severe chronic fatigue.
Nijs J, Aerts A, De Meirleir K.	Department of Human Physiology-Faculty of Physical Education and Physiotherapy Vrije Universiteit Brussel (VUB), Belgium. jo.Nijs@vub.ac.be	Generalized joint hypermobility is more common in chronic fatigue syndrome than in healthy control subjects.	J Manipulative Physiol Ther. 2006 Jan;29(1):32-9.	OBJECTIVES: This study aimed at (1) comparing the prevalence of generalized hypermobility in patients with chronic fatigue syndrome (CFS) and healthy volunteers, (2) examining the clinical importance of generalized hypermobility in patients with CFS, and (3) examining whether knee proprioception is associated with hypermobility in patients with CFS. METHODS: Sixty-eight patients with CFS filled out two self-reported measures (for the assessment of symptom severity and disability), were questioned about muscle and joint pain, and were screened for generalized hypermobility. Afterward, the patients performed a knee repositioning test (assessment of knee proprioception), and it was examined whether or not they fulfilled the criteria for benign joint hypermobility syndrome (BJHS). Sixty-nine age- and sex-matched healthy volunteers were screened for generalized joint hypermobility and performed the same knee repositioning test. RESULTS: Compared with the healthy volunteers (4.3%, 3/68), significantly more patients with CFS (20.6%, 14/69) fulfilled the criteria for generalized joint hypermobility (Fisher exact test, $P < .004$). No associations were found between generalized joint hypermobility and the self-reported measures (including pain severity) or knee proprioception (Spearman correlation analysis). Knee proprioception was similar in both groups (Mann-Whitney $U = 1961$, $z = -1.745$, $P = .81$). Forty patients with CFS (58.8%) fulfilled the criteria for BJHS. CONCLUSIONS: These data indicate that a subgroup of patients with CFS present with generalized joint hypermobility and most patients with of CFS fulfill the

				diagnostic criteria for BJHS. There appears to be no association between musculoskeletal pain and joint hypermobility in patients with CFS.
Nijs J, De Meirleir K.		Nitric oxide and chronic fatigue syndrome: Are we caring for our patients or are we practicing selfcare?	Med Hypotheses. 2006;66(2):449-50. Epub 2005 Oct 10. Comment on: Med Hypotheses. 2005;65(3):631-3.	
Nijs J, Meeus M, De Meirleir K.	Department of Human Physiology, Faculty of Physical Education and Physiotherapy, Vrije Universiteit Brussel, Belgium; Department of Health Sciences, Division of Musculoskeletal Physiotherapy, Higher Institute of Physiotherapy, Hogeschool Antwerpen, Belgium.	Chronic musculoskeletal pain in chronic fatigue syndrome: Recent developments and therapeutic implications.	Man Ther. 2006 Aug;11(3):187-191. Epub 2006 Jun 14.	Patients with chronic fatigue syndrome (CFS) experience chronic musculoskeletal pain which is even more debilitating than fatigue. Scientific research data gathered around the world enables clinicians to understand, at least in part, chronic musculoskeletal pain in CFS patients. Generalized joint hypermobility and benign joint hypermobility syndrome appear to be highly prevalent among CFS sufferers, but they do not seem to be of any clinical importance. On the other hand, pain catastrophizing accounts for a substantial portion of musculoskeletal pain and is a predictor of exercise performance in CFS patients. The evidence concerning pain catastrophizing is supportive of the indirect evidence of a dysfunctional pain processing system in CFS patients with musculoskeletal pain. CFS sufferers respond to incremental exercise with a lengthened and accentuated oxidative stress response, explaining muscle pain, postexertional malaise, and the decrease in pain threshold following graded exercise in CFS patients. Applying the scientific evidence to the manual physiotherapy profession, pacing self-management techniques and pain neurophysiology education are indicated for the treatment of musculoskeletal pain in CFS patients. Studies examining the effectiveness of these strategies for CFS patients are warranted.
O'Dowd H, Gladwell P, Rogers CA, Hollinghurst S, Gregory A.	Pain Management Centre, Frenchay Hospital, Bristol, UK.	Cognitive behavioural therapy in chronic fatigue syndrome: a randomised controlled trial of an outpatient group programme.	Health Technol Assess. 2006 Oct;10(37):iii-iv, ix-x, 1-121.	OBJECTIVES: To test the hypothesis that group cognitive behavioural therapy (CBT) will produce an effective and cost-effective management strategy for patients in primary care with chronic fatigue syndrome/myalgic encephalopathy (CFS/ME). DESIGN: A double-blind, randomised controlled trial was adopted with three arms. Outcomes were assessed at baseline and 6 and 12 months after first assessment and results were analysed on an intention-to-treat basis. SETTING: A health psychology department for the management of chronic illness in a general hospital in Bristol, UK. PARTICIPANTS: Adults with a diagnosis of CFS/ME referred by their GP. INTERVENTIONS: The three interventions were group CBT incorporating graded activity scheduling, education and support group (EAS) and standard medical care (SMC). OUTCOME MEASURES: The primary outcome measure was the Short Form with 36 Items (SF-36) physical and mental health summary scales. Other outcome measures included the Chalder fatigue scale, Hospital Anxiety and Depression Scale, General Health Questionnaire, physical function (shuttles walked, walking speed and perceived fatigue), health utilities index and cognitive function (mood, recall and reaction times). RESULTS: A total of 153 patients were recruited to the trial and 52 were randomised to receive CBT, 50 to EAS and 51 to SMC. Twelve patients failed to attend for the 12-month follow-up and 19 patients attended one follow-up, but not both. The sample was found

				to be representative of the patient group and the characteristics of the three groups were similar at baseline. Three outcome measures, SF-36 mental health score, Chalder fatigue scale and walking speed, showed statistically significant differences between the groups. Patients in the CBT group had significantly higher mental health scores [difference +4.35, 95% confidence interval (CI) +0.72 to +7.97, p = 0.019], less fatigue (difference -2.61, 95% CI -4.92 to -0.30, p = 0.027) and were able to walk faster (difference +2.83 shuttles, 95% CI +1.12 to +5.53, p = 0.0013) than patients in the SMC group. CBT patients also walked faster and were less fatigued than those randomised to EAS (walking speed: difference +1.77, 95% CI +0.025 to +3.51, p = 0.047; fatigue: difference -3.16, 95% CI -5.59 to -0.74, p = 0.011). Overall, no other statistically significant difference across the groups was found, although for many measures a trend towards an improved outcome with CBT was seen. Except for walking speed, which, on average, increased by +0.87 shuttles (95% CI +0.09 to +1.65, p = 0.029) between the 6- and 12-month follow-ups, the scores were similar at 6 and 12 months. At baseline, 30% of patients had an SF-36 physical score within the normal range and 52% had an SF-36 mental health score in the normal range. At 12 months, the physical score was in the normal range for 46% of the CBT group, 26% of the EAS group and 44% of SMC patients. For mental health score the percentages were CBT 74%, EAS 67% and SMC 70%. Of the CBT group, 32% showed at least a 15% increase in physical function and 64% achieved a similar improvement in their mental health. For the EAS and SMC groups, this improvement in physical and mental health was achieved for 40 and 60% (EAS) and 49 and 53% (SMC), respectively. The cost-effectiveness of the intervention proved very difficult to assess and did not yield reliable conclusions. CONCLUSIONS: Group CBT did not achieve the expected change in the primary outcome measure as a significant number did not achieve scores within the normal range post-intervention. The treatment did not return a significant number of subjects to within the normal range on this domain; however, significant improvements were evident in some areas. Group CBT was effective in treating symptoms of fatigue, mood and physical fitness in CFS/ME. It was found to be as effective as trials using individual therapy in these domains. However, it did not bring about improvement in cognitive function or quality of life. There was also evidence of improvement in the EAS group, which indicates that there is limited value in the non-specific effects of therapy. Further research is needed to develop better outcome measures, assessments of the broader costs of the illness and a clearer picture of the characteristics best fitted to this type of intervention.
Oleske JM, Friedman KJ, Kaufman KK, Palumbo D, Sterling J, Evans TL		REVIEW Chronic Fatigue Syndrome in Children and Adolescents	Journal of Chronic Fatigue Syndrome 2006;13(2/3): 97-115	Objective: An overview of the unique aspects of Chronic Fatigue Syndrome in children and adolescents (CACFS) is herein provided for healthcare professionals who may be called upon to diagnose and/or treat this illness. Young age of onset, puberty, and interactions with peers and the educational system provide greater diagnostic and treatment challenges than found with adult onset CFS. Method: A review of diagnostic procedures and treatment protocols found in the contemporary literature is coupled with the professional experiences of the authors in treating CACFS to delineate the roles and responsibilities of family, healthcare providers and educators in diagnosing, treating and supporting the CACFS patient. Results: Areas discussed include: pathogenesis, patient evaluation, clinical evaluation, laboratory evaluation, treatment options, psychological issues, role of schools, and the roles of primary and tertiary care providers. Conclusion: CACFS can be diagnosed and treated with varying levels of success if all the professionals involved in the treatment program have a clear

				understanding of their roles and responsibilities. Primary care physicians, pediatricians, other subspecialists, family members, social workers and educators, may all be called upon to participate in the treatment program of CACFS. While it is best to have one, compassionate physician in charge of care, the CACFS may benefit from the inclusion of specialized treatment options available from or through a tertiary care provider. To the extent possible, socialization, education and psychological support of the CACFS should be provided.
Ouyang A, Wrzos HF.	Division of Gastroenterology and Hepatology, The Milton S. Hershey Medical Center, College of Medicine, Pennsylvania State University, Hershey, Pennsylvania.	Contribution of Gender to Pathophysiology and Clinical Presentation of IBS: Should Management Be Different in Women?	Am J Gastroenterol. 2006 Dec;101 Suppl 3:S602-9.	The irritable bowel syndrome (IBS) is found more commonly in women than men. It is more prevalent in patients with chronic fatigue syndrome, fibromyalgia, and chronic pelvic pain, all syndromes characterized by pain and found predominantly in women. This article reviews evidence for a role of biological sex factors and gender on the pathways mediating visceral pain. The effect of gonadal hormones on gastrointestinal motility and the sensory afferent pathway and central processing of visceral stimuli and the contribution of gender role to the clinical presentation are discussed. Although differences in responses to treatment modalities between genders exist, the approach to IBS patients in both genders is quite similar. Nevertheless, a special attention to gender role and stress-related factors should be addressed. New developments in research, outlined in the paper, might bring more gender-specific treatments in the future.
Padhan P.		Chronic fatigue.	CMAJ. 2006 Aug 15;175(4):386-7; author reply 387-8. Comment on: CMAJ. 2006 Mar 14;174(6):765-7.	
Page WF.	Medical Follow-up Agency, Institute of Medicine, 500 Fifth Street NW, Washington, DC 20001, USA. wpage@nas.edu	Update on the NAS-NRC Twin Registry.	Twin Res Hum Genet. 2006 Dec;9(6):985-7.	The National Academy of Sciences-National Research Council (NAS-NRC) Twin Registry is one of the oldest, national population-based twin registries in the United States. It consists of 15,924 white male twin pairs born in the years 1917 to 1927 (inclusive), both of whom served in the armed forces, mostly during World War II. This article updates activity in this registry since the earlier 2002 article in Twin Research. The results of clinically based studies on dementia, Parkinson's disease, age-related macular degeneration, and primary osteoarthritis were published, as well as articles based on previously collected questionnaire data on chronic fatigue syndrome, functional limitations, and healthy aging. In addition, risk factor studies are being planned to merge clinical data with earlier collected risk factor data from questionnaires. Examination data from the subset of National Heart, Lung, and Blood Institute (NHLBI) twins resulted in a number of articles, including the relationship of endogenous sex hormones to coronary heart disease and morphological changes in aging brain structures. The NEO Five-Factor Personality Inventory (a paper-and-pencil self-administered questionnaire) has been fielded for the first time. A push to consolidate the various data holdings of the registry is being made.
Pardaens K, Haagdorens L, Van Wambeke P, Van den Broeck A, Van	Chronic Fatigue Reference Centre, University Hospitals and	How relevant are exercise capacity measures for evaluating	Clin Rehabil. 2006 Jan;20(1):56-66.	OBJECTIVE: To evaluate the outcome of a multidisciplinary treatment programme for patients with chronic fatigue syndrome, including health-related quality of life (HRQoL) and psychosocial variables, and exercise capacity measures. DESIGN: A six-month prospective outcome study. SETTING: University outpatient rehabilitation clinic; group setting. SUBJECTS: One hundred and sixteen women fulfilling

Houdenhove B.	Department of Rehabilitation Sciences, KU Leuven, Belgium.	treatment effects in chronic fatigue syndrome? Results from a prospective, multidisciplinary outcome study.		chronic fatigue syndrome criteria. INTERVENTIONS: Cognitive behaviourally and graded exercise-based strategies; emphasis on adaptive lifestyle changes. MEASURES: Short Form General Health Survey (SF-36); Symptom Checklist (SCL-90); Causal Attribution List (CAL); Self-Efficacy Scale (SE); maximum progressive bicycle ergometer test with respiratory gas analysis; and isokinetic leg strength test, before and after treatment. RESULTS: The total group significantly improved on nearly all reported HRQoL/psychosocial variables. Changes in exercise capacity measures were rather modest and did not correlate or only weakly correlated with HRQoL/psychosocial variables. Subgroup analyses indicated that less fit patients improved significantly more on exercise capacity measures than their more fit counterparts. Patients who were fitter at baseline scored better on pretreatment HRQoL/psychosocial variables, but both subgroups improved similarly on these variables. CONCLUSIONS: Health-related quality of life and psychosocial functioning in patients with chronic fatigue syndrome improves after a six-month cognitive behaviourally and graded exercise-based multidisciplinary treatment programme. Increase in exercise capacity measures is not a necessary condition for reported improvements, except for less fit patients.
Parker NR, Barralet JH, Bell AM.	Darling Downs Public Health Unit, Queensland Health, Australia. neil_parker@health.qld.gov.au	Q fever.	Lancet. 2006 Feb 25;367(9511):679-88.	Q fever is a zoonosis with many manifestations. The most common clinical presentation is an influenza-like illness with varying degrees of pneumonia and hepatitis. Although acute disease is usually self-limiting, people do occasionally die from this condition. Endocarditis is the most frequent chronic presentation. Although Q fever is widespread, practitioner awareness and clinical manifestations vary from region to region. Geographically limited studies suggest that chronic fatigue syndrome and cardiovascular disease are long-term sequelae. An effective whole-cell vaccine is licensed in Australia. Live and acellular vaccines have also been studied, but are not currently licensed.
Peakman M, Skowera A, Hotopf M.	Department of Immunobiology, King's College London, School of Medicine at Guy's, UK.	Immunological dysfunction, vaccination and Gulf War illness.	Philos Trans R Soc Lond B Biol Sci. 2006 Apr 29;361(1468):681-7.	One candidate cause of Gulf War illness is vaccination against infectious diseases including medical counter-measures against biological weapons. One influential theory has suggested that such mass-vaccination caused a shift in immune response to a Type 2 cytokine pattern (Th2), which it was suggested was accompanied by a chronic fatigue syndrome-like illness. This article critically appraises this theory. We start by examining epidemiological evidence, which indicates that single vaccines are unlikely to be a substantial cause of Gulf War illness, but that there was a modest relationship with multiple vaccines, which was strongest in those vaccinated while deployed to the Gulf. These relationships may be affected by recall bias. We conclude by examining the results of immunological studies carried out in veterans or in a relevant setting in vitro. The balance of evidence from immunological studies on veterans returning from the War, including those developing multi-symptom illness, is that the immune response has not become polarized towards Th2. In summary, the epidemiological evidence for a multiple vaccine effect on Gulf War-related illness remains a potentially important aetiological lead, but mechanistic studies available at this stage do not identify any immunological basis for it.
Pedersen BK, Saltin B.	The Centre of Inflammation and Metabolism, Department of Infectious	Evidence for prescribing exercise as therapy in chronic disease.	Scand J Med Sci Sports. 2006 Feb;16 Suppl 1:3-63.	Considerable knowledge has accumulated in recent decades concerning the significance of physical activity in the treatment of a number of diseases, including diseases that do not primarily manifest as disorders of the locomotive apparatus. In this review we present the evidence for prescribing exercise therapy in the treatment of metabolic syndrome-related disorders (insulin resistance, type 2 diabetes, dyslipidemia, hypertension, obesity), heart and pulmonary diseases (chronic obstructive pulmonary

	Diseases, Copenhagen, Denmark. bkp@rh.dk			disease, coronary heart disease, chronic heart failure, intermittent claudication), muscle, bone and joint diseases (osteoarthritis, rheumatoid arthritis, osteoporosis, fibromyalgia, chronic fatigue syndrome) and cancer, depression, asthma and type 1 diabetes. For each disease, we review the effect of exercise therapy on disease pathogenesis, on symptoms specific to the diagnosis, on physical fitness or strength and on quality of life. The possible mechanisms of action are briefly examined and the principles for prescribing exercise therapy are discussed, focusing on the type and amount of exercise and possible contraindications.
Petersen I, Thomas JM, Hamilton WT, White PD.	Centre for Psychiatry, Barts and The London, Queen Mary's School of Medicine and Dentistry, UK.	Risk and predictors of fatigue after infectious mononucleosis in a large primary-care cohort.	QJM. 2006 Jan;99(1):49-55. Epub 2005 Dec 5.	BACKGROUND: Fatigue has been found to complicate infectious mononucleosis (IM) when patients are directly asked about it. We do not know whether such fatigue is clinically significant, nor whether IM is a specific risk for fatigue (or whether it can follow other common infections). Various risk markers for post-infectious fatigue have been identified, but findings are inconsistent. AIM: To determine the risk of clinically reported fatigue (compared with depression) after IM (compared with both influenza and tonsillitis) in patients attending primary care, and to examine risk markers for post-IM fatigue. DESIGN: Comparison of matched primary-care cohorts. METHODS: We identified 1438 adult patients with a positive heterophil antibody test for IM from the UK General Practice Research Database. These patients were individually matched on age, sex and practice to two comparison groups; one with a clinical diagnosis of influenza and the other of tonsillitis. RESULTS: The odds ratios (ORs) (95%CI) for reported fatigue after IM vs. influenza and tonsillitis were 4.4 (2.9-6.9) and 6.6 (4.2-10.4), respectively. Risk markers for post-IM fatigue included female sex and premorbid mood disorder. By comparison, the ORs for depression after IM vs. influenza and tonsillitis were 1.6 (0.9-2.6) and 2.3 (1.4-3.9), respectively. DISCUSSION: IM is a specific and significant risk for clinically reported fatigue, which is both separate from, and more common than, depression. Female sex and premorbid mood disorder are risk markers for fatigue. These can be used both to target prevention strategies and to explore aetiological mechanisms.
Pittion-Vouyovitch S, Debouverie M, Guillemin F, Vandenberghe N, Anxionnat R, Vespignani H.	Department of Neurology, Central Hospital, 54000 Nancy, France. sophie-pittion@wanadoo.fr	Fatigue in multiple sclerosis is related to disability, depression and quality of life.	J Neurol Sci. 2006 Apr 15;243(1-2):39-45. Epub 2006 Jan 24.	Fatigue in multiple sclerosis is a frequent and disabling symptom that can interfere in daily functioning. The aim of this study is to demonstrate the relationship between fatigue and disability, disease course, depression and quality of life. We administered French valid versions of the Fatigue Impact Scale (EMIF-SEP), the short form of the Beck depression inventory (13 items) and the SF-36 to 237 out of 312 patients with clinically definite multiple sclerosis with EDSS<or=6.5. The EMIF-SEP is composed of four dimensions (cognitive, physical, social role and psychological) and allows a multidimensional evaluation. Using a multivariate analysis, EMIF-SEP total scores with physical and social role subscales were highly correlated with EDSS ($p < 0.0001$). Cognitive and psychological dimensions of the EMIF-SEP were not linked to EDSS. EMIF-SEP was not correlated with disease course after adjusting for EDSS. EMIF-SEP scores were significantly associated with depression scores ($r = 0.74$, $p < 0.0001$). The multivariate analysis also showed a significant impact of fatigue on each scale of quality of life of the SF-36. These data confirm that fatigue is correlated with disability, but cognitive and psychological dimensions of fatigue remain independent. Fatigue is also associated with depression and quality of life.
Prins JB, van der Meer JW,	Department of Medical	Chronic fatigue syndrome.	Lancet. 2006 Jan 28;367(9507):346-	During the past two decades, there has been heated debate about chronic fatigue syndrome (CFS) among researchers, practitioners, and patients. Few illnesses have been discussed so extensively. The

Bleijenberg G.	Psychology, Radboud University Nijmegen Medical Centre, Nijmegen, Netherlands. j.prins@mps.umcn.nl		55. Comment in: Lancet. 2006 May 13;367(9522):1573-4; author reply 1575. Lancet. 2006 May 13;367(9522):1574; author reply 1575	existence of the disorder has been questioned, its underlying pathophysiology debated, and an effective treatment opposed; patients' organisations have participated in scientific discussions. In this review, we look back on several controversies over CFS with respect to its definition, diagnosis, pathophysiology, and treatment. We review issues of epidemiology and clinical manifestations, focusing on the scientific status of CFS. Modern neuroscience and genetics research offer interesting findings for new hypotheses on the aetiology and pathogenesis of the illness. We also discuss promising future issues, such as psychopathophysiology and mechanisms of improvement, and suggest multidisciplinary prospective studies of CFS and fatigue in the general population. These studies should pay particular attention to similarities to and differences from functional somatic syndromes and other fatiguing conditions.
Puri BK.	MRC Clinical Sciences Centre, Imperial College, Hammersmith Hospital, London, UK. basant.puri@csc.mrc.ac.uk	Proton and 31-phosphorus neurospectroscopy in the study of membrane phospholipids and fatty acid intervention in schizophrenia, depression, chronic fatigue syndrome (myalgic encephalomyelitis) and dyslexia.	Int Rev Psychiatry. 2006 Apr;18(2):145-7.	Neurospectroscopy allows biochemical processes in the brain to be studied non-invasively. At magnetic field strengths of 1.5 T or higher, cerebral proton neurospectroscopy allows the ascertainment of values of myo-inositol, choline-containing compounds, creatine, glutamate, glutamine, and N-acetyl aspartate. At similar field strengths, cerebral 31-phosphorus neurospectroscopy allows the ascertainment of values of phosphomonoesters, inorganic phosphate, phosphodiesters, phosphocreatine, and the gamma, alpha and beta nucleotide triphosphate (mainly adenosine triphosphate) resonances. Since choline is a common polar head group at the Sn3 position of membrane phospholipid molecules, a raised level of free choline, as indexed by proton neurospectroscopy, can indicate relatively low anabolism of membrane phospholipid molecules. Furthermore, the choline peak includes phosphorylcholine and glycerophosphorylcholine and even ethanolamine. The phosphomonoesters peak measured using 31-phosphorus spectroscopy includes major contributions from phosphocholine, phosphoethanolamine and L-phosphoserine, which are important precursors of membrane phospholipids, while the phosphodiesters peak includes contributions from glycerophosphocholine and glycerophosphoethanolamine, which are important products of membrane phospholipid catabolism. Hence proton neurospectroscopy and 31-phosphorus neurospectroscopy can yield important information relating to the metabolism of cerebral membrane phospholipids. The application of these techniques to the investigation of membrane phospholipid metabolism in schizophrenia, depression, chronic fatigue syndrome (myalgic encephalomyelitis or M.E.) and dyslexia is described.
Puri BK.	MRC Clinical Sciences Centre, Imperial College, Hammersmith Hospital, London, UK. basant.puri@csc.mrc.ac.uk	High-resolution magnetic resonance imaging sinc-interpolation-based subvoxel registration and semi-automated quantitative lateral ventricular morphology employing	Int Rev Psychiatry. 2006 Apr;18(2):149-54.	Serial high-resolution structural magnetic resonance imaging scans of the brain can now be precisely aligned, with six degrees of freedom (three mutually orthogonal translational and three rotational degrees of freedom around three mutually orthogonal axes), using a rigid-body subvoxel registration technique. This is driven by the in-plane point spread function for images acquired in the Fourier domain with data obtained over a bounded region of k-space, namely the sinc interpolation function, where sinc z = (sin z)/z, with z being any complex number (including zero). Computational subtraction of the three-dimensional Cartesian spatial representation matrices of serially acquired scan data allows for the determination of structural cerebral changes with great precision, since voxel signals from unchanged structures are almost completely cancelled. Thus changes readily show up against a background of noise. Furthermore, lateral ventricular changes can now be accurately quantified using a semi-automated method involving contour production, threshold computation, binary image

		threshold computation and binary image creation in the study of fatty acid interventions in schizophrenia, depression, chronic fatigue syndrome and Huntington's disease.		creation and ventricular extraction. These techniques have been applied to the investigation of the effects on cerebral structure of intervention with fatty acids, particularly the long-chain polyunsaturated n-3 fatty acid eicosapentaenoic acid (EPA), in disorders such as schizophrenia, treatment-resistant depression, chronic fatigue syndrome (myalgic encephalomyelitis or ME), and Huntington's disease.
Puri BK.	Hammersmith Hospital, United Kingdom.	Long-chain polyunsaturated fatty acids and the pathophysiology of myalgic encephalomyelitis (chronic fatigue syndrome).	J Clin Pathol. 2006 Aug 25; [Epub ahead of print]	Evidence is put forward to suggest that myalgic encephalomyelitis, also known as chronic fatigue syndrome, may be associated with persistent viral infection. In turn, such infections are likely to impair the ability of the body to biosynthesize n-3 and n-6 long-chain polyunsaturated fatty acids by inhibiting the delta-6 desaturation of the precursor essential fatty acids alpha-linolenic acid and linoleic acid. In turn, this would impair the proper functioning of cell membranes, including cell signalling, and have an adverse effect of the biosynthesis of eicosanoids from the long-chain polyunsaturated fatty acids dihomo-a-linolenic acid, arachidonic acid and eicosapentaenoic acid. These actions might offer an explanation for some of the symptoms and signs of myalgic encephalomyelitis. A potential therapeutic avenue may be offered by bypassing the inhibition of the enzyme delta-6-desaturase by administering both virgin cold-pressed non-raffinated evening primrose oil and eicosapentaenoic acid. The former would supply gamma-linolenic acid and lipophilic pentacyclic triterpenes. The gamma-linolenic acid can readily be converted into dihomo-a-linolenic acid and thence arachidonic acid, while triterpenes have important free radical scavenging, cyclooxygenase and neutrophil elastase inhibitory activities. Furthermore, both arachidonic acid and eicosapentaenoic acid are, at relatively low concentrations, directly virucidal.
Quarmby L, Rimes KA, Deale A, Wessely S, Chalder T.	King's College London, Academic Department of Psychological Medicine, Weston Education Centre, Cutcombe Road, London SE5 9RJ, UK.	Cognitive-behaviour therapy for chronic fatigue syndrome: Comparison of outcomes within and outside the confines of a randomised controlled trial.	Behav Res Ther. 2006 Oct 27; [Epub ahead of print]	Outcomes for cognitive-behaviour therapy (CBT) in randomised controlled trials (RCTs) have rarely been compared to those in routine clinical practice. Taking the case of CBT for chronic fatigue syndrome (CFS), we evaluated the results of a successful RCT against those of the same treatment given in the same setting as part of routine practice. Fatigue and social adjustment scores were compared for patients who received CBT for CFS as part of a RCT (N=30) and patients who received CBT as part of everyday clinical practice (N=384). The results in the RCT were superior to those in routine clinical practice. Between pre-treatment and 6-month follow-up, the RCT showed a larger reduction in fatigue and greater improvement in social adjustment than those in routine treatment. The changes in fatigue scores were similar for both groups during treatment but were greater in the RCT between post-treatment and follow-up. Potential reasons for the superior results of the RCT include patient selection, therapist factors and the use of a manualised treatment protocol. Practitioners need to pay particular attention to relapse prevention and ensuring adequate follow-up in addition to encouraging patients to continue with cognitive-behavioural strategies once treatment

				has ended.
Rajeevan MS, Smith AK, Dimulescu I, Unger ER, Vernon SD, Heim C, Reeves WC.	Division of Viral and Rickettsial Diseases, National Center for Infectious Diseases, Centers for Disease Control and Prevention, Atlanta, GA, USA.	Glucocorticoid receptor polymorphisms and haplotypes associated with chronic fatigue syndrome.	Genes Brain Behav. 2006 Jun 1; [Epub ahead of print]	Chronic fatigue syndrome (CFS) is a significant public health problem of unknown etiology, the pathophysiology has not been elucidated, and there are no characteristic physical signs or laboratory abnormalities. Some studies have indicated an association of CFS with deregulation of immune functions and hypothalamic-pituitary-adrenal (HPA) axis activity. In this study, we examined the association of sequence variations in the glucocorticoid receptor gene (NR3C1) with CFS because NR3C1 is a major effector of the HPA axis. There were 137 study participants (40 with CFS, 55 with insufficient symptoms or fatigue, termed as ISF, and 42 non-fatigued controls) who were clinically evaluated and identified from the general population of Wichita, KS. Nine single nucleotide polymorphisms (SNPs) in NR3C1 were tested for association of polymorphisms and haplotypes with CFS. We observed an association of multiple SNPs with chronic fatigue compared to non-fatigued (NF) subjects ($P < 0.05$) and found similar associations with quantitative assessments of functional impairment (by the SF-36), with fatigue (by the Multidimensional Fatigue Inventory) and with symptoms (assessed by the Centers for Disease Control Symptom Inventory). Subjects homozygous for the major allele of all associated SNPs were at increased risk for CFS with odds ratios ranging from 2.61 (CI 1.05-6.45) to 3.00 (CI 1.12-8.05). Five SNPs, covering a region of approximately 80 kb, demonstrated high linkage disequilibrium (LD) in CFS, but LD gradually declined in ISF to NF subjects. Furthermore, haplotype analysis of the region in LD identified two associated haplotypes with opposite alleles: one protective and the other conferring risk of CFS. These results demonstrate NR3C1 as a potential mediator of chronic fatigue, and implicate variations in the 5' region of NR3C1 as a possible mechanism through which the alterations in HPA axis regulation and behavioural characteristics of CFS may manifest.
Reeves WC, Heim C, Maloney EM, Youngblood LS, Unger ER, Decker MJ, Jones JF, Rye DB.	Viral Exanthems & Herpesvirus Branch, Division of Viral & Rickettsial Diseases, National Center for Infectious Diseases, Centers for Disease Control & Prevention, Atlanta, GA, USA. wcr1@cdc.gov	Sleep characteristics of persons with chronic fatigue syndrome and non-fatigued controls: results from a population-based study.	BMC Neurol. 2006 Nov 16;6:41.	BACKGROUND: The etiology and pathophysiology of chronic fatigue syndrome (CFS) remain inchoate. Attempts to elucidate the pathophysiology must consider sleep physiology, as unrefreshing sleep is the most commonly reported of the 8 case-defining symptoms of CFS. Although published studies have consistently reported inefficient sleep and documented a variable occurrence of previously undiagnosed primary sleep disorders, they have not identified characteristic disturbances in sleep architecture or a distinctive pattern of polysomnographic abnormalities associated with CFS. METHODS: This study recruited CFS cases and non-fatigued controls from a population based study of CFS in Wichita, Kansas. Participants spent two nights in the research unit of a local hospital and underwent overnight polysomnographic and daytime multiple sleep latency testing in order to characterize sleep architecture. RESULTS: Approximately 18% of persons with CFS and 7% of asymptomatic controls were diagnosed with severe primary sleep disorders and were excluded from further analysis. These rates were not significantly different. Persons with CFS had a significantly higher mean frequency of obstructive apnea per hour ($p = .003$); however, the difference was not clinically meaningful. Other characteristics of sleep architecture did not differ between persons with CFS and controls. CONCLUSION: Although disordered breathing during sleep may be associated with CFS, this study generally did not provide evidence that altered sleep architecture is a critical factor in CFS. Future studies should further scrutinize the relationship between subjective sleep quality relative to objective polysomnographic measures.

Ryall C, Coggon D, Peveler R, Reading I, Palmer KT.	MRC Epidemiology Resource Centre, University of Southampton, Southampton General Hospital, Tremona Road, Southampton SO16 6YD, UK.	A case-control study of risk factors for arm pain presenting to primary care services.	Occup Med (Lond). 2006 Mar;56(2):137-43. Epub 2006 Feb 1.	OBJECTIVES: To investigate the association of occupational activities, mental health and comorbidity with care seeking for arm pain, and to test the hypothesis that specific disorders arise from physical risk factors and non-specific pain from psychological ones. METHODS: Patients with a new episode of arm pain and matched controls were recruited from eight general practices. A questionnaire about risk factors was completed and cases were classified using a validated examination schedule. Questions were asked about occupational activities and psychosocial stressors. Mental health was assessed using the Hospital Anxiety Depression Scale, elements of the Brief Symptom Inventory (somatizing tendency) and the Whiteley Index (health anxiety); comorbidity from chronic fatigue syndrome (CFS) and chronic widespread pain (CWP) was ascertained using standard definitions. Associations were explored using logistic regression and summarized as odds ratios (ORs) with 95% confidence intervals (95% CIs). RESULTS: Altogether, 132 cases and 127 controls were studied. Consulting with arm pain was strongly associated with all of the mental health variables and with CFS and CWP, irrespective of the site of arm pain or diagnosis. The OR in those with >3 versus <3 distressing somatic symptoms was 3.9 (95% CI 1.7-9.0). There were several significant associations with physical activity, but none with occupational psychosocial stressors. Repeated wrist/finger movements and carrying weights were more strongly associated with specific diagnoses than with non-specific pain. CONCLUSIONS: Somatizing tendency, health anxiety, low mood, CFS and CWP are more common in arm pain consulters. Certain mechanical activities are also overrepresented, particularly in those with specific pathology.
Saggini R, Vecchiet J, Iezzi S, Racciatti D, Affaitati G, Bellomo RG, Pizzigallo E.	Physical Therapy Institute, Department of Medicine and Aging, G. D'Annunzio University, Chieti, Italy.	Submaximal aerobic exercise with mechanical vibrations improves the functional status of patients with chronic fatigue syndrome.	Eura Medicophys. 2006 Jun;42(2):97-102.	AIM: Chronic fatigue syndrome (CFS) is an illness characterised by disabling fatigue of uncertain aetiology and other nonspecific symptoms. Typically CFS patients complain of a severe fatigue made worse by exercise, with a consistent reduction of working activity. A physical deconditioning could explain CFS features as well as a neuromuscular dysfunction, of central or peripheric origin. METHODS: Ten CFS patients were enrolled in a protocol of a rehabilitative treatment over a six-month period: they underwent a submaximal and predominantly aerobic exercise with a reduced O2 consumption using a Galileo 2000 system that provides mechanical vibrations characterised by sinusoid vertical sollecitations. Before and after such treatment, all patients underwent a pressure pain thresholds profile, an evaluation of physical and psychosocial parameters using the visual analogue scale (VAS) of Scott-Huskisson, and a muscle performance analysis by the CIBEX 6000 dynamometer. RESULTS: After the six-month period of study there was an overall improvement of the above described parameters as compared to the basal determinations. CONCLUSION: We conclude that the rehabilitative exertion provides an useful treatment for CFS patients particularly to realize an effective training of the explosive strength.
Saidi G, Haines L.	Research Division, Royal College of Paediatrics and Child Health, 50 Hallam Street, London W1W 6DE, UK.	The management of children with chronic fatigue syndrome-like illness in primary care: a cross-sectional study.	Br J Gen Pract. 2006 Jan;56(522):43-7.	BACKGROUND: Most studies on children with chronic fatigue syndrome (CFS)/myalgic encephalomyelitis (ME) have been undertaken in tertiary care and little is known about their management in primary care. AIM: To describe the characteristics of patients aged 5-19 years with CFS-like illness in primary care and to examine how GPs investigate and manage patients. DESIGN OF STUDY: Descriptive retrospective questionnaire study. SETTING: Sixty-two UK GP practices in the MRC General Practice Research Framework (GPRF). METHOD: One hundred and twenty-two practices were approached; 62 identified 116 patients consulting a GP with severe fatigue lasting over 3 months.

				Practice nurses and GPs completed questionnaires from medical notes and patients completed postal questionnaires. RESULTS: Ninety-four patients were considered by a clinical panel, blind to diagnosis, to meet the Oxford CFS criteria with a fatigue duration of 3 months. Seventy-three per cent were girls, 94% white, mean age was 12.9 years and median illness duration 3.3 years. GPs had principal responsibility for 62%. A diagnosis of CFS/ME was made in 55%, 30% of these within 6 months. Fifty per cent had a moderate illness severity. Paediatric referrals were made in 82% and psychiatric referrals in 46% (median time of 2 and 13 months respectively). Advice given included setting activity goals, pacing, rest and graded exercise. CONCLUSIONS: Patient characteristics are comparable to those reported in tertiary care, although fewer are severe cases. GPs have responsibility for the majority of patients, are diagnosing CFS/ME within a short time and applying a range of referral and advice strategies.
Sakudo A, Kuratsune H, Kobayashi T, Tajima S, Watanabe Y, Ikuta K.	Department of Virology, Center for Infectious Disease Control, Research Institute for Microbial Diseases, Osaka University, Yamadaoka, Suita, Japan.	Spectroscopic diagnosis of chronic fatigue syndrome by visible and near-infrared spectroscopy in serum samples.	Biochem Biophys Res Commun. 2006 Jul 14;345(4):1513-6. Epub 2006 May 22.	To investigate visible and near-infrared (Vis-NIR) spectroscopy enabling chronic fatigue syndrome (CFS) diagnosis, we subjected sera from CFS patients as well as healthy donors to Vis-NIR spectroscopy. Vis-NIR spectra in the 600-1100 nm region for sera from 77 CFS patients and 71 healthy donors were subjected to principal component analysis (PCA) and soft independent modeling of class analogy (SIMCA) to develop multivariate models to discriminate between CFS patients and healthy donors. The model was further assessed by the prediction of 99 masked other determinations (54 in the healthy group and 45 in the CFS patient group). The PCA model predicted successful discrimination of the masked samples. The SIMCA model predicted 54 of 54 (100%) healthy donors and 42 of 45 (93.3%) CFS patients of Vis-NIR spectra from masked serum samples correctly. These results suggest that Vis-NIR spectroscopy for sera combined with chemometrics analysis could provide a promising tool to objectively diagnose CFS.
Schikler KN.		Potential polygenic influences on chronic fatigue syndrome.	Pediatrics. 2006 Oct;118(4):1799-800; author reply 1800. Comment on: Pediatrics. 2006 Jun;117(6):2074-9.	Letter
Schonfeldt-Lecuona C, Connemann BJ, Wolf RC, Braun M, Freudenmann RW.		Bupropion augmentation in the treatment of chronic fatigue syndrome with coexistent major depression episode.	Pharmacopsychiatry. 2006 Jul;39(4):152-4.	While psychoeducational strategies and general support are always indicated for the treatment of chronic fatigue syndrome (CFS), pharmacological strategies are yet not well established. Antidepressants such as selective serotonin re-uptake inhibitors have been shown to influence positively symptoms and immunological parameters. However, a considerable part of CFS patients do not satisfactorily respond to them. Bupropion, a centrally acting catecholamine-transporter blocker without classic psycho-analeptic properties, shows theoretical potential to improve fatigue symptoms. In the reported case paroxetine was augmented with bupropion at high dosage, a strategy which consecutively led to a rapid relief of CFS-symptoms.
Sene D, Saadoun D, Limal N, Piette JC, Cacoub P.	Service de medecine interne, hopital de la Pitie-	[Update in Hepatitis C virus associated	Rev Med Interne. 2006 Nov 7; [Epub ahead of print]	INTRODUCTION: Since the discovery of the hepatitis C virus, many manifestations, so called extra-hepatic manifestations (EHM), are largely reported with more or less relationship proofs. ACTUALITIES AND MAIN POINTS: This article proposes a review of the main extra-hepatic manifestations associated

	Salpetriere, 91, boulevard de l'Hopital, 75651 Paris cedex 13, France.	extrahepatic manifestations.] [Article in French]		with the Hepatis C Virus infection and which remain a topical subject, more than fifteen years after the discovery of this virus. Mixed cryoglobulin and its vasculitic manifestations are still one of the more frequent Hepatis C Virus associated-extra-hepatic manifestations. Its management may be critically changed due to the increasing use of anti-CD20 therapy. Among other HCV-EHM, the following extra-hepatic manifestations are still of interest: the chronic fatigue syndrome, the sicca syndrome, the non-insulin-dependent diabetes mellitus, malignant B cell proliferations, mainly the Hepatis C Virus-related splenic lymphoma with villous lymphocytes and the production of auto-antibodies. PERSPECTIVES AND PROJECTS: The mechanisms underlying these HCV-associated EHM are ill-elucidated and still remain of great interest as proved by current studies. The use of anti-CD20 antibodies in the treatment of cryoglobulinemic vasculitis is also under investigation.
Shapiro CM.		Chronic fatigue and chronic fatigue syndrome: pathogenesis and measurement scales.	J Psychosom Res. 2006 Jun;60(6):549-50.	
Shepherd C.		The debate: myalgic encephalomyelitis and chronic fatigue syndrome.	Br J Nurs. 2006 Jun 22-Jul 12;15(12):662-9.	Almost every aspect of myalgic encephalomyelitis (or encephalopathy) and chronic fatigue syndrome is the subject of disagreement and uncertainty -- something that has undoubtedly hampered recognition, understanding and research. Although the pathogenesis remains the subject of intense medical debate, a number of predisposing, precipitating and perpetuating factors are now starting to emerge. Therapeutic nihilism is no longer appropriate as there is a great deal that can be done to alleviate some of the more distressing symptoms and improve quality of life for these patients.
Shor S		Lyme Disease Presenting as Chronic Fatigue Syndrome	Journal of Chronic Fatigue Syndrome 2006; 13(4): 73-82	Objective: Chronic Fatigue Syndrome (CFS) by definition represents a diagnosis of exclusion. Late stage or "Chronic Lyme" infection with or without "co-infections" is a difficult diagnosis to establish. The symptom complex of both conditions can be very similar. This case study represents an attempt to support serious consideration for a subpopulation of patients otherwise diagnosed with "CFS," as actually representing chronic Lyme disease. Method: A case study is presented of a 33-year-old man, who for two years, was being managed as having CFS. However, after ~2 years of utilizing multiple modalities of management with limited success, the diagnosis of Lyme was reconsidered. Historical exposure risks to Lyme in this individual were high. He had prolonged exposure in the highly tick-infested mountains of North Carolina for 18 months, several years prior to becoming ill. More aggressive investigation confirmed the diagnosis of Lyme. Appropriate changes in management were associated with an improved level of functioning that was far in excess of what maximal management of CFS was able to achieve. The features of CFS and chronic Lyme can be very similar and include the following: Profound fatigue often associated with cognitive impairment. Other common symptoms related to both of these conditions include sleep disturbances, fibromyalgia, and dysautonomias. In pursuing clarification of this diagnosis, the author was exposed to a contrast in medical opinion regarding diagnostic tools and criteria that were perceived as creating potential barriers to the management of patients presenting with these symptoms. Conclusion: Acceptance and awareness of the possibility that Lyme disease can present as CFS has important therapeutic and prognostic

				implications.

Siegel SD, Antoni MH, Fletcher MA, Maher K, Segota MC, Klimas N.	Department of Psychology, Behavioral Medicine Research Center, University of Miami, FL, USA.	Impaired natural immunity, cognitive dysfunction, and physical symptoms in patients with chronic fatigue syndrome: preliminary evidence for a subgroup?	J Psychosom Res. 2006 Jun;60(6):559-66.	OBJECTIVE: The diagnostic criteria of chronic fatigue syndrome (CFS) define a heterogeneous population composed of several subgroups. Past efforts to identify subgroup markers have met with mixed success. This study was designed to examine natural killer cell activity (NKCA) as a potential subgroup marker by comparing the clinical presentations of CFS patients with and without clinically reduced NKCA. METHODS: Forty-one female CFS patients were classified into having either low or normal NKCA levels. These subgroups were then compared on objective measures of cognitive functioning and subjective assessments of fatigue, vigor, cognitive impairment, and daytime dysfunction. RESULTS: Relative to CFS patients in the normal-NKCA subgroup, low-NKCA patients reported less vigor, more daytime dysfunction, and more cognitive impairment. In addition, low-NKCA patients performed less on objective measures of cognitive functioning relative to normal-NKCA patients. CONCLUSIONS: The results are offered as preliminary evidence in support of using NKCA as an immunological subgroup marker in CFS. Findings are also discussed in terms of known associations between dysregulated immune functions, somatic symptoms, and psychological stress.
Smith AK, White PD, Aslakson E, Vollmer-Conna U, Rajeevan MS.	Centers for Disease Control and Prevention, Division of Viral and Rickettsial Diseases, National Center for Infectious Diseases, 1600 Clifton Road, MSG41, Atlanta, GA 30333, USA.	Polymorphisms in genes regulating the HPA axis associated with empirically delineated classes of unexplained chronic fatigue.	Pharmacogenomics. 2006 Apr;7(3):387-94.	Chronic fatigue syndrome (CFS) is characterized by persistent or relapsing fatigue that is not alleviated by rest, causes substantial reduction in activities and is accompanied by a variety of symptoms. Its unknown etiology may reflect that CFS is heterogeneous. Latent class analyses of symptoms and physiological systems were used to delineate subgroups within a population-based sample of fatigued and nonfatigued subjects [1] . This study examined whether genetic differences underlie the individual subgroups of the latent class solution. Polymorphisms in 11 candidate genes related to both hypothalamic-pituitary-adrenal (HPA) axis function and mood-related neurotransmitter systems were evaluated by comparing each of the five ill classes (Class 1, n = 33; Class 3, n = 22; Class 4, n = 22; Class 5, n = 17; Class 6, n = 11) of fatigued subjects with subjects defined as well (Class 2, n = 35). Of the five classes of subjects with unexplained fatigue, three classes were distinguished by gene polymorphsims involved in either HPA axis function or neurotransmitter systems, including proopiomelanocortin (POMC), nuclear receptor subfamily 3, group C, member 1 (NR3C1), monoamine oxidase A (MAOA), monoamine oxidase B (MAOB), and tryptophan hydroxylase 2 (TPH2). These data support the hypothesis that medically unexplained chronic fatigue is heterogeneous and presents preliminary evidence of the genetic mechanisms underlying some of the putative conditions.
Smith WR, Noonan C, Buchwald D.	Department of Psychiatry, University of	Mortality in a cohort of chronically	Psychol Med. 2006 Sep;36(9):1301-6.	BACKGROUND: Comprehensive studies of mortality among patients with chronic fatigue (CF) and chronic fatigue syndrome (CFS) have not been published, but several sources suggest that CFS is associated with an elevated risk for suicide. METHOD: Data on 1201 chronically fatigued patients

	Washington, Seattle, WA, USA. wrsmith@u.washington.edu	fatigued patients.		followed in a university-affiliated tertiary-care clinic for up to 14 years were submitted to the Center for Disease Control and Prevention (CDC) National Death Index (NDI) to evaluate all-cause and suicide-caused death rates against standardized mortality rates (SMRs). We used Life Table Analysis to examine the influence of sex and diagnoses of CFS and depression. RESULTS: All-cause mortality in chronically fatigued patients was no higher than expected, but suicide-caused death rates were more than eight times higher than in the US general population. The significant elevation in the SMR of suicide was restricted to those who did not meet criteria for CFS [SMR(CF)=14.2, 95% confidence interval (CI) 5.7-29.3 versus SMR(CFS)=3.6, 95% CI 0.4-12.9]. Among chronically fatigued patients who did not meet CFS criteria, those with a lifetime history of major depression (MD) had higher suicide-caused death rates than among their non-depressed counterparts (SMR(MD)=19.1, 95% CI 7.0-41.5 versus SMR(NMD)=5.6, 95% CI 0.1-31.4), although the difference was not significant. CONCLUSIONS: CFS does not appear to be associated with increased all-cause mortality or suicide rates. Clinicians, however, should carefully evaluate patients with CF for depression and suicidality.
Smith WR, White PD, Buchwald D.	Department of Psychiatry and Behavioral Sciences, University of Washington, Seattle, WA, USA. wrsmith@u.washington.edu	A case control study of premorbid and currently reported physical activity levels in chronic fatigue syndrome.	BMC Psychiatry. 2006 Nov 13;6:53.	BACKGROUND: Patients with chronic fatigue syndrome typically report high levels of physical activity before becoming ill. Few studies have examined premorbid and current activity levels in chronically fatigued patients. METHODS: In a case-control study, 33 patients with chronic, unexplained, disabling fatigue attending a university-based clinic specializing in fatigue were compared to 33 healthy, age- and sex-matched controls. Patients rated their activity levels before their illness and currently, using scales designed for this purpose. Controls reported their level of activity of 2 years previously and currently. Chi-square analyses, Student's t tests, and Wilcoxon signed rank tests were used in pair matched analyses. RESULTS: Compared to healthy controls, patients with chronic, unexplained fatigue rated themselves as more active before their illness ($p < or = 0.001$) and less active currently ($p < or = 0.001$). The patients also reported they currently stood or walked less than the controls (median [inter-quartile range] = 4 2345 versus 9 [7.5-12] hours, $p < or = 0.001$), and spent more time reclining (median [inter-quartile range] = 12 10111213141516 versus 8 [8-9.5] hours, $p < or = 0.001$). These differences remained significant for the subset of patients who met strict criteria for chronic fatigue syndrome or fibromyalgia. CONCLUSION: Patients with chronic, unexplained, disabling fatigue reported being more active before becoming ill than healthy controls. This finding could be explained by greater premorbid activity levels that could predispose to illness, or by an overestimation of previous activity. Either possibility could influence patients' perceptions of their current activity levels and their judgments of recovery. Perceived activity should be addressed as part of management of the illness.
St Clair Gibson A, Grobler LA, Collins M, Lambert MI, Sharwood K, Derman EW, Noakes TD.	UCT/MRC Research Unit of Exercise Science and Sports Medicine, Department of Human Biology, University of Cape	Evaluation of maximal exercise performance, fatigue, and depression in athletes with acquired chronic training	Clin J Sport Med. 2006 Jan;16(1):39-45.	OBJECTIVE: This study compared differences in maximal strength and aerobic capacity and symptoms of fatigue and depression in athletes with acquired training intolerance (ATI) and control athletes (CON) matched for age and current training volume who did not have symptoms of excessive or chronic fatigue associated with their sporting activity. SETTING: University of Cape Town, Sports Science Institute of South Africa. PARTICIPANTS: Twenty ATI and 10 CON athletes participated in the trial. Although the ATI athletes reported symptoms of excessive fatigue during exercise, or symptoms of fatigue that occurred at rest and during activities of daily living, they did not fulfill the criteria for a diagnosis of chronic fatigue syndrome. MAIN OUTCOME MEASURES: A training and comprehensive

	Town, Cape Town, South Africa. agibson@sports.uct.ac.za	intolerance.		medical history was recorded from all subjects. The Beck Depression Inventory Short Form (BDI-SF) was used to assess levels of depression in both ATI and control subjects. Maximal force output during a 5-second isometric voluntary knee extensor muscle contraction, and maximal aerobic capacity (VO2max), maximal heart rate (HRmax), and maximal blood lactate concentrations during a treadmill running test were measured in all subjects. RESULTS: There were no differences in maximal isometric force output, peak treadmill running speed, VO2max, HRmax, or blood lactate concentration at rest or after maximal exercise testing between the ATI and CON athletes. However, the BDI-SF scores were higher in the ATI (7.7 +/- 6.6 arbitrary units) than in the CON athletes (1.7 +/- 1.5 arbitrary units; (P = 0.0052). CONCLUSIONS: These findings suggest that the symptoms of excessive fatigue and acquired training intolerance described by these ATI athletes do not affect their maximal isometric and maximal aerobic capacity, and may be associated with psychologic depression in these athletes.
Staines DR.		Phosphodiesterase inhibitors may be indicated in the treatment of postulated vasoactive neuropeptide autoimmune fatigue-related disorders.	Med Hypotheses. 2006;66(1):203-4. Epub 2005 Sep 19.	
Staines DR.	Gold Coast Public Health Unit, 10-12 Young Street, Southport, Qld, 4215, Australia. don_staines@health.qld.gov.au	Postulated vasoactive neuropeptide autoimmunity in fatigue-related conditions: a brief review and hypothesis.	Clin Dev Immunol. 2006 Mar;13(1):25-39.	Disorders such as chronic fatigue syndrome (CFS) and gulf war syndrome (GWS) are characterised by prolonged fatigue and a range of debilitating symptoms of pain, intellectual and emotional impairment, chemical sensitivities and immunological dysfunction. Sudden infant death syndrome (SIDS) surprisingly may have certain features in common with these conditions. Post-infection sequelae may be possible contributing factors although ongoing infection is unproven. Immunological aberration may prove to be associated with certain vasoactive neuropeptides (VN) in the context of molecular mimicry, inappropriate immunological memory and autoimmunity. Adenylate cyclase-activating VNs including pituitary adenylate cyclase-activating polypeptide (PACAP), vasoactive intestinal peptide (VIP) and calcitonin gene-related peptide (CGRP) act as hormones, neurotransmitters, neuroregulators, immune modulators and neurotrophic substances. They and their receptors are potentially immunogenic. VNs are widely distributed in the body particularly in the central and peripheral nervous systems and have been identified in the gut, adrenal gland, blood cells, reproductive system, lung, heart and other tissues. They have a vital role in maintaining cardio-respiratory function, thermoregulation, memory, concentration and executive functions such as emotional responses including social cues and appropriate behaviour. They are co-transmitters for a number of neurotransmitters including acetylcholine and gaseous transmitters, are potent immune regulators with primarily anti-inflammatory activity, and have a significant role in protection of the nervous system against toxic assault as well as being important in the maintenance of homeostasis. This paper describes a biologically plausible mechanism for the development of certain fatigue-related

				syndromes based on loss of immunological tolerance to these VNs or their receptors following infection, other events or de novo resulting in significant pathophysiology possibly mediated via CpG fragments and heat shock (stress) proteins. These conditions extend the public health context of autoimmunity and VN dysregulation and have implications for military medicine where radiological, biological and chemical agents may have a role in pathogenesis. Possible treatment and prevention options are considered.

Beneficial effect of brewers' yeast extract on daily activity in a murine model of chronic fatigue syndrome.	Evid Based Complement Alternat Med. 2006 Mar;3(1):109-15. Epub 2006 Jan 23.	The aim of this study was to assess the effect of Brewers' yeast extract (BYE) on daily activity in a mouse model of chronic fatigue syndrome (CFS). CFS was induced by repeated injection of Brucella abortus (BA) antigen every 2 weeks. BYE was orally administered to mice in a dose of 2 g per kg per day for 2 weeks before injecting BA and for 4 weeks thereafter. We evaluated daily running activity in mice receiving BYE as compared with that in untreated mice. Weekly variation of body weight (BW) and survival in both groups was monitored during the observation period. Spleen weight (SW), SW/BW ratio, percent splenic follicular area and expression levels of interferon-gamma (IFN-gamma) and interleukin-10 (IL-10) mRNA in spleen were determined in both groups at the time of sacrifice. The daily activity during 2 weeks after the second BA injection was significantly higher in the treated group than in the control. There was no difference in BW between both groups through the experimental course. Two mice in the control died 2 and 7 days after the second injection, whereas no mice in the treated group died. Significantly decreased SW and SW/BW ratio were observed in the treated mice together with elevation of splenic follicular area. There were suppressed IFN-gamma and IL-10 mRNA levels in spleens from the treated mice. Our results suggest that BYE might have a protective effect on the marked reduction in activity following repeated BA injection via normalization of host immune responses.
Tanaka M, Sadato N, Okada T, Mizuno K, Sasabe T, Tanabe HC, Saito DN, Onoe H,	Department of Physiology, Osaka City University Graduate School of Medicine, 1-4-3	Reduced responsiveness is an essential feature of chronic fatigue syndrome:	BMC Neurol. 2006 Feb 22;6:9.	BACKGROUND: Although the neural mechanism of chronic fatigue syndrome has been investigated by a number of researchers, it remains poorly understood. METHODS: Using functional magnetic resonance imaging, we studied brain responsiveness in 6 male chronic fatigue syndrome patients and in 7 age-matched male healthy volunteers. Responsiveness of auditory cortices to transient, short-lived, noise reduction was measured while subjects performed a fatigue-inducing continual visual

Kuratsune H, Watanabe Y.	Asahimachi, Osaka 545-8585, Japan. masa-t@msic.med.osaka-cu.ac.jp	a fMRI study.		search task. RESULTS: Responsiveness of the task-dependent brain regions was decreased after the fatigue-inducing task in the normal and chronic fatigue syndrome subjects and the decrement of the responsiveness was equivalent between the 2 groups. In contrast, during the fatigue-inducing period, although responsiveness of auditory cortices remained constant in the normal subjects, it was attenuated in the chronic fatigue syndrome patients. In addition, the rate of this attenuation was positively correlated with the subjective sensation of fatigue as measured using a fatigue visual analogue scale, immediately before the magnetic resonance imaging session. CONCLUSION: Chronic fatigue syndrome may be characterised by attenuation of the responsiveness to stimuli not directly related to the fatigue-inducing task.
Taylor RR		Rehabilitation Programs for Individuals with Chronic Fatigue Syndrome A Review	Journal of Chronic Fatigue Syndrome 2006;13(1): 41-55	Over the past two decades, a small but growing number of rehabilitation programs for individuals with chronic fatigue syndrome (CFS) have been initiated. The aims of this paper were to review existing literature on these programs, to compare and contrast findings emerging from inpatient and outpatient programs, and to comment on the rigor and quality of methodologies used in outcomes research in this area. The studies reviewed herein varied widely in case selection criteria, program intensity, length of participation, program content, and outcome variables measured. Moreover, many were limited by selection bias, the absence of valid and reliable measures, and the absence of a control group. These limitations made it difficult to draw definitive conclusions regarding the effectiveness of any single approach to rehabilitation (whether inpatient or outpatient). However, there is some preliminary evidence that both inpatient and outpatient rehabilitation programs may lead to improvements in physical and occupational functioning, decreased perception of symptom severity, improved quality of life, and greater resource acquisition-at least for certain subgroups of individuals with CFS that participate in specific types of programs. Taken together, these preliminary findings support the need for additional funding and support for the development of comprehensive rehabilitative program centers that include both inpatient and outpatient programs with follow-up sessions and ongoing evaluation. Recommendations for future program development and outcomes research in this area are discussed.
Taylor RR, Kulkarni S, Shiraishi Y.		Conservation of Resources and Quality of Life in Individuals with Chronic Fatigue Syndrome	Journal of Chronic Fatigue Syndrome 2006;13(4):	No abstract available at September 2006
Taylor RR, Supriya Kulkarni, Yukiko Shiraishi		Conservation of Resources and Quality of Life in Individuals with Chronic Fatigue Syndrome	Journal of Chronic Fatigue Syndrome 2006; 13(4): 5-18	Objective: To examine the relationship between resources and quality of life in individuals with chronic fatigue syndrome (CFS). Participants and Study Design: A cross-sectional design was used to describe associations between resource loss and gain and quality of life for 47 individuals diagnosed with CFS. Main Outcome Measures: The Conservation of Resources Evaluation was used to measure resources in terms of perceived loss and gain. Health-related quality of life was assessed with the Quality of Life Index. Results: Total resource loss and total resource gain were significant correlates of overall quality of life. Gains in self-esteem, energy, and work resources were associated with higher-perceived quality of life. Material loss and energy loss were associated with lower-perceived quality of

				life. Conclusions: Findings for the relationships between perceived resources of self-esteem, work, material items, and energy and perceived quality of life can be used inform future rehabilitation efforts. These relationships appear to occur independently of illness severity among individuals CFS
Taylor RR, Thanawala SG, Shiraishi Y, Schoeny ME.	Department of Occupational Therapy, College of Applied Health Sciences, University of Illinois at Chicago, Chicago, IL 60612, USA. rtaylor@uic.edu	Long-term outcomes of an integrative rehabilitation program on quality of life: a follow-up study.	J Psychosom Res. 2006 Dec;61(6):835-9.	OBJECTIVE: To assess the long-term effects of an integrative rehabilitation program on the overall quality of life of individuals with chronic fatigue syndrome (CFS). METHODS: This study utilized a within-subjects, repeated measures cohort design. Twenty-three subjects diagnosed with CFS attended eight sessions of an illness-management group followed by 7 months of goal-oriented, individualized counseling that occurred once weekly for 30 min per session. Quality of life was assessed at five time points (baseline, following the group phase, following the one-on-one phase, and 4 and 12 months following program completion). RESULTS: A within-subjects repeated measures ANOVA revealed significant increases in overall quality of life for up to 1 year following program completion [F(4, 21)=23.5, P<.001]. CONCLUSIONS: Definitive conclusions about program efficacy are limited by design issues. However, findings suggest that the program may have led to improvement in quality of life for up to 1 year following program completion.
Teitelbaum JE, Johnson C, St Cyr J.	Fibromyalgia and Fatigue Centers, Dallas, TX, USA. Endfatigue@aol.com	The use of D-ribose in chronic fatigue syndrome and fibromyalgia: a pilot study.	J Altern Complement Med. 2006 Nov;12(9):857-62.	OBJECTIVES: Fibromyalgia (FMS) and chronic fatigue syndrome (CFS) are debilitating syndromes that are often associated with impaired cellular energy metabolism. As D-ribose has been shown to increase cellular energy synthesis in heart and skeletal muscle, this open-label uncontrolled pilot study was done to evaluate if D-ribose could improve symptoms in fibromyalgia and/or chronic fatigue syndrome patients. DESIGN: Forty-one (41) patients with a diagnosis of FMS and/or CFS were given D-ribose, a naturally occurring pentose carbohydrate, at a dose of 5 g t.i.d. for a total of 280 g. All patients completed questionnaires containing discrete visual analog scales and a global assessment pre- and post-D-ribose administration. RESULTS: D-ribose, which was well-tolerated, resulted in a significant improvement in all five visual analog scale (VAS) categories: energy; sleep; mental clarity; pain intensity; and well-being, as well as an improvement in patients' global assessment. Approximately 66% of patients experienced significant improvement while on D-ribose, with an average increase in energy on the VAS of 45% and an average improvement in overall well-being of 30% ($p < 0.0001$). CONCLUSIONS: D-ribose significantly reduced clinical symptoms in patients suffering from fibromyalgia and chronic fatigue syndrome.
ter Wolbeek M, van Doornen LJ, Kavelaars A, Heijnen CJ.	Laboratory of Psychoneuroimmunology, University Medical Center Utrecht, Utrecht, The Netherlands.	Severe fatigue in adolescents: a common phenomenon?	Pediatrics. 2006 Jun;117(6):e1078-86.	OBJECTIVE: The purpose of this study was to determine the prevalence of severe fatigue in adolescent boys and girls, to explore the role of lifestyle factors in fatigue, and to investigate whether severe fatigue in a healthy population is associated with depression, anxiety, and comorbid factors also observed in chronic fatigue syndrome patients. METHODS: In a sample of 1718 boys and 1749 girls, fatigue severity and duration were measured using a multidimensional questionnaire (Checklist Individual Strength). In addition, self-reports of depressive symptoms, anxiety, chronic fatigue syndrome-related symptoms, and lifestyle characteristics were assessed by means of questionnaires. Prevalence rates of severe fatigue and severe fatigue for > or =1 month, based on a clinical cutoff score of the Checklist Individual Strength, were determined for boys and girls separately, and gender-specific predictors of fatigue were identified by multiple regression analysis. RESULTS: The data showed high prevalence rates of severe fatigue in adolescents. Remarkable differences between boys and girls were observed: 20.5% of girls and 6.5% of the boys scored above the clinical cutoff score on

				the Checklist Individual Strength. Of these subjects 80.0% of the girls and 61.5% of the boys reported severe fatigue for > or =1 month. Of the examined lifestyle characteristics, only sleep characteristics and the participation in sports played a role in predicting fatigue in both genders. Moreover, in girls, fatigue was associated with higher age, an early menarche, medication use, and the absence of an additional job. Overall, girls scored higher on depression, anxiety, and chronic fatigue syndrome-related symptoms. However, the relation between fatigue and these comorbid symptoms did not differ between genders. In both girls and boys, the duration of fatigue was positively related to fatigue severity, severity of depression and anxiety, and the number of chronic fatigue syndrome-related symptoms. CONCLUSIONS: Fatigue prevalence among adolescents is high, especially in girls. Adolescent girls seem to be more vulnerable to symptoms of fatigue and comorbidity than boys. Interestingly, despite a female predominance in complaints, the relation between fatigue and depression, anxiety, and chronic fatigue syndrome-related symptoms was not gender specific and emerged as a cluster. In both genders, fatigue duration was associated with the severity of fatigue and the level of psychological comorbidity and chronic fatigue syndrome-related symptoms, and we, therefore, hypothesize that enduring severe fatigue may form a risk factor for the development of chronic fatigue syndrome.
Tharakan B, Dhanasekaran M, Brown-Borg HM, Manyam BV.	Plummer Movement Disorders Center, Department of Neurology, Scott & White Clinic, Temple, TX 76508, USA.	Trichopus zeylanicus combats fatigue without amphetamine-mimetic activity.	Phytother Res. 2006 Mar;20(3):165-8.	Chronic fatigue is a complex and little understood symptom for which there is no safe and effective pharmacotherapy. The present study was conducted to investigate the effectiveness of Trichopus zeylanicus whole plant powder on fatigue in young Sprague Dawley rats, and aged normal and long-living mutant Ames dwarf mice. Fatigue was evaluated by subjecting the animals to a forced swim test. Trichopus zeylanicus (250 and 500 mg/kg) treated young Sprague-Dawley rats resisted fatigue at a significant level ($p < 0.005$) compared with controls by an extended swim time in the forced swim test. Oral Trichopus zeylanicus (500 mg/kg) treatment for 2 weeks significantly increased the mobility time in the aged mutant ($p < 0.05$) and normal mice ($p < 0.01$) and significantly increased the swim time in the forced swim test in the aged normal mice ($p < 0.05$). Amphetamine-mimetic activity in Trichopus zeylanicus was excluded by suitable tests. These results show that Trichopus zeylanicus whole plant powder has anti-fatigue effects in young Sprague-Dawley rats and aged normal and mutant Ames dwarf mice providing scientific evidence for the Kani tribal practice in India. Thomas HV, Stimpson NJ, Weightman AL, Dunstan F, Lewis G.	Department of Psychological Medicine, School of Medicine, Cardiff University, UK.	Systematic review of multi-symptom conditions in Gulf War veterans.	Psychol Med. 2006 Jun;36(6):735-47. Epub 2006 Jan 26.	BACKGROUND: Gulf War veterans have a number of health complaints. We therefore decided to carry out a systematic review to identify and summarize the findings from studies that have assessed multi-symptom conditions in Gulf War veterans and in an unexposed comparison group. METHOD: Studies published between January 1990 and May 2004 were identified by searching a large number of electronic databases. Reference lists and websites were also searched and key researchers were contacted. Studies were included if they compared the prevalence of chronic fatigue syndrome, multiple chemical sensitivity, CDC-defined chronic multi-symptom illness, fibromyalgia, or symptoms of either fatigue or numbness and tingling in Gulf War veterans and non-Gulf veterans. A total of 2401 abstracts were independently reviewed by two authors. RESULTS: Twenty-three publications fulfilled the inclusion criteria. Gulf deployment was most strongly associated with chronic fatigue syndrome (OR 3.8, 95% CI 2.2-6.7). Gulf War veterans were also approximately three and a half times more likely than non-Gulf veterans to report multiple chemical sensitivity or chronic multi-symptom illness as defined by CDC. The methodological quality of the studies varied but the later and larger studies were of a high methodological standard with robust sampling strategies, adequate response rates and good adjustment for confounders. CONCLUSIONS: The results support the hypothesis that deployment to the Gulf War is associated with greater reporting of multi-symptom conditions.
Thomas MA, Smith AP.	Centre for Occupational and Health Psychology, School of Psychology, Cardiff University, UK. thomasma@cf.ac.uk	An investigation of the long-term benefits of antidepressant medication in the recovery of patients with chronic fatigue syndrome.	Hum Psychopharmacol. 2006 Dec;21(8):503-9.	Two hundred and seventy-five patients fulfilling the Centre for Disease Control (CDC) criteria for Chronic Fatigue Syndrome (CFS) completed measures assessing illness history, global ratings of well being, sleep, activity and psychopathology at baseline, 6 months, 18 months and 3 year follow-up. Forty-nine of these patients had been prescribed antidepressant medication, namely Tricyclic drugs or Selective Serotonin Re-uptake Inhibitors (SSRI). Data from the current study suggests that patients in the antidepressant medication group recover at a faster rate over time when compared to the untreated patient sample. In addition, the positive effects of antidepressant therapy are maintained at the 3-year follow-up point. It appears from these data that the SSRI in particular are responsible for improvements in the condition. Most importantly, these improvements include a reduction in the levels of fatigue recorded by patients. These findings have not been demonstrated in previous studies of the effect of antidepressant therapy for patients with this illness and this may reflect the short time periods studied in the earlier research.
Thompson TD, Weiss M.	Academic Unit of Primary Care, Cotham House, Cotham Hill, Bristol BS6 6JL, UK. trevor.thompson@bris.ac.uk	Homeopathy--what are the active ingredients? An exploratory study using the UK Medical Research Council's framework for the evaluation of complex interventions.	BMC Complement Altern Med. 2006 Nov 13;6:37.	BACKGROUND: Research in homeopathy has traditionally addressed itself to defining the effectiveness of homeopathic potencies in comparison to placebo medication. There is now increasing awareness that the homeopathic consultation is in itself a therapeutic intervention working independently or synergistically with the prescribed remedy. Our objective was to identify and evalute potential "active ingredients" of the homeopathic approach as a whole, in a prospective formal case series, which draws on actual consultation data, and is based on the MRC framework for the evaluation of complex interventions. METHODS: Following on from a theoretical review of how homeopathic care might mediate its effects, 18 patients were prospectively recruited to a case series based at Bristol Homeopathic Hospital. Patients, who lived with one of three index conditions, were interviewed before and after a five visit "package of care". All consultations were recorded and transcribed verbatim. Additional data, including generic and condition-specific questionnaires, artwork and

				"significant other" reports were collected. Textual data was subject to thematic analysis and triangulated with other sources. RESULTS: We judged that around one third of patients had experienced a major improvement in their health over the study period, a third had some improvement and a third had no improvement. Putative active ingredients included the patients' "openness to the mind-body connection", consultational empathy, in-depth enquiry into bodily complaints, disclosure, the remedy matching process and, potentially, the homeopathic remedies themselves. CONCLUSION: This study has has identified, using primary consultation and other data, a range of factors that might account for the effectiveness of homeopathic care. Some of these, such as empathy, are non-specific. Others, such as the remedy matching process, are specific to homeopathy. These findings counsel against the use of placebo-controlled RCT designs in which both arms would potentially be receiving specific active ingredients. Future research in homeopathy should focus on pragmatic trials and seek to confirm or refute the therapeutic role of constructs such as patient "openness", disclosure and homeopathicity.
Toda K, Kimura H.	Department of Rehabilitation, Hiroshima Prefectural Rehabilitation Center, Higashi-Hiroshima, Hiroshima, Japan.	Efficacy of neurotropin in chronic fatigue syndrome: a case report.	Hiroshima J Med Sci. 2006 Mar;55(1):35-7.	Chronic fatigue syndrome (CFS) is a disorder that causes general fatigue and chronic widespread pain. A 28-year-old male visited an outpatient department due to general fatigue and pain involving the entire body. He did not suffer from fibromyalgia, but he was diagnosed with CFS. At the initial visit, he complained of lack of concentration, memory decline, frequent urination, insomnia and occasional difficulty of emotional control, as well as general fatigue and pain involving the entire body. Four tablets of Neurotropin per day alone were administered. General fatigue and pain were gradually alleviated one week later. His sleep condition, concentration power, and memory also improved two weeks later. Medication was discontinued from 11 weeks based on the patient's judgment as he felt little general fatigue and pain involving the entire body. Treatment was completed 3 months later. The symptoms disappeared and did not recur five months after the discontinuation of Neurotropin. He was looking for a job without fatigue and pain 8 months later (5 months after the cessation of treatment). The functional mechanisms of Neurotropin in CFS are unknown.
Torenbeek M, Mes CA, van Liere MJ, Schreurs KM, ter Meer R, Kortleven GC, Warmerdam CG.	Het Roessingh, Centrum voor Revalidatie, divisie Pijnrevalidatie, Enschede. m.torenbeek@roessingh.nl	[Favourable results of a rehabilitation programme with cognitive behavioural therapy and graded physical activity in patients with the chronic-fatigue syndrome] [Article in Dutch]	Ned Tijdschr Geneeskd. 2006 Sep 23;150(38):2088-94. Comment in: Ned Tijdschr Geneeskd. 2006 Sep 23;150(38):2067-8.	OBJECTIVE: To determine whether a specific course of interdisciplinary rehabilitation might lead to clinically significant changes in fatigue, experienced disability and physical function in patients with the chronic-fatigue syndrome (CFS). DESIGN: Prospective and uncontrolled. METHOD: 'Het Roessingh', a rehabilitation centre in Enschede, the Netherlands, has developed an interdisciplinary clinical rehabilitation programme for patients with CFS in cooperation with the 'Nijmeegs Kenniscentrum Chronische Vermoeidheid' [Chronic-Fatigue Knowledge Centre] in Nijmegen, the Netherlands. In this programme, physical, mental and social activities are gradually increased on the basis of cognitive behavioural principles and graded activity. Of the 127 successive persons who enrolled for the therapy during the period from August 2000 to December 2004, 99 fulfilled the inclusion criteria; they had a median duration of symptoms of 6 years. The results of treatment were evaluated by a measurement with the 'Checklist individuele spankracht' [Checklist individual muscle tone] before and after treatment and the scores on the 'Patientspecifieke beperkingen' [Patient-specific disability] and the Short form-36. The measured data were complete in 74 patients. RESULTS: Before rehabilitation, the levels of fatigue, disability and distress were high. After treatment, the studied population showed significant improvement in fatigue, experienced disability and physical function. The magnitude of the

				improvement was generally 'average'. At the end of treatment, 70% of the patients were clinically less fatigued, 68% experienced less disability and 55% functioned better physically. In 34% the level of fatigue was normalised after treatment, but 9.5% of the patients was more fatigue. CONCLUSION: The rehabilitation programme offered for CFS led to significant improvements in function and fatigue.
Torres-Harding SR, Jordan J, Jason LA, Arias R.		Psychosocial and Physical Impact of Chronic Fatigue in a Community-Based Sample of Children and Adolescents	Journal of Chronic Fatigue Syndrome 2006;13(2/3): 55-74	Background: Few studies have examined the problem of chronic fatigue in children and adolescents and its potential impact on functioning. Chronic fatigue may have a negative impact on school functioning, family activities, psychological well-being, physical functioning, and severity of medical symptomatology. Objectives: This study compared psychosocial, family, and physical functioning between a randomly selected community based sample of 36 children and adolescents with chronic fatigue and a group of 21 children and adolescents without fatigue. Methods: Children and parents completed a comprehensive medical history questionnaire and questionnaires assessing psychological functioning, family functioning, and school attendance. Results: Results indicated that children with chronic fatigue tended to have more difficulties in overall physical and psychological functioning, as measured by the Child Health Questionnaire and the Child Behavior Checklist. In addition, children in the chronic fatigue group experienced disruptions in a range of activities and reported more severe physical symptomatology when compared to children without fatigue. Conclusions: Findings suggest that children and adolescents with chronic fatigue may have a range of associated difficulties, including limitations in physical and psychosocial functioning and a negative impact on the ability to engage in normative activities.
Underhill RA, O'Gorman RL		Prevalence of Chronic Fatigue Syndrome and Chronic Fatigue Within Families of CFS Patients	Journal of Chronic Fatigue Syndrome 2006;13(1): 3-13	The prevalence of CFS (Chronic Fatigue Syndrome) and chronic fatigue were investigated in family members of CFS patients using a questionnaire-based study. Significant differences were seen between the prevalence of CFS in all groups of family members relative to the published community prevalence of 0.422% (spouses/partners: 3.2%, $p < 0.001$; offspring: 5.1%, $p < .001$; parents and siblings: 1.1%, $p < 0.02$; second and third degree blood relatives 0.8%, $p < 0.02$). The prevalence of CFS was higher in genetically unrelated household contacts and in nonresident genetic relatives than in the community, indicating that both household contact and genetic relationship are risk factors for CFS
Van Damme S, Crombez G, Van Houdenhove B, Mariman A, Michielsen W.	Department of Experimental-Clinical and Health Psychology, Ghent University, Ghent, Belgium. stefaan.vandamme@ugent.be	Well-being in patients with chronic fatigue syndrome: the role of acceptance.	J Psychosom Res. 2006 Nov;61(5):595-9.	OBJECTIVE: Research in chronic pain patients has shown that accepting the chronic nature of their illness is positively related to quality of life. The aim of this study was to investigate whether acceptance is also associated with better well-being in patients suffering from chronic fatigue syndrome (CFS). METHODS: Ninety-seven patients completed a battery of questionnaires measuring fatigue, functional impairment, psychological distress, and acceptance. RESULTS: Results indicated that acceptance has a positive effect upon fatigue and psychological aspects of well-being. More specifically, acceptance was related to more emotional stability and less psychological distress, beyond the effects of demographic variables, and fatigue severity. CONCLUSION: We suggest that promoting acceptance in patients with CFS may often be more beneficial than trying to control largely uncontrollable symptoms.
van de Putte EM, Engelbert RH, Kuis	Department of Paediatrics,	How fatigue is related to other	Arch Dis Child. 2006	AIMS: To assess the relation between fatigue and somatic symptoms in healthy adolescents and adolescents with chronic fatigue syndrome/myalgic encephalopathy (CFS/ME). METHODS: Seventy

W, Kimpen JL, Uiterwaal CS.	Wilhelmina Children's Hospital, University Medical Center Utrecht, Utrecht, The Netherlands. E.vandePutte@umcutrecht.nl	somatic symptoms.	Oct;91(10):824-7. Epub 2006 Jun 5.	two adolescents with CFS were compared within a cross-sectional study design with 167 healthy controls. Fatigue and somatic complaints were measured using self-report questionnaires, respectively the subscale subjective fatigue of the Checklist Individual Strength (CIS-20) and the Children's Somatization Inventory. RESULTS: Healthy adolescents reported the same somatic symptoms as adolescents with CFS/ME, but with a lower score of severity. The top 10 somatic complaints were the same: low energy, headache, heaviness in arms/legs, dizziness, sore muscles, hot/cold spells, weakness in body parts, pain in joints, nausea/upset stomach, back pain. There was a clear positive relation between log somatic symptoms and fatigue (linear regression coefficient: 0.041 points log somatic complaints per score point fatigue, 95% CI 0.033 to 0.049) which did not depend on disease status. CONCLUSIONS: Results suggest a continuum with a gradual transition from fatigue with associated symptoms in healthy adolescents to the symptom complex of CFS/ME.
van de Putte EM, van Doornen LJ, Engelbert RH, Kuis W, Kimpen JL, Uiterwaal CS.	Department of Pediatrics, Wilhelmina Children's Hospital, University Medical Center, Utrecht, The Netherlands. e.vandeputte@wkz.azu.nl	Mirrored symptoms in mother and child with chronic fatigue syndrome.	Pediatrics. 2006 Jun;117(6):2074-9.	OBJECTIVE: Our aim with this study was to assess the relation between chronic fatigue syndrome in adolescents and fatigue and associated symptoms in their fathers and mothers, more specifically the presence of chronic fatigue syndrome-like symptoms and psychologic distress. METHOD: In this cross-sectional study, 40 adolescents with chronic fatigue syndrome according to the Centers for Disease Control and Prevention criteria were compared with 36 healthy control subjects and their respective parents. Questionnaires regarding fatigue (Checklist Individual Strength), fatigue-associated symptoms, and psychopathology (Symptom Checklist-90) were applied to the children and their parents. RESULTS: Psychologic distress in the mother corresponds with an adjusted odds ratio of 5.6 for the presence of CFS in the child. The presence of fatigue in the mother and dimensional assessment of fatigue with the Checklist Individual Strength revealed odds ratios of, respectively, 5.29 and 2.86 for the presence of chronic fatigue syndrome in the child. An increase of 1 SD of the hours spent by the working mother outside the home reduced the risk for chronic fatigue syndrome in their child with 61%. The fathers did not show any risk indicator for chronic fatigue syndrome in their child. CONCLUSIONS: Mothers of adolescents with chronic fatigue syndrome exhibit fatigue and psychologic symptoms similar to their child in contrast with the fathers. The striking difference between the absent association in fathers and the evident association in mothers suggests that the shared symptom complex of mother and child is the result of an interplay between genetic vulnerability and environmental factors.
van Heukelom RO, Prins JB, Smits MG, Bleijenberg G.	Department of Neurology, Sleep-Wake Disorders and Chronobiology, Hospital De Gelderse Vallei, Ede, and Department of Medical Psychology,	Influence of melatonin on fatigue severity in patients with chronic fatigue syndrome and late melatonin secretion.	Eur J Neurol. 2006 Jan;13(1):55-60.	The effect of melatonin, a chronobiotic drug, was explored in 29 patients with chronic fatigue syndrome (CFS) and Dim Light Melatonin onset (DLMO) later than 21.30 hours, reflective of delayed circadian rhythmicity. The patients took 5 mg of melatonin orally, 5 h before DLMO during 3 months. Their responses to the checklist individual strength (CIS), a reliable questionnaire measuring the severity of personally experienced fatigue, were assessed twice with a 6-week interval immediately before the treatment and once after 3 months treatment. In the pre-treatment period the fatigue sub-score improved significantly. After treatment, the total CIS score and the sub-scores for fatigue, concentration, motivation and activity improved significantly. The sub-score fatigue normalized in two of the 29 patients in the pre-treatment period and in eight of 27 patients during treatment. This change was significant. In the patients with DLMO later than 22.00 hours (n=21) the total CIS score and the sub-scores for fatigue, concentration and activity improved significantly more than in the

	Radbound University Medical Centre, Nijmegen, The Netherlands.			patients (n=8) with DLMO earlier than 22.00 hours. Melatonin may be an effective treatment for patients with CFS and late DLMO, especially in those with DLMO later than 22.00 hours.
Van Hoof E, De Becker P, De Meirleir K.		Pediatric Chronic Fatigue Syndrome and Muchausen-by-Proxy: A Case Study	Journal of Chronic Fatigue Syndrome 2006;13(2/3): 45-53	Pediatric chronic fatigue syndrome (CFS) posits even more challenges for professional caregivers in comparison with adult CFS samples. Most children with CFS display a decrease in school attendance and a decrease in social activities. As several conditions such as school phobia, primary psychiatric disorders or family disturbance present the same characteristics, the diagnostic process appears more complex. Family disturbance, moreover, is often specified as child abuse, neglect or even Muchausen-by-proxy. As skepticism is frequently associated with a diagnosis of CFS, patients and parents must fend for themselves fighting allegations of child abuse and neglect. This case study illustrates what happens when such allegations are put forward.
Van Houdenhove B, Bruyninckx K, Luyten P.	Chronic Fatigue Reference Centre, University Hospitals, K.U. Leuven, Leuven, Belgium. boudewijn.vanhoudenhove@uz.kuleuven.ac.be	In search of a new balance. Can high "action-proneness" in patients with chronic fatigue syndrome be changed by a multidisciplinary group treatment?	J Psychosom Res. 2006 Jun;60(6):623-5.	OBJECTIVE: The purpose of this study is to investigate changes in action-proneness (a cognitive and behavioral tendency toward direct action) after a multidisciplinary group intervention, including cognitive behaviour therapy (CBT) and graded exercise therapy (GET). METHODS: Patients with chronic fatigue syndrome (n=62) completed three versions of a Dutch self-report questionnaire evaluating action-proneness retrospectively that is (1) before illness onset, (2) before treatment and (3) after treatment. Significant others (n=62) also gave their opinion about the patients' action-proneness at time points 1 and 2. RESULTS: Premorbid action-proneness levels considerably dropped after illness onset. After treatment, action-proneness levels significantly increased again, although levels remained below premorbid levels. CONCLUSION: High action-proneness retrospectively reported by CFS patients can be adaptively modified by a multidisciplinary group treatment including CBT and GET.
Van Houdenhove B.		Psychiatric comorbidity and chronic fatigue syndrome.	Br J Psychiatry. 2006 Apr;188:395; author reply 396.	
van Staden WC.	Department of Psychiatry, University of Pretoria, Pretoria, South Africa. cwvanstaden@icon.co.za	Conceptual issues in undifferentiated somatoform disorder and chronic fatigue syndrome.	Curr Opin Psychiatry. 2006 Nov;19(6):613-8.	PURPOSE OF REVIEW: To review the conceptual problems in distinguishing between undifferentiated somatoform disorder and chronic fatigue syndrome, for both may present with fatigue as the main symptom. RECENT FINDINGS: The differences and/or similarities between undifferentiated somatoform disorder and chronic fatigue syndrome have not been studied, conceptually or empirically. The literature fails to present discriminant validity of chronic fatigue syndrome in relation to undifferentiated somatoform disorder. A critical feature is implied in the definition of undifferentiated somatoform disorder but absent from the definitions of chronic fatigue syndrome: some patients experience their fatigue as being exclusively physical and not as mental, which is prima facie peculiar, for fatigue is necessarily a mental experience. One is not able to experience fatigue without a mind (or a brain). This experience is characterized as a 'mindless' fatigue, underpinned by pathological reductionist thinking. By not recognizing this critical feature, diagnostic endeavours may perpetuate the problem as a function of the patient's difficulty. SUMMARY: Proponents of chronic fatigue syndrome should distinguish chronic fatigue syndrome from undifferentiated somatoform

				disorder, if chronic fatigue syndrome is a distinct entity at all. Further, the 'mindless' quality is a critical feature that needs consideration in refining the concept of undifferentiated somatoform disorder.
Vermeulen RC, Scholte HR.	CFS and Pain Research Center Amsterdam, Waalstraat 25-31, 1078 BR Amsterdam, The Netherlands. rv@cvscentrum.nl.	Azithromycin in Chronic Fatigue Syndrome (CFS), an analysis of clinical data.	J Transl Med. 2006 Aug 15;4:34.	ABSTRACT: BACKGROUND: CFS is a clinical state with defined symptoms, but undefined cause. The patients may show a chronic state of immune activation and treatment with an antibiotic in this subgroup has been suggested. METHODS: In a retrospective study, the response of CFS patients to azithromycin, an antibiotic and immunomodulating drug, has been scored from the patients records and compared with clinical and laboratory data. Azithromycin was not the first choice therapy, but offered when the effect of counseling and L-carnitine was considered insufficient by the patient and the clinician. RESULTS: Of the 99 patients investigated, 58 reported a decrease in the symptoms by the use of azithromycin. These responding patients had lower levels of plasma acetylcarnitine. CONCLUSION: The efficacy of azithromycin in the responsive patients could be explained by the modulating effect on a chronic primed state of the immune cells of the brain, or the activated peripheral immune system. Their lower acetylcarnitine levels may reflect a decreased antioxidant defense and/or an increased consumption of acetylcarnitine caused by oxidative stress.
Vermeulen RC.	CFS and Pain Research Center Amsterdam, Amsterdam, The Netherlands. rv@cvscentrum.nl.	Translation and validation of the Dutch language version of the CDC Symptom Inventory for assessment of Chronic Fatigue Syndrome (CFS).	Popul Health Metr. 2006 Oct 18;4:12.	ABSTRACT: BACKGROUND: In a study by Wagner et al., the CDC Symptom Inventory was validated in a population selected from the inhabitants of a city in the USA, and proofed reliable for the assessment of the accompanying symptoms of CFS. The Dutch translation of the CDC Symptom Inventory is compared to the original and the psychometric properties are presented for patients in a tertiary care setting. METHODS: One hundred thirty-nine consecutive patients who visited the CFS Center Amsterdam for the first time were asked to complete the CDC Symptom Inventory in the Dutch Language Version (DLV) together with the usual set of questionnaires. Sixty-one patients had Chronic Fatigue (CF) and 78 patients fulfilled the criteria for CFS. Forty-three healthy accompanying persons completed the CDC Symptom Inventory DLV, the Physical Functioning scale of the Medical Outcome Survey Short Form-36 DLV, and the Fatigue and Concentration scales of the Checklist Individual Strength (CIS-20). RESULTS: The healthy controls group contained fewer women and was overall older than the patient groups. The influence of gender on the CDC Symptom Inventory DLV was significant but the effect of age was not. The Dutch version had a good internal consistency and convergent validity. The results were comparable to the original English version, but the sex-related difference needs further study. CONCLUSION: The Dutch version of the CDC Symptom Inventory is a reliable tool for the assessment of the secondary criteria for CFS. The results show that it is comparable to the outcome of studies in English speaking countries.
Vernon SD, Reeves WC.	Centers for Disease Control and Prevention, National Center for Infectious Diseases, Atlanta, GA, USA. sdv2@cdc.gov	The challenge of integrating disparate high-content data: epidemiological, clinical and laboratory data collected during an in-hospital study of	Pharmacogenomics. 2006 Apr;7(3):345-54. Comment in: Pharmacogenomics. 2006 Apr;7(3):341-3.	Chronic fatigue syndrome (CFS) is a debilitating illness characterized by multiple unexplained symptoms including fatigue, cognitive impairment and pain. People with CFS have no characteristic physical signs or diagnostic laboratory abnormalities, and the etiology and pathophysiology remain unknown. CFS represents a complex illness that includes alterations in homeostatic systems, involves multiple body systems and results from the combined action of many genes, environmental factors and risk-conferring behavior. In order to achieve understanding of complex illnesses, such as CFS, studies must collect relevant epidemiological, clinical and laboratory data and then integrate, analyze and interpret the information so as to obtain meaningful clinical and biological insight. This issue of Pharmacogenomics represents such an approach to CFS. Data was collected during a 2-day in-hospital

		chronic fatigue syndrome.		study of persons with CFS, other medically and psychiatrically unexplained fatiguing illnesses and nonfatigued controls identified from the general population of Wichita, KS, USA. While in the hospital, the participants' psychiatric status, sleep characteristics and cognitive functioning was evaluated, and biological samples were collected to measure neuroendocrine status, autonomic nervous system function, systemic cytokines and peripheral blood gene expression. The data generated from these assessments was made available to a multidisciplinary group of 20 investigators from around the world who were challenged with revealing new insight and algorithms for integration of this complex, high-content data and, if possible, identifying molecular markers and elucidating pathophysiology of chronic fatigue. The group was divided into four teams with representation from the disciplines of medicine, mathematics, biology, engineering and computer science. The papers in this issue are the culmination of this 6-month challenge, and demonstrate that data integration and multidisciplinary collaboration can indeed yield novel approaches for handling large, complex datasets, and reveal new insight and relevance to a complex illness such as CFS.
Vernon SD, Whistler T, Aslakson E, Rajeevan M, Reeves WC.	Center for Infectious Diseases, Division of Viral and Rickettsial Diseases, National Centers for Disease Control and Prevention, Atlanta, GA 30333, USA. svernon@cdc.gov	Challenges for molecular profiling of chronic fatigue syndrome.	Pharmacogenomics. 2006 Mar;7(2):211-8.	Chronic fatigue syndrome (CFS) is prevalent, disabling and costly. Despite extensive literature describing the epidemiology and clinical aspects of CFS, it has been recalcitrant to diagnostic biomarker discovery and therapeutic intervention. This is due to the fact that CFS is a complex illness defined by self-reported symptoms and diagnosed by the exclusion of medical and psychiatric diseases that may explain the symptoms. Studies attempting to dissect the pathophysiology are challenging to design as CFS affects multiple body systems, making the choice of which system to study dependent on an investigators area of expertise. However, the peripheral blood appears to be facilitating the molecular profiling of several diseases, such as CFS, that involve bodywide perturbations that are mediated by the CNS. Successful molecular profiling of CFS will require the integration of genetic, genomic and proteomic data with environmental and behavioral data to define the heterogeneity in order to optimize intervention.
Vervoort T, Crombez G, Buysse A, Goubert L, De Backer T, Ickes W.	Department of Experimental-Clinical and Health Psychology, Ghent University, Belgium; Research Institute for Psychology and Health, The Netherlands.	Brief Report: The Accuracy of Parents for the Thoughts and Feelings of Their Adolescent Suffering from Chronic Fatigue: A Preliminary Study of Empathy.	J Pediatr Psychol. 2006 Sep 29; [Epub ahead of print]	Objective This study examined the actual and estimated empathic accuracy (EA) of the parents of adolescents with chronic fatigue syndrome (CFS). Methods The actual EA of both parents (n = 24) was assessed in relation to the thoughts and feelings of their child (n = 14) about CFS and about other life events. Adolescents were also asked to estimate the parents' EA. Results For the actual EA, both parents were significantly less accurate regarding the adolescent's thoughts and feelings about CFS than about other life events. Fathers were just as empathically accurate as mothers. For the estimated EA, however, results indicated that adolescents perceived their mother to be more empathically accurate than their father. Actual EA and estimated EA about CFS were negatively correlated for fathers, not for mothers. Conclusions Results are discussed in terms of the importance of assessing EA in relation to other dimensions of empathic understanding and distress in the observer.
Vollmer-Conna U, Aslakson E, White PD.	University of New South Wales, School of Psychiatry, 30 Botany Street,	An empirical delineation of the heterogeneity of chronic unexplained	Pharmacogenomics. 2006 Apr;7(3):355-64.	OBJECTIVES: To test the hypothesis that medically unexplained chronic fatigue and chronic fatigue syndrome (CFS) are heterogeneous conditions, and to define the different conditions using both symptom and laboratory data. METHODS: We studied 159 women from KS, USA. A total of 51 of these suffered from fatigue consistent with established criteria for CFS, 55 had chronic fatigue of insufficient symptoms/severity for a CFS diagnosis and 53 were healthy controls matched by age and body mass

	Sydney UNSW 2052, Australia. ute@unsw.edu.au	fatigue in women.		index (BMI) against those with CFS. We used principal components analyses to define factors that best described the variable space and to reduce the number of variables. The 38 most explanatory variables were then used in latent class analyses to define discrete subject groups. RESULTS: Principal components analyses defined six discrete factors that explained 40% of the variance. Latent class analyses provided several interpretable solutions with four, five and six classes. The four-class solution was statistically most convincing, but the six-class solution was more interpretable. Class 1 defined 41 (26%) subjects with obesity and relative sleep hypnoea. Class 2 were 38 (24%) healthy subjects. Class 3 captured 24 (15%) obese relatively hypnoeic subjects, but with low heart rate variability and cortisol. Class 4 were 23 (14%) sleep-disturbed and myalgic subjects without obesity or significant depression. The two remaining classes with 22 (14%) and 11 (7%) subjects consisted of the most symptomatic and depressed, but without obesity or hypnoea. Class 5 had normal sleep indices. Class 6 was characterized by disturbed sleep, with low sleep heart rate variability, cortisol, and sex hormones. CONCLUSION: Chronic medically unexplained fatigue is heterogeneous. The putative syndromes were differentiated by obesity, sleep hypnoea, depression, physiological stress response, sleep disturbance, interoception and menopausal status. If these syndromes are externally validated and replicated, they may prove useful in determining the causes, pathophysiology and treatments of CFS.
Wallace DJ.	Cedars-Sinai/David Geffen School of Medicine at UCLA, Los Angeles, CA, USA. dwallace@ucla.edu	Is there a role for cytokine based therapies in fibromyalgia.	Curr Pharm Des. 2006;12(1):17-22.	Cytokines are glycoproteins that serve as chemical messengers between cells. They assist in the regulation of cell growth and repair and also have immune modulating properties. Cytokines play a role in diverse clinical processes and phenomena such as fatigue, fever, sleep, pain, stress and aching. A review of the fibromyalgia literature and related studies suggest that IL-1, IL-6 and IL-8 are dysregulated in the syndrome. Therapies directed against these cytokines may be of potential importance in the management of fibromyalgia.

Waltman P, Pearlman A, Mishra B.	New York University, Courant Institute of Mathematical Sciences, 715 Broadway, New York, NY 10003, USA. mishra@nyu.edu	Interpreter of maladies: redescription mining applied to biomedical data analysis.	Pharmacogenomics. 2006 Apr;7(3):503-9.	Comprehensive, systematic and integrated data-centric statistical approaches to disease modeling can provide powerful frameworks for understanding disease etiology. Here, one such computational framework based on redescription mining in both its incarnations, static and dynamic, is discussed. The static framework provides bioinformatic tools applicable to multifaceted datasets, containing genetic, transcriptomic, proteomic, and clinical data for diseased patients and normal subjects. The dynamic redescription framework provides systems biology tools to model complex sets of regulatory, metabolic and signaling pathways in the initiation and progression of a disease. As an example, the case of chronic fatigue syndrome (CFS) is considered, which has so far remained intractable and unpredictable in its etiology and nosology. The redescription mining approaches can be applied to the Centers for Disease Control and Prevention's Wichita (KS, USA) dataset, integrating transcriptomic, epidemiological and clinical data, and can also be used to study how pathways in the hypothalamic-pituitary-adrenal axis affect CFS patients.
Wang JJ, Meng H, Cui CB, Song YJ,	Institute of Acupuncture &	[On the important role of Siguan	Zhongguo Zhen Jiu. 2006	OBJECTIVE: To probe into the role of Siguan points in treatment of chronic fatigue syndrome. CONCLUSION: Acupuncture at Siguan as main points has a better therapeutic effect on chronic fatigue syndrome.
Wearden AJ, Riste L, Dowrick C, Chew-Graham C, Bentall RP, Morriss RK, Peters S, Dunn G, Richardson G, Lovell K, Powell P.	School of Psychological Sciences, University of Manchester, Manchester, M13 9PL, UK. alison.wearden@manchester.ac.uk	Fatigue Intervention by Nurses Evaluation--the FINE Trial. A randomised controlled trial of nurse led self-help treatment for patients in primary care with chronic fatigue syndrome: study protocol. [ISRCTN74156610].	BMC Med. 2006 Apr 7;4:9.	BACKGROUND: Chronic fatigue syndrome, also known as ME (CFS/ME), is a condition characterised primarily by severe, disabling fatigue, of unknown origin, which has a poor prognosis and serious personal and economic consequences. Evidence for the effectiveness of any treatment for CFS/ME in primary care, where most patients are seen, is sparse. Recently, a brief, pragmatic treatment for CFS/ME, based on a physiological dysregulation model of the condition, was shown to be successful in improving fatigue and physical functioning in patients in secondary care. The treatment involves providing patients with a readily understandable explanation of their symptoms, from which flows the rationale for a graded rehabilitative plan, developed collaboratively with the therapist. The present trial will test the effectiveness and cost-effectiveness of pragmatic rehabilitation when delivered by specially trained general nurses in primary care. We selected a client-centred counselling intervention, called supportive listening, as a comparison treatment. Counselling has been shown to be as effective as cognitive behaviour therapy for treating fatigue in primary care, is more readily available, and controls for supportive therapist contact time. Our control condition is treatment as usual by the general practitioner (GP). METHODS AND DESIGN: This study protocol describes the design of an ongoing, single-blind, pragmatic randomized controlled trial of a brief (18 week) self-help treatment, pragmatic rehabilitation, delivered by specially trained nurse-therapists in patients' homes, compared with nurse-therapist delivered supportive listening and treatment as usual by the GP. An economic evaluation, taking a societal viewpoint, is being carried out alongside the clinical trial. Three adult general nurses were trained over a six month period to deliver the two interventions. Patients aged over 18 and fulfilling the Oxford criteria for CFS are assessed at baseline, after the intervention, and again one year later. Primary outcomes are self-reported physical functioning and fatigue at one year, and will be analysed on an intention-to-treat basis. A qualitative study will examine the interventions' mechanisms of change, and also GPs' drivers and barriers towards referral.
Weidenhammer W, Wessel A, Hutter A, Melchart D, Schroder A.	Zentrum fur naturheilkundliche Forschung, II. Medizinische Klinik und Poliklinik, TU Munchen, Kaiserstrasse 9, 80801 Munich. Wolfgang.Weidenhammer@ltz.tu-muenchen.de	[Chronic fatigue in complementary rehabilitative medicine--predictors of the outcomes] [Article in German]	Rehabilitation (Stuttg). 2006 Oct;45(5):299-308.	Chronic exhaustion and fatigue are increasingly important in rehabilitation medicine. Objectives of this study were (a) to describe the effects of in-patient rehabilitation on patients with chronic fatigue syndromes, (b) to identify predictors for treatment outcome, and (c) to analyze the impact of comprehensive diagnosing on these issues. A total of 171 patients with chronic exhaustion or fatigue (90 % female, mean age 55 +/- 10 yrs) from a rehabilitation hospital with a complementary medicine-based treatment concept were included in a prospective observational study. Within the longitudinal study patients were examined three times (on admission to hospital, at discharge as well as six months later). Participation rate of the postal inquiry was 69 %. Besides items constructed ad hoc, Patient questionnaires included the Symptom Checklist and assessment instruments for depression, quality of life, sense of coherence as well as for changes in experience and behaviour. Treatment outcome was defined as sum score of binary-coded response criteria. The pattern of complaints differed clearly between diagnostic subgroups (neurasthenia, affective disorders, adjustment

				disorders) before treatment. At discharge from hospital patients showed clinically relevant improvements lasting for six months after rehabilitation. Multiple regression analyses revealed a statistically significant relationship (R (mult) = 0.59) between predictors and outcome at discharge from hospital. A better result was associated with higher trust in treatment success, active information seeking on complementary medicine, healthier feeding habits, better somatic health and a decreased mental status, with regard to the status before treatment. The prediction of outcome after six months was comparably poorer (R (mult) = 0.42). Treatment success was higher in the absence of a diagnosis of neurasthenia, in patients accepting the group-oriented treatment concept and in patients not believing that their disease was due to their own way of living. Trust in the success of the treatment was a highly ranked predictor for longer lasting outcome, too. The results underline the importance of motivation aspects for treatment outcome indicating that individual expectations and attitudes should be considered in a more distinct way when allocating patients to rehabilitative programmes.
Weir PT, Harlan GA, Nkoy FL, Jones SS, Hegmann KT, Gren LH, Lyon JL.	Department of Family and Preventive Medicine, University of Utah, Salt Lake City, Utah 84108, USA. peter.weir@hsc.utah.edu	The incidence of fibromyalgia and its associated comorbidities: a population-based retrospective cohort study based on International Classification of Diseases, 9th Revision codes.	J Clin Rheumatol. 2006 Jun;12(3):124-8.	BACKGROUND: The epidemiology of fibromyalgia is poorly defined. The incidence of fibromyalgia has not been determined using a large population base. Previous studies based on prevalence data demonstrated that females are 7 times more likely to have fibromyalgia than males and that the peak age for females is during the childbearing years. OBJECTIVE: We have calculated the incidence rate of fibromyalgia in a large, stable population and determined the strength of association between fibromyalgia and 7 comorbid conditions. METHODS: We conducted a retrospective cohort study of a large, stable health insurance claims database (62,000 nationwide enrollees per year). Claims from 1997 to 2002 were examined using the International Classification of Diseases, 9th Revision, Clinical Modification (ICD-9-CM) codes to identify fibromyalgia cases (ICD code 729.1) and 7 predetermined comorbid conditions. RESULTS: A total of 2595 incident cases of fibromyalgia were identified between 1997 and 2002. Age-adjusted incidence rates were 6.88 cases per 1000 person-years for males and 11.28 cases per 1000 person-years for females. Females were 1.64 times (95% confidence interval = 1.59-1.69) more likely than males to have fibromyalgia. Patients with fibromyalgia were 2.14 to 7.05 times more likely to have one or more of the following comorbid conditions: depression, anxiety, headache, irritable bowel syndrome, chronic fatigue syndrome, systemic lupus erythematosus, and rheumatoid arthritis. CONCLUSION: Females are more likely to be diagnosed with fibromyalgia than males, although to a substantially smaller degree than previously reported, and there are strong associations for comorbid conditions that are commonly thought to be associated with fibromyalgia.
Whistler T, Taylor R, Craddock RC, Broderick G, Klimas N, Unger ER.	Centers for Disease Control and Prevention, Viral Exanthems and Herpesvirus Branch, Atlanta, GA 30333, USA. taw6@cdc.gov	Gene expression correlates of unexplained fatigue.	Pharmacogenomics. 2006 Apr;7(3):395-405.	Quantitative trait analysis (QTA) can be used to test whether the expression of a particular gene significantly correlates with some ordinal variable. To limit the number of false discoveries in the gene list, a multivariate permutation test can also be performed. The purpose of this study is to identify peripheral blood gene expression correlates of fatigue using quantitative trait analysis on gene expression data from 20,000 genes and fatigue traits measured using the multidimensional fatigue inventory (MFI). A total of 839 genes were statistically associated with fatigue measures. These mapped to biological pathways such as oxidative phosphorylation, gluconeogenesis, lipid metabolism, and several signal transduction pathways. However, more than 50% are not functionally annotated or associated with identified pathways. There is some overlap with genes implicated in other studies

				using differential gene expression. However, QTA allows detection of alterations that may not reach statistical significance in class comparison analyses, but which could contribute to disease pathophysiology. This study supports the use of phenotypic measures of chronic fatigue syndrome (CFS) and QTA as important for additional studies of this complex illness. Gene expression correlates of other phenotypic measures in the CFS Computational Challenge (C3) data set could be useful. Future studies of CFS should include as many precise measures of disease phenotype as is practical.
Whitehead L.	Department of Nursing and Midwifery, University of Stirling, Western Isles Hospital, Macaulay Road, Stornoway, UK. lw6@stir.ac.uk	Toward a trajectory of identity reconstruction in chronic fatigue syndrome/myalgic encephalomyelitis: a longitudinal qualitative study.	Int J Nurs Stud. 2006 Nov;43(8):1023-31. Epub 2006 Mar 9.	BACKGROUND: Chronic fatigue syndrome/myalgic encephalomyelitis (CFS/ME) is an illness associated with high levels of physical and cognitive disability over a prolonged period of time. Recovery from CFS/ME can be interspersed with relapses. Further, the legitimacy of the illness continues to be questioned within and beyond the health profession. AIM: This paper examines the reconstruction of self-identity for those experiencing CFS/ME. METHOD: This longitudinal qualitative study involved up to three in-depth interviews with 17 people with CFS/ME and family members. RESULTS: A trajectory that describes transitions in identity over time and the range of elements that influence these is proposed. During the acute phase of illness, characterised by total debility, people adopted the traditional sick role. The medium term phase highlighted movement between disability as part of the total self, total debility, and/or the adoption of a supernormal identity. The longer-term phase was defined for the majority of participants as the positive reconstruction of self. Identity was contingent with positive and negative experiences and responses co-existing with the potential to 'tip' the balance and perceived identity. In the longer term people's identity became more static with the development of coping strategies to maintain this. The trajectory can be described as pendular and movement between each type of identity was possible during all phases of the illness experience depending on the nature and impact of the illness and responses given to these. The proposed trajectory represents a dynamic model of identity reconstruction. CONCLUSION: Understanding the patients' experience and recognising that different stages may exist is important for health professionals. This awareness can enhance shared understanding and opportunities to work with people in negotiating the impact of illness.
Whitehead LC.	University of Stirling Stornoway, UK. lw6@stir.ac.uk	Quest, chaos and restitution: living with chronic fatigue syndrome/myalgic encephalomyelitis.	Soc Sci Med. 2006 May;62(9):2236-45. Epub 2005 Oct 19.	Chronic illness is disruptive, threatening people's sense of identity and taken for granted assumptions. Transformations in values, expectations and life priorities are likely to be experienced and in order to regain a coherent sense of self, people must interpret their experiences. People with difficult to diagnose illnesses can find themselves living with greater uncertainty and stigma. This paper explores how people with chronic fatigue syndrome/myalgic encephalomyelitis (CFS/ME) describe and interpret their illness experience by applying Arthur Frank's narrative typologies to analyse interviews with 17 British people with CFS/ME. The analysis proposes that a trajectory of narrative typologies is experienced, starting with a restitution narrative, moving to a chaos narrative and, for most, back to a restitution narrative and on to a quest narrative. The presentation of narrative types put forward by people living with CFS/ME differ to those presented by people who are HIV positive and have been treated for breast cancer.

Yoshiuchi K, Farkas J, Natelson BH.	Department of Neurosciences, Fatigue Research Center, UMDNJ-New Jersey Medical School, Newark, USA. kyoshiuc-tky@umin.ac.jp	Patients with chronic fatigue syndrome have reduced absolute cortical blood flow.	Clin Physiol Funct Imaging. 2006 Mar;26(2):83-6.	Prior studies on brain blood flow in chronic fatigue syndrome (CFS) did not find consistent results. This may be because they used single-photon emission computed tomography to measure brain blood flow, which could not measure absolute blood flow. Therefore, the aim of this study was to test the hypothesis that patients with CFS have reduced absolute cerebral blood flow. Xenon-computed tomography blood flow studies were done on 25 CFS patients and seven healthy controls. Analyses were done after stratifying the CFS patients based on the presence or absence of a current psychiatric disorder. Flow was diminished in both groups as follows: patients with no current psychiatric disorders had reduced cortical blood flow in the distribution of both right and left middle cerebral arteries ($P<0.05$ for both) while those with current psychiatric disorders had reduced blood flow only in the left middle cerebral artery territory ($P<0.05$). These data indicate that patients with CFS have reduced absolute cortical blood flow in rather broad areas when compared with data from healthy controls and that those devoid of psychopathology had the most reductions in cortical flow. These data support, in part, our earlier findings that patients devoid of psychopathology are the group most at risk of having some of the symptoms of CFS due to brain dysfunction.
Yuemei L, Hongping L, Shulan F, Dongfang G.	First Hospital Affiliated to Guangzhou University of Traditional Chinese Medicine, Guangzhou 510405, China.	The therapeutic effects of electrical acupuncture and auricular-plaster in 32 cases of chronic fatigue syndrome.	J Tradit Chin Med. 2006 Sep;26(3):163-4.	OBJECTIVE: To observe the therapeutic effects of electrical acupuncture and auricular-plaster therapy for chronic fatigue syndrome (CFS). METHOD: 64 CFS patients were randomly divided into two groups. 32 cases in the treatment group were treated by the electrical acupuncture and auricular-plaster therapy, and 32 cases in the control group with oral hydrocortisone. RESULTS: The total effective rates were respectively 93.75% in the treatment group and 75.00% in the control group, with a statistically significant difference between the two groups ($P < 0.05$). CONCLUSION: Electrical acupuncture and auricular-plaster therapy may show a better anti-fatigue effect than that of routine Western drugs.
Zuckerman JN.	Academic Centre for Travel Medicine and Vaccines and WHO Collaborating Centre for Reference, Research and Training in Travel Medicine, Royal Free and University College Medical School, University College London,	Protective efficacy, immunotherapeutic potential, and safety of hepatitis B vaccines.	J Med Virol. 2006 Feb;78(2):169-77.	Hepatitis B vaccines are highly effective and safe and have been incorporated into national immunization programs in over 150 countries. The major humoral immune response is to the common a determinant of the surface antigen protein of the virus. Approximately 5-10% of healthy immunocompetent subjects do not mount an antibody response (anti-HBs). Non-response is associated with different HLA-DR alleles and impaired Th cell response, among other factors such as route of injection, age, gender, body mass, and other factors. Important hepatitis B surface antigen variants have also been identified, which may have a potential impact on immunization and routine screening of blood, blood products and tissues, and organs for transplantation. Strategies for hepatitis B immunization are reviewed. Over 1,000 million doses of hepatitis B vaccine have been used with an outstanding record of safety. There is no evidence of an association between hepatitis B vaccines and the sudden infant death syndrome, chronic fatigue syndrome, and multiple sclerosis (MS). Several studies are in progress on treatment of chronic hepatitis B infection by immunization with multiple antigenic components, combination of vaccine with antiviral drugs and cytokines, T cell vaccines, DNA vaccines alone or with DNA encoded immunomodulatory cytokines, and direct genetic manipulation

Service de pediatrie-medecine neonatale, CHI Poissy-Saint-Germain, 78300 Poissy. darmenga@chi-psg.com	[Chronic fatigue and sleep disorders in adolescents] [Article in French]	Rev Prat. 2005 May 31;55(10):1095-8.	To be, or to feel tired, is a frequent complaint at any age, and which does not seem in itself to be specific of the teenager. If it frequently lies within the scope of an organic pathology, acute or chronic, besides while being able to be a revealing element for it, it is often insulated and asks a rigorous step in the evaluation of its various possible components. It is then important to be in an active listening and patient, and not in a hasty regulation of a "cosmetic" treatment of this subjective allegation. It is all the work of the doctor whom to support the emergence of the subjacent complaint whose tensions and stakes of adolescence post there their singularity.

Axe EK, Satz P, Rasgon NL, Fawzy FI		ORIGINAL RESEARCH Major Depressive Disorder in Chronic Fatigue Syndrome: A CDC Surveillance Study	Journal of Chronic Fatigue Syndrome 2005 12 (3): 7-23	Background: Controversy continues to exist as to whether Chronic Fatigue Syndrome is a psychological/psychiatric disorder. To further understand this condition the Centers for Disease Control (CDC) conducted a Surveillance Study. The CDC partitioned 565 subjects with fatiguing illnesses into four diagnostic groups, one of which met the 1988 CDC criteria for CFS. The non-CFS groups had either insufficient severity (idiopathic), medical exclusions or prior psychiatric disorders. Objectives: The present study reports on the psychiatric features in that study, estimates the time of onset of Major Depressive Disorder (MDD) and looks for possible relationships between 1988 CDC criteria for Chronic Fatigue Syndrome and psychiatric disorders. Methods: The study design is cross-sectional. The Diagnostic Interview Schedule (DIS) assessed for four Axis I psychiatric disorders. Time of onset ofMDDwas estimated from the DIS and validated by an examination of the medical records. Odds ratios and confidence intervals were calculated as tests of association between 1988 CDC criteria and psychiatric disorders. Results: Subjects classified as CFS and non-CFS had similar rates of psychiatric disorders. A minority of subjects had preexisting MDD. Three 1988 CDC criteria were

				associated with current MDD whilst no criteria were associated with prior MDD. Conclusions: CFS subjects did not demonstrate any unique patterns of psychiatric disorders. MDD may not be an important predisposing factor for CFS or the other fatiguing illnesses. Some 1988 CDC criteria may be preferentially endorsed by subjects with current MDD.
Badawy AA, Morgan CJ, Llewelyn MB, Albuquerque SR, Farmer A.	Cardiff & Vale NHS Trust, Biomedical Research Laboratory, Whitchurch Hospital, Cardiff, Wales, UK. Abdulla.Badawy@cardiffandvale.wales.nhs.uk	Heterogeneity of serum tryptophan concentration and availability to the brain in patients with the chronic fatigue syndrome.	J Psychopharmacol. 2005 Jul;19(4):385-91.	We assessed the serotonin status of patients with the chronic fatigue syndrome (CFS). Tryptophan (Trp) availability to the brain, expressed as the ratio of concentration of serum Trp to the sum of those of its five competitors (CAA), and other parameters of Trp disposition were compared in 23 patients with the CFS and 42 healthy controls. The serum [free Trp]/[CAA] ratio was 43% higher in CFS patients, due to a 48% higher [free Trp]. [Total Trp] was also significantly higher (by 19%) in CFS patients, and, although the [total Trp]/[CAA] ratio did not differ significantly between the control and patient groups, the difference became significant when the results were co-varied with age and gender. [CAA] was not significantly different between groups, but was significantly lower in females, compared to males, of the CFS patient group. We have established normal ranges for Trp disposition parameters and propose criteria for defining the serotonin-biosynthetic status in humans. We have provisionally identified two subgroups of CFS patients, one with normal serotonin and the other with a high serotonin status. The relevance of our findings to, and their implications for, the pharmacological and other therapies of the chronic fatigue syndrome are discussed.
Baraniuk JN, Casado B, Maibach H, Clauw DJ, Pannell LK, Hess S S.	Georgetown University Proteomics Laboratory, Division of Rheumatology, Immunology & Allergy, Room B-105, Lower Level Kober-Cogan Building, Georgetown University, Washington, DC 20007-2197, USA. HUbaraniuj@georgetown.eduUH	A Chronic Fatigue Syndrome - related proteome in human cerebrospinal fluid.	BMC Neurol. 2005 Dec 1;5:22.	BACKGROUND: Chronic Fatigue Syndrome (CFS), Persian Gulf War Illness (PGI), and fibromyalgia are overlapping symptom complexes without objective markers or known pathophysiology. Neurological dysfunction is common. We assessed cerebrospinal fluid to find proteins that were differentially expressed in this CFS-spectrum of illnesses compared to control subjects. METHODS: Cerebrospinal fluid specimens from 10 CFS, 10 PGI, and 10 control subjects (50 mul/subject) were pooled into one sample per group (cohort 1). Cohort 2 of 12 control and 9 CFS subjects had their fluids (200 mul/subject) assessed individually. After trypsin digestion, peptides were analyzed by capillary chromatography, quadrupole-time-of-flight mass spectrometry, peptide sequencing, bioinformatic protein identification, and statistical analysis. RESULTS: Pooled CFS and PGI samples shared 20 proteins that were not detectable in the pooled control sample (cohort 1 CFS-related proteome). Multilogistic regression analysis (GLM) of cohort 2 detected 10 proteins that were shared by CFS individuals and the cohort 1 CFS-related proteome, but were not detected in control samples. Detection of >or=1 of a select set of 5 CFS-related proteins predicted CFS status with 80% concordance (logistic model). The proteins were alpha-1-macroglobulin, amyloid precursor-like protein 1, keratin 16, orosomucoid 2 and pigment epithelium-derived factor. Overall, 62 of 115 proteins were newly described. CONCLUSION: This pilot study detected an identical set of central nervous system, innate immune and amyloidogenic proteins in cerebrospinal fluids from two independent cohorts of subjects with overlapping CFS, PGI and fibromyalgia. Although syndrome names and definitions were different, the proteome and presumed pathological mechanism(s) may be shared.
Baraniuk JN, Petrie KN, Le U, Tai CF, Park YJ, Yuta A, Ali M, Vandenbussche	Division of Rheumatology, Immunology and Allergy,	Neuropathology in rhinosinusitis.	Am J Respir Crit Care Med. 2005 Jan 1;171(1):5-11. Epub 2004 Oct 11.	Pathophysiologic differences in neural responses to hypertonic saline (HTS) were investigated in subjects with acute sinusitis (n = 25), subjects with chronic fatigue syndrome (CFS) with nonallergic rhinitis (n = 14), subjects with active allergic rhinitis (AR; n = 17), and normal (n = 20) subjects. Increasing strengths of HTS were sprayed into their nostrils at 5-minute intervals. Sensations of nasal

CJ, Nelson B.	Georgetown University, 3800 Reservoir Road, N.W., Washington, DC 20007-2197, USA. baraniuj@georgetown.edu			pain, blockage, and drip increased with concentration and were significantly elevated above normal. These parallels suggested activation of similar subsets of afferent neurons. Urea and lysozyme secretion were dose dependent in all groups, suggesting that serous cell exocytosis was one source of urea after neural stimulation. Only AR and normal groups had mucin dose responses and correlations between symptoms and lysozyme secretion (R(2) = 0.12-0.23). The lysozyme dose responses may represent axon responses in these groups. The neurogenic stimulus did not alter albumin (vascular) exudation in any group. Albumin and mucin concentrations were correlated in sinusitis, suggesting that nonneurogenic factors predominated in sinusitis mucous hypersecretion. CFS had neural hypersensitivity (pain) but reduced serous cell secretion. HTS nasal provocations identified significant, unique patterns of neural and mucosal dysregulation in each rhinosinusitis syndrome.

Impact of a maximal exercise test on symptoms and activity in chronic fatigue syndrome.	J Psychosom Res. 2005 Oct;59(4):201-8.	OBJECTIVE: This study examined the effects of exercise on symptoms and activity in chronic fatigue syndrome (CFS). METHODS: Twenty CFS patients and 20 neighborhood controls performed an incremental exercise test until exhaustion. Fatigue, muscle pain, minutes spent resting, and the level of physical activity were assessed with a self-observation list. Physical activity was assessed with an actometer as well. Data were obtained 3 days before the maximal exercise test (MET) up to 5 days thereafter. RESULTS: For CFS patients, daily observed fatigue was increased up to 2 days after the exercise test. For controls, self-observed fatigue returned to baseline after 2 h. Both CFS patients and controls spent more minutes resting on the day before and on the day after the MET. For CFS patients, self-observed minutes resting increased on the day of the exercise test. For neither group, a decrease of actometer recorded or self-observed physical activity after exercise was found. CONCLUSION: Fatigue in CFS patients increased after exercise, but the level of actual physical activity remained unchanged.

JB, Lulofs R, van der Meer JW, Bleijenberg G; The Netherlands Fatigue Research Group Nijmegen.	Medical Psychology, University Medical Centre Nijmegen, Nijmegen, The Netherlands. E.Bazelmans@cukz.umcn.nl	behaviour group therapy for chronic fatigue syndrome: a non-randomised waiting list controlled study.	Psychosom. 2005;74(4):218-24.	treatment for chronic fatigue syndrome (CFS). The aim of the present study was to investigate the effectiveness of cognitive behaviour group therapy (CBGT) in an unselected group of CFS patients. Additionally, pretreatment characteristics of CFS patients who improve after CBGT were explored. METHODS: In a non-randomised waiting list controlled design, 31 patients were allocated to CBGT and 36 to the waiting list condition. CBGT consisted of 12 two-hour sessions during 6 months. Main outcome measures were fatigue (Checklist Individual Strength) and functional impairment (Sickness Impact Profile). RESULTS: A moderate effect on fatigue in favour of CBGT was found. For functional impairment, the effect was opposite to what was expected. Patients who improved after CBGT had less complaints at baseline compared to patients who did not improve. CONCLUSIONS: An explanation for the moderate effect might be that during CBGT, rest and relaxation were too much emphasised. Furthermore, an unselected group of CFS patients and therapists inexperienced in CB(G)T for CFS participated. Suggestions to improve CBGT for future research are given. Copyright (c) 2005 S. HUibell@u.arizona.eduUH	JP-8 jet fuel exposure and divided attention test performance in 1991 Gulf War veterans.	Aviat Space Environ Med. 2005 Dec;76(12):1136-44.	INTRODUCTION: Previous research indicates that a large cohort of veterans from the 1991 Gulf War report polysymptomatic conditions. These syndromes often involve neurocognitive complaints, fatigue, and musculoskeletal symptoms, thus overlapping with civilian illnesses from low levels of environmental chemicals, chronic fatigue syndrome, and fibromyalgia. METHODS: To test for time-dependent changes over repeated intermittent exposures, we evaluated objective performance on a computerized visual divided attention test in chronically unhealthy Gulf War veterans (n = 22 ill with low-level chemical intolerance (CI); n = 24 ill without CI), healthy Gulf War veterans (n = 23), and healthy Gulf War era veterans (n = 20). Testing was done before and after each of three weekly, double blind, low-level JP-8 jet fuel or clean air sham exposure laboratory sessions, including acoustic startle stimuli. RESULTS: Unhealthy veterans receiving jet fuel had faster mean peripheral reaction times over sessions compared with unhealthy veterans receiving sham clean air exposures. Unhealthy Gulf veterans with CI exhibited faster post- vs. pre-session mean central reaction times compared with unhealthy Gulf veterans without CI. Findings were controlled for psychological distress variables. DISCUSSION: These data on unhealthy Gulf veterans show an acceleration of divided attention task performance over the course of repeated low-level JP-8 exposures. The present faster reaction times are consistent with rat neurobehavioral studies on environmental toxicant cross-sensitization and nonlinear dose-response patterns with stimulant drugs, as well as some previous civilian studies using other exposure agents. Together with previous research findings, the data suggest involvement of central nervous system dopaminergic pathways in affected Gulf veterans.
Bellanti JA, Sabra A, Castro HJ, Chavez JR, Malka-Rais J, de Inocencio JM.	Departments of Pediatrics , Georgetown University Medical Center, Washington, D.C. 20057, USA.	Are attention deficit hyperactivity disorder and chronic fatigue syndrome allergy related? what is fibromyalgia?	Allergy Asthma Proc. 2005 Jan-Feb;26(1):19-28.	Despite the progress made in the field of allergy-immunology in recent years, there are a group of diseases that the allergist-immunologist may be called on to manage in which their precise etiologies have not been identified but that appear to be initiated or exacerbated by allergic mechanisms. Attention deficit hyperactivity disorder (ADHD), chronic fatigue syndrome (CFS), and fibromyalgia (FM) fall into this category of disorders. Although the precise etiology of ADHD still remains unknown, the most prevalent theory is that it represents a neurobiologically based developmental disability leading to inadequate production of the neurotransmitter dopamine. In patients with CFS, there appears to be a fundamental dysfunction of the neuroendocrine-immunological system with deficiencies of

				immunological and neurological function, which, together with chronic viral infection, may lead to a sequence of events responsible for the symptoms of this disorder. FM appears to be a variant of CFS with a predominance of hypothalamic pituitary axis dysfunction. The disorder is characterized by chronic widespread pain and the finding of 11/18 tender points on examination. Now, there is emerging evidence to suggest that adverse reactions to foods or food components also may be associated with behavioral disturbances that may play a role in each of these disorders. An understanding of the interactive responses involved in the neuroendocrine-immunological network is essential for a comprehension of the pathophysiology of ADHD, CFS, and FM and the role of allergies appears to be an important triggering event in each of the disorders.
Bentler SE, Hartz AJ, Kuhn EM.	Department of Family Medicine, College of Medicine, University of Iowa, Iowa City, IA 52242-1097, USA.	Prospective observational study of treatments for unexplained chronic fatigue.	J Clin Psychiatry. 2005 May;66(5):625-32.	BACKGROUND: Unexplained chronic fatigue is a frequent complaint in primary care. A prospective observational study design was used to evaluate whether certain commonly used therapies for unexplained chronic fatigue may be effective. METHOD: Subjects with unexplained chronic fatigue of unknown etiology for at least 6 months were recruited from the Wisconsin Chronic Fatigue Syndrome Association, primary care clinics, and community chronic fatigue syndrome presentations. The primary outcome measure was change in a 5-question fatigue score from 6 months to 2 years. Self-reported interventions tested included prescribed medications, non-prescribed supplements and herbs, lifestyle changes, alternative therapies, and psychological support. Linear regression analysis was used to test the association of each therapy with the outcome measure after adjusting for statistically significant prognostic factors. RESULTS: 155 subjects provided information on fatigue and treatments at baseline and follow-up. Of these subjects, 87% were female and 79% were middle-aged. The median duration of fatigue was 6.7 years. The percentage of users who found a treatment helpful was greatest for coenzyme Q10 (69% of 13 subjects), dehydroepiandrosterone (DHEA) (65% of 17 subjects), and ginseng (56% of 18 subjects). Treatments at 6 months that predicted subsequent fatigue improvement were vitamins (p = .08), vigorous exercise (p = .09), and yoga (p = .002). Magnesium (p = .002) and support groups (p = .06) were strongly associated with fatigue worsening from 6 months to 2 years. Yoga appeared to be most effective for subjects who did not have unclear thinking associated with the fatigue. CONCLUSION: Certain alternative therapies for unexplained chronic fatigue, especially yoga, deserve testing in randomized controlled trials.
Black CD, McCully KK.	Department of Kinesiology, The University of Georgia, Athens, GA, USA. HUblackcd@uga.eduUH	Time course of exercise induced alterations in daily activity in chronic fatigue syndrome.	Dyn Med. 2005 Oct 28;4:10.	In a previous study we demonstrated that while people with CFS had lower daily activity levels than control subjects, they were able to increase daily activity via a daily walking program. We reanalyzed our data to determine the time course of activity changes during the walking program. Daily activity assessed via an accelometer worn at the hip was divided into sleep, active, and walking periods. Over the first 4-10 days of walking the subjects with CFS were able to reach the prescribed activity goals each day. After this time, walking and total activity counts decreased. Sedentary controls subjects were able to maintain their daily walking and total activity goals throughout the 4 weeks. Unlike our previous interpretation of the data, we feel this new analysis suggests that CFS patients may develop exercise intolerance as demonstrated by reduced total activity after 4-10 days. The inability to sustain target activity levels, associated with pronounced worsening of symptomology, suggests the subjects with CFS had reached their activity limit.
Black CD,	Department of	Increased daily	Dyn Med. 2005	Individuals with chronic fatigue syndrome (CFS) have been shown to have reduced activity levels

O'connor PJ, McCully KK.	Exercise Science, The University of Georgia, Athens, GA, USA. kmccully@coe.uga.edu.	physical activity and fatigue symptoms in chronic fatigue syndrome.	Mar 3;4(1):3.	associated with heightened feelings of fatigue. Previous research has demonstrated that exercise training has beneficial effects on fatigue-related symptoms in individuals with CFS. PURPOSE: The aim of this study was to sustain an increase in daily physical activity in CFS patients for 4 weeks and assess the effects on fatigue, muscle pain and overall mood. METHODS: Six CFS and seven sedentary controls were studied. Daily activity was assessed by a CSA accelerometer. Following a two week baseline period, CFS subjects were asked to increase their daily physical activity by 30% over baseline by walking a prescribed amount each day for a period of four weeks. Fatigue, muscle pain and overall mood were reported daily using a 0 to 100 visual analog scale and weekly using the Profile of Mood States (Bipolar) questionnaire. RESULTS: CFS patients had significantly lower daily activity counts than controls (162.5 +/- 51.7 x 103 counts/day vs. 267.2 +/- 79.5 x 103 counts/day) during a 2-week baseline period. At baseline, the CFS patients reported significantly ($P < 0.01$) higher fatigue and muscle pain intensity compared to controls but the groups did not differ in overall mood. CFS subjects increased their daily activity by 28+/-19.7% over a 4 week period. Overall mood and muscle pain worsened in +the CFS patients with increased activity. CONCLUSION: CFS patients were able to increase their daily physical activity for a period of four weeks. In contrast to previous studies fatigue, muscle pain, and overall mood did not improve with increased activity. Increased activity was not presented as a treatment which may account for the differential findings between this and previous studies. The results suggest that a daily "activity limit" may exist in this population. Future studies on the impact of physical activity on the symptoms of CFS patients are needed.
Blotman F, Thomas E, Myon E, Andre E, Caubere JP, Taieb C.	Rheumatology Department, Lapeyronie Hospital, Montpellier, France. francis.blotman@wanadoo.fr	Awareness and knowledge of fibromyalgia among french rheumatologists and general practitioners.	Clin Exp Rheumatol. 2005 Sep-Oct;23(5):697-700.	OBJECTIVES: Fibromyalgia is a chronic disorder characterized by widespread musculoskeletal pain and fatigue. Its prevalence is estimated to be at 3.4% in women and 0.5% in men. It is a major cause of morbidity. Our objective was to evaluate, using a self-questionnaire sent by mail, the level of knowledge of French physicians, general practitioners, and rheumatologists on fibromyalgia and to analyse their therapeutic approach. METHODS: The demographic characteristics of a sample of general practitioners and rheumatologists were compared to those of the overall data available. This comparison demonstrated the good representativeness of our sample. RESULTS: Fibromyalgia was considered as a disease by 23% of rheumatologists and 33% of general practitioners. While on average, each rheumatologist followed 30 fibromyalgia patients, each general practitioner followed 6.1 patients (i.e., 2 to 5% of their practice's patient base). Among rheumatologists, 6.4% made no distinction between this disease and depression vs. 13.1% of general practitioners. The diagnosis of fibromyalgia was made based on tenderness that occurs in precise, localized areas of the body (trigger points) by 94% of rheumatologists and 79.1% of general practitioners. Of general practitioners and rheumatologists, 93.7% and 73.7% respectively, have not received any medical school training on fibromyalgia or chronic fatigue syndrome. CONCLUSION: Given the lack of medical school training and continuing professional education concerning fibromyalgia (rare use of pain rating scales, confusion in the classification of rheumatic diseases), there is an urgent need to initiate an explicit teaching effort on chronic pain, and on fibromyalgia in particular.
Bolk JH.	Leids Universitair Medisch Centrum, afd Algemene	[Report from the Health Council of the Netherlands on	Ned Tijdschr Geneeskd. 2005 Apr 2;149(14):739-	The Health Council of the Netherlands has issued a report on the chronic fatigue syndrome (CFS). CFS is a real and seriously debilitating condition which imposes limitations on an individual's personal, occupational and social functioning. It is a syndrome of unknown aetiology without physical signs or

	Interne Geneeskunde, 2300 RC Leiden.	the chronic fatigue syndrome: moving away from the body-mind dichotomy with a view to effective prevention and treatment] [Article in Dutch]	41.	biological markers. Although there is no disease, patients both feel ill and give the appearance of being ill. There is no consensus on whether CSF patients are able to work or whether they should be entitled to social security benefits. An imbalance between demand and coping is central in CFS, with stress as an important intermediary factor. It is little use concluding that unexplained signs are 'psychological' or that 'I cannot find anything wrong with you so you must be healthy'. The classical view that mind and body are separate systems is outmoded. The bio-psycho-social model of disease may be helpful in describing the interaction between body, mind and circumstance. Putting the CFS patient at ease and explaining the pathophysiology of the symptoms is a useful approach but many patients and patient associations are still very somatically orientated, thereby sustaining the condition. However, in patients who accept that their problems may be stress-induced and are prepared to participate in therapy, some therapies have been proven to be effective, notably cognitive behavioural therapy.
Bowen J, Pheby D, Charlett A, McNulty C.	Health Protection Agency Primary Care Unit, Gloucester, UK. jill.whiting@hpa.org.uk	Chronic Fatigue Syndrome: a survey of GPs' attitudes and knowledge.	Fam Pract. 2005 Aug;22(4):389-93. Epub 2005 Apr 1.	BACKGROUND: GPs need evidence and guidance to help them diagnose and manage Chronic Fatigue Syndrome (CFS)/ME appropriately. OBJECTIVES: The aim of this survey was to obtain baseline data and identify the factors associated with GPs' attitudes to and knowledge of CFS/ME. The attitude of GPs to the condition is an important indicator of likely prognosis. METHODS: A postal questionnaire was sent to 1054 GPs served by Taunton, Bristol and Gloucester laboratories. GPs' attitudes to nine statements about CFS/ME were assessed and the factors associated with positive or negative responses were determined. Knowledge of the clinical features was also assessed. RESULTS: 811 GPs (77%) returned the questionnaire. 48% of GPs did not feel confident with making a diagnosis of CFS/ME and 41% did not feel confident in treatment. 72% of GPs accepted CFS/ME as a recognisable clinical entity and those GPs had significantly more positive attitudes. Three other key factors that were significantly, positively associated with GPs' attitudes were knowing someone socially with CFS/ME, being male and seeing more patients with the condition in the last year. CONCLUSION: Despite the publication of guidance for GPs on CFS/ME, confidence with making a diagnosis and management was found to be low. Educational initiatives and guidance for GPs should stress the importance of accepting CFS/ME as a recognisable clinical entity, as this is linked to having a positive attitude and could lead to improved confidence to make a diagnosis and treat CFS/ME patients.
Brimacombe M, Lange G, Bisuchio K, Ciccone DS, Natelson B		ORIGINAL RESEARCH Cognitive Function Index for Patients with Chronic Fatigue Syndrome	Journal of Chronic Fatigue Syndrome 2005 12 (4): 3 - 23	Background: A comprehensive approach to assessing neuropsychological deficits in CFS patients is developed by assessing cognitive function across a number of domains using a battery of tests, rather than relying on any single instrument. Objective: A factor analytic approach was employed to examine the underlying dimensionality of 15 standard cognitive function related test variables in CFS patients. A cognitive function index (CFI) was then developed using appropriately weighted and interpreted factors. Methods: Factor analysis was applied to an initial sample of 65 CFS patients, identifying eight factors accounting for over 70% of total variation. This factor structure was then independently verified on a separate sample of 124 CFS patients. An overall combined CFS sample of 212 was then used to derive the CFI using an appropriately interpreted and weighted average of the derived factors. Results: After including age and education as separate factors, the CFI consists of nine factors accounting for 70% of total variation in the overall CFS group. The CFI was not affected by the presence of current psychiatric comorbidity. A cut-off score for cognitive dysfunction was established

				using the lower quartile value of a group of sedentary controls on the same index. Conclusions: The CFI will provide a useful summary measure for researchers investigating cognitive function performance in CFS patients. It does not replace existing individual specialized tests.
Buskila D, Neumann L, Press J.	Department of Internal Medicine, Faculty of Health Sciences, Ben Gurion University of the Negev, Beer Sheva 84101, Israel. dbuskila@bgumail.bgu.ac.il	Genetic factors in neuromuscular pain.	CNS Spectr. 2005 Apr;10(4):281-4.	Recent evidence suggests that fibromyalgia, a chronic widespread pain condition and related syndromes (chronic fatigue syndrome, irritable bowel syndrome, etc.) may share heritable pathophysiologic features. We review the recent literature on genetic and familial factors found to participate in the pathogenesis of these syndromes, specifically fibromyalgia, including evidence suggesting that serotonin- and dopamine-related genes may play a role in the pathogenesis of these illnesses. The importance of environmental factors triggering these conditions in predisposed individuals is also discussed.
Cairns R, Hotopf M.	Department of Psychological Medicine, Institute of Psychiatry, London, UK.	A systematic review describing the prognosis of chronic fatigue syndrome.	Occup Med (Lond). 2005 Jan;55(1):20-31.	AIM: To perform a systematic review of studies describing the prognosis of chronic fatigue (CF) and chronic fatigue syndrome (CFS) and to identify occupational outcomes from such studies. METHOD: A literature search was used to identify all studies describing the clinical follow-up of patients following a diagnosis of CF or CFS. The prognosis is described in terms of the proportion of individuals improved during the period of follow-up. Return to work, other medical illnesses and death as outcomes are also considered, as are variables which may influence prognosis. RESULTS: Twenty-eight articles met the inclusion criteria and, for the 14 studies of subjects meeting operational criteria for CFS, the median full recovery rate was 5% (range 0-31%) and the median proportion of patients who improved during follow-up was 39.5% (range 8-63%). Less fatigue severity at baseline, a sense of control over symptoms and not attributing illness to a physical cause were all associated with a good outcome. Return to work at follow-up ranged from 8 to 30% in the three studies that considered this outcome. CONCLUSIONS: Full recovery from untreated CFS is rare. The prognosis for an improvement in symptoms is less gloomy. This review looks at the course of CF/CFS without systematic intervention. However, there is increasing evidence for the effectiveness of cognitive behavioural and graded exercise therapies. Medical retirement should be postponed until a trial of such treatment has been given.
Cairns V, Godwin J.	Consultant Statistician, Am Rothlauf 9, 61476 Kronberg, Germany.	Post-Lyme borreliosis syndrome: a meta-analysis of reported symptoms.	Int J Epidemiol. 2005 Jul 22; [Epub ahead of print]	BACKGROUND: This meta-analysis compares the prevalence of fatigue, musculoskeletal pain, and neurocognitive difficulties in patients who have had Lyme borreliosis (LB) and control subjects without LB. METHODS: Titles and abstracts in PubMed were reviewed for studies with data on the symptoms listed above that compared patients who had had LB with controls from the general population. Five studies with 504 patients and 530 controls were included in the meta-analysis. RESULTS: The prevalence of symptoms was significantly higher in the LB patients, with P-values between <0.00001 and 0.007 for 8 of the 10 symptoms in the three categories listed above. The higher prevalence of certain neurocognitive symptoms but not others, in the same pattern as reported in the literature, is further confirmation of this syndrome. The pattern of symptoms appears to be different from that seen in fibromyalgia, depression, and chronic fatigue syndrome. CONCLUSIONS: This meta-analysis provides strong evidence that some patients with LB have fatigue, musculoskeletal pain, and

				neurocognitive difficulties that may last for years despite antibiotic treatment.
Cairns V, Godwin J.	Clinical Trial Service Unit, University of Oxford, UK. HUcairns@t-online.deUH	Post-Lyme borreliosis syndrome: a meta-analysis of reported symptoms.	Int J Epidemiol. 2005 Dec;34(6):1340-5. Epub 2005 Jul 22. Casado B, Zanone C, Annovazzi L, Iadarola P, Whalen G, Baraniuk JN.	Department of Biochemistry A. Castellani, University of Pavia, V.le Taramelli 3/B, 27100 Pavia, Italy. bc48@georgetown.edu	Urinary electrophoretic profiles from chronic fatigue syndrome and chronic fatigue syndrome/fibromyalgia patients: a pilot study for achieving their normalization.	J Chromatogr B Analyt Technol Biomed Life Sci. 2005 Jan 5;814(1):43-51.	Aim of our study was to determine if there were distinct, disease-related patterns of urinary analytes in chronic fatigue syndrome (CFS) and chronic fatigue syndrome/fibromyalgia (CFS/FM) compared to normal controls (NC). Urine was collected from these subjects for two consecutive 24 h periods and aliquots were submitted to micellar electrokinetic chromatography (MEKC). To compensate for the differences in peak migration times, these were normalized from the 35 min duration of run to a 100-point scale, and each peak was assigned its normalized time measure. Peak heights were also normalized by dividing the mAU by that of the internal standard (creatinine) and multiplying by 100. MEKC with normalization for peak height and migration time generated comparable results within each of the patient groups. CFS/FM and CFS had significant differences in peaks compared to NC that may be of significance as biomarkers of illnesses.
Cervera C, Alegre J, Ruiz E, Vasquez A, Armadans L, Garcia-Quintana AM, Aleman C, de Sevilla TF		Employment Status and Financial Repercussions in 60 Patients with Chronic Fatigue Syndrome in Spain: Utility of the Fatigue Impact Scale	Journal of Chronic Fatigue Syndrome 2005 12 (2): 35-45	Chronic fatigue syndrome (CFS) is a disabling disorder with implications in employment status. We enrolled 60 patients who fulfilled the CDC diagnostic criteria of Holmes and those of Fukuda. All patients underwent a protocol involving a structured questionnaire to record diagnostic criteria items, clinical features of fatigue, social features and associated symptoms; application of the Fatigue Impact Scale (FIS); an employment repercussion questionnaire; and information on evolution of the symptoms. Statistical comparisons were performed with the Mann-Whitney U test and correlations with the Spearman test. A close correlation was found between work inactivity and higher scores in the FIS cognitive dimension. Patient age and duration of symptoms also correlated with high cognitive scores. Chronic fatigue syndrome patients report a considerable decrease in quality of life, and most of them have work limitations, particularly those with poor overall FIS scores and cognitive function scores.
Chalmers RA, Jones MG, Goodwin CS, Amjad S.	St George's Hospital Medical School, Cranmer Terrace, London SW17 0RE, UK.	CFSUM1 and CFSUM2 in urine from patients with chronic fatigue syndrome are	Clin Chim Acta. 2005 Aug 8; [Epub ahead of print]	McGregor et al. reported increased levels of an unidentified urinary compound (CFSUM1) in patients with chronic fatigue syndrome (CFS), with reduced excretion of another unidentified compound (CFSUM2), and suggested the possibility of chemical or metabolic 'markers' for CFS. The identity of CFSUM1 as reported was erroneous and the identities of these compounds have remained unknown until now. Urine samples were obtained from 30 patients with ME/CFS, 30 age- and sex-matched

		methodological artefacts.		healthy controls, 20 control patients with depression and 22 control patients with rheumatoid arthritis. Samples were prepared using the published methods of McGregor et al. to produce heptafluorobutyryl-isobutyl derivatives of urinary metabolites. Alternative preparations utilised isopropyl, n-butyl and trifluoroacetyl derivatives. These were separated and identified using gas chromatography-mass spectrometry. CFSUM2 was identified as being partially derivatised [isobutyl ester-mono-heptafluorobutyryl (HFB)] serine. CFSUM1 was identified as partially derivatised pyroglutamic acid, being the isobutyl ester without formation of a HFB derivative. Both CFSUM1 and CFSUM2 are artefacts of the sample preparation procedure and previously reported quantitative abnormalities of CFSUM1 and CFSUM2 in urine from patients with ME/CFS are also artefactual. Pyroglutamic acid may be of primarily dietary origin. The methods used cannot provide reliable qualitative or quantitative data on urinary metabolites. No clinical or biochemical significance can be drawn between these compounds in ME/CFS or any other clinical conditions.
Chaudhuri A.		Cognitive behaviour therapy for adolescents with chronic fatigue syndrome: data are insufficient and conclusion inappropriate. Comment on: BMJ. 2005 Jan 1;330(7481):14.	BMJ. 2005 Apr 2;330(7494):789-90; author reply 790.	Letter
Chia JK.	CEI Research Center, Torrance, CA 90505, USA. HUChiiasann@pol.netUH	The role of enterovirus in chronic fatigue syndrome.	J Clin Pathol. 2005 Nov;58(11):1126-32.	Two and a half decades after coining of the term chronic fatigue syndrome (CFS), the diagnosis of this illness is still symptom based and the aetiology remains elusive. Enteroviruses are well known causes of acute respiratory and gastrointestinal infections, with tropism for the central nervous system, muscles, and heart. Initial reports of chronic enteroviral infections causing debilitating symptoms in patients with CFS were met with skeptism, and had been largely forgotten for the past decade. Observations from in vitro experiments and from animal models clearly established a state of chronic persistence through the formation of double stranded RNA, similar to findings reported in muscle biopsies of patients with CFS. Recent evidence not only confirmed the earlier studies, but also clarified the pathogenic role of viral RNA through antiviral treatment. This review summarises the available experimental and clinical evidence that supports the role of enterovirus in chronic fatigue syndrome.
Cho HJ, Hotopf M, Wessely S.	Section of General Hospital Psychiatry, Institute of Psychiatry, King's College London,	The placebo response in the treatment of chronic fatigue syndrome: a systematic review	Psychosom Med. 2005 Mar-Apr;67(2):301-13.	OBJECTIVE: The placebo response is conventionally asserted to be high in chronic fatigue syndrome (CFS) because of the latter's subjective nature and obscure pathogenesis, but no systematic review of placebo responses has been undertaken. We report such a study. Patient expectation is known to be important in the placebo response. It is also known that CFS patients attending specialist clinics often have strong physical attributions regarding causation and hence skepticism about psychological or psychiatric interventions. If so, the placebo response in CFS may be influenced by the type of

	United Kingdom. h.cho@iop.kcl.ac.uk	and meta-analysis.		intervention according to its perceived rationale. We aimed to estimate the summary placebo response in clinical trials of CFS and to determine whether intervention type influences the placebo response in CFS. METHODS: We searched Medline, Embase, Cochrane Library, PsychInfo, and the references of the identified articles, and contacted experts for controlled trials (randomized or nonrandomized) of any intervention on CFS patients reporting the placebo response as a clinical improvement in physical or general outcomes. Data were extracted from the articles and validity assessment conducted by one reviewer and checked by a second. Meta-analysis and metaregression were performed. RESULTS: The pooled placebo response was 19.6% (95% confidence interval, 15.4-23.7), lower than predicted and lower than in some other medical conditions. The meta-regression revealed that intervention type significantly contributed to the heterogeneity of placebo response (p = .03). CONCLUSION: In contrast with the conventional wisdom, the placebo response in CFS is low. Psychological-psychiatric interventions were shown to have a lower placebo response, perhaps linked to patient expectations.

Christie D, Wilson C.	University College and Middlesex Hopsitals, London, UK. HUdeborah.christie@uclh.orgUH	CBT in paediatric and adolescent health settings: a review of practice-based evidence.	Pediatr Rehabil. 2005 Oct-Dec;8(4):241-7.	Cognitive Behavioural therapy (CBT) has strong theoretical underpinnings that facilitate the systematic evaluation of outcomes and process of change adults. CBT has been extensively adapted for use with children and young people with session content and method of delivery modified to acknowledge developmental stage and ability. Current approaches emphasise the psychological management of the impact of symptoms of particular types of physical health difficulties and prevention of the development of psychological difficulties, as well as in the alleviation of procedurally related stress. The need for collaboration with families and other parts of a child's network is particularly relevant in the paediatric setting. This review describes what we have found helpful in our work and provides a road map of where to go to find out more about how to do more. General CBT approaches are described as well as examples of how CBT has been used specifically for procedural distress, diabetes, sickle cell disease, chronic pain and chronic fatigue.

Cleare AJ, Messa C, Rabiner EA, Grasby PM.	Section of Neurobiology of Mood Disorders, Division of Psychological Medicine, Institute of Psychiatry and Guy-s, King-s and St. Thomas- School of Medicine, London, United Kingdom. a.cleare@iop.kcl.ac.uk	Brain 5-HT1A receptor binding in chronic fatigue syndrome measured using positron emission tomography and [11C]WAY-100635.	Biol Psychiatry. 2005 Feb 1;57(3):239-46.	BACKGROUND: Research from neuroendocrine challenge and other indirect studies has suggested increased central 5-HT function in chronic fatigue syndrome (CFS) and increased 5-HT1A receptor sensitivity. We assessed brain 5-HT1A receptor binding potential directly using the specific radioligand [11C]WAY-100635 and positron emission tomography (PET). METHODS: We selected 10 patients from a tertiary referral clinic who fulfilled the CDC consensus criteria for CFS. To assemble a homogenous group and avoid confounding effects, we enrolled only subjects who were completely medication-free and did not have current comorbid psychiatric illness. We also scanned 10 healthy control subjects. RESULTS: There was a widespread reduction in 5-HT1A receptor binding potential in CFS relative to control subjects. This was particularly marked in the hippocampus bilaterally, where a 23% reduction was observed. CONCLUSIONS: There is evidence of decreased 5-HT1A receptor number or affinity in CFS. This may be a primary feature of CFS, related to the underlying pathophysiology, or a finding secondary to other processes, such as previous depression, other biological changes or the behavioral consequences of CFS.
Cook DB, Nagelkirk PR, Peckerman A, Poluri A, Mores J, Natelson BH.	University of Wisconsin-Madison, Department of Kinesiology, USA. cookdb@njneuromed.org	Exercise and cognitive performance in chronic fatigue syndrome.	Med Sci Sports Exerc. 2005 Sep;37(9):1460-7.	PURPOSE: To determine the effect of submaximal steady-state exercise on cognitive performance in patients with chronic fatigue syndrome (CFS) alone, CFS with comorbid fibromyalgia FM (CFS + FM), and sedentary healthy controls (CON). METHODS: Twenty CFS-only patients, 19 CFS + FM, and 26 CON completed a battery of cognitive tests designed to assess speed of information processing, variability, and efficiency. Tests were performed at baseline, immediately before, and twice following 25 min of either cycle ergometry set at 40% of peak oxygen capacity or quiet rest. RESULTS: There were no group differences in average percentage of peak oxygen consumption during exercise (CFS = 45%; CFS + FM = 47%; Control = 43%: P = 0.2). There were no significant effects of acute exercise on cognitive performance for any group. At baseline, one-way ANOVA indicated that CFS patients displayed deficits in speed of processing, performance variability, and task efficiency during several cognitive tests compared with healthy controls. However, the CFS + FM patients were not different than controls. Repeated measures ANOVA indicated that across all tests (pre- and postexercise) CFS, but not CFS + FM, were significantly less consistent ($F_{2,59} = 3.7$, $P = 0.03$) and less efficient ($F_{2,59} = 4.6$, $P = 0.01$) than controls. CONCLUSION: CFS patients without comorbid FM exhibit subtle cognitive deficits in terms of speed, consistency, and efficiency that are not improved or exacerbated by light exercise. Importantly, our data suggest that CFS + FM patients do not exhibit cognitive deficits either pre- or postexercise. These results highlight the importance of disease heterogeneity in studies determining acute exercise and cognitive function in CFS.
Covelli V, Passeri ME, Leogrande D, Jirillo E, Amati L.	Division of Neurology, Polyclinic Hospital, Bari Italy.	Drug targets in stress-related disorders.	Curr Med Chem. 2005;12(15):1801-9.	Nervous and immune systems mutually cooperate via release of mediators of both neurological and immunological derivation. Adrenocorticotropin hormone (ACTH) is a product of the hypothalamus-pituitary adrenal axis (HPAA) which stimulates secretion of corticosteroids from adrenals. In turn, corticosteroids modulate the immune response in virtue of their anti-inflammatory activity. On the other hand, catecholamines, products of the sympathetic nervous system (SNS), regulate immune function by acting on specific beta-adrenergic receptors. Conversely, cytokines released by monocytes/macrophages and lymphocytes, upon antigenic stimulation, are able to cross the blood-brain-barrier, thus modulating nervous functions (e.g., thermoregulation, sleep, and appetite).

				However, cytokines are locally produced in the brain, especially in the hypothalamus, thus contributing to the development of anorexic, pyrogenic, somnogenic and behavioural effects. Besides pathogens and/or their products, the so-called stressors are able to activate both HPAA and SNS, thus influencing immune responses. In this respect, many studies conducted in medical students taking exams have evidenced an array of stress-induced immune alterations. Phobic disorders and migraine without aura (MWA) represent examples of stress-related disorders in which phagocytic immune deficits, endotoxemia and exaggerated levels of proinflammatory cytokines [Tumor Necrosis Factor-alpha (TNF- alpha), and interleukin- 1 beta] have been detected. Quite interestingly, administration of a thymic hormone could ameliorate clinical symptoms in phobic patients. In MWA patients, a beta-blocker, propranolol, could mitigate migraine, whose cessation coincided with a drop of TNF-alpha serum concentration. In phobic disorders and in MWA, benzodiazepines are very often administered and, in this respect, some of them, such as diazepam, inhibit immune functions, while others, e.g., alprazolam, enhance immune responses. Alprazolam could improve clinical symptoms in MWA patients. Chronic Fatigue Syndrome (CFS) is a disorder whose etiology and pathogenesis are still unknown. In this syndrome both abnormalities of nervous and immune systems have been reported. Despite many immune parameters evaluated in CFS no specific biomarkers of disease have been found. Our own data are in agreement with current literature in that we found decreased levels of serum (IFN)-gamma in these patients, thus indicating a predominance of T helper (h)1 response in CFS. Also leptin, a hormone which regulates food intake, fluctuates within normal ranges in CFS individuals. Quite interestingly, in depressed patients, used as controls, leptinaemia was more elevated than in CFS. Finally, in a series of recent therapeutic trials several immunomodulating agents have been used, such as staphypan Berna, lactic acid bacteria, kuibitang and intravenous immunoglobulin. In conclusion, it seems that major drug targets in stress-related disorders are immune cells in terms of inhibition of proinflammatory cytokines and modulation of Th responses. In particular, according to recent evidences, antidepressants seem to exert beneficial effects in experimental autoimmune neuritis in rats by decreasing IFN- beta release or augmenting NK activity in depressed patients.
Crowhurst G.	25% Severe ME Group, Great Walsingham, Norfolk. gregcrowhurst@yahoo.co.uk	Supporting people with severe myalgic encephalomyelitis.	Nurs Stand. 2005 Feb 2-8;19(21):38-43.	This article aims to raise nurses' awareness of myalgic encephalomyelitis (ME) also known as chronic fatigue syndrome (CFS). Key symptoms are presented along with possible service responses and treatment options. It emphasises that this condition is often misunderstood but that it can be serious and more research is needed to promote better understanding of the physical symptoms.
Darbishire L, Seed P, Ridsdale L.	Department of General Practice and Primary Care, Guy's, King's and St Thomas' School ol of Medicine, 5 Lambeth Walk,	Predictors of outcome following treatment for chronic fatigue.	Br J Psychiatry. 2005 Apr;186:350-1.	We explored the role of baseline characteristics of 105 patients who presented with fatigue in primary care in determining outcome following either graded exercise or cognitive-behavioural therapy. Meeting the criteria for chronic fatigue syndrome was the most powerful predictor of poor outcome and this negative effect was enhanced by greater functional impairment or greater perceived negative consequences, but was not further enhanced by both.

Davidson J.	Department of Geography, Queen's University, Kingston, Ont., K7L 3N6, Canada. HUjoyce.davidson@queensu.caUH	Contesting stigma and contested emotions: personal experience and public perception of specific phobias.	Soc Sci Med. 2005 Nov;61(10):2155-64.	This paper draws on interviews with members of the United Kingdom National Phobics Society to explore the implications of the contested nature of specific phobias for their experience and perception. In common with other chronic and contested conditions such as Chronic Fatigue Syndrome, phobias are stigmatised and subjected to widespread judgmental attitudes in both medical and lay populations. In contrast, however, phobic experience is rarely characterised by difficulty in describing symptoms and obtaining a diagnosis: core fearful reaction to and avoidance of particular objects is usually obvious and uncontested. The crucial difference is that phobias are constituted by emotions and behaviours considered irrational and inconsequential, and it is their (perceived absence of) significance that raises questions and eyebrows. In other words, what does it matter and who cares if you happen to be scared of snakes? Using phobics' own words as far as possible, the paper explores the processes through which phobic emotions are constructed as contested, and examines phobic means of managing experience and perception of these emotions. It reveals that many respondents are resourceful and resistant, continually renegotiating their positioning as irrational, incapable and emotionally weak.
de Lange FP, Kalkman JS, Bleijenberg G, Hagoort P, van der Meer JW, Toni I.	F.C. Donders Centre for Cognitive Neuroimaging, Radboud University Nijmegen, NL-6500 HB Nijmegen, The Netherlands. floris.delange@fcdonders.ru.nl	Gray matter volume reduction in the chronic fatigue syndrome.	Neuroimage. 2005 Jul 1;26(3):777-81. Epub 2005 Apr 7.	The chronic fatigue syndrome (CFS) is a disabling disorder of unknown etiology. The symptomatology of CFS (central fatigue, impaired concentration, attention and memory) suggests that this disorder could be related to alterations at the level of the central nervous system. In this study, we have used an automated and unbiased morphometric technique to test whether CFS patients display structural cerebral abnormalities. We mapped structural cerebral morphology and volume in two cohorts of CFS patients (in total 28 patients) and healthy controls (in total 28 controls) from high-resolution structural magnetic resonance images, using voxel-based morphometry. Additionally, we recorded physical activity levels to explore the relation between severity of CFS symptoms and cerebral abnormalities. We observed significant reductions in global gray matter volume in both cohorts of CFS patients, as compared to matched control participants. Moreover, the decline in gray matter volume was linked to the reduction in physical activity, a core aspect of CFS. These findings suggest that the central nervous system plays a key role in the pathophysiology of CFS and point to a new objective and quantitative tool for clinical diagnosis of this disabling disorder.
Di Giorgio A, Hudson M, Jerjes W, Cleare AJ.	Department of Neurological and Psychiatric Services, University of Bari, Bari, Italy	24-hour pituitary and adrenal hormone profiles in chronic fatigue syndrome.	Psychosom Med. 2005 May-Jun;67(3):433-40.	OBJECTIVES: Disturbances of neuroendocrine function, particularly the hypothalamo-pituitary-adrenal (HPA) axis, have been implicated in the pathophysiology of chronic fatigue syndrome (CFS). However, few studies have attempted to measure blood levels of pituitary or adrenal hormones across a whole 24-hour period in CFS, and those that did so have used infrequent sampling periods. Our aim was to assess 24-hour pituitary and adrenal function using frequent blood sampling. METHODS: We recruited 15 medication-free patients with CFS without comorbid psychiatric disorder and 10 healthy control subjects. Blood samples were collected over 24 hours and assayed for cortisol, corticotropin (ACTH), growth hormone (GH), and prolactin (PRL) levels on an hourly basis during daytime hours (10 am to 10 pm) and every 15 minutes thereafter (10 pm to 10 am). RESULTS: Repeated-measures analyses of

				variance were undertaken using hormone levels averaged over 2-hour blocks to smooth curves by reducing the influence of sample timing relative to secretory burst. For ACTH, there was both a main effect of group, suggesting reduced mean ACTH secretion in patients with CFS over the whole monitoring period, and a group-by-time interaction, suggesting a differential pattern of ACTH release. Post hoc analysis showed reduced ACTH levels in CFS during the 8 am to 10 am period. In contrast, there were no significant abnormalities in the levels of cortisol, GH, and PRL in patients with CFS over the full cycle compared with control subjects. Cosinor analysis found no differences in the cortisol circadian rhythm parameters, but the ACTH rhythm did differ, patients with CFS showing an earlier acrophase. CONCLUSIONS: Patients with CFS demonstrated subtle alterations in HPA axis activity characterized by reduced ACTH over a full circadian cycle and reduced levels during the usual morning physiological peak ACTH secretion. This provides further evidence of subtle dysregulation of the HPA axis in CFS. Whether this dysregulation is a primary feature of the illness or instead represents a biologic effect secondary to having the illness itself remains unclear.
Doljansky JT, Kannety H, Dagan Y.	The Institute for Sleep and Fatigue Medicine, Chaim Sheba Health Center, Tel-Hashomer, Israel. Julia.Tamir@Sheba.health.gov.il	Working under daylight intensity lamp: an occupational risk for developing circadian rhythm sleep disorder?	Chronobiol Int. 2005;22(3):597-605.	A 47-yr-old male was admitted to the Institute for Fatigue and Sleep Medicine complaining of severe fatigue and daytime sleepiness. His medical history included diagnosis of depression and chronic fatigue syndrome. Antidepressant drugs failed to improve his condition. He described a gradual evolvement of an irregular sleep-wake pattern within the past 20 yrs, causing marked distress and severe impairment of daily functioning. He had to change to a part-time position 7 yrs ago, because he was unable to maintain a regular full-time job schedule. A 10-day actigraphic record revealed an irregular sleep-wake pattern with extensive day-to-day variability in sleep onset time and sleep duration, and a 36 h sampling of both melatonin level and oral temperature (12 samples, once every 3 h) showed abnormal patterns, with the melatonin peak around noon and oral temperature peak around dawn. Thus, the patient was diagnosed as suffering from irregular sleep-wake pattern. Treatment with melatonin (5 mg, 2 h before bedtime) did not improve his condition. A further investigation of the patient's daily habits and environmental conditions revealed two important facts. First, his occupation required work under a daylight intensity lamp (professional diamond-grading equipment of more than 8000 lux), and second, since the patient tended to work late, the exposure to bright light occurred mostly at night. To recover his circadian rhythmicity and stabilize his sleep-wake pattern, we recommended combined treatment consisting of evening melatonin ingestion combined with morning (09:00 h) bright light therapy (0800 lux for 1 h) plus the avoidance of bright light in the evening. Another 10-day actigraphic study done only 1 wk after initiating the combined treatment protocol revealed stabilization of the sleep-wake pattern with advancement of sleep phase. In addition, the patient reported profound improvement in maintaining wakefulness during the day. This case study shows that chronic exposure to bright light at the wrong biological time, during the nighttime, may have serious effects on the circadian sleep-wake patterns and circadian time structure. Therefore, night bright light exposure must be considered to be a risk factor of previously unrecognized occupational diseases of altered circadian time structure manifested as irregularity of the 24 h sleep-wake cycle and melancholy.
Driver C.		An under-active or over-active	J Anal Psychol. 2005	This paper explores the dynamics brought into analytic work when there is a symmetric fusion between psyche and soma within the patient. It will consider how such a fusion may emerge from

		internal world? An exploration of parallel dynamics within psyche and soma, and the difficulty of internal regulation, in patients with Chronic Fatigue Syndrome and Myalgic Encephalomyelitis.	Apr;50(2):155-73.	reverberations between physical constitution and a lack of maternal attunement, containment and reflective function. I will describe the work with a patient, Jane, who was diagnosed with Myalgic Encephalomyelitis (ME) during the course of her analysis. The dynamic of her physical symptoms within the analytic work, and the impact of her internal affects and internal 'objects' within the transference and countertransference, indicated a difficulty in finding an homeostatic balance resulting in overactivity and underactivity at both somatic and psychological levels. Using the clinical work with Jane this paper will also examine the interrelationship between mother-infant attachment, an inadequate internalized maternal reflective function, affect dysregulation, unconscious fusion, the lack of psyche-soma differentiation and the impact of the latter in relation to internal regulation systems, or lack of, in patients with Chronic Fatigue Syndrome (CFS) and Myalgic Encephalomyelitis (ME). I will draw on similar work carried out by Holland (1997), Simpson (1997) and Simpson et al. (1997). The paper will also employ the concept of the reflective function (Fonagy 2001; Knox 2003), and consider Matte-Blanco's (1999) concepts of generalization and unconscious symmetry in relation to the patient's internal world. I go on to consider how analysis provides a point outside the 'fusion' that can enable the 'deadlock' to be broken.
Dumit J.	Program in Science, Technology & Society, Massachusetts Institute of Technology, E51-296D MIT, Cambridge, MA 02139-4307, USA.	Illnesses you have to fight to get: Facts as forces in uncertain, emergent illnesses.	Soc Sci Med. 2005 Aug 5; [Epub ahead of print]	Chronic fatigue syndrome and multiple chemical sensitivity are two clusters of illnesses that are pervaded by medical, social and political uncertainty. This article examines how facts are talked about and experienced in struggles over these emergent, contested illnesses in the US. Based principally on a large archive of internet newsgroup postings, and also on fieldwork and on published debates, it finds that (1) sufferers describe their experiences of being denied healthcare and legitimacy through bureaucratic categories of exclusion as dependent upon their lack of biological facts; (2) institutions manage these exclusions rhetorically through exploiting the open-endedness of science to deny efficacy to new facts; (3) collective patient action responds by archiving the systematic nature of these exclusions and developing counter-tactics. The result is the maintenance of these very expensive struggles for all involved.
Durlach J, Pages N, Bac P, Bara M, Guiet-Bara A.	SDRM, Universite Pierre et Marie Curie, 75252 Paris Cedex 05, France. jean.durlach@wanadoo.fr	Magnesium depletion with hypo- or hyper-function of the biological clock may be involved in chronopathological forms of asthma.	Magnes Res. 2005 Mar;18(1):19-34.	Asthma is a chronic, inflammatory disorder of the airways leading to airflow limitation. Its worldwide rise, mainly in developed countries, is a matter of concern. Nocturnal asthma (NA) frequently occurs and concerns two thirds of asthmatics. But, it remains controversial whether NA is a distinct entity or is a manifestation of more severe asthma. Generally, it is considered as an exacerbation of the underlying pathology. The pathological mechanisms most likely involve endogenous circadian rhythms with pathological consequences on both respiratory inflammation and hyperresponsiveness. A decrease in blood and tissue magnesium levels is frequently reported in asthma and often testifies to a true magnesium depletion. The link with magnesium status and chronobiology are well established. The quality of magnesium status directly influences the Biological Clock (BC) function, represented by the suprachiasmatic nuclei and the pineal gland. Conversely, BC dysrythmias influence the magnesium status. Two types of magnesium deficits must be clearly distinguished: deficiency corresponding to an insufficient intake which can be corrected through mere nutritional Mg supplementation and depletion due to a dysregulation of the magnesium status which cannot be corrected through nutritional supplementation only, but requires the more or less specific correction of the dysregulation mechanisms. Both in clinical and in animal experiments, the dysregulation mechanisms

				of magnesium depletion associate a reduced magnesium intake with various types of stress including biological clock dysrhythmias. The differenciation between Mg depletion forms with hyperfunction of BC (HBC) and forms with hypofunction of BC (hBC) is seminal and the main biological marker is melatonin (MT) production alteration. We hypothesize that magnesium depletion with HBC or hBC may be involved in chronopathological forms of asthma. Nocturnal asthma would be linked to HBC, represented by an increase in MT levels. The corresponding clinical forms associate diverse expressions of nervous hypoexcitability such as depression, cluster headaches, dyssomnia, mainly advanced sleep phase syndrome, some clinical forms of chronic fatigue syndrome and of fibromyalgia. The main comorbidities are depression and/or asthenia. They take place during the night or the "bad" seasons (autumn and winter) when sunshine is at a minimum. The corresponding chronopathological therapy relies on bright light phototherapy sometimes with additional psychoanaleptics. Conversely, asthma forms linked to hBC are less frequently studied as a whole and present a decrease in MT levels. They associate various signs of nervous hyperexcitability such as anxiety, diurnal cephalalgia (mainly migraine), dyssomnia, mainly delayed sleep phase syndrome, and some clinical forms of chronic fatigue syndrome and of fibromyalgia. The treatment relies on diverse forms of "darkness therapy", possibly with the help of some psycholeptics. Finally, the treatment of asthma involves the maintenance of a standard dosing schedule of anti-asthma drugs, a balanced magnesium intake and the appropriate treatment of the chronopathological disorders.
Ehrlich GE.		Silicone breast implants. Comment on: J Rheumatol. 2004 May;31(5):1015; author reply 1015-6.	J Rheumatol. 2005 Jun;32(6):1173-4; author reply 1174.	Letter
Eisen SA, Kang HK, Murphy FM, Blanchard MS, Reda DJ, Henderson WG, Toomey R, Jackson LW, Alpern R, Parks BJ, Klimas N, Hall C, Pak HS, Hunter J, Karlinsky J, Battistone MJ, Lyons MJ; Gulf War Study Participating Investigators.	Veterans Affairs Medical Center, Washington University School of Medicine, St. Louis, Missouri 63106, USA. seth.eisen@med.va.gov	Gulf War veterans' health: medical evaluation of a U.S. cohort.	Ann Intern Med. 2005 Jun 7;142(11):881-90.	BACKGROUND: United States military personnel reported various symptoms after deployment to the Persian Gulf during the 1991 Gulf War. However, the symptoms' long-term prevalence and association with deployment remain controversial. OBJECTIVE: To assess and compare the prevalence of selected medical conditions in a national cohort of deployed and nondeployed Gulf War veterans who were evaluated by direct medical and teledermatologic examinations. DESIGN: A cross-sectional prevalence study performed 10 years after the 1991 Gulf War. SETTING: Veterans were examined at 1 of 16 Veterans Affairs medical centers. PARTICIPANTS: Deployed (n = 1061) and nondeployed (n = 1128) veterans of the 1991 Gulf War. MEASUREMENTS: Primary outcome measures included fibromyalgia, the chronic fatigue syndrome, dermatologic conditions, dyspepsia, physical health-related quality of life (Short Form-36 [SF-36]), hypertension, obstructive lung disease, arthralgias, and peripheral neuropathy. RESULTS: Of 12 conditions, only 4 conditions were more prevalent among deployed than nondeployed veterans: fibromyalgia (deployed, 2.0%; nondeployed, 1.2%; odds ratio, 2.32 [95% CI, 1.02 to 5.27]); the chronic fatigue syndrome (deployed, 1.6%; nondeployed 0.1%; odds ratio, 40.6 [CI, 10.2 to 161]); dermatologic conditions (deployed, 34.6%; nondeployed, 26.8%; odds ratio, 1.38 [CI, 1.06 to 1.80]), and dyspepsia (deployed, 9.1%; nondeployed, 6.0%; odds ratio, 1.87 [CI, 1.16 to 2.99]).

				The mean physical component summary score of the SF-36 for deployed and nondeployed veterans was 49.3 and 50.8, respectively. LIMITATIONS: Relatively low participation rates introduce potential participation bias, and deployment-related illnesses that resolved before the research examination could not, by design, be detected. CONCLUSIONS: Ten years after the Gulf War, the physical health of deployed and nondeployed veterans is similar. However, Gulf War deployment is associated with an increased risk for fibromyalgia, the chronic fatigue syndrome, skin conditions, dyspepsia, and a clinically insignificant decrease in the SF-36 physical component score.
Elena Garralda M, Chalder T.	Imperial College, London, UK. HUegarralda@imperial.ac.ukUH	Practitioner review: chronic fatigue syndrome in childhood.	J Child Psychol Psychiatry. 2005 Nov;46(11):1143-51.	BACKGROUND: Chronic fatigue syndrome (CFS) is being increasingly recognized in children and adolescents. Yet comparatively little attention has been given in the literature to management. METHODS: Description of the main features of the disorder, precipitating and maintaining factors and diagnostic assessment. Outline of different views on the nature and treatment of CFS in childhood. Description of a rehabilitation program based on cognitive behavior therapy and graded activity. RESULTS: Using adult research criteria, CFS can be diagnosed in children and adolescents. In its severe form it is often triggered by infectious illness episodes. It is commonly associated with mood disorders in the child and with mental distress and high levels of emotional involvement in parents. A number of patient support groups hold the view that CFS is a medical disorder, contest a psychiatric contribution and advocate 'pacing' as an approach to rehabilitation which includes avoiding activities. To date there is no empirical evidence for the efficacy of this approach. Research in adults, open and clinical reports in children support the use of graded activity and family cognitive behavior therapy. The main aim is to enable children, with the help of their family, to carry out their own rehabilitation with some support and guidance from a health professional. Engaging the child and family in treatment and forming a therapeutic alliance is a continual process and a crucial aspect of management, as many families view the condition as a medical disorder and are initially ambivalent towards this approach. CONCLUSIONS: There is controversy about the nature and management of CFS in childhood but a rehabilitation program based on family cognitive behavior therapy can be implemented and seems to hold most promise in the management of children with CFS. Family engagement is a crucial aspect of management.
Evengard B, Jacks A, Pedersen NL, Sullivan PF.	Department of Laboratory Medicine, Karolinska Institutet at Karolinska University Hospital Huddinge, Stockholm, Sweden.	The epidemiology of chronic fatigue in the Swedish Twin Registry.	Psychol Med. 2005 Sep;35(9):1317-26.	BACKGROUND: Chronic fatigue syndrome (CFS) remains an idiopathic and controversial entity. METHOD: We screened 31405 individual members of the Swedish Twin Registry (aged 42-64 years) for the symptoms of fatiguing illness via a telephone questionnaire. We refined self-reported symptoms via data from several national registries and from physician review of all available medical records in order to approximate closely the dominant case definition of CFS. FINDINGS: The 6-month prevalence of CFS-like illness was 2.36% (95% CI 2.19-2.53) and was markedly higher in women than men, odds ratio 3.92 (95% CI 3.24-4.72) with no significant association with age or years of education. There was a highly significant association with occupation that disappeared after accounting for gender. INTERPRETATION: CFS-like illness may be more common that previously acknowledged. There is a marked increase in risk by gender. Previous reports that CFS is more prevalent in individuals in certain occupational categories were not confirmed and may have been due to confounding by gender.
Fernandez-Sola J, Lluis Padierna M,	Servicio de Medicina Interna.	[Chronic fatigue syndrome and	Med Clin (Barc). 2005 Apr	Background and objective: Chronic Fatigue Syndrome (CFS) and Multiple Chemical Sensitivity (MCS) are well-defined illnesses that may appear after some toxic exposures. Patients and method: We

Nogue Xarau S, Munne Mas P.	Unidad Multidisciplinar de Fatiga Cronica. Hospital Clinic de Barcelona. IDIBAPS. Universitat de Barcelona. Barcelona. Spain.	multiple chemical hypersensitivity after insecticide exposition.] [Article in Spanish]	2;124(12):451-3.	report a consecutive series of 26 patients who developed CFS after exposure to insecticide products. It was associated with MCS in a third of cases. RESULTS: Toxic exposure was of labour origin after returning to usual work place after a process of fumigation. In 42% of cases there was no fulfilment of fumigation safety rules. The majority of patients were mean-aged women who developed an acute upper airway inflammatory syndrome, without muscarinic or nicotinic manifestations, followed by digestive syndrome, neurocognitive, fibromyalgic and chronic fatigue manifestations. The course of disease was shorter than 1 year in 5 cases (19%), longer than 1 year in 15(58%), and disabling in 6 cases (23%). CONCLUSIONS: Due to the possible prevention of this toxic exposure, it is very important to carefully follow measures of environment isolation and ventilation after insecticide use in order to avoid the development of these diseases.
Ferre Ybarz L, Cardona Dahl V, Cadahia Garcia A, Ruiz E, Vazquez A, Fernandez de Sevilla T, Alegre Martin J.	Hospital Vall d'Hebron, Barcelona, Spain. laiafy@vodafone.es	[Prevalence of atopy in chronic fatigue syndrome] [Article in Spanish]	Allergol Immunopathol (Madr). 2005 Jan-Feb;33(1):42-7.	BACKGROUND: Several hypotheses have been postulated to explain the etiopathogenesis of chronic fatigue syndrome (CFS). Among these, immunologic dysfunction has been proposed. Up to 30 % of these patients have a history of allergic disease. The aim of this study was to investigate whether allergic sensitization is higher in patients with CFS than in the general population. METHODS: Twenty-five patients with CFS and 20 controls were evaluated. A clinical history for allergy was taken and immediate hypersensitivity tests were performed. RESULTS: Twelve patients (48 %) and eight controls (40 %) had a family history of atopy. Personal histories of atopy were as follows: rhinoconjunctivitis: 12 patients (48 %), seven controls (35 %); asthma: five patients (20 %), two controls (10 %); food allergy: three patients (12 %); atopic dermatitis: two patients; contact dermatitis: two patients. No statistically significant differences were found between the groups in any of the variables ($p > 0.05$). In the CSF group, 3.4 % (15/441) of the inhalant prick tests were positive, and in the control group 3.8 % (16/420) were positive. None of the tests for hypersensitivity to food or latex were positive. CONCLUSIONS: In our study atopy was not more prevalent in patients with CFS than in healthy controls, although the CSF group tended to report more respiratory symptoms and drug allergies.
Fowler T, Duthie P, Thapar A, Farmer A.	Department of Psychological Medicine, Wales College of Medicine, Cardiff University, UK. fowlerta@cardiff.ac.uk	The definition of disabling fatigue in children and adolescents.	BMC Fam Pract. 2005 Aug 9;6:33.	BACKGROUND: Disabling fatigue is the main illness related reason for prolonged absence from school. Although there are accepted criteria for diagnosing chronic fatigue in adults, it remains uncertain as to how best to define disabling fatigue and Chronic Fatigue Syndrome (CFS) in children and adolescents. In this population-based study, the aim was to identify children who had experienced an episode of disabling fatigue and examine the clinical and demographic differences between those individuals who fulfilled a narrow definition of disabling fatigue and those who fulfilled broader definitions of disabling fatigue. METHODS: Participants (aged 8-17 years) were identified from a population-based twin register. Parent report was used to identify children who had ever experienced a period of disabling fatigue. Standardised telephone interviews were then conducted with the parents of these affected children. Data on clinical and demographic characteristics, including age of onset, gender, days per week affected, hours per day spent resting, absence from school, comorbidity with depression and a global measure of impairment due to the fatigue, were examined. A narrow definition was defined as a minimum of 6 months disabling fatigue plus at least 4 associated symptoms, which is comparable to the operational criteria for CFS in adults. Broader definitions included those with at least 3 months of disabling fatigue and 4 or more of the associated symptoms and those with simply a minimum of 3 months of disabling fatigue. Groups were mutually exclusive. RESULTS: Questionnaires were returned

				by 1468 families (65% response rate) and telephone interviews were completed on 99 of the 129 participants (77%) who had experienced fatigue. There were no significant differences in demographic and clinical characteristics or levels of impairment between those who fulfilled the narrower definition and those who fulfilled the broader definitions. The only exception was the reported number of days per week that the child was affected by the fatigue. All groups demonstrated evidence of substantial impairment associated with the fatigue. CONCLUSION: Children and adolescents who do not fulfil the current narrow definition of CFS but do suffer from disabling fatigue show comparable and substantial impairment. In primary care settings, a broader definition of disabling fatigue would improve the identification of impaired children and adolescents who require support.
Fremont M, El Bakkouri K, Vaeyens F, Herst CV, De Meirleir K, Englebienne P.	RED Laboratories, Pontbeek 61, B-1731 Zellik, Belgium.	2',5'-Oligoadenylate size is critical to protect RNase L against proteolytic cleavage in chronic fatigue syndrome.	Exp Mol Pathol. 2005 Jun;78(3):239-46. Epub 2005 Mar 2.	A dysregulation in the 2',5'-oligoadenylate (2-5A)-dependent RNase L antiviral pathway has been detected in peripheral blood mononuclear cells (PBMC) of chronic fatigue syndrome (CFS) patients, which is characterized by upregulated 2-5A synthetase and RNase L activities, as well as by the presence of a low molecular weight (LMW) 2-5A-binding protein of 37-kDa related to RNase L. This truncated protein has been shown to originate from proteolytic cleavage of the native 83-kDa RNase L by m-calpain and human leukocyte elastase (HLE). We investigated the possible role of 2-5A oligomers in the proteolytic action toward the endonuclease and show that incubation of CFS PBMC extracts with 2-5A trimer and tetramer, but not with the dimer, results in a significant protection of the native 83-kDa RNase L against cleavage by endogenous and purified proteases. Similar results are obtained with a purified recombinant RNase L. An analysis of the size of 2-5A oligomers produced by the catalytic activity of the 2-5A synthetase present in PBMC extracts further shows that samples containing the 37-kDa RNase L preferentially produce 2-5A dimers instead of higher oligomers. Taken together, our results indicate that homodimerization of RNase L by 2-5A oligomers higher than the dimer prevents its cleavage by proteolytic enzymes. The presence of the truncated 37-kDa RNase L in PBMC extracts is therefore likely to result, not only from the abnormal activation of inflammatory proteases, but also from a dysregulation in 2-5A synthetase induction or activation towards the preferential production of 2-5A dimers.

Friedberg F, Leung DW, Quick J.	Department of Psychiatry, Stony Brook University, Stony Brook, New York 11794-8790, USA. HUfred.friedberg@stonybrook.eduUH	Do support groups help people with chronic fatigue syndrome and fibromyalgia? A comparison of active and inactive members.	J Rheumatol. 2005 Dec;32(12):2416-20.	OBJECTIVE: To examine the benefits and problems of a chronic fatigue syndrome (CFS) and fibromyalgia (FM) support organization as reported by its participants. METHODS: Active members (n = 32) and inactive members or dropouts (n = 135) of a regional support organization for people with CFS and FM completed a 26 item questionnaire by telephone interview or by self-completion and postal return. RESULTS: The most frequently endorsed benefits of membership were illness legitimization (67.8%), finding out helpful new information (66.4%), and feeling understood by others (62.2%). Lower frequency endorsements were given to: helped to find (35.0%) or deal with (38.5%) doctors, and helped to improve my illness (36.4%). The most frequently reported reasons for dropping out were inconvenient location (37.8%) or time (37.0%), too much negative talk or complaining (33.3%), too sick to attend (28.8%), and illness or coping improvement (29.6% each). The active-member group showed significantly higher ($p < 0.04$) symptom severity scores and less illness improvement ($p < 0.01$) in comparison to the inactive/dropout group. CONCLUSION: This cross-sectional study suggests that support groups for CFS are viewed as helpful by participants on a number of illness related issues. On the other hand, active members reported greater symptom severity and less illness improvement than inactive members or dropouts.
Fries E, Hesse J, Hellhammer J, Hellhammer DH.	Department for Psychobiology, University of Trier, Johanniterufer 15, 54290 Trier, Germany.	A new view on hypocortisolism.	Psychoneuroendocrinology. 2005 Nov;30(10):1010-6.	Low cortisol levels have been observed in patients with different stress-related disorders such as chronic fatigue syndrome, fibromyalgia, and post-traumatic stress disorder. Data suggest that these disorders are characterized by a symptom triad of enhanced stress sensitivity, pain, and fatigue. This overview will present data on the development, mechanisms and consequences of hypocortisolism on different bodily systems. We propose that the phenomenon of hypocortisolism may occur after a prolonged period of hyperactivity of the hypothalamic-pituitary-adrenal axis due to chronic stress as illustrated in an animal model. Further evidence suggests that despite symptoms such as pain, fatigue and high stress sensitivity, hypocortisolism may also have beneficial effects on the organism. This assumption will be underlined by some studies suggesting protective effects of hypocortisolism for the individual.
Frissora CL, Koch KL.	Department of Medicine, The Weill Medical College of Cornell University, 520 E. 70th Street, Suite J-314, New York, NY 10021, USA. cfrissor@med.corn	Symptom overlap and comorbidity of irritable bowel syndrome with other conditions.	Curr Gastroenterol Rep. 2005 Aug;7(4):264-71.	Irritable bowel syndrome (IBS) is one of several highly prevalent, multi-symptom gastrointestinal motility disorders that have a wide clinical spectrum and are associated with symptoms of gastrointestinal dysmotility and visceral hypersensitivity. Symptom overlap and comorbidity between IBS and other gastrointestinal motility disorders (eg, chronic constipation, functional dyspepsia, gastroesophageal reflux disease), with gastrointestinal disorders that are not related to motility (eg, celiac disease, lactose intolerance), and with somatic conditions (eg, fibromyalgia, chronic fatigue syndrome), are frequent. The clinical associations and pathophysiologic links between IBS and these disorders continue to be explored. This review discusses overlapping symptoms and comorbidity of IBS with select gastrointestinal and non-gastrointestinal disorders and attempts to identify

	ell.edu			commonalities among these conditions.
Furberg H, Olarte M, Afari N, Goldberg J, Buchwald D, Sullivan PF.	Department of Genetics, University of North Carolina, Chapel Hill, NC, USA.	The prevalence of self-reported chronic fatigue in a U.S. twin registry.	J Psychosom Res. 2005 Nov;59(5):283-90.	OBJECTIVE: To investigate the prevalence and correlates of various definitions of self-reported lifetime fatiguing illness in a U.S. twin registry. METHODS: Data from 4591 female and male twins from the population-based Mid-Atlantic Twin Registry were available for this study. Variables representing different definitions of lifetime fatiguing illness and personal characteristics were obtained through questionnaires. Odds ratios and 95% confidence intervals were calculated as measures of association between fatigue and gender. Kaplan-Meier curves were produced to examine the age at onset for lifetime fatiguing illnesses. RESULTS: Prevalences for different definitions of self-reported lifetime fatigue ranged from 36.7% for any fatigue to 2.7% for chronic fatigue syndrome-like illness. Females were two to three times more likely to report fatigue than males. Gender differences increased as fatigue definitions grew more restrictive. Ages at onset of chronic fatiguing illness were significantly earlier and the number of ancillary symptoms was greater for females than males. People with lifetime fatigue had significantly more compromised functional status than people without lifetime fatigue. CONCLUSION: The prevalence of self-reported lifetime fatiguing illness varied widely depending upon how it was defined. Given the debilitating consequences of fatiguing illnesses, the reasons for the female predominance and the earlier onset in women should receive increased research priority.
Gaab J, Rohleder N, Heitz V, Engert V, Schad T, Schurmeyer TH, Ehlert U.	Center for Psychobiological and Psychosomatic Research, University of Trier, Trier, Germany. j.gaab@psychology.unizh.ch	Stress-induced changes in LPS-induced pro-inflammatory cytokine production in chronic fatigue syndrome.	Psychoneuroendocrinology. 2005 Feb;30(2):188-98.	OBJECTIVE: It has been suggested that a hypofunctional hypothalamic-pituitary-adrenal (HPA) axis in chronic fatigue syndrome could result in an exaggerated release of pro-inflammatory cytokines during stress. As pro-inflammatory cytokines are involved in the induction of sickness behavior and thus constitute a potential physiological correlate of stress-induced symptom exacerbation in chronic fatigue syndrome, we set out to evaluate the LPS-induced production of pro-inflammatory cytokines during psychosocial stress in CFS and healthy controls. METHOD: Twenty-one CFS patients and 20 healthy controls matched for age and gender underwent a standardized psychosocial stress test (Trier social stress test, TSST). Adrenocorticotropine hormone (ACTH), salivary cortisol and plasma cortisol levels were measured before and repeatedly following exposure to the stressor. Lipopolysaccharide-stimulated production of interleukin-6 and tumor necrosis factor-alpha were assessed at baseline as well as 10 and 60 min after the stress test. RESULTS: CFS patients showed an inverse stress-induced response pattern of LPS-stimulated cytokines responses in comparison to healthy controls, i.e. stimulated cytokine production decreased shortly after stress in CFS patients, while it increased in controls. Fatigue scores and basal LPS-induced cytokine levels were significantly associated for TNF-alpha in controls and for both cytokines in CFS patients. Stress-induced changes in stimulated cytokine production were not associated with general fatigue scores in the control group, whereas in the CFS group, fatigue scores were significantly correlated with integrated levels of LPS-induced cytokines. However, partial correlations revealed that these results were due to the high correlations with basal LPS-induced cytokine levels. CONCLUSION: CFS patients do not show an exaggerated secretion of LPS-induced cytokines. Although cortisol responses to stress were normal, pro-inflammatory cytokine levels in CFS patients were significantly attenuated. Possible intracellular mechanisms, such as for example an enhanced sensitivity to inhibitory effects of glucocorticoids, a diminished responsivity to catecholaminergic stimulation, and a disruption of intracellular activation are discussed. Basal levels of

				stimulated pro-inflammatory Il-6 levels are generally related to fatigue scores. However, in CFS patients this association is of greater magnitude and can also be observed for TNF-alpha.
Gallagher AM, Coldrick AR, Hedge B, Weir WR, White PD.	Centre for Psychiatry, Institute of Community Health Sciences, Queen Mary School of Medicine and Dentistry, St. Bartholomew's Hospital, EC1A 7BE London, UK.	Is the chronic fatigue syndrome an exercise phobia? A case control study.	J Psychosom Res. 2005 Apr;58(4):367-73.	OBJECTIVE: The aim of this study was to test whether patients with chronic fatigue syndrome (CFS) have an exercise phobia, by measuring anxiety-related physiological and psychological reactions to ordinary activity and exercise. METHODS: Patients and healthy but sedentary controls were assessed over 8 h of an ordinary day, and before, during and after an incremental exercise test on a motorised treadmill. To avoid confounding effects, those with a comorbid psychiatric disorder were excluded. Heart rate, galvanic skin resistance (GSR) and the amount of activity undertaken were measured, along with state and trait measures of anxiety. RESULTS: Patients with CFS were more fatigued and sleep disturbed than were the controls and noted greater effort during the exercise test. No statistically significant differences were found in either heart rate or GSR both during a normal day and before, during and after the exercise test. Patients with CFS were more symptomatically anxious at all times, but this did not increase with exercise. CONCLUSION: The data suggest that CFS patients without a comorbid psychiatric disorder do not have an exercise phobia.
Garralda ME, Rangel L.	Academic Unit of Child and Adolescent Psychiatry, Faculty of Medicine, Imperial College London, St Mary's Campus, Norfolk Place, London W2 1PG, UK. HUe.garralda@imperial.ac.ukUH	Chronic fatigue syndrome of childhood. Comparative study with emotional disorders.	Eur Child Adolesc Psychiatry. 2005 Dec;14(8):424-30.	OBJECTIVE: To examine clinical specificity in chronic fatigue syndrome (CFS) of childhood, by comparing clinical features in childhood CFS and in emotional disorders (ED). METHOD SAMPLE: 28 children with CFS; 27 with ED. MEASURES: History of disorder; K-SADS psychiatric interviews; self-esteem and physical symptoms questionnaires; premorbid history, behavioural and personality assessments. RESULTS: There were high levels of comorbid emotional disorders in children with CFS, and the two groups were comparable on self-esteem, but CFS children endorsed more fatigue and other somatic symptoms. The two groups were comparable on age at illness onset, but parents of children with CSF reported more biological illness precipitants, more pre-morbid recurrent medical problems and infections. The CFS group had fewer pre-morbid psychological problems and less psychiatric comorbidity than the ED group. CONCLUSION: There is considerable clinical overlap between CFS and ED of childhood, but there are also differences in clinical presentation between these disorders.
Glaser R, Padgett DA, Litsky ML, Baiocchi RA, Yang EV, Chen M, Yeh PE, Klimas NG, Marshall GD, Whiteside T, Herberman R, Kiecolt-Glaser J, Williams MV.	Department of Molecular Virology, Immunology and Medical Genetics, The Ohio State University Medical Center, 333 W. 10th Avenue, Columbus, OH 43210, USA. glaser.1@osu.edu	Stress-associated changes in the steady-state expression of latent Epstein-Barr virus: implications for chronic fatigue syndrome and cancer.	Brain Behav Immun. 2005 Mar;19(2):91-103.	Antibodies to several Epstein-Barr virus (EBV)-encoded enzymes are observed in patients with different EBV-associated diseases. The reason for these antibody patterns and the role these proteins might play in the pathophysiology of disease, separate from their role in virus replication, is unknown. In this series of studies, we found that purified EBV deoxyuridine triphosphate nucleotidohydrolase (dUTPase) can inhibit the replication of human peripheral blood mononuclear cells in vitro and upregulate the production of TNF-alpha, IL-1beta, IL-6, IL-8, and IL-10. It also enhanced the ability of natural killer cells to lyse target cells. The EBV dUTPase also significantly inhibited the replication of mitogen-stimulated lymphocytes and the synthesis of IFN-gamma by cells isolated from lymph nodes and spleens obtained from mice inoculated with the protein. It also produced sickness behaviors known to be induced by some of the cytokines that were studied in the in vitro experiments. These symptoms include an increase in body temperature, a decrease in body mass and in physical activity. The data provide a new perspective on how an early nonstructural EBV-encoded protein can cause immune dysregulation and produce clinical symptoms observed in patients with chronic fatigue syndrome (CFS) separate from its role in virus replication and may serve as a new approach to help

				identify one of the etiological agents for CFS. The data also provide additional insight into the pathophysiology of EBV infection, inflammation, and cancer.

Gottschalk M, Kumpfel T, Flachenecker P, Uhr M, Trenkwalder C, Holsboer F, Weber F.	Max Planck Institute of Psychiatry, Munich, Germany.	Fatigue and regulation of the hypothalamo-pituitary-adrenal axis in multiple sclerosis.	Arch Neurol. 2005 Feb;62(2):277-80.	BACKGROUND: Fatigue is a common and disabling symptom in patients with multiple sclerosis (MS). Underlying mechanisms postulated so far have involved localization of brain lesions and abnormalities of the neuroendocrine system and cytokine regulation. OBJECTIVE: To investigate the relationship between fatigue and the hypothalamo-pituitary-adrenal (HPA) axis in patients with MS. DESIGN: A prospective survey. SETTING: Outpatient and inpatient study at the Max Planck Institute of Psychiatry, Munich, Germany. PATIENTS: Thirty-one patients with clinically definite MS, a relapsing-remitting disease course, and without MS-specific treatment. INTERVENTIONS: Assessment of fatigue with 3 questionnaires: the Fatigue Severity Scale (FSS), the Modified Fatigue Impact Scale (MFIS), and the Visual Analog Scale. Assessment of HPA axis regulation with the combined dexamethasone-corticotropin releasing hormone (Dex-CRH) test. RESULTS: The FSS score was significantly correlated with the MFIS score. Patients with fatigue had significantly elevated adrenocorticotropin (ACTH) levels in the combined Dex-CRH test. CONCLUSIONS: In contrast to results for chronic fatigue syndrome, where a hyporeactivity of the HPA axis has been shown, MS patients with fatigue exhibited a higher activity of the HPA axis than those without fatigue, as evidenced by significantly increased ACTH concentrations. Proinflammatory cytokines, known to be elevated in patients with MS, may cause both HPA axis alterations and fatigue.
Goudsmit E,		Chronic Fatigue	Journal of Chronic	A literature search identified all papers published on chronic fatigue syndrome (CFS) and myalgic

Stouten B		Syndrome: Editorial Bias in the British Medical Journal	Fatigue Syndrome 2005 12 (4): 47-59	encephalomyelitis (ME) in the British Medical Journal between 1995 and 2000. Analysis of the findings revealed a bias towards the views of one school of thought and a lack of papers on the immunological or virological aspects of CFS. This contrasts with the mainstream American journals, which generally covered a much wider range of subjects and views. We examine the arguments for and against covert editorial policies, and summarise the results of discussions with the relevant individuals and organisations.

Gutenbrunner C, Linden M, Gerdes N, Ehlebracht-Konig I, Grosch E.	Klinik fur Physikalische Medizin und Rehabilitation der Medizinischen Hochschule Hannover, Carl-Neuberg-Strasse 1, 30625 Hannover, Germany. gutenbrunner.christoph@mh-hannover.de	[Significance of the chronic fatigue syndrome in rehabilitation medicine--status and perspectives] [Article in German]	Rehabilitation (Stuttg). 2005 Jun;44(3):176-85.	It appears that from a clinical point of view chronic exhaustion or fatigue is an important factor in rehabilitation. This is, however, first of all a phenomenon that can be described as a function in accordance with the International Classification of Functioning, Disability and Health (JCF), caused by chronic illnesses or chronic excessive stress. The clinical and sociomedical ranking of chronic fatigue or exhaustion in respect of rehabilitation was discussed in the framework of a Workshop at the 12th Rehabilitation Science Colloquium, 2003 from the viewpoints of psychiatric rehabilitation, methodology, sociology and practical rehabilitation, and conclusions for future research were drawn. The definition of chronic fatigue is first of all mainly based on the feeling of chronic tiredness but also on phenomena of disturbed concentration, physical discomfort, headache and disorders of "drive" and mood. A psychiatric diagnosis linked with symptoms of chronic fatigue is neurasthenia, which is arrived at according to precisely defined criteria. Depressive disorder is one of the most important differential diagnoses in this sphere. Examinations by general practitioners revealed that about 90 % of the patients who had been diagnosed as suffering from psychovegetative disorders completely agreed with the diagnosis of neurasthenia. Neurasthenia resulted more often in work disability periods than disorders of somatisation and other psychosomatic diagnoses. Basing on the "IRES" scale "vital exhaustion", singular of even serious changes become evident in about 50 % to 90 % of the patients undergoing rehabilitation, depending on their individual range of indications. As was to be expected, the majority of pathologic findings concerns patients undergoing psychosomatic rehabilitation, since in such cases there is an overlapping with symptoms of psychosomatic diseases. It is, however, remarkable that also in somatically oriented orthopaedic rehabilitation symptoms of fatigue are seen in up to 50 % of the patients. Preliminary studies have shown that these symptoms can be definitely ameliorated within the rehabilitation framework, although pathological signs are still abundantly apparent in follow-up examinations. Markedly severe degrees of "vital exhaustion" and "vocational exhaustion" are also seen in rheumatology patients undergoing somatic rehabilitation. This agrees with case history details related by many female and male patients. Hence, it appears necessary to adapt rehabilitative intervention to both the psychovegetative and the medical

				behavioural aspects of this symptom. Scientific classification of the entire sphere of chronic fatigue in respect of rehabilitation requires classification of the relevant functions within the ICF framework. To this end it would be necessary to conduct patient inquiries within cross-sectional studies on the one hand and, on the other, a systematic consensus process among experts would have to be used for allocation to the relevant functions. This is the basis for development of suitable assessment tools for use in prospective studies in order to systematically evaluate the impact on functions and especially their effects on activities and participation.
Haines LC, Saidi G, Cooke RW.	Royal College of Paediatrics and Child Health, 50 Hallam Street, London W1W 6DE, UK. Linda.haines@rcpch.ac.uk	Prevalence of severe fatigue in primary care.	Arch Dis Child. 2005 Apr;90(4):367-8.	A postal survey of 1024 UK GP practices showed the prevalence of medically unexplained severe fatigue over three months in 5-19 year olds to be 62/100,000. Cases were predominantly adolescent girls and were more likely to come from practices in less deprived areas, which could reflect consulting behaviours.
Hamilton WT, Gallagher AM, Thomas JM, White PD.	The Grange, Bristol BS8 1AU, UK. w.hamilton@bristol.ac.uk	The prognosis of different fatigue diagnostic labels: a longitudinal survey.	Fam Pract. 2005 Aug;22(4):383-8. Epub 2005 Apr 1.	BACKGROUND: Several different diagnostic labels exist for the fatigue syndromes, including chronic fatigue syndrome (CFS), myalgic encephalomyelitis (ME) and postviral fatigue syndrome (PVFS). An allied condition is fibromyalgia. No study has examined prognostic differences across these different labels. OBJECTIVE: To compare the prognoses of patients labelled with different fatigue syndromes in primary care. METHODS: We performed a longitudinal survey, using electronic records from the General Practice Research Database. All 18,122 patients diagnosed by their GP with a fatigue syndrome from 1988-2001 with a minimum of one year of records after diagnosis were collated into four groups: CFS, ME, PVFS and fibromyalgia. CFS and ME were combined for the main analysis as no code for CFS was available until 1995. The length of illness was calculated as the interval between the diagnosis and the last recorded fatigue symptom, expressed as days per year, to account for differing lengths of record after diagnosis. RESULTS: Patients with CFS/ME combined had a worse prognosis (median length of illness 80 days per year; interquartile range 0-242) than fibromyalgia (51;0-244) or PVFS 0 (0-108), a significant difference, $P < 0.001$. In a subgroup analysis, ME had a worse prognosis (median length of illness in days per year 106; interquartile range 0-259) than CFS (33; 0-170), $P < 0.001$, in spite of a better course before diagnosis. Secondary outcome measures were consistent with these results. CONCLUSION: There were important differences in outcome between the various fatigue labels, with ME having the worst prognosis and PVFS the best. This could be an adverse effect of the label ME itself. Alternatively, patients who are destined to have a worse prognosis may preferentially attract the ME label. Our data support the first interpretation.
Henderson M, Tannock C.	Academic Department of Psychological Medicine, GKT School of Medicine and Institute of	Use of depression rating scales in chronic fatigue syndrome.	J Psychosom Res. 2005 Sep;59(3):181-4.	OBJECTIVE: The aim of this study was to examine the performance of three commonly used depression rating scales in a hospital sample of patients with chronic fatigue syndrome (CFS). METHODS: Sixty-one patients with CDC criteria for CFS completed the General Health Questionnaire (GHQ), the Hamilton Depression Scale (HAM-D) and the depression subscale of the Hospital Anxiety and Depression Scale (HADS-D). Current psychiatric status was assessed using the Structured Clinical Interview for DSM-III-R. DISORDERS: Patient version (SCID-P). Receiver operating curves were drawn

	Psychiatry, Weston Education Centre, Cutcombe Road, London SE5 9RJ, United Kingdom.			for each of the depression rating scales. RESULTS: Thirty-one percent of the patients were depressed according to the SCID-P. Using the standard cut-offs, both GHQ and HAM-D overestimated the number of depressed patients, whilst the HADS-D underestimated the number. The receiver operating curves suggest that the optimum cut-offs for GHQ, HAM-D and HADS-D in this population are 7/8, 13/14 and 8/9, respectively. CONCLUSIONS: Standard cutoffs may not be appropriate when using depression rating scales in CFS patients in a tertiary care setting.
Hershfield NB.	Division of Gastroenterology, Department of Medicine, University of Calgary, Calgary, Alberta. gutdoc1@shaw.ca	Nongastrointestinal symptoms of irritable bowel syndrome: an office-based clinical survey.	Can J Gastroenterol. 2005 Apr;19(4):231-4.	Irritable bowel syndrome (IBS) is the most prevalent gastrointestinal problem faced by practicing gastroenterologists. For many years, nongastrointestinal symptoms have been documented in IBS patients, but the medical literature does not emphasize them. The present study explored how IBS and inflammatory bowel disease patients differ in their reporting of nongastrointestinal symptoms. Information from 200 consecutive patients with IBS and a similar number of patients with Crohn's disease (in a single gastroenterology practice) was obtained at the initial visit using a simple questionnaire. Comparison of the data revealed that IBS patients describe certain nongastrointestinal symptoms far more frequently than do those with inflammatory bowel disease. It is recommended that these symptoms be considered along with the generally accepted criteria for making a positive diagnosis of IBS.
Hutchings A, Raine R, Sanderson C, Black N.	Health Services Research Unit, London School of Hygiene and Tropical Medicine, London WC1E 7HT, UK. andrew.hutchings@lshtm.ac.uk	An experimental study of determinants of the extent of disagreement within clinical guideline development groups.	Qual Saf Health Care. 2005 Aug;14(4):240-5.	OBJECTIVE: To assess the effect of design features and clinical and social cues on the extent of disagreement among participants in a formal consensus development process. METHODS: Factorial design involving 16 groups consisting of 135 general practitioners (GPs) and 42 mental health professionals from England. The groups rated the appropriateness of four mental health interventions for three conditions (chronic back pain, irritable bowel syndrome, and chronic fatigue syndrome) in the context of various clinical and social cues. The groups differed in three design features: provision of a systematic literature review (versus not provided), group composition (mixed versus GP only), and assumptions about the healthcare resources available (realistic versus idealistic). Disagreement was measured using the mean absolute deviation from a group's median rating for a scenario. RESULTS: None of the design features significantly affected the extent of disagreement within groups (all $p>0.3$). Disagreement did differ between treatments (closer consensus for cognitive behavioural therapy and behavioural therapy than for brief psychodynamic intervention therapy and antidepressants) and cues (closer consensus for depressed patients and patients willing to try any treatment). CONCLUSION: In terms of the extent of disagreement in the groups in this study, formal consensus development was a robust technique in that the results were not dependent on the way it was conducted.

Inder WJ, Prickett TC, Mulder RT.	Department of Endocrinology, Christchurch	Normal opioid tone and hypothalamic-	Clin Endocrinol (Oxf). 2005 Mar;62(3):343-8.	OBJECTIVE: To determine whether the functional impairment seen in chronic fatigue syndrome (CFS) is associated with reduced levels of central opioids and/or deficiency of the hypothalamic-pituitary-adrenal (HPA) axis. DESIGN: Single-blinded case-control study measuring functional and psychological

	Hospital, and Department of Psychological Medicine, Christchurch School of Medicine, Christchurch, New Zealand. winder@medstv.unimelb.edu.au	pituitary-adrenal axis function in chronic fatigue syndrome despite marked functional impairment.		status, basal hormonal parameters and ACTH/cortisol response to naloxone and ovine corticotrophin-releasing hormone (oCRH) vs. placebo in people with CFS and healthy controls. PATIENTS: Twelve people with CFS and 11 age-matched controls. MEASUREMENTS: Hormonal parameters: basal levels of 09:00 h plasma cortisol, dehydroepiandrosterone sulfate (DHEAS) and IGF-1. 24-h urinary free cortisol. Plasma ACTH and cortisol response to naloxone 125 microg/kg, oCRH 1 microg/kg and placebo (normal saline). Psychological parameters: SF-36, Hamilton Depression Score, Hospital Anxiety and Depression Scale and Fatigue Scale. RESULTS: There were highly significant differences between the CFS subjects and the controls with respect to the measures of fatigue and physical functioning. However, there were no differences in basal levels of 09:00 h cortisol (367 +/- 37 vs. 331 +/- 39 nmol/l, P = 0.51), DHEAS (4.2 +/- 0.6 vs. 4.0 +/- 0.5 micromol/l, P = 0.81), 24-h urinary free cortisol (182 +/- 27 vs. 178 +/- 21 nmol/24 h, P = 0.91) or IGF-1 (145 +/- 19 vs. 130 +/- 11 microg/l, P = 0.52) between the CFS group and controls, respectively. There was also no difference between the groups with respect to the ACTH and cortisol response to either oCRH or naloxone. CONCLUSIONS: Our data do not support an aetiological role for deficiency in central opioids or the HPA axis in the symptoms of CFS.
Iwakami E, Arashima Y, Kato K, Komiya T, Matsukawa Y, Ikeda T, Arakawa Y, Oshida S.	Department of Legal Medicine, Nihon University School of Medicine, Tokyo, Japan.	Treatment of chronic fatigue syndrome with antibiotics: pilot study assessing the involvement of Coxiella burnetii infection.	Intern Med. 2005 Dec;44(12):1258-63.	OBJECTIVE: To examine whether Coxiella burnetii (C. burnetii) is involved in chronic fatigue syndrome (CFS), we administered tetracycline antibiotics to subjects with CFS, and followed changes in clinical symptoms, PCR findings, and C. burnetii antibody titers. PATIENTS AND METHODS: The subjects were 8 patients with CFS and 213 with nonspecific complaints such as chronic fatigue and low-grade fever for several months or longer but not meeting the diagnostic criteria for CFS. All were examined for C. burnetii infection by nested PCR and the indirect immunofluorescence test (IF). RESULTS: Four CFS patients (the CFS group) and 54 controls [the post-Q fever fatigue syndrome (QFS) group] positive for C. burnetii were treated mainly with minocycline or doxycycline (100 mg/day) for 3 months. After treatment, all 58 patients tested negative for C. burnetii infection. In the CFS group, no significant difference was noted between the mean pre- and post-treatment temperatures or headache scores. Similarly, there was no significant improvement in performance status (PS) scores. In the QFS group, however, mean temperatures and headache scores were significantly decreased after treatment ($p<0.001$). PS scores were also improved. CONCLUSION: These results suggest the possibility of direct involvement of C. burnetii in the pathological state of CFS to be low, despite the C. burnetii infection rate being high in CFS patients. This is a pilot study and further larger investigations are necessary to confirm our preliminary results.

Jammes Y, Steinberg JG, Mambrini O, Bregeon F, Delliaux S.	Laboratoire de Physiopathologie Respiratoire (UPRES EA 2201), Faculte de Medecine, Institut Federatif de	Chronic fatigue syndrome: assessment of increased oxidative stress and altered muscle excitability in response to	J Intern Med. 2005 Mar;257(3):299-310.	OBJECTIVES: Because the muscle response to incremental exercise is not well documented in patients suffering from chronic fatigue syndrome (CFS), we combined electrophysiological (compound-evoked muscle action potential, M wave), and biochemical (lactic acid production, oxidative stress) measurements to assess any muscle dysfunction in response to a routine cycling exercise. DESIGN: This case-control study compared 15 CFS patients to a gender-, age- and weight-matched control group (n=11) of healthy subjects. INTERVENTIONS: All subjects performed an incremental cycling exercise continued until exhaustion. MAIN OUTCOME MEASURES: We measured the oxygen uptake

	Recherche Jean Roche, Marseille, France. jammes.y@jean-roche.univ-mrs.fr	incremental exercise.		(VO2), heart rate (HR), systemic blood pressure, percutaneous O2 saturation (SpO2), M-wave recording from vastus lateralis, and venous blood sampling allowing measurements of pH (pHv), PO2 (PvO2), lactic acid (LA), and three markers of the oxidative stress (thiobarbituric acid-reactive substances, TBARS, reduced glutathione, GSH, and ascorbic acid, RAA). RESULTS: Compared with control, in CFS patients (i) the slope of VO2 versus work load relationship did not differ from control subjects and there was a tendency for an accentuated PvO2 fall at the same exercise intensity, indicating an increased oxygen uptake by the exercising muscles; (ii) the HR and blood pressure responses to exercise did not vary; (iii) the anaerobic pathways were not accentuated; (iv) the exercise-induced oxidative stress was enhanced with early changes in TBARS and RAA and enhanced maximal RAA consumption; and (v) the M-wave duration markedly increased during the recovery period. CONCLUSIONS: The response of CFS patients to incremental exercise associates a lengthened and accentuated oxidative stress together with marked alterations of the muscle membrane excitability. These two objective signs of muscle dysfunction are sufficient to explain muscle pain and postexertional malaise reported by our patients.
Jason LA, Corradi K, Torres-Harding S, Taylor RR, King C.	DePaul University, Chicago, Illinois 60614, USA. ljason@depaul.edu	Chronic fatigue syndrome: the need for subtypes.	Neuropsychol Rev. 2005 Mar;15(1):29-58.	Chronic fatigue syndrome (CFS) is an important condition confronting patients, clinicians, and researchers. This article provides information concerning the need for appropriate diagnosis of CFS subtypes. We first review findings suggesting that CFS is best conceptualized as a separate diagnostic entity rather than as part of a unitary model of functional somatic distress. Next, research involving the case definitions of CFS is reviewed. Findings suggest that whether a broad or more conservative case definition is employed, and whether clinic or community samples are recruited, these decisions will have a major influence in the types of patients selected. Review of further findings suggests that subtyping individuals with CFS on sociodemographic, functional disability, viral, immune, neuroendocrine, neurology, autonomic, and genetic biomarkers can provide clarification for researchers and clinicians who encounter CFS' characteristically confusing heterogeneous symptom profiles. Treatment studies that incorporate subtypes might be particularly helpful in better understanding the pathophysiology of CFS. This review suggests that there is a need for greater diagnostic clarity, and this might be accomplished by subgroups that integrate multiple variables including those in cognitive, emotional, and biological domains.
Jerjes WK, Cleare AJ, Wessely S, Wood PJ, Taylor NF.	Department of Clinical Biochemistry, King's College Hospital, Denmark Hill, London SE5 9RX, United Kingdom. w_jerjes@yahoo.co.uk	Diurnal patterns of salivary cortisol and cortisone output in chronic fatigue syndrome.	J Affect Disord. 2005 Aug;87(2-3):299-304.	BACKGROUND: The aim of the present study was to obtain a naturalistic measure of diurnal hypothalamic-pituitary-adrenal (HPA) axis output in CFS patients unaffected by medication or comorbid psychiatric disorder likely to influence the axis. METHOD: Cortisol and cortisone levels were measured in saliva samples collected from 0600 h to 2100 h at 3-h intervals in CFS patients and healthy controls. RESULTS: Mean cortisol and cortisone concentrations were significantly lower in patients than controls across the whole day, as were levels at each individual time point except 2100 h. Cosinor analysis showed a significant diurnal rhythm of cortisol and cortisone that was not phase-shifted in CFS compared to controls. However, there was a lower rhythm-adjusted mean and a lower amplitude in CFS patients. The cortisol/cortisone ratio showed no diurnal rhythm and did not differ between CFS subjects and controls. LIMITATIONS: The sample size was relatively small, and drawn from specialist referral patients who had been ill for some time; generalisation of these results to other populations is therefore unwarranted. CONCLUSION: The main findings of this study are to

				provide further evidence for reduced basal HPA axis function in at least some patients with CFS and to show for the first time that salivary cortisone is also reduced in CFS and has a diurnal rhythm similar to that of cortisol. We have also demonstrated that the cortisol/cortisone ratio remains unchanged in CFS, suggesting that increased conversion of cortisol to cortisone cannot account for the observed lowering of salivary cortisol.
Jones JF, Kulkarni PS, Butera ST, Reeves WC.	Division of Viral and Rickettsial Diseases, Centers for Disease Control and Prevention, Atlanta, Georgia 30333, USA. jaj9@cdc.gov	GB virus-C--a virus without a disease: we cannot give it chronic fatigue syndrome.	BMC Infect Dis. 2005 Sep 28;5:78.	BACKGROUND: Chronic fatigue syndrome (CFS) is an illness in search of an infectious etiology. GB virus-C (GBV-C) virus is a flavivirus with cell tropism and host defense induction qualities compatible with a role in producing the syndrome. The GBV-C genome is detectable in 4% of the population and 12% of the population is seropositive. The present study evaluated the association between infection with GBV and CFS. METHODS: We used a commercial EIA to detect antibodies against the GBV-C E2 protein and a quantitative real-time RT-PCR assay to detect active GBV-C infection. Sera were from a case control study of CFS in Atlanta, Georgia. The Fisher's exact two-tailed test was used for statistical analysis. RESULTS: Two of 12 CFS patients and one of 21 controls were seropositive for prior GBV-C infection and one control had viral RNA detected, indicating active infection. The results are not statistically different. CONCLUSION: We found no evidence that active or past infection with GBV is associated with CFS.
Jones JF, Nicholson A, Nisenbaum R, Papanicolaou DA, Solomon L, Boneva R, Heim C, Reeves WC.	Division of Viral and Rickettsial Diseases, National Center for Infectious Diseases, Centers for Disease Control and Prevention, Atlanta, Ga 30333, USA. HUjaj9@cdc.govUH	Orthostatic instability in a population-based study of chronic fatigue syndrome.	Am J Med. 2005 Dec;118(12):1415.	PURPOSE: Autonomic nervous system dysfunction has been suggested as involved in the pathophysiology of chronic fatigue syndrome. This population-based case control study addressed the potential association between orthostatic instability (one sign of dysautonomia) and chronic fatigue syndrome. SUBJECTS AND METHODS: Fifty-eight subjects who fulfilled criteria of the 1994 chronic fatigue syndrome research case definition and 55 healthy controls participated in a 2-day inpatient evaluation. Subjects had been identified during a 4-year population-based chronic fatigue syndrome surveillance study in Wichita, Kan. The present study evaluated subjects' current medical and psychiatric status, reviewed past medical/psychiatric history and medication use, used a stand-up test to screen for orthostatic instability, and conducted a head-up tilt table test to diagnose orthostatic instability. RESULTS: No one manifested orthostatic instability in the stand-up test. The head-up tilt test elicited orthostatic instability in 30% of eligible chronic fatigue syndrome subjects (all with postural orthostatic tachycardia) and 48% of controls (50% with neurally mediated hypotension); intolerance was present in only nonfatigued (n=7) subjects. Neither fatigue nor illness severity were associated with outcome. CONCLUSIONS: Orthostatic instability was similar in persons with chronic fatigue syndrome and nonfatigued controls subjects recruited from the general Wichita population. Delayed responses to head-up tilt tests were common and may reflect hydration status. These findings suggest reappraisal of primary dysautonomia as a factor in the pathogenesis of chronic fatigue syndrome.
Jones MG, Cooper E, Amjad S, Goodwin CS, Barron JL, Chalmers RA.	St George's Hospital Medical School, Cranmer Terrace, London, SW17 0RE, UK.	Urinary and plasma organic acids and amino acids in chronic fatigue syndrome.	Clin Chim Acta. 2005 Nov;361(1-2):150-8.	Previous work by others have suggested the occurrence of one or more chemical or metabolic 'markers' for ME/CFS including specific amino acids and organic acids and a number of unidentified compounds (CFSUM1, CFSUM2). We have shown elsewhere that CFSUM1 is partially derivatised pyroglutamic acid and CFSUM2 partially derivatised serine and have suggested and demonstrated that the analytical methods used were unsuitable to identify or to accurately quantify urinary metabolites. We have now made a detailed analysis of plasma and urinary amino acids and of urinary organic acids

				from patients with ME/CFS and from three control groups. Fasting blood plasma and timed urine samples were obtained from 31 patients with CFS, 31 age and sex-matched healthy controls, 15 patients with depression and 22 patients with rheumatoid arthritis. Plasma and urinary amino acids and urinary organic acids were determined using established and validated methods and data compared by statistical analysis. None of the previously reported abnormalities in urinary amino acids or of organic acids could be confirmed. Results however provide some evidence in patients with ME/CFS for underlying inflammatory disease and for reduced intramuscular collagen with a lowered threshold for muscle micro-injury. These factors in combination may provide a basis for the fatigue and muscle pain that are the major symptoms in these patients.
Jones MG, Goodwin CS, Amjad S, Chalmers RA.	St. George's Hospital Medical School, Cranmer Terrace, London, SW17 0RE, UK.	Plasma and urinary carnitine and acylcarnitines in chronic fatigue syndrome.	Clin Chim Acta. 2005 Oct;360(1-2):173-7.	Contradictory reports have suggested that serum free carnitine and acylcarnitine concentrations are decreased in patients with chronic fatigue syndrome (CFS) and that this is a cause of the muscle fatigue observed in these patients. Others have shown normal serum free carnitine and acylcarnitines in similar patients. We report here studies on free, total and esterified (acyl) carnitines in urine and blood plasma from UK patients with CFS and three control groups. Plasma and timed urine samples were obtained from 31 patients with CFS, 31 healthy controls, 15 patients with depression and 22 patients with rheumatoid arthritis. Samples were analysed using an established radioenzymatic procedure for total, free and esterified (acyl) carnitine. There were no significant differences in plasma or urinary total, free or esterified (acyl) carnitine between UK patients with CFS and the control groups or in renal excretion rates of these compounds. The data presented here show that, in the CFS patients studied, there are no significant abnormalities of free or esterified (acyl) carnitine. It is thus unlikely that abnormalities in carnitine homeostasis have any significant role in the aetiology of their chronic fatigue.
Jones MG, Goodwin CS, Amjad S, Chalmers RA.	St. George's Hospital Medical School, Cranmer Terrace, London, SW17 0RE, UK.	Plasma and urinary carnitine and acylcarnitines in chronic fatigue syndrome. It is thus unlikely that abnormalities in carnitine homeostasis have any significant role in the aetiology of their chronic fatigue.
Karmisholt K, Gotzsche PC.	Nordic Cochrane Centre, H:S Rigshospitalet, DK-2100 Kobenhavn O, Denmark.	Physical activity for secondary prevention of disease. Systematic reviews	Dan Med Bull. 2005 May;52(2):90-4.	BACKGROUND: Physical activity is recommended for secondary prevention of several diseases but it is not always clear how reliable the evidence is. METHODS: We searched MEDLINE and The Cochrane Library for systematic reviews of randomised clinical trials published 1998-2004. RESULTS: We identified 30 eligible systematic reviews and excluded 13 that contained trials covered in larger reviews or were older than other reviews on the same subject. Physical activity decreased all-cause

		of randomised clinical trials.		mortality in patients with coronary heart disease, odds ratio 0.73 (95% confidence interval 0.54 to 0.98), increased maximum walking time in patients with intermittent claudication by 6.5 min (4.4 to 8.7), and decreased pain in patients with osteoarthritis of the knee, standardised mean difference 0.34 (0.24 to 0.44). There were positive effects also in heart failure, chronic obstructive lung disease, type 2 diabetes and fibromyalgia, but they need confirmation in high-quality trials. Exercise improved quality of life in several conditions and generally led to improved physical performance. An effect was not shown in stroke, asthma, rheumatoid arthritis, acute or chronic low back pain, chronic fatigue syndrome, depression, cystic fibrosis or HIV/AIDS. The occurrence of harms was generally not reported. CONCLUSION: Physical activity can have important, and even life-saving, effects as secondary prevention of disease, but more and better trials are needed to fully assess its benefits and harms, in particular trials that compare exercise with drugs.
Kaushik N, Fear D, Richards SC, McDermott CR, Nuwaysir EF, Kellam P, Harrison TJ, Wilkinson RJ, Tyrrell DA, Holgate ST, Kerr JR.	Department of Paediatric Infectious Diseases, St Marys Campus, Imperial College, Norfolk Place, London W2 1PG, UK.	Gene expression in peripheral blood mononuclear cells from patients with chronic fatigue syndrome.	J Clin Pathol. 2005 Aug;58(8):826-32.	BACKGROUND: Chronic fatigue syndrome (CFS) is a multisystem disease, the pathogenesis of which remains undetermined. AIMS: To test the hypothesis that there are reproducible abnormalities of gene expression in patients with CFS compared with normal healthy persons. METHODS: To gain further insight into the pathogenesis of this disease, gene expression was analysed in peripheral blood mononuclear cells from 25 patients with CFS diagnosed according to the Centers for Disease Control criteria and 25 normal blood donors matched for age, sex, and geographical location, using a single colour microarray representing 9522 human genes. After normalisation, average difference values for each gene were compared between test and control groups using a cutoff fold difference of expression > or = 1.5 and a p value of 0.001. Genes showing differential expression were further analysed using Taqman real time polymerase chain reaction (PCR) in fresh samples. RESULTS: Analysis of microarray data revealed differential expression of 35 genes. Real time PCR confirmed differential expression in the same direction as array results for 16 of these genes, 15 of which were upregulated (ABCD4, PRKCL1, MRPL23, CD2BP2, GSN, NTE, POLR2G, PEX16, EIF2B4, EIF4G1, ANAPC11, PDCD2, KHSRP, BRMS1, and GABARAPL1) and one of which was downregulated (IL-10RA). This profile suggests T cell activation and perturbation of neuronal and mitochondrial function. Upregulation of neuropathy target esterase and eukaryotic translation initiation factor 4G1 may suggest links with organophosphate exposure and virus infection, respectively. CONCLUSION: These results suggest that patients with CFS have reproducible alterations in gene regulation.
Kazar J.	Research Base of the Slovak Medical University, Bratislava, Slovak Republic. HUjan.kazar@szu.skUH.	Coxiella burnetii Infection.	Ann N Y Acad Sci. 2005 Dec;1063:105-14.	Coxiella burnetii is an obligate intracellular bacterium that causes a worldwide zoonosis, Q fever, and can be misused as a biological warfare agent. Infection in animals (coxiellosis) is mostly persistent. Infection in humans is often asymptomatic, but it can manifest as an acute disease (usually a self-limited flu-like illness, pneumonia, or hepatitis) or as a chronic form (mainly endocarditis, but also hepatitis and chronic fatigue syndrome). C. burnetii infection in pregnant women may result in abortions, premature deliveries, and stillbirths. Infection in nature is maintained and transmitted by ticks as the principal vector and reservoir. Cattle, sheep, and goats are the most important source of human infections. Humans contract C. burnetii infection mostly by aerosol in contact with contaminated environs, wind playing an important factor in spreading the infection. The wide distribution of C. burnetii contributes to a high resistance of its extracellular small cell variant to environmental conditions. Its intracellular large cell variant, adapted to survive under harsh conditions

				of phagolysosomes, enables long-term survival and persistence of C. burnetii, namely in monocytes/macrophages. Host factors such as underlying disease and cell-mediated immunity play a decisive role in the clinical expression of C. burnetii infection. Complete genome analysis of C. burnetii will certainly contribute to better understanding of the pathogenesis of C. burnetii infection and will improve Q fever diagnosis and immunoprophylaxis.
Kennedy G, Spence VA, McLaren M, Hill A, Underwood C, Belch JJ.	Vascular Diseases Research Unit, The Institute of Cardiovascular Research, Ninewells Hospital and Medical School, Dundee, Scotland DD1 9SY, UK. g.y.kennedy@dundee.ac.uk	Oxidative stress levels are raised in chronic fatigue syndrome and are associated with clinical symptoms.	Free Radic Biol Med. 2005 Sep 1;39(5):584-9.	The aetiology of chronic fatigue syndrome (CFS) is unknown; however, recent evidence suggests excessive free radical (FR) generation may be involved. This study investigated for the first time levels of 8-iso-prostaglandin-F(2 alpha)-isoprostanes alongside other plasma markers of oxidative stress in CFS patients and control subjects. Forty-seven patients (18 males, 29 females, mean age 48 [19--63] years) who fulfilled the Centres for Disease Control classification for CFS and 34 healthy volunteers (13 males, 21 females, 46 [19--63] years) were enrolled in the study. The CFS patients were divided into two groups; one group had previously defined cardiovascular (CV) risk factors of obesity and hypertension (group 1) and the second were normotensive and nonobese (group 2). Patients had significantly increased levels of isoprostanes (group 1, P=0.007; group 2, P=0.03, unpaired t test compared to controls) and oxidised low-density lipoproteins (group 2, P=0.02) indicative of a FR attack on lipids. CFS patients also had significantly lower high-density lipoproteins (group 1, P=0.011; group 2, P=0.005). CFS symptoms correlated with isoprostane levels, but only in group 2 low CV risk CFS patients (isoprostanes correlated with; total symptom score P=0.005; joint pain P=0.002; postexertional malaise P=0.027, Pearson). This is the first time that raised levels of the gold standard measure of in vivo oxidative stress (isoprostanes) and their association with CFS symptoms have been reported.
Kim CH, Shin HC, Won CW.	Department of Family Medicine, Sungkyunkwan University School of Medicine, Korea. kchjp@hanafos.com	Prevalence of chronic fatigue and chronic fatigue syndrome in Korea: community-based primary care study.	J Korean Med Sci. 2005 Aug;20(4):529-34.	There have been many epidemiological and clinical researches on chronic fatigue (CF) and chronic fatigue syndrome (CFS) since the 1990s, but such studies have been quite limited in Korea. The aim of this study was to investigate the point prevalence of CF and CFS in patients who visited community-based eight primary care clinics in Korea. The study subjects were 1,648 patients aged 18 yr and over who visited one of eight primary care clinics in Korea between the 7th and 17th of May 2001. The physicians determined the status of the subjects through fatigue-related questionnaires, medical history, physical examination, and laboratory tests. The subjects were categorized into no fatigue, prolonged fatigue, CF and then CF were further classified to medically explained CF (Physical CF and Psychological CF) and medically unexplained CF (CFS and idiopathic chronic fatigue). The point prevalence of CF and CFS were 8.4% (95% CI 7.1-9.7%) and 0.6% (95% CI 0.2-1.0%). Medically explained CF was 80.5% of CF, of which 57.1% had psychological causes. The clinical characteristics of CFS were distinguished from explained CF. CF was common but CFS was rare in community-based primary care settings in Korea.
King C, Jason LA.	Spinal Cord Injury Service (128), Hines VA Hospital, P.O. Box 5000, Hines, IL 60141-5128, USA.	Improving the diagnostic criteria and procedures for chronic fatigue syndrome.	Biol Psychol. 2005 Feb;68(2):87-106.	Since the publication of the case definition for chronic fatigue syndrome (CFS) in 1988 the diagnostic criteria have been revised twice in the U.S. None of the case definitions were derived empirically. As a result, there is concern regarding the sensitivity, specificity, and reliability of the criteria. The goal of the present study was to identify methods for improving the diagnostic criteria for CFS. Three groups of 15 participants each were recruited: participants with (1) CFS, (2) major depressive disorder (MDD), and (3) healthy controls. Using statistical procedures, three methods for improving the diagnostic

	cpking@rcn.com			criteria were explored: identification of new diagnostic symptoms, the use of severity ratings for symptomatology, and the identification of standardized measures that differentiate cases of CFS from other conditions. Results of the present study suggest that these three methods hold promise for improving the sensitivity, specificity, and reliability of the diagnostic criteria for CFS.
Kodama M, Kodama T.	Kodama Research Institute of Preventive Medicine, 50-5 Chikusaku, Chikusaku, Nagoya 464-0005, Japan.	The clinical course of interstitial pneumonia alias chronic fatigue syndrome under the control of megadose vitamin C infusion system with dehydroepiandrosterone-cortisol annex.	Int J Mol Med. 2005 Jan;15(1):109-16.	The year 1995 marked the onset of interstitial pneumonia spread in Nagoya, Japan. For the last 9 years, we have been accumulating clinical experience with the disease control using the combination of prophylactic use of anti-biotics and regular practice of megadose vitamin C infusion with either dehydroepiandrosterone-annex or dehydroepiandrosterone-cortisol annex. The purpose of this study is to assess the usefulness of our new treatment system for the control of interstitial pneumonia alias chronic fatigue syndrome. The results obtained are given as follows: i) The long-term maintenance of the above treatment system was effective not only for decreasing the risk for recurrence of active form pneumonia, but also for prevention of malignancy emergence in aged patients with interstitial pneumonia. ii) Evidence is presented to indicate that interstitial pneumonia was associated with increased risk for depression of which the emergence is a candidate subject causally related to the long-term use of glucocorticoid. iii) A patient with both interstitial pneumonia and depression was found to be less responsive to our treatment system. It is suggested that the use of more dehydroepiandrosterone at the sacrifice of cortisol in the infusion annex may be a choice for the control of both interstitial pneumonia and depression. iv) The description of chronic fatigue syndrome as regards the endocrinological, epidemiological and psychiatric characteristics are in good agreement with our experience on patients having interstitial pneumonia, evidence in support of our proposal that there is no convincing reasoning to separate chronic fatigue syndrome from interstitial pneumonia. v) The long-term practice of our treatment system for the control of interstitial pneumonia (an autoimmune disease) was found to suppress the inflammatory process but not the fibrotic process in the long run. vi) A few innovations were made in our treatment system to reduce the risk of bleeding or thrombosis--vascular complications of pneumonia. vii) The merit of our treatment system is to create a new hormonal environment to improve the state of immunodeficiency by use of a non-steroid substance--vitamin C which encounters little resistance from the feedback mechanism of steroid metabolism in the in vivo system.
Kop WJ, Lyden A, Berlin AA, Ambrose K, Olsen C, Gracely RH, Williams DA, Clauw DJ.	Department of Medical and Clinical Psychology, Uniformed Services University of the Health Sciences, 4301 Jones Bridge Road, Bethesda, MD 20814, USA. wjkop@usuhs.mil	Ambulatory monitoring of physical activity and symptoms in fibromyalgia and chronic fatigue syndrome.	Arthritis Rheum. 2005 Jan;52(1):296-303.	OBJECTIVE: Fibromyalgia (FM) and chronic fatigue syndrome (CFS) are associated with substantial physical disability. Determinants of self-reported physical disability are poorly understood. This investigation uses objective ambulatory activity monitoring to compare patients with FM and/or CFS with controls, and examines associations of ambulatory activity levels with both physical function and symptoms during activities of daily life. METHODS: Patients with FM and/or CFS (n = 38, mean +/- SD age 41.5 +/- 8.2 years, 74% women) completed a 5-day program of ambulatory monitoring of physical activity and symptoms (pain, fatigue, and distress) and results were compared with those in age-matched controls (n = 27, mean +/- SD age 38.0 +/- 8.6 years, 44% women). Activity levels were assessed continuously, ambulatory symptoms were determined using electronically time-stamped recordings at 5 time points during each day, and physical function was measured with the 36-item Short Form health survey at the end of the 5-day monitoring period. RESULTS: Patients had significantly lower peak activity levels than controls (mean +/- SEM 8,654 +/- 527 versus 12,913 +/-

				1,462 units; P = 0.003) and spent less time in high-level activities when compared with controls (P = 0.001). In contrast, patients had similar average activity levels as those of controls (mean +/- SEM 1,525 +/- 63 versus 1,602 +/- 89; P = 0.47). Among patients, low activity levels were associated with worse self-reported physical function over the preceding month. Activity levels were inversely related to concurrent ambulatory pain (P = 0.031) and fatigue (P < 0.001). Pain and fatigue were associated with reduced subsequent ambulatory activity levels, whereas activity levels were not predictive of subsequent symptoms. CONCLUSION: Patients with FM and/or CFS engaged in less high-intensity physical activities than that recorded for sedentary control subjects. This reduced peak activity was correlated with measures of poor physical function. The observed associations may be relevant to the design of behavioral activation programs, because activity levels appear to be contingent on, rather than predictive of, symptoms.
Lange G, Steffener J, Cook DB, Bly BM, Christodoulou C, Liu WC, Deluca J, Natelson BH.	Department of Radiology, University of Medicine and Dentistry of New Jersey-New Jersey Medical School, Newark, 07103, USA. lange@njneurome d.org	Objective evidence of cognitive complaints in Chronic Fatigue Syndrome: a BOLD fMRI study of verbal working memory.	Neuroimage. 2005 Jun;26(2):513-24. Epub 2005 Apr 7.	Individuals with Chronic Fatigue Syndrome (CFS) often have difficulties with complex auditory information processing. In a series of two Blood Oxygen Level Dependent (BOLD) functional Magnetic Resonance Imaging (fMRI) studies, we compared BOLD signal changes between Controls and individuals with CFS who had documented difficulties in complex auditory information processing (Study 1) and those who did not (Study 2) in response to performance on a simple auditory monitoring and a complex auditory information processing task (mPASAT). We hypothesized that under conditions of cognitive challenge: (1) individuals with CFS who have auditory information processing difficulties will utilize frontal and parietal brain regions to a greater extent than Controls and (2) these differences will be maintained even when objective difficulties in this domain are controlled for. Using blocked design fMRI paradigms in both studies, we first presented the auditory monitoring task followed by the mPASAT. Within and between regions of interest (ROI), group analyses were performed for both studies with statistical parametric mapping (SPM99). Findings showed that individuals with CFS are able to process challenging auditory information as accurately as Controls but utilize more extensive regions of the network associated with the verbal WM system. Individuals with CFS appear to have to exert greater effort to process auditory information as effectively as demographically similar healthy adults. Our findings provide objective evidence for the subjective experience of cognitive difficulties in individuals with CFS.
Li YJ, Gao XG, Wang DX, Lin T, Bai XL, Yang FZ.	Department of Neurology, People's Hospital, Peking University, Beijing 100044, China.	[Cognitive function and psychological characteristics of patients with chronic fatigue syndrome] [Article in Chinese]	Zhonghua Yi Xue Za Zhi. 2005 Nov 2;85(41):2926-9.	OBJECTIVE: To investigate the cognitive function and psychological characteristics of the patients with chronic fatigue syndrome (CFS) in China and analyze its relation with primary psychological diseases. METHODS: Ninety-one patients with CFS who visited the People's Hospital, Peking University, in Beijing from Beijing, Shanghai, Tianjin, Heilongjiang, Jilin, Hebei, Inner Mongolia, Shanxi, Shandong, Sichuan, Gansu, Fujian, and Guangdong, 42 males and 49 females, aged 37 +/- 7, 43% of which had the record of formal schooling of regular college course or over and 21 of which had the record of formal schooling of college for professional training, and 58% of which showed clear causes, diagnosed by the CDC criteria 1994, underwent case history collection, physical examination, necessary laboratory test, memory test, and SCL-90, Hamilton depression rating scale (HAMD), and Hamilton anxiety rating scale (HAMA) testing. Thirty healthy persons, 14 males and 16 females, aged 37 +/- 7, were used as controls., A table of case file was established based on the CDC criteria 1994 for each patient to record the relevant data. Independent-Samples T Test was used to compare the memory quotient, the total

				score and general mean score of SCL-90, the score of HAMD and HAMA. Analyzed the impairment of cognitive function and psychological characteristics of patients with CFS. RESULTS: The most common symptoms was descent of remembrance and/or attention (82/91, 90%). The memory quotient of the CFS patients was 85 +/- 14, significantly lower than that of the healthy controls (98 +/- 12, t = 4.627, P = 0.000). The total score of SCL-90 of the CFS patients was 192 +/- 47, significantly higher than that of the healthy controls (140 +/- 46, t = 5.297, P = 0.000). The symptoms with a factor score > or = 2.0 in SCL-90 included obsessive-compulsive symptoms (61/91, 67%), somatization (61/91, 67 %), depression (57/91, 63%), and anxiety (49/91, 54%). The HAMD score of the CFS patients was 9.9 +/- 6.1, significantly higher than that of the healthy controls (6.5 +/- 2.5, t = 2.948, P = 0.004). The HAMA score of the CFS patients was 9.9 +/- 7.0, significantly higher than that of the healthy controls (5.9 +/- 2.9, t = 3.015, P = 0.003). CONCLUSION: The CFS patients in China have an obvious impairment of remembrance and show different psychological abnormalities that are different from those of the patients with primary psychological diseases.
Li YJ, Wang DX, Bai XL, Chen J, Liu ZD, Feng ZJ, Zhao YM.	Department of Neurology, People's Hospital, Beijing University, Beijing 100044, China.	[Clinical characteristics of patients with chronic fatigue syndrome: analysis of 82 cases] [Article in Chinese]	Zhonghua Yi Xue Za Zhi. 2005 Mar 16;85(10):701-4.	OBJECTIVE: To analyze the clinical characteristics of Chinese patients suffering from chronic fatigue syndrome (CFS) and provide clinical and laboratory evidence for the study of its etiology and treatment. METHODS: 82 patients with CFS diagnosed based on the CDC criteria 1994 were recruited. History was collected, and physical examination was made. SCL-90 and memory test were used, and Hamilton Anxiety Rating Scale was used to those showing depression and/or anxiety. Laboratory examination, including examination of electrolytes, blood sugar, creatinine, bilirubin, alkaline phosphatase, alanine trasaminase, etc, was conducted. Western blotting was used to detect the protein-24 of Borna disease virus (BDV) in the plasma of 61 patients and 73 healthy controls. High-pressure chromatography was conducted to detect n-6 fatty acids on the membrane of erythrocytes of 42 patients and 37 healthy controls. Plasma L-carnitine in 61 patients and 73 healthy controls was detected by zymological analysis. In different examinations sex and age-matched controls were used. RESULTS: Most of the patients were 21 approximately 50 years old (74/82, 90.24%). No gender difference was found. The patients usually had 4 approximately 6 symptoms besides distinctive fatigue. Descent of remembrance and/or attention was the most conspicuous accompanying symptoms (69/82, 84.15%). Abnormalities in SCL-90 scores were present in 57 patients (69.51%), e.g, somatization existed most commonly (32/82, 39.02%), and anxiety and depression were 20.73% (17/82) and 18.29% (15/82) respectively. The prevalence of anti-BDV-p24 antibody was 20.73% (17/82), significantly higher than that of the controls (0%, chi(2) = 6.673, P = 0.010). The arachidonic acid level was significantly lower in the CFS group than in the controls (P > 0.05) and there were no differences in linoleic acid and ETA (both P > 0.05). The level of L-carnitine was 6.4336 +/- 3.4225, significantly lower than that of the control group (7.6666 +/- 3.5819, t = 2.025, P = 0.045) and the L-carnitine level was increased 2 weeks after supplementary treatment, together with improvement of symptoms. CONCLUSION: Most of the CFS patients are young and middle-aged. Descent of reorganization is common in these patients. Psychological abnormalities exist in most patients. Some patients are infected with BDV, some with deficiency of nutrition and/or abnormality of energy metabolism.

Maes M, Mihaylova I, De Ruyter M.	M-Care4U outpatient Clinics, and the Clinical Research Center for Mental Health, Olmenlaan 9, 2610 Antwerp, Belgium.	Decreased dehydroepiandrosterone sulfate but normal insulin-like growth factor in chronic fatigue syndrome (CFS): relevance for the inflammatory response in CFS.	Neuro Endocrinol Lett. 2005 Oct;26(5):487-92.	There are a few reports that chronic fatigue syndrome (CFS) may be accompanied by changes in hormones, such as dehydroepiandrosterone (DHEA) and insulin-like growth factor (IGF1). This study examines the serum concentrations of DHEA-sulfate (DHEAS), IGF1 and IGF1 binding protein-3 (IGFBP3) in 20 patients with CFS and in 12 normal controls. The IGFBP3/IGF1 ratio was computed as an index for IGF1 availability. We found significantly lower serum DHEAS concentrations in CFS, but no significant differences either in IGF1 or the IGFBP3/IGF1 ratio between CFS patients and normal controls. The decrease in serum DHEAS was highly sensitive and specific for CFS. There were significant and positive correlations between serum DHEAS and serum zinc and the mitogen-induced expression of the CD69 molecule on CD3+CD8+ T cells (an indicator of early T cell activation). There was a significant and negative correlation between serum DHEAS and the increase in the serum alpha-2 protein fraction (an inflammatory marker). Serum IGF1, but not DHEAS, was significantly and inversely correlated to age. The results show that CFS is accompanied by lowered levels of DHEAS and that the latter may play a role in the immune (defect in the early activation of T cells) and the inflammatory pathophysiology of CFS.
Maes M, Mihaylova I, Leunis JC.	M-Care4U Outpatient Clinics, and the Clinical Research Center for Mental Health, Belgium.	In chronic fatigue syndrome, the decreased levels of omega-3 poly-unsaturated fatty acids are related to lowered serum zinc and defects in T cell activation.	Neuro Endocrinol Lett. 2005 Dec 28;26(6):745-751 [Epub ahead of print]	There is now evidence that major depression is accompanied by decreased levels of omega3 poly-unsaturated fatty acids (PUFA), such as eicosapentaenoic acid (EPA) and docosahexaenoic acid (DHA). There is a strong comorbidity between major depression and chronic fatigue syndrome (CFS). The present study has been carried out in order to examine PUFA levels in CFS. In twenty-two CFS patients and 12 normal controls we measured serum PUFA levels using gas chromatography and mass spectrometry. We found that CFS was accompanied by increased levels of omega6 PUFAs, i.e. linoleic acid and arachidonic acid (AA), and mono-unsaturated fatty acids (MUFAs), i.e. oleic acid. The EPA/AA and total omega3/omega6 ratios were significantly lower in CFS patients than in normal controls. The omega3/omega6 ratio was significantly and negatively correlated to the severity of illness and some items of the FibroFatigue scale, i.e. aches and pain, fatigue and failing memory. The severity of illness was significantly and positively correlated to linoleic and arachidonic acid, oleic acid, omega9 fatty acids and one of the saturated fatty acids, i.e. palmitic acid. In CFS subjects, we found significant positive correlations between the omega3/omega6 ratio and lowered serum zinc levels and the lowered mitogen-stimulated CD69 expression on CD3+, CD3+CD4+, and CD3+CD8+ T cells, which indicate defects in early T cell activation. The results of this study show that a decreased availability of omega3 PUFAs plays a role in the pathophysiology of CFS and is related to the immune

				pathophysiology of CFS. The results suggest that patients with CFS should respond favourably to treatment with - amongst other things - omega3 PUFAs, such as EPA and DHA.
Maher KJ, Klimas NG, Fletcher MA.	Department of Medicine, University of Miami Miller School of Medicine, Miami, FL 33176, USA.	Chronic fatigue syndrome is associated with diminished intracellular perforin.	Clin Exp Immunol. 2005 Dec;142(3):505-11.	Chronic fatigue syndrome (CFS) is an illness characterized by unexplained and prolonged fatigue that is often accompanied by abnormalities of immune, endocrine and cognitive functions. Diminished natural killer cell cytotoxicity (NKCC) is a frequently reported finding. However, the molecular basis of this defect of in vitro cytotoxicy has not been described. Perforin is a protein found within intracellular granules of NK and cytotoxic T cells and is a key factor in the lytic processes mediated by these cells. Quantitative fluorescence flow cytometry was used to the intracellular perforin content in CFS subjects and healthy controls. A significant reduction in the NK cell associated perforin levels in samples from CFS patients, compared to healthy controls, was observed. There was also an indication of a reduced perforin level within the cytotoxic T cells of CFS subjects, providing the first evidence, to our knowledge, to suggest a T cell associated cytotoxic deficit in CFS. Because perforin is important in immune surveillance and homeostasis of the immune system, its deficiency may prove to be an important factor in the pathogenesis of CFS and its analysis may prove useful as a biomarker in the study of CFS.
Masuda A, Kihara T, Fukudome T, Shinsato T, Minagoe S, Tei C.	Respiratory and Stress Care Center, Kagoshima University Hospital, 8-35-1 Sakuragaoka, Kagoshima 890-8520, Japan. masudaak@m.kufm.kagoshima-u.ac.jp	The effects of repeated thermal therapy for two patients with chronic fatigue syndrome.	J Psychosom Res. 2005 Apr;58(4):383-7.	OBJECTIVE: This paper describes the successful treatment of two patients with chronic fatigue syndrome (CFS) using repeated thermal therapy. METHODS: Two patients with CFS underwent treatment with prednisolone (PSL), with no satisfactory effect. They were subjected to thermal therapy that consisted of a far-infrared ray dry sauna at 60 degrees C and postsauna warming. The therapy was performed once a day, for a total of 35 sessions. After discharge, these subjects continued the therapy once or twice a week on an outpatient basis for 1 year. RESULTS: Symptoms such as fatigue, pain, sleep disturbance, and low-grade fever were dramatically improved after 15 to 25 sessions of thermal therapy. Although PSL administration was discontinued, the subjects showed no relapse or exacerbation of symptoms during the first year after discharge. The patients became socially rehabilitated 6 months after discharge. CONCLUSIONS: These results suggest that repeated thermal therapy might be a promising method for the treatment of CFS.
McGhee SA, Kaska B, Liebhaber M, Stiehm ER.	Department of Pediatrics, David Geffen School of Medicine at UCLA, Los Angeles, CA, USA. smcghee@mednet.ucla.edu	Persistent parvovirus-associated chronic fatigue treated with high dose intravenous immunoglobulin.	Pediatr Infect Dis J. 2005 Mar;24(3):272-4.	We report a 16-year-old boy with no evidence of immunodeficiency who had a 2-year history of chronic fatigue, low grade fever and slapped-cheek rash associated with chronic parvovirus B19 viremia. Prolonged intravenous immunoglobulin therapy resulted in resolution of his symptoms and viremia. Intravenous immunoglobulin may be useful in the resolution of parvovirus viremia regardless of immune status.
Metcalf LN, McGregor NR, Roberts TK		Membrane Damaging Toxins from Coagulase-Negative Staphylococcus Are Associated	Journal of Chronic Fatigue Syndrome 2005 12 (3): 25-43	Aim: To assess whether there is any association between membrane damaging toxin production by Staphylococcus spp. and self-reported TMD symptom expression in a group of patients selected to have CFS. Methods: Thirty-three defined Chronic Fatigue Syndrome (CFS) patients and 33 ageand sex-matched controls were assessed to evaluate the relationship between carriage of membrane damaging toxin producing staphylococcus, CFS and temporomandibular dysfunction (TMD) symptoms. Results: The CFS patients had an increased prevalence of face pain (Odds Ratio = 21.0, 95% CL 4.2-106,

		with Self-Reported Temporomandibular Disorder (TMD) in Patients with Chronic Fatigue Syndrome		P < .001) and temporomandibular joint (TMJ) clicking/locking (OR = 5.7, 95% CL 1.423.5, P < .007), and the coagulase-negative staphylococcus maximum% B*-toxin haemolysis per patient. Both multivariate and univariate analyses revealed an association between the membrane damaging o*-toxin producing CoNS (MDT-CoNS) species per subject and face pain prevalence and intensity within both the CFS patients and the control subjects. No association was found between CoNS toxin production and TMJ clicking/locking. Importantly, áand B*-toxin production by CoNS was associated with patient reporting of arthritis. Conclusions: These data confirm the original observations of the association between MDTCoNS and facial muscle pain (Butt et al, 1998; McGregor et al, 2003). These data also suggest that MDT-CoNS associated facial muscle pain expression represents a distinct clinical entity, which has an increased prevalence in CFS patients.
Michielsen HJ, Van Houdenhove B, Leirs I, Vandenbroeck A, Onghena P.	Department of Psychology and Health, Tilburg University, Tilburg, The Netherlands.	Depression, attribution style and self-esteem in chronic fatigue syndrome and fibromyalgia patients: is there a link?	Clin Rheumatol. 2005 Jul 12; [Epub ahead of print]	The aims of the present study were to compare a single diagnosis (chronic fatigue syndrome, CFS) and a double diagnosis (CFS + fibromyalgia, CFS+FM) group regarding depression, attribution style and self-esteem as well as to examine whether attribution style is a mediator in the relationship between self-esteem and depression. Eighty-five patients (CFS: 47, CFS+FM: 38) completed questionnaires on attribution style, self-esteem and depression. The single and double diagnosis groups tended to differ slightly, but the differences were never statistically significant. In addition, only one condition was met of the four conditions mentioned by Baron and Kenny to establish that mediation exists between two variables. In conclusion, an external attribution style does not protect the CFS or CFS+FM patients with a low self-esteem from depression. The prevalence rate of depression was high in both patient samples, of which clinicians should be aware.
Mihrshahi R, Beirman R.	Department of Biological Sciences, Macquarie University, Sydney, NSW, Australia. HUrbeirman@els.mq.edu.auUH	Aetiology and pathogenesis of chronic fatigue syndrome: a review.	N Z Med J. 2005 Dec 16;118(1227):U1780.	Chronic fatigue syndrome (CFS) is a debilitating disease of uncertain aetiology that is characterised by unexplained, severe fatigue associated with a number of typical symptoms. This paper reviews the scientific literature related to current theories about the aetiology and pathogenesis of CFS by focussing on what appear to be the four most significant aspects in the development and perpetuation of this disease: the role of infectious agents as well as immunological, neuroendocrine, and psychiatric factors. A multifactorial model for the aetiology of CFS, which includes and draws together these four aspects, is proposed; and suggestions are offered regarding approaches to the diagnosis and treatment of this disease.

Mommersteeg PM, Heijnen CJ, Verbraak MJ, van Doornen LJ.	Department of Health Psychology, Utrecht University, P.O. Box 80.140, 3508 TC Utrecht, The Netherlands.	Clinical burnout is not reflected in the cortisol awakening response, the day-curve or the response to a low-dose dexamethasone	Psychoneuroendocrinology. 2005 Sep 5; [Epub ahead of print]	Burnout is presumed to be the result of chronic stress, and chronic stress is known to affect the HPA-axis. To date, studies on HPA-axis functioning in burnout have showed inconsistent results. In the present study, a large sample (n=74) of clinically diagnosed burnout individuals, mostly on sick-leave, were included and compared with 35 healthy controls. Salivary cortisol was sampled on 2 days to determine the cortisol awakening response (CAR) and the day-curve. In addition, the dexamethasone suppression test (DST) was applied to assess the feedback efficacy of the HPA-axis. There were no differences observed in the CAR, day-curve or CAR after DST in the burnout group as compared to a healthy control group. Burnout shows overlap in symptoms with chronic fatigue syndrome (CFS) and

		suppression test.		depression. Therefore, differential changes in HPA-axis functioning that resemble the hypo-functioning of the HPA-axis in CFS, or rather the hyper-functioning of the HPA-axis in depression, might have obscured the findings. However, no effect of fatigue or depressive mood on HPA-axis functioning was found in the burnout group. We concluded that HPA-axis functioning in clinically diagnosed burnout participants as tested in the present study, seems to be normal.
Moss J.	Association of Young People with ME, Milton Keynes MK2 2XD, UK. jill@ayme.org.uk	Development of a functional ability scale for children and young people with myalgic encephalopathy (ME)/chronic fatigue syndrome (CFS).	J Child Health Care. 2005 Mar;9(1):20-30.	The numerous symptoms and unpredictable pattern of myalgic encephalopathy (ME) make it difficult to describe, especially for children. It was left to carers to guess what the child could achieve each day, often leading to over/underestimates. A functional ability scale was needed, which measured from 0 to 100 percent able and that children and young people themselves designed. A new scale was developed from the Moss Ability Scale using the critique of 251 children and young people from the Association of Young People with ME (AYME). Responding to the shift in emphasis towards patients taking an active role in their own care, it was felt these young people would know whether the scale measured what it had set out to measure, and were asked questions on the face and content validity of the scale. There was a 99 percent agreement between the young people that the final scale was 'workable' or better.
Moss-Morris R, Sharon C, Tobin R, Baldi JC.	Health Psychology, The Faculty of Medical and Health Sciences, The University of Auckland, Private Bag 92 019, Auckland, New Zealand. r.moss-morris@auckland.ac.nz	A randomized controlled graded exercise trial for chronic fatigue syndrome: outcomes and mechanisms of change.	J Health Psychol. 2005 Mar;10(2):245-59.	The aim of this study was to investigate the potential mechanisms underlying the efficacy of graded exercise therapy for chronic fatigue syndrome (CFS). Forty-nine CFS patients were randomized to a 12-week graded exercise programme or to standard medical care. At the end of treatment the exercise group rated themselves as significantly more improved and less fatigued than the control group. A decrease in symptom focusing rather than an increase in fitness mediated the treatment effect. Graded exercise appears to be an effective treatment for CFS and it operates in part by reducing the degree to which patients focus on their symptoms.
Naschitz JE, Mussafia-Priselac R, Peck ER, Peck S, Naftali N, Storch S, Slobodin G, Elias N, Rosner I.	Department of Internal Medicine A, Bnai-Zion Medical Center, Haifa, Israel. Naschitz@tx.technion.ac.il	Hyperventilation and amplified blood pressure response: is there a link?	J Hum Hypertens. 2005 May;19(5):381-7.	Based on prior studies, the hypothesis that hyperventilation (HV) may have a pressor effect and play a causal role in hypertension has been suggested. The objective of this study was to correlate HV with blood pressure (BP)-change during a postural challenge. Consecutive subjects referred for evaluation of syncope, dizziness, chronic fatigue syndrome (CFS), fibromyalgia, or non-CFS fatigue were assessed with a 10-min supine 30-min head-up tilt test combined with capnography. We selected for analysis the records of patients aged 17-70 years, not taking vasoactive medications, having sitting systolic BP (SBP) < 140 mmHg, sitting diastolic BP (DBP) < 90 mmHg, and who completed 30 min of tilt. HV was diagnosed when end-tidal pressure of CO2 < 30 mmHg was recorded consecutively for > or = 10 min. Postural hypertension (PHT) was diagnosed when DBP on tilt > or = 90 mmHg was recorded consecutively for > or = 10 min. DBP-change was computed as (median DBP on tilt) -(median DBP supine). PHT and DBP-change were correlated with HV. A total of 320 patient charts were reviewed. PHT was present in 30 cases. The mean DBP-change in patients with PHT was +9.9 mmHg (s.d. 5.8), with three patients manifesting HV. Of the remaining 290 patients, 56 had HV, their mean DBP-change was -0.3 mmHg (s.d. 7.2). The other 234 patients without HV had a mean DBP-change +0.95 mmHg

				(s.d. 5.7), comparable to the DBP-change in patients with HV. In, conclusion, posturally induced HV was not associated with an increase in BP, nor was PHT associated with HV, except in a small minority of cases.
Naschitz JE, Rozenbaum M, Fields M, Isseroff H, Enis S, Babich JP, Peck S, Peck ER, Gaitini L, Naschitz S, Sabo E, Rosner I.	Department of Internal Medicine A, Bnai Zion Medical Center and Bruce Rappaport Faculty of Medicine, Technion-Israel Institute of Technology, Haifa, Israel. Naschitz@tx.technion.ac.il	Search for disease-specific cardiovascular reactivity patterns: developing the methodology.	Clin Sci (Lond). 2005 Jan;108(1):37-46.	Aberrations of CVR (cardiovascular reactivity), an expression of autonomic function, lack specificity for a particular disorder. Recently, a CVR pattern particular to chronic fatigue syndrome has been observed. In the present study, we aimed to develop methodologies for assessing disease-specific CVR patterns. As a prototype, a population of 50 consecutive patients with FMF (familial Mediterranean fever) was studied and compared with control populations. A 10 min supine/30 min head-up tilt test with recording of the heart rate and blood pressure or the pulse transit time was performed. Five studies were conducted applying different methods. In each study, statistical analysis identified independent predictors of CVR in FMF. Based on regression coefficients of these predictors, a linear DS (discriminant score) was computed for every subject. Each study established an equation to assess CVR, calculate DS for FMF and determine the sensitivity and specificity of the DS cut-off. In each of the five studies, abnormal CVR was observed in FMF patients. The best accuracy (88% sensitivity and 90.1% specificity for FMF) was obtained by a method based on beat-to-beat heart rate and pulse transit time recordings. Data was processed by fractal and recurrence quantitative analysis with recordings in FMF patients compared with a mixed control population. Identification of disease-specific CVR patterns was possible with the methodologies described in the present study. In FMF, disease-specific CVR may be explained by the interplay between neuroendocrine loops specific to FMF with cardiovascular homoeostatic mechanisms. Recognition of disease-specific CVR patterns may advance the understanding of homoeostatic mechanisms and have implications in clinical practice.
Naschitz JE, Rozenbaum M, Fields MC, Enis S, Manor H, Dreyfuss D, Peck S, Peck ER, Babich JP, Mintz EP, Sabo E, Slobodin G, Rosner I.	Department of Internal Medicine A and Rheumatology, Bnai Zion Medical Center and Bruce Rappaport Faculty of Medicine, Technion-Israel Institute of Technology, Haifa, Israel. Naschitz@tx.technion.ac.il	Cardiovascular reactivity in fibromyalgia: evidence for pathogenic heterogeneity.	J Rheumatol. 2005 Feb;32(2):335-9.	OBJECTIVE: To evaluate disease-specific cardiovascular reactivity patterns in patients with fibromyalgia (FM) using a recently described method called fractal and recurrence analysis score (FRAS). METHODS: The study group included 30 women with FM, average age 46.7 years (SD 7.03). An age matched group of 30 women with other rheumatic disorders or having a dysautonomic background [chronic fatigue syndrome (CFS), non-CFS fatigue, neurally mediated syncope, and psoriatic arthritis (PsA)] served as controls. Subjects were evaluated with a head-up tilt test with beat-to-beat recording of the heart rate (HR) and pulse transit time. A 10-minute supine phase was followed by 600 cardiac cycles recorded on tilt. Data were processed by recurrence plot and fractal analysis. Variables acting as independent predictors of the cardiovascular reactivity were identified in FM patients versus controls. RESULTS: No statistically significant differences were found between the groups by univariate analysis comparing 92 variables of cardiovascular reactivity in FM patients compared to controls. CONCLUSION: Study of cardiovascular reactivity utilizing a head-up tilt test and processing the data using the FRAS method did not reveal a specific FM-associated abnormality. Our data confirm studies that utilized other methodologies and reached similar conclusions. Patients with FM represent a heterogenous group with respect to their pattern of cardiovascular reactivity.
Natelson BH, Weaver SA, Tseng CL, Ottenweller JE.	CFS Cooperative Research Center and Department of Neurosciences,	Spinal fluid abnormalities in patients with chronic fatigue	Clin Diagn Lab Immunol. 2005 Jan;12(1):52-5.	Arguments exist as to the cause of chronic fatigue syndrome (CFS). Some think that it is an example of symptom amplification indicative of functional or psychogenic illness, while our group thinks that some CFS patients may have brain dysfunction. To further pursue our encephalopathy hypothesis, we did spinal taps on 31 women and 13 men fulfilling the 1994 case definition for CFS and on 8 women

	University of Medicine and Dentistry of New Jersey-New Jersey Medical School, Newark, New Jersey, USA. bhn@njneuromed.org	syndrome.		and 5 men serving as healthy controls. Our outcome measures were white blood cell count, protein concentration in spinal fluid, and cytokines detectable in spinal fluid. We found that significantly more CFS patients had elevations in either protein levels or number of cells than healthy controls (30 versus 0%), and 13 CFS patients had protein levels and cell numbers that were higher than laboratory norms; patients with abnormal fluid had a lower rate of having comorbid depression than those with normal fluid. In addition, of the 11 cytokines detectable in spinal fluid, (i) levels of granulocyte-macrophage colony-stimulating factor were lower in patients than controls, (ii) levels of interleukin-8 (IL-8) were higher in patients with sudden, influenza-like onset than in patients with gradual onset or in controls, and (iii) IL-10 levels were higher in the patients with abnormal spinal fluids than in those with normal fluid or controls. The results support two hypotheses: that some CFS patients have a neurological abnormality that may contribute to the clinical picture of the illness and that immune dysregulation within the central nervous system may be involved in this process.
Nicolson GL, Gan R, Haier J.		ORIGINAL RESEARCH Evidence for Brucella spp. and Mycoplasmaspp. Co-Infections in Blood of Chronic Fatigue Syndrome Patients	Journal of Chronic Fatigue Syndrome 2005 12 (2): 5 - 17	We examined the blood of 94 North American Chronic Fatigue Syndrome (CFS) patients using forensic polymerase chain reaction and found that a subset (10.6%) of CFS patients show evidence of Brucella spp. infections compared to one of 70 control subjects (Odds Ratio = 8.2; 95% Confidence Limits (CL) 1-66; P < .01). Rural patients showed a higher incidence of Brucella spp. infections over urban patients (OR = 5.5, 95% CL 1.3-23.5, P < .02). Since CFS patients also have a high prevalence of one of four Mycoplasma species and sometimes show evidence of infections with Chlamydia pneumoniae, we examined Brucella-positive patients for other bacterial infections. Previously we found that 8% of the CFS patients showed evidence of C. pneumoniae and about 50% show evidence of Mycoplasma spp. infections. Since the presence of one or more chronic systemic infections may predispose patients to other infections, we examined the prevalence of C. pneumoniae and Mycoplasma spp. infections in Brucella-positive patients. We found only one Brucella-positive patient with C. pneumoniae and four other patients with evidence of Mycoplasma spp., suggesting that such bacterial infections occur independently in CFS patients. Control subjects (N = 70) had low rates of Brucella spp. (1.4%), Mycoplasma spp. (7.2%) or C. pneumoniae (1.4%) infections, and there were no co-infections in control subjects. The results indicate that a subset of CFS patients show evidence of infection with Brucella spp., and some of these patients also have other bacterial infections.

	Faculty of Physical Education and Physiotherapy, Vrije University Brussel, Belgium; Division of Musculoskeletal Physiotherapy, Higher Institute of Physiotherapy, Department of Health Sciences, Hogeschool Antwerpen, Belgium.	syndrome: Are we caring for our patients or are we practicing selfcare?	ahead of print]	
Nijs J, De Meirleir K.	Department of Human Physiology, Faculty of Physical Education and Physiotherapy, Vrije Universiteit Brussel, Brussels, Belgium. HUJo.Nijs@vub.ac.beUH	Impairments of the 2-5A synthetase/RNase L pathway in chronic fatigue syndrome.	In Vivo. 2005 Nov-Dec;19(6):1013-21.	This paper provides an overview of the evidence addressing the impairments of the 2'-5' oligoadenylate (2-5 A) synthetase/RNase L pathway in Chronic Fatigue Syndrome (CFS) patients. The 2-5A synthetase/RNase L pathway in CFS patients appears to be both up-regulated (i.e. increased levels of bioactive 2-5A synthetase and increased activity of the RNase L enzyme) and deregulated (elastase and calpain initiate 83 kDa RNase L proteolysis, generating two major fragments with molecular masses of 37 and 30 kDa, respectively). The deregulation of the 2-5A synthetase/RNase L pathway in CFS accompanies decreased NK-function and deregulation of apoptotic pathways. Since various components of the pathway appear to be related to performance during a graded exercise stress test, some evidence supportive of the clinical importance of the impaired pathway in CFS patients has been provided. Studies addressing the treatment of the deregulation of the 2-5A synthetase/RNase L pathway in CFS are warranted.
Nijs J, Meeus M, McGregor NR, Meeusen R, de Schutter G, van Hoof E, de Meirleir K.	Department of Human Physiology, Faculty of Physical Education and Physiotherapy, Vrije Universiteit Brussel, Brussels, Belgium.	Chronic fatigue syndrome: exercise performance related to immune dysfunction.	Med Sci Sports Exerc. 2005 Oct;37(10):1647-54.	PURPOSE: To date, the exact cause of abnormal exercise response in chronic fatigue syndrome (CFS) remains to be revealed, but evidence addressing intracellular immune deregulation in CFS is growing. Therefore, the aim of this cross-sectional study was to examine the interactions between several intracellular immune variables and exercise performance in CFS patients. METHODS: After venous blood sampling, subjects (16 CFS patients) performed a maximal exercise stress test on a bicycle ergometer with continuous monitoring of cardiorespiratory variables. The following immune variables were assessed: the ratio of 37 kDa Ribonuclease (RNase) L to the 83 kDa native RNase L (using a radiolabeled ligand/receptor assay), RNase L enzymatic activity (enzymatic assay), protein kinase R activity assay (comparison Western blot), elastase activity (enzymatic-colorimetric assay), the percent of monocytes, and nitric oxide determination (for monocytes and lymphocytes; flow cytometry, live cell assay). RESULTS: Forward stepwise multiple regression analysis revealed 1) that elastase activity was the only factor related to the reduction in oxygen uptake at a respiratory exchange ratio (RER) of 1.0 (regression model: $R = 0.53$, $F(1,14) = 15.5$, $P < 0.002$; elastase activity $P < 0.002$); 2) that the protein kinase R activity was the principle factor related to the reduction in workload at RER = 1.0; and

				3) that elastase activity was the principle factor related to the reduction in percent of target heart rate achieved. CONCLUSION: These data provide evidence for an association between intracellular immune deregulation and exercise performance in patients with CFS. To establish a causal relationship, further study of these interactions using a prospective longitudinal design is required.
Nijs J, Vaes P, De Meirleir K.	Department of Physiology, Faculty of Physical Education and Physiotherapy, Vrije Universiteit Brussel (VUB), Brussels, Belgium. Jo.Nijs@vub.ac.be	The Chronic Fatigue Syndrome Activities and Participation Questionnaire (CFS-APQ): an overview.	Occup Ther Int. 2005;12(2):107-21.	Chronic fatigue syndrome (CFS) is characterized by severe fatigue and a reduction in activity levels. The purpose of this study was to provide an overview of design, reliability, and validity of the CFS Activities and Participation Questionnaire (CFS-APQ). The CFS-APQ was constructed based on a retrospective analysis of the Karnofsky Performance Status Questionnaire and the Activities of Daily Living Questionnaire (n = 141). In a reliability study of 34 participants the test-retest reliability coefficient of the CFS-APQ was 0.95. In two different studies, the Cronbach alpha coefficient for internal consistency varied between 0.87 (n = 88) and 0.94 (n = 47). The CFS-APQ was administered to 47 patients who listed 183 activities that had become difficult due to their chronic symptoms, and 157 (85.8%) answers matched the content of the CFS-APQ. The outcome of a cross-sectional study (n = 88) studying the correlations between the Medical Outcomes Short Form 36 Health Status Survey subscale scores and the CFS-APQ supported the validity of the CFS-APQ. The CFS-APQ scores correlated with a behavioural assessment of the patients' performance of activities encompassed by the questionnaire (r = 0.29-0.55; n = 63), and correlated with exercise capacity parameters (r = 0.26-0.39; n = 77) obtained during a maximal exercise capacity stress test. Finally, the CFS-APQ correlated with visual analogue scales for pain (r = 0.51) and fatigue (r = 0.50; n = 47). It is concluded that the CFS-APQ generates reliable and valid data, and can be used as a clinical measure of disease severity in patients with CFS. Future studies should aim at examining the sensitivity of the CFS-APQ.
Nijs J, Van de Putte K, Louckx F, De Meirleir K.	Department of Human Physiology, Faculty of Physical Education and Physiotherapy, Vrije Universiteit Brussel, Belgium. HUJo.Nijs@vub.ac.beUH	Employment status in chronic fatigue syndrome. A cross-sectional study examining the value of exercise testing and self-reported measures for the assessment of employment status.	Clin Rehabil. 2005 Dec;19(8):895-9.	OBJECTIVE: To examine the value of exercise testing and self-reported disability for the assessment of employment status in patients with chronic fatigue syndrome. DESIGN: Cross-sectional observational study. SETTING: A university-based chronic fatigue clinic. SUBJECTS: Fifty-four consecutive, Flemish, employed (not self-employed) chronic fatigue syndrome patients (49/54 female). INTERVENTIONS: Not applicable. MAIN OUTCOME MEASURES: Participants were questioned about their current and premorbid employment status, filled in the Chronic Fatigue Syndrome Activities and Participation Questionnaire (CFS-APQ), the Medical Outcomes Short Form 36 Health Status Survey (SF-36), and performed a maximal exercise test on a bicycle ergometer with continuous monitoring of cardiorespiratory variables. RESULTS: A significant association was observed between the current employment rate and two SF-36 subscales (i.e., role limitations due to physical functioning and social functioning; rho = 0.39 and 0.35 respectively) (n = 54). Analysing only the female chronic fatigue syndrome patients (n = 49), the current employment rate correlated significantly with the peak workload (rho = 0.38). CONCLUSIONS: The associations between either exercise testing or self-reported disability and employment status are too weak to predict employment status.
Nijs J, Van de Velde B, De Meirleir K.	Department of Human Physiology, Faculty of Physical Education and Physical Therapy,	Pain in patients with chronic fatigue syndrome: does nitric oxide trigger central	Med Hypotheses. 2005;64(3):558-62.	Previous studies have provided evidence supportive of the clinical importance of widespread pain in patients with chronic fatigue syndrome (CFS): pain severity may account for 26-34% of the variability in the CFS patient's activity limitations and participation restrictions. The etiology of widespread pain in CFS remains to be elucidated, but sensitisation of the central nervous system has been suggested to take part of CFS pathophysiology. It is hypothesised that a nitric oxide (NO)-dependent reduction in

	Vrije Universiteit Brussel (VUB), Belgium. jo.nijs@vub.ac.be	sensitisation?		inhibitory activity of the central nervous system and consequent central sensitisation accounts for chronic widespread pain in CFS patients. In CFS patients, deregulation of the 2',5'-oligoadenylate synthetase/RNase L pathway is accompanied by activation of the protein kinase R enzyme. Activation of the protein kinase R and subsequent nuclear factor-kappaB activation might account for the increased production of NO, while infectious agents frequently associated with CFS (Coxsackie B virus, Epstein-Barr Virus, Mycoplasma) might initiate or accelerate this process. In addition, the evidence addressing behavioural changes in CFS patients fits the central sensitisation-hypothesis: catastrophizing, avoidance behaviour, and somatization may result in, or are initiated by sensitisation of the central nervous system.
Nijs J, Van Parijs M		CRITICAL REVIEWS AND COMMENTS ON CURRENT RESEARCH Long-Term Effectiveness of Pool Exercise Therapy and Education in Patients with Fibromyalgia	Journal of Chronic Fatigue Syndrome 2005 12 (3): 73 - 79	
Njoku MG, Jason LA, Torres-Harding SR.	Center for Community Research, Chronic Fatigue Research Study, Chicago, IL 60614, USA. HUnmgloria@depaul.eduUH	The relationships among coping styles and fatigue in an ethnically diverse sample.	Ethn Health. 2005 Nov;10(4):263-78.	The present study focused on coping strategies among African Americans, Latinos, and European Americans with chronic fatigue syndrome (CFS) and idiopathic chronic fatigue (ICF). The coping strategies examined were measured by using the COPE Scales, which assess Seeking Emotional Social Support, Positive Reinterpretation and Growth, Acceptance, Denial, Turning to Religion, Behavioral Disengagement, and Focusing on and Venting Emotions. In addition, the four coping strategies specifically designed for people with CFS, including maintaining activity, accommodating to the illness, focusing on symptoms, and information-seeking, were used in this study. It was hypothesized that African Americans and Latinos in comparison to European Americans would be more likely to use religious coping, behavioral disengagement, and denial. As predicted, African Americans were significantly more likely to turn to religion than European Americans, and Latinos and African Americans used denial significantly more often than European Americans. An additional finding was that focusing on symptoms was associated with greater fatigue and more physical disability among African Americans. Within the Latino sample, acceptance was related to greater fatigue and less physical disability, and greater optimism predicted less mental disability. Among European American participants, maintaining activity was related to less mental disability, whereas accommodating to the illness predicted more physical disability. These results indicate that coping varies among various ethnic groups with CFS and ICF; however, denial is consistently related to less adaptive outcomes. Therefore, healthcare professionals should find ways to reduce patient use of denial and promote alternative strategies for managing life events.
Ohayon MM.	Stanford Sleep Epidemiology	Prevalence and correlates of	Arch Intern Med. 2005 Jan	BACKGROUND: Nonrestorative sleep (NRS) has been little studied in the general population, even though this symptom has an important role in several medical conditions such as heart disease,

	Research Center, Stanford University School of Medicine, Stanford, Calif., USA. mohayon@stanford.edu	nonrestorative sleep complaints.	10;165(1):35-41.	fibromyalgia, and chronic fatigue syndrome, as well as various sleep disorders. METHODS: A total of 25,580 individuals (age range, 15-100 years) from the noninstitutionalized general population representative of 7 European countries (France, the United Kingdom, Germany, Italy, Portugal, Spain, and Finland) were interviewed by telephone using the Sleep-EVAL system. Nonrestorative sleep was analyzed in relationship to sociodemographic determinants, environmental factors, life habits, health, sleep-wake schedule, and psychological factors. RESULTS: The prevalence of NRS was 10.8% (95% confidence interval, 10.4%-11.2%) in the sample, was higher in women than in men (12.5% vs 9.0%; P<.001), and decreased with age. The United Kingdom (16.1%) and Germany (15.5%) had the highest prevalence of NRS and Spain (2.4%), the lowest. In multivariate analyses, several factors were positively associated with NRS. The most important were younger age, dissatisfaction with sleep, difficulty getting started in the morning, stressful life, presence of anxiety, bipolar or a depressive disorder, and having a physical disease. When compared with subjects who have difficulty initiating or maintaining sleep (without NRS), subjects with NRS reported more frequently a variety of daytime impairment (irritability, physical, and mental fatigue) and consulted a physician twice as frequently for their sleeping difficulties than did other subjects with insomnia. CONCLUSIONS: Nonrestorative sleep is a frequent symptom in the general population, but its prevalence largely varies between countries. It is often associated with mental disorders and characteristics of sleep deprivation (such as extra sleep time on weekends). Nonrestorative sleep affected more frequently the active classes of the population and caused greater daytime impairment than difficulty initiating or maintaining sleep.

Patten SB, Beck CA, Kassam A, Williams JV, Barbui C, Metz LM.	Department of Community Health Sciences, University of Calgary, Alberta. patten@ucalgary.ca	Long-term medical conditions and major depression: strength of association for specific conditions in the general	Can J Psychiatry. 2005 Mar;50(4):195-202.	BACKGROUND: The prevalence of major depression (MD) in persons with nonpsychiatric medical conditions is an indicator of clinical need in those groups, an indicator of the feasibility of screening and case-finding efforts, and a source of etiologic hypotheses. This analysis explores the prevalence of MD in the general population in relation to various long-term medical conditions. METHODS: We used a dataset from a large-scale Canadian national health survey, the Canadian Community Health Survey (CCHS). The sample consisted of 115 071 subjects aged 18 years and over, randomly sampled from the Canadian population. The survey interview recorded self-reported diagnoses of various long-term

		population.		medical conditions and employed a brief predictive interview for MD, the Composite International Diagnostic Interview Short Form for Major Depression. Logistic regression was used to adjust estimates of association for age and sex. RESULTS: The conditions most strongly associated with MD were chronic fatigue syndrome (adjusted odds ratio [AOR] 7.2) and fibromyalgia (AOR 3.4). The conditions least strongly associated were hypertension (AOR 1.2), diabetes, heart disease, and thyroid disease (AOR 1.4 in each case). We found associations with various gastrointestinal, neurologic, and respiratory conditions. CONCLUSIONS: A diverse set of long-term medical conditions are associated with MD, although previous studies might have lacked power to detect some of these associations. The strength of association in prevalence data, however, varies across specific conditions.
Piche T, Vanbiervliet G, Cherikh F, Antoun Z, Huet PM, Gelsi E, Demarquay JF, Caroli-Bosc FX, Benzaken S, Rigault MC, Renou C, Rampal P, Tran A.	Department of Hepatogastroenterology, Chu de Nice, France. tpiche@fc.horus-medical.fr	Effect of ondansetron, a 5-HT3 receptor antagonist, on fatigue in chronic hepatitis C: a randomised, double blind, placebo controlled study.	Gut. 2005 Aug;54(8):1169-73.	BACKGROUND AND AIMS: There are no available effective therapies for fatigue associated with chronic hepatitis C (CHC). The serotonin antagonist ondansetron has been shown to be effective in the chronic fatigue syndrome. In this randomised, placebo controlled, double blind trial, we investigated the effect of orally administered ondansetron on fatigue in CHC. METHODS: Thirty six patients with CHC were included if fatigue was their predominant symptom and they scored more than 4 on a visual analogue scale (0-10). During the study, fatigue and depression were measured on days 0, 15, 30, and 60 using a validated self report questionnaire (fatigue impact scale and Beck depression inventory). Patients were randomised to receive ondansetron tablets 4 mg twice daily or placebo for one month followed by an additional four weeks of observation. RESULTS: Fatigue score was 85.4 (28.2) and 98.2 (26.9) in the ondansetron and placebo groups, respectively (NS). Ondansetron significantly reduced the fatigue score with more than 30% improvement on day 15 (57.1 (38.9); $p<0.01$), day 30 (54.5 (37.6); $p<0.01$), and day 60 (60.8 (37.3); $p<0.01$) whereas placebo did not. Overall, the reduction in fatigue was significantly higher with ondansetron compared with placebo (ANOVA for repeated measurements) for the whole follow up period ($p = 0.03$) or for the treatment period only ($p = 0.04$). Ondansetron also significantly reduced depression scores. CONCLUSIONS: The 5-hydroxytryptamine receptor type 3 antagonist ondansetron had a significant positive effect on fatigue in CHC. These observations support the concept that fatigue involves serotoninergic pathways and may encourage further evaluations of the efficacy of ondansetron on fatigue in chronic liver diseases.
Prins J, Bleijenberg G, Rouweler EK, van der Meer J.	Department of Psychology, Radboud University Nijmegen Medical Centre, Nijmegen, The Netherlands. j.prins@mps.umcn.nl	Effect of psychiatric disorders on outcome of cognitive-behavioural therapy for chronic fatigue syndrome.	Br J Psychiatry. 2005 Aug;187:184-5.	Psychiatric disorders have been associated with poor outcome in individuals with chronic fatigue syndrome (CFS). This study examines the impact of psychiatric disorders on outcome of cognitive-behavioural therapy (CBT). Psychiatric diagnoses were assessed with a structured psychiatric interview in a CBT trial of 270 people with CFS. Lifetime and current psychiatric disorders were found in 50 and 32% respectively. No significant differences in fatigue severity and functional impairment following treatment were found between participants with and without psychiatric diagnoses.
Rakib A, White PD, Pinching AJ, Hedge B, Newbery N, Fakhoury WK,	Queen Mary's School of Medicine and Dentistry, Newham Centre	Subjective quality of life in patients with chronic fatigue syndrome.	Qual Life Res. 2005 Feb;14(1):11-9.	The aim of this study was to (1) assess Subjective Quality of Life (SQOL) of patients with Chronic Fatigue Syndrome (CFS) using a generic concept and to compare the findings with those in groups with mental disorders and healthy subjects, and (2) investigate whether and, if so, to what extent socio-demographic and clinical variables predict SQOL in CFS patients. Seventy-three patients diagnosed

Priebe S.	for Mental Health, London, UK.			with CFS were randomly selected and interviewed from two specialised clinics. CFS was diagnosed using the Oxford Criteria. SQOL was assessed on the Manchester Short Assessment of Quality of Life (MANSA) and Health-Related Quality of Life (HRQOL) on the Medical Outcome Study Short-Form 36 (MOS) SF-36. A battery of mood and symptom questionnaires, including the Symptom Checklist Questionnaire (SCL-90-R), was administered to assess various aspects of symptomatology as potential predictor variables. Multiple regression analyses were conducted to identify predictors of SQOL. Overall, SQOL was low in CFS patients and less favourable than in groups with mental disorders and healthy subjects. Satisfaction was particularly low with life as a whole, leisure activities and financial situation. Whilst SQOL was only moderately correlated with HRQOL, the SCL-90-R score, especially SCL-90-R Depression scale score, was the best predictor of SQOL explaining 35% of the variance. HRQOL and generic SQOL appear distinct despite some overlap. The findings underline that SQOL is significantly disrupted in CFS patients. Depressive symptoms are statistically the strongest 'predictor' of SQOL, although the direction of the relationship is not established. These data suggest that treatment of depression associated with CFS, regardless of causation, could help to improve SQOL in CFS patients.
Randall DC, Cafferty FH, Shneerson JM, Smith IE, Llewelyn MB, File SE.	Psychopharmacology Research Unit, Centre for Neuroscience Research, King's College London, London, UK.	Chronic treatment with modafinil may not be beneficial in patients with chronic fatigue syndrome.	J Psychopharmacol. 2005 Nov;19(6):647-60.	Fourteen patients (7 male, 7 female, 22-63 years), classified as having chronic fatigue syndrome (CFS), but without concurrent major depression, significant sleepiness or use of psychoactive medication, completed a double-blind, placebo-controlled, crossover study of the effects of the selective wakefulness-promoting agent, modafinil (200 and 400mg/day). The treatment periods were each 20 days, with washout periods of 2 weeks. The primary aim was to determine effects on cognition and the secondary aim was to determine effects on self-ratings of fatigue, quality of life and mood. Modafinil had mixed effects in two cognitive tasks. In a test of sustained attention, treatment with 200mg reduced the latency to correctly detect sequences, but 400mg increased the number of missed targets. In a test of spatial planning, the 200mg dose resulted in a slower initial thinking time for the easiest part of the task, whereas 400mg reduced the initial thinking time for the hardest part of the test. Lastly, in a test of mental flexibility and one of motor speed, patients performed worse whilst on modafinil (400mg), compared with the placebo period. No effects were observed on the performance of other psychometric tests or on self-ratings of fatigue, quality of life or mood, but this may have been due to insufficient statistical power. It is discussed whether the limited and mixed cognitive effects that we observed could have occurred by chance, or whether a subgroup of CFS patients with daytime sleepiness would have shown greater benefits.
Rangel L, Garralda ME, Jeffs J, Rose G.	Academic Unit of Child and Adolescent Psychiatry, Imperial College, London, UK.	Family health and characteristics in chronic fatigue syndrome, juvenile rheumatoid arthritis, and emotional disorders of childhood.	J Am Acad Child Adolesc Psychiatry. 2005 Feb;44(2):150-8.	OBJECTIVE: To compare family health and characteristics in children with chronic fatigue syndrome (CFS), in juvenile rheumatoid arthritis (JRA), and emotional disorders. METHOD: Parents of 28 children and adolescents aged 11 to 18 years with CFS, 30 with JRA, and 27 with emotional disorders (i.e., anxiety and/or depressive disorders) were recruited from specialty clinical settings and completed interviews and questionnaires assessing family health problems, parental mental distress, illness attitudes, and family burden of illness. RESULTS: Parents of children with CFS were significantly more likely than those of children with JRA to report a history of CFS-like illness, high levels of mental distress, and a tendency to experience functional impairment in response to physical symptoms. Families of children with CFS were characterized by significantly greater emotional involvement and

				reported greater family burden related to the child's illness in comparison with families of children with JRA. CONCLUSIONS: CFS in childhood and adolescence is associated with higher levels of parental CFS-like illness, mental distress, emotional involvement, and family illness burden than those observed in association with JRA, a chronic pediatric physical illness.
Ranjith G.	Department of Psychological Medicine, King's College Hospital, London, UK. g.ranjith@iop.kcl.ac.uk	Epidemiology of chronic fatigue syndrome.	Occup Med (Lond). 2005 Jan;55(1):13-9.	BACKGROUND: Chronic fatigue syndrome (CFS) is a controversial disorder with different case definitions, aetiological models and proposed treatments. An epidemiological approach is likely to bring some clarity to the field. AIM: The aim of this article is to review the literature on the epidemiology of fatigue, chronic fatigue and CFS. METHOD: A literature search was conducted using the databases Medline and Pubmed as well as the reference lists of recent reviews to identify the relevant studies. The aim was not to do a systematic review but to review the key studies in the area to highlight the methodological issues. RESULTS: The review is organized according to the following areas: the prevalence of fatigue and chronic fatigue, the prevalence and incidence of CFS, epidemiological associations such as gender, social class and psychiatric co-morbidity and CFS in special groups such as those recovering from a viral infection, specific occupational groups and Gulf War veterans. CONCLUSION: While fatigue as a symptom is very common, CFS is relatively rare. Many of the epidemiological associations seen in specialist clinics are not found in community samples. It is unlikely that one specific causal factor can explain CFS. Future studies should go beyond estimating the prevalence to testing more complex aetiological models.
Reeves WC, Wagner D, Nisenbaum R, Jones JF, Gurbaxani B, Solomon L, Papanicolaou DA, Unger ER, Vernon SD, Heim C.	Division of Viral and Rickettsial Diseases, Centers for Disease Control and Prevention, Atlanta, GA, USA. HUwcr1@cdc.govUH	Chronic fatigue syndrome--a clinically empirical approach to its definition and study.	BMC Med. 2005 Dec 15;3:19.	BACKGROUND: The lack of standardized criteria for defining chronic fatigue syndrome (CFS) has constrained research. The objective of this study was to apply the 1994 CFS criteria by standardized reproducible criteria. METHODS: This population-based case control study enrolled 227 adults identified from the population of Wichita with: (1) CFS (n = 58); (2) non-fatigued controls matched to CFS on sex, race, age and body mass index (n = 55); (3) persons with medically unexplained fatigue not CFS, which we term ISF (n = 59); (4) CFS accompanied by melancholic depression (n = 27); and (5) ISF plus melancholic depression (n = 28). Participants were admitted to a hospital for two days and underwent medical history and physical examination, the Diagnostic Interview Schedule, and laboratory testing to identify medical and psychiatric conditions exclusionary for CFS. Illness classification at the time of the clinical study utilized two algorithms: (1) the same criteria as in the surveillance study; (2) a standardized clinically empirical algorithm based on quantitative assessment of the major domains of CFS (impairment, fatigue, and accompanying symptoms). RESULTS: One hundred and sixty-four participants had no exclusionary conditions at the time of this study. Clinically empirical classification identified 43 subjects as CFS, 57 as ISF, and 64 as not ill. There was minimal association between the empirical classification and classification by the surveillance criteria. Subjects empirically classified as CFS had significantly worse impairment (evaluated by the SF-36), more severe fatigue (documented by the multidimensional fatigue inventory), more frequent and severe accompanying symptoms than those with ISF, who in turn had significantly worse scores than the not ill; this was not true for classification by the surveillance algorithm. CONCLUSION: The empirical definition includes all aspects of CFS specified in the 1994 case definition and identifies persons with CFS in a precise manner that can be readily reproduced by both investigators and clinicians.
Richards J, Turk J,	Child and Family	Children and	Eur Child Adolesc	BACKGROUND: Adolescents with Chronic Fatigue Syndrome (CFS) seen in specialist centres have

White S.	Clinic, Unit 5 Des Roches Square, Witan Way, Witney, OX28 4BE, Oxfordshire, UK.	adolescents with Chronic Fatigue Syndrome in non-specialist settings Beliefs, functional impairment and psychiatric disturbance.	Psychiatry. 2005 Sep;14(6):310-8.	substantial psychological and functional impairment. Beliefs about activity levels may be important in the development of CFS. METHOD: The aim was to investigate psychological and functional impairment, and beliefs in children and adolescents with CFS recruited from non-specialist services. A total of 30 such individuals participated, and 30 young people with Inflammatory Bowel Disease (IBD) formed the comparison group. RESULTS: Emotional symptoms and disorder were high in both groups. In all, 50% of those with CFS and 30% with IBD reached the threshold for emotional disorder according to the Strengths and Difficulties Questionnaire (SDQ) parent report, although this difference did not reach statistical significance. Participants with CFS scored statistically significantly higher on measures of functional impairment, including school non-attendance, compared to those with IBD. According to questionnaire responses, those with CFS were statistically significantly more likely to favour rest rather than exercise compared to those with IBD. Comparison of parental beliefs did not show such a difference. CONCLUSIONS: These young people with CFS were at high risk of psychiatric disorder. They were substantially disabled when compared to individuals with a known chronic illness. Also, as a group, they were characterised by a preference for rest rather than exercise.
Richards RS, McGregor NR, Roberts TK		Association Between Oxidative Damage Markers and Self-Reported Temporomandibular Dysfunction Symptoms in Patients with Chronic Fatigue Syndrome	Journal of Chronic Fatigue Syndrome 2005 12 (3): 45 - 61	Full blood counts, erythrocyte sedimentation rate (ESR), C-reactive protein (CRP), haematinics and markers for oxidative stress were measured on thirty-three patients diagnosed with chronic fatigue syndrome (CFS) and twenty-seven age and sex matched controls. The CFS patients had increased prevalence of symptoms of temporomandibular dysfunction (TMD). Jaw muscle pain was associated with increases in methaemoglobin ($P < .002$), ferritin ($P < .02$) and malondialdehyde ($P < .007$) whilst temporomandibular joint (tmj) clicking and/or locking was associated with increases in methaemoglobin ($P < .001$), malondialdehyde ($P < .05$) and vitamin B12 ($P < .02$) levels. Multiple regression analysis found methaemoglobin to be the principle component associated with TMD symptoms in the CFS patients. Increases in scalar severity responses to jaw muscle pain and TMJ clicking and/or locking were positively correlated with methaemoglobin by multiple regression. These data indicate that oxidative stress due to excess free radical formation was associated with jaw muscle pain in CFS patients and suggest that these symptoms were likely to be associated with a pathogen-associated aetiology.
Rimes KA, Chalder T.	Department of Psychological Medicine, Institute of Psychiatry, London, UK. k.rimes@iop.kcl.ac.uk	Treatments for chronic fatigue syndrome.	Occup Med (Lond). 2005 Jan;55(1):32-9.	AIMS: To review studies evaluating the treatment of chronic fatigue and chronic fatigue syndrome, to describe predictors of response to treatment and to discuss the role of the occupational health physician. METHODS: A literature search was carried out using Medline and PsychInfo. RESULTS: Studies evaluating cognitive behaviour therapy, graded exercise therapy, pharmacological interventions (e.g. antidepressants and corticosteroids), immunological interventions and nutritional supplements were reviewed. The most promising results have been found with cognitive behaviour therapy and graded exercise therapy, and some predictors of outcome have been identified. Most of the other interventions were evaluated in just one or two studies and therefore evidence is insufficient to draw firm conclusions. CONCLUSIONS: By applying the models of fatigue that form the bases for cognitive behaviour therapy and graded exercise therapy, occupational health physicians may play an important role in helping the patients with chronic fatigue syndrome to reduce their symptoms, improve their functioning and return to work.
Robertson MJ,	Division of	Lymphocyte subset	Clin Exp Immunol.	Chronic fatigue syndrome (CFS) is a heterogeneous disorder of unknown aetiology characterized by

Schacterle RS, Mackin GA, Wilson SN, Bloomingdale KL, Ritz J, Komaroff AL.	Hematologic Malignancies, Dana-Farber Cancer Institute, Harvard Medical School, Boston, MA, USA. mjrobert@iupui.edu	differences in patients with chronic fatigue syndrome, multiple sclerosis and major depression.	2005 Aug;141(2):326-32.	debilitating fatigue, along with other symptoms, for at least 6 months. Many studies demonstrate probable involvement of the central and autonomic nervous system, as well as a state of generalized immune activation and selective immune dysfunction in patients with CFS. The aim of this study was to compare the lymphocyte subsets of patients with chronic fatigue syndrome to those of patients with major depression and multiple sclerosis as well as those of healthy control subjects. No differences were found in total numbers of T cells, B cells or natural killer (NK) cells. However, differences were found in T, B and NK cell subsets. Patients with major depression had significantly fewer resting T (CD3(+)/CD25(-)) cells than the other groups. Patients with major depression also had significantly more CD20(+)/CD5(+) B cells, a subset associated with the production of autoantibodies. Compared to patients with multiple sclerosis, patients with CFS had greater numbers of CD16(+)/CD3(-) NK cells. Further study will be required to determine whether these alterations in lymphocyte subsets are directly involved in the pathophysiology of these disorders, or are secondary effects of the causal agent(s).
Rubin GJ, Hotopf M, Papadopoulos A, Cleare A.	Division of Psychological Medicine, Institute of Psychiatry and Guy's, King's and St. Thomas' School of Medicine, King's College London, London, UK. g.rubin@iop.kcl.ac.uk	Salivary cortisol as a predictor of postoperative fatigue.	Psychosom Med. 2005 May-Jun;67(3):441-7.	OBJECTIVE: Some patients with chronic fatigue syndrome (CFS) exhibit low basal cortisol levels, but it is not known whether low cortisol is a cause of CFS, predates the onset of CFS symptoms, or is an epiphenomenon caused by the behavioral changes typical of CFS. Because elective surgery is one of the few predictable risk factors for chronic fatigue, in this study, we followed a cohort of surgery patients from before to 6 months after their operation to test these theories. METHOD: One hundred sixty-one patients completed fatigue questionnaires and provided salivary cortisol samples before undergoing an elective inpatient surgical procedure, and then 2 days, 3 weeks, and 6 months afterward. RESULTS: Controlling for relevant demographic and surgical variables and for preoperative fatigue, low preoperative cortisol did not predict postoperative fatigue severity on any occasion ($p > .05$). Similarly, there was no correlation between low postoperative cortisol and postoperative fatigue severity at 3 weeks or 6 months ($p > .05$). Although 16 patients met our case definition for "chronic fatigue" at the 6-month follow up, low preoperative and low postoperative cortisol did not significantly predict fatigue caseness ($p > .05$). CONCLUSIONS: Any association between chronic fatigue and low cortisol would seem to develop after the onset of fatigue symptoms. Low cortisol is therefore unlikely to be the primary cause of chronic fatigue states.
Sanchez Rodriguez A, Gonzalez Marono C, Sanchez Ledesma M.	Servicio de Medicina Interna 1, Hospital Universitario de Salamanca, Salamanca.	[Chronic fatigue syndrome: a syndrome in search of definition] [Article in Spanish]	Rev Clin Esp. 2005 Feb;205(2):70-4.	
Segal TY, Hindmarsh PC, Viner RM.	University College London Hospitals, UK.	Disturbed adrenal function in adolescents with chronic fatigue syndrome.	J Pediatr Endocrinol Metab. 2005 Mar;18(3):295-301.	OBJECTIVE: To investigate adrenal function in children and adolescents with chronic fatigue syndrome (CFS) compared with age-matched controls. METHODS: Case-control study of low dose (500 ng/m2) synacthen tests (LDST) in 23 adolescents with CFS and 17 age-matched controls. Serum cortisol concentrations were measured at 5-min intervals from 10 to 45 minutes. Peak serum cortisol concentration, time to peak, rise in cortisol and area under the curve (AUC) were derived. RESULTS: Patients with CFS had significantly lower mean cortisol levels during the LDST ($p <0.001$), lower peak

				cortisol (p <0.025), reduced cortisol AUC (p <0.005) and longer time to peak cortisol (p <0.05). Abnormalities were seen in both sexes but were more pronounced in females. Unstimulated adrenal androgen and 17-hydroxyprogesterone concentrations were normal. CONCLUSIONS: Adolescents with CFS have subtle alterations in adrenal function suggesting a reduction in central stimulation of the adrenal glands. The more pronounced effects in females may reflect differential central effects of stress on hypothalamic-pituitary-adrenal axis regulation between the sexes.
Shephard RJ.	Faculty of Physical Education and Health and , Department of Public Health Sciences, Faculty of Medicine , University of Toronto, Toronto, ON, Canada.	Chronic fatigue syndrome. A brief review of functional disturbances and potential therapy.	J Sports Med Phys Fitness. 2005 Sep;45(3):381-92.	The chronic fatigue syndrome (CFS) is debilitating for both athletes and the general population. A review of etiology and mechanisms underlying functional disturbances is undertaken to provide a valid basis for therapeutic options. The review focuses on CFS as characterized by standard diagnostic criteria, building on previous reviews through use of articles identified by Medline search. Overtraining, a negative energy balance, excessive physical or environmental stress, disorders of personality and affect, dysfunction of the hypophyseal-pituitary adrenal axis, hormonal imbalance, nutritional deficits, immune suppression or activation and chronic infection have all been proposed as factors precipitating CFS, but none of these precipitants are observed consistently. Impairments of peak aerobic power and muscle strength, together with many functional disturbances, seem related to patient- or physician-imposed inactivity. Once CFS is established, treatment should aim at breaking the vicious cycle of effort avoidance, deterioration in physical condition and increasing fatigue through a combination of psychotherapy, general encouragement and a progressive exercise regimen.
Shin YI, Lee MS.	Department of Physical Medicine and Rehabilitation, Wonkwang University School of Medicine, Institute of Medical Science, Wonkwang University, Iksan 570-749, Republic of Korea.	Qi therapy (external qigong) for chronic fatigue syndrome: case studies.	Am J Chin Med. 2005;33(1):139-41.	The aim of this study was to examine the effects of Qi therapy (QT) on the symptoms of chronic fatigue syndrome (CFS), including fatigue and complications. QT affected the experience of mental and emotional relaxation in the subjects of these case studies, who also gained strength to overcome their pain and fatigue. Although the results of these two case studies may not constitute conclusive evidence, they provide a foundation for the exploration of QT as a complementary therapy in the reduction of negative symptoms of chronic fatigue syndrome.
Singal A, Kaur S, Tirkey N, Chopra K.	Pharmacology Division, University Institute of Pharmaceutical Sciences, Panjab University, Chandigarh, India.	Green tea extract and catechin ameliorate chronic fatigue-induced oxidative stress in mice.	J Med Food. 2005 Spring;8(1):47-52.	Chronic fatigue syndrome (CFS) is an illness characterized by persistent and relapsing fatigue, often accompanied by numerous symptoms involving various body systems. The etiology of CFS remains unclear, but a number of studies have shown that oxidative stress may be involved in its pathogenesis. The present study was designed to investigate the protective effect of green tea extract (GTE) and catechin in the mouse model of CFS. Animals were subjected to a forced swimming test session of 6 minutes every day for 7 days; a significant increase in immobility time on successive days represented the CFS in mice. Biochemical analysis revealed that the chronic swim test significantly increased lipid peroxidation levels and decreased glutathione levels in mouse whole-brain homogenate. Treatment with GTE (25 or 50 mg/kg, i.p.) and catechin (50 or 100 mg/kg, i.p.) for 7 days reversed the increase in immobility time. Protection was correlated with the lowered levels of lipid peroxidation and

				restoration of reduced glutathione levels in the brains of fatigued mice. These findings strongly suggest the pivotal role of oxidative stress in the pathophysiology of CFS and that GTE and catechin could be used as potential agents in the management of CFS and warrant the inclusion of GTE and catechin in the treatment regimen of CFS patients.
Siniscalchi M, Iovino P, Tortora R, Forestiero S, Somma A, Capuano L, Franzese MD, Sabbatini F, Ciacci C.	Gastrointestinal Unit, Department of Clinical and Experimental Medicine, Federico II University of Naples, Italy.	Fatigue in adult coeliac disease.	Aliment Pharmacol Ther. 2005 Sep 1;22(5):489-94.	BACKGROUND: Fatigue is reported by many adults at the moment of diagnosis of coeliac disease and during follow-up. AIM: To evaluate the prevalence, characteristics and associations of fatigue in adult coeliac disease patients. METHODS: The investigated sample comprised adults from Campania, Italy. A total of 130 coeliac disease patients were consecutively recruited in both treated (59 on gluten-free diet) and untreated conditions (71 on normal diet). The control group was made up of 80 healthy controls. Coeliac disease patients and healthy controls underwent laboratory tests, a set of questionnaires for studying fatigue: visual analogue scale for fatigue, chronic fatigue syndrome questionnaire, fatigue severity scale and a modified version of the Zung self-rating depression scale. RESULTS: Coeliac disease patients showed a significantly lower body mass index than controls (P = 0.0001), lower serum iron (P = 0.04). The entire cohort of coeliac disease patients reported greater modified version of the Zung self-rating depression scale score (P = 0.001), greater visual analogue scale for fatigue score (P = 0.0001) and greater chronic fatigue syndrome questionnaire score (P = 0.0001) compared with healthy controls. Coeliac disease patients on a gluten-free diet had a significantly higher modified version of the Zung self-rating depression scale score than coeliacs on a normal diet (P = 0.001). The prevalence of pathological modified version of the Zung self-rating depression scale score was 17% in all coeliac disease patients and 0% in healthy controls. A significant correlation was found between modified version of the Zung self-rating depression scale score and fatigue scale scores in coeliacs on a normal diet. Presence/absence of gastrointestinal symptoms did not show any significant correlation with modified version of the Zung self-rating depression scale score and fatigue scale scores. In coeliacs on a gluten-free diet, modified version of the Zung self-rating depression scale and fatigue scales scores did not significantly differ from coeliacs on a normal diet and were not related to dietetic compliance. CONCLUSION: In coeliacs, fatigue is a common finding, which ameliorates with the gluten-free diet and is strictly correlated to depression although coeliacs on a gluten-free diet showed more frequent and more severe depression symptoms than coeliacs on a normal diet.
Smith J, Fritz EL, Kerr JR, Cleare AJ, Wessely S, Mattey DL.	Tissue Typing Laboratory, Harefield Hospital, Middlesex UB9 6JH, UK.	Association of chronic fatigue syndrome with human leucocyte antigen class II alleles.	J Clin Pathol. 2005 Aug;58(8):860-3.	BACKGROUND: A genetic component to the development of chronic fatigue syndrome (CFS) has been proposed, and a possible association between human leucocyte antigen (HLA) class II antigens and chronic fatigue immune dysfunction has been shown in some, but not all, studies. AIMS: To investigate the role of HLA class II antigens in CFS. METHODS: Forty nine patients with CFS were genotyped for the HLA-DRB1, HLA-DQA1, and HLA-DQB1 alleles and the frequency of these alleles was compared with a control group comprising 102 normal individuals from the UK. All patients and controls were from the same region of England and, apart from two patients, were white. RESULTS: Analysis by 2 x 2 contingency tables revealed an increased frequency of HLA-DQA1*01 alleles in patients with CFS (51.0% v 35%; odds ratio (OR), 1.93; p = 0.008). HLA-DQB1*06 was also increased in the patients with CFS (30.2% v 20.0%; OR, 1.73, p = 0.052). Only the association between HLA-DQA1*01 and CFS was significant in logistic regression models containing HLA-DQA1*01 and HLA-

				DRQB1*06, and this was independent of HLA-DRB1 alleles. There was a decreased expression of HLA-DRB1*11 in CFS, although this association disappeared after correction for multiple comparisons. CONCLUSIONS: CFS may be associated with HLA-DQA1*01, although a role for other genes in linkage disequilibrium cannot be ruled out.
Snell CR, Vanness JM, Strayer DR, Stevens SR.	University of the Pacific, Department of Sport Sciences, Stockton, CA 95211-0197, USA. snells@juno.com	Exercise capacity and immune function in male and female patients with chronic fatigue syndrome (CFS).	In Vivo. 2005 Mar-Apr;19(2):387-90.	Hyperactivition of an unwanted cellular cascade by the immune-related protein RNase L has been linked to reduced exercise capacity in persons with chronic fatigue syndrome (CFS). This investigation compares exercise capacities of CFS patients with deregulation of the RNase L pathway and CFS patients with normal regulation, while controlling for potentially confounding gender effects. Thirty-five male and seventy-one female CFS patients performed graded exercise tests to voluntary exhaustion. Measures of peak VO2, peak heart rate, body mass index, perceived exertion, and respiratory quotient were entered into a two-way factorial analysis with gender and immune status as independent variables. A significant multivariate main effect was found for immune status ($p < 0.01$), with no gender effect or interaction. Follow-up analyses identified VO2(peak) as contributing most to the difference. These results implicate abnormal immune activity in the pathology of exercise intolerance in CFS and are consistent with a channelopathy involving oxidative stress and nitric oxide-related toxicity.
Soderlund A, Malterud K.	Section for General Practice, Department of Public Health and Primary Health Care, University of Bergen, Norway. HUmpkat@msn.comUH	Why did I get chronic fatigue syndrome? A qualitative interview study of causal attributions in women patients.	Scand J Prim Health Care. 2005 Dec;23(4):242-7.	OBJECTIVES: To explore causal attributions among women with chronic fatigue syndrome (CFS). DESIGN: Qualitative study where data from individual semi-structured interviews were analysed according to Malterud's systematic text condensation. SETTING: Bergen, Norway. SUBJECTS: A purposeful sample of eight women aged 25-55, recruited among members of a self-help organization. MAIN OUTCOME MEASURES: Accounts of causal attribution for CFS among the informants, focusing on gender. RESULTS: The participants agreed that their way of living could have increased the vulnerability of their resistance resources. Pressure they put upon themselves, workload burdens without subsequent relaxation, emotional conflicts, or preparing for assumed problem-solving were mentioned as gendered dimensions. They presented different explanations regarding potential triggers encountering their fragile immune systems, most often a virus infection. The participants thought women might have a weaker immune system than men, or that CFS was caused by a virus that women are more likely to catch. In their experience, their symptoms were activated when people put pressure on them, such that they might be nervous as to whether they could live up to the demands of their surroundings, and in the case of emotional strain related to family and work. CONCLUSION: More studies are needed exploring hypotheses concerning the complex interplay between molecular predispositions and more or less gendered lifestyle issues in CFS. Doctors need to challenge their strong beliefs regarding medically unexplained conditions, where facts still remain unresolved. Recognizing this, the doctor may provide realistic support and advice, and contribute to the establishment of common ground for understanding and managing the condition.
Staevska M, Baraniuk JN.	Division of Rheumatology, Immunology and Allergy, Room B105, Georgetown	Persistent nonallergic rhinosinusitis.	Curr Allergy Asthma Rep. 2005 May;5(3):233-42.	Nonallergic rhinitis is a complex of syndromes that are united by the absence of atopic, T(H)2 lymphocyte, immunoglobulin E (IgE)-mediated mechanisms. We propose a classification system based on the presence or absence of inflammatory granulocytes. Eosinophilic nonallergic rhinosinusitis may also be called chronic eosinophilic sinusitis syndromes (CESS) to help classify these disorders in which diverse mechanisms of eosinophil chemoattraction and survival predominate. Allergic fungal sinusitis,

	University, Lower Level Kober-Cogan Building, 3800 Reservoir Road, NW, Washington, DC 20007-2197, USA.			eosinophilic nasal polyps, aspirin sensitivity, and related disorders would fit in this category. Accumulation of neutrophils occurs in chronic infectious rhinosinusitis, foreign body reactions, and immunodeficiencies. More complex and variable combinations of leukocytes are found in Wegner's granulomatosis and related syndromes, and during the evolution of viral infections. The noninflammatory disorders can be divided by mechanism into hormonal; sympathetic dysfunction (including antihypertensive adrenergic drug therapy); cholinergic rhinitis; and nociceptive syndromes with hyperalgesia and other features (eg, the nonallergic rhinitis of chronic fatigue syndrome). Therapy based on the most likely pathophysiologic mechanism is anticipated to have the most success, but requires acceptance of the wide differential diagnosis of nonallergic rhinitis and rejection of the obsolete term of "vasomotor rhinitis."
Staines D.	Gold Coast Public Health Unit, 10-12 Young Street, Southport 4215, Queensland, Australia. don_staines@health.qld.gov.au	Do vasoactive neuropeptide autoimmune disorders explain pyridostigmine's association with Gulf War syndrome?	Med Hypotheses. 2005;65(3):591-4.	Gulf War syndrome (GWS) is a perplexing multi-symptom condition comprising a constellation of signs and symptoms consistently described in the literature. These include muscle fatigue and tiredness, malaise, myalgia, impaired cognition, ataxia, diarrhoea, bladder dysfunction, sweating disturbances, headaches, fever, arthralgia, skin rashes, and gastrointestinal and sleep disturbances. Excessive chemical sensitivity and odour intolerance is reported. Epidemiological analysis suggests association with pyridostigmine bromide (PB) use as nerve gas prophylaxis, insect repellent, certain vaccination regimes, a variety of possible chemical exposures and physical and psychological stress. Pituitary adenylate cyclase-activating polypeptide (PACAP), calcitonin gene-related peptide (CGRP) and vasoactive intestinal peptide (VIP) are potent vasoactive (vasodilatory) neuropeptides (VNs) having pleiotropic functions as immunomodulators, neuroregulators and hormones. VNs also have neurotrophic and anti-apoptotic roles. VNs act on G protein-coupled receptors (GPCRs) to activate adenylate cyclase, an important step in cyclic AMP metabolism. Autoimmune dysfunction of these VNs or their receptors is postulated to give rise to fatigue-related conditions such as chronic fatigue syndrome (CFS). Complex mechanisms involving heat shock proteins (hsps) and cytosine-guanine dinucleotide (CpG) DNA fragments may also be associated with autoimmunity to VNs or their GPCRs in contributing to fatigue-related conditions. Dysfunction of certain VNs may be the missing link in explaining the nebulous nexus between PB and GWS. This paper explores a possible link between exposures to PB and other chemical, physical and psychological stressors in producing a fatigue-related illness possibly related to autoimmune dysfunction of certain VNs. Treatment options involving restoration of VN function are considered in the context of analogues with other neurotransmitter fatigue-related conditions such as myasthenia gravis (MG). While evidence associating these conditions is thin, vasoactive neuropeptide neurotransmitters of the VIP/PACAP family have acetylcholine co-transmission functions via specific GPCRs. Autoimmune reactions to these receptors may have parallels with muscarinic (e.g., Sjogren's syndrome) and nicotinic (e.g., MG) acetylcholine neurotransmission. Hence theoretically, treatment options such as thymectomy, corticosteroids, plasma exchange, anti-idiotype antibodies and receptor genomic expression reactivation/suppression may be considered. Paradoxically pyridostigmine may prove to have a role in therapy although VN treatment/replacement may be associated with tachyphylaxis.
Staines D.	Gold Coast Public Health Unit, 10-12	Are vasoactive neuropeptide	Med Hypotheses. 2005;65(1):29-31.	Vasoactive neuropeptides such as pituitary adenylate cyclase activating polypeptide (PACAP), calcitonin gene related peptide (CGRP) and vasoactive intestinal peptide (VIP) have been implicated in

	Young Street, Southport 4215, Qld., Australia. don_staines@health.qld.gov.au	autoimmune fatigue-related disorders mediated via G protein-coupled receptors?		a number of fatigue-related conditions. Associations of these vasoactive neuropeptides with heat shock proteins (hsps) and cytosine-guanosine dinucleotide (CpG) DNA fragments in autoimmune phenomena have been postulated to interfere with receptor signal activation for adenylate cyclase and other vital cellular processes. However, a specific mechanism for receptor dysfunction has not been explored to date. G protein-coupled receptors (GPCRs) constitute a high proportion of biological receptor mechanisms and serve a wide range of substances including nucleosides, nucleotides, catecholamines, calcium, histamine, serotonin and prostaglandins. They are complex transmembrane hepta-helical serpentine structures with specific binding capabilities resulting in conformational changes that activate cognate cyclic GMP (G proteins). GPCRs adapt to certain stimuli through desensitisation and changes in phosphorylation and are subject to distortions of signalling processes. Hence, these vital signalling structures are susceptible to impairment of function through a range of mechanisms. One of their vital functions is signalling through adenylate cyclase, a vital step in cyclic AMP metabolism. This step involves ATP metabolism and therefore is a crucial mediator of cellular energy pathways. Some GPCRs act to inhibit adenylate cyclase (Gi proteins). Also vasoactive neuropeptides, such as PACAP display a number of receptor isotypes including null variants. Overexpression of Gi proteins and null variant receptors may account for major disruptions of signal transduction and ATP/cAMP metabolism. This paper examines the possible role of GPCR dysfunction in contributing to fatigue-related vasoactive neuropeptide autoimmune disorders which may include chronic fatigue syndrome (CFS), Gulf War syndrome (GWS) and even sudden infant death syndrome (SIDS).
Staines DR.	Gold Coast Public Health Unit, 10-12 Young Street, Southport 4215, Queensland, Australia. don_staines@health.qld.gov.au	Therapeutic and preventive interventions for postulated vasoactive neuropeptide autoimmune fatigue-related disorders.	Med Hypotheses. 2005;65(4):797-803.	Major advances have been made in understanding the relatively novel group of vasoactive (vasodilatory) neuropeptides (VNs) in humans. VNs comprise a novel but expanding group of substances having immunoregulation, inflammation modulation, neurotransmitter, neurotrophic, hormonal and metabolic functions. These substances may control gene expression for mRNA for themselves and their receptors. They have complex relationships with gaseous and other neurotransmitters and xenobiotic substances. Theoretical arguments have implicated these substances in autoimmune phenomena resulting in fatigue-related conditions such as chronic fatigue syndrome (CFS), sudden infant death syndrome (SIDS), fibromyalgia (FM) and Gulf War syndrome (GWS) but remain unproven. As well as possibly spontaneous onset, the precipitating causes of VN autoimmune dysfunction are likely to be a combination of genetic predisposition, infection and xenobiotic substances. Therapeutic and preventive possibilities for postulated VN autoimmune conditions will be influenced by the complex pathophysiology underpinning them. Some speculative possibilities are VN substitution/replacement, preservation of biological effect, epigenetic DNA modifications, plasma exchange, anti-cholinesterases, e.g., pyridostigmine, corticosteroids and other drug treatments, thymectomy, intravenous immunoglobulin and anti-idiotype antibodies, and CpG/DNA vaccines. Prevention and treatment of possible VN autoimmune fatigue-related disorders may prove to be important areas for future research and development.
Staines DR.	Gold Coast Public Health Unit, 10-12 Young Street,	Does dysregulation of key epigenetic and biochemical	Med Hypotheses. 2005;65(6):1154-60. Epub 2005 Jul	Autoimmune dysfunction of certain vasoactive neuropeptides (VNs) has been postulated as a contributing cause of sudden infant death syndrome (SIDS), chronic fatigue syndrome (CFS), Gulf War syndrome (GWS) and other fatigue-related disorders. This family of VNs includes pituitary adenylate

	Southport 4215, Queensland, Australia.	pathways occur in postulated vasoactive neuropeptide autoimmune disorders?	18.	cyclase activating polypeptide (PACAP), vasoactive intestinal peptide (VIP) and calcitonin gene related peptide (CGRP). The postulated mechanism is compromise of adenylate cyclase activation, a vital and unique step in cyclic AMP production from ATP, through autoimmune dysfunction of VNs, their receptors or their genes possibly involving cytosine-phosphate-guanine (CpG) fragments. CpG fragments are immunomodulatory dinucleotides serving as 'friend or foe' recognition systems to differentiate bacterial and viral (hypomethylated CpG) from mammalian (methylated CpG) DNA. However hypomethylation disorders affecting these fragments in mammals may convert them to dysfunctional states by promoting autoimmune inflammatory reactions. Epigenetic mechanisms acting on gene promoter regions may contribute to the development of VN autoimmune fatigue-related disorders through CpG fragments located in vital segments of VN/receptor genes by causing signalling defects with profound implications for VN function. Neurotransmitter dysfunction particularly glutamatergic transmission could also result with disruption of neuronal cellular biochemical functions such as ammonia regulation. Endosomal acidity and mitochondrial membrane potential modifiers such as chloroquine, together with immunoregulatory therapies, may have therapeutic implications in protecting against these apparent autoimmune disorders. This paper examines specific epigenetic and biochemical mechanisms possibly mediated by VN or receptor genes resulting in postulated VN autoimmune fatigue-related disorders. These mechanisms may have implications for treatment and prevention options for VN autoimmune disorders. VN autoimmune processes have implications for military medicine where radiological, chemical and biological agents may play an important role in pathogenesis.
Staines DR.	Gold Coast Public Health Unit, 10-12 Young Street, Southport 4215, Qld., Australia. don_staines@health.qld.gov.au	Do cytosine guanine dinucleotide (CpG) fragments induce vasoactive neuropeptide mediated fatigue-related autoimmune disorders?	Med Hypotheses. 2005;65(2):370-3.	Autoimmune dysfunction of certain vasoactive neuropeptides (e.g., vasoactive intestinal peptide, pituitary adenylate cyclase activating polypeptide) may be implicated in a range of disorders associated with fatigue-like states (chronic fatigue syndrome, Gulf War syndrome) and even sudden infant death syndrome (SIDS). The important roles of these vasoactive neuropeptides make them a vulnerable target for autoimmune dysfunction. They are known to be associated with heat shock proteins for intracellular functioning with which they may form immunostimulating complexes. Cytosine guanine dinucleotide (CpG) fragments are potently immunogenic DNA fragments which serve as friend or foe recognition systems between bacterial (hypomethylated) and mammalian (methylated) DNA and are being assessed for suitability for use in human vaccines as adjuvants. Interactions between CpG fragments, heat shock proteins and vasoactive neuropeptides may be associated with fatigue-related autoimmune conditions.
Staines DR.	Gold Coast Public Health Unit, 10-12 Young Street, Southport 4215, Qld, Australia. don_staines@health.qld.gov.au	Do vasoactive neuropeptides and heat shock proteins mediate fatigue-related autoimmune disorders?	Med Hypotheses. 2005;64(3):539-42.	Autoimmune dysfunction of certain vasoactive neuropeptides may be implicated in a range of disorders associated with fatigue like states (chronic fatigue syndrome, Gulf War syndrome) and even sudden infant death syndrome. These substances have neurotrophic, neuroregulatory, and neurotransmission functions, as well as that of immune modulators and hormones. They exert significant control over carbohydrate and lipid metabolism. The hypothesis is that because these substances have vital and indispensable roles in cellular processes, loss or compromise of these roles would lead to predictable and severe cellular and systemic effects. The important roles of certain VNs make them a vulnerable target for autoimmune dysfunction. They are known to be associated with heat shock proteins for intracellular functioning with which they may form immunostimulating

				complexes. While peptide-HSP complexes are a relatively new area for research, this paper asserts that attention could be focused on these substances and complexes in an effort to elucidate a number of perplexing fatigue-associated disorders.
Stang A, Korn K, Wildner O, Uberla K.	Department of Molecular and Medical Virology, Ruhr University Bochum, D-44780 Bochum, Germany.	Characterization of virus isolates by particle-associated nucleic acid PCR.	J Clin Microbiol. 2005 Feb;43(2):716-20.	Diagnostic virus isolation is still frequently used, particularly from respiratory tract secretions. Testing positive virus cultures for all possible viruses is time-consuming, and unexpected or unknown viruses may escape detection. Therefore, a novel random PCR approach was developed that allows sequence-independent amplification of viral nucleic acids from virus isolation-positive cultures. Selectivity for viral sequences is obtained by preferential isolation of nucleic acids that are particle associated and resistant to nucleases. Using primers with a degenerated 3' end, the isolated nucleic acids are amplified and the randomly amplified PCR products are cloned and sequenced. As proof of the concept, the PAN-PCR approach was applied to supernatants of coxsackievirus B3 and murine adenovirus type 1-infected cells. Enterovirus and adenovirus sequences were obtained, demonstrating that the random PCR approach allows detection of RNA and DNA viruses. As a first application of this PAN-PCR approach, we characterized a virus isolate from mouth-washing material of a patient with chronic fatigue syndrome and high antibody titers to coxsackievirus B2. The virus isolate had tested negative for enteroviruses and respiratory viruses (influenza viruses A and B, parainfluenza virus types 1 to 3, respiratory syncytial virus, and adenovirus) by immunofluorescence and PCR. Particle-associated, nuclease-resistant RNA and DNA were prepared from the supernatant of infected cells. The DNA and the reverse-transcribed RNA were randomly amplified, and PCR products were cloned and sequenced. Of 25 sequences obtained from the DNA preparation, 24 contained herpes simplex virus type 1 (HSV-1) sequences from 14 different loci spread over the HSV-1 genome. This result was confirmed by using a standard diagnostic HSV-PCR, demonstrating that the PAN-PCR correctly identified the virus isolate. Although the identification of HSV-1 in mouth-washing material is not surprising in retrospect, it clearly demonstrates the applicability of the PAN-PCR approach. This method should be particularly useful for characterizing virus isolates that have tested negative for all expected viruses and for identifying unknown viruses.
Stouten B.		Identification of ambiguities in the 1994 chronic fatigue syndrome research case definition and recommendations for resolution.	BMC Health Serv Res. 2005 May 13;5(1):37.	BACKGROUND: A recent article by Reeves et al. on the identification and resolution of ambiguities in the 1994 chronic fatigue syndrome (CFS) research case definition recommended the Checklist Individual Strength, the Chalder Fatigue Scale, and the Krupp Fatigue Severity Scale for evaluating fatigue in CFS studies. To be able to discriminate between various levels of severe fatigue, extreme scoring on the individual items of these questionnaires must not occur too often. METHODS: We derived an expression that allows us to compute a lower bound for the number of items with the maximum item score for a given study from the reported mean scale score, the number of reported subjects, and the properties of the fatigue rating scale. Several CFS studies that used the recommended fatigue rating scales were selected from literature and analyzed to verify whether abundant extreme scoring had occurred. RESULTS: Extreme scoring occurred on a large number of the items for all three recommended fatigue rating scales across several studies. The percentage of items with the maximum score exceeded 40% in several cases. The amount of extreme scoring for a certain scale varied from one study to another, which suggests heterogeneity in the selected subjects across studies. CONCLUSION: Because all three instruments easily reach the extreme ends of their scales on a

				large number of the individual items, they do not accurately represent the severe fatigue that is characteristic for CFS. This should lead to serious questions about the validity and suitability of the Checklist Individual Strength, the Chalder Fatigue Scale, and the Krupp Fatigue Severity Scale for evaluating fatigue in CFS research.
Stulemeijer M, de Jong LW, Fiselier TJ, Hoogveld SW, Bleijenberg G.	Expert Centre Chronic Fatigue, University Medical Centre Nijmegen, PO Box 9101, 6500 HB, Netherlands.	Cognitive behaviour therapy for adolescents with chronic fatigue syndrome: randomised controlled trial.	BMJ. 2005 Jan 1;330(7481):14. Epub 2004 Dec 7.	OBJECTIVE: To evaluate the efficacy of cognitive behaviour therapy for adolescents aged 10-17 years with chronic fatigue syndrome. DESIGN: Randomised controlled trial. SETTING: Department of child psychology. PARTICIPANTS: 71 consecutively referred patients with chronic fatigue syndrome; 36 were randomly assigned to immediate cognitive behaviour therapy and 35 to the waiting list for therapy. INTERVENTION: 10 sessions of therapy over five months. Treatment protocols depended on the type of activity pattern (relatively active or passive). All participants were assessed again after five months. MAIN OUTCOME MEASURES: Fatigue severity (checklist individual strength), functional impairment (SF-36 physical functioning), and school attendance. RESULTS: 62 patients had complete data at five months (29 in the immediate therapy group and 33 on the waiting list). Patients in the therapy group reported significantly greater decrease in fatigue severity (difference in decrease on checklist individual strength was 14.5, 95% confidence interval 7.4 to 21.6) and functional impairment (difference in increase on SF-36 physical functioning was 17.3, 6.2 to 28.4) and their attendance at school increased significantly (difference in increase in percentage school attendance was 18.2, 0.8 to 35.5). They also reported a significant reduction in several accompanying symptoms. Self reported improvement was largest in the therapy group. CONCLUSION: Cognitive behaviour therapy is an effective treatment for chronic fatigue syndrome in adolescents.
Sullivan PF, Pedersen NL, Jacks A, Evengard B.	Department of Genetics, University of North Carolina at Chapel Hill, NC 27599-7264, USA. pfsulliv@med.unc.edu	Chronic fatigue in a population sample: definitions and heterogeneity.	Psychol Med. 2005 Sep;35(9):1337-48.	BACKGROUND: Numerous nosological decisions are made when moving from the common human symptom of unusual fatigue to the rare chronic fatigue syndrome (CFS). These decisions have infrequently been subjected to rigorous evaluation. METHOD: We obtained telephone interview data on fatiguing symptoms from 31406 individuals twins in the Swedish Twin Registry aged 42-64 years; 5330 subjects who endorsed fatigue and possessed no exclusionary condition formed the analytic group. We evaluated the definition and classification of CFS-like illness using graphical methods, regression models, and latent class analysis. RESULTS: Our results raise fundamental questions about the 1994 Centers for Disease Control criteria as (1) there was no empirical support for the requirement of four of eight cardinal CFS symptoms; (2) these eight symptoms were not equivalent in their capacity to predict fatigue; and (3) no combination of symptoms was markedly more heritable. Critically, latent class analysis identified a syndrome strongly resembling CFS-like illness. CONCLUSIONS: Our data are consistent with the 'existence' of CFS-like illness although the dominant nosological approach captures population-level variation poorly. We suggest that studying a more parsimonious case definition - impairing chronic fatigue not due to a known cause - would represent a way forward.

HUthomasma@cf.ac.ukUH	Primary healthcare provision and Chronic Fatigue Syndrome: a survey of patients' and General Practitioners' beliefs.	BMC Fam Pract. 2005 Dec 13;6:49.	BACKGROUND: The current study was conducted as part of a research project into the evaluation and assessment of healthcare provision and education in Chronic Fatigue Syndrome (CFS). One aim of the study was the development of informative and educational literature for both General Practitioners (GP) and sufferers. Issues such as diagnosis, management and treatment of the syndrome should be included in information booklets written by healthcare professionals. It was important to begin the process by assessing the level of specialist knowledge that existed in typical GP surgeries. This data would then be compared to data from CFS patients. METHOD: 197 survey booklets were sent to CFS sufferers from an existing research panel. The patients approached for the purpose of the study had been recruited onto the panel following diagnosis of their illness at a specialised CFS outpatient clinic in South Wales. A further 120 booklets were sent to GP surgeries in the Gwent Health Authority region in Wales. RESULTS: Results from the study indicate that the level of specialist knowledge of CFS in primary care remains low. Only half the GP respondents believed that the condition actually exists. CONCLUSION: Steps are recommended to increase the knowledge base by compiling helpful and informative material for GPs and patient groups.

Tomoda A, Joudoi T, Rabab el-M, Matsumoto T, Park TH, Miike T.	Department of Child Development, School of Medicine, Kumamoto University, Kumamoto, Japan. atomoda@mclean.harvard.edu	Cytokine production and modulation: comparison of patients with chronic fatigue syndrome and normal controls.	Psychiatry Res. 2005 Mar 30;134(1):101-4.	We studied cytokine production in 15 patients with chronic fatigue syndrome (CFS) and 23 controls. CFS patients' peripheral blood mononuclear cells were cultured with lipopolysaccharide or phytohemagglutinin. Enzymatic immunoassay indicated cytokine concentration in culture supernatants. CFS patients showed significantly lower mRNA levels and transforming growth factor-beta1 (TGF-beta1) production. Cytokine dysregulation affects CFS pathogenesis. TGF-beta1 may aid treatment because it affects CFS inflammatory characteristics.
Torres-Harding SR, Jason LA, Dicle		Family Medical History of Persons	Journal of Chronic Fatigue Syndrome	Background: Little research has examined the family history of persons with CFS, although a few studies have found people with CFS may be more likely to have family members with fatigue or CFS-

Turkoglu O		with Chronic Fatigue Syndrome	2005 12 (4): 25-35	like conditions, cancers, autoimmune illness, and early parental death. Research into the family history of fatigue, chronic fatigue syndrome, and other medical or psychiatric illness may help inform the etiology of this illness. Objectives: The present investigation examined the occurrence of medical and psychiatric illness in the family history of persons with CFS, and then compared these results with the family history of medical illness reported by a control group of persons without fatigue. Methods: Family medical history data was obtained from questionnaire responses, a medical assessment, and medical records, and were then classified into specific illness categories, using the International Classification of Diseases, Tenth Revision (ICD-10). Family history data was compared among three groups using logistic regression analyses. Results: Results indicated that persons with chronic fatigue syndrome were significantly more likely to report a family history of endocrine/ metabolic disorders when compared to the control group. Conclusions: Findings suggest an underlying familial predisposition toward the development of both CFS and endocrine/metabolic disorders. This finding is consistent with the hypothesis that CFS represents a deregulation of the endocrine system.
Vallings R		Hypnosis in the Management of Chronic Fatigue Syndrome	Journal of Chronic Fatigue Syndrome 2005 12 (4): 37-46	During the past 30 years hypnosis has become recognised as a useful adjunct to traditional medical therapies, and has become part of mainstream medicine. Hypnosis societies provide training for health professionals to obtain registrable qualifications. The modality has been incorporated in the management of many medical conditions and diseases, with opportunities for symptom control, building confidence and enhancing the benefits of regular therapies. There are many opportunities for using hypnosis as an adjunctive therapy in the management of Chronic Fatigue Syndrome, despite some early difficulties. Problems likely to be encountered are discussed and the structure of the hypnosis session is outlined. Suggestions are given for practitioners to construct useful scripts, which can be used to teach self-hypnosis.

van de Putte EM, Engelbert RH, Kuis W, Sinnema G, Kimpen JL, Uiterwaal CS.	Department of Paediatrics, Wilhelmina Children's Hospital, University Medical Center, Utrecht, Netherlands. e.vandeputte@wkz.azu.nl	Chronic fatigue syndrome and health control in adolescents and parents.	Arch Dis Child. 2005 Oct;90(10):1020-4. Epub 2005 Jul 27.	AIMS: To explore the locus of health control in adolescents with chronic fatigue syndrome (CFS) and their parents in comparison with healthy adolescents and their parents. METHODS: In this cross-sectional study 32 adolescents with CFS were compared with 167 healthy controls and their respective parents. The Multidimensional Health Locus of Control (MHLC) questionnaire was applied to all participants. RESULTS: There was significantly less internal health control in adolescents with CFS than in healthy controls. An increase of internal health control of one standard deviation was associated with a 61% reduced risk for CFS (OR = 0.39, 95% CI 0.25 to 0.61). Internal health control of the parents was also protective (OR fathers: 0.57 (95% CI 0.38 to 0.87); OR mothers: 0.74 (95% CI 0.50 to 1.09)). The external loci of health control were higher in adolescents with CFS and in their parents. Increased levels of fatigue (56%) were found in the mothers of the adolescents with CFS, in contrast with the fathers who reported a normal percentage of 13. CONCLUSIONS: In comparison with healthy adolescents, adolescents with CFS and their parents show less internal health control. They attribute their health more to external factors, such as chance and physicians. This outcome is of relevance for

				treatment strategies such as cognitive behaviour therapy, for which health behaviour is the main focus.

van de Putte EM, Uiterwaal CS, Bots ML, Kuis W, Kimpen JL, Engelbert RH.	Department of Pediatric, Wilhelmina Children's Hospital, University Medical Center Utrecht, Utrecht, Netherlands. e.vandeputte@wkz.azu.nl	Is chronic fatigue syndrome a connective tissue disorder? A cross-sectional study in adolescents.	Pediatrics. 2005 Apr;115(4):e415-22.	OBJECTIVES: To investigate whether constitutional laxity of the connective tissues is more frequently present in adolescents with chronic fatigue syndrome (CFS) than in healthy controls. Increased joint hypermobility in patients with CFS has been previously described, as has lower blood pressure in fatigued individuals, which raises the question of whether constitutional laxity is a possible biological predisposing factor for CFS. DESIGN: Cross-sectional study. PARTICIPANTS: Thirty-two adolescents with CFS (according to the criteria of the Centers for Disease Control and Prevention) referred to a tertiary hospital and 167 healthy controls. METHODS: The 32 adolescents with CFS were examined extensively regarding collagen-related parameters: joint mobility, blood pressure, arterial stiffness and arterial wall thickness, skin extensibility, and degradation products of collagen metabolism. Possible confounding factors (age, gender, height, weight, physical activity, muscle strength, diet, alcohol consumption, and cigarette smoking) were also measured. The results were compared with findings in 167 healthy adolescents who underwent the same examinations. RESULTS: Joint mobility, Beighton score, and collagen biochemistry, all indicators of connective tissue abnormality, were equal for both groups. Systolic blood pressure, however, was remarkably lower in patients with CFS (117.3 vs. 129.7 mm Hg; adjusted difference: -13.5 mm Hg; 95% confidence interval [CI]: -19.1, -7.0). Skin extensibility was higher in adolescents with CFS (mean z score: 0.5 vs. 0.1 SD; adjusted difference: 0.3 SD; 95% CI: 0.1, 0.5). Arterial stiffness, expressed as common carotid distension, was lower in adolescents with CFS, indicating stiffer arteries (670 vs 820 mum; adjusted difference: -110 mum; 95% CI: -220, -10). All analyses were adjusted for age, gender, body mass index, and physical activity. Additionally, arterial stiffness was adjusted for lumen diameter and pulse pressure. CONCLUSIONS: These findings do not consistently point in the same direction of an abnormality in connective tissue. Patients with CFS did have lower blood pressure and more extensible skin but lacked the most important parameter

				indicating constitutional laxity, ie, joint hypermobility. Moreover, the collagen metabolism measured by crosslinks and hydroxyproline in urine, mainly reflecting bone resorption, was not different. The unexpected finding of stiffer arteries in patients with CFS warrants additional investigation.
Van Hoof E, Coomans D, Cluydts R, De Meirleir K		Association Between Fennel Phase Inventory Scores and Immune and RNase-L Parameters in Chronic Fatigue Syndrome	Journal of Chronic Fatigue Syndrome 2005 12 (2): 19 - 34	All patients suffering from a chronic condition, are challenged to manage the reality of their disease, the accompanying anxiety, the problems of daily living, and the effect on relationships. Therefore, when confronted with debilitating complaints, patients suffering from chronic fatigue syndrome (CFS) need to adapt to a new way of living during the course of their illness. Fennell developed an integrated model to manage CFS. This article is a follow-up of a study by Jason et al. (9, 10) to verify the existence of the different phases. Although not all differences are statistically significant, a clear distinction is made according to the conclusions drawn by Jason et al. (9, 10). Relationships between these distinctions and measures of symptoms, disability, psychological distress, coping, and immune parameters were revealed using non-parametric statistical tests.
Van Hoof E, De Meirleir K		The Influence of Chronic Fatigue Syndrome on the Personality Profile: A Case Report	Journal of Chronic Fatigue Syndrome 2005 12 (3): 63 - 71	Objective: Chronic fatigue syndrome (CFS) functionally impairs many patients. Despite numerous studies and reviews in CFS, little is known about the behavioral consequences. Several researchers have already suggested the influential role of personality as a possible predisposing or perpetuating factor. Method: Acase study is presented of a 34-year-old man with a history of CFS. Psychological profiling using the MMPI-2 was performed during the course of his condition. Results: His passive-aggressive manner during the medical encounter was underscored by his personality profile (code type 3-2). After his recovery, however, a spike 3 profile emerged indicating a fulfilled individual. Somatic items included in the inventory, created a secondary increase of the clinical scales. Physical complaints diminished as his condition improved and subsequently, decreased the clinical scales. Conclusion: The relevance of classifying personality characteristics in CFS patients as traits could not be supported by this case report.
Vernon SD, Reeves WC.	Division of Viral and Rickettsial Diseases, National Center for Infectious Diseases, Centers for Disease Control and Prevention, Atlanta, Georgia 30333, USA. svernon@cdc.gov	Evaluation of autoantibodies to common and neuronal cell antigens in Chronic Fatigue Syndrome.	J Autoimmune Dis. 2005 May 25;2:5.	People with chronic fatigue syndrome (CFS) suffer from multiple symptoms including fatigue, impaired memory and concentration, unrefreshing sleep and musculoskeletal pain. The exact causes of CFS are not known, but the symptom complex resembles that of several diseases that affect the immune system and autoantibodies may provide clues to the various etiologies of CFS. We used ELISA, immunoblot and commercially available assays to test serum from subjects enrolled in a physician-based surveillance study conducted in Atlanta, Georgia and a population-based study in Wichita, Kansas for a number of common autoantibodies and antibodies to neuron specific antigens. Subsets of those with CFS had higher rates of antibodies to microtubule-associated protein 2 (MAP2) ($p = 0.03$) and ssDNA ($p = 0.04$). There was no evidence of higher rates for several common nuclear and cellular antigens in people with CFS. Autoantibodies to specific host cell antigens may be a useful approach for identifying subsets of people with CFS, identify biomarkers, and provide clues to CFS etiologies.

Division of Viral and Rickettsial Diseases, National Center for Infectious Diseases, Centers for Disease Control and Prevention, Atlanta, GA, USA. dieter_krefeld@web.de	Psychometric properties of the CDC Symptom Inventory for assessment of chronic fatigue syndrome.	Popul Health Metr. 2005 Jul 22;3:8.	OBJECTIVES: Validated or standardized self-report questionnaires used in research studies and clinical evaluation of chronic fatigue syndrome (CFS) generally focus on the assessment of fatigue. There are relatively few published questionnaires that evaluate case defining and other accompanying symptoms in CFS. This paper introduces the self-report CDC CFS Symptom Inventory and analyzes its psychometric properties. METHODS: One hundred sixty-four subjects (with CFS, other fatiguing illnesses and non fatigued controls) identified from the general population of Wichita, Kansas were enrolled. Evaluation included a physical examination, a standardized psychiatric interview, three previously validated self-report questionnaires measuring fatigue and illness impact (Medical Outcomes Survey Short-Form-36 [MOS SF-36], Multidimensional Fatigue Inventory [MFI], Chalder Fatigue Scale), and the CDC CFS Symptom Inventory. Based on theoretical assumptions and statistical analyses, we developed several different Symptom Inventory scores and evaluated them on their ability to differentiate between participants with CFS and non-fatigued controls. RESULTS: The Symptom Inventory had good internal consistency and excellent convergent validity. A Total score (all symptoms), Case Definition score (CFS case defining symptoms) and Short Form score (6 symptoms with minimal correlation) differentiated CFS cases from controls. Furthermore, both the Case Definition and Short Form scores distinguished people with CFS from fatigued subjects who did not meet criteria for CFS. CONCLUSION: The Symptom Inventory appears to be a reliable and valid instrument to assess symptoms that accompany CFS. It is a positive addition to existing instruments measuring fatigue because it allows other dimensions of the illness to be assessed. Further research is needed to confirm and replicate the current findings in a normative population.

OBJECTIVE: To observe clinical therapeutic effect of acupuncture at Back-shu acupoints of five zang-organs on chronic fatigue syndrome (CFS). METHODS: Forty cases of CFS were treated with electroacupuncture at main acupoints Back-shu, and Fatigue Assessment Instrument (FAI) and Mental State Self-rating Scale (SCL-90) were used for assessment of therapeutic effect. RESULTS: After

	Guangdong 510405, China. HUzxxjxl@hotmail.comUH	chronic fatigue syndrome] [Article in Chinese]		electroacupuncture treatment, clinical symptoms improved. The cumulative scores of FAI decreased from 148.36 +/- 26.53 before treatment to 98.63 +/- 28.36 after treatment (P < 0.01). And the scores of somatization, depression, anxiety and interpersonal relationship in SCL-90 reduced significantly (P < 0.01). CONCLUSION: Electroacupuncture has a definite therapeutic effect on chronic fatigue syndrome.
Wernham W, Pheby D, Saffron L.		SHORT COMMUNICATION /PILOT STUDIES Risk Factors for the Development of Severe ME/CFS–: A Pilot Study	Journal of Chronic Fatigue Syndrome 2005 12 (2): 47-50	The pilot phase is reported of a case-control study to determine risk factors for severe CFS/ME. One hundred fifty-seven members of the ME Association, selected at random, were sent postal questionnaires, with a 56% response. The Barthel index was used as a validated proxy measure to distinguish severe disease (cases) and those less severe. Thirteen of 88 respondents had severe disease, and 44 mild disease. Two matched controls from the 'mild' group were selected per case. Of possible risk factors, odds ratios greater than 2 were found for comorbidities, damaging initial treatment and occupational chemical exposure, although in this study they were not statistically significant. These data suggest that additional studies are warranted.
Wheatland R.	The Endocrine Research Project, 574 Sims Road, Santa Cruz, CA 95060, USA. rwheatla@query.com	Chronic ACTH autoantibodies are a significant pathological factor in the disruption of the hypothalamic-pituitary-adrenal axis in chronic fatigue syndrome, anorexia nervosa and major depression.	Med Hypotheses. 2005;65(2):287-95.	Dysregulation of the hypothalamic-pituitary-adrenal (HPA) axis is a commonly recognized feature of many pathological conditions. Abnormal adrenal responses to experimental manipulation have been well documented in patients suffering from chronic fatigue syndrome, anorexia nervosa and major depression. Yet no defect of any single organ, gland or brain region has been identified as a cause of these abnormalities. The disruption of the HPA axis that occurs in these conditions can be understood if an interfering factor is present in these patients. Evidence indicates that this interfering factor is adrenocorticotropin hormone (ACTH) autoantibodies. Chronic high levels of ACTH autoantibodies will significantly disrupt the HPA axis and force the body to compensate for an impaired cortisol response. The resulting effect of chronic ACTH autoantibody interference is the manifestation of adrenocortical insufficient symptoms and psychological disturbances. Some symptoms of chronic fatigue syndrome, anorexia nervosa and major depression, such as anxiety, are the adverse effects of mechanisms compensating for less effective ACTH due to autoantibodies. Furthermore, these patients engage in extraordinary behaviors, such as self-injury, to increase their cortisol levels. When this compensation is inadequate, symptoms of adrenocortical insufficiency appear. Corticosteroid supplements have been demonstrated to be an effective treatment for chronic fatigue syndrome, anorexia nervosa and major depression. It allows the patients to have the corticosteroids they require for daily functioning and daily stressors. This therapy will relieve the patients of their symptoms of adrenocortical insufficiency and permit their cortisol-stimulating mechanisms to operate at levels that will not cause pathological problems.
Whistler T, Jones JF, Unger ER, Vernon SD.	Viral Exanthems and Herpesvirus Branch, Centers for Disease Control and Prevention, Atlanta, GA 30333, USA. taw6@cdc.gov	Exercise responsive genes measured in peripheral blood of women with chronic fatigue syndrome and matched control	BMC Physiol. 2005 Mar 24;5(1):5.	BACKGROUND: Chronic fatigue syndrome (CFS) is defined by debilitating fatigue that is exacerbated by physical or mental exertion. To search for markers of CFS-associated post-exertional fatigue, we measured peripheral blood gene expression profiles of women with CFS and matched controls before and after exercise challenge. RESULTS: Women with CFS and healthy, age-matched, sedentary controls were exercised on a stationary bicycle at 70% of their predicted maximum workload. Blood was obtained before and after the challenge, total RNA was extracted from mononuclear cells, and signal intensity of the labeled cDNA hybridized to a 3800-gene oligonucleotide microarray was measured. We identified differences in gene expression among and between subject groups before and after

		subjects.		exercise challenge and evaluated differences in terms of Gene Ontology categories. Exercise-responsive genes differed between CFS patients and controls. These were in genes classified in chromatin and nucleosome assembly, cytoplasmic vesicles, membrane transport, and G protein-coupled receptor ontologies. Differences in ion transport and ion channel activity were evident at baseline and were exaggerated after exercise, as evidenced by greater numbers of differentially expressed genes in these molecular functions. CONCLUSION: These results highlight the potential use of an exercise challenge combined with microarray gene expression analysis in identifying gene ontologies associated with CFS.
White PD, Nye KE, Pinching AJ, Yap TM, Power N, Vleck V, Bentley DJ, Thomas JM, Buckland M, Parkin JM		Immunological Changes After Both Exercise and Activity in Chronic Fatigue Syndrome: A Pilot Study	Journal of Chronic Fatigue Syndrome 2005 12 (2): 51-66	Background: The chronic fatigue syndrome (CFS) is characterized by post-exertional malaise and fatigue. We designed this pilot study to explore whether the illness was associated with alterations in immunological markers following exercise. Methods: We measured immunological markers before and up to three days after either a sub-maximal or maximal bicycle exercise test.We studied nine patients with CFS and nine ageand sex-matched healthy but sedentary controls. We also studied the same patients with CFS at home after a night's sleep and then after traveling to the study center. Results: There were no significant differences in any of the cell markers after a sub-maximal exercise test compared to a maximal test. However, we found elevated concentrations of plasma transforming growth factor beta (TGF-ß), even before exercise, in subjects with CFS (median (IQR) of 904 (182-1072) pg/ml) versus controls (median (IQR) of 50 (45-68) pg/ml) (P < .001). Traveling from home to the hospital significantly elevated TGF-ß concentrations from a resting median (IQR) concentration of 1161 (130-1246) pg/ml to a median (IQR) concentration of 1364 (1155-1768) pg/ml (P < .02). There was also a sustained increase in plasma tumor necrosis factor alpha (TNF-α) after exercise in CFS patients, but not in controls (P = .004 for the area under the curve), although traveling had no such effect. CD3, CD4 and HLA DR-expressing lymphocyte counts were lower in CFS patients, but exercise had the same effect in both groups, causing an immediate increase in circulating cell numbers that lasted less than three hours. Conclusions: These results suggest that the relationship between physical activity and both pro-inflammatory and anti-inflammatory cytokines merits further investigation in patients with CFS. The results also emphasize the importance of defining a truly resting baseline condition in such studies.
Whitehead LC.	University of Stirling Stornoway, UK.	Quest, chaos and restitution: Living with chronic fatigue syndrome/myalgic encephalomyelitis.	Soc Sci Med. 2005 Oct 15; [Epub ahead of print]	Chronic illness is disruptive, threatening people's sense of identity and taken for granted assumptions. Transformations in values, expectations and life priorities are likely to be experienced and in order to regain a coherent sense of self, people must interpret their experiences. People with difficult to diagnose illnesses can find themselves living with greater uncertainty and stigma. This paper explores how people with chronic fatigue syndrome/myalgic encephalomyelitis (CFS/ME) describe and interpret their illness experience by applying Arthur Frank's narrative typologies to analyse interviews with 17 British people with CFS/ME. The analysis proposes that a trajectory of narrative typologies is experienced, starting with a restitution narrative, moving to a chaos narrative and, for most, back to a restitution narrative and on to a quest narrative. The presentation of narrative types put forward by people living with CFS/ME differ to those presented by people who are HIV positive and have been treated for breast cancer.

Yiu YM, Qiu MY.	School of Chinese Medicine, University of Hong Kong, Hong Kong, China. yoyo@hku.hk	[A preliminary epidemiological study and discussion on traditional Chinese medicine pathogenesis of chronic fatigue syndrome in Hong Kong] [Article in Chinese]	Zhong Xi Yi Jie He Xue Bao. 2005 Sep;3(5):359-62.	OBJECTIVE: Our purpose is to conduct an epidemiological study of chronic fatigue syndrome (CFS) and its syndrome types and symptoms of traditional Chinese medicine (TCM) among adults (20-50 years old) in Hong Kong, and to discuss the TCM pathogenesis. METHODS: Design: Cross-sectional questionnaire survey. Measures: Demographic data, CDC (1994) CFS diagnostic criteria, Trudie Chalder fatigue scale, and China national standard for TCM syndrome types criteria. Subjects: Twenty to fifty years old adults by convenient sampling. RESULTS: One thousand and thirteen subjects were successfully interviewed. Five hundred and eighty-five subjects (57.8%) had different levels of fatigue. Sixty-five subjects (6.4%) met CFS diagnostic criteria. In terms of TCM syndrome types, blood stasis due to qi deficiency had the highest prevalence (35.7%) among CFS. In the 54 symptoms investigated in total, the first eight symptoms in order of appearing rates were soreness of loins and weakness in knees, poor spirit, lassitude, pain, insomnia, forgetting, vessels blood stasis, vertigo and dazzle. The mostly appeared tongue figures were pale and corpulent or pale dim tongue proper, white and white greasy tongue coating, and the mostly appeared pulse figure was sunken-thin. CONCLUSION: The point prevalence of CFS among adults of 20 to 50 years old was found to be 6.4%. The most prevalent TCM syndrome type was blood stasis due to qi deficiency. The TCM pathogenesis of CFS was deficiency of origin, mainly deficiency of qi and kidney, with excess of superficiality.

Aceves-Avila FJ, Ferrari R, Ramos-Remus C.	Hospital General Regional No. 46, Instituto Mexicano del Seguro Social, Unidad de Investigacion en Enfermedades Cronico-Degenerativas SC, Guadalajara, Jalisco, Mexico.	New insights into culture driven disorders.	Best Pract Res Clin Rheumatol. 2004 Apr;18(2):155-71.	Rheumatologists frequently encounter patients whose illnesses lack face-value; that is, they lack the typical objective features of pathology that rheumatologists traditionally rely on for diagnosis and developing effective treatment approaches: namely fibromyalgia, chronic fatigue syndrome, Gulf War syndrome, chronic whiplash, chronic low back pain, etc. In this article, we examine this group of illnesses as culture-driven disorders to emphasize the central importance of various societal constraints in the ultimate presentation of patients with these illnesses. We will examine them by first understanding the purpose they serve, the underlying factors that compel societal institutions to sanctify these disorders as diseases, and how research is beginning to examine the behaviour that captures and packages these symptoms to produce their clinical presentation. With this research understanding, rheumatologists may be able to offer patients more useful action plans, but likely changes in societal approaches to the expressions of distress and changes in disability and compensation systems will also be required.
Adler RH.	University of Berne Medical School, Kehrsatz, Switzerland. rolf.adler@tele2.ch	Chronic fatigue syndrome (cfs).	Swiss Med Wkly. 2004 May 15;134(19-20):268-76.	The Chronic Fatigue Syndrome (CFS) is described based on the revision of Fukuda et al. The question "whether CFS can be discussed as a homogenous disorder?" has been reviewed and the answer is "no". Other overlapping syndromes are mentioned. Disorders with fatigue as a symptom are depression, somatisation, irritable bowel syndrome, effort-syndrome, hyperventilation, conservation-withdrawal. Among the pathogenetic factors of CFS immune systems disorders, neuroendocrine abnormalities, autonomic activity, neuroimaging, neuropsychological abnormalities, exercise capacity and muscle function and psychological processes (attribution, perception, symptom avoidance and neutralisation of conflicts) are discussed. Since CFS cannot be comprehended without knowledge of the ontogenetic development of the affect "fatigue", it is extensively described. Based on this knowledge, fatigue as an affect and the CFS are embedded in a context, which has as its basis the fight-flight reaction and the conservation-withdrawal reaction. Weighing the evidence, it is concluded that CFS in its varieties can best be understood as a manifestation of the activation of the two biological emergency reactions: fight-flight and conservation-withdrawal. The physician should interview and examine each individual patient according to the Harvey Cushing dictum: The physician should not only study the diseased organ, but the man with his diseased organ, and not only these. He should comprehend the man with his diseased organ in his environment. This leads to study of the biological, psychological and social factors contributing to each patient's illness. Work-up and therapy have to be based on this integrated approach. The latter encompasses conflict centred psychotherapy, stepwise increasing physical activation and antidepressive drugs.

Andersen MM, Permin H, Albrecht F.	Department of Infectious Diseases M5132, Rigshospitalet, Blegdamsvej 9, DK-2100 Copenhagen, Denmark.	Illness and disability in Danish Chronic Fatigue Syndrome patients at diagnosis and 5-year follow-up.	J Psychosom Res. 2004 Feb;56(2):217-29.	OBJECTIVE: Evaluation of the life impact of Chronic Fatigue Syndrome (CFS) over 5 years. METHODS: Thirty-three adult patients meeting 1988 and 1994 CDC case criteria answered identical questionnaires at diagnosis and 5 years later, when a retrospective questionnaire was also completed. RESULTS: Work disability was very high and increased further, social isolation remained high, emotional adjustment improved. There were increased problems with reading and with allergies. Two measures of improvement were used: The relation between these measures was weak. Length of illness, extent of disability and emotional adjustment were poorly related to measures of improvement. Average illness scores were unchanged, but most individuals improved in some ways while worsening or remaining the same in others. Only one participant (3%) neared recovery, one other was substantially better but still severely disabled. CONCLUSION: CFS patients exhibit severe, long-term functional impairment. Substantial improvement is uncommon, less than 6%. Allergies and aspects of cognition may worsen, emotional adjustment often improves.
Arashima Y, Kato K, Komiya T, Kumasaka K, Matsukawa Y, Murakami M, Takahashi K, Ikeda T, Arakawa Y.	Department of Laboratory Medicine, Nihon University School of Medicine, Tokyo,	Improvement of chronic nonspecific symptoms by long-term minocycline treatment in Japanese patients with Coxiella burnetii infection considered to have post-Q fever fatigue syndrome.	Intern Med. 2004 Jan;43(1):49-54. Comment in: Intern Med. 2004 Jan;43(1):1-2.	OBJECTIVE: To address the presence of post-Q fever fatigue syndrome (post-QFS) in Japan, and to evaluate the efficacy of minocycline for this condition. PATIENTS AND METHODS: In 20 Coxiella burnetii (C. burnetii) seropositive patients with persistent nonspecific symptoms including general fatigue, low-grade fever, myalgia and arthralgia, changes in subjective symptoms, C. burnetii antibody titers and C. burnetii DNA were evaluated after antibiotic treatment. RESULTS: After treatment mainly with minocycline (100 mg/day for 3 months), the clinical picture improved in all 20 patients as evidenced by decreases in body temperature (13/17), general fatigue (20/20) and headache (9/12). The mean performance status (PS) score improved from 5.0 to 1.8 ($p<0.01$). All 7 who had been positive for C. burnetii DNA, became negative together with an improvement in subjective symptoms. Indirect immunofluorescence tests demonstrated 6 of the 20 patients to be positive for C. burnetii IgM antibody to phase II antigen (1:32), and 18 to be positive for IgG antibody (1:128, 1:256). Antibody titers of both IgM (6/6, 1:16) and IgG (18/18, 1:16) decreased markedly after treatment. CONCLUSION: These results of an open label study in Japan suggest that minocycline administration is useful for improving chronic nonspecific symptoms considered to be post-Q fever fatigue syndrome caused by C. burnetii infection.
Asbring P, Narvanen AL.	Stockholm Center of Public Health, Department of Public Health Sciences, Karolinska Institutet, Stockholm, Sweden.	Patient power and control: a study of women with uncertain illness trajectories.	Qual Health Res. 2004 Feb;14(2):226-40.	The authors interviewed 12 women diagnosed with chronic fatigue syndrome and 13 with fibromyalgia with the aim of determining the strategies they perceive themselves as using to gain control over their situation during the health care process. The results highlight various strategies that the women report applying to find a way of managing the illness and to influence caregivers. They describe, for example, how they try to gain control over their situation by acquiring knowledge about the illness. The women also describe various power strategies they use in their interaction with the caregivers to take command of their situation, namely exiting, noncompliance, confrontation, persuasion/insistence, making demands, and demonstrative distancing.
Ball N, Buchwald DS, Schmidt D, Goldberg J, Ashton S, Armitage R.	Virginia Mason Sleep Disorders Center, University of Washington,	Monozygotic twins discordant for chronic fatigue syndrome:	J Psychosom Res. 2004 Feb;56(2):207-12.	PURPOSE: Chronic fatigue syndrome (CFS) is characterized by profound fatigue accompanied by disturbances of sleep, cognition, mood, and other symptoms. Our objective was to describe sleep architecture in CFS-discordant twin pairs. METHODS: We conducted a co-twin control study of 22 pairs of monozygotic twins where one twin met criteria for CFS and the co-twin was healthy. Twins

	Seattle, WA, USA.	objective measures of sleep.		underwent two nights of polysomnography. RESULTS: The percentage of Stage 3 and REM sleep was greater among the CFS twins than their healthy co-twins (P< or = .05 for both), but no other differences in sleep architecture including sleep latency, REM latency, and total sleep time were observed. Compared to their co-twins, CFS twins had higher values for the apnea-hypopnea index and apnea-hypopnea arousal index (P< or =.05 for both). CONCLUSION: These results do not provide strong evidence for a major role for abnormalities in sleep architecture in CFS. Respiration appears impaired in CFS, but these clinical abnormalities cannot alone account for the prominence of sleep complaints in this illness. The co-twin control methodology highlights the importance of selecting well-matched control subjects.
Barlow JH, Ellard DR.	Interdisciplinary Research Centre in Health, School of Health and Social Sciences, Coventry University, Coventry, UK. j.barlow@coventry.ac.uk	Psycho-educational interventions for children with chronic disease, parents and siblings: an overview of the research evidence base.	Child Care Health Dev. 2004 Nov;30(6):637-45.	BACKGROUND: The role of psycho-educational interventions in facilitating adaptation to chronic disease has received growing recognition and is in keeping with policy developments advocating greater involvement of patients in their own care. The purpose of this paper is to provide an overview of the current literature regarding the effectiveness of psycho-educational interventions for children and adolescents with chronic disease, their parents and siblings. METHODS: Electronic searches were conducted using AMED, CINAHL, Cochrane Database, DARE, HTA, MEDLINE, NHS EED, PsycLIT, PsycINFO, and PubMED. Inclusion criteria were systematic reviews, meta-analyses and overviews based on traditional reviews of published literature. The titles of papers were reviewed, abstracts were obtained and reviewed, and full copies of selected papers were obtained. RESULTS: No reviews of psycho-educational interventions were found for either parents or siblings. Twelve reviews of interventions for children and adolescents were identified: chronic disease in general (three); chronic pain (one); asthma (three); chronic fatigue syndrome (CFS)/myalgic encephalomyelitis (ME) (one); diabetes (two); juvenile idiopathic arthritis (JIA) (one) and one informational intervention for paediatric cancer patients. The main focus was on disease management (particularly in asthma and diabetes) with less attention being paid to psychosocial aspects of life with a chronic condition. Overall, there is evidence of effectiveness for interventions incorporating cognitive-behavioural techniques on variables such as self-efficacy, self-management of disease, family functioning, psychosocial well-being, reduced isolation, social competence, knowledge, hope, pain (for chronic headache), lung function (asthma), days absent from school (asthma), visits to A & E (asthma), fatigue (CFS), and metabolic control (diabetes). A number of gaps and limitations were identified across all disease categories, such as inadequate description of interventions, small sample sizes, and lack of evidence regarding cost-effectiveness. CONCLUSION: This overview has highlighted the need to extend the evidence base for psycho-educational interventions, particularly in a UK context. It is essential that effective interventions are implemented and embedded in service provision in order to maximize empowerment through self-care for children, adolescents and their parents.

Bates MN, Fawcett J, Garrett N, Cutress T, Kjellstrom T.	Institute of Environmental Science and Research Ltd. (ESR), PO Box 50-348, Porirua, New Zealand.	Health effects of dental amalgam exposure: a retrospective cohort study.	Int J Epidemiol. 2004 Aug;33(4):894-902. Epub 2004 May 20.	BACKGROUND: Whether dental amalgam fillings (containing mercury) are hazardous is a long-standing issue, with few epidemiological investigations. Allegations have particularly involved nervous system disorders, such as multiple sclerosis, Alzheimer's disease, and chronic fatigue syndrome. This retrospective cohort study, the largest of its kind, contained people in the New Zealand Defence Force (NZDF) between 1977 and 1997. The NZDF has its own dental service, providing all personnel with regular and consistent treatment. Comprehensive treatment records are maintained and archived. METHODS: Yearly dental treatment histories, including amalgam filling placements, were compiled from individual records. To minimize amalgam exposure misclassification the cohort was restricted to people who, at NZDF entry, were aged <26 years and had all their posterior teeth. The cohort was linked with morbidity records. Data were analysed with a proportional hazards model, using a time-varying exposure unit of 100 amalgam surface-years. RESULTS: The final cohort contained 20 000 people, 84% males. Associations with medical diagnostic categories, particularly disorders of the nervous system and kidney, were examined. Of conditions allegedly associated with amalgam, multiple sclerosis had an adjusted hazard ratio (HR) of 1.24 (95% CI: 0.99, 1.53, P = 0.06), but there was no association with chronic fatigue syndrome (HR = 0.98, 95% CI: 0.94, 1.03), or kidney diseases. There were insufficient cases for investigation of Alzheimer's or Parkinson's diseases. CONCLUSIONS: Results were generally reassuring, and provide only limited evidence of an association between amalgam and disease. Further follow-up of the cohort will permit investigation of diseases more common in the elderly.
Benca RM, Ancoli-Israel S, Moldofsky H.	University of Wisconsin, Madison, USA.	Special considerations in insomnia diagnosis and management: depressed, elderly, and chronic pain populations.	J Clin Psychiatry. 2004;65 Suppl 8:26-35.	Patients with insomnia who also have chronic pain or depression or who are elderly represent segments of the population that are particularly difficult to treat. These populations tend to be at higher risk for experiencing difficulty sleeping and are more likely to experience chronic insomnia, sleep maintenance problems, and/or nonrestorative sleep. Worsening insomnia may exacerbate other somatic and psychological symptoms and vice versa. Conversely, there is evidence that appropriate recognition and management of the sleep complaint may alleviate other symptoms related to the associated condition and help interrupt this vicious cycle.

Diseases, National Center for Infectious Diseases, Centers for Disease Control and Prevention, Atlanta, GA 30333, USA. wcr1@cdc.gov	fatiguing illnesses in the United States: a pilot study.		realistic context for public health officials and others responsible for allocating resources. METHODS: We conducted a pilot random-digit-dialing survey to estimate the prevalence of fatiguing illnesses in different geographic regions and in urban and rural populations of the United States. This report focuses on 884 of 7,317 respondents 18 to 69 years old. Fatigued (440) and randomly selected non-fatigued (444) respondents completed telephone questionnaires concerning fatigue, other symptoms, and medical history. RESULTS: We estimated 12,186 per 100,000 persons 18 to 69 years of age suffered from fatigue lasting for at least 6 months (chronic fatigue), and 1,197 per 100,000 described an illness that, though lacking clinical evaluation, met criteria for CFS (CFS-like). Chronic fatigue and CFS-like illness were more common in rural than in urban populations, although the differences were not significant. The prevalence of these fatiguing illnesses did not differ meaningfully among the four regions surveyed, and no significant geographic trends were observed. CONCLUSIONS: This investigation estimated that nearly 2.2 million American adults suffer from CFS-like illness. The study also suggested the need to focus future investigations of fatigue on populations with lower incomes and less education. There was no evidence for regional differences in the occurrence of fatiguing illnesses.
Blacker CV, Greenwood DT, Wesnes KA, Wilson R, Woodward C, Howe I, Ali T.	Department of Health and Social Sciences, University of Exeter, Exeter, England. c.v.r.blacker@btinternet.com	Effect of galantamine hydrobromide in chronic fatigue syndrome: a randomized controlled trial.	JAMA. 2004 Sep 8;292(10):1195-204.	CONTEXT: There is no established pharmacological treatment for the core symptoms of chronic fatigue syndrome (CFS). Galantamine hydrobromide, an acetyl cholesterone inhibitor, has pharmacological properties that might benefit patients with CFS. OBJECTIVE: To compare the efficacy and tolerability of galantamine hydrobromide in patients with CFS. DESIGN, SETTING, AND PATIENTS: Randomized, double-blind trial conducted June 1997 through July 1999 at 35 outpatient centers in the United Kingdom (n = 17), United States (n = 14), the Netherlands (n = 2), Sweden (n = 1), and Belgium (n = 1) involving 434 patients with a clinical diagnosis of CFS (modified US Centers for Disease Control and Prevention criteria). INTERVENTIONS: A total of 89 patients were randomly assigned to receive 2.5 mg of galantamine hydrobromide; 86 patients, 5.0 mg; 91 patients, 7.5 mg; and 86 patients, 10 mg (these patients received medicine in the tablet form 3 times per day); a total of 82 patients received matching placebo tablets 3 times per day. MAIN OUTCOME MEASURES: The primary efficacy variable was the global change on the Clinician Global Impression Scale after 4, 8, 12, and 16 weeks of treatment. Secondary outcomes were changes in core symptoms of CFS on the Chalder Fatigue Rating Scale, the Fibromyalgia Impact Questionnaire, and the Pittsburgh Sleep Quality Index; changes in quality of life on the Nottingham Health Profile; and assessment of plasma-free cortisol levels and cognitive performance on a computer-based battery of tests. RESULTS: After 16 weeks, there were no statistically significant differences between any of the galantamine or placebo groups in clinical condition on the Clinician Global Impression Scale, or for any of the secondary end points. Exploratory regression analysis failed to detect any consistent prognostic factor that might have influenced the primary or any secondary outcome measures. CONCLUSION: This trial did not demonstrate any benefit of galantamine over placebo in the treatment of patients with CFS.

Bruera E, Moyano JR, Sala R, Rico MA, Bosnjak S, Bertolino M, Willey J, Strasser F, Palmer JL.	Department of Palliative Care & Rehabilitation Medicine, The University of Texas MD Anderson Cancer Center, Houston 77030, USA.	Dexamethasone in addition to metoclopramide for chronic nausea in patients with advanced cancer: a randomized controlled trial.	J Pain Symptom Manage. 2004 Oct;28(4):381-8.	Chronic nausea occurs in most patients with advanced cancer. This study was done to assess the antiemetic effects of dexamethasone in patients with chronic nausea refractory to metoclopramide. Secondary outcomes included appetite, fatigue, and pain. Fifty-one patients who had nausea (> or = 3/10 on a 0-10 scale) for > or = 2 weeks despite 48 hours of oral metoclopramide therapy (40-60 mg/day) were enrolled. Patients received 20 mg/day dexamethasone (DM) orally (n = 25) or placebo (n = 26) for severe nausea in addition to metoclopramide (60 mg/day orally). At baseline the mean nausea intensity ratings in the DM and placebo groups were 8.0 and 7.4. At Day 8 they were 2.1 and 2.0, respectively. At Day 3 and Day 8, the mean difference in nausea intensity for the DM and placebo groups was 4.5 and 2.9 (P = 0.16) and 5.9 and 5.7 (P = 0.85), respectively. Improvement in appetite and fatigue were observed on Day 3 and Day 8 in both groups as compared with the baseline. Pain, vomiting, well-being, and quality of life remained unchanged in both groups at both times. We conclude that DM was not superior to placebo in the management of chronic nausea in our patients with advanced cancer.
Brustia D, Uglietti A, Garavelli PL.	SCDO Malattie Infettive, Azienda Sanitaria Ospedaliera Maggiore della Carita, Novara.	[Polyneuritis cranialis HHV-6 infection associated][Article in Italian]	Recenti Prog Med. 2004 May;95(5):257-8.	Human herpesvirus 6 (HHV-6) has been shown to be a common cause of acute febrile disease in young children, including exanthema subitum. HHV-6 has also been associated with a number of neurologic disorders including encephalitis and the virus has been postulated to play a role in acquired immunodeficiency syndrome, multiple sclerosis and chronic fatigue syndrome. The disorder of multiple cranial nerve palsies without spinal cord involvement is referred to as polyneuritis cranialis and is rare. The Authors describe a case of polyneuritis cranialis in a 52-year old woman treated with ganciclovir and only complete eradication of the virus.
Burnet RB, Chatterton BE.		Gastric Emptying is Slow in Chronic Fatigue Syndrome.	BMC Gastroenterol. 2004 Dec 26;4(1):32 [Epub ahead of print]	BACKGROUND: Gastrointestinal symptoms are common in patients with Chronic Fatigue Syndrome (CFS). The objective of this study was to determine the frequency of these symptoms and explore their relationship with objective (radionuclide) studies of upper GI function. METHODS: Thirty-two (32) patients with CFS and 45 control subjects completed a questionnaire on upper GI symptoms, and the 32 patients underwent oesophageal clearance, and simultaneous liquid and solid gastric emptying studies using radionuclide techniques compared with historical controls. RESULTS: The questionnaires showed a significant difference in gastric ($p>0.01$) symptoms and swallowing difficulty. Nocturnal diarrhoea was a significant symptom not previously reported. 5/32 CFS subjects showed slightly delayed oesophageal clearance, but overall there was no significant difference from the control subjects, nor correlation of oesophageal clearance with symptoms. 23/32 patients showed a delay in liquid gastric emptying, and 12/32 a delay in solid gastric emptying with the delay significantly correlated with the mean symptom score (for each $p<<0.001$). CONCLUSION: GI symptoms in patients with chronic fatigue syndrome are associated with objective changes of upper GI motility.
Busichio K, Tiersky LA, Deluca J, Natelson BH.	Chronic Fatigue Syndrome Center, Newark, New Jersey 07666, USA.	Neuropsychological deficits in patients with chronic fatigue syndrome.	J Int Neuropsychol Soc. 2004 Mar;10(2):278-85.	The degree of neuropsychological dysfunction across multiple domains was examined in individuals suffering from chronic fatigue syndrome (CFS). In this descriptive study, a similar series of neuropsychological tests was administered to a group of CFS patients and healthy participants. More specifically, CFS patients (n = 141) who met the 1994 Case Definition criteria were compared to 76 healthy control participants on tests of memory, attention (concentration), speed of information processing, motor speed, and executive functioning. On the 18 measures administered, CFS patients

				scored 1 standard deviation below the healthy mean on nine measures and scored 2 standard deviations below the healthy mean on four of the measures. Moreover, results indicated that CFS patients were more likely than healthy controls to fail (1.6 SD below the healthy mean) at least one test in each of the following domains: attention, speed of information processing, and motor speed, but not on measures of memory and executive functioning. Finally, CFS patients demonstrated a greater total number of tests failed across domains.

Candy B, Chalder T, Cleare AJ, Wessely S, Hotopf M.	Department of Psychological Medicine, Guy's, King's and St. Thomas' School of Medicine, 103 Denmark Hill, London SE5 8AZ, UK.	A randomised controlled trial of a psycho-educational intervention to aid recovery in infectious mononucleosis.	J Psychosom Res. 2004 Jul;57(1):89-94.	OBJECTIVES: Glandular fever is associated with an approximate fivefold increase in fatigue at 6 months. Reduced levels of fitness and illness beliefs may be important predictors of fatigue following glandular fever. We therefore developed a brief psycho-educational intervention aimed at improving recovery from infectious mononucleosis, and piloted a randomised controlled trial to evaluate the intervention. METHODS: We performed a randomised-controlled trial in primary health care in Southeast London and Kent. Sixty-nine patients aged between 16 and 45 years who were diagnosed, serologically and clinically, with acute infectious mononucleosis between December 1999 and December 2000 were randomised. The control group received a standardised fact-sheet about infectious mononucleosis, which gave no advice on rehabilitation. Patients who were randomised to the intervention received an individual treatment session, two follow-up telephone calls, and an information booklet. Fatigue score 6 months after the onset of infectious mononucleosis was the main outcome measure. RESULTS: Sixty-nine out of 139 patients referred were recruited and randomised. Eighty-seven percent of those recruited completed the Fatigue Questionnaire at 6 months. The intervention was acceptable to all who received it. There were fewer fatigue cases in the intervention group than the control group at 6 months follow-up (odds ratio 0.31, 95% confidence interval 0.09-0.91). CONCLUSIONS: A brief intervention at the diagnosis of infectious mononucleosis is acceptable, and may help prevent the development of chronic fatigue. Definitive randomised controlled trials are required to test the intervention.
Carlo-Stella N, Lorusso L, Candura SM, Cuccia M.	Laboratorio di Immunogenetica, Dipartimento di Genetica e	[Chronic fatigue syndrome: a review] [Article in Italian]	Recenti Prog Med. 2004 Nov;95(11):546-52;	Chronic fatigue sindrome is a relatively unknown and underdiagnosed entity in Italy where its epidemiology remains uncertain, as well as its etiology, although it causes important disability in those affected. Classification criteria by Fukuda are available to diagnose the syndrome. Its epidemiology indicates that it is probably more frequent in Northern countries and it is described in Gulf War

	Microbiologia, Universita, Pavia.			veterans. Etiological hypotheses include infectious diseases, immunology and neurology. Among these hypotheses sickness behavior mimes certain aspects of this syndrome and is characterized by a cytokine imbalance in the central nervous system and in the periphery. There are no valid therapies available at the moment. In the laboratory of Immunogenetics, we are constituting a biological bank of the syndrome to study the immunogenetic aspects of the disease in the hope of delucidating some of the obscure areas of its etiopathogenesis.
Cevik R, Gur A, Acar S, Nas K, Sarac AJ.	Physical Medicine and Rehabilitation, School of Medicine, Dicle University, Diyarbakir, Turkey. ftremzi@dicle.edu.tr	Hypothalamic-pituitary-gonadal axis hormones and cortisol in both menstrual phases of women with chronic fatigue syndrome and effect of depressive mood on these hormones.	BMC Musculoskelet Disord. 2004 Dec 08;5(1):47.	BACKGROUND: Chronic fatigue syndrome (CFS) is a disease which defined as medically unexplained, disabling fatigue of 6 months or more duration and often accompanied by several of a long list of physical complaints. We aimed to investigate abnormalities of hypothalamic-pituitary-gonadal (HPG) axis hormones and cortisol concentrations in premenopausal women with CFS and find out effects of depression rate on these hormones. METHODS: We examined follicle stimulating hormone (FSH), luteinizing hormone (LH), estradiol, progesterone and cortisol concentrations in 43 premenopausal women (mean age: 32.86 +/- 7.11) with CFS and compared matched 35 healthy controls (mean age: 31.14 +/- 6.19). Patients were divided according to menstrual cycle phases (follicular and luteal) and compared with matched phase controls. Depression rate was assessed by Beck Depression Inventory (BDI), and patients with high BDI scores were compared to patients with low BDI scores. RESULTS: There were no significant differences in FSH, LH, estradiol and progesterone levels in both of menstrual phases of patients versus controls. Cortisol levels were significantly lower in patients compared to controls. There were no significant differences in all hormone levels in patients with high depression scores versus patients with low depression scores. CONCLUSION: In spite of high depression rate, low cortisol concentration and normal HPG axis hormones of both menstrual phases are detected in premenopausal women with CFS. There is no differentiation between patients with high and low depression rate in all hormone levels. Depression condition of CFS may be different from classical depression and evaluation of HPG and HPA axis should be performed for understanding of pathophysiology of CFS and planning of treatment.
Chaudhuri A, Behan PO.	Division of Clinical Neurosciences, Institute of Neurological Sciences, Southern General Hospital, University of Glasgow, 1345 Govan Road, Glasgow G51 4TF, UK. ac54p@udcf.gla.ac.uk	In vivo magnetic resonance spectroscopy in chronic fatigue syndrome.	Prostaglandins Leukot Essent Fatty Acids. 2004 Sep;71(3):181-3.	The pathogenic mechanisms of chronic fatigue syndrome (CFS) are not clearly known. Fatigue, poor short-term memory and muscle pain are the most disabling symptoms in CFS. Research data on magnetic resonance spectroscopy (MRS) of muscles and brain in CFS patients suggest a cellular metabolic abnormality in some cases. 31P MRS of skeletal muscles in a subset of patients indicate early intracellular acidosis in the exercising muscles. 1H MRS of the regional brain areas in CFS have shown increased peaks of choline derived from the cell membrane phospholipids. Cell membrane oxidative stress may offer a common explanation for the observed MRS changes in the muscles and brain of CFS patients and this may have important therapeutic implications. As a research tool, MRS may be used as an objective outcome measure in the intervention studies. In addition, regional brain 1H MRS has the potential for wider use to substantiate a clinical diagnosis of CFS from other disorders of unexplained chronic fatigue.
Chaudhuri A, Behan PO.	Division of Clinical Neurosciences,	Fatigue in neurological	Lancet. 2004 Mar 20;363(9413):978-	Chronic fatigue is a typical symptom of neurological diseases, and is most disabling in multiple sclerosis, postpoliomyelitis, poststroke, and in chronic fatigue syndrome. Disorders of neuromuscular

	University of Glasgow, Glasgow G51 4TF, UK. ac54p@udcf.gla.ac.uk	disorders.	88.	junction transmission and metabolic diseases cause muscle fatigability, which is characterised by failure to sustain the force of muscle contraction (peripheral fatigue). Fatigue is also seen in diseases that affect the central, peripheral, and autonomic nervous systems (central fatigue). Enhanced perception of effort and limited endurance of sustained physical and mental activities are the main characteristics of central fatigue. Metabolic and structural lesions that disrupt the usual process of activation in pathways interconnecting the basal ganglia, thalamus, limbic system, and higher cortical centre are implicated in the pathophysiological process of central fatigue. A state of pre-existing relative hypocortisolaemia might sensitise the hypothalamic-pituitary-adrenal axis to development of persistent central fatigue after stress. The contributions of physiological, cognitive, and affective changes underlying fatigue are variable, and treatment is largely symptomatic and rehabilitative.
Clark C.		Patient organisations in ME and CFS seek only understanding. Comment on: BMJ. 2004 Jun 5;328(7452):1354-7.	BMJ. 2004 Jul 10;329(7457):112-3.	
Cleare AJ, O'Keane V, Miell JP.	Division of Psychological Medicine, The Institute of Psychiatry and Guy's, King's and St Thomas' School of Medicine, London SE5 8AF, UK. a.cleare@iop.kcl.ac.uk	Levels of DHEA and DHEAS and responses to CRH stimulation and hydrocortisone treatment in chronic fatigue syndrome.	Psychoneuroendocrinology. 2004 Jul;29(6):724-32.	Background: An association between chronic fatigue syndrome (CFS) and abnormalities of the hypothalamo-pituitary-adrenal axis has been described, and other adrenal steroid abnormalities have been suggested. Dehydroepiandrostenedione (DHEA) and its sulphate (DHEA-S), apart from being a precursor of sex steroids, have other functions associated with memory, depression and sleep. It has been suggested that CFS may be associated with a state of relative DHEA(-S) deficiency. Therefore we investigated basal levels of DHEA(-S), the cortisol/DHEA molar ratio and the responsiveness of DHEA to stimulation by corticotrophin-releasing hormone (CRH). Recent studies have also suggested that low dose hydrocortisone may be effective at reducing fatigue in CFS. We therefore also assessed these parameters prior to and following treatment with low dose oral hydrocortisone. Methods: Basal levels of serum DHEA, DHEAS and cortisol were measured in 16 patients with CFS without depression and in 16 controls matched for age, gender, weight, body mass index and menstrual history. CRH tests (1 g/kg i.v.) were carried out on all subjects and DHEA measured at 0, +30 and +90 min. In the patient group, CRH tests were repeated on two further occasions following treatment with hydrocortisone (5 or 10 mg, p.o.) or placebo for 1 month each in a double-blind cross over study protocol. Results: Basal levels of DHEA were higher in the patient, compared to the control, group (14.1+/-2.2 vs. 9.0+/-0.90 ng/ml, P=0.04), while levels of DHEAS in patients (288.7+/-35.4 microg/dl) were not different from controls (293.7+/-53.8, P=NS). Higher DHEA levels were correlated with higher disability scores. Basal cortisol levels were higher in patients, and consequently the cortisol/DHEA molar ratio did not differ between patients and controls. Levels of DHEA (8.9+/-0.97 ng/ml, P=0.015) and DHEAS (233.4+/-41.6 microg/dl, P=0.03) were lower in patients following treatment with hydrocortisone. There was a rise in DHEA responsiveness to CRH in the patients after treatment but this did not attain significance (AUCc:

				2.5+/-1.7 ng/ml h pre-treatment vs. 6.4+/-1.2 ng/ml h post-hydrocortisone, P=0.053). However, those patients who responded fully to hydrocortisone in terms of reduced fatigue scores did show a significantly increased DHEA responsiveness to CRH (AUCc: -1.4+/-2.5 ng/ml h at baseline, 5.0+/-1.2 ng/ml h after active treatment, P=0.029). Conclusions: DHEA levels are raised in CFS and correlate with the degree of self-reported disability. Hydrocortisone therapy leads to a reduction in these levels towards normal, and an increased DHEA response to CRH, most marked in those who show a clinical response to this therapy.
Cleare AJ.	Section of Neurobiology of Mood Disorders, Division of Psychological Medicine, The Institute of Psychiatry, London, SE5 8AF, UK. a.cleare@iop.kcl.ac.uk	The HPA axis and the genesis of chronic fatigue syndrome.	Trends Endocrinol Metab. 2004 Mar;15(2):55-9.	Many studies of patients with long-standing chronic fatigue syndrome (CFS) have found alterations to the hypothalamo-pituitary-adrenal (HPA) axis, including mild hypocortisolism, heightened negative feedback and blunted responses to challenge. However, recent prospective studies of high-risk cohorts suggest that there are no HPA axis changes present during the early stages of the genesis of fatiguing illnesses. Moreover, HPA axis changes can be reversed by modifying behavioural features of the illness, such as inactivity, deconditioning and sleep disturbance. Nevertheless, raising levels of cortisol pharmacologically can temporarily alleviate symptoms of fatigue. This article presents the case that there is no specific change to the HPA axis in CFS and that the observed changes are of multifactorial aetiology, with some factors occurring as a consequence of the illness. Nevertheless, the HPA axis might play a role in exacerbating or perpetuating symptoms late on in the course of the illness.
Cook DB, Lange G, Ciccone DS, Liu WC, Steffener J, Natelson BH.	Chronic Fatigue Syndrome Cooperative Research Center, New Jersey Medical School, Newark, New Jersey 07018, USA. cookdb@njneurom ed.org	Functional imaging of pain in patients with primary fibromyalgia.	J Rheumatol. 2004 Feb;31(2):364-78.	OBJECTIVE: To examine the function of the nociceptive system in patients with fibromyalgia (FM) using functional magnetic resonance imaging (fMRI). METHODS: Two groups of women, 9 with FM and 9 pain-free, volunteered to participate. In Experiment 1, we assessed psychophysical responses to painful stimuli and prepared participants for fMRI testing. For Experiment 2, subjects underwent fMRI scanning while receiving painful and nonpainful heat stimuli. Conventional and functional MR images were acquired using a 1.5 T MR scanner. Scanning occurred over 5 conditions. Condition 1 served as a practice session (no stimuli). Conditions 2 and 5 consisted of nonpainful warm stimuli. Conditions 3 and 4 consisted of an absolute thermal pain stimulus (47 degrees C) and a perceptually equivalent pain stimulus delivered in counterbalanced order. RESULTS: Experiment 1 indicated that subjects with FM were significantly more sensitive to experimental heat pain than controls ($p < 0.001$). In Experiment 2, fMRI data indicated that the FM group exhibited greater activity than controls over multiple brain regions in response to both nonpainful and painful stimuli ($p < 0.01$). Specifically, in response to nonpainful warm stimuli, FM subjects had significantly greater activity than controls in prefrontal, supplemental motor, insular, and anterior cingulate cortices ($p < 0.01$). In response to painful stimuli, FM subjects had greater activity in the contralateral insular cortex ($p < 0.01$). Data from the practice session indicated brain activity in pain-relevant areas for the FM group but not for controls. CONCLUSION: Our results provide further evidence for a physiological explanation for FM pain.
Cox IJ, Puri BK.	Faculty of Medicine, Imaging Sciences	In vivo MR spectroscopy in diagnosis and	Prostaglandins Leukot Essent Fatty Acids. 2004	Magnetic resonance spectroscopy is one of the most important tools for quantitative analysis of chemical composition and structure, and this non-invasive technique is now being applied in vivo to study biochemical processes in those neuropsychiatric disorders that are part of the phospholipid

	Department, Imperial College London, Division of Clinical Sciences, Robert Steiner Magnetic Resonance Unit, Hammersmith Campus, Du Cane Road, London W12 0HS, UK. j.cox@imperial.ac.uk	research of neuropsychiatric disorders.	Apr;70(4):357-60.	spectrum. Interpretation of a clinical magnetic resonance spectrum can provide information about membrane phospholipid turnover, cellular energetics, neuronal function, selected neurotransmitter activity and intracellular pH. Cerebral proton and phosphorus magnetic resonance spectroscopy findings are summarized in relation to schizophrenia, dyslexia and chronic fatigue syndrome.
Crofford LJ, Young EA, Engleberg NC, Korszun A, Brucksch CB, McClure LA, Brown MB, Demitrack MA.	Department of Internal Medicine, University of Michigan School of Medicine, Ann Arbor, MI, USA. crofford@umich.edu	Basal circadian and pulsatile ACTH and cortisol secretion in patients with fibromyalgia and/or chronic fatigue syndrome.	Brain Behav Immun. 2004 Jul;18(4):314-25.	The objective of this study was to evaluate and compare the basal circadian and pulsatile architecture of the HPA axis in groups of patients with FMS, CFS, or both syndromes with individually matched control groups. Forty patients with either FMS (n = 13), FMS and CFS (n = 12), or CFS (n = 15) were matched by age (18-65), sex, and menstrual status to healthy controls. Subjects were excluded if they met criteria for major Axis I psychiatric disorders by structured clinical interview (SCID). Subjects were admitted to the General Clinical Research Center where meals and activities were standardized. Blood was collected from an intravenous line every 10 min over 24 h for analysis of ACTH and cortisol. Samples were evaluable for ACTH in 36 subject pairs and for cortisol in 37 subject pairs. There was a significant delay in the rate of decline from acrophase to nadir for cortisol levels in patients with FMS ($P < .01$). Elevation of cortisol in the late evening quiescent period was evident in half of the FMS patients compared with their control group, while cortisol levels were numerically, but not significantly, lower in the overnight period in patients with CFS compared with their control group. Pulsatility analyses did not reveal statistically significant differences between patient and control groups. We conclude that the pattern of differences for basal circadian architecture of HPA axis hormones differs between patients with FMS and CFS compared to their matched control groups. The abnormalities in FMS patients are consistent with loss of HPA axis resiliency.
de Lange FP, Kalkman JS, Bleijenberg G, Hagoort P, van der Werf SP, van der Meer JW, Toni I.	F.C. Donders Centre for Cognitive Neuroimaging, University of Nijmegen, NL-6500 HB Nijmegen, The Netherlands E-mail: floris.delange@fcdonders.kun.nl	Neural correlates of the chronic fatigue syndrome--an fMRI study.	Brain. 2004 Sep;127(Pt 9):1948-57. Epub 2004 Jul 07.	Chronic fatigue syndrome (CFS) is characterized by a debilitating fatigue of unknown aetiology. Patients who suffer from CFS report a variety of physical complaints as well as neuropsychological complaints. Therefore, it is conceivable that the CNS plays a role in the pathophysiology of CFS. The purpose of this study was to investigate neural correlates of CFS, and specifically whether there exists a linkage between disturbances in the motor system and CFS. We measured behavioural performance and cerebral activity using rapid event-related functional MRI in 16 CFS patients and 16 matched healthy controls while they were engaged in a motor imagery task and a control visual imagery task. CFS patients were considerably slower on performance of both tasks, but the increase in reaction time with increasing task load was similar between the groups. Both groups used largely overlapping neural resources. However, during the motor imagery task, CFS patients evoked stronger responses in visually related structures. Furthermore, there was a marked between-groups difference during

				erroneous performance. In both groups, dorsal anterior cingulate cortex was specifically activated during error trials. Conversely, ventral anterior cingulate cortex was active when healthy controls made an error, but remained inactive when CFS patients made an error. Our results support the notion that CFS may be associated with dysfunctional motor planning. Furthermore, the between-groups differences observed during erroneous performance point to motivational disturbances as a crucial component of CFS.
d'Elia G.	Center for kognitiv psykoterapi i Linkoping. gidelia@telia.com	[Chronic fatigue syndrome in a cognitive perspective. A therapeutic model] [Article in Swedish]	Lakartidningen. 2004 Jan 29;101(5):358-64.	The cognitive approach to the treatment of chronic fatigue syndrome (CSF) is based on a multifactor etiological hypothesis, i.e. inaccurate beliefs and attitudes to the illness interact with pathophysiological processes, ineffective coping behaviours, negative states of mood, social problem, to perpetuate the illness. Patients suffering from CFS are supposed to be hypervigilant to somatic sensations and to interpret them as signs of impending physical catastrophe. The aim of the this paper is to describe the clinical implementation of principles of cognitive therapy in the treatment of CFS. Basic to the treatment approach is a collaborative, listening and empathic attitude, sensitive to the patient's personal beliefs and potential threats to self-esteem. The aim is to develop more useful, functional, formulations of the illness. The patient and the therapist work together to look at how the patient thinks about herself/himself and the illness, detect unhelpful attitudes, thoughts and mental images about the illness, and to make them accessible to Socratic reasoning. Graded behavioural interventions are planned in order to disconfirm unhelpful beliefs and reverse the spiral of tiredness, demoralization and reduced activity. The treatment is structured according to the general principles of cognitive therapy.
Deluca J, Christodoulou C, Diamond BJ, Rosenstein ED, Kramer N, Natelson BH.	Department of Physical Medicine and Rehabilitation, University of Medicine and Dentistry of New Jersey, New Jersey Medical School, Newark, New Jersey, USA. Jdeluca@kmrrec.org	Working memory deficits in chronic fatigue syndrome: differentiating between speed and accuracy of information processing.	J Int Neuropsychol Soc. 2004 Jan;10(1):101-9.	To examine the relative influence of speed of information processing versus working memory ability, CFS participants with psychiatric comorbidity (CFS-Psych) and CFS without a psychiatric history (CFS-noPsych) were examined on tests of visual and auditory processing speed and visual and auditory working memory. Compared to healthy controls (HC) and a group of participants with rheumatoid arthritis (RA), the CFS-noPsych group displayed significantly reduced performance on tests of information processing speed, but not on tests of working memory. No significant differences were observed between the CFS-Psych group and any other group in the study. The implications of group heterogeneity on the understanding of cognitive impairment in CFS are discussed.
DiVasta AD, Alexander ME.	Division of Adolescent and Young Adult Medicine, Department of Cardiology, Children's Hospital Boston, Harvard	Fainting freshmen and sinking sophomores: cardiovascular issues of the adolescent.	Curr Opin Pediatr. 2004 Aug;16(4):350-6.	PURPOSE OF REVIEW: Syncope is a common symptom in adolescents. The vast majority of cases are the result of benign neurocardiogenic syncope, without associated risk of sudden death. This paper reviews the mainstays of diagnosis and treatment for syncopal episodes, differentiation of syncope from life-threatening arrhythmia and aborted sudden cardiac death, and the patient populations at highest risk for cardiac symptoms and cardiac disease. RECENT FINDINGS: A detailed history (including past medical history and family history that focus on cardiac disease) combined with dynamic physical examination and electrocardiogram identifies the vast majority of adolescents with significant heart disease. Further diagnostic modalities have limited utility. Reassurance and supportive measures

	Medical School, Boston, Massachusetts 02115, USA. amy.divasta@childrens.harvard.edu			remain the treatment of choice, although drug therapy can sometimes be helpful, even if data are limited. Divergent approaches to the screening of the young competitive athlete exist. Particular attention is required in adolescents and young adults with exercise-associated syncope, eating disorders, chronic fatigue syndrome, or history of congenital heart disease. Their symptoms may be either more serious or challenging to manage. SUMMARY: Syncope in the adolescent patient is very common; true cardiac disease is not. The traditional diagnostic screen of history and physical combined with an electrocardiogram will identify the overwhelming majority of patients with significant disease. Patients with abnormalities on this initial office evaluation, history of cardiac disease, or complicating medical illness may benefit from referral to a cardiologist. Even within this patient subset, many will prove to have benign disease.

Edmonds M, McGuire H, Price J.		Exercise therapy for chronic fatigue syndrome.	Cochrane Database Syst Rev. 2004;(3):CD003200.	BACKGROUND: Chronic fatigue syndrome (CFS) is an illness characterised by persistent medically unexplained fatigue. CFS is a serious health-care problem with a prevalence of up to 3%. Treatment strategies for CFS include psychological, physical and pharmacological interventions. OBJECTIVES: To investigate the relative effectiveness of exercise therapy and control treatments for CFS. SEARCH STRATEGY: CCDANCTR-Studies and CENTRAL were searched using "Chronic Fatigue" and Exercise. The Journal of Chronic Fatigue Syndrome and CFS conferences were handsearched. Experts in the field were contacted. Clinicaltrials.gov and controlled-trials.com were searched. SELECTION CRITERIA: Only Randomised Controlled Trials (RCT) including participants with a clinical diagnosis of CFS and of any age were included. DATA COLLECTION AND ANALYSIS: The full articles of studies identified were inspected by two reviewers (ME and HMG). Continuous measures of outcome were combined using standardised mean differences. An overall effect size was calculated for each outcome with 95% confidence intervals. One sensitivity analysis was undertaken to test the robustness of the results. MAIN RESULTS: Nine studies were identified for possible inclusion in this review, and five of those studies were included. At 12 weeks, those receiving exercise therapy were less fatigued than the control participants (SMD -0.77, 95% CIs -1.26 to -0.28). Physical functioning was significantly improved with exercise therapy group (SMD -0.64, CIs -0.96 to -0.33) but there were more dropouts with exercise therapy (RR 1.73, CIs 0.92 to 3.24). Depression was non-significantly improved in the exercise therapy group compared to the control group at 12 weeks (WMD -0.58, 95% CIs -2.08 to 0.92).Participants receiving exercise therapy were less fatigued than those receiving the antidepressant fluoxetine at 12 weeks (WMD -1.24, 95% CIs -5.31 to 2.83). Participants receiving the combination of the two interventions, exercise + fluoxetine, were less fatigued than those receiving exercise therapy alone at 12 weeks, although again the difference did not reach significance (WMD 3.74, 95% CIs -2.16 to 9.64).When exercise therapy was combined with patient education, those

				receiving the combination were less fatigued than those receiving exercise therapy alone at 12 weeks (WMD 0.70, 95% CIs -1.48 to 2.88). REVIEWERS' CONCLUSIONS: There is encouraging evidence that some patients may benefit from exercise therapy and no evidence that exercise therapy may worsen outcomes on average. However the treatment may be less acceptable to patients than other management approaches, such as rest or pacing. Patients with CFS who are similar to those in these trials should be offered exercise therapy, and their progress monitored Further high quality randomised studies are needed.

Engstrom JW.	Professor of Neurology, Department of Neurology, University of California, San Francisco, California 94143-0114, USA.	Myasthenia gravis: diagnostic mimics.	Semin Neurol. 2004 Jun;24(2):141-7.	The clinical hallmark of myasthenia gravis (MG) is fluctuating, painless weakness of muscles that most often affect extraocular, lower bulbar, or limb musculature. Predicting the probability of successful treatment for the patient assumes that the physician has made an accurate diagnosis. In this review, the practical differential diagnosis of MG is reviewed from the perspective of conditions (at presentation of symptoms and signs) that may mimic the disorder. The differential diagnosis includes disorders that limit eye movements (with or without associated diplopia), cause false-positive laboratory studies, and mimic MG but have normal eye movements. The differential diagnosis includes disorders that affect the upper brainstem, cranial nerves, neuromuscular junction, muscles, or local orbit anatomy. Nonneurological systemic diseases (i.e., encephalopathy, sepsis) can produce fluctuating ptosis or eye movements that can occasionally be confused with MG. Although MG is considered often in the differential diagnosis of weakness or fatigue symptoms that lack a correlate on neurological examination (subjective fatigue, breakaway weakness, chronic fatigue syndrome), MG is almost never found. Eriksen HR, Ursin H.	Department of Biological and Medical Psychology, University of Bergen, Jonas Lies vei 91, N-5009 Bergen, Norway.	Subjective health complaints, sensitization, and sustained cognitive activation (stress).	J Psychosom Res. 2004 Apr;56(4):445-8.	INTRODUCTION: This review argues that "subjective health complaints" is a better and neutral term for "unexplained medical symptoms." The most common complaints are musculoskeletal pain, gastrointestinal complaints and "pseudoneurology" (tiredness, sleep problems, fatigue, and mood changes). These complaints are common in the general population, but for some these complaints reach a level that requires care and assistance. THEORETICAL ASSUMPTIONS: We suggest that these complaints are based on sensations from what in most people are normal physiological processes. In some individuals these sensations become intolerable. In some cases it may signal somatic disease, in most cases not. Cases without somatic disease, or with minimal somatic findings, occur under diagnoses like burnout, epidemic fatigue, multiple chemical sensitivity, chronic musculoskeletal pain, chronic low back pain, chronic fatigue syndrome, and fibromyalgia. These complaints are particularly common in individuals with low coping and high levels of helplessness and hopelessness. CONCLUSION: The psychobiological mechanisms for this is suggested to be sensitization in neural loops maintained by sustained attention and arousal.

Famularo G, DE Simone C, Trinchieri V, Mosca	Department of Internal Medicine, San Camillo Hospital, Circonvallazione Gianicolense, 00152 Rome, Italy. gfamularo@scamilloforlanini.rm.it.	Carnitines and its congeners: a metabolic pathway to the regulation of immune response and inflammation. .	Ann N Y Acad Sci. 2004 Nov;1033:132-8.	Carnitine and its congeners may regulate the immune networks, and their influence on functions of immune cells predominantly or exclusively relies on carnitine-dependent energy production from fatty acids. A reduced pool of carnitines has been demonstrated in either serum or tissues, or both, from patients with a wide spectrum of disorders characterized by unregulated or impaired immune responses ranging from sepsis syndrome to systemic sclerosis, infection with human immunodeficiency virus, and chronic fatigue syndrome. Furthermore, experimental studies have consistently reported that the deranged immune responses and the less efficient inflammation towards infectious organisms associated with aging may be enhanced or modulated by treatment with carnitines. There is also evidence that carnitine deprivation could adversely affect the course of the sepsis syndrome, at least in experimental models, and preliminary studies suggest that carnitine deficiency is ultimately implicated in the pathophysiology of endotoxin-mediated multiple organ failure. Several data indicate that carnitine deficiency is a contributing factor to the progression of infection with human immunodeficiency virus, and carnitine therapy in those patients could counteract the unregulated process of lymphocyte apoptosis and improve CD4 counts. Some case reports have suggested the use of carnitine for the treatment of the severe lactic acidosis that complicates in some patients the use of reverse transcriptase inhibitors.
Farmer A, Fowler T, Scourfield J, Thapar A.	MRC Social, Genetic, Developmental Psychiatric Research Centre, Institute of Psychiatry, London, UK. spjuaef@iop.kcl.ac.uk.	Prevalence of chronic disabling fatigue in children and adolescents.	Br J Psychiatry. 2004 Jun;184:477-81.	BACKGROUND: The epidemiology of chronic fatiguing illnesses in young people is poorly understood. AIMS: To estimate the lifetime prevalence of different definitions of chronic fatigue in 8- to 17-year-olds. METHOD: Participants came from two population-based twin series. Parents completed self-report questionnaires that inquired whether either child had ever experienced more than a few days of disabling fatigue. Telephone interviews were undertaken for individuals who had experienced such an episode. RESULTS: Questionnaires were returned by 1468 families (65% response rate) and telephone interviews were undertaken regarding 99 of the 129 subjects (77%) who had experienced fatigue. The lifetime prevalence estimates ranged from 2.34% (95% CI 1.75-2.94) for disabling fatigue lasting 3 months to 1.29% (95% CI 0.87-1.71) for a disorder resembling adult operationally defined chronic fatigue syndrome. CONCLUSIONS: From the age of 11 years, young people have similar rates and types of chronic fatiguing illnesses to adults.
Farney RJ, Lugo A, Jensen RL, Walker JM, Cloward TV.	Intermountain Sleep Disorders Center, LDS Hospital, Salt Lake City, UT 84143, USA. rjfmd@msn.com	Simultaneous use of antidepressant and antihypertensive medications increases likelihood of diagnosis of obstructive sleep apnea syndrome.	Chest. 2004 Apr;125(4):1279-85.	BACKGROUND: Essential hypertension and symptoms of depression such as unexplained fatigue and tiredness are frequently encountered in primary medical care clinics. Although, exhaustive evaluation rarely detects unsuspected underlying disorders, obstructive sleep apnea (OSA) is commonly associated with each of these conditions. We tested the hypothesis that therapy with antihypertensive and antidepressant medications predicts the increased likelihood of OSA. METHODS: We analyzed the computer archive of 212,972 patients for prescriptions for antihypertensive medications, antidepressant medications, and International Classification of Diseases, Ninth Revision codes for OSA. Prevalence, prevalence odds ratio (POR), and confidence intervals (CIs) were calculated correcting for gender and age group. RESULTS: The prevalence rates of OSA were 0.8%, 2.8%, and 3.2% for men and 0.4%, 1.4%, and 1.8% for women aged 20 to 39 years, 40 to 59 years, and >or= 60 years, respectively. Compared to groups of corresponding age and gender who had not received prescriptions for either hypertension or depression, the highest PORs were found in patients receiving medications from both categories: 18.30 (95% CI, 10.69 to 25.66), 5.72 (95% CI, 4.10 to 6.70), and 4.47

				(95% CI, 2.45 to 7.01) for men, and 17.43 (95% CI, 9.54 to 28.67), 7.29 (95% CI, 5.20 to 9.29), and 2.72 (95% CI, 1.48 to 4.73) for women. CONCLUSIONS: We found that the likelihood of having a diagnosis of OSA increases when either antihypertensive or antidepressant medications have been prescribed. The probability is highest in the young and middle-age groups receiving prescriptions for both medications. The possibility of OSA should be considered in any patient with hypertension and depression or unexplained fatigue who is receiving antihypertensive and antidepressant medications.
Gaab J, Engert V, Heitz V, Schad T, Schurmeyer TH, Ehlert U.	Center for Psychobiological and Psychosomatic Research, University of Trier, Germany.	Associations between neuroendocrine responses to the Insulin Tolerance Test and patient characteristics in chronic fatigue syndrome.	J Psychosom Res. 2004 Apr;56(4):419-24.	OBJECTIVE: Subtle dysregulations of the hypothalamic-pituitary-adrenal (HPA) axis have been proposed as an underlying pathophysiological mechanism in chronic fatigue syndrome (CFS). This study attempted to assess the relationship between patient characteristics and HPA axis functioning using a neuroendocrine challenge test. METHOD: A test battery designed to assess different dimensions of CFS was given to 18 CFS patients and 17 controls. To evaluate the integrity of the HPA axis, the Insulin Tolerance Test (ITT), a centrally acting neuroendocrine challenge test, was performed on patients and controls. ACTH, salivary free cortisol and total plasma cortisol levels were assessed as a measure of the HPA axis stress response. Correlations of patient characteristics were calculated with integrated responses for all endocrine parameters. RESULTS: CFS patients had a significantly reduced area under the ACTH response curve (AUC) in the ITT. The AUC was significantly associated with the duration of CFS symptoms (r=-.592, P=.005) and the severity of fatigue symptomatology (r=-.41, P=.045). In addition, duration of CFS was correlated with the severity of fatigue symptoms (r=.38, P=.045). Similar associations were not observed for cortisol parameters. CONCLUSION: It has been postulated that neuroendocrine dysregulations observed in CFS are of an acquired nature. The results of a strong association between the integrated ACTH response and the duration of CFS emphasizes the need to consider factors known to be risk factors for the chronicity of CFS symptoms, such as profound inactivity, deconditioning and sleep abnormalities, as possible candidates for secondary causes of neuroendocrine dysregulations in CFS.
Gallagher AM, Thomas JM, Hamilton WT, White PD.	Centre for Psychiatry and Department of Information Services, Queen Mary School of Medicine and Dentistry, St Bartholomew's Hospital, London EC1A 7BE.	Incidence of fatigue symptoms and diagnoses presenting in UK primary care from 1990 to 2001.	J R Soc Med. 2004 Dec;97(12):571-5.	Little is known about whether the incidence of symptoms of fatigue presented in primary care, and the consequent diagnoses made, change over time. The UK General Practice Research Database was used to investigate the annual incidence of both fatigue symptoms and diagnoses recorded in UK primary care from 1990 to 2001. The overall incidence of all fatigue diagnoses decreased from 87 per 100 000 patients in 1990 to 49 in 2001, a reduction of 44%, while postviral fatigue syndromes decreased from 81% of all fatigue diagnoses in 1990 to 60% in 2001. Chronic fatigue syndrome (CFS) and myalgic encephalomyelitis (ME) together increased from 9% to 26% of all fatigue diagnoses. The incidence of fibromyalgia increased from less than 1 per 100 000 to 35 per 100 000. In contrast, there was no consistent change in the incidence of all recorded symptoms of fatigue, with an average of 1503 per 100 000, equivalent to 1.5% per year. CFS/ME and fibromyalgia were rarely diagnosed in children and were uncommon in the elderly. All symptoms and diagnoses were more common in females than in males. The overall incidence of fatigue diagnoses in general has fallen, but the incidence rates of the specific diagnoses of CFS/ME and fibromyalgia have risen, against a background of little change in symptom reporting. This is likely to reflect fashions in diagnostic labelling rather than true changes in incidence.
Garralda ME,	Academic Unit of	Impairment and	J Child Psychol	BACKGROUND: Functional impairment is a key feature of chronic fatigue syndrome (CFS) of childhood.

Rangel L.	Child and Adolescent Psychiatry, Imperial College, Faculty of Medicine, London, UK. e.garralda@imperial.ac.uk	coping in children and adolescents with chronic fatigue syndrome: a comparative study with other paediatric disorders.	Psychiatry. 2004 Mar;45(3):543-52.	AIM: To compare impairment, illness attitudes and coping mechanisms in childhood CFS and in other paediatric disorders. METHOD: Participants were 28 children and adolescents with CFS, 30 with juvenile idiopathic arthritis (JIA) and 27 with emotional disorders (ED). The measures used were interviews with children and parents, with detailed enquiry on impairment, including the Functional Disability Inventory (FDI), Illness Attitudes Scales (IAS), and Kidcope to measure coping styles in relation to common problems, illness and disability. RESULTS: Children with CFS reported significantly more illness impairment, especially in school attendance, than those with JIA and ED. They had higher 'worry about illness' scores on the IAS. On the Kidcope they named school issues (work, expectations, attendance) as illness- or disability-related problems more than the other two groups. Fewer CFS participants reported using problem solving as a strategy to cope with illness and disability than with other problems in their lives. More in the CFS than in the JIA group used emotional regulation to cope with illness and disability. Fewer in the CFS than in the ED groups used social withdrawal to cope with illness and self-criticism for disability, but more used resignation to cope with disability. CONCLUSION: Severe illness-related impairment, particularly through school non-attendance, and high levels of illness-related school concerns appear specific to CFS. CFS may also have characteristically high levels of generalised illness worry and particular styles of coping with illness and disability.
Gill AC, Dosen A, Ziegler JB.	Department of General Pediatrics, Sydney Children's Hospital, Sydney, Australia.	Chronic fatigue syndrome in adolescents: a follow-up study. Comment in: Arch Pediatr Adolesc Med. 2004 Mar;158(3):207-8.	Arch Pediatr Adolesc Med. 2004 Mar;158(3):225-9.	OBJECTIVES: To compare the frequency of persistent symptoms up to 8 years after illness onset in adolescents diagnosed as having chronic fatigue syndrome, idiopathic chronic fatigue, and unexplained fatigue for less than 6 months, and to determine if hospital admission is associated with outcome. DESIGN: A cohort study using questionnaire follow-up. SETTING: A tertiary referral hospital. PATIENTS: Consecutive adolescents referred for assessment of persistent fatigue were identified and retrospectively divided into 3 groups according to the diagnostic criteria for chronic fatigue syndrome and idiopathic chronic fatigue. INTERVENTION: A questionnaire was designed and administered by telephone at a mean of 4.57 years after the initial examination. MAIN OUTCOME MEASURE: The persistence of self-reported symptoms was compared with respect to patient group and admission. RESULTS: Outcome data were obtained for 34 (69%) of the 49 eligible subjects. Twenty-five percent of the chronic fatigue syndrome group showed near to complete improvement, 31% showed partial improvement, and 44% showed no improvement. The idiopathic chronic fatigue group had near to complete recovery in 50%, partial in 10%, and no improvement in 40%. Those with unexplained fatigue for less than 6 months had all recovered. There was no difference between the outcome of the subjects admitted to the hospital and those managed as outpatients. CONCLUSIONS: Adolescents with less than 6 months of fatigue have a good outcome. Unexplained fatigue lasting more than 6 months has a similar outcome regardless of the presence of minor criteria for chronic fatigue syndrome.
Glass JM, Lyden AK, Petzke F, Stein P, Whalen G, Ambrose K, Chrousos G, Clauw DJ.	Department of Psychiatry and Institute for Social Research, University of Michigan, Ann Arbor, MI, USA.	The effect of brief exercise cessation on pain, fatigue, and mood symptom development in healthy, fit	J Psychosom Res. 2004 Oct;57(4):391-8.	OBJECTIVE: Abnormalities of the biological stress response (hypothalamic-pituitary-adrenal axis and the autonomic nervous system) have been identified in both fibromyalgia (FM) and chronic fatigue syndrome (CFS). Although these changes have been considered to be partly responsible for symptom expression, we examine an alternative hypothesis that these HPA and autonomic changes can be found in subsets of healthy individuals in the general population who may be at risk of developing these conditions. Exposure to "stressors" (e.g., infections, trauma, etc.) may lead to symptom expression (pain, fatigue, and other somatic symptoms) in part by precipitating lifestyle changes. In

	jglass@umich.edu	individuals.		particular, we focus on the effect of deprivation of routine aerobic exercise on the development of somatic symptoms. METHODS: Eighteen regularly exercising (>/=4 h/week) asymptomatic, healthy adults refrained from physical activity for 1 week. We predicted that a subset of these individuals would develop symptoms of FM/CFS with exercise deprivation, and this manuscript focuses on the baseline HPA axis, immune, and autonomic function measures that may predict the development of symptoms. RESULTS: Eight of the subjects reported a 10% increase in one or more symptoms (pain, fatigue, mood) after 1 week of exercise deprivation. These symptomatic subjects had lower HPA axis (baseline cortisol prior to VO2max testing), immune (NK cell responsiveness to venipuncture), and autonomic function (measured by heart rate variability) at baseline (prior to cessation of exercise) when compared to the subjects who did not develop symptoms. CONCLUSIONS: A subset of subjects developed symptoms of pain, fatigue, or mood changes after exercise deprivation. This cohort was different from the individuals who did not develop symptoms in baseline measures of HPA axis, immune, and autonomic function. We speculate that a subset of healthy individuals who have hypoactive function of the biological stress response systems unknowingly exercise regularly to augment the function of these systems and thus suppress symptoms. These individuals may be at risk for developing chronic multisymptom illnesses (CMIs) (e.g., FM or CFS among others) when a "stressor" leads to lifestyle changes that disrupt regular exercise.

Gur A, Cevik R, Nas K, Colpan L, Sarac S.	Department of Physical Medicine and Rehabilitation, School of Medicine, Dicle University, Diyarbakir, Turkey. alig@dicle.edu.tr	Cortisol and hypothalamic-pituitary-gonadal axis hormones in follicular-phase women with fibromyalgia and chronic fatigue syndrome and effect of depressive symptoms on these hormones.	Arthritis Res Ther. 2004;6(3):R232-8. Epub 2004 Mar 15.	We investigated abnormalities of the hypothalamic-pituitary-gonadal axis and cortisol concentrations in women with fibromyalgia and chronic fatigue syndrome (CFS) who were in the follicular phase of their menstrual cycle, and whether their scores for depressive symptoms were related to levels of these hormones. A total of 176 subjects participated - 46 healthy volunteers, 68 patients with fibromyalgia, and 62 patients with CFS. We examined concentrations of follicle-stimulating hormone, luteinizing hormone (LH), estradiol, progesterone, prolactin, and cortisol. Depressive symptoms were assessed using the Beck Depression Inventory (BDI). Cortisol levels were significantly lower in patients with fibromyalgia or CFS than in healthy controls ($P < 0.05$); there were no significant differences in other hormone levels between the three groups.Fibromyalgia patients with high BDI scores had significantly lower cortisol levels than controls ($P < 0.05$), and so did CFS patients, regardless of their BDI scores ($P < 0.05$). Among patients without depressive symptoms, cortisol levels were lower in CFS than in fibromyalgia ($P < 0.05$). Our study suggests that in spite of low morning cortisol concentrations, the only abnormalities in hypothalamic-pituitary-gonadal axis hormones among follicular-phase women with fibromyalgia or CFS are those of LH levels in fibromyalgia patients with a low BDI score. Depression may lower cortisol and LH levels, or, alternatively, low morning cortisol may be a biological factor that contributes to depressive symptoms in fibromyalgia. These parameters therefore must be taken into account in future investigations.

Hamlen R.	rhamlen@iximd.com	Lyme borreliosis: perspective of a scientist-patient.	Lancet Infect Dis. 2004 Oct;4(10):603-4. Comment on: Lancet Infect Dis. 2003 Aug;3(8):489-500.	
Hartz AJ, Bentler S, Noyes R, Hoehns J, Logemann C, Sinift S, Butani Y, Wang W, Brake K, Ernst M, Kautzman H. .	University of Iowa, College of Medicine, Department of Family Medicine, Iowa City 52242-1097, USA	Randomized controlled trial of Siberian ginseng for chronic fatigue.	Psychol Med. 2004 Jan;34(1):51-61.	BACKGROUND: Chronic fatigue greatly affects quality of life and is a common reason for consulting a physician. Since conventional therapy is often of limited help, fatigued patients may use herbal treatments. This randomized controlled trial evaluated the effectiveness of Siberian ginseng. METHOD: Subjects were recruited from advertisements in Iowa (82%) and members of chronic fatigue syndrome support groups (18%). Potential subjects were required to have substantial fatigue > or = 6 months with no identifiable cause. The mean change in a fatigue measure was compared for placebo and Siberian ginseng at 1 and 2 months. Comparisons were for all subjects and for subjects with characteristics previously identified in the literature as important for categorizing chronic fatigue. RESULTS: Ninety-six subjects were randomized to treatment groups, and 76 provided information at 2 months of follow-up. Fatigue among subjects assigned to either placebo or Siberian ginseng was substantially reduced during the study, but differences between treatment groups were not statistically significant in the full sample. Fatigue severity and duration had a statistically significant interaction with response to Siberian ginseng at the P < 0.05 level. Treatment was effective at 2 months for 45 subjects with less severe fatigue (P = 0.04 unadjusted for multiple comparisons) and for 41 subjects with fatigue for > or = 5 years (P = 0.09 unadjusted for multiple comparisons). CONCLUSION: Overall efficacy was not demonstrated. However, the findings of possible efficacy for patients with moderate fatigue suggests that further research may be of value.
Hausotter W.		[Appraisal of Lyme borreliosis][Article in German]	Versicherungsmedizin. 2004 Mar 1;56(1):25-9.	Lyme borreliosis is due to infection with a tick-borne spirochete. The variety of signs and symptoms and also the laboratory tests of this multisystem illness often cause great problems in the appraisal of this disease. Frequently indispositions are associated with positive antibody tests for Borrelia burgdorferi. Terms as fibromyalgia or chronic fatigue syndrome are often connected with the diagnosis of Lyme disease. Outdoor workers such as farmers, foresters, hunters, woodcutters and gamekeepers in areas of endemic disease take a great occupational risk of infection with borreliosis. In the German health and social insurance the appraisal of this disease is of great importance. Affected working people can receive financial compensation. Not only serological investigations with the presence of specific antibodies, but also clinical findings must be considered.
Heim C, Bierl C, Nisenbaum R, Wagner D, Reeves WC.	Division of Viral and Rickettsial Diseases, Viral Exanthems and Herpesvirus Branch, National Center for	Regional prevalence of fatiguing illnesses in the United States before and after the terrorist attacks of	Psychosom Med. 2004 Sep-Oct;66(5):672-8.	OBJECTIVE: Stress or emotional traumas are considered risk factors for unexplained fatiguing illnesses. From July to December 2001, the Centers for Disease Control and Prevention conducted a multigeographical pilot study to test the feasibility of a survey to estimate the prevalence of fatiguing illnesses in the United States. We used data obtained during this survey to estimate the effect of the coincidentally occurring terrorist attacks of September 11, 2001, on the regional prevalence of fatiguing illnesses. METHODS: Identified by random-digit dialing, 2,728 households in eight regional strata were interviewed, and 7,317 respondents were screened for severe fatigue of at least 1 month

	Infectious Diseases, Centers for Disease Control and Prevention, Atlanta, Georgia, USA. cmheim@emory.edu	September 11, 2001.		duration. Identified fatigued people of age 18 to 69 years (N = 440) and a sample of nonfatigued people of the same age range (N = 444) were interviewed in detail concerning fatigue, other symptoms, and medical and psychiatric histories. RESULTS: Weighted prevalence estimates based on interviews performed after the attacks were significantly lower compared with estimates based on interviews performed before the attacks (prolonged fatigue: 5,450 vs. 1,530/100,000, p =.010; chronic fatigue: 18,510 vs. 10,070/100,000, p =.002; chronic fatigue syndrome-like illness: 2,510 vs. 960/100,000, p =.014).CONCLUSION: Our findings suggest decreased regional prevalence of fatiguing illnesses in the aftermath of the terrorist attacks. The causes of this effect are unknown but might involve acute psychological and physiological adaptations that modify the perception or manifestation of fatigue. Future studies should be specifically designed to scrutinize the relationship between stress and fatiguing illnesses and the mediating mechanisms of such a relationship.
Henderson M, Tannock C.	Academic Department of Psychological Medicine, GKT School of Medicine and Institute of Psychiatry, Guys Kings and St. Thomas' Hospital, Weston Education Centre, Cutcombe Road, London SE5 9RJ, UK. m.henderson@iop.kcl.ac.uk	Objective assessment of personality disorder in chronic fatigue syndrome.	J Psychosom Res. 2004 Feb;56(2):251-4.	OBJECTIVES: This study aims to objectively assess the prevalence and nature of personality disorders in depressed and nondepressed chronic fatigue syndrome (CFS) patients and compare this to depressed and healthy control groups. METHODS: Sixty-one patients attending a tertiary referral clinic with chronic fatigue syndrome, 40 psychiatric inpatients with depressive disorder and 45 healthy medical students completed the Structured Clinical Interview for DSM-III-R Diagnoses (SCID-II) in addition to providing routine clinical and demographic information. RESULTS: Thirty-nine percent of the CFS group, 73% of the depressed group and 4% of the healthy group were diagnosed with personality disorders. Cluster C disorders were the most common in both the CFS and depressed group. The depressed CFS patients had more Cluster B personality disorders than nondepressed CFS patients. Overall for CFS patients there was no association between mood state and personality disorder. CONCLUSIONS: High levels of personality disorder are found on objective assessment of CFS patients attending a teaching hospital clinic. This cannot be accounted for by comorbid depression.
Horton-Salway M.	Department of Social Sciences, Open University, UK. mkhs2@tutor.open.ac.uk	The local production of knowledge: disease labels, identities and category entitlements in ME support group talk.	Health (London). 2004 Jul;8(3):351-71.	This article uses discursive psychology to analyse how knowledge claims and entitlements are locally produced in an ME support group meeting and a research interview. The article demonstrates how 'expertise' and 'experience' associated with lay and professional membership are locally constituted in the activity of reasoning, arguing and claims making. The analysis shows how expertise and experiential claims are constructed, disclaimed, warranted and undermined in relationship to membership categorization and entitlements to knowledge that are co-constructed in the process of a discussion about disease labels and the nature of the illness as physical or psychological. In a discussion about the definition of contested disease categories, what is 'at stake' for the group members is the entitlement to speak from experience as members who can 'know' their own minds.
Huibers MJ, Bleijenberg G, van Amelsvoort LG, Beurskens AJ, van Schayck CP,	Department of Epidemiology, Maastricht University, P.O. Box 616,	Predictors of outcome in fatigued employees on sick leave Results from	J Psychosom Res. 2004 Nov;57(5):443-449.	OBJECTIVE: The main objective of this study was to identify predictors of fatigue caseness, work resumption and chronic fatigue syndrome (CFS)-like caseness in a sample of fatigued employees on sick leave. METHODS: For 12 months, 151 fatigued employees on sick leave, 44% of whom met research criteria for CFS at baseline, were followed. Measures included fatigue, health aspects, psychological problems, burnout, causal attributions and self-efficacy. Logistic regression analysis was

Bazelmans E, Knottnerus JA.	Maastricht 6200 MD, The Netherlands; Department of Medical Psychology, UMC Nijmegen, The Netherlands; Department of General Practice, Maastricht University, P.O. Box 616, Maastricht 6200 MD, The Netherlands.	a randomised trial.		used to determine associations between predictor variables at baseline and outcome at follow-up. RESULTS: After 12 months, 43% of the patients were no longer fatigue cases, and 62% had resumed work. Recovery from fatigue caseness was predicted by stronger psychological attributions and other perception-related factors, whereas work resumption was predicted by lower age, male sex, CFS-like caseness and less cognitive difficulties. Lower physical functioning scores were predictive of (the development of) CFS-like caseness. CONCLUSION: Recovering from persistent fatigue and work resumption seem to result from different underlying processes and do not necessarily fall together. As many factors associated with outcome in fatigue reflect illness perception, the prevention of persistent fatigue and CFS may partly be achieved by the modification of perception.
Huibers MJ, Beurskens AJ, Van Schayck CP, Bazelmans E, Metsemakers JF, Knottnerus JA, Bleijenberg G.	Department of Epidemiology, Maastricht University, The Netherlands. m.huibers@dmkep.unimaas.nl	Efficacy of cognitive-behavioural therapy by general practitioners for unexplained fatigue among employees: Randomised controlled trial.	Br J Psychiatry. 2004 Mar;184:240-6.	BACKGROUND: Fatigue is a common complaint that may lead to long-term sick leave and work disability. AIMS: To assess the efficacy of cognitive-behavioural therapy by general practitioners for unexplained, persistent fatigue among employees. METHOD: A randomised controlled trial, using a pre-randomisation design in primary care, investigated 151 employees on sick leave with fatigue. Participants in the experimental group were offered five to seven 30 min sessions of cognitive-behavioural therapy by a general practitioner; those in the control group were offered no treatment. Main outcome measures (fatigue severity, self-reported absenteeism, registered absenteeism and clinical recovery) were assessed at 4 months, 8 months and 12 months. RESULTS: At baseline, 44% of the patients already met research criteria for chronic fatigue syndrome. There was no significant difference between the experimental group and the control group on primary or secondary outcomes at any point. CONCLUSIONS: Cognitive-behavioural therapy by general practitioners for unexplained, persistent fatigue did not prove to be an effective intervention. Since these doctors were unable to deliver this therapy effectively under ideal circumstances, it is unlikely that doctors in routine practice would be more successful in doing so.
Huibers MJ, Kant IJ, Knottnerus JA, Bleijenberg G, Swaen GM, Kasl SV.	Department of Epidemiology, Maastricht University, PO Box 616, 6200 MD Maastricht, Netherlands. m.huibers@dmkep.unimaas.nl	Development of the chronic fatigue syndrome in severely fatigued employees: predictors of outcome in the Maastricht cohort study.	J Epidemiol Community Health. 2004 Oct;58(10):877-82.	STUDY OBJECTIVE: To identify risk factors of the development of the chronic fatigue syndrome (CFS), the persistence or recurrence of fatigue, or recovery from fatigue in a large sample of fatigued employees. DESIGN: Analyses were based on the Maastricht cohort study (MCS), a prospective population based cohort study among more than 12 000 employees. Multiple regression models were used to identify predictors of CFS-like caseness (meeting research criteria for CFS), non-CFS fatigue caseness, or no fatigue caseness. SETTING: The working population in the Netherlands. PARTICIPANTS: 1143 employees with medically unexplained fatigue were followed up prospectively for 44 months. MAIN RESULTS: At 44 month follow up, 8% of the employees were CFS-like cases (none of who reported to have received a CFS diagnosis), 40% were non-CFS fatigue cases, and 52% were no longer fatigue cases. Factors that predicted CFS-like caseness compared with non-CFS fatigue caseness were

				high age, exhaustion, female sex, low education, and visits to the general practitioner. Factors that predicted CFS-like caseness compared with no fatigue caseness were fatigue, exhaustion, low education, visits to the GP and occupational physician, and bad self rated health. Factors that predicted non-CFS fatigue caseness compared with no fatigue caseness were fatigue, low self perceived activity, exhaustion, anxious mood, and bad self rated health. CONCLUSIONS: Unexplained fatigue among employees in some instances is a precursor of the development of CFS. The prognostic role of self rated health suggests that prevention and treatment of chronic fatigue should be aimed at changing the perception of health or illness. Less clear is the role of health care seeking or receiving a CFS diagnosis.
Huibers MJ, Kant IJ, Swaen GM, Kasl SV.	Department of Medical, Clinical & Experimental Psychology, Maastricht University, Netherlands. marcus.huibers@hag.unimaas.nl	Prevalence of chronic fatigue syndrome-like caseness in the working population: results from the Maastricht cohort study.	Occup Environ Med. 2004 May;61(5):464-6.	AIM: To determine the prevalence of chronic fatigue syndrome (CFS)-like caseness in the working population. METHODS: Using data from the prospective Maastricht Cohort Study on Fatigue at Work, the prevalence and incidence of CFS-like cases (employees meeting research criteria for CFS) were determined among 5499 employees who responded to the follow up assessment 3 years and 8 months after baseline. RESULTS: Of the 5499 employees, 199 (3.6%) were identified as CFS-like cases. By deleting possible CFS-like cases at baseline, the annual incidence of CFS-like caseness was estimated to be 85 per 10 000. Twenty employees (0.36%) reported having been diagnosed with CFS by a physician. CONCLUSIONS: The prevalence of CFS-like cases (3.6%) was considerably higher than the prevalence of CFS reported in previous studies (0.006-3%). These findings suggest that the CFS-like caseness may be underdetected in the working population and perhaps in other populations as well.
Jason LA, Torres-Harding SR, Jurgens A, Helgerson J.		Comparing the Fukuda et al. Criteria and the Canadian Case Definition for Chronic Fatigue Syndrome	Journal of Chronic Fatigue Syndrome 2004; 12(1):37–52.	Fibromyalgia syndrome (FMS) is characterized by widespread pain, fatigue, sleep abnormalities, and distress. Because FMS lacks consistent evidence for tissue abnormalities, recent investigations have focused on central nervous system mechanisms of pain. Abnormal temporal summation of second pain (AWindup@) and central sensitization (CS) have recently been described in FMS patients. Windup (WU) and central sensitization, which rely on central pain mechanisms, occur after prolonged C-nociceptor input and depend on activation of nociceptor specific neurons as well as wide dynamic range neurons in the dorsal horn of the spinal cord. The important role of WU is also supported by its ability to predict the clinical pain intensity of FMS patients. Furthermore, brain-imaging techniques that can detect neuronal activation following nociceptive stimuli have provided additional evidence for abnormal central pain mechanisms in FMS. Most importantly, brain images have corroborated the augmented reported pain experience of FMS patients during experimental pain stimuli. These findings may have important implications for future research as well as the treatment of FMS pain.
Jason LA PhD, Susan R. Torres-Harding PHD, Amber Jurgens BA, Jean Helgerson BA		Article: Comparing the Fukuda et al. Criteria and the Canadian Case Definition for Chronic Fatigue Syndrome	Journal of Chronic Fatigue Syndrome 2004 12 (1): 37- 52	Because the pathogenesis of Chronic Fatigue Syndrome (CFS) has yet to be determined, case definitions have relied on clinical observation in classifying signs and symptoms for diagnosis. The selection of diagnostic signs and symptoms has major implications for which individuals are diagnosed with CFS and how seriously the illness is viewed by health care providers, disability insurers and rehabilitation planners, and patients and their families and friends. Diagnostic criteria also have implications for whether research based on varying definitions can be synthesized. The current investigation examined differences between CFS as defined by Fukuda et al. (1994) and a set of criteria that has been proposed for a clinical Canadian Case definition. There were twentythree participants who met the Canadian criteria, 12 in the CFS (Fukuda et al. (7) criteria) group and the 33

				from the chronic fatigue (CF)-psychiatric group. Dependent measures included: work status, psychiatric comorbidity, symptoms, and functional impairment (measured by the Medical Outcomes Study). People meeting the Fukuda et al. and Canadian criteria were compared with people who had a chronically fatiguing illness explained by a psychiatric condition. Statistical tests used included binomial logistic regression and analysis of variance. The Canadian criteria group, in contrast to the Fukuda et al. criteria group, had more variables that statistically significantly differentiated them from the psychiatric comparison group. Overall, there were 17 symptom differences between the Canadian and CF-psychiatric group, but only 7 symptom differences between the CFS and CF-psychiatric group. The findings suggest that both the Canadian and Fukuda et al. case definitions select individuals who are statistically significantly different from psychiatric controls with chronic fatigue, with the Canadian criteria selecting cases with less psychiatric co-morbidity, more physical functional impairment, and more fatigue/weakness, neuropsychiatric, and neurological symptoms.

Jones JF, Nisenbaum R, Solomon L, Reyes M, Reeves WC.	National Jewish Medical and Research Center, Denver, Colorado, USA.	Chronic fatigue syndrome and other fatiguing illnesses in adolescents: a population-based study.	J Adolesc Health. 2004 Jul;35(1):34-40.	PURPOSE: To estimate the prevalence of chronic fatigue syndrome (CFS) and describe characteristics of other fatiguing illnesses in adolescents (aged 12 through 17 years). METHODS: We conducted a random digit dialing survey of the residents of Wichita, Kansas. Adults identified fatigued adolescents in the household and answered questions relating to the child's health. Selected adolescents were invited to attend a clinic with a parent/guardian. After clinical evaluation they were classified as CFS or another fatigue state as defined in the 1994 CFS definition. Annual telephone interviews and clinical evaluations monitored subjects' fatigue status. Data were analyzed using the Kruskal-Wallis test, the Mantel-Haenszel test, and the exact McNemar test. RESULTS: The survey contacted 34,018 households with 90,316 residents. Of 8586 adolescents, 138 had fatigue for > or =1 month and most (107 or 78%) had chronic fatigue (> or =6 months) at some point during the 3-year follow-up. Twenty-eight had exclusionary diagnoses. Thirty-one were considered to have a CFS-like illness and were invited for clinical evaluation. Eleven agreed to participate and none met the CFS case definition. The baseline weighted prevalence of CFS-like illness was 338 per 100,000. Significant differences existed between parental and adolescents' descriptions of illness. CONCLUSIONS: The prevalence of CFS

				among adolescents was considerably lower than among adults. Evaluation of CFS in adolescents must consider both parent and patient perception of fatigue and other illnesses that might explain the symptom complex.
Kapfhammer HP, Rothenhausler HB.	Universitatsklinik fur Psychiatrie Auenbruggerplatz 31, A-8036 Graz/Osterreich. Hans-Peter.Kapfhammer @klinikum-graz.at	[Chronic fatigue syndrome] [Article in German]	MMW Fortschr Med. 2004 Jul 22;146(29-30):29, 31-3.	The symptoms of fatigue and exhaustion, which are central to chronic fatigue syndrome and neurasthenia, can lay claim to being"psychopathological entities" in their own right. Although ubiquitous, they by no means reflect a homogeneous clinical picture. Chronic fatigue may occur after physical illness, such as viral infections, or be associated with a range of different psychiatric disorders. There is wide overlap with affective, anxiety, somatoform, and personality disorders, and this should be borne in mind when it comes to classifying these symptoms.To investigate the etiopathogenesis, multifactorial models are required. For treatment, adapted cognitive-behavioral therapy, possibly accompanied by an antidepressant, is effective.
Kennedy G, Spence V, Underwood C, Belch JJ.	Vascular Diseases Research Unit, University Department of Medicine, Ninewells Hospital and Medical School, Dundee DD1 9SY, UK. g.kirk@dundee.ac.uk	Increased neutrophil apoptosis in chronic fatigue syndrome.	J Clin Pathol. 2004 Aug;57(8):891-3.	BACKGROUND/AIMS: Many patients with chronic fatigue syndrome (CFS) have symptoms that are consistent with an underlying viral or toxic illness. Because increased neutrophil apoptosis occurs in patients with infection, this study examined whether this phenomenon also occurs in patients with CFS. METHODS: Apoptosis was assessed in patients with CFS in conjunction with concentrations of the anti-inflammatory cytokine, transforming growth factor beta1 (TGFbeta1). RESULTS: The 47 patients with CFS had higher numbers of apoptotic neutrophils, lower numbers of viable neutrophils, increased annexin V binding, and increased expression of the death receptor, tumour necrosis factor receptor-I, on their neutrophils than did the 34 healthy controls. Patients with CFS also had raised concentrations of active TGFbeta1 ($p < 0.005$). CONCLUSIONS: These findings provide new evidence that patients with CFS have an underlying detectable abnormality in their immune cells.
Kennedy G, Abbot NC, Spence V, Underwood C, Belch JJ.	Vascular Diseases Research Unit, University Department of Medicine, Ninewells Hospital & Medical School, Dundee, UK. g.kirk@dundee.ac.uk	The specificity of the CDC-1994 criteria for chronic fatigue syndrome: comparison of health status in three groups of patients who fulfill the criteria.	Ann Epidemiol. 2004 Feb;14(2):95-100.	PURPOSE: The Centers for Disease Control (CDC)-1994 definition of chronic fatigue syndrome (CFS) is very broad, and there have been suggestions that it lacks specificity. To test this, we have compared three groups of patients, all of whom fulfill the criteria but self-report different etiologies. METHODS: Patients with self-reported symptoms which developed sporadically (sCFS, n=48); after Gulf War service (GW, n=24); and following exposure to organophosphate insecticides (OP, n=25) underwent a clinical examination, completed the MOS SF-36 quality of life and Hospital Anxiety and Depression scales, and were assessed for major and minor criteria for CDC-1994 CFS. RESULTS: Significant differences in simple clinical measures and outcome measures were observed between groups. The GW group had significantly more severe physical symptoms-fatigue, muscle and multi-joint pain-than OP or sCFS, and the sCFS group was significantly less impaired than the other two groups in terms of role emotional and mental health. In all three groups, a majority of patients exhibited muscle weakness in the lower limbs, and significant numbers of patients had absent or abnormal reflexes. CONCLUSIONS: Differences in simple, easily performed clinical outcome measurements can be observed between groups of patients, all of whom fulfill the CDC-1994 criteria for CFS. It is likely that their response to treatment may also vary. The specificity of the CFS case definition should be improved to define more homogeneous groups of patients for the purposes of treatment and research.

Vascular Diseases Research Unit, University Department of Medicine, Ninewells Hospital and Medical School, Dundee DD1 9SY, Scotland, U.K. f.khan@dundee.ac.uk	Peripheral cholinergic function in humans with chronic fatigue syndrome, Gulf War syndrome and with illness following organophosphate exposure.	Clin Sci (Lond). 2004 Feb;106(2):183-9.	In the present study, we have investigated whether the peripheral cholinergic abnormalities that we have reported previously [Spence, Khan and Belch (2000) Am. J. Med. 108, 736-739] in patients with chronic fatigue syndrome (CFS) are also present in those with Gulf War syndrome (GWS) and agricultural workers exposed to organophosphate pesticides, where cholinesterase inhibition is specifically implicated. We also looked at whether these abnormalities might be due to a reduction in the activity of cholinesterase expressed on the vascular endothelium. We used laser Doppler imaging to measure the forearm skin blood flow responses to iontophoresis of acetylcholine and of methacholine (which is resistant to breakdown by cholinesterase) in patients with CFS, GWS and those with a history of ill health after definite organophosphate exposure, as well as in matched healthy controls. The response to acetylcholine was significantly higher in patients with CFS than in controls (P =0.029, repeated-measures ANOVA), but was normal in those with GWS and those exposed to organophosphates. The methacholine response was higher than the acetylcholine response in all patient groups except for those with CFS, where there was no difference between the responses. Although there are many clinical similarities between these three illnesses, our results indicate peripheral cholinergic abnormalities in the vascular endothelium of only patients with CFS, suggesting that this syndrome has a different aetiology, which might involve inhibition of vascular cholinesterase.

Department of Medicine, William Beaumont Hospital, Royal Oak, Michigan, USA. lerner@cdimed.com	Prevalence of abnormal cardiac wall motion in the cardiomyopathy associated with incomplete multiplication of Epstein-barr Virus and/or cytomegalovirus in patients with	In Vivo. 2004 Jul-Aug;18(4):417-24.	We reported unique incomplete herpesvirus (Epstein-Barr Virus (EBV) and/or nonstructural (HCMV) cytomegalovirus) multiplication in 2 distinct subsets of CFS patients. The CFS subsets were identified by: a) presence of IgM serum antibodies to HCMV nonstructural gene products p52 and CM2 (UL44 and UL57), and/or b) IgM serum antibodies to Epstein-Barr virus viral capsid antigen (EBV, VCA IgM). Diagnostic IgM serum antibodies were found in two independent blinded studies involving 49 CFS patients, but the same antibodies were absent in 170 control patients ($p<0.05$). Abnormal 24 Hr-electrocardiographic monitoring, tachycardias at rest and, in severe chronic cases, abnormal cardiac wall motion (ACWM) were seen in these same CFS patients. We now report a prospective consecutive case control study from 1987--1999 of cardiac dynamics as measured by radionuclide ventriculography in 98 CFS patients from 1987--1999. Controls were patients with various malignancies who were evaluated in protocols requiring radionuclide ventriculography before

		chronic fatigue syndrome.		initiation of cardiotoxic chemotherapeutic agents. The prevalence of abnormal cardiac wall motion (ACWM) at rest in CFS patients was 10 out of 87 patients (11.5%). With stress exercise, 21 patients (24.1%) demonstrated ACWM. Cardiac biopsies in 3 of these CFS patients with ACWM showed a cardiomyopathy. Among the controls, ACWM at rest was present in 4 out of 191 patients (2%) (p=0.0018). A progressive cardiomyopathy caused by incomplete virus multiplication of EBV and/or HCMV in CFS patients is present.
Lerner AM, Beqaj SH, Deeter RG, Fitzgerald JT.	Department of Medicine, William Beaumont Hospital and Wayne State University School of Medicine, Royal Oak, Michigan, USA. lerner@cdimed.com	IgM serum antibodies to Epstein-Barr virus are uniquely present in a subset of patients with the chronic fatigue syndrome.	In Vivo. 2004 Mar-Apr;18(2):101-6.	BACKGROUND: A unique subset of patients with chronic fatigue syndrome (CFS) and IgM serum antibodies to cytomegalovirus (HCMV) non-structural gene products p52 and CM2 (UL 44 and UL 57) has been described. PATIENTS AND METHODS: Fifty-eight CFS patients and 68 non-CFS matched controls were studied. Serum antibodies to EBV viral capsid antigen (VCA) IgM and EBV Early Antigen, diffuse (EA, D) as well HVCMV(V), IgM and IgG; VP (sucrose, density purified V); p52 and CM2 IgM serum antibodies were assayed. RESULTS: Mean age of CFS patients was 44 years (75% women). Control patients were 9 years older (73% women). Serum EBV VCA IgM positive antibody titers were identified in 33 CFS patients (Group A subset EBV VCA IgM 62.3+/-8.3, neg. <20), but were not present in other CFS patients, (Group B subset EBV VCA IgM 6.8+/-0.7) controls (p<0.0001). EBV VCA IgM titers remained positive in CFS patients from Group A for 24-42 months. CONCLUSION: Serum antibody to EBV VCA IgM may be a specific diagnostic test for a second subset of CFS patients.
Liu Z, Wang D, Xue Q, Chen J, Li Y, Bai X, Chang L.	Department of Neurology, Beijing Friendship Hospital, Affiliated Hospital of Capital University of Medical Science, 95 Yong-an Rd, Beijing 100050, China. liuzhandong99@sina.com.cn	Determination of fatty acid levels in erythrocyte membranes of patients with chronic fatigue syndrome.	Nutr Neurosci. 2003 Dec;6(6):389-92.	Chronic fatigue syndrome (CFS) is an illness characterized by persistent and relapsing fatigue, often accompanied by numerous symptoms involving various systems of whole body. The etiology of CFS remains unclear. Literature reported whether the concentrations of the essential fatty acids in red cell membranes of CFS patients were decreased is controversial. In our study, Forty-two patients who fulfilled the diagnostic criteria defined by Centers for Disease Control and Prevention (CDC). Thirty-seven age- and sex-matched controls were selected from healthy medical staffs and volunteers. After lipid analysis, we found that the levels of the arachidonic acid (ARA) and docosahexanoic acid (DHA) were decreased in patients suffered from CFS. However, the levels of the palmitic acid and oleic acid were increased. We speculated that there are two possible mechanisms--one of which is that oxidative stress has led to an excessive oxidation and resulting in the above fatty acids. Alternatively, insufficiency of ingestion of fatty acids might not be the major cause.

Looper KJ, Kirmayer LJ.	Department of Psychiatry, Sir Mortimer B. Davis-Jewish General Hospital, 3755 Chemin de la Cote-Ste-Catherine, Montreal, PQ, Canada. karl.looper@mail.mcgill.ca	Perceived stigma in functional somatic syndromes and comparable medical conditions.	J Psychosom Res. 2004 Oct;57(4):373-8.	OBJECTIVE: To determine if patients with functional somatic syndromes (FSS) perceive greater levels of stigma than patients with comparable medical conditions that have a clear medical pathology. METHODS: Patients with chronic fatigue syndrome (CFS), fibromyalgia (FM), or irritable bowel syndrome (IBS) were compared to multiple sclerosis (MS), rheumatoid arthritis (RA), and inflammatory bowel disease (IBS), respectively. RESULTS: There were greater levels of perceived stigma in the combined group of FSS compared to the medical control group. When each FSS was compared to its matched control group, only CFS had a higher level of perceived stigma. These results remained when controlling for other variables relevant to stigma. CONCLUSIONS: The higher level of perceived stigma in CFS may be due to the ambiguity of its status as a medical condition. The absence of this effect in FM and IBS is consistent with a greater level of acceptance of these disorders as medical illnesses.
Lorenzo Gomez MF, Gomez Castro S.	Area de Urologia Femenina de la Clinica San Marcos, Investigadora en el Centro Biosanitario de Investigacion Experimental de la Universidad de Salamanca, Salamanca. mflorenzogo@yahoo.es	[Physiopathologic relationship between interstitial cystitis and rheumatic, autoimmune, and chronic inflammatory diseases][Article in Spanish]	Arch Esp Urol. 2004 Jan-Feb;57(1):25-34.	OBJECTIVES: To evaluate the current knowledge about interstitial cystitis pathophysiology and its relationship with rheumatic, autoimmune and chronic inflammatory diseases. METHODS: Literature search under "interstitial cystitis pathophysiology" either clinical or experimental trials and reports, in Medline, PubMed, Digital Urology Journal and Doctor's Guide, in addition to our own clinical research experience results. RESULTS: Both human and experimental trials show resemblances between interstitial cystitis and rheumatic, autoimmune, and chronic inflammatory diseases on clinical presentations, pathophysiology. Some interstitial cystitis patients show the bladder infiltrated with specific mononuclear cells, high incidence of circulating antinuclear antibodies, good response to anti-inflammatory and/or immunosuppressive therapies. Interstitial cystitis in association with rheumatic, autoimmune and chronic inflammatory diseases is very common. Many patients with systemic lupus erythematosus, Sjogren syndrome and fibromyalgia syndrome show antibodies against urothelium and/or muscle cells and/or other connective tissue components of urinary bladder. Systemic lupus erythematosus and Sjogren syndrome are the autoimmune diseases which bear strongest similarity with interstitial cystitis. Moreover, rheumatoid arthritis, chronic pelvic pain syndrome, irritable bowel syndrome, fibromyalgia, chronic fatigue syndrome, Evan's syndrome and atopic dermatitis share some pathogenic characteristics. CONCLUSIONS: Nowadays, interstitial cystitis pathophysiology is unknown. Based on clinical presentations, epidemiology, pathology and laboratory findings and treatment response, there is an important correlation among interstitial cystitis and rheumatic, autoimmune and chronic inflammatory diseases. These disorders may share some pathophysiologic mechanisms. Rigorous studies of pathophysiology of these group of diseases are needed to confirm consistently this approach for such conditions.
Luthra A, Wessely S.	King's College School of Medicine, Institute of Psychiatry, 103 Denmark Hill, London SE5 8AZ, UK.	Unloading the trunk: neurasthenia, CFS and race.	Soc Sci Med. 2004 Jun;58(11):2363-9.	The aetiologies of both chronic fatigue syndrome (CFS) and its predecessor neurasthenia, have been linked to technological advances in 'developed' countries. This paper discusses how this has led to a form of race thinking within discussions about fatigue which has persisted for more than a century. We review the historical development of this race thinking from neurasthenia to CFS and describe how it is manifested in both the lay- and medical literature. We also review the epidemiological literature on CFS and ethnicity to better understand the relatively low percentage of non-white patients seen in tertiary referral clinics for CFS. The aim of this paper is to act as a starting point for a

				debate on race and CFS.
Mahurin RK, Claypoole KH, Goldberg JH, Arguelles L, Ashton S, Buchwald D.	Department of Radiology, University of Washington, Seattle, WA 98195-6465, USA. mahurin@u.washington.edu	Cognitive processing in monozygotic twins discordant for chronic fatigue syndrome.	Neuropsychology. 2004 Apr;18(2):232-9.	Twenty-one pairs of monozygotic twins discordant for chronic fatigue syndrome (CFS) and 21 matched healthy control (HC) subjects were assessed with 5 untimed tests and 5 timed tests from the computer-based NeuroCognitive Assessment Battery (R. K. Mahurin, 1993). Random effects regression showed no difference between CFS and healthy twins on any of the cognitive tests. Further, the twin groups did not differ from the HC group on any content-dependent measure. In contrast, both sets of twins performed worse than the HC group on all speed-dependent tests except Finger Tapping. Self-rated fatigue and dysphoric mood were only weakly correlated with cognitive performance. These data point toward a shared genetic trait related to information processing that is manifest in the CFS context. The findings have implications for differentiating genetic and acquired vulnerability in the symptomatic expression of the disorder. ((c) 2004 APA, all rights reserved)
Madill PV.		Chronic fatigue syndrome and the cholinergic hypothesis.	JAMA. 2004 Dec 8;292(22):2723; author reply 2723. Comment on: JAMA. 2004 Sep 8;292(10):1195-204.	
Martinez S, Guilleminault C.	Stanford University Sleep Disorders Clinic, Stanford, California 94305, USA.	Periodic leg movements in prepubertal children with sleep disturbance.	Dev Med Child Neurol. 2004 Nov;46(11):765-70.	This study's aims were to determine: (1) prevalence of periodic leg movements (PLMs) in walking prepubertal children consulting a sleep clinic for any sleep disorder; (2) associations between PLMs and other sleep and medical disorders; and (3) the response of other sleep disorders to treatment with the dopamine agonist pramipexol. Clinical evaluation and polysomnography were carried out for a period of 12 months on 252 consecutively seen, prepubertal children with sleep disorders (156 males, 96 females; aged 15mo to 11y, mean 7y 1mo, SD3y 10mo). Sleep disorders unrelated to PLMs were treated, and six children received pramipexol for PLMs. Follow-up included clinical evaluation and polysomnography. Twenty-three per cent of children were diagnosed with PLMs on the basis of polysomnography. The presence of PLMs had usually been unrecognized clinically. The only clinical symptom that could be related to periodic limb movement disorder was a report of leg pains at morning awakening. Only two of 58 children had PLMs without other clinical or polysomnographic findings. Comorbidity seen with PLMs included neuropsychiatric syndromes (n=20), isolated sleep disordered breathing (SDB; n=29), and several other comorbid conditions (n=7). Seven of 11 children seen with attention-deficit-hyperactivity disorder also had PLMs. Surgery for SDB was associated with subsequent cessation of PLMs in 15 of 29 children. Five out of six children with PLMs who received pramipexol were able to tolerate the drug and experienced a complete disappearance of their PLMs. Presence of chronic fatigue, sleepiness, disrupted nocturnal sleep, and difficulties in falling asleep should lead to a systematic search for PLMs that is independent of associated syndromes. Isolated treatment of SDB might help eliminate some, but not all, PLMs.
McCrone P, Ridsdale L, Darbishire L, Seed	Centre for the Economics of Mental Health,	Cost-effectiveness of cognitive behavioural	Psychol Med. 2004 Aug;34(6):991-9.	BACKGROUND: Chronic fatigue is a common condition, frequently presenting in primary care. The aim of this study was to compare the cost-effectiveness of cognitive behavioural therapy (CBT) and graded exercise therapy (GET), and to compare therapy with usual care plus a self-help booklet (BUC).

P.	Health Services Research Department, Institute of Psychiatry, King's College, London, UK. p.mccrone@iop.kcl.ac.uk	therapy, graded exercise and usual care for patients with chronic fatigue in primary care.		METHOD: Patients drawn from general practices in South East England were randomized to CBT or GET. The therapy groups were then compared to a group receiving BUC recruited after the randomized phase. The main outcome measure was clinically significant improvements in fatigue. Cost-effectiveness was assessed using the net-benefit approach and cost-effectiveness acceptability curves. RESULTS: Costs were available for 132 patients, and cost-effectiveness results for 130. Costs were dominated by informal care. There were no significant outcome or cost differences between the therapy groups. The combined therapy group had significantly better outcomes than the standard care group, and costs that were on average 149 pounds higher (a non-significant difference). Therapy would have an 81.9% chance of being cost-effective if society were willing to attach a value of around 500 pounds to each four-point improvement in fatigue. CONCLUSION: The cost-effectiveness of cognitive behavioural therapy and graded exercise were similar unless higher values were placed on outcomes, in which case CBT showed improved cost-effectiveness. The cost of providing therapy is higher than usual GP care plus a self-help booklet, but the outcome is better. The strength of this evidence is limited by the use of a non-randomized comparison. The cost-effectiveness of therapy depends on how much society values reductions in fatigue.
McCully KK, Smith S, Rajaei S, Leigh JS Jr, Natelson BH.	Department of Exercise Science, University of Georgia, Athens, GA 30602, USA. kmccully@coe.uga.edu	Muscle metabolism with blood flow restriction in chronic fatigue syndrome.	J Appl Physiol. 2004 Mar;96(3):871-8. Epub 2003 Oct 24.	The purpose of this study was to determine whether chronic fatigue syndrome (CFS) is associated with reduced blood flow and muscle oxidative metabolism. Patients with CFS according to Centers for Disease Control criteria (n = 19) were compared with normal sedentary subjects (n = 11). Muscle blood flow was measured in the femoral artery with Doppler ultrasound after exercise. Muscle metabolism was measured in the medial gastrocnemius muscle with (31)P-magnetic resonance spectroscopy. Muscle oxygen saturation and blood volume were measured using near-infrared spectroscopy. CFS and controls were not different in hyperemic blood flow or phosphocreatine recovery rate. Cuff pressures of 50, 60, 70, 80, and 90 mmHg were used to partially restrict blood flow during recovery. All pressures reduced blood flow and oxidative metabolism, with 90 mmHg reducing blood flow by 46% and oxidative metabolism by 30.7% in CFS patients. Hyperemic blood flow during partial cuff occlusion was significantly reduced in CFS patients ($P < 0.01$), and recovery of oxygen saturation was slower ($P < 0.05$). No differences were seen in the amount of reduction in metabolism with partially reduced blood flow. In conclusion, CFS patients showed evidence of reduced hyperemic flow and reduced oxygen delivery but no evidence that this impaired muscle metabolism. Thus CFS patients might have altered control of blood flow, but this is unlikely to influence muscle metabolism. Furthermore, abnormalities in muscle metabolism do not appear to be responsible for the CFS symptoms.
Mears CJ, Taylor RR, Jordan KM, Binns HJ; Pediatric Practice Research Group.	Department of Pediatrics, Feinberg School of Medicine, Northwestern University, Chicago, Illinois, USA.	Sociodemographic and symptom correlates of fatigue in an adolescent primary care sample.	J Adolesc Health. 2004 Dec;35(6):528e.21-6.	PURPOSE: To describe the prevalence of prolonged fatigue, chronic fatigue syndrome (CFS)-like illness, and associated symptom patterns in adolescents attending primary care. METHODS: The design was cross-sectional. A questionnaire designed by the authors assessing fatigue and associated symptoms was administered to 901 adolescents (aged 11-18 years) attending 12 primary care clinics in the Chicago area. Prevalence rates for prolonged fatigue and CFS-like illness were calculated. Univariate comparisons involving sociodemograpic data and fatigue severity were made between adolescents with and without prolonged fatigue, and sociodemographic and symptom predictors of prolonged fatigue were identified using logistic regression analysis. RESULTS: Prolonged fatigue (> or = 1 month)

				occurred at a rate of 8.0% and CFS-like illness occurred at a rate of 4.4%. Adolescents with prolonged fatigue were significantly older and also reported greater fatigue severity than those without fatigue. Findings from logistic regression indicated that, in addition to increasing age, headaches, muscle pains, fever, and fatigue made worse by exercise were significantly associated with prolonged fatigue. CONCLUSIONS: Abnormal fatigue is a disabling and prevalent condition in adolescents in primary care. It is associated with a number of additional symptoms, many of which may have viral origins.
Miike T, Tomoda A, Jhodoi T, Iwatani N, Mabe H.	Department of Child Development, Faculty of Medical and Pharmaceutical Sciences, Kumamoto University Graduate School, 1-1-1 Honjo, Kumamoto 860-8556, Kumamoto, Japan. miketeru@kaiju.medic.kumamoto-u.ac.jp	Learning and memorization impairment in childhood chronic fatigue syndrome manifesting as school phobia in Japan.	Brain Dev. 2004 Oct;26(7):442-7.	For the last 15 years, we have tried to understand the pathophysiology of childhood chronic fatigue syndrome (CCFS) in Japan. In this condition, two major symptoms are important: easy fatigability and disturbed learning and memorization. In CCFS patients we clinically evaluated autonomic nervous system function, circadian rhythm of hormonal secretion (melatonin, cortisol and 3-endorphin), core body temperature, and sleep-wake pattern. Most patients showed autonomic nervous system dysfunction and circadian rhythm disturbances, similar to those observed in jet lag. Radiological imaging studies (SPECT, Xe-CT, and MRS) revealed decreased blood flow in the frontal and thalamic areas, and accumulation of choline in the frontal lobe. We analyzed the relationship between the laboratory data and clinical symptoms in CCFS.
Mourot L, Bouhaddi M, Perrey S, Cappelle S, Henriet MT, Wolf JP, Rouillon JD, Regnard J.	Laboratoire de Physiologie Medecine, Faculte de Medecine, Besancon Cedex, France. mourotlaurent@hotmail.com	Decrease in heart rate variability with overtraining: assessment by the Poincare plot analysis.	Clin Physiol Funct Imaging. 2004 Jan;24(1):10-8.	Numerous symptoms have been associated with the overtraining syndrome (OT), including changes in autonomic function. Heart rate variability (HRV) provides non-invasive data about the autonomic regulation of heart rate in real-life conditions. The aims of the study were to: (i) characterize the HRV profile of seven athletes (OA) diagnosed as suffering of OT, compared with eight healthy sedentary (C) and eight trained (T) subjects during supine rest and 60 degrees upright, and (ii) compare the traditional time- and frequency-domain analysis assessment of HRV with the non-linear Poincare plot analysis. In the latter each R-R interval is plotted as a function of the previous one, and the standard deviations of the instantaneous (SD1) and long-term R-R interval variability are calculated. Total power was higher in T than in C and OA both in supine (1158 +/- 1137, 6092 +/- 3554 and 2970 +/- 2947 ms2 for C, T and OA, respectively) and in upright (640 +/- 499, 1814 +/- 806 and 1092 +/- 712 ms2 for C, T and OA, respectively; P<0.05) positions. In supine position, indicators of parasympathetic activity to the sinus node were higher in T compared with C and OA (high-frequency power: 419.1 +/- 381.2, 1105.3 +/- 781.4 and 463.7 +/- 715.8 ms2 for C, T and OA, respectively; P<0.05; SD1: 29.5 +/- 18.5, 75.2 +/- 17.2 and 37.6 +/- 27.5 for C, T and OA, respectively; P<0.05). OA had a marked predominance of sympathetic activity regardless of the position (LF/HF were 0.47 +/- 0.35, 0.47 +/- 0.50 and 3.96 +/- 5.71 in supine position for C, T and OA, respectively, and 2.09 +/- 2.17, 7.22 +/- 6.82 and 12.04 +/- 10.36 in upright position for C, T and OA, respectively). The changes in HRV indexes

				induced by the upright posture were greater in T than in OA. The shape of the Poincare plots allowed the distinction between the three groups, with wide and narrow shapes in T and OA, respectively, compared with C. As Poincare plot parameters are easy to compute and associated with the 'width' of the scatter gram, they corroborate the traditional time- and frequency-domain analysis. We suggest that they could be used to indicate fatigue and/or prevent OT.
Murphy BE, Abbott FV, Allison CM, Watts C, Ghadirian AM.	Department of Psychiatry, McGill University, 1033 Pine Avenue West, Montreal, Canada H3A 1A1. bev.murphy@mcgill.ca	Elevated levels of some neuroactive progesterone metabolites, particularly isopregnanolone, in women with chronic fatigue syndrome.	Psychoneuroendocrinology. 2004 Feb;29(2):245-68.	Chronic fatigue syndrome (CFS) is a controversial entity whose cause is unknown. In this study we have explored the possibility that progesterone metabolites may be involved. Plasma levels of the progesterone precursor pregnenolone, progesterone itself, and five ring A-reduced metabolites of progesterone were measured in 20 women with CFS and in 13 age-matched controls. To minimize the contribution of the ovary, women were either post-menopausal or in the follicular phase of the menstrual cycle (day 4-8), and progesterone levels were all well within the expected range (< or = 3.5 nmol/l). Mean values for progesterone and all of its metabolites were higher in CFS patients, the most marked being a 2.3-fold elevation in isopregnanolone (3beta,5alpha-tetrahydroprogesterone; p < or = 0.001). Progesterone levels were correlated with those of its metabolites, but even after controlling for progesterone by ANCOVA, isopregnanolone levels were still elevated (p < or = 0.001). These elevated levels of isopregnanolone could not be attributed to medications (antidepressants and anxiolytics). When the CFS patients were divided into two groups according to their Hamilton depression scale ratings, mean (+/-SD) isopregnanolone levels were higher (274+/-160 vs 197+/-119 pmol/l) in the less depressed group (ratings 2-14) than in the more depressed group (ratings 17-28), although this difference did not reach significance. Progesterone levels were negatively correlated with Hamilton depression rating scores (r=-0.56; p<0.01). These results suggest that increases in ring A-reduced progesterone metabolites, particularly isopregnanolone, are associated with CFS, and that the pathophysiology of CFS is unlikely to be due to depression.
Naschitz J, Dreyfuss D, Yeshurun D, Rosner I.	Department of Internal Medicine A, Bnai Zion Medical Center and Bruce Rappaport Faculty of Medicine, Technion-Israel Institute of Technology, Haifa, Israel. Naschitz@tx.technion.ac.il	Midodrine treatment for chronic fatigue syndrome.	Postgrad Med J. 2004 Apr;80(942):230-2.	The long term results of midodrine treatment in a patient having debilitating chronic fatigue syndrome (CFS) are reported. Midodrine treatment, directed at the autonomic nervous system, resulted in correction of the dysautonomia followed by improvement of fatigue. This finding is consistent with the hypothesis that dysautonomia plays a major part in the pathophysiology of CFS and that therapies directed at the autonomic nervous system may be effective in the treatment of CFS.
Naschitz JE, Rozenbaum M, Fields M, Isseroff H, Enis S, Babich		Search for disease-specific cardiovascular reactivity patterns	Clin Sci (Lond). 2004 Aug 26 [Epub ahead of print]	Objectives. Aberrations of cardiovascular reactivity (CVR), an expression of autonomic function, lack specificity for a particular disorder. Recently, a CVR pattern particular to chronic fatigue syndrome has been observed. We aimed to develop methodologies for assessment of disease-specific CVR patterns. Subjects. As a prototype, a population of 50 consecutive patients with Familial Mediterranean Fever

JP, Peck S, Rubin Peck E, Gaitini L, Naschitz S, Sabo E, Rosner I.		- Developing the methodology.		(FMF) was studied compared with control populations. Methods. A 10-minute supine-30 minute head-up tilt test with recording the heart rate and blood pressure or the pulse transit time was performed. Five studies were conducted, applying different methods. In each study, statistical analysis identified independent predictors of the CVR in FMF. Based on regression coefficients of these predictors, a linear discriminant score (DS) was computed for every subject. Each study established an equation to assess the CVR, calculate the DS for FMF and determine the sensitivity and specificity of the DS cut-off. Results. In each of the five studies, abnormal CVR was observed in FMF patients. The best accuracy (88% sensitivity and 90.1% specificity for FMF) was obtained by a method based on beat-to-beat heart rate and pulse transit time recordings. Data was processed by fractal and recurrence quantitative analysis with recordings in FMF patients compared with a mixed control population. Conclusions. Identification of disease-specific CVR patterns became possible with methodologies like those described in the present work. In FMF, disease-specific CVR may be explained by the interplay between neuro-endocrine loops specific to FMF with cardiovascular homeostatic mechanisms. Recognition of disease-specific CVR patterns may advance the understanding of homeostatic mechanisms and have implications in clinical practice.
Naschitz JE, Rosner I, Rozenbaum M, Fields M, Isseroff H, Babich JP, Zuckerman E, Elias N, Yeshurun D, Naschitz S, Sabo E.	Departments of Internal Medicine A and Rheumatology, Bnai Zion Medical Center and Bruce Rappaport Faculty of Medicine, Technion-Israel Institute of Technology, Haifa, Israel. naschitz@tx.technion.ac.il	Patterns of cardiovascular reactivity in disease diagnosis.	QJM. 2004 Mar;97(3):141-51.	BACKGROUND: Aberrations of cardiovascular reactivity (CVR), an expression of autonomic function, occur in a number of clinical conditions, but lack specificity for a particular disorder. Recently, a CVR pattern particular to chronic fatigue syndrome was observed. Aim: To assess whether specific CVR patterns can be described for other clinical conditions. METHODS: Six groups of patients, matched for age and gender, were evaluated with a shortened head-up tilt test: patients with chronic fatigue syndrome (CFS) (n = 20), non-CFS fatigue (F) (n = 15), neurally-mediated syncope (SY) (n = 21), familial Mediterranean fever (FMF) (n = 17), psoriatic arthritis (PSOR) (n = 19) and healthy subjects (H) (n = 20). A 10-min supine phase was followed by recording 600 cardiac cycles on tilt (5-10 min). Beat-to-beat heart rate (HR) and pulse transit time (PTT) were measured. Results were analysed using conventional statistics, recurrence plot analysis and fractal analysis. RESULTS: Multivariate analysis evaluated independent predictors of the CVR in each patient group vs. all other groups. Based on these predictors, equations were determined for a linear discriminant score (DS) for each group. The best sensitivities and specificities of the DS, consistent with disease-related phenotypes of CVR, were noted in the following groups: CFS, 90.0% and 60%; SY, 93.3% and 62.5%; FMF, 90.1% and 75.4%, respectively. DISCUSSION: Pathological disturbances may alter cardiovascular reactivity. Our data support the existence of disease-related CVR phenotypes, with implications for pathogenesis and differential diagnosis.
Naschitz JE, Yeshurun D, Rosner I.	Department of Internal Medicine A, Bnai Zion Medical Center and Bruce Rappaport Faculty of Medicine, Technion - Israel	Dysautonomia in chronic fatigue syndrome: facts, hypotheses, implications.	Med Hypotheses. 2004;62(2):203-6.	The diagnosis of chronic fatigue syndrome (CFS) is based on patient history and treatment on cognitive behavior therapy and graded exercise. There is increasing evidence that dysautonomia occurs in CFS manifest primarily as disordered regulation of cardiovascular responses to stress. We impart our experience relating to diagnosis, monitoring, and treatment of CFS based on identification and management of dysautonomia. Recently proposed methods for assessment of the cardiovascular reactivity, the 'hemodynamic instability score' (HIS) and the 'Fractal and Recurrence Analysis-based Score' (FRAS), served for this purpose. On HUTT, a particular dysautonomia is revealed in CFS patients that differ from dysautonomia in several other disorders. This distinct abnormality in CFS can be

	Institute of Technology, PO Box 4940, Haifa 31048, Israel. naschitz@tx.technion.ac.il			identified by HIS >-0.98 (sensitivity 84.5% and specificity 85.1%) and FRAS > +0.22 (sensitivity 70% and specificity 88%). Therefore, the HIS and FRAS may be used, in the appropriate clinical context, to support the diagnosis of CFS, which until now, could only be subjectively inferred. A pilot study suggested that midodrine treatment, directed at the autonomic nervous system in CFS, results first in correction of dysautonomia followed by improvement of fatigue. This finding implies that dysautonomia is pivotal in the pathophysiology CFS, at least in a large part of the patients, and that manipulating the autonomic nervous system may be effective in the treatment of CFS.
Ng BY, Lim CC, Yeoh A, Lee WL.	Department of Behavioral Medicine, Singapore General Hospital, Republic of Singapore. gdmnby@sgh.com.sg	Neuropsychiatric sequelae of Nipah virus encephalitis.	J Neuropsychiatry Clin Neurosci. 2004 Fall;16(4):500-4.	The authors followed nine patients with Nipah virus encephalitis over the course of 24 months. Eight of the nine developed psychiatric features assigned to the encephalitis. Three patients developed major depressive disorder immediately after recovering from the encephalitis, and two developed depression approximately 1 year after the outbreak. Two patients developed personality changes, and two suffered chronic fatigue syndrome. Neuropsychological testing was accomplished in eight of the nine patients. Deficits in attention, verbal, and/or visual memory were substantial in seven of the eight patients tested. Verbal memory was more impaired than visual memory in these patients. Comparison between psychiatric and cognitive impairment and total number of brain lesions showed no discernible trends.

Nijs J, De Meirleir K, Duquet W.	Department of Human Physiology, Vrije Universiteit Brussel, Brussel, Belgium. Jo.Nijs@vub.ac.be	Kinesiophobia in chronic fatigue syndrome: assessment and associations with disability.	Arch Phys Med Rehabil. 2004 Oct;85(10):1586-92.	OBJECTIVES: To investigate aspects of the validity of the total scores of the Tampa Scale for Kinesiophobia (TSK), Dutch Version, which was modified to make it an appropriate questionnaire for the assessment of kinesiophobia (fear of movement) in chronic fatigue syndrome (CFS) patients (the Dutch TSK-CFS), and, using this assessment tool, to examine the associations between kinesiophobia, exercise capacity, and activity limitations and participation restrictions in patients with CFS. DESIGN: Prospective observational studies. SETTING: An outpatient fatigue clinic. PARTICIPANTS: In the first study, 40 patients fulfilling the 1994 US Centers for Disease Control and Prevention (CDC) criteria for CFS were enrolled. The sample of the second study consisted of 51 CDC-defined patients with CSF. INTERVENTIONS: Not applicable.Main outcome measures Study 1: Subjects completed a set of questionnaires; the Utrechtse Coping List (UCL), the Dutch TSK-CFS, and the Dutch Baecke Questionnaire of Habitual Physical Activity. Study 2: All patients completed 2 questionnaires (Chronic Fatigue Syndrome Activities and Participation Questionnaire [CFS-APQ], Dutch TSK-CFS) and performed a maximal exercise stress test on a bicycle ergometer. The heart rate was monitored continuously by use of an electrocardiograph. Metabolic and ventilatory parameters were measured through spirometry. RESULTS: Study 1: The Cronbach alpha coefficient for the individual item scores on the TSK-CFS was .80. The total scores on the Dutch TSK-CFS showed a statistically significant correlation with both the avoidance/abide subscale of the UCL (Spearman rho=.35, P=.029) and the total score of the Baecke Questionnaire (rho=-.45, P=.004). Study 2: The total scores on the Dutch TSK-CFS showed a statistically significant correlation with the total scores on the CFS-APQ (rho=.39,

				P=.004). No statistically significant associations were observed between the exercise capacity parameters and the total scores on the Dutch TSK-CFS. CONCLUSIONS: These results provide evidence for the internal consistency and the convergent and congruent validity of the scores obtained by use of the Dutch TSK-CFS. Kinesiophobia appears to be associated with activity limitations/participation restrictions but not with exercise capacity in patients with CFS.
Nijs J, De Meirleir K.	Department of Human Physiology, Faculty of Physical Education and Physical Therapy and Chronic Fatigue Clinic, Vrije Universiteit Brussel, Belgium. Jo.Nijs@vub.ac.be	Prediction of peak oxygen uptake in patients fulfilling the 1994 CDC criteria for chronic fatigue syndrome.	Clin Rehabil. 2004 Nov;18(7):785-92.	PURPOSE: To establish an inexpensive, simple method of predicting peak oxygen uptake (VO2peak) in patients fulfilling the 1994 Centers for Disease Control and Prevention (CDC) criteria for chronic fatigue syndrome (CFS). DESIGN: A retrospective observational study. SETTING: An outpatient tertiary care chronic fatigue clinic. SUBJECTS: Two hundred and forty consecutive patients fulfilling the 1994 CDC criteria for CFS. INTERVENTIONS: Heart rate, metabolic and ventilatory parameters were measured continuously during a maximal exercise stress test on a bicycle ergometer. Using the equation peak oxygen uptake = 13.1 x peak workload +284 (used by Mullis et al., Br J Sports Med 1999; 33: 352-56), VO2peak was predicted from the peak workload of a maximal exercise capacity test. Pearson correlation coefficient and linear regression analysis were used to establish the most accurate way to predict VO2peak. RESULTS: Percentage error encountered when comparing actual measured VO2peak with predicted value was 17.3% (+/-10.0). A strong correlation between VO2peak and peak workload was observed ($r= 0.89$, $p < 0.001$). A regression analysis established the relation as VO2peak = 10.47 x peak workload +284.1, where VO2peak is given in ml/min and peak workload in W (error in prediction = 11.0+/-9.5%). CONCLUSIONS: Monitoring of the peak workload during a maximal, graded bicycle ergometric test suffices to predict the VO2peak. When predicting VO2peak the used operational definition for the diagnosis of CFS could be taken into account. Compared with the equation used by Mullis et al., peak workload is multiplied by 10.47 in order to predict peak oxygen uptake in CDC-defined CFS patients.
Nijs J, Vanherberghen K, Duquet W, De Meirleir K.	Department of Human Physiology, Faculty of Physical Education and Physical Therapy Science, Vrije Universiteit Brussel, Brussels, Belgium. Jo.Nijs@vub.ac.be	Chronic fatigue syndrome: lack of association between pain-related fear of movement and exercise capacity and disability.	Phys Ther. 2004 Aug;84(8):696-705.	BACKGROUND AND PURPOSE: Patients who experience pain, a symptom of chronic fatigue syndrome (CFS), often exhibit kinesiophobia (irrational fear of movement). The purpose of this study was to examine whether pain-related fear of movement is associated with exercise capacity, activity limitations, or participation restrictions in patients with CFS who experience widespread pain. SUBJECTS AND METHODS: Sixty-four subjects met the inclusion criteria. All subjects fulfilled the 1994 Centers for Disease Control and Prevention case definition for CFS and experienced widespread myalgias or arthralgias. The subjects completed the Tampa Scale for Kinesiophobia-Dutch Version (TSK-DV) and the Dutch Chronic Fatigue Syndrome-Activities and Participation Questionnaire (CFS-APQ). They then performed a maximal exercise test on a bicycle ergometer. Heart rate was monitored continuously by use of an electrocardiograph. Ventilatory factors were measured through spirometry. Correlations between the TSK-DV scores and both the exercise capacity data and the CFS-APQ scores were assessed using the Spearman rank correlation coefficient. Using the Mann-Whitney U test, the TSK-DV scores were compared between subjects who performed a maximal exercise stress test and those who did not perform the test. RESULTS: Forty-seven subjects (73.4%) attained a total score of greater than 37 on the TSK-DV, indicating high fear of movement. Neither the exercise capacity data nor the CFS-APQ scores indicated a correlation with the TSK-DV scores (n=64). Subjects who did not perform a maximal exercise capacity test had more fear of movement (median TSK-DV score=43.0,

				interquartile range=10.3) compared with those who did perform a maximal exercise capacity test (median TSK-DV score=38.0, interquartile range=13.2; Mann-Whitney U-test score=322.5, z=-1.974, P=.048), but the correlation analysis was unable to reveal an association between exercise capacity and kinesiophobia in either subgroup. DISCUSSION AND CONCLUSION: These results indicate a lack of correlation between kinesiophobia and exercise capacity, activity limitations, or participation restrictions, at least in patients with CFS who are experiencing widespread muscle or joint pain.
Nijs J, De Meirleir K, Meeus M, McGregor NR, Englebienne P.	Department of Human Physiology, Faculty of Physical Education and Physical Therapy Science, Vrije Universiteit Brussel (VUB), Brussel 1090, Belgium.	Chronic fatigue syndrome: intracellular immune deregulations as a possible etiology for abnormal exercise response.	Med Hypotheses. 2004;62(5):759-65.	The exacerbation of symptoms after exercise differentiates Chronic fatigue syndrome (CFS) from several other fatigue-associated disorders. Research data point to an abnormal response to exercise in patients with CFS compared to healthy sedentary controls, and to an increasing amount of evidence pointing to severe intracellular immune deregulations in CFS patients. This manuscript explores the hypothetical interactions between these two separately reported observations. First, it is explained that the deregulation of the 2-5A synthetase/RNase L pathway may be related to a channelopathy, capable of initiating both intracellular hypomagnesaemia in skeletal muscles and transient hypoglycemia. This might explain muscle weakness and the reduction of maximal oxygen uptake, as typically seen in CFS patients. Second, the activation of the protein kinase R enzyme, a characteristic feature in atleast subsets of CFS patients, might account for the observed excessive nitric oxide (NO) production in patients with CFS. Elevated NO is known to induce vasidilation, which may limit CFS patients to increase blood flow during exercise, and may even cause and enhanced postexercise hypotension. Finally, it is explored how several types of infections, frequently identified in CFS patients, fit into these hypothetical pathophysiological interactions.
Nijs J, De Meirleir K, Wolfs S, Duquet W.	Department of Human Physiology, Faculty of Physical Education and Physical Therapy and Chronic Fatigue Clinic, Vrije Universiteit Brussel (VUB), Belgium. Jo.Nijs@vub.ac.be	Disability evaluation in chronic fatigue syndrome: associations between exercise capacity and activity limitations/participation restrictions.	Clin Rehabil. 2004 Mar;18(2):139-48.	OBJECTIVE: In an attempt to examine whether impairments in cardiorespiratory fitness are associated with daily functioning in patients with chronic fatigue syndrome (CFS), this study addresses the correlations between exercise capacity and activity limitations/participation restrictions. DESIGN: Prospective observational study. SETTING: An outpatient tertiary care, chronic fatigue clinic at the Vrije Universiteit Brussel (VUB), Belgium. SUBJECTS: Seventy-seven patients fulfilling the 1994 Centers for Disease Control and Prevention (CDC) case definition for CFS. INTERVENTIONS: All patients filled in the Chronic Fatigue Syndrome Activities and Participation Questionnaire (CFS-APQ) and performed a maximal exercise stress test on a bicycle ergometer. Heart rate was monitored continuously by use of an electrocardiograph. Metabolic and ventilatory parameters were measured through spirometry. RESULTS: A statistically significant correlation between the score obtained with the CFS-APQ and the body weight-adjusted peak oxygen uptake (Spearman rho = -0.32; p = 0.005), functional aerobic impairment (rho = 0.33; p = 0.004), workload/body weight (rho = -0.30; p = 0.009), exercise duration (rho = -0.30; p = 0.008), and the percentage of target heart rate achieved (rho = -0.33; p = 0.004) was observed. The correlations between the remaining exercise capacity parameters and the scores obtained with the CFS-APQ all indicated a trend towards association (0.01 <p<0.05). CONCLUSIONS: These results suggest a moderate association between exercise capacity and activity limitations/participation restrictions in patients with CFS. The observed correlations lack strength to predict activity limitations/ participation restriction based on exercise capacity parameters. Disability evaluation in CFS should therefore encompass both exercise capacity testing and measurements at the activity/participation dimension.

Nijs J, Nicolson GL.		Gulf War Veterans: Evidence for Chromosome Alternations and Their Significance	Journal of Chronic Fatigue Syndrome 2004; 12(1):79–83.	
Nijs J, Vaes P, McGregor N, Lambrecht L, Van Hoof E, De Meirleir K	Department of Human Physiology, Faculty of Physical Education and Physical Therapy, Vrije Universiteit Brussel (VUB), Belgium, Jo.Nijs@vub.ac.be	Comparison of Activity Limitations/Participation Restrictions Among Fibromyalgia and Chronic Fatigue Syndrome Patients	Journal of Chronic Fatigue Syndrome 2004; Mar;11(4):3–18.	Fibromyalgia (FM) and Chronic Fatigue Syndrome (CFS) are related yet overlapping disorders; the current case definitions prohibit a clear-cut differential diagnosis. These diagnostic criteria mainly address the impairment level of the World Health Organization's International Classification of Functioning, Disability and Health. This study aimed at comparing activity limitations and participation restrictions in patients with FM (n = 90) and CFS (n = 47). The Chronic Fatigue Syndrome Activities and Participation Questionnaire (CFS-APQ) was used for assessing functionality in both groups. The convergent validity of the scores obtained with the questionnaire with visual analogue scales for pain, fatigue and concentration was investigated in FM patients, as well as the content validity. No differences in total scores and 25 out of 26 individual items on the CFS-APQ were observed between the 2 groups (independent samples Mann-Whitney U test). This sample of FM patients reported to be more disabled in 'sitting for two hours' as compared to the CFS group (mean scores 3.0 ± 1.0 and 2.3 ± 1.0; P = .004). Four hundred and thirty-seven of the 497 (87.9 %) responses to the request to list difficult activities matched the content of the CFS-APQ. The overall scores of the CFS-APQ correlated statistically significant in respect to visual analogue scales for pain and concentration (Spearman rho for the total scores ranged between .44 and .49). These data question the disease specificity of the CFS-APQ for CFS, but suggests its applicability in 'the Chronic Pain-Fatigue Syndromes'. The present report provides evidence for both the content and convergent validity of the CFS-APQ in FM patients.

J Psychosom Res. 2004 Feb;56(2):171-8.	OBJECTIVE: Chronic fatigue syndrome (CFS) case definitions agree that fatigue must be unexplained, debilitating and present for at least 6 months, but they differ over accompanying symptoms. Our objective was to compare the 1994 CFS case-defining symptoms with those identified by factor analysis. METHODS: We surveyed the Wichita population and measured the occurrence of 21 symptoms in 1391 chronically fatigued subjects who did not report fatigue-associated medical or psychiatric conditions. We used factor analyses to identify symptom dimensions of fatigue and cluster analysis to assign subjects to subgroups. RESULTS: Forty-three subjects had CFS. We confirmed three factors: musculoskeletal, infection and cognition-mood-sleep, essentially defined by CFS symptoms. Although factor scores were higher among CFS subjects, CFS and non-CFS distributions overlapped substantially. Three clusters also showed overlap between CFS and non-CFS subjects. CONCLUSION: CFS symptomatology is a multidimensional phenomenon overlapping with other unexplained fatiguing syndromes and this must be considered in CFS research.

Ohashi K, Bleijenberg G, van der Werf S, Prins J, Amaral LA, Natelson BH, Yamamoto Y.	Educational Physiology Laboratory, Graduate School of Education, The University of Tokyo, 7-3-1 Hongo, Bunkyo-ku, Tokyo 113-0033, Japan. yamamoto@edcom.p.u-tokyo.ac.jp	Decreased fractal correlation in diurnal physical activity in chronic fatigue syndrome.	Methods Inf Med. 2004;43(1):26-9.	OBJECTIVES: Our objectives were to study the temporal correlation of physical activity time series in patients with chronic fatigue syndrome (CFS) during normal daily life and to examine if it could identify the altered physical activity in these patients. METHODS: Fractal scaling exponents of diurnal and nocturnal physical activity time series in 10 CFS patients and 6 healthy control subjects (CON) were calculated by the detrended fluctuation analysis (DFA) and the wavelet transform modulus maxima (WTMM) method. We hypothesized that, due to their illness- and/or fatigue-induced resting episodes, altered physical activity patterns in CFS patients might be observed at the interruption of activity bursts. Thus, we further developed a new method, the wavelet transform negative modulus maxima (WTNMM) method, which could evaluate the temporal correlation at the interruption of activities. We compared the fractal scaling exponents for CFS and CON by each method. RESULTS: Both for CFS and CON, we found the fractal time structures in their diurnal physical activity records for at least up to 35 minutes. No group difference was found in nocturnal activities. The WTNMM method revealed that, in diurnal activities, CFS patients had significantly ($p < 0.01$) smaller fractal scaling exponent (0.87 +/- 0.03) compared to controls (1.01 +/- 0.03). Such a difference was identified neither by the DFA nor WTMM method. CONCLUSIONS: CFS patients had more abrupt interruptions of voluntary physical activity during diurnal periods in normal daily life, probed by the decreased correlation in the negative modulus maxima of the wavelet-transformed activity data, possibly due to their exaggerated fatigue.
Okada T, Tanaka M, Kuratsune H, Watanabe Y, Sadato N.	National Institute for Physiological Sciences, 38 Nishigonaka, Myodaiji, Okazaki, Aichi 444-8585, Japan. tomokada@ibri-kobe.org <tomokada@ibri-kobe.org>	Mechanisms underlying fatigue: a voxel-based morphometric study of chronic fatigue syndrome.	BMC Neurol. 2004 Oct 04;4(1):14.	BACKGROUND: Fatigue is a crucial sensation that triggers rest, yet its underlying neuronal mechanisms remain unclear. Intense long-term fatigue is a symptom of chronic fatigue syndrome, which is used as a model to study the mechanisms underlying fatigue. METHODS: Using magnetic resonance imaging, we conducted voxel-based morphometry of 16 patients and 49 age-matched healthy control subjects. RESULTS: We found that patients with chronic fatigue syndrome had reduced gray-matter volume in the bilateral prefrontal cortex. Within these areas, the volume reduction in the right prefrontal cortex paralleled the severity of the fatigue of the subjects. CONCLUSION: These results are consistent with previous reports of an abnormal distribution of acetyl-L-carnitine uptake, which is one of the biochemical markers of chronic fatigue syndrome, in the prefrontal cortex. Thus, the prefrontal cortex might be an important element of the neural system that regulates sensations of fatigue.
Papanicolaou DA, Amsterdam JD, Levine S, McCann SM, Moore RC, Newbrand CH, Allen G,	Department of Medicine/Endocrinology, Emory University, Atlanta, GA, USA.	Neuroendocrine aspects of chronic fatigue syndrome.	Neuroimmunomodulation. 2004;11(2):65-74.	Chronic fatigue syndrome (CFS) is a serious health concern affecting over 800000 Americans of all ages, races, socioeconomic groups and genders. The etiology and pathophysiology of CFS are unknown, yet studies have suggested an involvement of the neuroendocrine system. A symposium was organized in March 2001 to explore the possibility of an association between neuroendocrine dysfunction and CFS, with special emphasis on the interactions between neuroendocrine dysfunction and other abnormalities noted in the immune and autonomic nervous systems of individuals with CFS.

Pazderka-Robinson H, Morrison JW, Flor-Henry P.	Clinical Diagnostics and Research Centre, Alberta Hospital Edmonton, Box 307, 17480 Fort Road, Edmonton, Alberta, Canada T5J 2J7. hannah@ualberta.ca	Electrodermal dissociation of chronic fatigue and depression: evidence for distinct physiological mechanisms.	Int J Psychophysiol. 2004 Aug;53(3):171-82.	Chronic fatigue syndrome (CFS) has an estimated prevalence between 0.5% and 3%, yet its diagnosis remains contentious. CFS is characterized by subjective symptoms that can be difficult to verify; moreover, depression is a commonly reported CFS complaint, whereas fatigue is a common symptom of depression. Our primary goal was dissociation of these disorders using psychophysiological methods. As previous research has implicated the autonomic nervous system in CFS, we conducted what we believe to be the first analysis of bilateral electrodermal and skin temperature responses of dextral females in a cross-modal orienting task, to investigate differences between these two patient groups and controls. A multivariate analysis of variance (MANOVA) examining three measures of electrodermal activity revealed prestimulus tonic skin conductance levels (SCLs) were markedly lower for the CFS group, with no difference between controls and depressives. Concurrent skin temperature levels were higher for the CFS group than the other two groups. These findings indicate that, despite overtly similar cognitive and symptom profiles, depression and CFS patients can be differentiated with psychophysiological measures. This study adds to the growing body of evidence demonstrating that CFS and depression have distinct neurobiological profiles, consistent with unique aetiologies. Copyright 2004 Elsevier B.V.
Pearce JM.	Emeritus Consultant Neurologist, Department of Neurology, Hull Royal Infirmary, Hull, UK.	Myofascial Pain, Fibromyalgia or Fibrositis?	Eur Neurol. 2004 Jul 13;52(2):67-72.	The terms myofascial pain, fibromyalgia and fibrositis are critically examined. They constitute diagnostic labels for non-specific musculoskeletal aches and pains. Analysis of the evidence shows that none of these labels is substantiated by hard physical signs or by laboratory evidence of consistent pathological or biochemical abnormality. What is the objective evidence for disorder(s) of muscle, fascia or fibrous tissues, so clearly indicated by these diagnostic names? Alternative terms such as 'regional pain syndrome' or 'chronic pain syndrome' merely redefine the clinical problem without providing a mechanism or basis for diagnosis. Despite different diagnostic criteria, these conditions, along with chronic fatigue syndrome, have many demographic and clinical similarities, most notably tender trigger points. Indeed, the terms are often used interchangeably. There are few differences in the symptoms, physical findings, laboratory tests, functional status, psychosocial features and psychiatric disorders. This paper seeks not to deny the existence of aches and pains, but to critically examine the utility of these terms. The only claimed physical sign is the presence of tender trigger points over muscles or muscle attachments. Research suggests that tender points are a measure of general distress related to pain complaints but separately associated with fatigue and depression. They are present in some normal subjects and are variable in occurrence in time in the same individual. They reflect no demonstrable pathology. It is therefore argued that none of these commonly used diagnoses represent distinct disease entities. A possible but unproven alternative hypothesis is that such symptoms relate to neural pain with both peripheral and central components, and in some instances psychological or wilful embellishment. Pendergast DR, Fisher NM,	Department of Physiology,	The distribution of white blood cell fat	J Inherit Metab Dis. 2004;27(1):89-	Fat oxidation is important for maintaining health and for supplying energy for exercise. We have proposed that the predisposition for individual rates of fat oxidation is determined genetically but

Meksawan K, Doubrava M, Vladutiu GD.	University at Buffalo, Buffalo, New York 14214, USA. dpenderg@buffalo.edu	oxidation in health and disease.	99.	may be modulated by acute exercise or exercise training. The purpose of this study was to examine cellular fat oxidation in white blood cells (WBC) using [9,10-3H]palmitic acid. Sedentary controls free of symptoms (SED-C, n=32), were compared with known carnitine palmitoyltransferase (CPT) II-deficient patients (n =2), patients with fatiguing diseases (chronic fatigue syndrome, CFS, n=6; multiple sclerosis, MS, n=31), obesity (OB, n=5), eating disorders (ED, n=16), sedentary individuals prior to and after exercise (SED-Ex, n=12), exercise-trained sedentary individuals (SED-Tr, n=12), and elite runners (ER, n=5). Fat oxidation in WBC for all subjects was normally distributed (mean=0.270 +/- 0.090 nmol/h per 10(9) WBC) and ranged from 0.09 nmol/h per 10(9) WBC in CPT II-deficient patients to 0.59 nmol/h per 10(9) WBC in ER. There were no significant sex or acute exercise effects on WBC fat oxidation. Patients with MS, OB or ED were not different from SED-C; however, in CPT II-deficient patients, fat oxidation was low, while that of CFS patients was high. Exercise training in SED-C resulted in a 16% increase in fat oxidation but in ER it was still 97% higher than in SED-C. We propose that while WBC fat oxidation is not significantly affected by sex or acute exercise, and only by 15-20% with training, genetic factors play a role in determining both high and low fat oxidation in certain groups of individuals. The genetic predisposition for individual rates of fat oxidation may be easily measured using WBC fat oxidation, as has been shown for CPT II-deficient patients and for elite runners. Ranges of WBC fat oxidation that are abnormally low (<20 nmol/h per 10(9) WBC, normal 20-35) or high (>35 nmol/h per 10(9) WBC) are proposed based on genetic factors evaluated in this study.

Powell P, Bentall RP, Nye FJ, Edwards RH.	Department of Psychology, University of Manchester, UK.	Patient education to encourage graded exercise in chronic fatigue syndrome. 2-year	Br J Psychiatry. 2004 Feb;184:142-6.	BACKGROUND: An earlier trial demonstrated good outcomes after 1 year for patients with chronic fatigue syndrome (CFS) who received an educational intervention designed to encourage graded activity. AIMS: To determine 2-year outcomes for the same treated patients and the response to treatment of patients formerly in the control condition. METHOD: Patients in the treatment groups (n=114) were followed up at 2 years; 32 patients from the control group were offered the intervention

		follow-up of randomised controlled trial.		after 1 year and were assessed 1 year later. Assessments were the self-rated measures used in the original trial. RESULTS: At 2 years 63 of the treated patients (55%) no longer fulfilled trial criteria for CFS compared with 64 patients (56%) at 1 year. Fourteen of 30 crossover patients (47%) achieved a good outcome at 1 year and seven (23%) no longer fulfilled criteria for CFS. CONCLUSIONS: Benefits of the intervention were maintained at 2 years. Delaying treatment is associated with reduced efficacy and required more intensive therapy.
Price JS, Gardner R Jr, Erickson M.	Odintune Place, Plumpton, East Sussex BN7 3AN, UK. john.price@lycosmail.com	Can depression, anxiety and somatization be understood as appeasement displays?	J Affect Disord. 2004 Apr;79(1-3):1-11.	BACKGROUND: No satisfactory basis in normal function characterizes major depression and its co-morbid disorders. Yet these may represent maladaptive expression of adaptive communicational states exhibited normally in many species. METHODS: We examined the signal value of depressive and anxious mood states, fatigue syndrome and somatoform disorders and found them to resemble appeasement or submission to conspecifics (members of a same species) as studied in other animals. Moreover, applying game theory formulations of conflict resolution and the triune brain theory of MacLean supported the hypothesis. LIMITATIONS: Direct experimental evidence must still test hypotheses that emanate from the presented framework. Conclusions: Implications for this approach include improved understanding and treatment of depression, improved research strategies, and a potential future pathogenesis-focused nosology.
Prins JB, Bos E, Huibers MJ, Servaes P, van der Werf SP, van der Meer JW, Bleijenberg G.	Department of Medical Psychology, University Medical Centre Nijmegen, Nijmegen, The Netherlands. j.prins@cukz.umcn.nl	Social support and the persistence of complaints in chronic fatigue syndrome.	Psychother Psychosom. 2004 May-Jun;73(3):174-82.	BACKGROUND: Several studies suggested that the surroundings of chronic fatigue syndrome (CFS) patients are of importance in the persistence of complaints. Contrary to what was expected, participation in support groups has not led to clinical improvement. The purpose of the present study was to describe social support in CFS patients as compared with other fatigued and non-fatigued groups. Further, changes in social support and the influence of social support on the course of CFS over a period of more than 1 year were studied in patients with and without treatment. METHODS: Baseline data were assessed in 270 CFS patients, 150 disease-free breast cancer patients, 151 fatigued employees on sick-leave and 108 healthy subjects using the Social Support List and Significant Others Scale. CFS patients were followed in cognitive behaviour therapy (CBT), guided support groups and natural course at 8 and 14 months. RESULTS: CFS patients and fatigued employees reported more negative interactions and insufficiency of supporting interactions than cancer patients and healthy controls. No differences in frequency of supporting interactions were found. Negative interactions decreased significantly after treatment with CBT, but did not change in support groups or natural course. In the natural course, higher fatigue severity at 8 months was predicted by more negative interactions at baseline. CONCLUSIONS: In CFS patients and fatigued employees, social support is worse than in disease-free cancer patients and healthy controls. Lack of social support was identified as a new factor in the model of perpetuating factors of fatigue severity and functional impairment in CFS. Copyright 2004 S. Karger AG, Basel
Puri BK, Holmes J, Hamilton G.	MRI Unit, Imaging Sciences Department, MRC Clinical Sciences Centre, Imperial College School of	Eicosapentaenoic acid-rich essential fatty acid supplementation in chronic fatigue syndrome	Int J Clin Pract. 2004 Mar;58(3):297-9.	Lateral ventricular enlargement has been reported in chronic fatigue syndrome, while cerebral neurospectroscopy has recently indicated that essential fatty acid treatment may be of value in this condition. An essential fatty acid supplement rich in eicosapentaenoic acid (EPA) was therefore given daily to a female patient with a 6-year history of unremitting symptoms of chronic fatigue syndrome. Cerebral magnetic resonance scanning was carried out at baseline and 16 weeks later. The EPA-rich essential fatty acid supplementation led to a marked clinical improvement in her symptoms of chronic

	Medicine, Hammersmith Hospital, London, UK.	associated with symptom remission and structural brain changes.		fatigue syndrome, starting within 6-8 weeks. Accurate quantification of the lateral ventricular volumes in the baseline and 16-week follow-up registered images of high-resolution magnetic resonance imaging structural scans showed that the treatment was accompanied by a marked reduction in the lateral ventricular volume during this period, from 28,940-23,660 mm3.
Puri BK.	MRI Unit, Imaging Sciences Department, MRC Clinical Sciences Centre, Imperial College School of Medicine, Hammersmith Hospital, Du Cane Road, London W12 0HS, England, UK. basant.puri@csc.mrc.ac.uk	The use of eicosapentaenoic acid in the treatment of chronic fatigue syndrome.	Prostaglandins Leukot Essent Fatty Acids. 2004 Apr;70(4):399-401.	There is evidence that there is an association between chronic fatigue syndrome, a condition of unknown aetiology, and essential fatty acids. This evidence is based on the actions of essential fatty acids, the results of proton neurospectroscopy studies, and essential fatty acid trial data. A series of patients with chronic fatigue syndrome were treated solely with a high-eicosapentaenoic acid-containing essential fatty acid supplement. All showed improvement in their symptomatology within eight to 12 weeks. These results, which are consistent with a recent detailed report of cerebral and clinical changes associated with a high intake of eicosapentaenoic acid, suggest that this n-3 highly unsaturated fatty acid may offer the hope of effective treatment for at least some patients with chronic fatigue syndrome.
Raine R, Sanderson C, Hutchings A, Carter S, Larkin K, Black N.	Health Services Research Unit, London School of Hygiene and Tropical Medicine, Keppel Street, London WC1E 7HT, UK. rosalind.raine@lshtm.ac.uk	An experimental study of determinants of group judgments in clinical guideline development. Comment in: Lancet. 2004 Jul 31;364(9432):392-3.	Lancet. 2004 Jul 31;364(9432):429-37.	BACKGROUND: Clinical guidelines for improving the quality of care are a familiar part of clinical practice. Formal consensus methods such as the nominal group technique are often used as part of guideline development, but little is known about factors that affect the statements produced by nominal groups, and on their consistency with the research evidence. METHODS: Cognitive behavioural therapy, behavioural therapy, brief psychodynamic interpersonal therapy, and antidepressants for irritable bowel syndrome, chronic fatigue syndrome, and chronic back pain were selected for study. 16 nominal groups in a factorial design allowed comparison of GP-only with mixed groups of GPs and specialists, provision of a literature review with no provision, and ratings made in the context of realistic or ideal levels of health-care resources. Participants rated appropriateness independently, and again after a facilitated meeting. Audiotapes of four group discussions were analysed. FINDINGS: There was agreement with the research evidence for 51% of 192 scenarios. Agreement was more likely if the group was GP-only, if a literature review was provided, or if the evidence was in accordance with clinicians' beliefs. Assumptions about the level of resources available had no impact. Clinical and social cues had mixed effects, irrespective of the research evidence. Qualitative analysis showed the modifying effect of clinical experience and beliefs about research evidence. INTERPRETATION: Guidelines cannot be based on data alone; judgment is unavoidable. The nominal group technique is a method of eliciting and aggregating judgments in a transparent and structured way. It can provide important information on levels of agreement between experts. However, conclusions can be at odds with the published literature. If they are, reasons need to be explicit.
Raine R, Carter S, Sensky T, Black N.	Department of Public Health and	General practitioners'	BMJ. 2004 Jun 5;328(7452):1354-	OBJECTIVES: To compare general practitioners' perceptions of chronic fatigue syndrome and irritable bowel syndrome and to consider the implications of their perceptions for treatment. DESIGN:

	Policy, London School of Hygiene and Tropical Medicine, London WC1E 7HT. rosalind.raine@lshtm.ac.uk	perceptions of chronic fatigue syndrome and beliefs about its management, compared with irritable bowel syndrome: qualitative study. Comment in: BMJ. 2004 Jul 10;329(7457):112-3.	7. Epub 2004 May 28.	Qualitative analysis of transcripts of group discussions. PARTICIPANTS AND SETTING: A randomly selected sample of 46 general practitioners in England. RESULTS: The participants tended to stereotype patients with chronic fatigue syndrome as having certain undesirable traits. This stereotyping was due to the lack of a precise bodily location; the reclassification of the syndrome over time; transgression of social roles, with patients seen as failing to conform to the work ethic and "sick role" and conflict between doctor and patient over causes and management. These factors led to difficulties for many general practitioners in managing patients with chronic fatigue syndrome. For both conditions many participants would not consider referral for mental health interventions, even though the doctors recognised social and psychological factors, because they were not familiar with the interventions or thought them unavailable or unnecessary. CONCLUSIONS: Barriers to the effective clinical management of patients with irritable bowel syndrome and chronic fatigue syndrome are partly due to doctors' beliefs, which result in negative stereotyping of patients with chronic fatigue syndrome and the use of management strategies for both syndromes that may not take into account the best available evidence.
Reeves WC, Lloyd A, Vernon SD, Klimas N, Jason LA, Bleijenberg G, Evengard B, White PD, Nisenbaum R, Unger ER, .	Centers for Disease Control and Prevention, Atlanta, Georgia, United States of America. wcr1@cdc.gov	Identification of ambiguities in the 1994 chronic fatigue syndrome research case definition and recommendations for resolution.	BMC Health Serv Res. 2003 Dec 31;3(1):25.	BACKGROUND: Chronic fatigue syndrome (CFS) is defined by symptoms and disability, has no confirmatory physical signs or characteristic laboratory abnormalities, and the etiology and pathophysiology remain unknown. Difficulties with accurate case ascertainment contribute to this ignorance. METHODS: Experienced investigators from around the world who are involved in CFS research met for a series of three day workshops in 2000, 2001 and 2002 intended to identify the problems in application of the current CFS case definition. The investigators were divided into focus groups and each group was charged with a topic. The investigators in each focus group relied on their own clinical and scientific knowledge, brainstorming within each group and with all investigators when focus group summaries were presented. Relevant literature was selected and reviewed independent of the workshops. The relevant literature was circulated via list-serves and resolved as being relevant by group consensus. Focus group reports were analyzed and compiled into the recommendations presented here. RESULTS: Ambiguities in the current CFS research definition that contribute to inconsistent case identification were identified. Recommendations for use of the definition, standardization of classification instruments and study design issues are presented that are intended to improve the precision of case ascertainment. The International CFS Study Group also identified ambiguities associated with exclusionary and comorbid conditions and reviewed the standardized, internationally applicable instruments used to measure symptoms, fatigue intensity and associated disability. CONCLUSION: This paper provides an approach to guide systematic, and hopefully reproducible, application of the current case definition, so that case ascertainment would be more uniform across sites. Ultimately, an operational CFS case definition will need to be based on empirical studies designed to delineate the possibly distinct biological pathways that result in chronic fatigue.
Reuter K, Harter M.	Freiburg University Medical Center, Department of Psychiatry and Psychotherapy,	The concepts of fatigue and depression in cancer.	Eur J Cancer Care (Engl). 2004 May;13(2):127-34.	REUTER K. & HARTER M. (2004) European Journal of Cancer Care13, 127-134 The concepts of fatigue and depression in cancer A strong association between fatigue and depression in cancer patients has been reported repeatedly in clinical studies. The distinction remains difficult, mainly because of the similar phenomenology of fatigue and depression. It is the aim of this paper to work out similarities and differences in the conception of fatigue and depressive disorders. For that, a differentiation

	Freiburg, Germany.			between depression as emotional distress and depression as clinical syndrome, according to the current classification systems, has to be made. Therefore, the classification of depressive disorders and their criteria is presented in the second section of this paper, especially in view of the diagnosis of depressive disorders in cancer patients. The comparison of the multidimensional fatigue construct and depression shows a strong overlap of symptoms. None of the fatigue symptoms are specific for fatigue, all being elements of depressive syndromes. It is in particular the psychological symptoms of depressive disorders that differentiate between the two concepts. To that end, the question is discussed whether fatigue in its current conceptualization can be defined as a diagnostic entity independent of depressive disorders. Additionally, research approaches are presented from the area of the chronic fatigue syndrome and neurasthenia, which could be adapted to cancer-related fatigue and help to clarify the clinical differences between fatigue and depression. In order to ensure better differential diagnostics in the future, criteria-orientated research in particular is needed.
Reynolds KJ, Vernon SD, Bouchery E, Reeves WC.	Division of Viral and Rickettsial Diseases, Centers for Disease Control and Prevention, Atlanta, U,S,A. wcr1@cdc.gov	The economic impact of chronic fatigue syndrome.	Cost Eff Resour Alloc. 2004 Jun 21;2(1):4.	BACKGROUND: Chronic fatigue syndrome (CFS) is a chronic incapacitating illness that affects between 400,000 and 800,000 Americans. Despite the disabling nature of this illness, scant research has addressed the economic impact of CFS either on those affected or on the national economy. METHODS: We used microsimulation methods to analyze data from a surveillance study of CFS in Wichita, Kansas, and derive estimates of productivity losses due to CFS. RESULTS: We estimated a 37% decline in household productivity and a 54% reduction in labor force productivity among people with CFS. The annual total value of lost productivity in the United States was $9.1 billion, which represents about $20,000 per person with CFS or approximately one-half of the household and labor force productivity of the average person with this syndrome. CONCLUSION: Lost productivity due to CFS was substantial both on an individual basis and relative to national estimates for other major illnesses. CFS resulted in a national productivity loss comparable to such losses from diseases of the digestive, immune and nervous systems, and from skin disorders. The extent of the burden indicates that continued research to determine the cause and potential therapies for CFS could provide substantial benefit both for individual patients and for the nation.
Richardson RD, Engel CC Jr.	VA Puget Sound Healthcare System, Seattle, WA, USA.	Evaluation and management of medically unexplained physical symptoms.	Neurologist. 2004 Jan;10(1):18-30.	BACKGROUND: Medically unexplained physical symptoms (MUPS) and related syndromes are common in medical care and the general population, are associated with extensive morbidity, and have a large impact on functioning. Much of medical practice emphasizes specific pharmacological and surgical intervention for discrete disease states. Medical science, with its emphasis on identifying etiologically meaningful diseases comprised of homogeneous groups of patients, has split MUPS into a number of diagnostic entities or syndromes, each with its own hypothesized pathogenesis. However, research suggests these syndromes may be more similar than different, sharing extensive phenomenological overlap and similar risk factors, treatments, associated morbidities, and prognoses. Examples of syndromes consisting of MUPS include chronic fatigue syndrome, fibromyalgia, multiple chemical sensitivities, somatoform disorders, and 'Gulf War Syndrome.' REVIEW SUMMARY: This paper is a narrative review of the increasing body of evidence suggesting that MUPS and related syndromes are common, disabling, and costly. It emphasizes that MUPS occur along a continuum of symptom count, severity, and duration and may be divided into acute, subacute (or recurrent), and chronic types. Predisposing, precipitating, and perpetuating factors influence the natural history of

				MUPS. CONCLUSIONS: Effective symptom management involves collaborative doctor-patient approaches for identification of problems based on a combination of medical importance and patient readiness to initiate behavioral change, negotiated treatment goals and outcomes, gradual physical activation and exercise prescription. Additionally, efforts should be made to teach and support active rather than passive coping with the symptoms.
Ridsdale L, Darbishire L, Seed PT.	Department of Neurology, Guy's, King's and St Thomas's School of Medicine, London.	Is graded exercise better than cognitive behaviour therapy for fatigue? A UK randomized trial in primary care.	Psychol Med. 2004 Jan;34(1):37-49.	BACKGROUND: Patients frequently present with unexplained fatigue in primary care, but there have been few treatment trials in this context. We aimed to test cognitive behaviour therapy (CBT) and graded exercise therapy (GET) for patients presenting to their family doctor with fatigue. Secondly, we described the outcome for a cohort of patients who presented to the same doctors with fatigue, who received standard care, plus a booklet. METHOD: This was a randomized trial, followed by a prospective cohort study. Twenty-two practices in SE England referred 144 patients aged 16 to 75 years with over 3 months of unexplained fatigue. Self-rated fatigue score, the hospital anxiety and depression rating scale, functional impairment, physical step-test performance and causal attributions were measured. In the trial six sessions of CBT or GET were randomly allocated. RESULTS: In the therapy groups the mean fatigue score decreased by 10 points (95% confidence interval (CI) = -25 to -15), with no significant difference between groups (mean difference = -1.3; CI = -3.9 to 1.3). Fewer patients attended for GET. At outcome one-half of patients had clinically important fatigue in both randomized groups, but patients in the group offered CBT were less anxious. Twenty-seven per cent of the patients met criteria for CFS at baseline. Only 25% of this subgroup recovered, compared to 60% of the subgroup that did not meet criteria for CFS. CONCLUSIONS: Short courses of GET were not superior to CBT for patients consulting with fatigue of over 3 months in primary care. CBT was easier 'to sell'. Low recovery in the CFS subgroup suggests that brief treatment is too short.
Roberts AD, Wessely S, Chalder T, Papadopoulos A, Cleare AJ.	Section of General Hospital Psychiatry, Division of Psychological Medicine, Guy's, King's and St Thomas' School of Medicine and Dentistry, London, UK.	Salivary cortisol response to awakening in chronic fatigue syndrome.	Br J Psychiatry. 2004 Feb;184:136-41.	BACKGROUND: There is accumulating evidence of hypothalamic-pituitary-adrenal (HPA) axis disturbances in chronic fatigue syndrome (CFS). The salivary cortisol response to awakening has been described recently as a non-invasive test of the capacity of the HPA axis to respond to stress. The results of this test correlate closely with those of more invasive dynamic tests reported in the literature; furthermore, it can be undertaken in a naturalistic setting. AIMS: To assess the HPA axis using the salivary cortisol response to awakening in CFS. METHOD: We measured salivary cortisol upon awakening and 10, 20, 30 and 60 min afterwards in 56 patients with CFS and 35 healthy volunteers. RESULTS: Patients had a lower cortisol response to awakening, measured by the area under the curve. CONCLUSIONS: This naturalistic test of the HPA axis response to stress showed impaired HPA axis function in CFS.
Ross SD, Estok RP, Frame D, Stone LR, Ludensky V, Levine CB.	MetaWorks Inc, 10 President's Landing, Medford, MA 02155, USA.	Disability and chronic fatigue syndrome: a focus on function.	Arch Intern Med. 2004 May 24;164(10):1098-107.	BACKGROUND: Evidence was sought in the published literature on how best to measure, monitor, and treat disability in patients with chronic fatigue syndrome (CFS). METHODS: A systematic review was performed of English-language literature published between January 1, 1988, and November 15, 2001. Interventional and observational studies of adults with CFS were eligible if they reported measures of disability and employment. A qualitative synthesis of results relating impairment measures to employment was performed. RESULTS: Of 3840 studies identified, 37 reported employment status and some measure of mental or physical impairment associated with disability. Most patients with CFS in these studies were unemployed. In 22 studies, the employment status of control subjects was also

				available. Only depression seemed to be associated with unemployment in patients with CFS. No other measurable impairment seemed to be consistently associated with disability or work outcomes. Only cognitive behavior therapy, rehabilitation, and exercise therapy interventions were associated with restoring the ability to work. No specific patient characteristics were identified as best predictors of positive employment outcomes. No quantitative syntheses of results were performed. CONCLUSIONS: For questions of disability and employment in CFS, the limitations inherent in the current literature are extensive. Methodologically rigorous, longitudinal, and interventional studies are needed to determine baseline characteristics that are associated with the inability to work and interventions that are effective in restoring the ability to work in the CFS population. Simple and consistent evaluations of functional capacity in patients with CFS are needed.
Roy-Byrne P, Smith WR, Goldberg J, Afari N, Buchwald D.	Department of Psychiatry and Behavioral Science, University of Washington, Seattle, WA, USA.	Post-traumatic stress disorder among patients with chronic pain and chronic fatigue.	Psychol Med. 2004 Feb;34(2):363-8.	BACKGROUND: Fibromyalgia (FM), a chronic pain condition of unknown aetiology often develops following a traumatic event. FM has been associated with post-traumatic stress disorder (PTSD) and major depression disorder (MDD). METHOD: Patients seen in a referral clinic (N=571) were evaluated for FM and chronic fatigue syndrome (CFS) criteria. Patients completed questionnaires, and underwent a physical examination and a structured psychiatric evaluation. Critical components of the diagnostic criteria of FM (tender points and diffuse pain) and CFS (persistent debilitating fatigue and four of eight associated symptoms) were examined for their relationship with PTSD. RESULTS: The prevalence of lifetime PTSD was 20% and lifetime MDD was 42%. Patients who had both tender points and diffuse pain had a higher prevalence of PTSD (OR=3.4, 95% CI 2.0-5.8) compared with those who had neither of these FM criteria. Stratification by MDD and adjustment for sociodemographic factors and chronic fatigue revealed that the association of PTSD with FM criteria was confined to those with MDD. Patients with MDD who met both components of the FM criteria had a three-fold increase in the prevalence of PTSD (95% CI 1.5-7.1); conversely, FM patients without MDD showed no increase in PTSD (OR=1.3, 95% CI 0.5-3.2). The components of the CFS criteria were not significantly associated with PTSD. CONCLUSION: Optimal clinical care for patients with FM should include an assessment of trauma in general, and PTSD in particular. This study highlights the importance of considering co-morbid MDD as an effect modifier in analyses that explore PTSD in patients with FM. PMID: 14982142 [PubMed - in process]
Sackner MA, Gummels EM, Adams JA.	Mt. Sinai Medical Center of Greater Miami, Division of Pulmonary Disease and Critical Care Medicine, Miami Beach, FL 33140, USA. artchive@msn.com	Say NO to fibromyalgia and chronic fatigue syndrome: an alternative and complementary therapy to aerobic exercise.	Med Hypotheses. 2004;63(1):118-23.	Increased shear stress to the endothelium increases activity of endothelial nitric oxide synthase (eNOS) with subsequent release of small quantities (nMol) of nitric oxide (NO) into the circulation. It occurs during moderate aerobic exercise mostly as a result of laminar shear stress and with whole body, periodic acceleration as a result of pulsatile shear stress. The latter is administered by means of a new, non-invasive, passive exercise device. Moderate exercise has long been known to alleviate the symptoms of fibromyalgia and chronic fatigue syndrome and in the current study, whole body, periodic acceleration did as well. Since NO through action of eNOS has potent anti-inflammatory properties mainly by suppressing nuclear factor kappabeta activity, it is hypothesized that both diseases have chronic inflammation as their basis. Whole body periodic acceleration can be applied separately or supplementary to aerobic exercise in the treatment of fibromyalgia and chronic fatigue syndrome.
Schacterle RS,	Department of	A comparison of	Arch Intern Med.	BACKGROUND: Many women with chronic fatigue syndrome (CFS) fear that pregnancy will worsen

Komaroff AL.	Medicine, Brigham and Women's Hospital, Harvard Medical School, Boston, Massachasetts 02115, USA.	pregnancies that occur before and after the onset of chronic fatigue syndrome.	2004 Feb 23;164(4):401-4.	their condition, increase the risks of maternal complications of pregnancy, or threaten the health of their offspring. Little empirical evidence, however, has been published on this matter. METHODS: A detailed questionnaire was administered to 86 women regarding 252 pregnancies that occurred before or after the onset of CFS and the outcomes of these pregnancies were observed. RESULTS: During pregnancy, there was no change in CFS symptoms in 29 (41%), an improvement of symptoms in 21 (30%), and a worsening of symptoms in 20 (29%) of 70 subjects. After pregnancy, there was no change in CFS symptoms in 21 (30%), an improvement of symptoms in 14 (20%), and a worsening of symptoms in 35 (20%) of the subjects. The rates of many complications were similar in pregnancies occurring before the onset and in those occurring after the onset of CFS. There was a higher frequency of spontaneous abortions in the pregnancies occurring after, vs before, the onset of CFS (22 [30%] of 73 pregnancies after vs 13 [8%] of 171 before; P<.001), but no differences in the rates of other complications. Developmental delays or learning disabilities were reported more often in the offspring of women who became pregnant after, vs before, the onset of CFS (9 [21%] of 43 children vs 11 [8%] of 139 children; P =.01). CONCLUSIONS: Pregnancy did not consistently worsen the symptoms of CFS. Most maternal and infant outcomes were not systematically worse in pregnancies occurring after the onset of CFS. The higher rates of spontaneous abortions and of developmental delays in offspring that we observed could be explained by maternal age or parity differences, and should be investigated by larger, prospective studies with control populations.
Schacterle RS, Milford EL, Komaroff AL	Division of General Medicine and Primary Care, Brigham and Women's Hospital, and Harvard Medical School, Boston, MA, 02115, USA	The Frequency of HLA Class II Antigens in Chronic Fatigue Syndrome	Journal of Chronic Fatigue Syndrome 2004; Mar;11(4):33–42.	Chronic fatigue syndrome is a condition characterized by unexplained, persistent fatigue in conjunction with other generalized symptoms. However, the patients as a group are more likely to have objective abnormalities of the immune system than control subjects. We measured the frequency of certain HLA antigens in a representative group of 35 patients. We restricted our analysis to class II molecules as these appear to be more specific predictors of susceptibility to immunologicallybased disorders. The frequency of the HLA-DQ1 antigen was increased in patients compared to general population Caucasian controls. This association between chronic fatigue syndrome and the HLA-DQ1 antigen translates into a relative risk of 3.2. This association has not been reported previously in chronic fatigue syndrome. Differences in the ethnic sub-grouping of patients in this study and in previous studies also could have contributed to the difference between our findings and those of previous investigators. Conversely, this study did not find HLA associations that have been reported by previous studies. The sample size of this study could have led to type II statistical errors and a failure to recognize certain HLA associations as significant.
Schillings ML, Kalkman JS, van der Werf SP, van Engelen BG, Bleijenberg G, Zwarts MJ.	Department of Clinical Neurophysiology, University Medical Centre Nijmegen, Internal postal code 314, P.O. Box 9101, 6500 HB Nijmegen,	Diminished central activation during maximal voluntary contraction in chronic fatigue syndrome.	Clin Neurophysiol. 2004 Nov;115(11):2518-24.	OBJECTIVE: We have investigated whether central activation failure (CAF) is increased during local muscle fatigue in chronic fatigue syndrome (CFS). METHODS: Fourteen female CFS patients and 14 age-matched healthy female controls made a 2 min sustained maximal voluntary contraction (MVC) of the biceps brachii muscle. Before, during, and after sustained MVC, electrical endplate stimulation was applied. Force and 5 channel surface EMG (sEMG) were registered. RESULTS: Although force responses upon stimulation during rest did not differ between patients and controls, MVC was significantly lower in patients. Already at the beginning of sustained MVC, CFS patients showed significantly larger CAF than controls (36.5+/-17.0% and 12.9+/-13.3%, respectively). For all individual patients mean CAF over the first 45 s was higher than 30%, while it was below 30% for all controls.

	Netherlands.			Less peripheral fatigue in patients was demonstrated by the changes in muscle fibre conduction velocity and the differences between force responses before and after contraction. CONCLUSIONS: Central activation is diminished in CFS patients. Possible causes include changed perception, impaired concentration, reduced effort and physiologically defined changes, e.g. in the corticospinal excitability or the concentration of neurotransmitters. As a consequence, demands on the muscle are lower, resulting in less peripheral fatigue. SIGNIFICANCE: CFS patients show reduced central activation during MVC. The underlying pathophysiological processes remain still to be determined.

Severens JL, Prins JB, van der Wilt GJ, van der Meer JW, Bleijenberg G.	Department of Medical Technology Assessment, University Medical Centre Nijmegen, The Netherlands. h.severens@boez.unimaas.nl	Cost-effectiveness of cognitive behaviour therapy for patients with chronic fatigue syndrome.	QJM. 2004 Mar;97(3):153-61.	BACKGROUND: There is some evidence that cognitive behaviour therapy (CBT) is efficacious in chronic fatigue syndrome (CFS), but little data on its cost-effectiveness. DESIGN: Prospective economic analysis alongside a randomized clinical trial. METHODS: CFS patients were randomly assigned to CBT, guided support groups (SG), or the 'natural course' (NC, no protocol-based interventions). Patients were treated for 8 months and followed-up for another 6 months. Costs per patient showing clinically significant improvement, based on the CIS fatigue scale, and costs per quality-adjusted life year, were determined for a time period of 14 months. RESULTS: Data were available for 171 patients at 8 months and for 128 at 14 months. At 8 and 14 months, the percentages of improved patients were 31% and 27% for CBT, 9% and 11% for SG, and 12% and 20% for NC. Mean QALYs gained at 14 months were, for CBT, SG and NC, respectively, 0.0737, -0.0018 and 0.0458. CBT and SG mean treatment costs were euro1490 and euro424. Other medical costs for CBT, SG, and NC, respectively, were euro324, euro623 and euro412 for the first period, and euro232, euro561 and euro378 for the second period. Non-medical costs for these periods for CBT, SG and NC were euro262, euro550, euro427 and euro226, euro439, euro287, respectively. Productivity costs were considerable, but not significantly different between groups. DISCUSSION: CBT was less costly and more effective than SG. Compared to NC, the baseline incremental cost-effectiveness of CBT was euro20 516 per CFS patient showing clinically significant improvement, and euro21 375 per QALY. The bootstrap ratios showed considerable uncertainty regarding the results. Future research should focus on productivity costs, and follow patients prospectively over a longer period.

Shin HY, An NH, Cha YJ, Shin EJ, Shin TY, Baek SH, Kim CH, Lyu YS, Lee EJ, Kim HM.	Department of Pharmacology, College of Oriental Medicine, Kyung Hee University, Seoul, South Korea.	Effect of Kuibitang on lipopolysaccharide-induced cytokine production in peripheral blood mononuclear cells of chronic fatigue syndrome patients.	J Ethnopharmacol. 2004 Feb;90(2-3):253-9.	Kuibitang (KBT) is clinically used to treat patients suffering from chronic fatigue syndrome (CFS) in South Korea. However, its effect has not been investigated experimentally. Recent reports have shown that CFS patients display an altered cytokine production. We examined the effect of KBT on lipopolysaccharide (LPS)-induced various cytokines production in peripheral blood mononuclear cells (PBMC) of CFS patients and healthy controls. KBT (1 mg/ml) significantly inhibited LPS-induced tumor necrosis factor-alpha, interleukin-10, and transforming growth factor-beta1 production in PBMC of CFS patients. However, LPS-induced interferon-gamma production was significantly increased by KBT (0.01 mg/ml). These results provide evidence of a novel activity of the KBT that regulate cytokines production related with CFS.
Siemionow V, Fang Y, Calabrese L, Sahgal V, Yue GH.	Department of Biomedical Engineering, The Lerner Research Institute, The Cleveland Clinic Foundation, 9500 Euclid Avenue, Cleveland, OH 44195, USA.	Altered central nervous system signal during motor performance in chronic fatigue syndrome.	Clin Neurophysiol. 2004 Oct;115(10):2372-81.	OBJECTIVE: The purpose of this study was to determine whether brain activity of chronic fatigue syndrome (CFS) patients during voluntary motor actions differs from that of healthy individuals. METHODS: Eight CFS patients and 8 age- and gender-matched healthy volunteers performed isometric handgrip contractions at 50% maximal voluntary contraction level. They first performed 50 contractions with a 10 s rest between adjacent trials--'Non-Fatigue' (NFT) task. Subsequently, the same number of contractions was performed with only a 5 s rest between trials--'Fatigue' (FT) task. Fifty-eight channels of surface EEG were recorded simultaneously from the scalp. Spectrum analysis was performed to estimate power of EEG frequency in different tasks. Motor activity-related cortical potential (MRCP) was derived by triggered averaging of EEG signals associated with the muscle contractions. RESULTS: Major findings include: (i) Motor performance of the CFS patients was poorer than the controls. (ii) Relative power of EEG theta frequency band (4-8 Hz) during performing the NFT and FT tasks was significantly greater in the CFS than control group ($P < 0.05$). (iii) The amplitude of MRCP negative potential (NP) for the combined NFT and FT tasks was higher in the CFS than control group ($P < 0.05$) (iv) Within the CFS group, the NP was greater for the FT than NFT task ($P<0.01$), whereas no such difference between the two tasks was found in the control group. CONCLUSIONS: These results clearly show that CFS involves altered central nervous system signals in controlling voluntary muscle activities, especially when the activities induce fatigue. SIGNIFICANCE: Physical activity-induced EEG signal changes may serve as physiological markers for more objective diagnosis of CFS.

Skapinakis P, Lewis G, Mavreas V.	Department of Psychiatry, University of Ioannina, School of Medicine, Greece. pskapin@cc.uoi.gr	Temporal relations between unexplained fatigue and depression: longitudinal data from an international study in primary care.	Psychosom Med. 2004 May-Jun;66(3):330-5.	OBJECTIVE: Unexplained fatigue syndromes, such as chronic fatigue syndrome and neurasthenia, are strongly associated with depression, but the temporal nature of this association is not clear. METHODS: The authors examined this issue by using data from the World Health Organization collaborative study of psychological problems in general health care. Three thousand two hundred one subjects from 15 primary care centers in 14 countries were followed up for 12 months. The Composite International Diagnostic Interview was the main instrument used. Odds ratios and their 95% confidence intervals (CI) were calculated using logistic regression models adjusted for sociodemographic variables, physical morbidity and intercenter variability. RESULTS: Cases of depression were found to have an increased risk of developing a new episode of unexplained fatigue at follow-up with an adjusted odds ratio of 4.15 (95% CI = 2.64-6.54). Similarly, cases of unexplained fatigue were found to have an increased risk of developing a new episode of depression at follow-up with an adjusted odds ratio of 2.76 (95% CI = 1.32-5.78). Further adjustment for subthreshold symptoms at baseline weakened the reported associations, especially between fatigue and development of a new episode of depression, but these remained significant. CONCLUSIONS: The findings support the view that unexplained fatigue and depression might act as independent risk factors for each other.
Skowera A, Cleare A, Blair D, Bevis L, Wessely SC, Peakman M.	Department of Immunology, Guy's, King's & St Thomas's School of Medicine, King's College London, London, UK.	High levels of type 2 cytokine-producing cells in chronic fatigue syndrome.	Clin Exp Immunol. 2004 Feb;135(2):294-302.	The aetiology of chronic fatigue syndrome (CFS) is not known. However, it has been suggested that CFS may be associated with underlying immune activation resulting in a Th2-type response. We measured intracellular production of interferon (IFN)-gamma and interleukin (IL)-2; type 1 cytokines), IL-4 (type 2) and IL-10 (regulatory) by both polyclonally stimulated and non-stimulated CD4 and CD8 lymphocytes from patients with CFS and control subjects by flow cytometry. After polyclonal activation we found evidence of a significant bias towards Th2- and Tc2-type immune responses in CFS compared to controls. In contrast, levels of IFN-gamma, IL-2 and IL-10-producing cells were similar in both study groups. Non-stimulated cultures revealed significantly higher levels of T cells producing IFN-gamma or IL-4 in CFS patients. Concluding, we show evidence for an effector memory cell bias towards type 2 responsiveness in patients with CFS, as well as ongoing type 0 immune activation in unstimulated cultures of peripheral blood cells.
Smith MS.		Adolescent chronic fatigue syndrome. Comment on: Arch Pediatr Adolesc Med. 2004 Mar;158(3):225-9.	Arch Pediatr Adolesc Med. 2004 Mar;158(3):207-8.	
Solomon L, Reeves WC.	Division of Viral and Rickettsial Diseases, National Center for Infectious Diseases, Centers for Disease Control	Factors influencing the diagnosis of chronic fatigue syndrome.	Arch Intern Med. 2004 Nov 8;164(20):2241-5.	BACKGROUND: Most of what is believed about chronic fatigue syndrome (CFS) is based on clinic-based studies. These studies may not reflect CFS cases in the population. METHODS: We used data from a population-based study of CFS to identify factors associated with receiving a CFS diagnosis. Wichita, Kan, residents were screened by random-digit dialing. Eligible individuals completed a telephone interview. Respondents meeting CFS criteria were invited for a clinical evaluation to confirm CFS. We analyzed all persons with confirmed CFS. The main outcomes of this study, prevalence and incidence of CFS, are published elsewhere. Herein, we present an exploratory analysis with previous CFS

	and Prevention, Atlanta, GA 30333, USA.			diagnosis as the outcome, predicted by demographic and symptom characteristics. RESULTS: We confirmed CFS in 90 subjects; 14 (16%) had been previously diagnosed as having CFS. Persons in the middle- vs the higher-income group were more likely to have been diagnosed as having CFS (9 [29%] of 31 subjects vs 3 [8%] of 39 subjects; P = .03), as were those with sudden vs gradual fatigue onset (7 [41%] of 17 subjects vs 4 [6%] of 64 subjects; P < .01), those reporting tender lymph nodes (7 [33%] of 21 subjects vs 7 [10%] of 69 subjects; P = .02), and those reporting a sore throat (6 [35%] of 17 subjects vs 8 [11%] of 73 subjects; P = .02). Only 17 (21%) of 81 subjects had sudden fatigue onset, and tender lymph nodes (reported in 21 [23%] of 90 subjects) and a sore throat (reported in 17 [19%] of 90 subjects) were the least common symptoms. CONCLUSION: Most cases of CFS in the population are unrecognized by the medical community; persons diagnosed as having CFS may be different from persons with CFS in the general population.
Spence VA, Khan F, Kennedy G, Abbot NC, Belch JJ.	Vascular Diseases Research Unit, University Department of Medicine, Ninewells Hospital & Medical School, Dundee DD1 9SY, UK.	Acetylcholine mediated vasodilatation in the microcirculation of patients with chronic fatigue syndrome.	Prostaglandins Leukot Essent Fatty Acids. 2004 Apr;70(4):403-7.	The aetiology of chronic fatigue syndrome (CFS) remains controversial and a number of hypotheses have been put forward to explain it. Research into the condition is hindered by the considerable heterogeneity seen across patients but several reports have highlighted disturbances to cholinergic mechanisms in terms of central nervous system activity, neuromuscular function and autoantibodies to muscarinic cholinergic receptors. This paper examines an altogether separate function for acetylcholine and that is its role as an important and generalized vasodilator. Most diseases are accompanied by a blunted response to acetylcholine but the opposite is true for CFS. Such sensitivity is normally associated with physical training so the finding in CFS is anomalous and may well be relevant to vascular symptoms that characterise many patients. There are several mechanisms that might lead to ACh endothelial sensitivity in CFS patients and various experiments have been designed to unravel the enigma. These are reported here.
Staines DR.	Gold Coast Public Health Unit, 10-12 Young Street, Southport, Qld. 4215, Australia.	Is gulf war syndrome an autoimmune disorder of endogenous neuropeptides, exogenous sandfly maxadilan and molecular mimicry?	Med Hypotheses. 2004;62(5):658-64.	Gulf war syndrome (GWS) remains a contentious diagnosis with conflicting laboratory investigation and lack of a biologically plausible aetiology. This paper discusses the potential role of maxadilan, a potent sandfly vasoactive peptide, in causing autoimmune responses in susceptible individuals through possible molecular mimicry with pituitary adenylate cyclase activating polypeptide (PACAP) and the PAC1R receptor. Gulf war syndrome may share some causative pathology with Chronic Fatigue Syndrome (CFS), a disorder characterised by prolonged fatigue and debility mostly associated with post-infection sequelae although ongoing infection is unproven. Immunological aberration associated with an expanding group of vasoactive neuropeptides in the context of molecular mimicry and inappropriate immunological memory has been recently raised as possible cause of CFS. Vasoactive neuropeptides act as hormones, neurotransmitters, immune modulators and neurotrophes. They are readily catalysed to small peptide fragments. They and their binding sites are immunogenic and are known to be associated with a range of autoimmune conditions. Maxadilan, while not sharing substantial sequence homology with PACAP is a known agonist of the PACAP specific receptor (PAC1R) and therefore emulates these functions. Moreover a specific amino acid sequence peptide deletion within maxadilan converts it to a PACAP receptor antagonist raising the possibility of this substance provoking a CFS like response in humans exposed to it. This paper describes a biologically plausible mechanism for the development of a GWS-like chronic fatigue state based on loss of immunological tolerance to the vasoactive neuropeptide PACAP or its receptor following bites

				of the sandfly Phlebotomus papatasi and injection of the vasodilator peptide maxadilan. Exacerbation of this autoimmune response as a consequence of recent or simultaneous multiple vaccination exposures deserves further investigation. While the possible association between the relatively recently discovered vasoactive neuropeptides and chronic fatigue conditions has only recently been reported in the literature, this paper explores links for further research into GWS and CFS.
Staines DR.	Gold Coast Public Health Unit, 10-12 Young Street, Southport 4215, Qld, Australia.	Is chronic fatigue syndrome an autoimmune disorder of endogenous neuropeptides, exogenous infection and molecular mimicry?	Med Hypotheses. 2004;62(5):646-52.	Chronic fatigue syndrome is a disorder characterised by prolonged fatigue and debility and is mostly associated with post-infection sequelae although ongoing infection is unproven. Immunological aberration is likely and this may prove to be associated with an expanding group of vasoactive neuropeptides in the context of molecular mimicry and inappropriate immunological memory. Vasoactive neuropeptides including vasoactive intestinal peptide (VIP) and pituitary adenylate activating polypeptide (PACAP) belong to the secretin/glucagon superfamily and act as hormones, neurotransmitters, immune modulators and neurotrophes. They are readily catalysed to smaller peptide fragments by antibody hydrolysis. They and their binding sites are immunogenic and are known to be associated with a range of autoimmune conditions. Vasoactive neuropeptides are widely distributed in the body particularly in the central, autonomic and peripheral nervous systems and have been identified in the gut, adrenal gland, reproductive organs, vasculature, blood cells and other tissues. They have a vital role in maintaining vascular flow in organs, and in thermoregulation, memory and concentration. They are co-transmitters for acetylcholine, nitric oxide, endogenous opioids and insulin, are potent immune regulators with primarily anti-inflammatory activity, and have a significant role in protection of the nervous system to toxic assault, promotion of neural development and the maintenance of homeostasis. This paper describes a biologically plausible mechanism for the development of CFS based on loss of immunological tolerance to the vasoactive neuropeptides following infection, significant physical exercise or de novo. It is proposed that release of these substances is accompanied by a loss of tolerance either to them or their receptor binding sites in CFS. Such an occurrence would have predictably serious consequences resulting from compromised function of the key roles these substances perform. All documented symptoms of CFS are explained by vasoactive neuropeptide compromise, namely fatigue and nervous system dysfunction through impaired acetylcholine activity, myalgia through nitric oxide and endogenous opioid dysfunction, chemical sensitivity through peroxynitrite and adenosine dysfunction, and immunological disturbance through changes in immune modulation. Perverse immunological memory established against these substances or their receptors may be the reason for the protracted nature of this condition. The novel status of these substances together with their extremely small concentrations in blood and tissues means that clinical research into them is still in its infancy. A biologically plausible theory of CFS causation associated with vasoactive neuropeptide dysfunction would promote a coherent and systematic approach to research into this and other possibly associated disabling conditions.
Staud R.		Abnormal Pain Processing in Patients with Fibromyalgia	Journal of Chronic Fatigue Syndrome 2004; 12(1):71–77.	Fibromyalgia syndrome (FMS) is characterized by widespread pain, fatigue, sleep abnormalities, and distress. Because FMS lacks consistent evidence for tissue abnormalities, recent investigations have focused on central nervous system mechanisms of pain. Abnormal temporal summation of second pain (AWindup@) and central sensitization (CS) have recently been described in FMS patients. Windup

		Syndrome		(WU) and central sensitization, which rely on central pain mechanisms, occur after prolonged C-nociceptor input and depend on activation of nociceptor specific neurons as well as wide dynamic range neurons in the dorsal horn of the spinal cord. The important role of WU is also supported by its ability to predict the clinical pain intensity of FMS patients. Furthermore, brain-imaging techniques that can detect neuronal activation following nociceptive stimuli have provided additional evidence for abnormal central pain mechanisms in FMS. Most importantly, brain images have corroborated the augmented reported pain experience of FMS patients during experimental pain stimuli. These findings may have important implications for future research as well as the treatment of FMS pain.
Steinau M, Unger ER, Vernon SD, Jones JF, Rajeevan MS.	Division of Viral and Rickettsial Diseases, National Center for Infectious Diseases, Centers for Disease Control and Prevention, 1600 Clifton Rd., MSG-41, Atlanta, GA 30333, USA.	Differential-display PCR of peripheral blood for biomarker discovery in chronic fatigue syndrome.	J Mol Med. 2004 Nov;82(11):750-5. Epub 2004 Nov.	We used differential-display PCR of peripheral blood mononuclear cells (PBMCs) to search for candidate biomarkers for chronic fatigue syndrome (CFS). PBMCs were collected from a subject with CFS and an age- and sex-matched control before and 24 h after exercise. RNA expression profiles were generated using 46 primer combinations, and the similarity between the individuals was striking. Differentially expressed bands were excised, reamplified, and sequenced, yielding 95 nonredundant sequences, of which 50 matched to known gene transcripts, 38 matched to genes with unknown functions, and 7 had no similarity to any database entry. Most (86%) of the differences between the two subjects were present at baseline. Differential expression of ten genes was verified by real-time reverse-transcription PCR: five (cystatin F, MHC class II, platelet factor 4, fetal brain expressed sequence tag, and perforin) were downregulated, and the remaining five genes (cathepsin B, DNA polymerase epsilon4, novel EST PBMC191MSt, heparanase precursor, and ORF2/L1 element) were upregulated in the subject with CFS. Many of these genes have known functions in defense and immunity, thus supporting prior suggestions of immune dysregulation in the pathogenesis of CFS. Differential-display PCR is a powerful tool for identification of candidate biomarkers. Investigation of these markers in samples from well-designed epidemiological studies of CFS will be required to determine the validity of these candidate biomarkers. The real-time reverse-transcription PCR assays that we developed for assay of these biomarkers will facilitate high-throughput testing of these additional samples.

Suhadolnik RG, Peterson DL, Reichenbach NL, Roen G, Metzger M, McCahan J, O'Brien K, Welsch S, Gabriel J, Gaughan JP, McGregor NR.		Clinical and Biochemical Characteristics Differentiating Chronic Fatique Syndrome from Major Depression and Healthy Control Populations: Relation to Dysfunction and RNase L Pathway	Journal of Chronic Fatigue Syndrome 2004; 12(1):5–35.	Patterns of immune dysfunction have emerged in chronic fatigue syndrome (CFS) that include an immune activation state (evidenced by increased activated T lymphocytes and circulating cytokines) and poor cellular function (low natural killer (NK) cell cytotoxicity and impaired T lymphocyte response to mitogens). Therefore, the aim of the current study was to examine the relationship between clinical and functional characteristics, immune abnormalities and status of the RNase L pathway in CFS compared with healthy control and depression control populations. All study participants were assessed with respect to their general health, functional status, blood count and chemistry, biochemical and immune parameters. The CFS group (N = 66) demonstrated clinical, functional and biochemical abnormalities distinct from the healthy (N = 62) and depression (N = 51) control groups. The CFS group showed marked functional impairment compared with both control groups (P < .001) as measured by the Medical Outcomes Study 36-Item Short Form Health Survey (SF-36) (P < .001). The CFS group also showed decreased cognitive performance on a computerized test battery compared to healthy (P < .001) and depression controls (P < .009) and significantly higher 37/80 kDa RNase L ratio (P < .001) compared with both control groups. The odds ratios of a 37/80 kDa RNase L ratio > 2 compared with the CFS patients were 3.9 for the healthy controls (95% confidence limit (CL) 1.0-15.2, P < .05) and 65.8 for the depression controls (95% CL 10.7-406.6, P < .001). The CFS group demonstrated low NK cell cytotoxicity compared to healthy controls (P = .045). The correlation between abnormalities in the RNase L pathway and impaired NKcell function (r = .21, P < .006) suggests that both may be part of the same underlying disease mechanism, at least in this homogeneous population of very disabled CFS patients. Healthy contact-control subjects who had exposure to CFS patients showed a number of characteristics similar to the CFS patients, including an increased mean 37/80 kDa RNase L ratio (P < .04) and prevalence of the 37/80 kDa RNase L ratio > 2 (P < .03). In these contact-control subjects, the 37/80 kDa RNase L ratio was correlated with the interferon-á levels (r = .58, P < .02), suggestive of activation of the interferon pathway. The results of the present study support the cytokine/immune activation model in this well-characterized CFS

				patient group.
Taylor RR, Braveman B, Hammel J.	Department of Occupational Therapy (MC 811), College of Applied Health Sciences, University of Illinois at Chicago, 1919 West Taylor Street, 3rd Floor, Chicago, Illinois 60612-7250, USA. rtaylor@uic.edu	Developing and evaluating community-based services through participatory action research: two case examples.	Am J Occup Ther. 2004 Jan-Feb;58(1):73-82.	Occupational therapy has a strong history of embracing concepts of client empowerment. However there is limited literature in the field on how to achieve empowerment, or on how to extend empowerment to the level of the community and social groups and services within it. This article discusses how concepts and strategies of participatory action research, an extension of empowerment theory, can be used to inform service development and evaluation in occupational therapy. The participatory action research approach is illustrated using two case examples of participatory action research programs for persons with chronic fatigue syndrome and individuals with autoimmune deficiency syndrome (AIDS). A critical analysis of the application of this approach to research and practice is provided. Finally, the paper identifies key principles of participatory action research that can be used to guide occupational therapy services and empower both individuals and communities.
Taylor RR.	University of Illinois at Chicago, Department of Occupational Therapy (MC 811), College of Applied Health Sciences, 1919 West Taylor Street, 3rd Floor, Chicago, Illinois 60612-7250, USA. rtaylor@uic.edu	Quality of life and symptom severity for individuals with chronic fatigue syndrome: findings from a randomized clinical trial.	Am J Occup Ther. 2004 Jan-Feb;58(1):35-43.	OBJECTIVE: Chronic fatigue syndrome is a profoundly disabling condition characterized by severe, unrelenting fatigue and a number of other physical and cognitive symptoms. Currently, there is no cure or widely accepted treatment for chronic fatigue syndrome, and few rehabilitation programs exist to address quality of life issues in chronic fatigue syndrome. In the present randomized clinical trial, the effects of an integrative, consumer-driven rehabilitation program on quality of life and symptom severity for individuals with chronic fatigue syndrome were examined. METHOD: Forty-seven participants were randomly assigned to either an immediate program group (n = 23) or a delayed program control group (n = 24) and assessed with the Chronic Fatigue Syndrome Symptom Rating Scale and the Quality of Life Index before the program, after program participants completed the group phase, and after program participants completed the one-on-one phase. It was hypothesized that the program would lead to improvements in quality of life and an overall reduction in symptom severity. RESULTS: Linear growth models were estimated comparing program and control conditions over time using random-effects regression analyses. Significant condition by time interactions were observed for the main outcomes of symptom severity and overall quality of life. Effect sizes for these interactions involving symptom severity (Cohen's d = 0.71) and overall quality of life (Cohen's d = .66) were moderate. CONCLUSIONS: Findings indicate that consumer driven programs such as this one can have a positive impact on symptom severity and quality of life over time for individuals with chronic fatigue syndrome.
Tomassini V, Pozzilli C, Onesti E, Pasqualetti P, Marinelli F, Pisani A, Fieschi C.	Department of Neurological Sciences, University of Rome "La Sapienza", viale dell' Universita 30, Rome 00185, Italy.	Comparison of the effects of acetyl L-carnitine and amantadine for the treatment of fatigue in multiple sclerosis: results of a pilot, randomised,	J Neurol Sci. 2004 Mar 15;218(1-2):103-8.	Treatment with acetyl L-carnitine (ALCAR) has been shown to improve fatigue in patients with chronic fatigue syndrome, but there have been no trials on the effect of ALCAR for treating fatigue in multiple sclerosis (MS). To compare the efficacy of ALCAR with that of amantadine, one of the drugs most widely used to treat MS-related fatigue, 36 MS patients presenting fatigue were enrolled in a randomised, double-blind, crossover study. Patients were treated for 3 months with either amantadine (100 mg twice daily) or ALCAR (1 g twice daily). After a 3-month washout period, they crossed over to the alternative treatment for 3 months. Patients were rated at baseline and every 3 months according to the Fatigue Severity Scale (FSS), the primary endpoint of the study. Secondary outcome variables were: Fatigue Impact Scale (FIS), Beck Depression Inventory (BDI) and Social

		double-blind, crossover trial.		Experience Checklist (SEC). Six patients withdrew from the study because of adverse reactions (five on amantadine and one on ALCAR). Statistical analysis showed significant effects of ALCAR compared with amantadine for the Fatigue Severity Scale (p = 0.039). There were no significant effects for any of the secondary outcome variables. The results of this study show that ALCAR is better tolerated and more effective than amantadine for the treatment of MS-related fatigue.
Torpy DJ, Bachmann AW, Gartside M, Grice JE, Harris JM, Clifton P, Easteal S, Jackson RV, Whitworth JA.	University of Queensland Department of Medicine, Greenslopes Hospital, Brisbane, Queensland, Australia. dtorpy@mail.rah.sa.gov.au	Association between chronic fatigue syndrome and the corticosteroid-binding globulin gene ALA SER224 polymorphism.	Endocr Res. 2004 Aug;30(3):417-29.	Chronic fatigue syndrome (CFS) is characterized by idiopathic fatigue of greater than 6 months' duration with postexertional exacerbation and many other symptoms. A trend toward relative hypocortisolism is described in CFS. Twin and family studies indicate a substantial genetic etiologic component to CFS. Recently, severe corticosteroid-binding globulin (CBG) gene mutations have been associated with CFS in isolated kindreds. Human leukocyte elastase, an enzyme important in CBG catabolism at inflammatory sites, is reported to be elevated in CFS. We hypothesized that CBG gene polymorphisms may act as a genetic risk factor for CFS. A total of 248 patients with CFS defined by Centers for Disease Control criteria, and 248 controls were recruited. Sequencing and restriction enzyme testing of the CBG gene coding region allowed detection of severe CBG gene mutations and a common exon 3 polymorphism (c.825G-->T, Ala-Ser224). Plasma CBG levels were measured in 125 CFS patients and 198 controls by radioimmunoassay. Total and free (calculated and measured) cortisol levels were ascertained in single samples between 8-10 a.m. The age of onset (mid 30s) and gender ratio (2.2:1, female:male) of the patients were similar to those reported in U.S. epidemiologic studies. A trend toward a preponderance of serine224 homozygosity among the CFS patients was noted, compared with controls (chi2 = 5.31, P = 0.07). Immunoreactive-CBG (IR-CBG) levels were higher in Serine/Alanine (Ser/Ala) than Ala/Ala subjects and higher again in Ser/Ser subjects, this effect was strongest in controls; Ser/Ser: 46.1+/-1.8 (n = 31, P = 0.03) vs. Ser/Ala: 42.4+/-1.0 (n = 56, P = 0.05) vs. Ala/Ala: 40.8+/-1.7 microg/mL (n = 21). Despite higher CBG levels, there was a nonsignificant trend toward lower total and free plasma cortisol in serine allele positive patients, total cortisol: Ser/Ser: 13.3+/-1.4 (n = 34) vs. Ser/Ala: 14.0+/-0.7 (n = 66) vs. Ala/Ala: 15.4+/-1.0 (n = 23). Homozygosity for the serine allele of the CBG gene may predispose to CFS, perhaps due to an effect on hypothalamic-pituitary-adrenal axis function related to altered CBG-cortisol transport function or immune-cortisol interactions.
Tritt K, Nickel M, Mitterlehner F, Nickel C, Forthuber P, Leiberich P, Rother W, Loew T.	Section of Psychosomatic Medicine, University Clinic of the University Regensburg, Regensburg, Germany.	Chronic fatigue and indicators of long-term employment disability in psychosomatic inpatients.	Wien Klin Wochenschr. 2004 Mar 31;116(5-6):182-9.	The major goal of this study was to determine indictors of long-term disability for psychosomatic inpatients with chronic fatigue syndrome. To this end, a cross-sectional study was performed with a random sample of patients (n=1000, response rate: 83.9%) at a psychosomatic inpatient clinic. 51.1% of the patients (n=429) reported intensely persistent exhaustion that had no logical relation to actual exertion. 159 (37.1%) patients in this group were disabled from working and these comprised the main target group of this study. Significantly more patients in the target group worked part time, were disabled for a disproportionately long period of time (50.9% of all were disabled for more than 6 months in the previous year), and felt stressed because of conflicts with their superiors and/or colleagues (in each case, P<0.01). While more frequent psychological comorbidity was not found, they reported physical complaints more often. It was not the patients fit for work who felt more burdened with chronic fatigue, but rather the employment-disabled, who were actually exposed to fewer demands. These patients had, in comparison with those fit to work, a stronger fixation on somatic

				complaints, inadequate perception of physical and psychic sensations, difficulties getting along with other people and in coping with a regular job (in each case, P<0.01). Prospective examination of these indicators could help detect predictor variables for long-term disability in chronic fatigue. Such predictors could contribute to timely social-medical assessment and treatment.
Tryon WW, Jason L, Frankenberry E, Torres-Harding S.	Department of Psychology, Fordham University, 441 East Fordham Road, Bronx, NY 10458-5198, USA. wtryon@fordham.edu	Chronic fatigue syndrome impairs circadian rhythm of activity level.	Physiol Behav. 2004 Oct 15;82(5):849-53.	Some of the symptoms of chronic fatigue syndrome (CFS) are the same as for disrupted circadian rhythm. Activity level is frequently used to study circadian rhythm. Continuous waist activity measurements taken every minute 24 h/day for from 5 to 7 days in 10 controls and from 2 to 7 days in 8 patients with CFS yielded two primary findings: (a) lower daytime activity and (b) less regular activity-rest cycles in persons with CFS than in controls.
Turkington D, Hedwat D, Rider I, Young AH.	Royal Victoria Infirmary, Newcastle upon Tyne, UK.	Recovery from chronic fatigue syndrome with modafinil.	Hum Psychopharmacol. 2004 Jan;19(1):63-4.	PMID: 14716715 [PubMed - in process]
Unger ER, Nisenbaum R, Moldofsky H, Cesta A, Sammut C, Reyes M, Reeves WC.		Sleep assessment in a population-based study of chronic fatigue syndrome.	BMC Neurol. 2004 Apr 19;4(1):6.	Background Chronic fatigue syndrome (CFS) is a disabling condition that affects approximately 800,000 adult Americans. The pathophysiology remains unknown and there are no diagnostic markers or characteristic physical signs or laboratory abnormalities. Most CFS patients complain of unrefreshing sleep and many of the postulated etiologies of CFS affect sleep. Conversely, many sleep disorders present similarly to CFS. Few studies characterizing sleep in unselected CFS subjects have been published and none have been performed in cases identified from population-based studies. Methods. The study included 339 subjects (mean age 45.8 years, 77% female, 94.1% white) identified through telephone screen in a previously described population-based study of CFS in Wichita, Kansas. They completed questionnaires to assess fatigue and wellness and 2 self-administered sleep questionnaires. Scores for five of the six sleep factors (insomnia/hypersomnia, non-restorative sleep, excessive daytime somnolence, sleep apnea, and restlessness) in the Centre for Sleep and Chronobiology's Sleep Assessment Questionnaire(c) (SAQ(c)) were dichotomized based on threshold. The Epworth Sleepiness Scale score was used as a continuous variable. Results. 81.4% of subjects had an abnormality in at least one SAQ(c) sleep factor. Subjects with sleep factor abnormalities had significantly lower wellness scores but statistically unchanged fatigue severity scores compared to those without SAQ(c) abnormality. CFS subjects had significantly increased risk of abnormal scores in the non-restorative (adjusted odds ratio [OR] = 28.1; 95% confidence interval [CI]= 7.4-107.0) and restlessness (OR = 16.0; 95% CI = 4.2-61.6) SAQ(c) factors compared to non-fatigued, but not for factors of sleep apnea or excessive daytime somnolence. This is consistent with studies finding that, while fatigued, CFS subjects are not sleepy. A strong correlation (0.78) of Epworth score was found only for the excessive daytime somnolence factor. Conclusions. SAQ(c) factors describe sleep abnormalities associated with CFS and provide more information than the Epworth score. Validation of these promising results will require formal polysomnographic sleep studies.

Van Engelen BG, Kalkman JS, Schillings ML, Van Der Werf SP, Bleijenberg G, Zwarts MJ.	Neuromusculair Centrum Nijmegen, Instituut voor Neurologie, Universitair Medisch Centrum St Radboud, Postbus 9101, 6500 HB Nijmegen.	[Fatigue in neuromuscular disease] [Article in Dutch]	Ned Tijdschr Geneeskd. 2004 Jul 3;148(27):1336-41.	Chronic fatigue is a symptom of diseases such as cancer, multiple sclerosis, Parkinson's and cerebrovascular disease. Fatigue can also be present in people with no demonstrable somatic disease. If certain criteria are met, chronic-fatigue syndrome may be diagnosed in these cases. Fatigue is a multi-dimensional concept with physiological and psychological dimensions. The 'Short Fatigue Questionnaire' consisting of 4 questions is a tool to measure fatigue with a high degree of reliability and validity. Within the group of neuromuscular disorders, fatigue has been reported by patients with post-polio syndrome, myasthenia gravis, and Guillain-Barre syndrome. The percentage of neuromuscular patients suffering from severe fatigue (64%) is comparable with that of patients with multiple sclerosis, a disease in which fatigue is an acknowledged symptom. Now that reliable psychological and clinical neurophysiological techniques are available, a multidisciplinary approach to fatigue in patients with well-defined neuromuscular disorders may contribute towards the elucidation of the pathophysiological mechanisms of chronic fatigue, with the ultimate goal being to develop methods of treatment for fatigue in neuromuscular patients.
Van Hoof Elke Clin Psych		Article: Cognitive Behavioural Therapy as Cure-All for CFS	Journal of Chronic Fatigue Syndrome 2004 11 (4): 43 - 47	
Van Hoof E, Coomans D, Cluydts R, De Meirleir K.		The Fennell Phase Inventory in a Belgian Sample	Journal of Chronic Fatigue Syndrome 2004; 12(1):53–69.	The present study is a follow-up of the research conducted by Jason, Fennell et al. (1995, 1999, 2000) on a multistage theory for chronic fatigue syndrome (CFS). This multistage model is a very promising method for the evaluation of patients suffering from CFS and could facilitate the appropriate selection of various psychosocial therapies that improve the patient's ability to cope with their illness. Four predictive factors emerged with moderate to excellent reliability. A Spearman's rank correlation revealed positive correlations between our four-factor model and the three-factor model identified by Jason et al. (1999). A correlation matrix between the dimensional psychological investigation and the Fennell Phases revealed characteristics as suggested by previous research. Biological parameters varied over the different phases suggesting an important interaction between body and psyche.
Van Houdenhove B, Egle UT.	Faculty of Medicine, K.U.Leuven, Leuven, Belgium. boudewijn.vanhoudenhove@uz.kuleuven.ac.be	Fibromyalgia: a stress disorder? Piecing the biopsychosocial puzzle together.	Psychother Psychosom. 2004 Sep-Oct;73(5):267-75.	Fibromyalgia (FM) is a controversial syndrome, characterised by persistent widespread pain, abnormal pain sensitivity and additional symptoms such as fatigue and sleep disturbance. The syndrome largely overlaps with other functional somatic disorders, particularly chronic fatigue syndrome (CFS). Although the exact aetiology and pathogenesis of FM are still unknown, it has been suggested that stress may play a key role in the syndrome. This article first reviews the function of the stress response system, placing special emphasis on the relationships between adverse life experiences, stress regulation and pain-processing mechanisms, and summarising the evidence for a possible aetiopathogenetic role of stress in FM. Finally, an integrative biopsychosocial model that

				conceptualizes FM as a stress disorder is proposed, and the clinical and research implications of the model are discussed.
Vermeulen RC, Scholte HR.	Research Center Amsterdam, Amsterdam, Netherlands. info@cfscentrumamsterdam.nl	Exploratory open label, randomized study of acetyl- and propionylcarnitine in chronic fatigue syndrome.	Psychosom Med. 2004 Mar-Apr;66(2):276-82.	OBJECTIVES: We compared the effects of acetylcarnitine, propionylcarnitine and both compounds on the symptoms of chronic fatigue syndrome (CFS). METHODS: In an open, randomized fashion we compared 2 g/d acetyl-L-carnitine, 2 g/d propionyl-L-carnitine, and its combination in 3 groups of 30 CFS patients during 24 weeks. Effects were rated by clinical global impression of change. Secondary endpoints were the Multidimensional Fatigue Inventory, McGill Pain Questionnaire, and the Stroop attention concentration test. Scores were assessed 8 weeks before treatment; at randomization; after 8, 16, and 24 weeks of treatment; and 2 weeks later. RESULTS: Clinical global impression of change after treatment showed considerable improvement in 59% of the patients in the acetylcarnitine group and 63% in the propionylcarnitine group, but less in the acetylcarnitine plus propionylcarnitine group (37%). Acetylcarnitine significantly improved mental fatigue (p =.015) and propionylcarnitine improved general fatigue (p =.004). Attention concentration improved in all groups, whereas pain complaints did not decrease in any group. Two weeks after treatment, worsening of fatigue was experienced by 52%, 50%, and 37% in the acetylcarnitine, propionylcarnitine, and combined group, respectively. In the acetylcarnitine group, but not in the other groups, the changes in plasma carnitine levels correlated with clinical improvement. CONCLUSIONS: Acetylcarnitine and propionylcarnitine showed beneficial effect on fatigue and attention concentration. Less improvement was found by the combined treatment. Acetylcarnitine had main effect on mental fatigue and propionylcarnitine on general fatigue.
Vermeulen RC, Scholte HR.	CFS Research Centre Amsterdam, Waalstraat 25-31, 1078 BR Amsterdam, The Netherlands. rcwvermeulen@cfscentrumamsterdam.nl	Chronic fatigue syndrome and sexual dysfunction.	J Psychosom Res. 2004 Feb;56(2):199-201.	OBJECTIVE: The study was undertaken to determine if ambulant female patients with the chronic fatigue syndrome (CFS) report problems with their sexual functioning. METHODS: We studied 35 female CFS patients and 36 healthy female controls. The severity of CFS was measured with a fatigue questionnaire and the presence and severity of sexual dysfunction with a questionnaire about sexual functioning. RESULTS: The mean fatigue score was 24.8 in the CFS patients and 11.9 in the controls (P=.000). No increase in sexual dysfunction was found in the CFS group. The control group showed negative correlations between the score of the fatigue questionnaire and the frequency of "sexual fantasies," "(desire for) sexual contact" and "satisfaction with sex life." Such correlations were absent in the CFS group. CONCLUSION: The satisfaction with sex life was similar in patients and controls. The results suggest that patients and controls have a different perception of fatigue.
Viner R, Gregorowski A, Wine C, Bladen M, Fisher D, Miller M, El Neil S.	Department of Adolescent Medicine, Great Ormond Street Hospital for Children and University College London Hospitals, London, UK. R.Viner@ich.ucl.ac.	Outpatient rehabilitative treatment of chronic fatigue syndrome (CFS/ME).	Arch Dis Child. 2004 Jul;89(7):615-9.	AIMS: To assess the outcome of outpatient multidisciplinary rehabilitative treatment (graded activities/exercise programme, family sessions, and supportive care) compared with supportive care alone for children and adolescents with chronic fatigue syndrome (CFS/ME). METHODS: Fifty six young people (aged 9-17 years) with CFS/ME by standard criteria were followed up for 3-24 months. All subjects received supportive care. Families additionally opted to either enter the rehabilitation programme (supportive care plus graded activities/exercise programme and family sessions) or have no additional treatment. RESULTS: Twenty two (39%) subjects had supportive care alone and 26 (46%) entered the programme. Treatment groups were comparable at baseline in terms of age, severity and duration of illness, Wellness score, and school attendance. At end of follow up, those in the programme group had significantly higher Wellness score and school attendance than those having

	uk			supportive care alone. The programme significantly reduced the overall severity of illness: after the programme, 43% had complete resolution of CFS/ME compared to only 4.5% of those having supportive care alone. The presence of depressed mood and family beliefs about the aetiology of CFS/ME were not significantly associated with outcomes. CONCLUSIONS: Outpatient rehabilitative treatment offers significant potential to improve the prognosis of CFS/ME in childhood and adolescence.
Viner R, Hotopf M.	Department of Paediatrics, Royal Free and University College Medical School, Middlesex Hospital, London W1T 3AA. R.Viner@ich.ucl.ac.uk	Childhood predictors of self reported chronic fatigue syndrome/myalgic encephalomyelitis in adults: national birth cohort study.	BMJ. 2004 Oct 23;329(7472):941. Epub 2004 Oct 06. Comment in: BMJ. 2004 Oct 23;329(7472):928-9.	OBJECTIVE: To study childhood risk factors for chronic fatigue syndrome in adult life. DESIGN: Examination of data from the 1970 British birth cohort. PARTICIPANTS: 16,567 babies born 5-11 April 1970, followed up at 5, 10, 16, and 29-30 years. MAIN OUTCOME MEASURES: Chronic fatigue syndrome/myalgic encephalomyelitis (CFS/ME) identified by self report at age 30 years. Data from childhood from questionnaires given to parents and teachers. Maternal mental health assessed with the malaise inventory. RESULTS: 93 (0.8%, 95% confidence interval 0.7 to 1.0) of 11 261 participants reported ever having CFS/ME, and 48 (0.4%, 0.3 to 0.6) had the condition currently. Higher risk of CFS/ME was associated with having a limiting longstanding condition in childhood (odds ratio 2.3, 1.4 to 3.9), female sex (2.3, 1.4 to 2.6), and high social class in childhood (2.2, 1.4 to 3.5). Higher levels of exercise in childhood were associated with lower risk (0.5, 0.2 to 0.9). Maternal psychological disorder, psychological problems in childhood, birth weight, birth order, atopy, obesity, school absence, academic ability, and parental illness were not associated with risk of CFS/ME. CONCLUSIONS: We identified no association between maternal or child psychological distress, academic ability, parental illness, atopy, or birth order and increasing risk of lifetime CFS/ME. Sedentary behaviour increased the risk.
Vladutiu GD, Natelson BH.	Department of Pediatrics, School of Medicine & Biomedical Sciences, State University of New York at Buffalo, Buffalo, New York, USA. gdv@buffalo.edu	Association of medically unexplained fatigue with ACE insertion/deletion polymorphism in Gulf War veterans.	Muscle Nerve. 2004 Jul;30(1):38-43.	Genes associated with muscle metabolism and physical endurance were evaluated for variants that may contribute to the etiology of medically unexplained severe and chronic fatigue. Subjects included 49 Gulf War veterans and 61 nonveterans with chronic fatigue syndrome (CFS) or idiopathic chronic fatigue (ICF) and 30 veterans and 45 nonveterans who served as healthy controls. Increased risk for CFS/ICF was associated with alterations of the insertion/deletion (I/D) polymorphism in the angiotensin-converting enzyme gene within the Gulf War veteran sample only. The I allele frequency was decreased in affected versus unaffected veterans (0.15 versus 0.48; odds ratio [OR], 5.08; 95% confidence interval [CI], 1.97-13.35; P < 0.0001). Correspondingly, the II genotype was decreased fourfold in affected veterans (0.08 versus 0.35; OR = 5.87; 95% CI: 1.21-28.36; P = 0.02), and the DD genotype was increased twofold (0.78 versus 0.39; OR, 5.4; 95% CI, 1.6-18.4; P = 0.007). Veterans with the DD genotype were eight times more likely to develop CFS/ICF than were those with the II genotype (OR, 8.30; 95% CI, 1.50-56.09; P = 0.009).
Vojdani A, Thrasher JD.	Section of Neuroimmunology, Immunosciences Lab Inc., 8693 Wilshire Boulevard, Suite 200, Beverly Hills,	Cellular and humoral immune abnormalities in Gulf War veterans.	Environ Health Perspect. 2004 Jun;112(8):840-6.	We examined 100 symptomatic Gulf War veterans (patients) and 100 controls for immunologic assays. The veterans and controls were compared for the percentage of T cells (CD3); B cells (CD19); helper:suppressor (CD4:CD8) ratio; natural killer (NK) cell activity; mitogenic response to phytohemagglutin (PHA) and pokeweed mitogen (PWM); level of immune complexes; myelin basic protein (MBP) and striated and smooth muscle autoantibodies; and antibodies against Epstein-Barr virus, cytomegalovirus, herpes simplex virus type 1 (HSV-1), HSV-2, human herpes Type 6 (HHV-6), and Varicella zoster virus (VZV). The percentage of T cells in patients versus controls was not significantly

	CA 90211, USA. drari@msn.com			different, whereas a significantly higher proportion of patients had elevated T cells compared with controls. The percentage of B cells was significantly elevated in the patients versus the controls. The NK cell (NK) activity was significantly decreased in the patients (24.8 +/- 16.5 lytic units) versus the controls (37.3 +/- 26.4 lytic units). The percentage of patients with lower than normal response to PHA and PWM was significantly different from controls. Immune complexes were significantly increased in the patients (53.1 +/- 18.6, mean +/- SD) versus controls (34.6 +/- 14.3). Autoantibody titers directed against MBP and striated or smooth muscle were significantly greater in patients versus controls. Finally, the patients had significantly greater titers of antibodies to the viruses compared with the controls ($p < 0.001$). These immune alterations were detected 2-8 years after participation in the Gulf War. The immune alterations are consistent with exposure to different environmental factors. We conclude that Gulf War syndrome is a multifaceted illness with immune function alterations that may be induced by various factors and are probably associated with chronic fatigue syndrome.
Vos R, Willems D, Houtepen R.	Health Ethics and Philosophy, Department of Health Care Studies, University of Maastricht, Maastricht, The Netherlands. Rein.Vos@ZW.unimaas.nl	Coordinating the norms and values of medical research, medical practice and patient worlds-the ethics of evidence based medicine in orphaned fields of medicine.	J Med Ethics. 2004 Apr;30(2):166-70.	Evidence based medicine is rightly at the core of current medicine. If patients and society put trust in medical professional competency, and on the basis of that competency delegate all kinds of responsibilities to the medical profession, medical professionals had better make sure their competency is state of the art medical science. What goes for the ethics of clinical trials goes for the ethics of medicine as a whole: anything that is scientifically doubtful is, other things being equal, ethically unacceptable. This particularly applies to so called orphaned fields of medicine, those areas where medical research is weak and diverse, where financial incentives are lacking, and where the evidence regarding the aetiology and treatment of disease is much less clear than in laboratory and hospital based medicine. Examples of such orphaned fields are physiotherapy, psychotherapy, medical psychology, and occupational health, which investigate complex syndromes such as RSI, whiplash, chronic low back pain, and chronic fatigue syndrome. It appears that the primary ethical problem in this context is the lack of attention to the orphaned fields. Although we agree that this issue deserves more attention as a matter of potential injustice, we want to argue that, in order to do justice to the interplay of heterogeneous factors that is so typical of the orphaned fields, other ethical models than justice are required. We propose the coordination model as a window through which to view the important ethical issues which relate to the communication and interaction of scientists, health care workers, and patients.
Wallman KE, Morton AR, Goodman C, Grove R, Guilfoyle AM.	School of Human Movement and Exercise Science, University of Western Australia, Stirling Highway, Nedlands, WA 6009, Australia. kwallman@cyllene.uwa.edu.au	Randomised controlled trial of graded exercise in chronic fatigue syndrome.	Med J Aust. 2004 May 3;180(9):444-8.	OBJECTIVE: To investigate whether 12 weeks of graded exercise with pacing would improve specific physiological, psychological and cognitive functions in people with chronic fatigue syndrome (CFS). DESIGN: Randomised controlled trial. SETTING: Human performance laboratory at the University of Western Australia. PARTICIPANTS: 61 patients aged between 16 and 74 years diagnosed with CFS. INTERVENTIONS: Either graded exercise with pacing (32 patients) or relaxation/flexibility therapy (29 patients) performed twice a day over 12 weeks. MAIN OUTCOME MEASURES: Changes in any of the physiological, psychological or cognitive variables assessed. RESULTS: Following the graded exercise intervention, scores were improved for resting systolic blood pressure ($P = 0.018$), work capacity ($W.kg(-1)$) ($P = 0.019$), net blood lactate production ($P = 0.036$), depression ($P = 0.027$) and performance on a modified Stroop Colour Word test ($P = 0.029$). Rating of perceived exertion scores, associated with an exercise test, was lower after graded exercise ($P = 0.013$). No such changes were

				observed in the relaxation/flexibility condition, which served as an attention-placebo control. CONCLUSIONS: Graded exercise was associated with improvements in physical work capacity, as well as in specific psychological and cognitive variables. Improvements may be associated with the abandonment of avoidance behaviours.
Wallman K, Goodman C, Morton A, Grove R, Dawson B	Department of Human Movement, University of Western Australia, Nedlands, Western Australia, Australia	Test-Retest Reliability of the Aerobic Power Index Test in Patients with Chronic Fatigue Syndrome	Journal of Chronic Fatigue Syndrome 2004; Mar;11(4):19–32.	Use of maximal aerobic exercise testing in a chronically ill population may not only deter potential subjects from participating in trials, or returning for repeat trials, but may also result in the exacerbation of symptoms related to CFS. The Aerobic Power Index represents a submaximal exercise test that forms the aerobic component of the Trilevel Fitness Profile. This incremental bike test has a predetermined termination point based on a target heart rate (THR) of 75% of age predicted heart rate maximum, making successful completion of the test more likely in chronically ill subjects. The aim of this study was to determine reliability of the Aerobic Power Index in 20 CFS subjects. Results for the 17 subjects who reached THR for both trials, demonstrated high reliability for watts per kilogram and oxygen uptake (ml·kg-1·min-1), as demonstrated by an intraclass correlation coefficient (ICC) of .97 and .91 respectively, while RPE resulted in moderate reliability (ICC = .87). The results of this study indicate that that the Aerobic Power Index is a reliable submaximal test for use in a CFS population.
Wallman KE, Morton AR, Goodman C, Grove R.	School of Human Movement and Exercise Science, The University of Western Australia, Crawely, Western Australia, Australia. kwallman@cyllene.uwa.edu.au	Physiological responses during a submaximal cycle test in chronic fatigue syndrome.	Med Sci Sports Exerc. 2004 Oct;36(10):1682-8.	INTRODUCTION/PURPOSE: Numerous studies have assessed physical function in individuals suffering from chronic fatigue syndrome (CFS) but neglected to match control subjects according to current activity levels, consequently casting doubt on reported results. The purpose of this study was to include current activity levels as one criterion for matching CFS subjects with healthy control subjects in order to more accurately assess physical function in these subjects. METHODS: Thirty-one healthy control subjects were matched to CFS subjects according to age, gender, body mass, height, and current activity levels. Physiological function was assessed weekly over a 4-wk period using a submaximal cycle test. RESULTS: Comparison of absolute physiological results recorded at the end of each incremental work level of the exercise test showed that ratings of perceived effort (RPE) was the only variable that was significantly different between the two groups. Scores for RPE were significantly higher in CFS subjects for each incremental work level assessed. Conversely, results recorded on completion of the exercise test showed that the control group was capable of a greater power output than the CFS group as reflected by significantly higher scores for watts per kilogram ($P < 0.0005$), net lactate production ($P = 0.003$), oxygen uptake (mL x kg(-1) x min(-1); $P < 0.0005$), respiratory exchange ratio ($P = 0.021$), and HR values as a percentage of age predicted HR(max) ($P = 0.001$). End-point RPE scores were again significantly higher in the CFS group ($P < 0.0005$). CONCLUSION: It is proposed that the reduced exercise tolerance in CFS is due to impairment in the mechanisms that constitute effort sense and/or to avoidance behaviors that result in a reluctance by these subject to exercise to full capacity.
Wang XQ, Takahashi T, Zhu SJ, Moriya J, Saegusa S, Yamakawa J, Kusaka K, Itoh T,	Department of General Medicine, Kanazawa Medical University, Ishikawa, Japan.	Effect of Hochu-ekki-to (TJ-41), a Japanese Herbal Medicine, on Daily Activity in a Murine Model of	Evid Based Complement Alternat Med. 2004 Sep 1;1(2):203-206.	We aimed to evaluate the effect of a Japanese herbal medicine, Hochu-ekki-to (TJ-41), on daily activity in a murine model of chronic fatigue syndrome (CFS). CFS was induced by repeated injection of Brucella abortus (BA) antigen every 2 weeks. TJ-41 was orally administered to mice in a dose of 500 mg/kg/day for 1 week before injecting BA and for 4 weeks thereafter. We evaluated daily running activity in mice receiving TJ-41 as compared with that in untreated mice. Survival of both mouse groups was also monitored during the observation period. Body weight (BW), spleen weight (SW),

Kanda T.		Chronic Fatigue Syndrome.		SW/ BW ratio and expression levels of interleukin-10 (IL-10) mRNA in spleen were determined in both groups at the time of sacrifice. The daily activity was significantly higher in the treated group than in the control. Two mice in the untreated group died 2 days after the second injection of BA, whereas no mice in the group treated with TJ-41 died. The SW and SW/BW ratio were significantly lower in the treated mice than in the control. Suppressed IL-10 mRNA levels were observed in the spleens of the mice treated with TJ-41. Our data suggest that Hochu-ekki-to might possess an inhibitory effect on the marked decrease in running activity following BA injection.
Watanabe A.		Various clinical types of Q-fever disease.Comment on: Intern Med. 2004 Jan;43(1):49-54.	Intern Med. 2004 Jan;43(1):1-2.	
Watson NF, Jacobsen C, Goldberg J, Kapur V, Buchwald D.	Department of Neurology, University of Washington, Seattle 98104-2499, USA. nwatson@u.washington.edu	Subjective and objective sleepiness in monozygotic twins discordant for chronic fatigue syndrome.	Sleep. 2004 Aug 1;27(5):973-7.	STUDY OBJECTIVE: To examine the association of chronic fatigue syndrome (CFS) with measures of objective and subjective sleepiness. DESIGN: Monozygotic co-twin control study. SETTING: Academic medical center. PATIENTS AND PARTICIPANTS: Twenty monozygotic twin pairs discordant for CFS. INTERVENTIONS: N/A. MEASUREMENTS AND RESULTS: All twins completed an Epworth Sleepiness Scale (ESS), 4 Stanford Sleepiness Scales (SSS), and underwent a standard 4-nap multiple sleep latency test. We compared the ESS scores, average SSS scores, and average sleep latency in CFS and healthy twins. The CFS twins reported more sleepiness as measured by mean scores on the ESS (10.9 vs 8.2; 95% confidence interval [CI] = 0.3-5.5; P = .03) and the SSS (3.4 versus 2.1; 95% CI = 0.7-1.9; P < .001). The mean sleep latency on the Multiple Sleep Latency Test was not significantly different between the CFS and healthy twins (8.9 vs 10.0 minutes; 95% CI -4.4-1.7; P = .33). Mean SSS scores increased among the CFS twins and decreased among healthy twins from nap 1 to nap 4 (P < .001). The individual ESS scores and mean sleep latencies on the Multiple Sleep Latency Test were negatively correlated for all the twins (Pearson's r = - 0.40; P = .01), with a slightly stronger association among the healthy twins (Pearson's r = -0.42, P = .07) than the CFS twins (Pearson's r = -0.36, P = .15). CONCLUSIONS: CFS twins reported significantly more subjective sleepiness than their healthy co-twins despite similar nonpathologic mean sleep latencies on the Multiple Sleep Latency Test. Patients with CFS may mistake their chronic disabling fatigue for sleepiness.
Weatherley-Jones E, Nicholl JP, Thomas KJ, Parry GJ, McKendrick MW, Green ST, Stanley PJ, Lynch SP.	Medical Care Research Unit, School of Health and Related Research, University of Sheffield, Regent Court, 30 Regent Street, Sheffield S1 4DA, UK.	A randomised, controlled, triple-blind trial of the efficacy of homeopathic treatment for chronic fatigue syndrome.	J Psychosom Res. 2004 Feb;56(2):189-97.	OBJECTIVE: There is no management regime for chronic fatigue syndrome (CFS) that has been found to be universally beneficial and no treatment can be considered a "cure". Patients with CFS may use complementary and alternative medicine (CAM). Our aim was to evaluate homeopathic treatment in reducing subjective symptoms of CFS. METHOD: Using a triple-blind design (patient and homeopath blind to group assignment and data analyst blind to group until after initial analyses to reduce the possibility of bias due to data analyst), we randomly assigned patients to homeopathic medicine or identical placebo. One hundred and three patients meeting the Oxford criteria for CFS were recruited from two specialist hospital out patient departments. Patients had monthly consultations with a professional homeopath for 6 months. Main outcome measures were scores on the subscales of the Multidimensional Fatigue Inventory (MFI) and proportions of each group attaining clinically significant

	e.weatherley-jones@sheffield.ac.uk			improvements on each subscale. Secondary outcome measures were the Fatigue Impact Scale (FIS) and the Functional Limitations Profile (FLP). Ninety-two patients completed treatment in the trial (47 homeopathic treatment, 45 placebo). Eighty-six patients returned fully or partially completed posttreatment outcome measures (41 homeopathic treatment group who completed treatment, 2 homeopathic treatment group who did not complete treatment, 38 placebo group who completed treatment, and 5 placebo group who did not complete treatment). RESULTS: Seventeen of 103 patients withdrew from treatment or were lost to follow-up. Patients in the homeopathic medicine group showed significantly more improvement on the MFI general fatigue subscale (one of the primary outcome measures) and the FLP physical subscale but not on other subscales. Although group differences were not statistically significant on four out of the five MFI subscales (the primary outcome measures), more people in the homeopathic medicine group showed clinically significant improvement. More people in the homeopathic medicine group showed clinical improvement on all primary outcomes (relative risk=2.75, P=.09). CONCLUSIONS: There is weak but equivocal evidence that the effects of homeopathic medicine are superior to placebo. Results also suggest that there may be nonspecific benefits from the homeopathic consultation. Further studies are needed to determine whether these differences hold in larger samples.
White PD.		What causes chronic fatigue syndrome?	BMJ. 2004 Oct 23;329(7472):928-9.	
White PD, Thomas JM, Sullivan PF, Buchwald D.	Department of Psychological Medicine, Barts, London and Queen Mary School of Medicine and Dentistry, University of London. p.d.white@qmul.ac.uk	The nosology of sub-acute and chronic fatigue syndromes that follow infectious mononucleosis.	Psychol Med. 2004 Apr;34(3):499-507.	BACKGROUND: A previous principal components analysis of symptoms occurring after infectious mononucleosis suggested that a discrete fatigue syndrome occurs, which is independent of psychiatric disorder. This work has not been replicated and no latent class analysis of subjects has been published. METHOD: We prospectively examined a cohort of 150 American primary care patients 2 and 6 months after the onset of corroborated infectious mononucleosis. A subset of 50 subjects was studied 4 years after onset. We performed principal components analyses of both psychological and somatic symptoms and latent class analyses of subjects. RESULTS: Principal components analyses consistently delineated two fatigue factors at 2 and 6 months and one fatigue factor at 4 years. These factors were separate from a mixed anxiety and depressive factor. A four-class solution for the latent class analyses consisted of most subjects with few symptoms, a few with many symptoms, a group with predominantly mood symptoms and some subjects with fatigue symptoms. CONCLUSIONS: The symptoms of the principal factors with fatigue were similar to those previously described. Both the factors and classes were independent of an equally delineated mood factor and class. These results support the existence of two discrete chronic fatigue syndromes after infectious mononucleosis, one of which is still demonstrable 4 years after onset.
Whitehead L.	Department of Nursing and Midwifery, University of Stirling, Stirling, UK.	Enhancing the quality of hermeneutic research: decision trail.	J Adv Nurs. 2004 Mar;45(5):512-8.	BACKGROUND: Researchers have ethical and professional obligations to produce research of a high standard. The constituents of quality in research appear to differ between authors, leaving readers unsure about which pathway to follow. This can reflect inadequate consideration of the theoretical framework guiding the study. Many papers fail to consider the theoretical underpinnings of the methodology chosen and the link between these and the methods employed. These need to be accessible to readers in order to assess the trustworthiness of the research. AIM: This paper discusses

	lisa.whitehead@stir.ac.uk			the development of trustworthiness in hermeneutic phenomenological research. DISCUSSION: Referring to a study on lived experience of Chronic Fatigue Syndrome/myalgic encephalitis, I describe the decision trail and discuss the strengths and limitations of the choices made throughout the study. CONCLUSION: The methodology focused my approach more fully on the importance of recognizing the influences that I brought to the study and the impact of these in generating the data. It highlighted the fact that the process of setting out my horizon can never be complete, the importance of analysing the data at a macro and micro level, acknowledging the evolution of the data over time, and ensuring that analysis does not move beyond the data and out of the hermeneutic circle. In seeking to make the decision trail clear to others, researchers must distill the philosophical principles of the methodology and set these out in a way that is accessible and open to scrutiny.
Whiteside A, Hansen S, Chaudhuri A.	Departments of Clinical Physics, Institute of Neurological Sciences, South Glasgow University Hospitals NHS Trust, Glasgow, UK.	Exercise lowers pain threshold in chronic fatigue syndrome.	Pain. 2004 Jun;109(3):497-9.	Post-exertional muscle pain is an important reason for disability in patients who are diagnosed to have Chronic Fatigue Syndrome (CFS). We compared changes in pain threshold in five CFS patients with five age and sex matched controls following graded exercise. Pain thresholds, measured in the skin web between thumb and index finger, increased in control subjects with exercise while it decreased in the CFS subjects. Increased perception of pain and/or fatigue after exercise may be indicative of a dysfunction of the central anti-nociceptive mechanism in CFS patients.
Winkler AS, Blair D, Marsden JT, Peters TJ, Wessely S, Cleare AJ.	Department of Medicine, Division of Psychological Medicine, GKT School of Medicine, Institute of Psychiatry, De Crespigny Park, London SE5 9RJ, UK.	Autonomic function and serum erythropoietin levels in chronic fatigue syndrome.	J Psychosom Res. 2004 Feb;56(2):179-83.	OBJECTIVE: Given previous findings, we wished to investigate whether there was evidence of autonomic dysfunction in patients with chronic fatigue syndrome, and whether this could be related to reduced erythropoietin levels and altered red blood cell indices. METHODS: We assessed autonomic function and analysed blood parameters (including erythropoietin) in 22 patients with chronic fatigue syndrome who were medication-free and without comorbid depression or anxiety. Results were compared to 23 iron-deficiency anaemia patients and 18 healthy individuals. RESULTS: Autonomic testing in patients with chronic fatigue syndrome yielded a significantly greater increase in heart rate together with a more pronounced systolic blood pressure fall on standing compared to healthy individuals. Heart rate beat-to-beat variation on deep breathing and responses to the Valsalva manoeuvre were normal. Two of 22 patients with chronic fatigue had mild normochromic normocytic anaemia with normal ferritin, vitamin B12 and folate levels. Serum erythropoietin levels were within reference range. CONCLUSION: Some autonomic dysfunction is present in chronic fatigue syndrome (CFS) patients; the explanation remains uncertain, but could relate to cardiovascular deconditioning. There were no major haematological, biochemical or immunological abnormalities in these patients.

Woolley J, Allen R, Wessely S.	Academic Department of Psychological Medicine, Guy's, King's & St Thomas's School of Medicine and Institute of Psychiatry, 103 Denmark Hill, London SE5 8AF, UK.	Alcohol use in chronic fatigue syndrome.	J Psychosom Res. 2004 Feb;56(2):203-6.	OBJECTIVE: To examine the anecdotal observation that patients with chronic fatigue syndrome develop alcohol intolerance. METHODS: A consecutive case series of 114 patients fulfilling UK criteria for chronic fatigue syndrome referred to a specialist clinic. Self-reported alcohol use pre- and postdiagnosis, fatigue symptoms and comorbidity measures were collected. RESULTS: Two-thirds reduced alcohol intake. The most common reasons were increased tiredness after drinking (67%), increased nausea (33%), exacerbated hangovers (23%) and sleep disturbance (24%). One-third of the subjects also stopped drinking because "it seemed sensible." Some had been advised to avoid alcohol, but the majority (66%) did so on the basis of personal experience. CONCLUSION: Our data supports the anecdotal belief that chronic fatigue syndrome patients reduce or cease alcohol intake. This is associated with greater impairment in employment, leisure and social domains of function, and may hint at psycho-pathophysiological processes in common with other conditions that result in alcohol intolerance.

Neuroreport. 2004 Dec 3;15(17):2571-2574.	To assess the involvement of serotonin in the symptoms of chronic fatigue syndrome, we investigated the serotonergic neurotransmitter system of chronic fatigue syndrome patients by the positron emission tomography (PET). Here we show that the density of serotonin transporters (5-HTTs) in the brain, as determined by using a radiotracer, [C](+)McN5652, was significantly reduced in the rostral subdivision of the anterior cingulate as compared with that in normal volunteers. This subdivision is different from that in the dorsal anterior cingulate in which binding potential values of individual patient showed a weak negative correlation with self-reported pain score of the patients. Therefore, an alteration of serotonergic system in the rostral anterior cingulate plays a key role in pathophysiology of chronic fatigue syndrome.

Yoshiuchi K, Quigley KS, Ohashi K, Yamamoto Y, Natelson BH.	Department of Psychiatry, University of Medicine and Dentistry of New Jersey, New Jersey	Use of time-frequency analysis to investigate temporal patterns of cardiac autonomic	Auton Neurosci. 2004 Jun 30;113(1-2):55-62.	Although a number of studies have reported alterations in cardiac autonomic nervous system function in chronic fatigue syndrome (CFS), the results are not consistent across studies. Reasons for these discrepancies include (1) the use of a heterogeneous patient sample that included those with orthostatic postural tachycardia (POTS), a condition with an autonomic changes, and (2) the use of frequency domain techniques which require a stationary signal and averaging data across relatively long epochs. To deal with these shortcomings, we used the smoothed pseudo-Wigner-Ville transform

	Medical School, East Orange, NJ 07018, USA.	response during head-up tilt in chronic fatigue syndrome.		(SPWVT) to analyze heart rate variability (HRV) and blood pressure variability (BPV) during head-up tilt (HUT) by separating CFS patients into those with and without POTS. SPWVT has the advantage of providing instantaneous information about autonomic function under nonstable physiological conditions. We studied 18 CFS patients without POTS, eight CFS patients with POTS and 25 sedentary healthy controls during supine rest and during the first 10 min after HUT. While we found significant effects of postural change in both groups for all autonomic variables, there were significant groupxtime interactions between CFS without POTS and controls for only instant center frequency (ICF) within the low frequency region both from HRV (p=0.02) and from BPV (p=0.01). Although the physiological meaning of ICF still remains unknown, the data suggest that even CFS patients without POTS may have a subtle underlying disturbance in autonomic function.
Zachrisson O, Colque-Navarro P, Gottfries CG, Regland B, Mollby R.	Institute of Clinical Neuroscience, SU/Molndal, 43180 Molndal, Sweden. olof.zachrisson@neuro.gu.se	Immune modulation with a staphylococcal preparation in fibromyalgia/chronic fatigue syndrome: relation between antibody levels and clinical improvement.	Eur J Clin Microbiol Infect Dis. 2004 Feb;23(2):98-105. Epub 2004 Jan 20.	The aims of this study were to evaluate the serological response to treatment with staphylococcal vaccine in fibromyalgia/chronic fatigue syndrome patients and to explore the relationship between serological response and clinical effect. Twenty-eight patients, half of whom served as controls, were recruited from a 6-month randomised trial in which repeated administration of the staphylococcal toxoid vaccine Staphypan Berna (Berna Biotech, Switzerland) was tested against placebo. Antibody status against extracellular toxins/enzymes, cell-wall components, and enterotoxins was evaluated at baseline and at endpoint. The clinical response to treatment was recorded in rating scales. In the group receiving active treatment, significant serological changes were recorded, whereas no significant changes were found in controls. Treatment led to a significantly increased capacity of serum to neutralise alpha-toxin and a significant increase in serum IgG to alpha-toxin and lipase. Furthermore, the increase in these parameters combined paralleled the improvement in clinical outcome. Thus, the greater the serological response, the greater was the clinical effect. In conclusion, this explorative study has shown that repeated administration of the Staphypan Berna vaccine in patients with fibromyalgia/chronic fatigue syndrome causes a serological response to several staphylococcal antigens, particularly to certain extracellular toxins and enzymes. The results further show that this response is related to the clinical outcome of treatment.
Zavestoski S, Brown P, McCormick S, Mayer B, D'Ottavi M, Lucove JC.	Department of Sociology, University of San Francisco, 2130 Fulton Street, San Francisco, CA 94117-1080, USA. smzavestoski@usfca.edu	Patient activism and the struggle for diagnosis: Gulf War illnesses and other medically unexplained physical symptoms in the US.	Soc Sci Med. 2004 Jan;58(1):161-75.	We examine Gulf War illnesses--which include the fatigue, joint pain, dermatitis, headaches, memory loss, blurred vision, diarrhea, and other symptoms reported by Gulf War veterans--in relation to other medically unexplained physical symptoms such as multiple chemical sensitivity, chronic fatigue syndrome, and fibromyalgia. Our intent is to examine the diagnosis negotiations involved in these mysterious diseases, by showing the different forms of legitimacy involved in such interactions. Factors involved in diagnostic legitimacy are: diagnostic legitimacy in the medical community, lay acceptance of the diagnosis, uncertainty in looking for causes, and social mobilization. We conclude by noting that research may not be able to find any cause for these diseases/conditions; hence, it may be necessary to embrace medical uncertainty, and also to accept patient experience in order to facilitate diagnosis, treatment, and recovery process. Such a change can alter patients' expectations and taken-for-granted assumptions about medicine, and perhaps in turn reduce the frequency with which dissatisfied individuals form illness groups that mobilize to challenge what they see as an unresponsive medical system.

Aaron LA, Buchwald D.	Department of Oral Medicine, University of Washington, 1959 NE Pacific Street, B316, P.O. Box 356370, 98195-6370, Seattle, WA, USA	Chronic diffuse musculoskeletal pain, fibromyalgia and co-morbid unexplained clinical conditions.	Best Pract Res Clin Rheumatol. 2003 Aug;17(4):563-74.	This chapter reviews our current knowledge on the presence of overlapping syndromes in one form of chronic diffuse pain, fibromyalgia. Patients with fibromyalgia often present with signs and symptoms of other unexplained clinical conditions, including chronic fatigue syndrome, irritable bowel syndrome, temporomandibular disorders, and multiple chemical sensitivities. The high prevalence, impact on function and opportunities for treatment underscore the need for clinicians and researchers to screen routinely for co-morbid unexplained clinical conditions among persons with fibromyalgia. We, therefore, describe a simple approach to screening for such conditions in accordance with published criteria. Interventions should directly address both fibromyalgia symptoms and co-morbid unexplained clinical conditions, as well as the multiple factors that propagate pain, fatigue and limitations in function.
Afari N, Buchwald D.	Department of Psychiatry, University of Washington, Seattle, USA. afari@u.washington.edu	Chronic fatigue syndrome: a review.	Am J Psychiatry. 2003 Feb;160(2):221-36.	OBJECTIVE: Chronic fatigue syndrome is an illness characterized by disabling fatigue of at least 6 months, accompanied by several other symptoms. This review summarizes the current state of knowledge about chronic fatigue syndrome. METHOD: The case definition, prevalence, clinical presentation, evaluation, and prognosis of chronic fatigue syndrome are discussed. Research on the pathophysiology and treatment of chronic fatigue syndrome is reviewed. RESULTS: Chronic fatigue syndrome is diagnosed on the basis of symptoms. Patients with chronic fatigue syndrome experience significant functional impairment. Pathophysiological abnormalities exist across many domains, suggesting that chronic fatigue syndrome is a heterogeneous condition of complex and multifactorial etiology. Evidence also is beginning to emerge that chronic fatigue syndrome may be familial. Although chronic fatigue syndrome has significant symptom overlap and comorbidity with psychiatric disorders, several lines of research suggest that the illness may be distinct from psychiatric disorders. Patients' perceptions, attributions, and coping skills, however, may help perpetuate the illness. Treatment for chronic fatigue syndrome is symptom-based and includes pharmacological and behavioral strategies. Cognitive behavior therapy and graded exercise can be effective in treating the fatigue and associated symptoms and disability. CONCLUSIONS: Chronic fatigue syndrome is unlikely to be caused or maintained by a single agent. Findings to date suggest that physiological and psychological factors work together to predispose an individual to the illness and to precipitate and perpetuate the illness. The assessment and treatment of chronic fatigue syndrome should be multidimensional and tailored to the needs of the individual patient.
Agadjanyan M, Vasilevko V, Ghochikyan A, Berns P, Kesslak P, Settineri RA, Nicolson GL		Nutritional Supplement (NT Factor™) Restores Mitochondrial Function and Reduces Moderately Severe Fatigue in Aged Subjects	Journal of Chronic Fatigue Syndrome 2003; 11 (3): 23-37	Decreased mitochondrial function is a characteristic of aging and fatigue. Here we determined if mild to moderately severe fatigue in a group of aged subjects (mean age > 60 years), as defined by the validated Piper Fatigue Scale (PFS), can be significantly improved by use of a glycophospholipid dietary supplement, NT Factor™ (NTF). In addition, we determined if mitochondrial function, as defined by transport of the redox dye Rhodamine-123, is reduced in aging subjects with mild to moderately severe fatigue, and if this can be reversed with NTF supplementation in concert with improvement in fatigue scores. Participants with mild to moderately severe fatigue, who fulfilled the entry requirements were admitted to the study

				when their fatigue could not be explained by an obvious clinical condition. Twenty of the respondents (mean age = 68.9 ± 4.18) completed the first part of the study on NTF for 12 weeks, and 16 of these subjects who agreed to discontinue the product also completed a wash-out period for an additional 12 weeks. Fatigue and mitochondrial function were determined every four weeks during the study. There was a time-dependent reduction in overall fatigue in moderately fatigued subjects (P < .001) but not in mildly fatigued subjects. Mitochondrial function at four and eight weeks of NTF use in moderately fatigued subjects increased by 15% and 26.8%, respectively, and restored mitochondrial function to levels similar to those found in young adults. No further increase was noted between 8 and 12 weeks. Post-NTF there was a slow redevelopment of fatigue and a fall in mitochondrial function in moderately fatigued subjects, indicating that continued use of NTF may be necessary to maintain lower fatigue scores and maintain mitochondrial function. The dietary supplement with NTF reduced moderate fatigue and increased mitochondrial function in aged subjects but had no effect upon mild fatigue expression.

Ambrose K, Lyden AK, Clauw DJ.	Chronic Pain and Fatigue Research Program, University of Michigan, 24 Frank Lloyd Wright Drive, PO Box 385, Ann Arbor, MI 48109-0483, USA. kambrose@med.umich.edu	Applying exercise to the management of fibromyalgia.	Curr Pain Headache Rep. 2003 Oct;7(5):348-54.	Fibromyalgia, chronic fatigue syndrome, and related illnesses fall under the spectrum of chronic multisymptom illnesses (CMI). This constellation of syndromes often is defined by chronic pain, unremitting fatigue, cognitive difficulties, and various other symptoms. In treating these illnesses, pharmacotherapy generally is the mode of choice, with exercise being overlooked often. However, research has shown that exercise is quite beneficial in reducing pain and fatigue in this population and should be included as part of a multimodal therapy regimen. This article reviews the exercise and CMI literature and provides a model for applying these evidence-based guidelines to a clinical population.
Amel Kashipaz MR, Swinden D, Todd I, Powell RJ.	Division of Molecular and Clinical Immunology, School of Clinical Laboratory Sciences, University of Nottingham, Queen's Medical Centre, Nottingham, UK.	Normal production of inflammatory cytokines in chronic fatigue and fibromyalgia syndromes determined by intracellular cytokine staining in short-term cultured blood mononuclear cells.	Clin Exp Immunol. 2003 May;132(2):360-5.	It has been proposed that cytokines play a role in the pathogenesis of chronic fatigue syndrome (CFS) and fibromyalgia syndrome (FMS). However, different studies have reported conflicting results using enzyme-linked immunosorbent assay or polymerase chain reaction to detect cytokines in these conditions. In the present study, for the first time, the production of inflammatory [interleukin (IL)-1alpha, IL-6, and TNF-alpha] and anti-inflammatory (IL-10) cytokines by CD14+ and CD14- peripheral blood mononuclear cells (PBMC) from chronic fatigue syndrome (CFS) and fibromyalgia syndrome (FMS) patients and sex- and age-matched normal subjects was investigated at the level of individual cells using the technique of intracellular cytokine staining and flow cytometry. Cultures were carried out in the presence of polymyxin B to inhibit the effect of endotoxins on cytokine production by monocytes. The mean intensity of fluorescence (MIF) and percentage of CD14+ (monocytes) and CD14- (lymphocytes) cytokine-

				producing mononuclear cells were comparable in patients and controls in either unstimulated or IFN-gamma-stimulated conditions. Our study indicates that dysregulation of cytokine production by circulating monocytes or non-monocytic cells (lymphocytes) is not a dominant factor in the pathogenesis of CFS/FMS.
Anyanwu E, Campbell AW, Jones J, Ehiri JE, Akpan AI.		The neurological significance of abnormal natural killer cell activity in chronic toxigenic mold exposures.	ScientificWorld Journal. 2003 Nov 13;3(11):1128-37.	Toxigenic mold activities produce metabolites that are either broad-spectrum antibiotics or mycotoxins that are cytotoxic. Indoor environmental exposure to these toxigenic molds leads to adverse health conditions with the main outcome measure of frequent neuroimmunologic and behavioral consequences. One of the immune system disorders found in patients presenting with toxigenic mold exposure is an abnormal natural killer cell activity. This paper presents an overview of the neurological significance of abnormal natural killer cell (NKC) activity in chronic toxigenic mold exposure. A comprehensive review of the literature was carried out to evaluate and assess the conditions under which the immune system could be dysfunctionally interfered with leading to abnormal NKC activity and the involvement of mycotoxins in these processes. The functions, mechanism, the factors that influence NKC activities, and the roles of mycotoxins in NKCs were cited wherever necessary. The major presentations are headache, general debilitating pains, nose bleeding, fevers with body temperatures up to 40C (104F), cough, memory loss, depression, mood swings, sleep disturbances, anxiety, chronic fatigue, vertigo/dizziness, and in some cases, seizures. Although sleep is commonly considered a restorative process that is important for the proper functioning of the immune system, it could be disturbed by mycotoxins. Most likely, mycotoxins exert some rigorous effects on the circadian rhythmic processes resulting in sleep deprivation to which an acute and transient increase in NKC activity is observed. Depression, psychological stress, tissue injuries, malignancies, carcinogenesis, chronic fatigue syndrome, and experimental allergic encephalomyelitis could be induced at very low physiological concentrations by mycotoxin-induced NKC activity. In the light of this review, it is concluded that chronic exposures to toxigenic mold could lead to abnormal NKC activity with a wide range of neurological consequences, some of which were headache, general debilitating pains, fever, cough, memory loss, depression, mood swings, sleep disturbances, anxiety, chronic fatigue, and seizures.
Arcari R, Crombie HD.	Department of Community Medicine and Healthcare, University of Connecticut School of Medicine, Farmington, USA.	Mark Twain and his family's health: Livy Clemens' neurasthenia in the gilded age and chronic fatigue syndrome of today.	Conn Med. 2003 May;67(5):293-6.	Our purpose is to compare and contrast the 19th century diagnosis and disease neurasthenia with the contemporary illness known as Chronic Fatigue Syndrome. The health of Mark Twain's wife, Olivia (Livy) Clemens, will then be discussed and evaluated with respect to these two medical conditions.
Asbring P, Narvanen AL.	Centre for Development of Health Services and the Department of	Ideal versus reality: physicians perspectives on patients with chronic	Soc Sci Med. 2003 Aug;57(4):711-20.	Encountering patients with chronic fatigue syndrome (CFS) or fibromyalgia can cause dilemmas for physicians due to the uncertainty inherent in these illnesses. The aim of this study was to investigate: (1) How physicians in a Swedish sample describe and categorise patients with CFS and fibromyalgia; (2) What the character of CFS and fibromyalgia, with regard to diagnosing,

	Public Health Sciences, Karolinska Institutet, Norrbacka, plan 2/7, 171 76, Stockholm, Sweden	fatigue syndrome (CFS) and fibromyalgia.		treatment and medical knowledge/aetiology, mean to the physicians in encounters with patients; and (3) Which strategies physicians describe that they use in the encounter with these patients. Semi-structured interviews were carried out with 26 physicians, specialists in various fields who all had some experience of either CFS or fibromyalgia. The results suggest that there is a discrepancy between the ideal role of the physician and reality in the everyday work in interaction with these patients. This may lead to the professional role being questioned. Different strategies are developed to handle the encounters with these patients. The results also illuminate the physician's interpretations of patients in moralising terms. Conditions given the status of illness were regarded, for example, as less serious by the physicians than those with disease status. Scepticism was expressed regarding especially CFS, but also fibromyalgia. Moreover, it is shown how the patients are characterised by the physicians as ambitious, active, illness focused, demanding and medicalising. The patient groups in question do not always gain full access to the sick-role, in part as a consequence of the conditions not being defined as diseases.
Assefi NP, Coy TV, Uslan D, Smith WR, Buchwald D.	Department of Medicine, University of Washington, Seattle, Washington, USA.	Financial, occupational, and personal consequences of disability in patients with chronic fatigue syndrome and fibromyalgia compared to other fatiguing conditions.	J Rheumatol. 2003 Apr;30(4):804-8.	OBJECTIVE: To examine the nature and degree of self-reported disability in patients with chronic fatigue syndrome (CFS) and its associated conditions, fibromyalgia (FM) and subsyndromal fatigue (CF), compared with a chronically fatiguing but unrelated medical condition (MED). METHODS: Six hundred and thirty patients evaluated at the University of Washington Chronic Fatigue Clinic were sent questionnaires asking them to identify the financial, occupational, and personal consequences of their fatiguing illness. Thorough medical evaluations had previously applied accepted criteria for defining CFS, FM, and CF. RESULTS: The FM groups (those with and without CFS) were among the least employed. Likewise, the FM and CFS groups, more frequently than the other groups, endorsed loss of material possessions (such as car), loss of job, and loss of support by friends and family, as well as recreational activities as a result of their fatiguing illness. There were no reliable differences between groups in use of disability benefits. CONCLUSION: There is substantial illness-related disability among those evaluated at a specialized chronic fatigue clinic. Those reporting the most pervasive disability met criteria for FM either alone or in conjunction with CFS. Employers and personal relations of patients with chronic fatigue should make a greater effort to accommodate the illness-related limitations of these conditions, especially for those with FM and CFS.

Aylett E, Fawcett TN.	School of Nursing Studies, University of Edinburgh. lizzie@aylett.co.uk	Chronic fatigue syndrome: the nurse's role.	Nurs Stand. 2003 May 14-20;17(35):33-7.	BACKGROUND: Chronic fatigue syndrome (CFS), a disorder of no proven cause, is characterised by extended periods of extreme, debilitating fatigue and related symptoms. This article discusses this distressing disorder and identifies the needs of those who have it. The authors suggest that the nurse could fulfil the role of key professional carer, interacting with the individual with CFS to co-ordinate care and form the pivotal therapeutic relationship. CONCLUSION: CFS remains a chronic illness of uncertain cause and prognosis. For those with CFS, care priorities involve validation, information and advocacy, a therapeutic relationship and co-ordinated care. The

				particular philosophy of care held by nurses makes them potentially ideal co-ordinators of care for those with CFS.

Blockmans D, Persoons P, Van Houdenhove B, Lejeune M, Bobbaers H.	Department of General Internal Medicine, University Hospital Gasthuisberg, Leuven, Belgium. Daniel.Blackmans@uz.kuleuven.ac.be	Combination therapy with hydrocortisone and fludrocortisone does not improve symptoms in chronic fatigue syndrome: a randomized, placebo-controlled, double-blind, crossover study.	Am J Med. 2003 Jun 15;114(9):736-41.	PURPOSE: Chronic fatigue syndrome has been associated with decreased function of the hypothalamic-pituitary-adrenal axis. Although neurally mediated hypotension occurs more frequently in patients with chronic fatigue syndrome than in controls, attempts to alleviate symptoms by administration of hydrocortisone or fludrocortisone have not been successful. The purpose of this study was to investigate the effect of combination therapy (5 mg/d of hydrocortisone and 50 microg/d of 9-alfa-fludrocortisone) on fatigue and well-being in chronic fatigue syndrome. METHODS: We performed a 6-month, randomized, placebo-controlled, double-blind, crossover study in 100 patients who fulfilled the 1994 Centers for Disease Control and Prevention criteria for chronic fatigue syndrome. Between-group differences (placebo minus treatment) were calculated on a 10-point visual analog scale. RESULTS: Eighty patients completed the 3 months of placebo and 3 months of active treatment in a double-blind fashion. There were no differences between treatment and placebo in patient-reported fatigue (mean difference, 0.1; 95% confidence interval [CI]: -0.3 to 0.6) or well-being (mean difference, -0.4; 95% CI: -1.0 to 0.1). There were also no between-group differences in fatigue measured with the Abbreviated Fatigue Questionnaire, the Short Form-36 Mental or Physical Factor scores, or in the Hospital Anxiety and Depression Scale. CONCLUSION: Low-dose combination therapy of hydrocortisone and fludrocortisone was not effective in patients with chronic fatigue syndrome.

Carothers B, Schmidt L, Puri V.		Case reports and review of Postural Orthostatic Tachycardia syndrome (POTS).	J Ky Med Assoc. 2003 Dec;101(12):549-52.	Postural Orthostatic Tachycardia Syndrome (POTS) is a type of orthostatic intolerance that is characterized by excessive tachycardia and decreased cerebral blood flow in the upright position. This can result in significant symptoms of dizziness and light-headedness that can eventually lead to syncope. In this review, we describe two patients with POTS that varied in their degree of symptoms and treatment. One patient was able to be treated as an outpatient, while the other

				required hospitalization and extensive medical therapy. We would like to emphasize with this review that POTS is probably more common than it is diagnosed and is often confused with other conditions, such as chronic fatigue syndrome or functional syncope. It is important to make the correct diagnosis in order to allow appropriate treatment and to improve the quality of life for these patients.
Carruthers BM, Jain AK, De Meirleir KL, Peterson DL, Klimas NG, Lerner AM, Bested AC, Flor-Henry P, Joshi P, Powles ACP, Sherkey JA, van de Sande MI.		Myalgic Encephalomyelitis/Chronic Fatigue Syndrome: Clinical Working Case Definition, Diagnostic and Treatment Protocols	Journal of Chronic Fatigue Syndrome 2003; 11 (1): 7-116	Recent years have brought growing recognition of the need for clinical criteria for myalgic encephalomyelitis (ME), which is also called chronic fatigue syndrome (CFS). An Expert Subcommittee of Health Canada established the Terms of Reference, and selected an Expert Medical Consensus Panel representing treating physicians, teaching faculty and researchers. A Consensus Workshop was held on March 30 to April 1, 2001 to culminate the review process and establish consensus for a clinical working case definition, diagnostic protocols and treatment protocols. We present a systematic clinical working case definition that encourages a diagnosis based on characteristic patterns of symptom clusters, which reflect specific areas of pathogenesis. Diagnostic and treatment protocols, and a short overview of research are given to facilitate a comprehensive and integrated approach to this illness. Throughout this paper, “myalgic encephalomyelitis” and “chronic fatigue syndrome” are used interchangeably and this illness is referred to as “ME/CFS.”
Chalder T, Godfrey E, Ridsdale L, King M, Wessely S.	Department of Psychological Medicine, Guy's, King's and St Thomas's School of Medicine, London.	Predictors of outcome in a fatigued population in primary care following a randomized controlled trial.	Psychol Med. 2003 Feb;33(2):283-7 Comment in: Psychol Med. 2003 Feb;33(2):197-201..	BACKGROUND: The objective of this study was to examine factors that predicted outcome in a chronically fatigued group of patients who were randomized to cognitive behaviour therapy or counselling in primary care. METHOD: Illness perceptions, attributions, fatigue, disability and demographic variables were recorded at assessment and levels of fatigue and disability were measured at 6 months post randomization. Logistic regression was used to examine associations. RESULTS: Factors that predicted a poor outcome (four or more on the fatigue questionnaire) were: poor social adjustment at assessment; the patients self-report that they had never seen the GP for an emotional reason; a physical illness attribution; and, a long perceived future illness duration. CONCLUSIONS: Patients who are more psychologically minded are more likely to improve with psychological treatments in primary care. General practitioners need to assess this before referring to an appropriate therapist.

Chaudhuri A, Condon BR, Gow JW, Brennan D, Hadley DM.	Department of Neurology, University of Glasgow, South Glasgow University Hospitals NHS Trust, UK. ac54p@udcf.gla.ac.uk	Proton magnetic resonance spectroscopy of basal ganglia in chronic fatigue syndrome.	Neuroreport. 2003 Feb 10;14(2):225-8.	Fatigue is a common symptom of neurological diseases that affect basal ganglia function. We used proton magnetic resonance spectroscopy ((1)H MRS) to study the metabolic functions of the basal ganglia in chronic fatigue syndrome (CFS) to test the hypothesis that fatigue in CFS may have a neurogenic component. (1)H MRS of left basal ganglia was carried out in eight non-psychiatric patients with CFS and their results were compared to age- and sex-matched healthy asymptomatic healthy controls. A highly significant increase in the spectra from choline-containing compounds was seen in the CFS patient group ($p < 0.001$). In the absence of regional structural or inflammatory pathology, increased choline resonance in CFS may be an indicator of higher cell membrane turnover due to gliosis or altered intramembrane signalling.
Chester AC.	Department of Medicine, Georgetown University Medical Center, Washington, DC 20016, USA. achester@foxhallinternists.com	Symptoms of rhinosinusitis in patients with unexplained chronic fatigue or bodily pain: a pilot study.	Arch Intern Med. 2003 Aug 11-25;163(15):1832-6.	BACKGROUND: Recent otolaryngologic studies document significant fatigue and bodily pain (BP) in patients with chronic rhinosinusitis. Studies of general medical patients are lacking. METHODS: A case-control study of 297 consecutive general medical outpatients. RESULTS: Sixty-five patients noted unexplained chronic fatigue (UCF), 33 reported BP, and 26 had both. Compared with 232 patients without UCF, patients with UCF more frequently had the following rhinosinusitis symptoms: facial pressure (odds ratio [OR], 9.7; 95% confidence interval [CI], 5.2-18.2), heavy-headedness (OR, 21.9; 95% CI, 10.9-44.0), nasal obstruction (OR, 4.3; 95% CI, 2.3-7.9), frontal headache (OR, 13.6; 95% CI, 6.5-28.5), postnasal drip (OR, 2.8; 95% CI, 1.6-5.0), sore throat (OR, 3.1; 95% CI, 1.5-6.6), and tender cervical lymph nodes (OR, 9.2; 95% CI, 4.3-19.7). A similar predominance of rhinosinusitis symptoms was noted in patients with BP and in 15 patients with UCF who had chronic fatigue syndrome. No increased prevalence of pollen allergy was noted in association with UCF, BP, or chronic fatigue syndrome. Gastrointestinal, sleep, and psychiatric problems were similar between patients with UCF and 38 patients with explained fatigue. Rhinosinusitis symptoms, however, were more common in UCF. CONCLUSIONS: There is an increased prevalence of rhinosinusitis symptoms but not pollen allergy among general medical outpatients with UCF, BP, or both. Rhinosinusitis symptoms are at least as common as gastrointestinal complaints, sleep disturbance, and psychiatric problems (previously well documented complaints associated with UCF and BP). Rhinosinusitis symptoms, furthermore, are more common in UCF than in fatigue explained by a physical or mental illness.

Chiaravalloti ND, Christodoulou C, Demaree HA, DeLuca J.	Kessler Medical Rehabilitation Research and Education Corporation, West Orange, NJ 07052, USA.	Differentiating simple versus complex processing speed: influence on new learning and memory performance.	J Clin Exp Neuropsychol. 2003 Jun;25(4):489-501.	The current study was designed to examine how the construct of human information processing speed is conceptualized and measured, while also examining the influence of information processing speed on higher cognitive processes (i.e., learning). A mixed medical sample of 92 subjects participated in this study. Subjects underwent a broad-based neuropsychological evaluation, including measures of verbal and visuospatial new learning, spatial and verbal working memory, simple reaction time, choice reaction time, and information processing speed. Principal components factor analysis with varimax rotation resulted in a three-factor solution, comprised of: (1) simple speed/reaction time, (2) complex information processing and new learning, and (3) working memory. Notably, this factor solution identified 2 distinct forms of processing speed--simple and complex information processing speeds. In contrast to the abundance of literature grouping these two constructs together under one term (i.e., processing speed), these results indicate simple and complex speed to be distinct constructs assessed with different neuropsychological instruments. While the expected relationship between complex information processing capacities and working memory abilities was evident in this study, information processing speed also showed a significant relationship with new learning ability. The implications of this intriguing relationship are discussed.
Ciccone DS, Busichio K, Vickroy M, Natelson BH.	Department of Psychiatry, UMDNJ-New Jersey Medical School, 07107, Newark, NJ, USA	Psychiatric morbidity in the chronic fatigue syndrome. Are patients with personality disorder more physically impaired?	J Psychosom Res. 2003 May;54(5):445-52.	OBJECTIVE: The long-term consequences of chronic fatigue syndrome (CFS) include substantial impairment in physical functioning and high levels of work disability. In the absence of a medical explanation for this impairment, some have speculated that it may be due to comorbid psychiatric illness or personality disorder. We addressed this possibility by comparing the functional status of three CFS groups: no psychiatric diagnosis, psychiatric illness only, psychiatric illness and personality disorder. A second aim of the study was to determine whether a continuous measure of psychological distress could provide a better account of impairment than psychiatric diagnosis. METHOD: The study sample consisted of 84 consecutive female referrals with CFS. All participants satisfied the case definition and completed an assessment protocol consisting of: physical examination, psychiatric interview and self-report questionnaires. RESULTS: Psychiatric illness, either alone or in combination with a comorbid personality disorder, was not associated with physical impairment or disability in female participants. A regression model of physical functioning found that psychological distress accounted for 6% and symptom severity for 41% of the variance (P=.06 and <.01, respectively). In the case of disability, the corresponding percentages were 2% and 18% (NS and P<.01, respectively). The modest effects of psychological distress could not be attributed to symptom severity. CONCLUSIONS: Although psychiatric illness and personality disorder was prevalent, neither could explain the effects of CFS on physical functioning and disability. As yet, there is no psychological or medical explanation for the behavioral consequences of CFS.
Ciccone DS, Natelson BH.	Departments of Psychiatry (D.S.C) and Neuroscience (B.H.N.), University of Medicine and	Comorbid illness in women with chronic fatigue syndrome: a test of the single syndrome	Psychosom Med. 2003 Mar-Apr;65(2):268-75.	OBJECTIVE: Evidence of comorbidity among unexplained illness syndromes raises the possibility that all are variants of a single functional disorder, leading some to suggest that separate case definitions for chronic fatigue syndrome (CFS), fibromyalgia (FM), and multiple chemical sensitivity (MCS) may be unnecessary. Our objective was to determine whether discrete diagnostic labels provide useful information about physical functioning, symptom severity, and

	Dentistry of New Jersey-New Jersey Medical School, Newark, New Jersey.	hypothesis.		risk of psychiatric illness. METHODS: The sample consisted of 163 consecutive female referrals with CFS enrolled at a tertiary clinic. Each participant was retrospectively assigned to one of four groups: CFS only, CFS/FM, CFS/MCS, and CFS/FM/MCS. At enrollment, participants gave their history, underwent a physical examination and a standardized psychiatric interview (Diagnostic Interview Schedule), and answered self-report questionnaires. RESULTS: Additional unexplained syndromes were prevalent: 37% met criteria for FM, and 33% met criteria for MCS. With the exception of FM-related pain and disability, there were few differences between the CFS only and CFS with comorbid illness groups. Patients with additional illness were more likely to have major depression and a higher risk of psychiatric morbidity compared with patients in the CFS only group ($p < .01$). Rates of lifetime depression increased from 27.4% in the CFS only group to 52.3% in the CFS/FM group, 45.2% in the CFS/MCS group, and 69.2% in the CFS/FM/MCS group. CONCLUSIONS: The prevalence of comorbid illness in the present CFS sample and the failure to find widespread differences in symptom severity can be seen as support for the single syndrome hypothesis. On the other hand, the existence of discrete syndromes could not be ruled out because of reliable differences between CFS and CFS/FM. Increasing comorbidity was associated with a corresponding increase in risk of major depression.
Clarke JN, James S.	Department of Sociology and Anthropology, Wilfrid Laurier University, Waterloo, N2L 3C5 ON, Canada. jclarke@wlu.ca	The radicalized self: the impact on the self of the contested nature of the diagnosis of chronic fatigue syndrome.	Soc Sci Med. 2003 Oct;57(8):1387-95.	Chronic fatigue syndrome (CFS) is a relatively new disease that is difficult to diagnose. It is also a contested disease immersed in dispute about whether it is a physical or psychiatric reality. Sufferers often claim to experience not only the physical challenges of the disease, and these can be extensive, but also, initially, the anomie of suffering from a condition whose very reality is debated both in the medical and in the wider communities. Theories of self in illness emphasize how people who are diagnosed as chronically ill work hard as they seek to maintain previous, or to develop supernormal, selves. Such goals are cast in a critical light by Foucault's notion of the technologies of self in the context of circulating neo-liberal discourses. As people with CFS, lacking an uncontested medical diagnosis, search for meaningful self-identities, they resist previously available discourses to take up an alternative discourse, one that we call radicalized selves. This paper raises questions about the constraints and liberties, power and powerlessness associated with a clear and undisputed medical diagnosis. It suggests a model of the self in chronic illness that considers not only changes in body and biography but also the availability of an uncontested diagnosis.
Cleare AJ.	Section of Neurobiology of Mood Disorders, Division of Psychological Medicine, The Institute of Psychiatry, London SE5 8AZ, United Kingdom.	The neuroendocrinology of chronic fatigue syndrome.	Endocr Rev. 2003 Apr;24(2):236-52.	Chronic fatigue syndrome (CFS) is a common and disabling problem; although most likely of biopsychosocial origin, the nature of the pathophysiological components remains unclear. There has been a wealth of interest in the endocrinology of this condition, which will be reviewed in this article. Most studied has been the hypothalamic-pituitary-adrenal (HPA) axis; although the quality of many studies is poor, the overall balance of evidence points to reduced cortisol output in at least some patients, with some evidence that this is linked to symptom production or persistence. There is evidence for heightened negative feedback and glucocorticoid receptor function and for impaired ACTH and cortisol responses to a variety of challenges. However, there is no evidence for a specific or uniform dysfunction of the HPA axis. Given the many factors that may impinge on the HPA axis in CFS, such as inactivity, sleep disturbance, psychiatric comorbidity,

				medication, and ongoing stress, it seems likely that HPA axis disturbance is heterogeneous and of multifactorial etiology in CFS. Studies assessing GH, dehydroepiandrostenedione and its sulfate, melatonin, leptin, and neuroendocrine-monoamine interactions are also reviewed. There is some evidence from these studies to suggest alterations of dehydroepiandrostenedione sulfate function and abnormal serotonin function in CFS, but whether these changes are of functional importance remains unclear. To obtain a clearer assessment of the etiological and pathophysiological relevance of endocrine changes in CFS, it is suggested that more prospective cohort studies be undertaken in groups at high risk for CFS, that patients with CFS are followed up into recovery, and that multidimensional assessments are undertaken to unravel the influence of the various confounding factors on the observed endocrine changes in CFS.

Perceived Exertion in Fatiguing Illness: Gulf War Veterans with Chronic Fatigue Syndrome.	Med Sci Sports Exerc. 2003 Apr;35(4):569-574.	COOK, D. B., P. R. NAGELKIRK, A. PECKERMAN, A. POLURI, J. J. LAMANCA, and B. H. NATELSON. Perceived Exertion in Fatiguing Illness: Gulf War Veterans with Chronic Fatigue Syndrome. Med. Sci. Sports Exerc., Vol. 35, No. 4, pp. 569-574, 2003.PURPOSEIt has been reported that ratings of perceived exertion (RPE) are elevated in chronic fatigue syndrome (CFS). We have challenged this notion by examining perceived exertion in civilian females with CFS and expressing the data relative to exercise capacity (%[OV0312]O(2max)). The purpose of the present investigation was to further examine RPE during exercise in a unique population of CFS patients, Gulf veterans (GV).METHODSThirty-four GV (N = 15 CFS, 42 +/- 8 yr; N = 19 healthy, 43 +/- 5 yr) performed a maximal exercise test on a cycle ergometer. After a 3-min warm-up, exercise intensity increased by 30 W every minute until exhaustion. RPE were obtained during the last 15 s of each minute using Borg's CR-10 scale.RESULTSWith the exception of peak [OV0312]E, there were no significant differences in any peak exercise variables. Repeated measures ANOVA revealed significantly higher RPE at each power output examined ($F(1,32) = 16.4$, $P < 0.001$). Group differences in RPE remained significant when analyzed relative to peak [OV0312]O(2) ($F(1,32) = 7.2$, $P = 0.01$). Both group main effects and the interaction were eliminated when self-reported fatigue symptoms were controlled for in the analyses. Power functions for RPE as a function of relative oxygen consumption were not different between groups and were significantly greater than a linear value of 1.0 (1.6 +/- 0.3 for both groups, $P < 0.02$).CONCLUSIONSOur results show that RPE are greater in GV with CFS regardless of whether the data were expressed in terms of absolute or relative exercise intensity. However, self-reported fatigue associated with CFS eliminated the group differences. These results suggest that GV with CFS were unique compared with their civilian counterparts. Future research aimed at determining the influence of preexisting fatigue on RPE during exercise is warranted.
Cook DB, Nagelkirk PR, Peckerman A, Poluri A, Lamanca JJ, Natelson BH.	1Center for the Study of War-Related Illnesses, VA NJ Health Care, East Orange, NJ; 2Chronic	Perceived Exertion in Fatiguing Illness: Civilians with Chronic Fatigue Syndrome.	Med Sci Sports Exerc. 2003 Apr;35(4):563-568.	COOK, D. B., P. R. NAGELKIRK, A. PECKERMAN, A. POLURI, J. J. LAMANCA, and B. H. NATELSON. Perceived Exertion in Fatiguing Illness: Civilians with Chronic Fatigue Syndrome. Med. Sci. Sports Exerc., Vol. 35, No. 4, pp. 563-568, 2003.PURPOSEIt has been reported that ratings of perceived exertion (RPE) are elevated in chronic fatigue syndrome (CFS). However, methodological limitations have rendered this conclusion suspect. The purpose of the present investigation was

	Fatigue Syndrome Cooperative Research Center, University of Medicine and Dentistry of New Jersey - New Jersey Medical School, Newark, NJ; and.			to examine RPE during exercise in civilians with CFS by comparing subjects at both absolute exercise stage and relative oxygen consumption reference criteria.METHODSA sample of 39 civilian females (N = 19 CFS, 34 +/- 7 yr; N = 20 healthy controls, 33 +/- 7 yr) underwent a maximal exercise test on a treadmill. RPE were obtained during the last 15 s of each 3-min stage using Borg's 6-20 scale.RESULTSThere were no significant differences in peak [OV0312]O(2), RER, or RPE. However, controls exercised longer (20.0 +/- 1.1 vs 15.9 +/- 1.1 min, P = 0.01, healthy vs CFS) and had higher peak HR (183 +/- 3 vs 174 +/- 2 bpm, P = 0.03, healthy vs CFS). Civilians with CFS reported higher RPE at stages 3 through 5 compared with controls (F(3,111)= 3.6,P = 0.017). Preexercise fatigue ratings were not a significant predictor of perceived exertion during exercise. There were no group differences (F(1,37)= 1.9,P = 0.17) when RPE were expressed relative to peak [OV0312]O(2).CONCLUSIONSOur results show that RPE are greater in civilians with CFS when the data are expressed in terms of absolute exercise intensity. However, by examining RPE relative to a common maximum (i.e., peak [OV0312]O(2)) no differences were observed. The findings of the present investigation challenge the notion that RPE are dysregulated in CFS.
Covelli V, Pellegrino NM, Jirillo E.	Division of Neurology, Azienda Policlinico, Bari, Italy. nm.pellegrino@midim.uniba.it	A point of view: The need to identify an antigen in psyconeuroimmunological disorders.	Curr Pharm Des. 2003;9(24):1951-5.	Several lines of evidence support a mutual relationship between the nervous system and the immune system. Therefore, it is not surprising that some neuropsychiatric disorders are also characterized by immune abnormalities. In patients with phobic disorders and in patients with migraine without aura some common immune abnormalities have been detected and, in particular, natural immunity deficits, exaggerated release of proinflammatory cytokines and circulating bacterial endotoxins have been found. In other neurological disease, some etiologic factors have been detected as in the case of Guillain-Barre syndrome in which molecular mimicry between Campylobacter jejuni endotoxin and GM1 ganglioside may cause an acute inflammatory polyneuropathy. On the other hand, attempts to identify an antigen have been made in patients with Alzheimer's disease and schizophrenia. Finally, the chronic fatigue syndrome, an old illness in search for an antigen, risk factors and precipitating agents have been described but evidence for a specific antigen is still lacking.
Creswell C, Chalder T.	Sub-Department of Clinical Health Psychology, University College London, UK. c.creswell@ucl.ac.uk	The relationship between illness attributions and attributional style in Chronic Fatigue Syndrome.	Br J Clin Psychol. 2003 Mar;42(Pt 1):101-4.	OBJECTIVE: To examine the relationship between illness attributions and general attributional style in Chronic Fatigue Syndrome (CFS). METHOD: Participants with CFS answered questions on their explanation for their illness and completed the Attributional Style Questionnaire (parallel form). RESULTS: Of the participants, 58.3% attributed their illness to predominantly physical factors. A significant relationship was found between the presence of a self-serving attributional style and illness attributions. CONCLUSION: Illness attributions were associated with an individual's general attributional style. It is suggested that illness attributions may be less important with regards prognosis than, for example, other variables which influence a person's general view of the world.

Darbishire L, Ridsdale L, Seed PT.	Department of General Practice, Guy's, King's College and St Thomas's School of Medicine, London. lucy.darbishire.ac.uk	Distinguishing patients with chronic fatigue from those with chronic fatigue syndrome: a diagnostic study in UK primary care.	Br J Gen Pract. 2003 Jun;53(491):441-5.	BACKGROUND: Chronic fatigue syndrome (CFS) has been defined, but many more patients consult in primary care with chronic fatigue that does not meet the criteria for CFS. General practitioners (GPs) do not generally use the CFS diagnosis, and have some doubt about the validity of CFS as an illness. AIM: To describe the proportion of patients consulting their GP for fatigue that met the criteria for CFS, and to describe the social, psychological, and physical differences between patients with CFS and those with non-CFS chronic fatigue in primary care. DESIGN OF STUDY: Baseline data from a trial of complex interventions for fatigue in primary care. SETTING: Twenty-two general practices located in London and the South Thames region of the United Kingdom recruited patients to the study between 1999 and 2001. METHOD: One hundred and forty-one patients who presented to their GP with unexplained fatigue lasting six months or more as a main symptom were recruited, and the Centers for Disease Control (CDC) case definition was applied to classify CFS. RESULTS: Approximately two-thirds (69%) of patients had chronic fatigue and not CFS. The duration of fatigue (32 months) and perceived control over fatigue were similar between groups; however, fatigue, functioning, associated symptoms, and psychological distress were more severe in the patients in the CFS group, who also consulted their GP significantly more frequently, were twice as likely to be depressed, and more than twice as likely to be unemployed. About half (CFS = 50%; chronic fatigue = 55%) in each group attributed their fatigue to mainly psychological causes. CONCLUSIONS: In primary care, CFS is a more severe illness than chronic fatigue, but non-CFS chronic fatigue is associated with significant fatigue and is reported at least twice as often. That half of patients, irrespective of CFS status, attribute their fatigue to psychological causes, more than is observed in secondary care, indicates an openness to the psychological therapies provided in that setting. More evidence on the natural history of chronic fatigue and CFS in primary care is required, as are trials of complex interventions. The results may help determine the usefulness of differentiating between chronic fatigue and CFS.
Davey NJ, Puri BK, Catley M, Main J, Nowicky AV, Zaman R.	Department of Sensorimotor Systems, Division of Neuroscience and Psychological Medicine, Imperial College Faculty of Medicine, Charing Cross Hospital, London W6 8RF, UK.	Deficit in motor performance correlates with changed corticospinal excitability in patients with chronic fatigue syndrome.	Int J Clin Pract. 2003 May;57(4):262-4.	Chronic fatigue syndrome (CFS) is characterised by fatigue and musculosketetal pain, the severity of which is variable. Simple reaction times (SRTs) and movement times (SMTs) are slowed in CFS. Our objective is to correlate the day-to-day changes in symptomatology with any change in SRT, SMT or corticospinal excitability. Ten CFS patients were tested on two occasions up to two years apart. Motor evoked potentials (MEPs) to transcranial magnetic stimulation (TMS) of the motor cortex were recorded from the thenar muscles. Threshold TMS strength to evoke MEPs was measured to index corticospinal excitability. SRTs and SMTs were measured. The percentage change in both SRTs and SMTs between the two test sessions correlated with the percentage change in corticospinal excitability assessed according to threshold TMS intensity required to produce MEPs. This study provides evidence that changing motor deficits in CFS have a neurophysiological basis. The slowness of SRTs supports the notion of a deficit in motor preparatory areas of the brain.

De Meirleir K, McGregor N.		Chronic Fatigue Syndrome Guidelines	Journal of Chronic Fatigue Syndrome 2003; 11 (1): 1	
Diaz-Mitoma F, Turgonyi E, Kumar A, Lim W, Larocque L, Hyde BM		Clinical Improvement in Chronic Fatigue Syndrome Is Associated with Enhanced Natural Killer Cell-Mediated Cytotoxicity: The Results of a Pilot Study with Isoprinosine	Journal of Chronic Fatigue Syndrome 2003; 11 (2): 71	Chronic fatigue syndrome is associated with systemic and cognitive symptoms and with several immune abnormalities. The clinical impact of Isoprinosine® was evaluated in sixteen CFS patients, followed for 28 weeks in a single-blind, placebo controlled trial. Patients were also monitored for various immune parameters. Improvement based on clinical staging was observed in six of ten treated patients (6)0%). Clinically improved patients showed significantly enhanced natural killer (NK) cell activity, which correlated with the duration of Isoprinosine treatment ($p < 0.03$). Treatment with Isoprinosine resulted in significantly increased numbers of CD4+ T helper cells ($p < 0.03$). Treatment with Isoprinosine for 12 weeks did not appreciably influence the in vitro production of IFN-?, IL-1?, IL-10 or IL-12. However, IL-12 was significantly increased at week 28 ($p < 0.02$) in patients who improved after treatment with Isoprinosine. These results suggest that taking Isoprinosine may benefit a subgroup of patients with CFS, and this clinical improvement is associated with enhanced NK cell function and IL-12 levels. Further trials to evaluate the use of Isoprinosine in the treatment of CFS patients are warranted.
Douche-Aourik F, Berlier W, Feasson L, Bourlet T, Harrath R, Omar S, Grattard F, Denis C, Pozzetto B.	Laboratory of Bacteriology-Virology (GIMAP), Faculte de Medecine Jacques Lisfranc, Saint-Etienne, France.	Detection of enterovirus in human skeletal muscle from patients with chronic inflammatory muscle disease or fibromyalgia and healthy subjects.	J Med Virol. 2003 Dec;71(4):540-7.	Enterovirus RNA has been found previously in specimens of muscle biopsy from patients with idiopathic dilated cardiomyopathy, chronic inflammatory muscle diseases, and fibromyalgia or chronic fatigue syndrome (fibromyalgia/chronic fatigue syndrome). These results suggest that skeletal muscle may host enteroviral persistent infection. To test this hypothesis, we investigated by reverse transcription-polymerase chain reaction (RT-PCR) assay the presence of enterovirus in skeletal muscle of patients with chronic inflammatory muscle diseases or fibromyalgia/chronic fatigue syndrome, and also of healthy subjects. Three of 15 (20%) patients with chronic inflammatory muscle diseases, 4 of 30 (13%) patients with fibromyalgia/chronic fatigue syndrome, and none of 29 healthy subjects was found positive. The presence of VP-1 enteroviral capsid protein was assessed by an immunostaining technique using the 5-D8/1 monoclonal antibody; no biopsy muscle from any patient or healthy subject was found positive. The presence of viral RNA in some muscle biopsies from patients exhibiting muscle disease, together with the absence of VP-1 protein, is in favor of a persistent infection involving defective viral replication. Copyright 2003 Wiley-Liss, Inc.
Duclos P.	Department of Vaccines and Biologicals, Health Technology and Pharmaceuticals, World Health Organization, Geneva, 20 Avenue Appia, CH-1211 Geneva 27,	Safety of immunisation and adverse events following vaccination against hepatitis B.	Expert Opin Drug Saf. 2003 May;2(3):225-31.	Hepatitis B vaccines (HBVs) are composed of highly purified preparations of hepatitis B virus surface antigen (HBsAg). An adjuvant, either aluminium phosphate or aluminium hydroxide, is added to the vaccines, which are sometimes preserved with thiomersal. In placebo-controlled studies, common side effects other than local reactions were reported no more frequently among vaccine recipients than among individuals receiving a placebo. A number of controversial adverse events have, however, been purported to be associated with HBVs, including rheumatoid arthritis (RA), diabetes, demyelinating diseases (e.g., multiple sclerosis [MS]), chronic fatigue syndrome, and more recently, lymphoblastic leukaemia. In addition, the safety of the thiomersal and aluminium contained in the vaccine has also been under close scrutiny. These issues have been reviewed by a number of country-specific or international independent review committees

	Switzerland. duclosp@who.int			such as that of the US Institute of Medicine (IOM) and the World Health Organization's (WHO) Global Advisory Committee on Vaccine Safety (GACVS). Upon review of the scientific evidence, none of the serious allegations have so far been confirmed. On the contrary, scientific evidence has accumulated to disprove many of the allegations. In particular, the IOM committee has concluded that the evidence favoured rejection of a causal relationship between HBV administered to adults and incident MS or MS relapse. Whilst it is important to continue monitoring some of the safety issues, there is no evidence to suggest that the WHO should consider altering its recommendation that all countries should have universal infant and/or adolescent immunisation programmes. The risks of hepatitis B vaccination are only theoretical in comparison with clear benefits in terms of cirrhosis and cancer prevention, and the HBV remains one with an excellent safety profile.
Eidelman D.	Ramat Hasharon, Israel	Chronic fatigue syndrome - medical fact or artifact.	Med Hypotheses. 2003 Jun;60(6):840-2.	Despite extensive investigation, the enigma of Chronic Fatigue Syndrome (CFS) continues to confound medical researchers. It is suggested that this may be due to two impediments inherent in their overall approach to the problem. Firstly, although fatigue is central to CFS, medical scientists appear not to understand what fatigue itself really is, nor what is its purpose or mode of function. A functional definition of fatigue is suggested to help resolve this. Secondly, physicians and other researchers - psychologists and alternative medicine practitioners - fail to observe an elementary and fundamental procedure of clinical medicine, namely, that of properly examining their patients before making a diagnosis or providing treatment. The notion of the 'black hole' of medicine is introduced. Recognizing the existence of these impediments is considered a self-evident precondition for further significant progress being made in this field.
Endresen GK.	Department of Rheumatology, The National Hospital, University of Oslo, Forskningsvn. 2-Block B, 0027, Oslo, Norway. gerhard.endresen@rikshospitalet.no	Mycoplasma blood infection in chronic fatigue and fibromyalgia syndromes.	Rheumatol Int. 2003 Sep;23(5):211-5. Epub 2003 Jul 16.	Chronic fatigue syndrome (CFS) and fibromyalgia syndrome (FMS) are characterised by a lack of consistent laboratory and clinical abnormalities. Although they are distinguishable as separate syndromes based on established criteria, a great number of patients are diagnosed with both. In studies using polymerase chain reaction methods, mycoplasma blood infection has been detected in about 50% of patients with CFS and/or FMS, including patients with Gulf War illnesses and symptoms that overlap with one or both syndromes. Such infection is detected in only about 10% of healthy individuals, significantly less than in patients. Most patients with CFS/FMS who have mycoplasma infection appear to recover and reach their pre-illness state after long-term antibiotic therapy with doxycycline, and the infection can not be detected after recovery. By means of causation and therapy, mycoplasma blood infection may permit a further subclassification of CFS and FMS. It is not clear whether mycoplasmas are associated with CFS/FMS as causal agents, cofactors, or opportunistic infections in patients with immune disturbances. Whether mycoplasma infection can be detected in about 50% of all patient populations with CFS and/or FMS is yet to be determined.
Englebienne P.		RNase L in Health and Disease–What Did We Learn Recently?	Journal of Chronic Fatigue Syndrome 2003; 11 (2): 97	The 29,59-oligoadenylate-dependent ribonuclease L (RNase L) is central to the innate cellular defense mechanism induced by type I interferons during intracellular infection. The protein, activated by 29,59-oligoadenylates, precludes the replication of the infectious agent by cleaving single-stranded RNA and, along with the double-stranded RNA-dependent protein kinase, its spreading by inducing the cell to undergo suicide (apoptosis). In absence of infection, the protein

				remains dormant. Recent evidence indicates however that the protein is activated in absence of infection and may play a role in cell differentiation, immune activation, and to act as a tumor-suppressor. A deregulation in this pathway has been documented in immune cells of chronic fatigue syndrome patients which involves the presence of a catalytically active truncated RNase L. This protein escapes the normal regulation which implies the development of a cascade of unwanted cellular events. The present article reviews our current understanding of this deregulation, enlightens its relevance in the pathological process and proposes new targets for therapeutic development.
Englebienne P, Verhas M, Herst CV, De Meirleir K.	University of Brussels (ULB/VUB), and RED Laboratories, N.V., Brussels, Belgium	Type I interferons induce proteins susceptible to act as thyroid receptor (TR) corepressors and to signal the TR for destruction by the proteasome: possible etiology for unexplained chronic fatigue.	Med Hypotheses. 2003 Feb;60(2):175-80.	In some patients complaining of chronic fatigue such as those suffering from the chronic fatigue syndrome (CFS), no underlying physical cause can be clearly identified and they typically present a normal thyroid function. Several studies indicate a dysregulation in the type I interferons (IFN-alpha/beta) pathway in CFS resulting in a sustained upregulation of 2('),5(')-oligoadenylate synthetases (2-5OAS). Likewise, patients treated with IFN-alpha/beta usually complain of severe fatigue as a limiting side effect. Beside the 2-5OAS, IFN-alpha/beta induce also the expression of three closely related proteins of unknown function termed the 2-5OAS-like (2-5OASL) proteins. The amino acid sequences of the 2-5OASL proteins display 96% identity with the partial sequence of the thyroid receptor interacting protein (TRIP) 14, further contain two typical thyroid hormone receptor (TR) coregulator domains and feature two ubiquitin C-terminal domains. From these observations, we raise the hypothesis that the 2-5OASL proteins are TRIPs capable of, respectively, repressing TR transactivation and/or signaling the receptor for destruction by the proteasome. Such molecular mechanisms could explain the development of a clinical hypothyroid state in presence of a normal thyroid function.
Evengard B, Jonzon E, Sandberg A, Theorell T, Lindh G.	Departments of Laboratory Medicine and Medicine, Karolinska Institute at Huddinge University Hospital and National Institute for Psychosocial Factors and Health, Stockholm, Sweden.	Differences between patients with chronic fatigue syndrome and with chronic fatigue at an infectious disease clinic in Stockholm, Sweden.	Psychiatry Clin Neurosci. 2003 Aug;57(4):361-8.	Background data were collected from patients presenting with fatigue at the clinic of infectious diseases at Huddinge University Hospital, Stockholm. The main purpose was to look for differences as to demographic and functional status for patients fulfilling criteria for chronic fatigue syndrome (CFS) and chronic fatigue (CF). A cross-sectional questionnaire survey was performed using a variety of instruments. A thorough medical investigation was performed. No difference was found as to social situation, occupation and illness attributions for patients in the two categories. Patients with CFS reported in general a higher degree of 'sickness' with more self-reported somatic symptoms, more self-reported functional impairment and more absence from work. A higher degree of psychiatric comorbidity was observed in CF than in CFS patients. A majority of CFS patients (80%) had an acute infectious onset compared to 43% in the CF group. Presently used criteria might, according to findings presented here, define two different patient categories in a population characterized by severe, prolonged fatigue. Because CFS patients (compared to patients with CF) have more somatic symptoms, more often report an infectious, sudden onset and have less psychiatric comorbidity, and CF patients seem to have more of an emotional, burn-out-like component one could speculate about the existence of different pathogenetic backgrounds behind the two diagnoses.
Fasih T, Pickin M, Cuschieri RJ.	Department of Vascular Surgery and	Non-vascular claudication: a	Int J Clin Pract. 2003 Mar;57(2):87-9.	This is a prospective study of patients referred to our department with symptoms of claudication unlikely to be of vascular origin. After clinical assessment these patients were referred to an

	Orthopaedic Medicine, Doncaster Royal Infirmary, Doncaster, Yorkshire.	clinical conundrum.		orthopaedic physician. Of 1070 patients referred, 33 patients were diagnosed with a non-vascular problem. Of these, 21 were cases of spinal stenosis with or without nerve root irritation, seven had a combination of spinal pathology and peripheral vascular disease, and five were diagnosed with intervertebral disc prolapse (n=3), diabetic neuropathy (n=1) and chronic fatigue syndrome (n=1). The prognosis for patients with non-vascular claudication in respect of the development of premature vascular events is likely to be different from vascular claudicants and they should be counselled appropriately. Furthermore, the potentially less favourable outcome following reconstruction must be clearly explained to patients with a non-vascular contribution to their symptoms before any therapeutic vascular intervention. Failure to do this is likely to have significant medicolegal implications.
Fisher L, Chalder T.	Guy's, King's and St. Thomas' School of Medicine, Chronic Fatigue Syndrome Research Unit, King's Denmark Hill Campus, New Medical School Building, SE5 9PJ, London, UK	Childhood experiences of illness and parenting in adults with Chronic Fatigue Syndrome.	J Psychosom Res. 2003 May;54(5):439-43.	OBJECTIVE: There are many similarities between chronic fatigue syndrome (CFS), the somatoform disorders and problems otherwise known as "medically unexplained symptoms." There is some evidence to suggest that a combination of inadequate parenting and early illness experience may predispose the individual to develop medically unexplained symptoms in adult life. The aim of this investigation was to compare the contributions of childhood experiences of illness and parenting in adults with CFS with a fracture clinic control group. METHOD: A retrospective case control design was used. Thirty patients with a diagnosis of CFS and 30 patients attending a fracture clinic in an inner London teaching hospital completed questionnaires measuring parental care and protection and were interviewed about childhood experiences of illness. RESULTS: There were no differences in childhood experience of illness in the two groups. However, logistic regression revealed that maternal overprotection and depression were associated with the diagnosis of CFS. CONCLUSION: The findings may represent risk factors for the development of CFS in adult life. It is possible that maternal overprotection in particular is related to the formation of belief systems about avoiding activity that operate to adversely influence behaviour in patients with CFS.
Fulle S, Belia S, Vecchiet J, Morabito C, Vecchiet L, Fano G.	Laboratorio Interuniversitario di Miologia, Universita 'G. d'Annunzio', Nuovo Polo Didattico, 66013 Chieti Scalo, Italy. s.fulle@unich.it	Modification of the functional capacity of sarcoplasmic reticulum membranes in patients suffering from chronic fatigue syndrome.	Neuromuscul Disord. 2003 Aug;13(6):479-84.	In chronic fatigue syndrome, several reported alterations may be related to specific oxidative modifications in muscle. Since sarcoplasmic reticulum membranes are the basic structures involved in excitation-contraction coupling and the thiol groups of Ca(2+) channels of SR terminal cisternae are specific targets for reactive oxygen species, it is possible that excitation-contraction coupling is involved in this pathology. We investigated the possibility that abnormalities in this compartment are involved in the pathogenesis of chronic fatigue syndrome and consequently responsible for characteristic fatigue. The data presented here support this hypothesis and indicate that the sarcolemmal conduction system and some aspects of Ca(2+) transport are negatively influenced in chronic fatigue syndrome. In fact, both deregulation of pump activities (Na(+)/K(+) and Ca(2+)-ATPase) and alteration in the opening status of ryanodine channels may result from increased membrane fluidity involving sarcoplasmic reticulum membranes.]
Gaab J, Huster D, Peisen R, Engert V, Heitz V, Schad T, Schurmeyer T,	Center for Psychobiological and Psychosomatic Research, University	Assessment of cortisol response with low-dose and high-dose ACTH in	Psychosomatics. 2003 Mar-Apr;44(2):113-9.	A reduced secretion of cortisol has been proposed as a possible explanation of the symptoms in chronic fatigue syndrome. However, the evidence of hypocortisolism in chronic fatigue syndrome is conflicting. In order to simultaneously assess possible alterations in adrenocortical sensitivity and secretory adrenal reserve, the authors administered both low-dose and high-dose ACTH to a

Ehlert U.	of Trier, Germany. jgaab@klipsy.unizh.ch	patients with chronic fatigue syndrome and healthy comparison subjects.		group of 18 chronic fatigue syndrome patients and 18 age- and gender-matched healthy comparison subjects. No response differences for salivary and plasma cortisol were detectable after administration of either low-dose or high-dose ACTH, indicating that primary adrenal insufficiency is unlikely to play a significant role in the etiology of chronic fatigue syndrome.
Garrison RL, Breeding PC.	3306 Montavesta Drive, Lexington, KY 40502, USA.	A metabolic basis for fibromyalgia and its related disorders: the possible role of resistance to thyroid hormone.	Med Hypotheses. 2003 Aug;61(2):182-9.	It has long been recognized that the symptom complex of fibromyalgia can be seen with hypothyroidism. Hypothyroidism may been categorized, like diabetes, into type I (hormone deficient) and type II (hormone resistant). Most cases of fibromyalgia fall into the latter category. The syndrome is reversible with treatment, and is usually of late onset. It is likely more often acquired than due to mutated receptors. Now that there is evidence to support the hypothesis that fibromyalgia may be due to thyroid hormone resistance, four major questions appear addressable. First, can a simple biomarker be found to help diagnose it? Second, what other syndromes similar to Fibromyalgia may share a thyroid-resistant nature? Third, in non-genetic cases, how is resistance acquired? Fourth, what other methods of treatment become available through this new understanding? Preliminary evidence suggests that serum hyaluronic acid is a simple, inexpensive, sensitive, and specific test that identifies fibromyalgia. Overlapping symptom complexes suggest that chronic fatigue syndrome, Gulf war syndrome, premenstrual syndrome, post traumatic stress disorder, breast implant silicone sensitivity syndrome, bipolar affective disorder, systemic candidiasis, myofascial pain syndrome, and idiopathic environmental intolerance are similar enough to fibromyalgia to merit investigation for possible thyroid resistance. Acquired resistance may be due most often to a recently recognized chronic consumptive coagulopathy, which itself may be most often associated with chronic infections with mycoplasmids and related microbes or parasites. Other precipitants of thyroid resistance may use this or other paths as well. In addition to experimentally proven treatment with supraphysiologic doses of thyroid hormone, the thyroid-resistant disorders might be treatable with anti-hypercoagulant, anti-infective, insulin-sensitizing, and hyaluronolytic strategies.
Georgiades E, Behan WM, Kilduff LP, Hadjicharalambous M, Mackie EE, Wilson J, Ward SA, Pitsiladis YP.		Chronic fatigue syndrome: new evidence for a central fatigue disorder.	Clin Sci (Lond). 2003 Apr 23 [Epub ahead of print].	Considerable evidence points towards a prominent role for central neural (CNS) mechanisms in the pathogenesis of chronic fatigue syndrome (CFS), a disorder characterised chiefly by persistent, often debilitating, fatigue. We wished to characterise circulating profiles of putative amino acid modulators of CNS serotoninergic and dopaminergic function in CFS patients at rest, during symptom-limited exercise and subsequent recovery. Twelve CFS patients and eleven age- and sex-matched sedentary controls, with similar physical activity histories, underwent ramp-incremental exercise to the limit of tolerance. Plasma amino acid concentrations, oxygen uptake (Vo 2) and ratings of perceived exertion (RPE) were measured at rest, during exercise and recovery. Peak oxygen uptake (Vo 2peak) was significantly lower in the CFS patients, compared to controls. RPE in the patients was higher at all measured time points, including rest, relative to controls. Levels of free tryptophan [free Trp];the rate-limiting serotoninergic precursor, were significantly higher in CFS patients at exhaustion and recovery, whereas concentrations of branched-chain and large-neutral amino acids (BCAA and LNAA, respectively) were lower in patients at exhaustion and, for [LNAA], also during recovery. Consequently, the [free Trp] : [BCAA] and [free Trp] : [LNAA] ratios were significantly higher in CFS patients, except at rest. On

				the other hand, levels of tyrosine, the rate-limiting dopaminergic precursor, were significantly lower at all time points in the patients. The significant differences observed in a number of key putative CNS serotoninergic and dopaminergic modulators, coupled with the exacerbated effort perception, provide further evidence for a potentially significant role of CNS mechanisms in CFS pathogenesis.
Gherardi RK.	Groupe Nerf-Muscle, Departement de Pathologie, Hopital Henri Mondor, Creteil. romain.gherardi@hmn.ap-hop-paris.fr	[Lessons from macrophagic myofasciitis: towards definition of a vaccine adjuvant-related syndrome] [Article in French]	Rev Neurol (Paris). 2003 Feb;159(2):162-4.	Macrophagic myofasciitis is a condition first reported in 1998, which cause remained obscure until 2001. Over 200 definite cases have been identified in France, and isolated cases have been recorded in other countries. The condition manifests by diffuse myalgias and chronic fatigue, forming a syndrome that meets both Center for Disease Control and Oxford criteria for the so-called chronic fatigue syndrome in about half of patients. One third of patients develop an autoimmune disease, such as multiple sclerosis. Even in the absence of overt autoimmune disease they commonly show subtle signs of chronic immune stimulation, and most of them are of the HLADRB1*01 group, a phenotype at risk to develop polymyalgia rheumatica and rheumatoid arthritis. Macrophagic myofasciitis is characterized by a stereotyped and immunologically active lesion at deltoid muscle biopsy. Electron microscopy, microanalytical studies, experimental procedures, and an epidemiological study recently demonstrated that the lesion is due to persistence for years at site of injection of an aluminum adjuvant used in vaccines against hepatitis B virus, hepatitis A virus, and tetanus toxoid. Aluminum hydroxide is known to potently stimulate the immune system and to shift immune responses towards a Th-2 profile. It is plausible that persistent systemic immune activation that fails to switch off represents the pathophysiologic basis of chronic fatigue syndrome associated with macrophagic myofasciitis, similarly to what happens in patients with post-infectious chronic fatigue and possibly idiopathic chronic fatigue syndrome. Therefore, the WHO recommended an epidemiological survey, currently conducted by the French agency AFSSAPS, aimed at substantiating the possible link between the focal macrophagic myofasciitis lesion (or previous immunization with aluminium-containing vaccines) and systemic symptoms. Interestingly, special emphasis has been put on Th-2 biased immune responses as a possible explanation of chronic fatigue and associated manifestations known as the Gulf war syndrome. Results concerning macrophagic myofasciitis may well open new avenues for etiologic investigation of this syndrome. Indeed, both type and structure of symptoms are strikingly similar in Gulf war veterans and patients with macrophagic myofasciitis. Multiple vaccinations performed over a short period of time in the Persian gulf area have been recognized as the main risk factor for Gulf War syndrome. Moreover, the war vaccine against anthrax, which is administered in a 6-shot regimen and seems to be crucially involved, is adjuvanted by aluminium hydroxide and, possibly, squalene, another Th-2 adjuvant. If safety concerns about long-term effects of aluminium hydroxide are confirmed it will become mandatory to propose novel and alternative vaccine adjuvants to rescue vaccine-based strategies and the enormous benefit for public health they provide worldwide.

Gusev EI, Demina TL, Boiko AN, Khachanova NV.		[Certain problems of therapy with beta-interferon preparations] [Article in Russian]	Zh Nevrol Psikhiatr Im S S Korsakova. 2003;Spec No 2:98-102.	The latest data on clinical effects of beta-interferon-1b (betaferon) in different clinical types of multile sclerosis (MS) are discussed in this review. All local and systemic side effects of this treatment are discussed as well as possible influence of neutralizing antibodies (NAB) on clinical efficacy of this treatment. Moderate and easily treated side effects as well as the absence of significant evidence for modulation of positive clinical effects of beta-interferons by NAT allow one to consider this medicine as one of the basic methods of MS treatment.
Hanley NR, Van de Kar LD.	Department of Pharmacology, Center for Serotonin Disorders Research, Loyola University of Chicago, Stritch School of Medicine, Maywood, Illinois 60153, USA.	Serotonin and the neuroendocrine regulation of the hypothalamic--pituitary-adrenal axis in health and disease.	Vitam Horm. 2003;66:189-255.	Serotonin (5-hydroxytryptamine, 5-HT)-containing neurons in the midbrain directly innervate corticotropin-releasing hormone (CRH)-containing cells located in paraventricular nucleus of the hypothalamus. Serotonergic inputs into the paraventricular nucleus mediate the release of CRH, leading to the release of adrenocorticotropin, which triggers glucocorticoid secretion from the adrenal cortex. 5-HT1A and 5-HT2A receptors are the main receptors mediating the serotonergic stimulation of the hypothalamic-pituitary-adrenal axis. In turn, both CRH and glucocorticoids have multiple and complex effects on the serotonergic neurons. Therefore, these two systems are interwoven and communicate closely. The intimate relationship between serotonin and the hypothalamic-pituitary-adrenal axis is of great importance in normal physiology such as circadian rhythm and stress, as well as pathophysiological disorders such as depression, anxiety, eating disorders, and chronic fatigue.
Hartz AJ, Bentler SE, Brake KA, Kelly MW.	Department of Family Medicine, University of Iowa College of Medicine, Iowa City 52242-	The effectiveness of citalopram for idiopathic chronic fatigue.	J Clin Psychiatry. 2003 Aug;64(8):927-35.	BACKGROUND: Chronic fatigue greatly affects quality of life and is a common reason for physician visits. Patients with chronic fatigue are often treated with antidepressants. METHOD: Prior to enrollment, all subjects had substantial fatigue for 6 months or more that was not explained by depression, organic illness, or lifestyle behaviors. Patients already taking an antidepressant were excluded from the study. Two designs were used. (1) Thirty-one subjects were given placebo for 1

	1097, USA. arthur-hartz@uiowa.edu.			week and then citalopram, 20 to 40 mg/day, for 2 months. Statistical testing evaluated whether fatigue (measured with the Rand Vitality Index) was reduced after citalopram was started. (2) Fatigue changes for subjects taking citalopram were compared with fatigue changes after 1 month and 2 months for 76 similar subjects taking an ineffective treatment. RESULTS: In design 1, fatigue for subjects taking citalopram was significantly and substantially reduced when subjects were switched from placebo to citalopram, p <.05. Benefits at 2 months were greatest for subjects who had fatigue less than 5 years, p <.01, and women, p <.01. In design 2, fatigue scores for subjects taking citalopram were not significantly better than the comparison group for all subjects but were significantly better at 2 months for subjects with less severe fatigue at baseline, p =.005, and for women, p =.08. Depression scores were not significantly better for citalopram subjects overall (p >.10) but were for certain subgroups. For all subjects, citalopram was associated with greater decrease in headaches and muscle aches at 1 month, p <.01. CONCLUSION: Citalopram may improve fatigue and symptoms associated with fatigue for some patients.
Hatcher S, House A.	Academic Unit of Psychiatry and Behavioural Sciences, School of Medicine, University of Leeds.	Life events, difficulties and dilemmas in the onset of chronic fatigue syndrome: a case-control study.	Psychol Med. 2003 Oct;33(7):1185-92.	BACKGROUND: The role of stress in the onset of chronic fatigue syndrome is unclear. Our objectives in this study were first, to determine the relation between the onset of chronic fatigue syndrome and stressful life events and difficulties. Secondly, we examined the role of a particular type of problem, dilemmas, in the onset of chronic fatigue syndrome. METHOD: We used a case-control design with 64 consecutive referrals from an Infectious Diseases/ Liaison Psychiatry Fatigue clinic and 64 age- and sex-matched controls from a general practice population control group in Leeds. We had two main outcome measures; the odds ratios of the risk of developing chronic fatigue syndrome after experiencing a severe life event, severe difficulties or both in the year and 3 months preceding onset; and the proportion of subjects in each group who experienced a dilemma prior to onset. RESULTS: Patients with chronic fatigue syndrome were more likely to experience severe events and difficulties in the 3 months (OR = 9, 95% CI 3.2 to 25.1) and year (OR = 4.3, 95% CI 1.8 to 10.2) prior to onset of their illness than population controls. In the 3 months prior to onset 19 of the 64 patients (30%) experienced a dilemma compared to none of the controls. CONCLUSIONS: Chronic fatigue syndrome is associated with stressful events and difficulties prior to onset. Those events and difficulties characterized as being dilemmas seem to be particularly important.
Hatchette TF, Hayes M, Merry H, Schlech WF, Marrie TJ.	Queen Elizabeth II Health Sciences Centre, Dalhousie University, Halifax, Nova Scotia, Canada.	The effect of C. burnetii infection on the quality of life of patients following an outbreak of Q fever.	Epidemiol Infect. 2003 Jun;130(3):491-5.	Sixty-six cases of Q fever were diagnosed in people affiliated with a goat-farming co-operative in rural Newfoundland in the spring of 1999. Follow-up studies which included administration of the Short Form 36 Health Survey (SF-36) were conducted 3 and 27 months after the initial outbreak to prospectively follow the effects of acute Q fever on the quality of life of the participants. Twenty-seven months after the outbreak 51% of those who had Q fever reported persistent symptoms including seven participants whose symptoms had initially resolved 3 months after the outbreak. Individuals with Q fever had significantly lower scores on five of the eight scales in the SF-36 and lower scores in the mental and physical summary scales compared to uninfected controls. Although this supports the hypothesis of a 'post Q fever fatigue syndrome' (QFFS), further study is warranted.

Helbig KJ, Heatley SL, Harris RJ, Mullighan CG, Bardy PG, Marmion BP.	Q Fever Research Group, IMVS, Adelaide, South Australia. kjhelbig@hotmail.com	Variation in immune response genes and chronic Q fever. Concepts: preliminary test with post-Q fever fatigue syndrome.	Genes Immun. 2003 Jan;4(1):82-5.	Acute primary Q fever is followed by various chronic sequelae. These include subacute Q fever endocarditis, granulomatous reactions in various organs or a prolonged debilitating post-infection fatigue syndrome (QFS). The causative organism, Coxiella burnetii, persists after an initial infection. The differing chronic outcomes may reflect variations within cytokine and accessory immune control genes which affect regulation of the level of persistence. As a preliminary test of the concept we have genotyped QFS patients and controls for gene variants spanning 15 genes and also examined HLA-B and DR frequencies. QFS patients exhibited a significantly increased frequency of HLA-DR-11 compared with controls and also significant differences in allelic variant frequencies within the NRAMP, and IFNgamma genes. These results indicate a possible genetic role in the expression of overt chronic Q fever. Further studies will be undertaken to increase sample sizes, to survey other forms of chronic Q fever and to examine Q fever patients who have recovered without sequelae.
Henningsen P, Zimmermann T, Sattel H.	Department of Psychosomatic Medicine, University of Heidelberg, Heidelberg, Germany. Peter_henningsen@med.uni-heidelberg.de	Medically unexplained physical symptoms, anxiety, and depression: a meta-analytic review.	Psychosom Med. 2003 Jul-Aug;65(4):528-33.	OBJECTIVE: Our objective was to review and compare, with meta-analytic methods, observational studies on the association of medically unexplained physical symptoms, anxiety, and depression with special emphasis on healthy and organically ill control groups and on different types of symptoms, measures, and illness behavior. METHODS: A search of MEDLINE and PsycLIT/PsycINFO for abstracts from 1980 to April 2001 was performed; principal investigators in the field were contacted and article reference lists were used to retrieve additional relevant articles. Two hundred forty-four studies were included on the basis of consensus ratings if they fulfilled seven of eight inclusion criteria pertaining to diagnostic accuracy and statistical appropriateness. Five hundred twenty-two studies were deferred or excluded. We focused specifically on the four functional somatic syndromes for which there were sufficient numbers for meta-analytic integration: irritable bowel syndrome (IBS), nonulcer dyspepsia (NUD), fibromyalgia (FM), and chronic fatigue syndrome (CFS). Data were extracted independently by two authors according to a prespecified coding manual with up to 70 parameters per study. RESULTS: Effect sizes for the association of the four functional somatic syndromes with depression and anxiety were of moderate magnitude but were highly significant statistically when compared with healthy persons and controls with medical disorders of known organic pathology. Moreover, this association was significant whether depression was measured with or without somatic items. Chronic fatigue syndrome is characterized by higher scores of depression, fibromyalgia by lower scores of anxiety than irritable bowel syndrome. Consulting behavior and severity of somatization is related to higher levels of anxiety and depression. CONCLUSIONS: Meta-analytic integration confirms that the four functional somatic syndromes (IBS, NUD, FM, CFS) are related to (but not fully dependent on) depression and anxiety. At present, there is only limited meta-analytic evidence for the same sort of association for medically unexplained physical symptoms in general. In view of the relative independence from depression and anxiety, classification and treatment of these symptoms and syndromes as "common mental disorders" does not seem fully appropriate.

		Fatigue Syndrome.	1989;4(2):139-40.	
Hofmann SG.	Department of Psychology, Boston University, Massachusetts, USA.	Review: cognitive behavioural interventions may be effective for chronic fatigue syndrome and chronic back pain..	Evid Based Ment Health. 2003 May;6(2):55. Comment on: BMJ. 2002 Nov 9;325(7372):1082	
Hokama Y, Uto GA, Palafox NA, Enlander D, Jordan E, Cocchetto A.	Department of Pathology, University of Hawaii-Manoa, Honolulu, Hawaii.	Chronic phase lipids in sera of chronic fatigue syndrome (CFS), chronic ciguatera fish poisoning (CCFP), hepatitis B, and cancer with antigenic epitope resembling ciguatoxin, as assessed with MAb-CTX.	J Clin Lab Anal. 2003;17(4):132-9.	Clinical reports and descriptions of chronic fatigue syndrome (CFS) and chronic ciguatera fish poisoning (CCFP) show great similarities in clinical symptomology. These similarities in the literature suggested the exploration of lipids in sera of CFS, CCFP, and other diseases with the membrane immunobead assay (MIA), which is typically used for screening ciguateric ocean fish. Sera from patients with other diseases, including hepatitis B, cancer, and diabetes, were included to assess the degree of specificity involved. Sera were treated with acetone in a ratio of 1 part serum to 4 parts acetone. The suspension was centrifuged, and the acetone layer was evaporated. The residue was weighed and redissolved in 1.0 mL methanol and tested by the MIA, undiluted and titered to 1:160. The undiluted acetone fraction of the 37 normal showed +/- activity to +activity with 16 no titer, 15 with 1:5 titer and two with 1:10 titer, and four with >/=1:40 titers. One hundred fifteen CFS sera showed 1 with 1+ and 114 with 2+ activity in the undiluted samples, 1 with 1:10 titer, 3 with 1:20 titer, 31 with 1:40 titer, 50 with 1:80 titer, and 30 with 160 titer. Thus 95.6% of the samples had >/=1:40 titer. Eight hepatitis B sera samples had >/=1:40 titers. Four CCFP samples had >/=1:40 titers. Three of 16 cancer samples had 1:40 titer. These data are summarized in Fig. 1. As shown in Table 1, a significant increase (P<0.001) in the chronic phase lipids (CPLs) was shown relative to the normal group. A preliminary chemical study in C18 octadecylsilyl columns showed all fractions (100% chloroform, 9:1 chloroform : methanol, 1:1 chloroform : methanol, and 100% methanol) to contain lipids reactive to MAb-CTX with different intensities. Prostaglandins were shown in 100% methanol fraction. Competitive MIA with crude fish ciguatoxin and CFS with synthetic JKLM ciguatoxin epitope suggested similarities in structure with ciguatoxin. This was compatible with the neuroblastoma assay demonstrated in the C(18) column fractions 9:1 and 1:1, chloroform : methanol solvents. J. Clin. Lab. Anal. 17:132-139, 2003. Huibers MJ, Beurskens AJ, Prins JB, Kant IJ, Bazelmans E, Van Schayck CP, Knottnerus JA, Bleijenberg G.	Department of Epidemiology, Maastricht University, Netherlands. marcus.huibers@hag.unimaas.nl	Fatigue, burnout, and chronic fatigue syndrome among employees on sick leave: do attributions make the difference?	Occup Environ Med. 2003 Jun;60 Suppl 1:i26-31.	BACKGROUND: Persistent fatigue among employees, burnout, and chronic fatigue syndrome (CFS) are three fatigue conditions that share some characteristics in theory. However, these conditions have not been compared in empirical research, despite conceptual similarities. METHODS: This cross sectional study aimed to investigate relations between persistent fatigue, burnout, and CFS by describing the clinical features of a sample of 151 fatigued employees on sick leave. Using validated instruments, subgroups based on research criteria for CFS and burnout within the sample of fatigued employees and a reference group of 97 diagnosed CFS patients were compared. Analyses of covariance were performed. RESULTS: A total of 66 (43.7%) fatigued employees met research criteria for CFS (except symptom criteria) and 76 (50.3%) met research

				criteria for burnout. "CFS-like employees" (fatigued employees who met CFS criteria) reported stronger somatic attributions than "non-CFS-like employees". Burnt out CFS-like employees were more depressed and distressed than CFS-like employees who were not burnt out. Burnout cases among the non-CFS-like employees had stronger psychological attributions than fatigued employees who were not burnt out. Compared to diagnosed CFS patients, CFS-like employees merely had a shorter duration of fatigue complaints. Burnt out CFS-like employees had stronger psychological attributions and were more distressed than CFS patients. CONCLUSIONS: Fatigued employees shared many important characteristics with CFS patients, regardless of burnout status, and many fatigued employees met CFS criteria and/or burnout criteria. Differences however concerned the causal attributions that were made. This raises questions about the role of causal attributions: are they modified by fatigue complaints or do they determine illness outcome?
Hyams KC.	Department of Veterans Affairs, Office of Public Health and Environmental Hazards, Washington, DC, USA	The investigation of chronic fatigue syndrome: a case-study of the limitations of inductive inferences and non-falsifiable hypotheses in medical research.	Med Hypotheses. 2003 May;60(5):760-6.	Karl Popper's argument that deductive logic and falsifiable hypotheses are necessary for the growth of scientific knowledge has been controversial. One approach to assess the relevance of his ideas to medical science has been to evaluate examples of successful research. Another approach is to analyze an unsuccessful investigation. The inconclusive search for a unique 'chronic fatigue syndrome' offers a well-documented case-study for this analysis. Over the past 130 years, numerous studies have provided clinical and epidemiological data, which have supported competing hypotheses about the etiology of chronic fatigue. However, few hypotheses have been refuted because it has not been possible to establish objective standards of inquiry for a subjective symptom like fatigue. As a result, intensive research efforts have not converged on correct explanations by eliminating erroneous ideas. This unsuccessful investigation illustrates how non-falsifiable hypotheses are insufficient to advance medical knowledge, even when there is an abundance of empirical data.
Ikuta K, Yamada T, Shimomura T, Kuratsune H, Kawahara R, Ikawa S, Ohnishi E, Sokawa Y, Fukushi H, Hirai K, Watanabe Y, Kurata T, Kitani T, Sairenji T.	Division of Biosignaling, Department of Biomedical Sciences, Faculty of Medicine, School of Life Science, Tottori University, Yonago 683-8503, Japan.	Diagnostic evaluation of 2', 5'-oligoadenylate synthetase activities and antibodies against Epstein-Barr virus and Coxiella burnetii in patients with chronic fatigue syndrome in Japan.	Microbes Infect. 2003 Oct;5(12):1096-102.	To investigate the association of viral infections with chronic fatigue syndrome (CFS), we assayed 2', 5'-oligoadenylate synthetase (2-5AS) activities in peripheral blood mononuclear cells from CFS patients in Japan. These patients were diagnosed in two hospitals, H1 and H2, located in different areas of the country. The activities were detected in 19 (86%) and 7 (32%) of each of the 22 patients in H1 and H2, respectively, while they were detected in only four (11%) out of the 38 healthy controls. IFN-alpha was similarly detected in a few CFS patients and healthy controls. We also assayed the antibody titers against Epstein-Barr virus (EBV) and Coxiella burnetii in these patients. The EBV anti-EA-IgG antibodies were detected in two (9%) and seven (32%) of each of the 22 patients in H1 and H2, respectively. Anti-C. burnetii IgG antibodies were detected in six (27%) out of 22 patients in H1 but not in 22 patients in H2, while they were detected in one (11%) of the nine healthy controls. Some CFS patients may be associated with EBV or C. burnetii infection. There were some statistical correlations between the 2-5AS activities and antibody titers of EA-IgG ($P < 0.05$, Student's t-test) but not to the antibody titers of C. burnetii. The up-regulation of 2-5AS activities suggests immunological dysfunctions with some virus infections in the CFS patients. Our results indicate that 2-5AS activities are useful for a diagnostic marker of CFS and for exploring the complicated pathogenesis of CFS.

Because the pathogenesis of CFS has yet to be determined, case definitions have relied on clinical observation in classifying signs and symptoms for diagnosis. The current investigation examined differences between CFS as defined by Fukuda and colleagues and a set of criteria that has been stipulated for myalgic encephalomyelitis (ME). Dependent measures included psychiatric comorbidity, symptom frequency, symptom severity, and functional impairment. The ME and Fukuda et al. (1994) CFS criteria were compared with a group having chronic fatigue due to psychiatric reasons. Significant differences occurred primarily with neurologic, neuropsychiatric, fatigue/weakness, and rheumatological symptoms. These findings suggest that it might be inappropriate to synthesize results from studies of this illness that use different definitions to select study populations.
Jason LA, Taylor RR, Kennedy CL, Jordan KM, Song S, Johnson D, Torres-Harding S.	Center for Community Research, DePaul University, Chicago, IL 60614, USA. ljason@wppost.depaul.edu	Chronic fatigue syndrome: symptom subtypes in a community based sample.	Women Health. 2003;37(1):1-13.	Most studies of Chronic Fatigue Syndrome (CFS) have been based on patients recruited from primary or tertiary care settings. Patients from such settings might not be typical of patients in the general population. The present investigation involved examining individuals with CFS from a community-based study. A random sample of 18,675 respondents in Chicago were first interviewed by telephone. A group of individuals with chronic fatigue accompanied by at least four Fukuda et al. (1994) symptoms associated with CFS were given medical and psychiatric examinations. From this sample, a physician review group diagnosed individuals with CFS. Those diagnosed with CFS were subclassified based on frequency of symptoms. Important differences emerged on measures of sociodemographics and disability. The implications of these findings and others are discussed.

Health Qual Life Outcomes. 2003 Dec 2;1(1):74. Epub 2003 Dec 02.	BACKGROUND: Chronic fatigue syndrome (CFS) is characterized by profound fatigue, which substantially interferes with daily activities, and a characteristic symptom complex. Patients use a variety of prescribed and self-administered medications, vitamins, and supplements for relief of their symptoms. The objective of this study was to describe utilization of medications and supplements by persons with CFS and non-fatigued individuals representative of the general population of Wichita, Kansas. METHODS: We used a random-digit dialing telephone survey to identify persons with CFS in the general population of Wichita, Kansas. Subjects who on the basis of telephone interview met the CFS case definition, and randomly selected non-fatigued controls, were invited for a clinic evaluation that included self-reported use of medications and supplements. Sex-adjusted odds ratios and 95% confidence interval were estimated to measure the association between CFS and use of various drug categories. RESULTS: We clinically evaluated and classified 90 subjects as CFS during the study and also collected clinical data on 63 who never described fatigue. Subjects with CFS reported using 316 different drugs compared to 157 reported by non-fatigued controls. CFS subjects were more likely to use any drug category than controls (p = 0.0009). Pain relievers and vitamins/supplements were the two most common agents listed by both groups. In addition CFS persons were more likely to use pain relievers, hormones, antidepressants, benzodiazepines, gastro-intestinal, and central nervous system

				medications (Sex-adjusted odds ratios range = 2.97 - 12.78). CONCLUSION: Although the reasons for increased use of these agents were not elucidated, the data indicated the CFS patients' need for symptom relief.
Kagawa FT, Wehner JH, Mohindra V.	Santa Clara Valley Medical Center, San Jose, CA 95128, USA. Frank.Kagawa@hhs.co.santa-clara.ca.us	Q fever as a biological weapon.	Semin Respir Infect. 2003 Sep;18(3):183-95.	Q fever is a bacterial zoonosis caused by Coxiella burnetii, a unique intracellular coccobacillus, adapted to live within the phagolysosomes of macrophages and monocytes. It is highly infectious, with as little as one organism needed to cause clinical infection, making it an attractive organism for use in biowarfare. Despite its high infectivity, it has low virulence, and most patients undergo only asymptomatic seroconversion. Acute clinical manifestations are a nonspecific febrile illness, pneumonia, hepatitis, and neurologic abnormalities ranging from headache to meningoencephalitis. Chronic Q fever can result in endocarditis, hepatitis, or a chronic fatigue syndrome. Diagnosis usually is made by serology because culture of the highly contagious organism is potentially hazardous. Tetracyclines are the antibiotics of choice. When individualized therapy is possible, a 14- to 21-day course of doxycycline usually is used. In a mass casualty situation, a 5- to 7-day course of doxycycline is recommended, both for therapy and prophylaxis. For chronic infections such as endocarditis, 18 months of doxycycline supplemented with hydroxychloroquine is currently the best therapy.
Kakumanu SS, Mende CN, Lehman EB, Hughes K, Craig TJ.	Division of Biology and Medicine, Brown Medical School, Brown University, Providence, RI, USA.	Effect of topical nasal corticosteroids on patients with chronic fatigue syndrome and rhinitis.	J Am Osteopath Assoc. 2003 Sep;103(9):423-7.	BACKGROUND: Chronic fatigue syndrome (CFS) is a disabling illness of persistent fatigue. Recent studies have shown that patients with CFS have an increased prevalence of nonallergic rhinitis. Inflammation of the nasal passages due to allergic rhinitis can cause nasal congestion resulting in an increased number of sleep disturbances and daytime fatigue. While topical nasal corticosteroids have been shown to alleviate nasal obstruction effectively in patients with rhinitis who do not have CFS, it is unknown whether topical nasal corticosteroids will reduce CFS symptoms. STUDY OBJECTIVE: The purpose of this study is to determine whether topical nasal corticosteroids will reduce daytime sleepiness in patients with CFS and rhinitis. METHODS: Twenty-eight of 31 subjects with rhinitis and a diagnosis of CFS completed the double-blind, randomized, placebo-controlled trial. Two subjects failed screening, and 3 subjects withdrew from the study prior to its completion. Subjects were randomized according to Balaam's crossover design, and one of the following interventions was used for each group in the study: 8-week treatment with a topical nasal corticosteroid, 8-week treatment with a placebo saline spray, 4-week treatment with a topical nasal corticosteroid followed by a 4-week treatment with a placebo saline spray, or a 4-week treatment with a placebo saline spray followed by a 4-week treatment with a topical nasal corticosteroid. Data focusing on rhinitis symptoms, severity of chronic fatigue symptoms, and quality of life were gathered at biweekly office visits and with daily diaries. RESULTS: The results indicated that daytime sleepiness was reduced when patients with rhinitis and CFS were treated with topical nasal corticosteroids. The severity of associated CFS symptoms, specifically fatigue, muscle pain, postexertional fatigue, and daily activity, did not improve with treatment. CONCLUSION: Treating the symptoms of rhinitis in patients with CFS does not appear to alleviate daytime fatigue or associated nasal, musculoskeletal, or cognitive complaints. Therefore, it is unlikely that aggressive treatment of such symptoms with topical nasal corticosteroids will provide significant benefit to patients with CFS who do not have allergic

				rhinitis. These results indicate that the nonallergic rhinitis seen in patients with CFS may arise from a mechanism other than chronic inflammation.
Karper WB, Stasik SC.	University of North Carolina at Greensboro, PO Box 26170, Greensboro, NC 27402, USA. wbkarper@uncg.edu	A successful, long-term exercise program for women with fibromyalgia syndrome and chronic fatigue and immune dysfunction syndrome.	Clin Nurse Spec. 2003 Sep;17(5):243-8.	This article describes an ongoing, long-term clinical exercise program for women with fibromyalgia syndrome (FMS), some of whom also have chronic fatigue and immune dysfunction syndrome (CFIDS). The recorded outcomes from the most recent year of the program also are reported. Participants engaged in sessions lasting 50-70 minutes, 5 days per week; each session involved aerobic activity, resistance training, and other dynamic exercise. One group was in the program for 3 years and another group was in the program for 2 years. Program outcomes for the year (comparing beginning and end-of-year results) are presented for both groups on physical fitness, psychosocial, and FMS/CFIDS symptoms. The outcomes support that all of the women appear to have benefited from the program in numerous ways, suggesting that the program works. Also, those outcomes are in agreement with past research reported in this journal. Implications for clinical nurse specialists working with FMS/CFIDS patients are discussed.
Kang HK, Natelson BH, Mahan CM, Lee KY, Murphy FM.	Veterans Health Administration, Department of Veterans Affairs, Washington, DC, USA. han.kang@mail.va.gov	Post-traumatic stress disorder and chronic fatigue syndrome-like illness among Gulf War veterans: a population-based survey of 30,000 veterans.	Am J Epidemiol. 2003 Jan 15;157(2):141-8.	The authors estimated the prevalence of post-traumatic stress disorder (PTSD) and illness resembling chronic fatigue syndrome (CFS) in the entire population of Gulf War and non-Gulf-War veterans. They also evaluated the relation between the extent of deployment-related stress and the risk of either PTSD or CFS. In 1995-1997, the authors conducted a health survey in which these two symptom-based medical diagnoses in a population-based sample of 15,000 Gulf War veterans representing four military branches and three unit components (active, reserve, and National Guard) were compared with those of 15,000 non-Gulf veteran controls. Gulf War veterans, compared with non-Gulf veteran controls, reported significantly higher rates of PTSD (adjusted odds ratio = 3.1, 95% confidence interval: 2.7, 3.4) and CFS (adjusted odds ratio = 4.8, 95% confidence interval: 3.9, 5.9). The prevalence of PTSD increased monotonically across six levels of deployment-related stress intensity (test for trend: $p < 0.01$), while the prevalence of CFS rose only at the low end of the stress spectrum. While deployment-related stress could account for the higher risks of both PTSD and CFS, additional factor(s) unique to the Gulf environment may have contributed to the risk of CFS among Gulf War veterans.
Kawamura Y, Kihara M, Nishimoto K, Taki M.	Department of Neurology, Kawamura Hospital, Gifu, Japan	Efficacy of a half dose of oral pyridostigmine in the treatment of chronic fatigue syndrome: three case reports.	Pathophysiology. 2003 May;9(3):189-194.	Chronic fatigue syndrome (CFS) is characterized by persistent mental and physical fatigue for at least 6 months. Its pathophysiology is unknown and there is no proven effective treatment. We describe three cases who fulfill the criteria of CFS, in whom a defect of neuromuscular transmission and dysautonomia are present and who respond to acetylcholine-esterase inhibition. Case 1: 18-year-old female with a 3-year history of CFS. Response of compound-muscle-action potential, recorded using surface recording electrode, over left abductor pollicis brevis muscle, to repetitive nerve stimulation (RNS) at a rate of 10 Hz showed a 42% incremental response. Composite autonomic scoring system (CASS) showed mild cholinergic impairment (cardiovagal score: 1; sudomotor score: 2). Serological tests for Epstein-Barr virus (EBV) revealed positive antiviral capsid antigens (anti-VCA) immunoglobulins G (IgG). Oral pyridostigmine therapy (30 mg) resulted in marked improvement in symptoms. Case 2: 28-year-old female with 10-year history of CFS. RNS, using identical protocol, showed a 60% incremental response over the same muscle. CASS showed mild cholinergic impairment (cardiovagal score: 1; sudomotor

				score: 2) and this patient was also positive for EBV. This patient responded dramatically to 10-mg pyridostigmine. Case 3: 29-year-old female with a history of CFS for longer than 15 years. Repetitive stimulation, using identical paradigm to left abductor pollicis brevis muscle, showed a 42% incremental response. CASS showed mildly cholinergic impairment (cardiovagal score: 2; sudomotor score: 1). EBV antibody titers were positive. Patient responded to 30-mg pyridostigmine with an improvement in her fatigue. These three cases generate the hypothesis that the fatigue in some patients with clinical CFS might be due to a combination of mild neuromuscular transmission defect combined with cholinergic dysautonomia. Support for this thesis derives from the improvement with cholinesterase inhibition.
Kerr JR, Cunniffe VS, Kelleher P, Bernstein RM, Bruce IN.	Department of Microbiology, Royal Brompton Hospital, Imperial College London, Sydney St, London SW3 6NP, United Kingdom. j.kerr@imperial.ac.uk	Successful intravenous immunoglobulin therapy in 3 cases of parvovirus B19-associated chronic fatigue syndrome.	Clin Infect Dis. 2003 May 1;36(9):e100-6. Epub 2003 Apr 22.	Three cases of chronic fatigue syndrome (CFS) that followed acute parvovirus B19 infection were treated with a 5-day course of intravenous immunoglobulin (IVIG; 400 mg/kg per day), the only specific treatment for parvovirus B19 infection. We examined the influence of IVIG treatment on the production of cytokines and chemokines in individuals with CFS due to parvovirus B19. IVIG therapy led to clearance of parvovirus B19 viremia, resolution of symptoms, and improvement in physical and functional ability in all patients, as well as resolution of cytokine dysregulation.
Kerr JR, Tyrrell DA.	Department of Microbiology, Royal Brompton Hospital, National Heart & Lung Institute, Imperial College London, UK. j.kerr@imperial.ac.uk	Cytokines in parvovirus B19 infection as an aid to understanding chronic fatigue syndrome.	Curr Pain Headache Rep. 2003 Oct;7(5):333-41.	Human parvovirus B19 infection has been associated with various clinical manifestations of a rheumatic nature such as arthritis, fatigue, and chronic fatigue syndrome (CFS), which can persist for years after the acute phase. The authors have demonstrated recently that acute B19 infection is accompanied by raised circulating levels of IL-1b, IL-6, TNF-a, and IFN-g and that raised circulating levels of TNF-a and IFN-g persist and are accompanied by MCP-1 in those patients who develop CFS. A resolution of clinical symptoms and cytokine dysregulation after intravenous immunoglobulin (IVIG) therapy, which is the only specific treatment for parvovirus B19 infection, also has been reported. Although CFS may be caused by various microbial and other triggers, that triggered by B19 virus is clinically indistinguishable from idiopathic CFS and exhibits similar cytokine abnormalities and may represent an accessible model for the study of CFS.
Khan F, Kennedy G, Spence VA, Newton DJ, Belch JJ.		Peripheral cholinergic function in humans with chronic fatigue syndrome, gulf war syndrome, and with illness following organophosphate exposure.	Clin Sci (Lond). 2003 Sep 23 [Epub ahead of print].	We investigated whether the peripheral cholinergic abnormalities we previously reported in patients with chronic fatigue syndrome (CFS) are also present in those with Gulf War syndrome (GWS) and agricultural workers exposed to organophosphate pesticides, where cholinesterase inhibition is specifically implicated. We also looked at whether these abnormalities might be due to a reduction in the activity of cholinesterase expressed on the vascular endothelium. We used laser Doppler imaging to measure the forearm skin blood flow responses to iontophoresis of acetylcholine and of methacholine (which is resistant to breakdown by cholinesterase) in patients with CFS, GWS, and those with a history of ill health after definite organophosphate exposure, as well as in matched, healthy controls. The response to acetylcholine was significantly higher in patients with CFS than in controls ($P = 0.029$, repeated-measures analysis of variance), but was normal in those with GWS and those exposed to organophosphates. The methacholine response was higher than the acetylcholine response in all patient groups except for CFS, where there was

				no difference between the responses. Although there are many clinical similarities between these three illnesses, our results indicate peripheral cholinergic abnormalities in the vascular endothelium of only patients with CFS, suggesting that this syndrome has a different aetiology, which might involve inhibition of vascular cholinesterase.
Khan F, Spence V, Kennedy G, Belch JJ.	Vascular Diseases Research Unit, University Department of Medicine, Ninewells Hospital and Medical School, Dundee, UK. f.khan@dundee.ac.uk.	Prolonged acetylcholine-induced vasodilatation in the peripheral microcirculation of patients with chronic fatigue syndrome.	Clin Physiol Funct Imaging. 2003 Sep;23(5):282-5.	Although the aetiology of chronic fatigue syndrome (CFS) is unknown, there have been a number of reports of blood flow abnormalities within the cerebral circulation and systemic blood pressure defects manifesting as orthostatic intolerance. Neither of these phenomena has been explained adequately, but recent reports have linked cerebral hypoperfusion to abnormalities in cholinergic metabolism. Our group has previously reported enhanced skin vasodilatation in response to cumulative doses of transdermally applied acetylcholine (ACh), implying an alteration of peripheral cholinergic function. To investigate this further, we studied the time course of ACh-induced vasodilatation following a single dose of ACh in 30 patients with CFS and 30 age- and gender-matched healthy control subjects. No differences in peak blood flow was seen between patients and controls, but the time taken for the ACh response to recover to baseline was significantly longer in the CFS patients than in control subjects. The time taken to decay to 75% of the peak response in patients and controls was 13.7 +/- 11.3 versus 8.9 +/- 3.7 min (P = 0.03), respectively, and time taken to decay to 50% of the peak response was 24.5 +/- 18.8 versus 15.1 +/- 8.9 min (P = 0.03), respectively. Prolongation of ACh-induced vasodilatation is suggestive of a disturbance to cholinergic pathways, perhaps within the vascular endothelium of patients with CFS, and might be related to some of the unusual vascular symptoms, such as hypotension and orthostatic intolerance, which are characteristic of the condition.
Kurup RK, Kurup PA.	Department of Neurology, Medical College Hospital, Trivandrum, Kerala, India.	Hypothalamic digoxin, cerebral chemical dominance and myalgic encephalomyelitis.	Int J Neurosci. 2003 May;113(5):683-701.	The isoprenoid pathway was assessed in 15 patients with chronic fatigue syndrome. The pathway was also assessed in individuals with differing hemispheric dominance to assess whether hemispheric dominance had any correlation with these disease states. The isoprenoid metabolites--digoxin, dolichol, and ubiquinone--RBC membrane Na+-K+ ATPase activity, serum magnesium and tyrosine/tryptophan catabolic patterns were assessed. The free-radical metabolism, glycoconjugate metabolism, and RBC membrane composition was also assessed. Membrane Na+-K+ ATPase activity and serum magnesium levels were decreased while HMG CoA reductase activity and serum digoxin levels were increased in myalgic encephalomyelitis (ME). There were increased levels of tryptophan catabolites--nicotine, strychnine, quinolinic acid, and serotonin--and decreased levels of tyrosine catabolites--dopamine, noradrenaline, and morphine in ME. There was an increase in dolichol levels, carbohydrate residues of glycoproteins, glycolipids, total/individual GAG fractions, and lysosomal enzymes in ME. Reduced levels of ubiquinone, reduced glutathione, and free-radical scavenging enzymes, as well as increased lipid peroxidation products and nitric oxide, were noticed in ME. The biochemical patterns in ME correlated with those obtained in right hemi spheric chemical dominance. The role of hypothalamic digoxin and neurotransmitter induced immune activation, altered glycoconjugate metabolism, and resultant defective viral antigen presentation, NMDA excitotoxicity and cognitive dysfunction, and mitochondrial dysfunction related myalgia in the pathogenesis of ME is stressed. ME occurs in individuals with right hemispheric chemical dominance.

Lane RJ, Soteriou BA, Zhang H, Archard LC.	Division of Clinical Neurosciences and Psychological Medicine, Imperial College, London SW7, UK. r.lane@imperial.ac.uk	Enterovirus related metabolic myopathy: a postviral fatigue syndrome.	J Neurol Neurosurg Psychiatry. 2003 Oct;74(10):1382-6. Comment in: J Neurol Neurosurg Psychiatry. 2003 Oct;74(10):1361-2.	OBJECTIVE: To detect and characterise enterovirus RNA in skeletal muscle from patients with chronic fatigue syndrome (CFS) and to compare efficiency of muscle energy metabolism in enterovirus positive and negative CFS patients. METHODS: Quadriceps muscle biopsy samples from 48 patients with CFS were processed to detect enterovirus RNA by two stage, reverse transcription, nested polymerase chain reaction (RT-NPCR), using enterovirus group specific primer sets. Direct nucleotide sequencing of PCR products was used to characterise the enterovirus. Controls were 29 subjects with normal muscles. On the day of biopsy, each CFS patient undertook a subanaerobic threshold exercise test (SATET). Venous plasma lactate was measured immediately before and after exercise, and 30 minutes after testing. An abnormal lactate response to exercise (SATET+) was defined as an exercise test in which plasma lactate exceeded the upper 99% confidence limits for normal sedentary controls at two or more time points. RESULTS: Muscle biopsy samples from 20.8% of the CFS patients were positive for enterovirus sequences by RT-NPCR, while all the 29 control samples were negative; 58.3% of the CFS patients had a SATET+ response. Nine of the 10 enterovirus positive cases were among the 28 SATET+ patients (32.1%), compared with only one (5%) of the 20 SATET- patients. PCR products were most closely related to coxsackie B virus. CONCLUSIONS: There is an association between abnormal lactate response to exercise, reflecting impaired muscle energy metabolism, and the presence of enterovirus sequences in muscle in a proportion of CFS patients.
Lashley FR.	College of Nursing, Rutgers, The State University of New Jersey, Newark, NJ 07102, USA. lashley@nightingale.rutgers.edu	A review of sleep in selected immune and autoimmune disorders.	Holist Nurs Pract. 2003 Mar-Apr;17(2):65-80.	Evidence for the reciprocal role of the immune system in sleep is growing. Sleep disturbances are believed to be both a cause and a consequence of various immune and autoimmune conditions.
Le Bon O, Minner P, Van Moorsel C, Hoffmann G, Gallego S, Lambrecht L, Pelc I, Linkowski P.	Department of Psychiatry, CHU Brugmann S48, Place Van Gehuchten 4, 1020 Brussels, Belgium. lebono@ulb.ac.be	First-night effect in the chronic fatigue syndrome.	Psychiatry Res. 2003 Sep 30;120(2):191-9.	Since the magnitude of the first-night effect has been shown to be a function of medical conditions and of settings in which polysomnographies are performed, it is essential to evaluate the habituation phenomenon in each case in order to determine the optimal recording methodology. A first-night effect was evidenced in certain cases of chronic fatigue syndrome, but not in others. To clarify this issue, a large group of patients with chronic fatigue syndrome who had no primary sleep disorders were selected and recorded for two consecutive nights in a hospital sleep unit. Several parameters, frequently associated with the first-night effect, were found to be influenced by the recording methodology: Total Sleep Time, Sleep Efficiency, Sleep Efficiency minus Sleep Onset, Sleep Onset Latency, Wake Time, Slow Wave Sleep, Rapid Eye Movement Sleep, Rapid Eye Movement Sleep Latency and Number of Sleep Cycles. Bland and Altman plots determined that the difference scores between the nights included a systematic bias linked to the order of recordings (first-night effect). Factorial analysis grouped the difference scores into three factors. No significant difference was observed between patients with generalized anxiety comorbidity and those with no psychiatric comorbidity, or between those with and without psychiatric comorbidity. Chronic fatigue syndrome must thus be added on the

				list of conditions where a clinically significant habituation effect takes place.
Lim BR, Tan SY, Zheng YP, Lin KM, Park BC, Turk AA.	Fuller Theological Seminary, Graduate School of Psychology, Pasadena, California, USA. blim@fuller.edu	Psychosocial factors in chronic fatigue syndrome among Chinese Americans: a longitudinal community-based study.	Transcult Psychiatry. 2003 Sep;40(3):429-41.	Chronic fatigue syndrome (CFS) is a relatively new condition of unknown etiology. Research suggests that psychosocial factors such as perceived social support, life stress, and acculturation may significantly influence individuals who are prone to CFS. For 57 Chinese American individuals initially diagnosed with CFS, those who recovered after one year reported lower levels of life stress than those who did not recover. Effects of changes in perceived social support also appeared to be mediated by life stress.
Logan AC, Venket Rao A, Irani D.	CFS-FM Integrative Care Centre, Toronto, Canada	Chronic fatigue syndrome: lactic acid bacteria may be of therapeutic value.	Med Hypotheses. 2003 Jun;60(6):915-23.	Chronic fatigue syndrome (CFS) is complex illness with unknown aetiology. Recent research shows that patients with CFS have marked alterations in microbial flora, including lowered levels of bifidobacteria and small intestinal bacterial overgrowth (SIBO). Research also indicates that CFS patients are under increased oxidative stress, have a type 2 helper cell dominate cytokine profile, frequently report allergies, have altered essential fatty acid (EFA) status and may have malabsorption of certain micronutrients. Lactic acid bacteria (LAB) have the potential to influence the immune system in CFS patients by supporting T helper cell 1 driven cellular immunity and may decrease allergies. In addition LAB are strong antioxidants, may improve EFA status, can enhance absorption of micronutrients by protecting the intestinal epithelial barrier, and have been used to treat SIBO. It is our contention that LAB may have a therapeutic role in the treatment of CFS.
Lyall M, Peakman M, Wessely S.	Department of Psychological Medicine, Guy's, King's and St. Thomas' School of Medicine, 103 Denmark Hill, London SE5 8AZ, UK.	A systematic review and critical evaluation of the immunology of chronic fatigue syndrome.	J Psychosom Res. 2003 Aug;55(2):79-90.	OBJECTIVE: Immune dysfunction in patients with chronic fatigue syndrome (CFS) has been widely but inconsistently reported. Traditional reviews of the literature have produced a variety of conclusions. We present the results of the first systematic review of the subject. METHODS: EMBASE, MEDLINE and PSYCHINFO databases were searched, and leading researchers in the field were contacted. Inclusion criteria were applied, and studies were then divided into groups based on the quality of their methodology. Study results were collated and described. RESULTS: Studies ranged widely in quality. There was an inverse association between study quality and finding low levels of natural killer cells, suggesting that the association may be related to study methodology. On the other hand, reports of abnormalities in T cells and cytokine levels were not related to study quality. CONCLUSIONS: The conclusions of this systematic review differ from a recent traditional narrative review of the immunology of CFS. No consistent pattern of immunological abnormalities is identified.
Madariaga MG, Rezai K, Trenholme GM, Weinstein RA.	Division of Infectious Disease, Cook County Hospital, Chicago and the Section of Infectious Diseases, Rush-Presbyterian-St Luke's Medical Center, Chicago, IL	Q fever: a biological weapon in your backyard.	Lancet Infect Dis. 2003 Nov;3(11):709-21.	Coxiella burnetii, which causes Q fever, is a highly infectious agent that is widespread among livestock around the world. Although the culture process for coxiella is laborious, large amounts of infectious material can be produced. If used as an aerosolised biological weapon, coxiella may not cause high mortality, but could provoke acute disabling disease. In its late course, Q fever can be complicated by fatal (eg, endocarditis) or debilitating (eg, chronic fatigue syndrome) disorders. The diagnosis of Q fever might be delayed because of non-specific and protean presentations. Effective antibiotic treatment is available for the acute form of disease but not for the chronic complications. Vaccination and chemoprophylaxis in selected individuals may be used in the event of bioterrorism.

Matano S, Kinoshita H, Tanigawa K, Terahata S, Sugimoto T.	Department of Hematology, Tonami General Hospital, Tonami, Toyama.	Acute parvovirus B19 infection mimicking chronic fatigue syndrome.	Intern Med. 2003 Sep;42(9):903-5.	A Japanese woman developed prolonged fatigue, neck and shoulder pain, headache, pyrexia, insomnia, anorexia, lymphadenopathy, and diarrhea for two months. She had experienced various stressors before these symptoms developed. Serological test demonstrated that she had acute parvovirus B19 infection. Major depressive disorder was also diagnosed by a psychiatrist. Her symptoms disappeared after administration of selective serotonin reuptake inhibitors and oriental herbs, although human parvovirus B19 viral genome has been present in her serum for nine months. These findings suggest that parvovirus B19 causes clinical features similar to those of chronic fatigue syndrome in cases who have prior life stressors.
McCrone P, Darbishire L, Ridsdale L, Seed P.	Centre for the Economics of Mental Health, Health Services Research Department, Institute of Psychiatry, King's College, London.	The economic cost of chronic fatigue and chronic fatigue syndrome in UK primary care.	Psychol Med. 2003 Feb;33(2):253-61. Comment in: Psychol Med. 2003 Feb;33(2):197-201	BACKGROUND: Chronic fatigue and chronic fatigue syndrome are most often encountered in primary care settings. Given the disabling nature of chronic fatigue it may have a substantial impact on service use and costs as well as on employment. This study estimates this impact. METHOD: Patients presenting to general practitioners with unexplained chronic fatigue were recruited to the study. Service use over a 3 month period was measured and lost employment recorded. These data were used to estimate economic costs. Patients with chronic fatigue syndrome were compared to patients with only chronic fatigue using a multiple regression model with sample differences controlled. RESULTS: The mean total cost of services and lost employment across the sample was Pound Sterling1906 for the 3-month period with formal services accounting for 9.3% of this figure. Service use was higher for patients with chronic fatigue syndrome compared to those with chronic fatigue alone. Total 3-month costs were on average higher for chronic fatigue syndrome (Pound Sterling3515 v. Pound Sterling1176) but when sample differences were taken account of the mean difference was reduced to Pound Sterling1406 (P = 0.086). Over 90% of the cost was accounted for by care provided by friends and family members and by lost employment. Patients with dependants had significantly higher costs than those with none and costs were also significantly higher for greater levels of functional impairment. CONCLUSION: Chronic fatigue imposes substantial economic costs on society, mainly in the form of informal care and lost employment. Treatments need to be developed which recognize these impacts.
McCully KK, Smith S, Rajaei S, Leigh Jr JS, Natelson BH.	Exercise Science, University of Georgia, Athens, GA, USA.	Muscle metabolism with blood flow restriction in chronic fatigue syndrome.	J Appl Physiol. 2003 Oct 24 [Epub ahead of print].	The purpose of this study was to determine if chronic fatigue syndrome (CFS) is associated with reduced blood flow and muscle oxidative metabolism. Patients with CFS according to CDC criteria (n=19) were compared to normal sedentary subjects (n = 11). Muscle blood flow was measured in the femoral artery with Doppler ultrasound after exercise. Muscle metabolism was measured in the medial gastrocnemius muscle using 31P magnetic resonance spectroscopy (MRS). Muscle oxygen saturation and blood volume were measured using near-infrared spectroscopy. CFS and controls were not different in hyperemic blood flow or phosphocreatine recovery rate. Cuff pressures of 50,60,70,80,and 90 mmHg were used to partially restrict blood flow during recovery. All pressures reduced blood flow and oxidative metabolism, with 90 mmHg reducing blood flow by 46% and oxidative metabolism by 30.7% in CFS patients. Hyperemic blood flow during partial

				cuff occlusion was significantly reduced in CFS patients (P < 0.01), and recovery of oxygen saturation was slower (P < 0.05). No differences were seen in the amount of reduction in metabolism with partially reduced blood flow. In conclusion, CFS patients showed evidence of reduced hyperemic flow and reduced oxygen delivery, but no evidence that this impaired muscle metabolism. Thus, CFS patients might have altered control of blood flow, but this is unlikely to influence muscle metabolism. Further, abnormalities in muscle metabolism do not appear to be responsible for the CFS symptoms.
McCully KK, Smith S, Rajaei S, Leigh Jr JS, Natelson BH.	Department of Exercise Science, University of Georgia, 300 River Road, Athens GA 30602, U.S.A.	Blood flow and muscle metabolism in chronic fatigue syndrome.	Clin Sci (Lond). 2003 Jun;104(6):641-7.	The purpose of this study was to determine if chronic fatigue syndrome (CFS) is associated with reduced blood flow and oxidative delivery to skeletal muscle. Patients with CFS according to CDC (Center for Disease Control) criteria (n =19) were compared with normal sedentary subjects (n =11). Muscle blood flow was measured with Doppler ultrasound after cuff ischaemia and exercise. Muscle oxygen delivery was measured as the rate of post-exercise and post-ischaemic oxygen-haem resaturation. Oxygen-haem resaturation was measured in the medial gastrocnemius muscle using continuous wavelength near-IR spectroscopy. Muscle metabolism was measured using (31)P magnetic resonance spectroscopy. CFS patients and controls were not different in the peak blood flow after cuff ischaemia, the rate of recovery of phosphocreatine after submaximal exercise, and the rate of recovery of oxygen saturation after cuff ischaemia. In conclusion, CFS patients showed no deficit in blood flow or oxidative metabolism. This suggests that CFS symptoms do not require abnormal peripheral function.
Moss-Morris R, Chalder T.	Health Psychology, The Faculty of Medical and Health Sciences, The University of Auckland, Private Bag 92 019, Auckland, New Zealand. r.moss-morris@auckland.ac.nz	Illness perceptions and levels of disability in patients with chronic fatigue syndrome and rheumatoid arthritis.	J Psychosom Res. 2003 Oct;55(4):305-8.	OBJECTIVE: To investigate the strength of chronic fatigue syndrome (CFS) patients' negative illness perceptions by comparing illness perceptions and self-reported disability in patients with CFS and rheumatoid arthritis (RA). METHODS: Seventy-four RA patients and 49 CFS patients completed the Illness Perception Questionnaire-Revised and the 36-item Short-Form Health Survey. RESULTS: When compared to the RA group, the CFS group attributed a wider range of everyday somatic symptoms to their illness, perceived the consequences of their illness to be more profound and were more likely to attribute their illness to a virus or immune system dysfunction. Both groups reported equivalent levels of physical disability but the CFS group reported significantly higher levels of role and social disability. CONCLUSION: Although the symptoms of CFS are largely medically unexplained, CFS patients have more negative views about their symptoms and the impact that these have had on their lives than do patients with a clearly defined and potentially disabling medical condition. The data support the cognitive behavioural models of CFS that emphasise the importance of patients' illness perceptions in perpetuating this disorder.
Moss-Morris R, Petrie KJ.	Department of Health Psychology, The University of Auckland, New Zealand.	Experimental evidence for interpretive but not attention biases towards somatic information in patients with chronic	Br J Health Psychol. 2003 May;8(Pt 2):195-208.	OBJECTIVE: This study tested whether CFS patients have an attentional information processing bias for illness-related information and a tendency to interpret ambiguous information in a somatic fashion. DESIGN: 25 patients meeting research criteria for a diagnosis of CFS were compared to 24 healthy matched controls on a modified Stroop task and an ambiguous cues task. METHOD: In the modified Stroop task, participants colour named a series of somatic, depressed and neutral words in order to ascertain whether the somatic words were more distracting to the CFS patients than the depressed and neutral words when compared to controls. In the

		fatigue syndrome.		ambiguous cues task, participants were presented with a tape-recorded list of 30 words including 15 ambiguous illness words (e.g., vein/vain) and 15 unambiguous words. For each word, they were asked to write down the first word that came into their head. A somatic bias score was obtained for each subject by summing the number of somatic responses to the ambiguous word cues. RESULTS: Although CFS patients were significantly slower in colour naming all of the Stroop word categories than controls, there was no evidence for illness or depressed words creating greater interference than neutral words. However, on the ambiguous cues task, CFS patients made significantly more somatic interpretations than controls and this bias was significantly associated with the extent to which they currently reported symptoms. CONCLUSION: CFS patients have an interpretive bias for somatic information which may play a part in the maintenance of the disorder by heightening patients' experience of physical symptoms and helping to maintain their negative illness schemas. Although patients did not show an attentional bias in this study, this may be related to the methodology employed.
Murdoch JC.	School of Primary, Aboriginal and Rural Health Care, Rural Clinical School, University of Western Australia. cmurdoch@rcs.uwa.edu.au	Chronic fatigue syndrome. The patient centred clinical method--a guide for the perplexed.	Aust Fam Physician. 2003 Nov;32(11):883-7.	BACKGROUND: Chronic fatigue states are common in general practice and over the past 20 years there has been considerable worldwide consensus developed on the criteria for chronic fatigue syndrome (CFS) also commonly known as myalgic encephalomyelitis (ME). Chronic fatigue syndrome is an illness characterised by the new onset of disabling fatigue, accompanied by cognitive, musculoskeletal and sleep symptoms. There are no specific diagnostic tests or biological markers and the diagnosis is made by ruling out other causes of fatigue. The pathophysiology of CFS is still unclear. OBJECTIVE: This article discusses the application of the patient centred clinical method to the diagnosis and treatment of CFS. DISCUSSION: There is no new breakthrough in the diagnosis or management of CFS in spite of much research and controversy. There is considerable evidence that the best place to manage CFS is in primary care under the care of the patient's own general practitioner, but it has been suggested that doctors feel unable to deal with the problem. The patient centred clinical method offers a constructive guide to management. The author considers that the best hope for sufferers is self management guided by a supportive and helpful health professional, preferably the patient's own GP.
Murphy BE, Abbott FV, Allison CM, Watts C, Ghadirian AM.	Department of Psychiatry, McGill University, 1033 Pine Avenue West, Montreal, Canada H3A 1A1. bev.murphy@mcgill.ca	Elevated levels of some neuroactive progesterone metabolites, particularly isopregnanolone, in women with chronic fatigue syndrome.	Psychoneuroendocrinology. 2004 Feb;29(2):245-68.	Chronic fatigue syndrome (CFS) is a controversial entity whose cause is unknown. In this study we have explored the possibility that progesterone metabolites may be involved. Plasma levels of the progesterone precursor pregnenolone, progesterone itself, and five ring A-reduced metabolites of progesterone were measured in 20 women with CFS and in 13 age-matched controls. To minimize the contribution of the ovary, women were either post-menopausal or in the follicular phase of the menstrual cycle (day 4-8), and progesterone levels were all well within the expected range (< or = 3.5 nmol/l). Mean values for progesterone and all of its metabolites were higher in CFS patients, the most marked being a 2.3-fold elevation in isopregnanolone (3beta,5alpha-tetrahydroprogesterone; p < or = 0.001). Progesterone levels were correlated with those of its metabolites, but even after controlling for progesterone by ANCOVA, isopregnanolone levels were still elevated (p < or = 0.001). These elevated levels of isopregnanolone could not be attributed to medications (antidepressants and anxiolytics). When the CFS patients were divided into two groups according to their Hamilton depression scale ratings, mean (+/-SD)

				isopregnanolone levels were higher (274+/-160 vs 197+/-119 pmol/l) in the less depressed group (ratings 2-14) than in the more depressed group (ratings 17-28), although this difference did not reach significance. Progesterone levels were negatively correlated with Hamilton depression rating scores (r=-0.56; p<0.01). These results suggest that increases in ring A-reduced progesterone metabolites, particularly isopregnanolone, are associated with CFS, and that the pathophysiology of CFS is unlikely to be due to depression.
Nagelkirk PR, Cook DB, Peckerman A, Kesil W, Sakowski T, Natelson BH, LaManca JJ.	Center for the Study of War-Related Illnesses, Veterans Affairs New Jersey Health Care, East Orange, NJ, USA.	Aerobic capacity of Gulf War veterans with chronic fatigue syndrome.	Mil Med. 2003 Sep;168(9):750-5.	A large overlap exists between the diagnosis of chronic fatigue syndrome (CFS) and the unexplained symptoms reported by many Gulf War veterans (GV). Previous investigations have reported reduced aerobic capacity in civilians with CFS. The present investigation examined metabolic responses to maximal exercise in GVs with CFS compared with healthy GVs. Cardiorespiratory and metabolic responses were recorded during a maximal exercise test on a cycle ergometer. The groups were not different in any demographic category (p > 0.05) or self-reported physical activity (p > 0.05). No differences were observed between groups for maximal oxygen uptake (28.9 +/- 6.7 mL/kg/min for CFS vs. 30.8 +/- 7.1 mL/kg/min for controls; p = 0.39), heart rate (155.8 +/- 16.1 bpm for CFS vs. 163.3 +/- 14.9 bpm for controls; p = 0.17), exercise time (9.6 +/- 1.5 minutes for CFS vs. 10.2 +/- 1.4 minutes for controls; p = 0.26), or workload achieved (208 +/- 36.7 W for CFS vs. 224 +/- 42.9 W for controls; p = 0.25). Likewise, no differences were observed at submaximal intensities (p > 0.05). Compared with healthy controls, GVs who report multiple medically unexplained symptoms and meet criteria for CFS do not show a decreased exercise capacity. Thus, it does not appear that the pathology of the GVs with CFS includes a deficiency with mobilizing the cardiopulmonary system for strenuous physical effort.
Narita M, Nishigami N, Narita N, Yamaguti K, Okado N, Watanabe Y, Kuratsune H.	Institute of Basic Medical Sciences, University of Tsukuba, Tennoudai 1-1-1, Tsukuba, Ibaraki 305-8575, Japan.	Association between serotonin transporter gene polymorphism and chronic fatigue syndrome.	Biochem Biophys Res Commun. 2003 Nov 14;311(2):264-6.	Interaction between the hypothalamo-pituitary-adrenal axis and the serotonergic system is thought to be disrupted in chronic fatigue syndrome (CFS) patients. We examined a serotonin transporter (5-HTT) gene promoter polymorphism, which affects the transcriptional efficiency of 5-HTT, in 78 CFS patients using PCR amplification of the blood genomic DNA. A significant increase of longer (L and XL) alleic variants was found in the CFS patients compared to the controls both by the genotype-wise and the allele-wise analyses (both p<0.05, by chi(2) test and Fisher's exact test). Attenuated concentration of extracellular serotonin due to longer variants may cause higher susceptibility to CFS.

Naschitz@tx.technion.ac.il	Assessment of cardiovascular reactivity by fractal and recurrence quantification analysis of heart rate and pulse transit time.	J Hum Hypertens. 2003 Feb;17(2):111-8.	Methods used for the assessment of cardiovascular reactivity are flawed by nonlinear dynamics of the cardiovascular responses to stimuli. In an attempt to address this issue, we utilized a short postural challenge, recorded beat-to-beat heart rate (HR) and pulse transit time (PTT), assessed the data by fractal and recurrence quantification analysis, and processed the obtained variables by multivariate statistics. A 10-min supine phase of the head-up tilt test was followed by recording 600 cardiac cycles on tilt, that is, 5-10 min. Three groups of patients were studied, each including 20 subjects matched for age and gender--healthy subjects, patients with essential hypertension (HT), and patients with chronic fatigue syndrome (CFS). The latter group was studied on account of the well-known dysautonomia of CFS patients, which served as contrast against the cardiovascular reactivity of the healthy population. A total of 52 variables of the HR and PTT were determined in each subject. The multivariate model identified the best predictors for the assessment of reactivity of healthy subjects vs CFS. Based on these predictors, the "Fractal & Recurrence Analysis-based Score" (FRAS) was calculated: FRAS=76.2+0.04*HR-supine-DET -12.9*HR-tilt-R/L -0.31*HR-tilt-s.d. -19.27*PTT-tilt-R/L -9.42*PTT-tilt-WAVE. The median values and IQR of FRAS in the groups were: healthy=-1.85 (IQR 1.89), hypertensives=+0.52 (IQR 5.78), and CFS=-24.2 (5.34) (HT vs healthy subjects: P=0.0036; HT vs CFS: P<0.0001). Since the FRAS differed significantly between the three groups, it appears likely that the FRAS may recognize phenotypes of cardiovascular reactivity.

Naschitz JE, Rosner I, Rozenbaum M, Naschitz S, Musafia-Priselac R, Shaviv N, Fields M, Isseroff H, Zuckerman E, Yeshurun D, Sabo E.	Department of Internal Medicine A, Bnai Zion Medical Center, Haifa, Israel. Naschitz@tx.technion.ac.il	The head-up tilt test with haemodynamic instability score in diagnosing chronic fatigue syndrome.	QJM. 2003 Feb;96(2):133-42. Comment in: QJM. 2003 Jun;96(6):454. QJM. 2003 May;96(5):379-80.	BACKGROUND: Studying patients with chronic fatigue syndrome (CFS), we have developed a method that uses a head-up tilt test (HUTT) to estimate BP and HR instability during tilt, expressed as a 'haemodynamic instability score' (HIS). Aim: To assess HIS sensitivity and specificity in the diagnosis of CFS. DESIGN:Prospective controlled study. METHODS: Patients with CFS (n=40), non-CFS chronic fatigue (n=73), fibromyalgia (n=41), neurally mediated syncope (n=58), generalized anxiety disorder (n=28), familial Mediterranean fever (n=50), arterial hypertension (n=28), and healthy subjects (n=59) were evaluated with a standardized head-up tilt test (HUTT). The HIS was calculated from blood pressure (BP) and heart rate (HR) changes during the HUTT. RESULTS: The tilt was prematurely terminated in 22% of CFS patients when postural symptoms occurred and the HIS could not be calculated. In the remainder, the median(IQR) HIS values were: CFS +2.14(4.67), non-CFS fatigue -3.98(5.35), fibromyalgia -2.81(2.62), syncope -3.7(4.36), generalized anxiety disorder -0.21(6.05), healthy controls -2.66(3.14), FMF -5.09(6.41), hypertensives -5.35(2.74) (p<0.0001 vs. CFS in all groups, except for anxiety disorder, p=NS). The

				sensitivity for CFS at HIS >-0.98 cut-off was 90.3% and the overall specificity was 84.5%. DISCUSSION: There is a particular dysautonomia in CFS that differs from dysautonomia in other disorders, characterized by HIS >-0.98. The HIS can reinforce the clinician's diagnosis by providing objective criteria for the assessment of CFS, which until now, could only be subjectively inferred.

Neri S, Pistone G, Saraceno B, Pennisi G, Luca S, Malaguarnera M.	Department of Senescence, Urological and Neurological Sciences, University of Catania, Catania, Italy.	L-carnitine decreases severity and type of fatigue induced by interferon-alpha in the treatment of patients with hepatitis C.	Neuropsychobiology. 2003;47(2):94-7.	BACKGROUND: Hepatitis C virus (HCV) is one of the major agents of chronic hepatitis and liver disease worldwide. Infection with HCV leads to chronic hepatitis in about 80% of the cases. The most used treatment is based on interferon (IFN)-alpha, which is effective in less than 50% of patients; however, a high proportion of responders may relapse after interferon withdrawal. Fatigue is a common complaint in patients with liver disease. The aim of our study was to evaluate the efficacy of carnitine on IFN-induced fatigue in subjects with chronic hepatitis C. PATIENTS AND METHODS: We studied 50 patients (30 males and 20 females) with chronic hepatitis C. Chronic hepatitis was diagnosed by determination of serum alanine aminotransferase (ALT) and aspartate aminotransferase (AST) levels (at least 2-fold upper normal values for 1 year). Our study series was divided into two groups and matched as to number, age, sex, as well as grade and duration of disease. Group 1, composed of 25 patients, was treated with leucocytic IFN-alpha at a dosage of 3 million IU thrice a week; group 2 (25 patients) was treated with the same protocol as group 1, but was also administered carnitine 2 g per os daily. Patients' response was evaluated on the basis of serum levels of AST and ALT as well as liver functions; fatigue was evaluated by Wessely and Powell scores. All patients studied were tested before treatment and then 1, 3 and 6 months after the beginning of IFN administration. RESULTS: The difference of physical fatigue between the two groups after 1 month of therapy was significant ($p < 0.01$) for patients treated with carnitine. This significance continued at the end of month 3 ($p < 0.01$). With reference to mental fatigue, the comparison between the two groups showed a significant difference for group 2 after 1 month ($p < 0.01$). Finally, with respect to the fatigue severity, the comparison between the two groups showed that after 1 and 3 months of therapy, fatigue was significantly less severe in group 2 than group 1 ($p < 0.0005$). CONCLUSIONS: If we take into account baseline values of mental and physical fatigue as well as the severity of this symptom in our study series, one observes that therapy with IFN alone induces fatigue in the majority of cases after 1 and 3 months, while at month 6, the values decrease. In contrast, patients treated with IFN + carnitine show a marked and early significant reduction of fatigue levels. These data suggest that the greater energetic substrate utilised by group 2 patients may in some way provide a better response of the patients to this side-effect. Abnormalities of neurotransmission concerning serotonine seem involved in the genesis of depression and fatigue. In addition,

				depression and fatigue commonly occur together, and the former is the most commonly observed symptom in patients with chronic fatigue syndrome. Copyright 2003 S. Karger AG, Basel
Nicolson GL, Gan R, Haier J.	The Institute for Molecular Medicine, Huntington Beach, California 92649, USA. gnicolson@immed.org	Multiple co-infections (Mycoplasma, Chlamydia, human herpes virus-6) in blood of chronic fatigue syndrome patients: association with signs and symptoms.	APMIS. 2003 May;111(5):557-66.	Previously we and others found that a majority of chronic fatigue syndrome (CFS) patients showed evidence of systemic mycoplasmal infections, and their blood tested positive using a polymerase chain reaction assay for at least one of the four following Mycoplasma species: M. fermentans, M. hominis, M. pneumoniae or M. penetrans. Consistent with previous results, patients in the current study (n=200) showed a high prevalence (overall 52%) of mycoplasmal infections. Using forensic polymerase chain reaction we also examined whether these same patients showed evidence of infections with Chlamydia pneumoniae (overall 7.5% positive) and/or active human herpes virus-6 (HHV-6, overall 30.5% positive). Since the presence of one or more infections may predispose patients to other infections, we examined the prevalence of C. pneumoniae and HHV-6 active infections in mycoplasma-positive and -negative patients. Unexpectedly, we found that the incidence of C. pneumoniae or HHV-6 was similar in Mycoplasma-positive and -negative patients, and the converse was also found in active HHV-6-positive and -negative patients. Control subjects (n=100) had low rates of mycoplasmal (6%), active HHV-6 (9%) or chlamydial (1%) infections, and there were no co-infections in control subjects. Differences in bacterial and/or viral infections in CFS patients compared to control subjects were significant. Severity and incidence of patients' signs and symptoms were compared within the above groups. Although there was a tendency for patients with multiple infections to have more severe signs and symptoms ($p<0.01$), the only significant differences found were in the incidence and severity of certain signs and symptoms in patients with multiple co-infections of any type compared to the other groups ($p<0.01$). There was no correlation between the type of co-infection and severity of signs and symptoms. The results indicate that a large subset of CFS patients show evidence of bacterial and/or viral infection(s), and these infections may contribute to the severity of signs and symptoms found in these patients.
Nicolson GL, Nasralla MY, De Meirleir K, Gan R, Haier J		Evidence for Bacterial (Mycoplasma, Chlamydia) and Viral (HHV-6) Co-Infections in Chronic Fatigue Syndrome Patients	Journal of Chronic Fatigue Syndrome 2003; 11 (2): 7	Using the blood of 100 CFS patients and forensic polymerase chain reaction we have found that a majority of Chronic Fatigue Syndrome (CFS) patients show evidence of multiple, systemic bacterial and viral infections (OR = 18.0, 95%CL 8.5-37.9, $P < 0.001$) that could play an important role in CFS morbidity. CFS patients had a high prevalence (5)1%) of one of four Mycoplasma species (OR = 13.8, 95%CL 5.8-32.9, $P < 0.001$) and often showed evidence of co-infections with different Mycoplasma species, Chlamydia pneumoniae (OR = 8.6, 95%CL 1.0-71.1, $P < 0.01$) and/or active Human Herpes Virus-6 (HHV-6) (OR = 4.5, 95%CL 2.0-10.2, $P < 0.001$). We found that 8% of the CFS patients showed evidence of C. pneumoniae and 31% of active HHV-6 infections. Since the presence of one or more chronic systemic infections may predispose patients to other infections, we examined the prevalence of C. pneumoniae and active HHV-6 infections in mycoplasma-positive and-negative patients. The incidence of C. pneumoniae or HHV-6 was similar in mycoplasma-positive and-negative patients, suggesting that such infections occur independently in CFS patients. Also, the incidence of C. pneumoniae in active HHV-6-positive and-negative patients was similar. Control subjects (n = 100) had low rates of mycoplasma (6)%), active HHV-6 (9)%) or Chlamydia (1)%) infections, and there were no co-

				infections in control subjects. Differences in bacterial and/or viral infections in CFS patients compared to control subjects were significant. The results indicate that a relatively large subset of CFS patients show evidence of bacterial and viral co-infections.
Nicolson GL, Nasralla MY, Nicolson NL, Haier J		High Prevalence of Mycoplasma Infections in Symptomatic (Chronic Fatigue Syndrome) Family Members of Mycoplasma-Positive Gulf War Illness Patients	Journal of Chronic Fatigue Syndrome 2003; 11 (2): 21	Immediate family members of veterans diagnosed with Gulf War Illnesses (GWI) often complain of fatiguing illnesses, and upon analysis they report similar signs and symptoms as their veteran family members. Since a relatively common finding in Gulf War illness patients is a bacterial infection due to Mycoplasma spp., we examined military families (1)49 patients: 42 veterans, 40 spouses, 32 other relatives and 35 children with at least one family complaint of illness) selected from a group of 110 veterans with Gulf War illness who tested positive (~41%) for at least one of four Mycoplasma spp.: M. fermentans, M. hominis, M. pneumoniae or M. genitalium. Consistent with previous results, over 80% of Gulf War illness patients who were positive for blood mycoplasma infections had only one Mycoplasma spp. (Odds ratio = 9.0, 95%CL 3.3-24.3, P < .0.001), in particular M. fermentans (Odds ratio = 17.9, 95%CL 4.1-78.1, P < .0.001). In healthy control subjects the incidence of mycoplasma infection was ~8.5% and none were found to have multiple mycoplasma species (Multiple species Odds ratio >25, Chi^2 = 8.1, P < .0.004). In 107 family members of mycoplasma-positive Gulf War illness patients there were 57 patients (5)3%) that had essentially the same signs and symptoms as the veterans and were diagnosed with Chronic Fatigue Syndrome (CFS) and/or Fibromyalgia Syndrome. Most of these CFS patients also had mycoplasma infections compared to the few non-symptomatic family members (Odds ratio = 16.9, 95%CL 6.0-47.6, P < .0.001), and the most common species found was M. fermentans (Odds ratio = 40.3, 95%CL 8.7-186.4, P < .0.001). In contrast, in the few non-symptomatic family members that tested mycoplasma-positive, the Mycoplasma spp. were often different from the species found in the Gulf War illness patients. The results suggest that a subset of Gulf War illness patients have mycoplasma infections, possibly obtained as contaminants from multiple vaccines given during deployment, and these infections can be transmitted to immediate family members who subsequently display similar signs and symptoms and are diagnosed with CFS and/or Fibromyalgia Syndrome.
Nicolson GL, Berns P, Nasralla MY, Haier J, Nicolson NL, Nass M.		Gulf War Illnesses: Chemical, Biological and Radiological Exposures Resulting in Chronic Fatiguing Illnesses Can Be Identified and Treated	Journal of Chronic Fatigue Syndrome 2003; 11 (1): 135	Gulf War illnesses involve multiple, complex chronic signs and symptoms that loosely fit the clinical criteria for Chronic Fatigue Syndrome/Myalgic Encephalomyelitis (CFS/ME) and/or Fibromyalgia Syndrome (FMS). Most Gulf War illness patients had multiple exposures: (a) complex chemical mixtures, including organophosphate pesticides, anti-nerve agents, carbamates and possibly nerve and blister agents, (b) radiological sources, subjecting patients to both heavy metal and radiation effects, and (c) biological sources, including bacteria and toxins and the effects of multiple vaccines. Chemically exposed patients may benefit by removing offending chemicals and depleting toxic chemicals from the patient's system and other symptomatic treatments. Patients with systemic infections, including mycoplasma and other chronic bacterial infections, can be treated with antibiotics and additional nutritional supplementation. Some patients may have their illness linked to radiological exposures, and a minority to battlefield stress. The vaccines are a prime suspect for immune dysfunction and chronic infections. The multiple, complex exposures resulted in poorly defined chronic illnesses, but subsets of Gulf War

				illness can be identified and effectively treated using appropriate procedures.
Nijs J, Demanet C, McGregor NR, De Becker P, Verhas M, Englebienne P, De Meirleir K.		Monitoring a Hypothetical Channelopathy in Chronic Fatigue Syndrome: Preliminary Observations	Journal of Chronic Fatigue Syndrome 2003; 11 (1): 117	This study was aimed at monitoring of a previously suggested channelopathy in Chronic Fatigue Syndrome, and at searching for possible explanations by means of immune system characteristics. Twenty-seven CFS patients and 20 age and sex matched healthy volunteers were recruited. RNase L-ratio, percent of the norm of whole body potassium content, serum electrolytes (sodium, calcium and potassium), immune cells, blood cell count and erythrocyte sedimentation rate were determined. More than fifty percent of our patients presented with abnormal whole body potassium content. Eight patients had increased, while six had depleted potassium content. Discriminant function analysis revealed that the CFS patients and control subjects could be differentiated on immunophenotyping with the predominant cell differences being the increase in CD19+ CD5+ (mature B-) cells and the decrease in CD32 CD16+ CD56+ (NK) cells in both the percentage and count distributions. The fall in NK-cells was very strongly associated with increases in the RNase L-ratio and falls in serum calcium levels. In addition, four patients with low serum calcium levels showed lower whole body potassium levels. In conclusion, these observations suggest a channelopathy in a subset of CFS patients, probably induced by the deregulated 2-5A RNase L antiviral pathway.

Nijs J, De Becker P, De Meirleir K, Demanet C, Vincken W, Schuermans D, McGregor N.	Department of Human Physiology, Faculty of Physical Education and Physical Therapy, Academic Hospital, Vrije Universiteit Brussel, Belgium. Jo.Nijs@vub.ac.be	Associations between bronchial hyperresponsiveness and immune cell parameters in patients with chronic fatigue syndrome.	Chest. 2003 Apr;123(4):998-1007.	STUDY OBJECTIVE: To examine whether bronchial hyperresponsiveness (BHR) in patients with chronic fatigue syndrome (CFS) is caused by immune system abnormalities. DESIGN: Prospective comparative study. SETTING: A university-based outpatient clinic (Vrije Universiteit; Brussels, Belgium). PARTICIPANTS: One hundred thirty-seven CFS patients and 27 healthy volunteers. MEASUREMENTS: Pulmonary function testing, histamine bronchoprovocation test, immunophenotyping, and ribonuclease (RNase) latent determination. RESULTS: Seventy-three of 137 patients presented with BHR, of whom 64 had normal results of the histamine bronchoprovocation test. No significant differences were found in age or sex characteristics between the groups. There were no differences in the RNase L ratio, total lung capacity, or FEV(1)/FVC ratio between CFS patients with or without BHR. The group of patients in whom BHR was present (BHR+) differs most significantly from the control group with eight differences in the immunophenotype profile in the cell count analysis and seven differences in the percentage distribution profile. The group of patients in whom no BHR was detected (BHR-) only differed from the control subjects in CD25+ count and in the percentage of CD25+ cells. We observed a significant increase in cytotoxic T-cell count and in the percentage of BHR+ patients compared to BHR- patients, which is consistent with the significant reduction in percentage naive T cells. CONCLUSIONS: These results refute any association between the cleaving of 80 kd RNase L and

				BHR. Immunophenotyping of our sample confirmed earlier reports on (chronic) immune activation in patients with CFS, compared to healthy control subjects. BHR+ CFS patients have more evidence of immune activation compared to BHR- patients. Inflammation and the consequent IgE-mediated activation of mast cells and eosinophils, as seen in asthma patients, is unlikely to be responsible for the presence of BHR in patients with CFS.
Nijs J, De Meirleir K, Englebienne P, McGregor N.	Department of Human Physiology, Faculty of Physical Education and Physiotherapy, Vrije Universiteit Brussel, Brussel, Belgium	Chronic fatigue syndrome: a risk factor for osteopenia?	Med Hypotheses. 2003 Jan;60(1):65-8.	No data documenting a possible depletion of bone mineral density in patients with chronic fatigue syndrome (CFS) are currently available. However, recent pathophysiological observations in CFS patients may have deleterious consequences on bone density. Firstly, the deregulation of the 2,5A synthetase RNase L antiviral pathway and its associated channelopathy, implicates increased demands for calcium and consequent increased calcium-re-absorption from the skeletal system. Secondly, Mycoplasma fermentans which has been frequently associated with CFS, produces a lipopeptide, named 2-kDa macrophage-activating lipopeptide (MALP-2), which stimulates macrophages. MALP-2 has been shown to enhance bone resorption in a dose-dependent manner, at least in part by stimulating the formation of prostaglandins. Thirdly, decreased levels of insulin-like growth factor I (IGF-I) have been reported in CFS-patients. IGF-I is critical to the proliferation of osteoblasts. Consequently, depleted levels of IGF-I may shift the balance between osteoclastic and osteoblastic activity towards bone resorption.
Nijs J, Vaes P, McGregor N, Van Hoof E, De Meirleir K.	Department of Human Physiology, Faculty of Physical Education and Physical Therapy, Vrije Universiteit Brussel, Belgium. Jo.Nijs@vub.ac.be	Psychometric properties of the Dutch Chronic Fatigue Syndrome--Activities and Participation Questionnaire (CFS-APQ).	Phys Ther. 2003 May;83(5):444-54.	BACKGROUND AND PURPOSE: The Chronic Fatigue Syndrome-Activities and Participation Questionnaire (CFS-APQ) is a recently developed disease-specific assessment tool for monitoring activity limitations and participation restrictions in patients with chronic fatigue syndrome (CFS). In this study, the convergent validity, content validity, and test-retest reliability of data obtained with the Dutch-language version of the questionnaire were examined. SUBJECTS AND METHODS: One hundred eleven consecutive patients with CFS were enrolled, of whom 47 fulfilled all inclusion criteria. The subjects were first asked to rate their pain, fatigue, and ability to concentrate using 3 visual analog scales, to list at least 5 activities that had become difficult to perform due to their complaints, and to complete the CFS-APQ. Furthermore, subjects were asked to complete a modified version of the CFS-APQ at home and return it to the investigators. The content of the questionnaire was reviewed using the World Health Organization's International Classification of Impairments, Disability and Health (ICIDH) beta II draft. Spearman rank correlation coefficients (R) were used for the convergent validity analysis, and intraclass correlation coefficients were computed for the assessment of the test-retest data. RESULTS: Overall scores on the CFS-APQ correlated with the scores from the visual analog scales for pain (R=.51, P<.001) and fatigue (R=.50, P<.001). The majority of the responses (157 out of 183 answers [85.8%]) to the request to "list difficult activities" matched the content of the CFS-APQ. Using the ICIDH beta II draft, 21 out of 26 questions were found to address activities, and the remaining 5 questions measured the participation level. The Cronbach alpha coefficient was.94, and intraclass correlation coefficients for test-retest reliability of the overall scores were >or= .95 (P<.001). DISCUSSION AND CONCLUSION: The results substantiate the convergent validity, content validity, and reliability of the CFS-APQ scores for patients with CFS.

Nijs J, De Meirleir K, Coomans D, De Becker P, Nicolson GL		Deregulation of the 2,5A Synthetase RNase L Antiviral Pathway by Mycoplasma spp. in Subsets of Chronic Fatigue Syndrome	Journal of Chronic Fatigue Syndrome 2003; 11 (2): 37	The deregulation of the 2,5A synthetase RNase L antiviral pathway and the prevalence of Mycoplasma spp. in subsets of Chronic Fatigue Syndrome (CFS) have been separately reported in the scientific literature. We hypothesised that a co-morbid pathophysiological mechanism involving infection by Mycoplasma spp. and the deregulation of the 2,5A synthetase/RNase L antiviral pathway may exist in CFS. Therefore, 186 consecutive CFS patients were enrolled. Mycoplasma detection was performed using forensic polymerase chain reaction. For RNase L determination, a radioactive probe was used to label 2,5A binding proteins in unfractionated peripheral blood mononuclear cell extracts. Mycoplasma-infected CFS patients presented with significantly elevated RNase L-ratio, compared to non-infected age- and sex-matched patients (p = 0.016). These results suggest that mycoplasma infections may cause deregulation of the 2,5A synthetase RNase L antiviral pathway in patients with CFS
Nijs J, Coomans D, Nicolson GL, De Becker P, Christian D, De Meirleir K		Immunophenotyping Predictive of Mycoplasma Infection in Patients with Chronic Fatigue Syndrome?	Journal of Chronic Fatigue Syndrome 2003; 11 (2): 51	An impaired immune system and opportunistic infections are considered important characteristics in the pathophysiology of Chronic Fatigue Syndrome (CFS). Using immunofluorescence we examined healthy subjects (N = 35) and two subsets of CFS patients: those without evidence of Mycoplasma (N = 55) and those with evidence of a Mycoplasma infection in their blood (N = 131). Using monoclonal antibodies and forensic polymerase chain reaction for detection of M. hominis, M. fermentans, M. pneumoniae and M. penetrans we examined leukocytes in peripheral blood samples. Both patients groups presented with significantly elevated CD25+ (activated) cells as compared to healthy volunteers. CFS patients without evidence of mycoplasma infection(s) had increased amounts of CD5+ B-cells. Stepwise discriminant analysis indicated the number of activated cells, number of memory CD4+ cells and percentage of suppressor T-cells (lower in Mycoplasma + patients as compared to Mycoplasma2 patients) as the discriminant variables. A classification tree, for predicting the presence of Mycoplasma species in CFS patients, was constructed. Taken together, these data confirm earlier reports on immune activation among CFS patients, but this does not appear to be specific for Mycoplasma-infected CFS patients.
Nisenbaum R, Jones JF, Unger ER, Reyes M, Reeves WC.	Division of Viral and Rickettsial Diseases, National Center for Infectious Diseases,	A population-based study of the clinical course of chronic fatigue syndrome.	Health Qual Life Outcomes. 2003 Oct 3;1(1):49. Epub 2003 Oct 03.	BACKGROUND: Chronic fatigue syndrome (CFS) presents a challenge for patients, health care providers, and health insurance groups because of its incapacitating nature, unknown cause, and poorly understood prognosis. We conducted a longitudinal population-based study to characterize the clinical course of CFS. METHODS: Sixty-five CFS subjects were identified from a

	Centers for Disease Control and Prevention, Atlanta, Georgia, USA. ran7@cdc.gov			random-digit-dialing survey of Wichita, Kansas residents and followed for up to 3 years. We evaluated changes in CFS classification (partial or total remission, alternative medical or psychiatric diagnoses), CFS case-defining criteria, wellness scores, hours of activities and sleep, and treatments used to reduce fatigue. Associations between risk factors and outcomes were determined by use of logistic regression and generalized estimating equations models. RESULTS: Only 20%-33% of the subjects were classified as having CFS at follow-up, 56.9% ever experienced partial or total remission, 10% sustained total remission, and 23.1% received alternative diagnoses, of which 20% were sleep disorders. Higher fatigue severity scores and total number of symptoms were negatively associated with ever remitting. Duration of illness leq; 2 years was positively associated with sustained remission. Unrefreshing sleep persisted in at least 79% of the subjects across all periods but, as with most of the CFS symptoms, tended to be less frequent over time. The number of activities affected by fatigue decreased over time, while wellness scores increased. At any follow-up, more than 35% of subjects reporting reduced fatigue used complementary and alternative medicine therapies, and of those subjects, at least 50% thought these therapies were responsible for reducing their fatigue. CONCLUSIONS: The clinical course of CFS was characterized by an intermittent pattern of relapse and remission. Remission rates documented by our population-based study were similar to those reported in clinical studies. Shorter illness duration was a significant predictor of sustained remission, and thus early detection of CFS is of utmost importance. The persistence of sleep complaints and identification of sleep disorders suggest that CFS subjects be evaluated for sleep disturbances, which could be treated.
Olson LG, Ambrogetti A, Sutherland DC.	Department of Respiratory and Sleep Medicine, John Hunter Hospital, Faculty of Medicine, University of Newcastle, Australia. lolson@mail.newcastle.edu.au	A pilot randomized controlled trial of dexamphetamine in patients with chronic fatigue syndrome.	Psychosomatics. 2003 Jan-Feb;44(1):38-43.	This study determined whether dexamphetamine improved symptoms and quality of life in patients with chronic fatigue syndrome. The setting was a specialized clinic within a tertiary referral hospital. This was a 6-week parallel-group, placebo-controlled trial with random allocation. There was a 2-week dose-adjustment phase and a 4-week stable treatment period. Outcome measures were the Fatigue Severity Scale, the Medical Outcomes Study 36-item Short-Form Health Survey, and two patient-determined outcomes. Ten patients were randomly assigned to dexamphetamine, and 10 were assigned to placebo. Fatigue Severity Scale scores improved in nine of 10 dexamphetamine and four of 10 placebo patients. The change in mean score was statistically significant. There were large but statistically nonsignificant changes in scores for the Short-Form Health Survey domains vitality and physical functioning. Dexamphetamine may be useful in the management of chronic fatigue syndrome; a larger and longer trial is justified by these results.
Patel MX, Smith DG, Chalder T, Wessely S.	Institute of Psychiatry and GKT School of Medicine, De Crespigny Park, London SE5 8AF, UK.	Chronic fatigue syndrome in children: a cross sectional survey.	Arch Dis Child. 2003 Oct;88(10):894-8.	BACKGROUND: Chronic fatigue syndrome (CFS) in children is a controversial diagnosis with unclear aetiology, ill defined but likely increasing incidence, and debatable clinical management options. However these children experience real and considerable suffering. Appropriate research in this clinical population is sparse and usually occurs in tertiary referral units. METHODS: Cross sectional survey of 36 children attending a GP specialist interest clinic in southeast England. RESULTS: Patient sociodemographics and clinical morbidity were largely comparable to the literature from tertiary referral research centres. Some prognostic indicators

				for adults did not readily transfer to this younger age group, although several children had a positive family psychiatric history. Receiving treatment was associated with increased school attendance, but one third of subjects obtained no qualifications. Return to normal health or significant overall improvement was reported by 29/36 subjects. CONCLUSIONS: The outcomes in this setting are favourable and comparable to those seen in a controlled setting; this study supports the concept that the prognosis for CFS in children and adolescents is generally good. However, the impact of the illness is significant and this is perhaps most evident in terms of education. Current methods of reporting educational outcomes in the literature are varied and merit development of standardised tools.
Peckerman A, Dahl K, Chemitiganti R, LaManca JJ, Ottenweller JE, Natelson BH.	VA Medical Center, East Orange, NJ 07018, USA. apeckerm@njneuromed.org	Effects of posttraumatic stress disorder on cardiovascular stress responses in Gulf War veterans with fatiguing illness.	Auton Neurosci. 2003 Oct 31;108(1-2):63-72.	Abnormal cardiovascular stress responses have been reported in Gulf War veterans with chronic fatigue. However, many of these veterans also suffer from posttraumatic stress disorder (PTSD), which could potentially explain the reported abnormalities. To test this hypothesis, 55 Gulf veterans (GVs) with chronic fatigue syndrome (CFS) or idiopathic chronic fatigue (ICF) were stratified into groups with (N=16) and without (N=39) comorbid PTSD, and were compared to healthy Gulf veterans (N=47) on cardiovascular responses to a series of stressors. The CFS/ICF with PTSD group had lower blood pressure responses to speech and arithmetic tasks, and more precipitous declines and slower recoveries in blood pressure after standing up than the controls. Similar trends in the CF/ICF group without PTSD were not significant, however. Both CFS/ICF groups had blunted increases in peripheral vascular resistance during mental tasks. However, only the veterans with comorbid PTSD had diminished cardiac output responses to the mental stressors and excessive vasodilatory responses to standing. Symptoms of posttraumatic stress were significant predictors of hypotensive postural responses, but only in veterans reporting a significant exposure to wartime stress. We conclude that comorbid PTSD contributes to dysregulation of cardiovascular responses to mental and postural stressors in Gulf veterans with medically unexplained fatiguing illness, and may provide a physiological basis for increased somatic complaints in Gulf veterans with symptoms of posttraumatic stress.
Peckerman A, LaManca JJ, Qureishi B, Dahl KA, Golfetti R, Yamamoto Y, Natelson BH.	VA Medical Center, War-Related Illness and Injury Study Center, East Orange, New Jersey 07018, USA. apeckerm@njneuromed.org	Baroreceptor reflex and integrative stress responses in chronic fatigue syndrome.	Psychosom Med. 2003 Sep-Oct;65(5):889-95.	OBJECTIVE: Altered cardiovascular responses to mental and postural stressors have been reported in chronic fatigue syndrome (CFS). This study examined whether those findings may involve changes in baroreceptor reflex functioning. METHODS: Chronotropic baroreceptor reflex (by sequential analysis) and cardiovascular stress responses were recorded during postural (5-minute of active standing) and cognitive (speech task) stress testing in patients with CFS grouped into cases with severe (N = 21) or less severe (N = 22) illness, and in 29 matched control subjects. RESULTS: Patients with CFS had a greater decline in baroreceptor reflex sensitivity (BRS) during standing, although only those with severe CFS were significantly different from the controls. Systolic blood pressure declined during standing in the control group but was maintained in the CFS patients. In contrast, the patients with less severe CFS had blunted increases in blood pressure during the speech task, which could not, however, be explained by inadequate inhibition of the baroreceptor reflex, with all groups showing an appropriate reduction in BRS during the task. CONCLUSIONS: These results indicate that in CFS, deficiencies in orthostatic regulation, but not in centrally mediated stress responses, may involve the baroreceptor reflex.

				This study also suggests that classifying patients with CFS on illness severity may discriminate between patients with abnormalities in peripheral vs. central mechanisms of cardiovascular stress responses.
Peckerman A, LaManca JJ, Dahl KA, Chemitiganti R, Qureishi B, Natelson BH.	Department of Neurosciences, CFS Cooperative Research Center, University of Medicine and Dentistry of New Jersey, Newark, NJ, USA. apeckerm@njneuromed.org	Abnormal impedance cardiography predicts symptom severity in chronic fatigue syndrome.	Am J Med Sci. 2003 Aug;326(2):55-60.	BACKGROUND: Findings indicative of a problem with circulation have been reported in patients with chronic fatigue syndrome (CFS). We examined this possibility by measuring the patient's cardiac output and assessing its relation to presenting symptoms. METHODS: Impedance cardiography and symptom data were collected from 38 patients with CFS grouped into cases with severe (n = 18) and less severe (n = 20) illness and compared with those from 27 matched, sedentary control subjects. RESULTS: The patients with severe CFS had significantly lower stroke volume and cardiac output than the controls and less ill patients. Postexertional fatigue and flu-like symptoms of infection differentiated the patients with severe CFS from those with less severe CFS (88.5% concordance) and were predictive (R2 = 0.46, P < 0.0002) of lower cardiac output. In contrast, neuropsychiatric symptoms showed no specific association with cardiac output. CONCLUSIONS: These results provide a preliminary indication of reduced circulation in patients with severe CFS. Further research is needed to confirm this finding and to define its clinical implications and pathogenetic mechanisms.
Pinching AJ.	Barts and the London, Queen Mary's School of Medicine and Dentistry.	AIDS and CFS/ME: a tale of two syndromes.	Clin Med. 2003 Jan-Feb;3(1):78-82.	Both HIV/AIDS and chronic fatigue syndrome/myalgic encephalomyelitis (CFS/ME) presented major challenges for medicine, science and society. This article explores what could have impeded investigation of--and specifically pharmaceutical engagement with--CFS/ME, in contrast to the impressive achievements seen in HIV/AIDS. It explores the obstruction of mind-body dualism in a historical context, and examines some of the possible obstacles to pharmaceutical enquiry. Nothing of real substance is identified that would justify the lack of investment and interest in solutions for patients with CFS/ME.
Planz O, Rziha HJ, Stitz L.	Institut fur Immunologie, Bundesforschungsanstalt fur Viruskrankheiten der Tiere, Tubingen. oliver.planz@tue.bfav.de	Genetic relationship of Borna disease virus isolates.	Virus Genes. 2003 Jan;26(1):25-30.	The infection of humans with Boma disease virus (BDV) is still a matter of debate. In a recent publication, we described a BDV (RW98) isolated from the blood of a psychiatric patient. The RNA of this virus differed more than 5% from that of the widely used strain He/80, which was supposed to represent our laboratory virus. Here, we show that the virus used in our laboratory was not He/80 and, furthermore, that RW98 has sequence identity to the laboratory strain. We also present data that BDV-specific nucleic acid detected in blood of the donor of the presumed RW98 isolate and one other patient differs from all known BDV-p24 sequences, arguing for the existence of BDV sequences in man.
Poteliakhoff A.		Adrenal insufficiency.	Lancet. 2003 Aug 16;362(9383):580. Comment on: Lancet. 2003 May 31;361(9372):1881-93.	
Powell R, Ren J, Lewith G, Barclay W, Holgate S, Almond J.	Southampton University Hospital, Southhampton, UK.	Identification of novel expressed sequences, up-	Clin Exp Allergy. 2003 Oct;33(10):1450-6.	BACKGROUND: Chronic fatigue syndrome (CFS) is an increasing medical phenomenon of unknown aetiology leading to high levels of chronic morbidity. Of the many hypotheses that purport to explain this disease, immune system activation, as a central feature, has remained

	rmp2@soton.ac.uk	regulated in the leucocytes of chronic fatigue syndrome patients.		prominent but unsubstantiated. Supporting this, a number of important cytokines have previously been shown to be over-expressed in disease subjects. The diagnosis of CFS is highly problematic since no biological markers specific to this disease have been identified. The discovery of genes relating to this condition is an important goal in seeking to correctly categorize and understand this complex syndrome. OBJECTIVE: The aim of this study was to screen for changes in gene expression in the lymphocytes of CFS patients. METHODS: 'Differential Display' is a method for comparing mRNA populations for the induction or suppression of genes. In this technique, mRNA populations from control and test subjects can be 'displayed' by gel electrophoresis and screened for differing banding patterns. These differences are indicative of altered gene expression between samples, and the genes that correspond to these bands can be cloned and identified. Differential display has been used to compare expression levels between four control subjects and seven CFS patients. RESULTS: Twelve short expressed sequence tags have been identified that were over-expressed in lymphocytes from CFS patients. Two of these correspond to cathepsin C and MAIL1 - genes known to be upregulated in activated lymphocytes. The expression level of seven of the differentially displayed sequences have been verified by quantifying relative level of these transcripts using TAQman quantitative PCR. CONCLUSION: Taken as a whole, the identification of novel gene tags up-regulated in CFS patients adds weight to the idea that CFS is a disease characterized by subtle changes in the immune system.
Prins JB, Elving LD, Koning H, Bleijenberg G, van der Meer JW.	Department of Medical Psychology, University Medical Centre St Radboud, PO Box 9101, 6500 HB Nijmegen, The Netherlands. j.prins@cukz.umcn.nl	Diagnosing chronic fatigue syndrome: comparison of a protocol and computerised questionnaires.	Neth J Med. 2003 Apr;61(4):120-6.	BACKGROUND: In the context of outpatient care and within the framework of scientific research, guidelines and measuring instruments have been developed to help improve CFS diagnostics. The purpose of this study was to measure the agreement between the evaluations of chronically fatigued patients by physicians using a CFS protocol and by researchers using computerised questionnaires. METHODS: The sample consisted of 516 patients referred to an internal medicine outpatient clinic with complaints of chronic fatigue. Retrospectively the medical records and the computerised questionnaires were checked separately and compared to see whether the criteria for diagnosis of CFS had been met. In addition, the reasons for not diagnosing CFS were evaluated. RESULTS: Agreement between the physicians' and the researchers' evaluations was 84%. Disagreement mostly concerned severity of fatigue and functional impairment, or premorbid exclusion criteria. A physical cause for the chronic fatigue was only found in 3% of the cases. CONCLUSIONS: For physicians, questionnaire assessment may be complementary to the CFS protocol in optimising the process of diagnosing CFS.
Rains JC, Penzien DB.	Center for Sleep Evaluation, Elliot Hospital, One Elliot Way, Manchester, NH 03102, USA. jrains@elliot-hs.org	Sleep and chronic pain: challenges to the alpha-EEG sleep pattern as a pain specific sleep anomaly.	J Psychosom Res. 2003 Jan;54(1):77-83.	OBJECTIVE: The alpha-EEG sleep anomaly has been associated with chronic benign pain syndromes. Although controversial, the anomaly is believed by some to be an important biologic correlate of certain otherwise poorly explained painful conditions (e.g., fibromyalgia and chronic fatigue syndrome). To shed further light on this phenomenon, this study compared the sleep and psychological characteristics of chronic pain patients who exhibited the alpha-EEG sleep anomaly with pain-free psychiatric and medical patients who also were found to exhibit the alpha-EEG anomaly. METHODS: The alpha-EEG sleep was identified in the polysomnographic records of 5% of over 1000 consecutive sleep patients. Objective sleep parameters, daytime sleepiness and psychological characteristics (Minnesota Multiphasic Personality Inventory [MMPI] scores) of

				patients exhibiting this anomaly were examined. RESULTS: The alpha-EEG anomaly was identified in only 5% of the total patient sample. Patients with the alpha-EEG anomaly could be further classified into three diagnostic subgroups: chronic pain, psychiatric and other medical/sleep disorders, The subgroups were compared on sleep parameters and psychological characteristics. Less than 40% of the patients exhibiting the alpha-EEG anomaly experienced chronic pain. Chronic pain patients evidenced disturbed sleep patterns and psychological characteristics that were for the most part similar to those observed in some pain-free medical and psychiatric patients. Only the medical subgroup exhibited objective daytime sleepiness. The alpha-EEG sleep disturbance was not accounted for by psychological characteristics. CONCLUSIONS: These findings challenge the notion that alpha-EEG sleep is of direct etiological significance in producing the pain complaint among patients with chronic pain since the alpha-EEG sleep was not a sufficient condition for pain. Copyright 2003 Elsevier Science Inc.
Rangel L, Garralda ME, Hall A, Woodham S.	Academic Unit of Child and Adolescent Psychiatry, Faculty of Medicine, Imperial College at St Mary's Campus, London.	Psychiatric adjustment in chronic fatigue syndrome of childhood and in juvenile idiopathic arthritis.	Psychol Med. 2003 Feb;33(2):289-97. Comment in: Psychol Med. 2003 Feb;33(2):197-201.	BACKGROUND: High rates of psychopathology and of personality problems have been reported in children and adolescents with chronic fatigue syndrome (CFS). It is not clear whether this is consequent on the experience of chronic physical ill health. We compare psychiatric adjustment in children with CFS and in children suffering from another chronic physical disorder (juvenile idiopathic arthritis or JIA). METHOD: Our sample consisted of 28 children with CFS and 30 with JIA attending tertiary paediatric centres (age range, 11 to 18 years, mean 15, S.D. 2.3). In order to assess psychiatric status and functioning, we used the K-SADS psychiatric interviews, CGAS and Harter Self-Esteem Questionnaire with child subjects; behavioural questionnaires (CBCL) and child personality assessment interviews (PAS) with parent informants. RESULTS: Psychiatric disorders in the year prior to interview had been present significantly more commonly in the CFS group (72% v. 34% in JIA) and were more impairing to them (CGAS scores of 45 v. 77). Most common diagnoses in both groups were depressive and anxiety disorders. Personality problems were also significantly more frequent in CFS subjects (48% disorder and 26% difficulty v. 11% and 11% in JIA). There were few differences between the two groups in self-esteem. CONCLUSIONS: Psychopathology and personality problems are common in children and adolescents with severe forms of CFS and cannot be explained strictly through the experience of chronic physical illness.
Razumovsky AY, DeBusk K, Calkins H, Snader S, Lucas KE, Vyas P, Hanley DF, Rowe PC.	Departments of Anesthesiology/Critical Care Medicine, Neurology, Johns Hopkins Medical Institutions, Baltimore, Maryland, USA. arazumov@surgicalmonitoring.net	Cerebral and systemic hemodynamics changes during upright tilt in chronic fatigue syndrome.	J Neuroimaging. 2003 Jan;13(1):57-67.	BACKGROUND AND PURPOSE: During head-up tilt (HUT), patients with chronic fatigue syndrome (CFS) have higher rates of neurally mediated hypotension (NMH) and postural tachycardia syndrome (POTS) than healthy controls. The authors studied whether patients with CFS were also more likely to have abnormal cerebral blood flow velocity (CBFV) compared with controls in response to orthostatic stress. METHODS: Transcranial Doppler monitoring of middle cerebral artery (MCA) CBFV was performed during 3-stage HUT prospectively in 26 patients with CFS and 23 healthy controls. At the same time, continuous monitoring of arterial blood pressure (BP), heart rate (HR), endtidal CO2 (ET-CO2) were performed. Results are reported as mean +/- SD. RESULTS: NMH developed in 21 patients with CFS and in 14 controls (P = .22). POTS was present in 9 CFS patients and 7 controls (P = .76). Supine HR was higher in CFS patients, but all other hemodynamics and CBFV measures were similar at baseline. The median time to hypotension did not differ, but the median time to onset of orthostatic symptoms was shorter in those with CFS (P

				< .001). The CBFV did not differ between groups in the supine posture, at 1 or 5 minutes after upright tilt, at 5 or 1 minute before the end of the test, or at termination of the test. Mean CBFV fell at termination of tilt testing in those with CFS and controls. ET-CO2 was lower at termination of the test in those with CFS versus controls (P = .002). CONCLUSIONS: The results of this study are not consistent with the hypothesis that patients with CFS have a distinctive pattern of MCA CBFV changes in response to orthostatic stress.

Reyes M, Nisenbaum R, Hoaglin DC, Unger ER, Emmons C, Randall B, Stewart JA, Abbey S, Jones JF, Gantz N, Minden S, Reeves WC.	Division of Viral and Rickettsial Diseases, National Center for Infectious Diseases, Centers for Disease Control and Prevention, Public Health Service, US Department of Health and Human Services, Atlanta, GA 30333, USA.	Prevalence and incidence of chronic fatigue syndrome in Wichita, Kansas.	Arch Intern Med. 2003 Jul 14;163(13):1530-6.	BACKGROUND: Chronic fatigue syndrome (CFS) is a debilitating illness with no known cause or effective therapy. Population-based epidemiologic data on CFS prevalence and incidence are critical to put CFS in a realistic context for public health officials and others responsible for allocating resources and for practicing physicians when examining and caring for patients. METHODS: We conducted a random digit-dialing survey and clinical examination to estimate the prevalence of CFS in the general population of Wichita, Kan, and a 1-year follow-up telephone interview and clinical examination to estimate the incidence of CFS. The survey included 33 997 households representing 90 316 residents. This report focuses on 7162 respondents aged 18 to 69 years. Fatigued (n = 3528) and randomly selected nonfatigued (n = 3634) respondents completed telephone questionnaires concerning fatigue, other symptoms, and medical history. The clinical examination included the Diagnostic Interview Schedule for Diagnostic and Statistical Manual of Mental Disorders, Fourth Edition, laboratory testing, and a physical examination. RESULTS: The overall weighted point prevalence of CFS, adjusted for nonresponse, was 235 per 100,000 persons (95% confidence interval, 142-327 per 100,000 persons). The prevalence of CFS was higher among women, 373 per 100,000 persons (95% confidence interval, 210-536 per 100,000 persons), than among men, 83 per 100,000 persons (95% confidence interval, 15-150 per 100,000 persons). Among subjects nonfatigued and fatigued for less than 6 months, the 1-year incidence of CFS was 180 per 100,000 persons (95% confidence interval, 0-466 per 100,000 persons). CONCLUSIONS: Chronic fatigue syndrome constitutes a major public health problem. Longitudinal follow-up of this cohort will be used to further evaluate the natural history of this illness.
Sabin TD.	Department of Neurology, Tufts University School of Medicine and New	An approach to chronic fatigue syndrome in adults.	Neurolog. 2003 Jan;9(1):28-34.	BACKGROUND: The neurologist is often asked to evaluate patients with a chief complaint of fatigue. Many neurologists do not believe in the pathologically based disease known as chronic fatigue syndrome, yet as a group, neurologists are well suited to guide the diagnostic work up of such patients to pinpoint treatable disorders in the realm of neurology, general medicine, and

	England Medical Center, Boston, Massachusetts. E-mail: tsabin@lifespan.org			psychiatry. REVIEW SUMMARY: Every patient should be carefully evaluated for certain medical, psychiatric, and neurologic disease that can cause fatigue as the most prominent symptom. This is most pressing because new work in virology, immunology, and imaging holds promise but still does not provide any diagnostic test or a mechanism for the production of these symptoms. Only a few treatments meet with even modest success in CFS. The goal of this paper is to provide the clinical neurologist with a framework for the investigation and management of this challenging group of patients. CONCLUSIONS: Neurologists are typically also trained in psychiatry and general medicine, and this is a strong position to evaluate the patient with fatigue. Because no presently available test can make the diagnosis of CFS, the assessment is vital to seek out more treatable illnesses.
Schaefer KM.	Department of Nursing, Temple University-CAHP, Philadelphia, Pa 19140, USA. karen.schaefer@temple.edu	Sleep disturbances linked to fibromyalgia.	Holist Nurs Pract. 2003 May-Jun;17(3):120-7.	Fibromyalgia (FM) is a chronic muscle disorder characterized by muscle aches and pain of varying intensities. Sleep disturbances have been recognized as one of the probable causes of this disorder. Pharmacological and nonpharmacological approaches are often used to manage the symptoms of sleep disturbances. This article provides a brief background on FM, discusses the physiology of sleep, reviews the current literature on sleep disturbances associated with FM, provides insight to interventions that might be beneficial given the data available, and recommends ongoing research.
Schmaling KB, Lewis DH, Fiedelak JI, Mahurin R, Buchwald DS. University of Washington, Seattle.	College of Health Sciences (K.B.S.), University of Texas, El Paso, Texas, and the Departments of Psychiatry and Behavioral Sciences (K.B.S., R.M.), Radiology (D.H.L.), and Medicine (J.I.F., D.S.B.),	Single-photon emission computerized tomography and neurocognitive function in patients with chronic fatigue syndrome.	Psychosom Med. 2003 Jan-Feb;65(1):129-36.	OBJECTIVE: The purposes of this study were to compare functional imaging under control and experimental conditions among patients with chronic fatigue syndrome (CFS) and healthy persons and to examine perceived and objective performance on a test of attention and working memory previously found to be difficult for persons with CFS. METHODS: Single-photon emission computerized tomography scans were completed on 15 subjects with CFS and 15 healthy persons twice: at rest and when performing the Paced Auditory Serial Addition Test (PASAT). RESULTS: No group differences were found for performance on the PASAT despite CFS subjects' perceptions of exerting more mental effort to perform the task than healthy subjects. Inspection of the aggregate scans by group and task suggested a pattern of diffuse regional cerebral blood flow among subjects with CFS in comparison with the more focal pattern of regional cerebral blood flow seen among healthy subjects. Between-group region-of-interest analysis revealed that although CFS subjects showed less perfusion in the anterior cingulate region, the change in CFS subjects' activation of the left anterior cingulate region during the PASAT was greater than that observed for healthy subjects. The differences were not attributable to lesser effort by the subjects with CFS, confounding effects of mood perturbation, or to poorer performance on the experimental task. CONCLUSIONS: Further research regarding CFS subjects' diffuse cerebral perfusion and its relationship to inefficient neuropsychological performance is warranted.
Schmaling KB, Fiedelak JI, Katon WJ, Bader JO, Buchwald DS.	Office of the Provost, University of Texas at El Paso, El Paso, TX 79968, USA. schmaling@utep.edu	Prospective study of the prognosis of unexplained chronic fatigue in a clinic-based cohort.	Psychosom Med. 2003 Nov-Dec;65(6):1047-54.	OBJECTIVES: To determine prospective changes in clinical status related to chronic fatigue over an 18-month period, and to test demographic and clinical predictors of outcome. METHODS: A cohort of 100 patients with unexplained chronic fatigue (UCF), which encompasses both chronic fatigue syndrome (CFS) and idiopathic chronic fatigue (ICF), completed questionnaire measures and medical and psychiatric evaluations on four occasions, each six months apart. RESULTS: Approximately 21% of the sample did not meet criteria for either CFS or ICF at their last research

				appointment 1.5 years after their index visit. Vitality increased over time, and physical functioning tended to improve, but UCF symptoms did not decrease significantly. Less education, being unemployed, worse mental health, more use of sedating and antidepressant medications, and more somatic attributions for their symptoms were associated with worsening symptom severity over time. Older age, current depression, and more somatic attributions predicted worsening physical functioning. Better mental health, less use of sedating medications, and fewer somatic attributions for illness were significant predictors of increases in vitality. CONCLUSIONS: Demographic and clinical variables predict outcomes over time among a cohort of patients with unexplained chronic fatigue.
Shapiro B.	barbarashapiro@earthlink.net	Building bridges between body and mind: The analysis of an adolescent with paralyzing chronic pain.	Int J Psychoanal. 2003 Jun;84(Pt 3):547-61.	This paper describes the evaluation, initial psychotherapy and subsequent psychoanalysis of an adolescent who presented with a severe psychosomatic process involving total body pain and profound fatigue. The author details the complex and multifaceted nature of the psychosomatic process as it unfolded in the treatment. The psychosomatic problem was not a single entity, but rather was comprised of diverse interwoven elements such as somatization, conversion on pre-oedipal and oedipal levels, conflicts over aggression, sexuality, identity, masochism, secondary gain, anaclitic depression, internalized self-other interactions with a depressed mother and transgenerational transmission of trauma. The author uses the case material to discuss technical approaches to problems that often arise in the analytic treatment of patients with complicated chronic pain and fatigue as the primary complaints. Such approaches include respecting the mind-body split as a primary defense, speaking the language of the body along with the language of the mind and developing the verbal sphere around the non-verbal symptoms. The author emphasizes that complicated chronic pain problems are common and can be helped by psychoanalysis as long as the unique and complex features are understood and reflected in the technical approach.
Shee CD.	Department of Medicine, Queen Mary's Sidcup NHS Trust, Kent, UK. charles.shee@qms-tr.sthames.nhs.uk	Phantom lymphadenopathy. An association with chronic fatigue syndrome.	Postgrad Med J. 2003 Jan;79(927):59-60. Comment in: Postgrad Med J. 2003 Mar;79(929):185.	Ten patients with self diagnosed enlarged lymph glands were referred to a general medicine outpatient clinic and careful examination did not confirm lymphadenopathy. All patients also complained of severe chronic fatigue associated with aches and miscellaneous somatic symptoms, and fulfilled criteria for diagnosis of chronic fatigue syndrome (CFS). Phantom lymphadenopathy may be a symptom in some people with CFS, and possible reasons for this are discussed.
Shin HY, Shin CH, Shin TY, Lee EJ, Kim HM.	Department of Pharmacology, College of Oriental Medicine, Kyung Hee University, Dongdaemun-Gu, Seoul, South Korea.	Effect of bojungikki-tang on lipopolysaccharide-induced cytokine production from peripheral blood mononuclear cells of chronic fatigue syndrome patients.	Immunopharmacol Immunotoxicol. 2003 Nov;25(4):491-501.	Bojungikki-tang (BIT) has been widely used to treat patients suffering from chronic fatigue syndrome (CFS). However, its effect has not been yet investigated experimentally. Based upon the clinical presentation of CFS, we hypothesized that cytokines may play a role in the pathogenesis of the disease. We studied the effect of BIT on lipopolysaccharide (LPS)-induced various cytokines production in peripheral blood mononuclear cells (PBMC) of CFS patients. Bojungikki-tang (1 mg/mL) significantly inhibited LPS-induced tumor necrosis factor (TNF)-alpha, interleukin (IL)-6, IL-10, transforming growth factor (TGF)-beta1 production by 63.55% +/- 0.19%, 55.06% +/- 0.27%, 48.23% +/- 0.48%, 54.09% +/- 0.76%, respectively ($P < 0.05$). Bojungikki-tang showed a slightly lower inhibitory effect of LPS-induced Interferon (IFN)-gamma production. These results suggest that BIT may be useful in treating fatigue associated with chronic diseases.

Shor S		Pathogenesis of Chronic Fatigue Syndrome, a Multisystem Hypothesis	Journal of Chronic Fatigue Syndrome 2003; 11 (3): 51-69	Fatigue is a very common complaint with a number of meanings. If the fatigue lasts for more than 6 months, it fulfills the definition of "chronic." The Center for Disease Control (CDC) has established specific criteria for the diagnosis of CFS. This is characterized by a persistent or relapsing debilitating fatigue for at least 6 months in the absence of a medical diagnosis that would otherwise explain the clinical presentation. CFS represents a heterogeneous group of patients that manifest symptom complexes with varying degrees of fatigue, limited exertional reserve and cognitive dysfunction. This treatise explores the pathogenesis of CFS as it relates to a complex multidimensional systemic process and offers a hypothesis for the disease processes. In particular, an up-regulated immune system, affecting mitochondrial dysfunction is described. These pathophysiologic mechanisms impact and in turn are being impacted by the neuroendocrine system and the HPA axis. In addition, the cardiovascular system involving blood pressure and heart rate anomalies along with neurocognitive pathology is characterized.
Siegmeth W.	Ludwig-Boltzmann-Forschungsstelle fur Epidemiologie rheumatischer Erkrankungen, Rheuma-Sonderkrankenanstalt der No. Gebietskrankenkasse, Baden. rska-med@noegkk.sozvers.at	[Article in German]	Wien Med Wochenschr. 2003;153(13-14):309-13.	Nowadays, fibromyalgia syndrome (FMS) should be diagnosed according to established criteria in order to differentiate it from other specified or unspecified pain conditions. Various underlying reasons for pain exist and possible correlations with FMS should be thoroughly discussed with the patient. Recent pathophysiological examinations suggest that fibromyalgia syndrome may constitute a disorder of the central nervous system, especially of the hypothalamus-hypophysis-axis, and/or of the autonomous nervous system and of pain regulating nerves. The most common co-morbidity comprises sleep disturbances. The patients' complaints usually prevail over a long period of time. There is a variety of trigger factors for the development of fibromyalgia syndrome, which leads to the suggestion that a number of fibromyalgia-syndrome subgroups exist. A genetic disposition is a topic of ongoing discussion. Treatment of fibromyalgia syndrome should be multidisciplinary. Drug therapy is often disappointing. Extensive patient information, therapeutic devotion and means of physical therapy seem to be more efficient, providing a multitude of therapeutic options. Both fibromyalgia syndrome and chronic fatigue syndrome have to be accepted as medical entities, treated efficiently and studied scientifically. By these means, patients suffering from fibromyalgia syndrome, will not be lost to non-established forms of therapy.
Siessmeier T, Nix WA, Hardt J, Schreckenberger M, Egle UT, Bartenstein P.	Department of Nuclear Medicine, Johannes Gutenberg University, Mainz, Germany. siessmeier@nuklear.klinik.uni-mainz.de	Observer independent analysis of cerebral glucose metabolism in patients with chronic fatigue syndrome.	J Neurol Neurosurg Psychiatry. 2003 Jul;74(7):922-8.	OBJECTIVES: To evaluate cerebral glucose metabolism, assessed by 18-fluorodeoxyglucose positron emission tomography (FDG-PET), in patients with chronic fatigue syndrome (CFS), using an observer independent analytical approach; and to characterise any observed alterations by correlating them with neuropsychological deficits. METHODS: 26 patients (13 female, 13 male) were examined. They all fulfilled the CDC diagnostic criteria for CFS. Their ages ranged from 26 to 61 years (mean (SD) age, 43 (9.3) years). They underwent extensive psychometric testing including the hospital anxiety and depression scale (HADS) and the short form 36 item health questionnaire (SF-36). Brain FDG-PET was done in all the subjects. After stereotactic normalisation, single subject comparisons with an age and sex matched normal database (n = 18) and a group comparison between the patients and normal controls were undertaken, along with additional correlation analyses between brain metabolism and psychometric test scores. RESULTS: 12 of the 26 patients showed no significant decrease in FDG uptake compared with the

				controls. Of the remaining 14, 12 showed hypometabolism bilaterally in the cingulate gyrus and the adjacent mesial cortical areas. Five of these 12 patients also had decreased metabolism in the orbitofrontal cortex. The two remaining patients had hypometabolism in the cuneus/praecuneus. Correlation analyses showed significant correlations between some test scores (anxiety, depression, health related quality of life) but not fatigue and regional reductions in glucose metabolism. CONCLUSIONS: Although abnormalities in FDG-PET were only detectable in approximately half the CFS patients examined, and no specific pattern for CFS could be identified, PET may provide valuable information in helping to separate CFS patients into subpopulations with and without apparent alterations in the central nervous system.
Skapinakis P, Lewis G, Mavreas V.	Department of Psychiatry, University of Bristol, Cotham Hill, UK. p.skapinakis@bristol.ac.uk	Unexplained fatigue syndromes in a multinational primary care sample: specificity of definition and prevalence and distinctiveness from depression and generalized anxiety.	Am J Psychiatry. 2003 Apr;160(4):785-7.	OBJECTIVE: The authors investigated whether narrow definitions of unexplained fatigue syndromes that require additional minor somatic symptoms are more strongly associated with psychiatric morbidity than wider ones. METHOD: This was a secondary analysis of the World Health Organization Collaborative Project on Psychological Problems in General Health Care. A total of 5,438 primary care patients from 14 countries were assessed with the Composite International Diagnostic Interview. RESULTS: The prevalence of fatigue syndromes fell from 7.99 to 1.69 as somatic criteria were added. Patients with depression or anxiety were more likely to report unexplained fatigue, but this association was stronger for definitions of unexplained fatigue with more somatic criteria. CONCLUSIONS: Definitions of unexplained fatigue syndromes that require more somatic criteria selected more patients with psychiatric disorders in this culturally diverse sample. These findings might have implications for the revision of existing international diagnostic criteria for neurasthenia or chronic fatigue syndrome.
Skapinakis P, Lewis G, Mavreas V.	Department of Psychiatry, University of Bristol, Cotham Hill.	One-year outcome of unexplained fatigue syndromes in primary care: results from an international study.	Psychol Med. 2003 Jul;33(5):857-66.	BACKGROUND: Outcome studies of chronic fatigue, neurasthenia and other unexplained fatigue syndromes are few and have been carried out in developed Western countries. This paper aimed to study the outcome of unexplained fatigue syndromes in an international primary care sample and to identify risk factors for persistence. METHOD: We used data from the WHO collaborative study of psychological problems in general health care, in which 3201 primary care attenders from 14 countries were followed-up for 12 months. The assessment included a modified version of the Composite International Diagnostic Interview. RESULTS: Unexplained fatigue persisted in one-fifth to one-third of the subjects depending on the definition of fatigue. From the factors studied only severity of fatigue and psychiatric morbidity at baseline were associated with persistence 12 months later. Outcome did not differ between countries of different stages of economic development. CONCLUSIONS: The prognosis of fatigue syndromes in international primary care is relatively good. The study underlines the importance of psychological factors in influencing short-term prognosis.
Smirnova IV, Pall ML.	Department of Medicine, Division of Nephrology, New York Medical College, Valhalla, NY, USA.	Elevated levels of protein carbonyls in sera of chronic fatigue syndrome patients.	Mol Cell Biochem. 2003 Jun;248(1-2):93-5.	Protein carbonyl levels, a measure of protein oxidation, were found to be significantly elevated ($p < 0.0005$) in the sera of chronic fatigue syndrome (CFS) patients vs. controls. In contrast, the total protein levels in sera CFS patients were unchanged from those of controls. The elevated protein carbonyl levels confirm earlier reports suggesting that oxidative stress is associated with chronic fatigue syndrome and are consistent with a prediction of the elevated nitric oxide/peroxynitrite theory of chronic fatigue syndrome and related conditions.

Smith MS, Martin-Herz SP, Womack WM, Marsigan JL.	Children's Hospital & Regional Medical Center, Department of Pediatrics, University of Washington, Seattle 98105, USA. mark.smith@seattlechildrens.org	Comparative study of anxiety, depression, somatization, functional disability, and illness attribution in adolescents with chronic fatigue or migraine.	Pediatrics. 2003 Apr;111(4 Pt 1):e376-81.	OBJECTIVE: To compare adolescents with migraine, unexplained profound chronic fatigue of >6 months duration, and normal school controls on measures of anxiety, depression, somatization, functional disability, and illness attribution. METHODS: Adolescents referred to Children's Hospital and Regional Medical Center for behavioral treatment of migraine (n = 179) or evaluation of chronic fatigue (n = 97) were compared with a group of healthy controls of similar age and sex from a middle school (n = 32). Subjects completed the Spielberger State-Trait Anxiety Inventory-Trait Form, the Children's Depression Inventory, the Childhood Somatization Inventory, and estimated the number of school days missed in the past 6 months because of illness. Migraine and fatigued subjects completed an illness attribution questionnaire. RESULTS: Subjects in the 3 groups were 56% to 70% female and ranged from 11 years old to 18 years old with a mean age of 14.0 +/- 2.0. Forty-six of the 97 chronically fatigued adolescents met 1994 Centers for Disease Control and Prevention (CDC) criteria for chronic fatigue syndrome (CDC-CFS), while 51 had idiopathic chronic fatigue syndrome (I-CFS) that did not meet full CDC criteria. Adolescents with migraine had significantly higher anxiety scores than those with I-CFS or controls and higher somatization scores than controls. Adolescents with CDC-CFS had significantly higher anxiety scores than those with I-CFS or controls, and higher depression and somatization scores than all other groups. There were significant differences between all groups for school days missed with CDC-CFS more than I-CFS more than migraine more than controls. Parents of adolescents with unexplained I-CFS had significantly lower attribution scores relating illness to possible psychological or stress factors than parents of adolescents with CDC-CFS or migraine. CONCLUSIONS: Adolescents referred to an academic center for evaluation of unexplained chronic fatigue had greater rates of school absenteeism than adolescents with migraine or healthy controls. Those meeting CDC-CFS criteria had higher anxiety scores than controls and higher depression and somatization scores than migraineurs or controls. Parents of adolescents with I-CFS were less likely to endorse psychological factors as possibly contributing to their symptoms than parents of adolescents with CDC-CFS or migraine.
Smith S, Sullivan K.	University of Queensland, Australia; Karen Sullivan, Queensland University of Technology, Australia, ssmith@psy.uq.edu.a	Examining the influence of biological and psychological factors on cognitive performance in chronic fatigue syndrome: a randomized, double-blind, placebo-controlled, crossover study.	Int J Behav Med. 2003;10(2):162-73.	The pathophysiology of chronic fatigue syndrome (CFS) remains unclear; however, both biological and psychological factors have been implicated in establishing or maintaining this condition. People with CFS report significant and disabling cognitive difficulties such as impaired concentration that in some cases are exacerbated by exposure to chemical triggers. The aim of this study was to determine if neuropsychological deficits in CFS are triggered by exposure to chemicals, or perceptions about the properties of these substances. Participants were 36 people with a primary diagnosis of CFS, defined according to Centers for Disease Control (CDC) criteria. A randomized, double-blind, placebo-controlled, crossover design was used, with objective assessment of neuropsychological function and participant rating of substance type, before and after exposure to placebo or chemical trigger. Results showed decrements in neuropsychological tests scores on three out of four outcome measures when participants rated the substance they had been exposed to as "chemical." No change in performance was found based on actual substance type. These results suggest that cognitive attributions about exposure substances in people with CFS may be associated with worse performance on neuropsychological tasks. In

				addition, these findings suggest that psychological interventions aimed at modifying substance-related cognitions may reduce some symptoms of CFS.
Solomon L, Nisenbaum R, Reyes M, Papanicolaou DA, Reeves WC.	Division of Viral and Rickettsial Diseases, National Center for Infectious Diseases, Centers for Disease Control and Prevention, Atlanta, GA, USA. wcr1@cdc.gov	Functional status of persons with chronic fatigue syndrome in the Wichita, Kansas, population.	Health Qual Life Outcomes. 2003 Oct 3;1(1):48. Epub 2003 Oct 03.	BACKGROUND: Scant research has adequately addressed the impact of chronic fatigue syndrome on patients' daily activities and quality of life. Enumerating specific problems related to quality of life in chronic fatigue syndrome patients can help us to better understand and manage this illness. This study addresses issues of functional status in persons with chronic fatigue syndrome and other fatiguing illnesses in a population based sample, which can be generalized to all persons with chronic fatigue. METHODS: We conducted a random telephone survey in Wichita, Kansas to identify persons with chronic fatigue syndrome and other fatiguing illnesses. Respondents reporting severe fatigue of at least 1 month's duration and randomly selected non-fatigued respondents were asked to participate in a detailed telephone interview. Participants were asked about symptoms, medical and psychiatric illnesses, and about physical, social, and recreational functioning. Those meeting the 1994 chronic fatigue syndrome case definition, as determined on the basis of their telephone responses, were invited for clinical evaluation to confirm a diagnosis of chronic fatigue syndrome. For this analysis, we evaluated unemployment due to fatigue, number of hours per week spent on work, chores, and other activities (currently and prior to the onset of fatigue), and energy level. RESULTS: There was no difference between persons with chronic fatigue syndrome and persons with a chronic fatigue syndrome-like illness that could be explained by a medical or psychiatric condition for any of the outcomes we measured except for unemployment due to fatigue (15% vs. 40%, P <.01). Persons with chronic fatigue syndrome and other fatiguing illnesses had substantially less energy and spent less time on hobbies, schooling, or volunteer work than did non-fatigued controls (P <.01). CONCLUSIONS: Persons with chronic fatigue syndrome are as impaired as persons whose fatigue could be explained by a medical or psychiatric condition, and they have less energy than non-fatigued controls.
Sorensen B, Streib JE, Strand M, Make B, Giclas PC, Fleshner M, Jones JF.	Department of Pediatrics, National Jewish Medical and Research Center, Denver, CO, USA.	Complement activation in a model of chronic fatigue syndrome.	J Allergy Clin Immunol. 2003 Aug;112(2):397-403.	BACKGROUND: A need exists to identify biological markers in chronic fatigue syndrome (CFS). OBJECTIVE: To use an exercise and/or allergen challenge to induce the symptoms of CFS and to identify a biological marker that correlates with these symptoms. METHODS: Patients with CFS (n = 32) and age-matched, normal control patients (n = 29) exercised for 20 minutes on a stationary bike at 70% of their predicted max work load (Watts). Patients from each group with positive skin test results were also challenged with intranasally administered relevant allergens. Symptoms were recorded for 2 weeks before and 1 week after each challenge, using 3 different instruments. Blood samples were taken before, and 0, 1, 6, and 24 hours after challenges. Levels of complement split products, cell-associated cytokines, and eosinophilic cationic protein were measured. Mean preexercise and postexercise symptom scores were evaluated for each group. RESULTS: Exercise challenge induced significant increases of the complement split product C4a, but not C3a or C5a, at 6 hours after exercise only in the CFS group (P <.01), regardless of allergy status. Mean symptom scores were significantly increased after exercise through the use of a daily diary (P <.03) and a weekly diary (P <.01) for the CFS group only. Mean scores for the

				Multidimensional Fatigue Inventory categories "reduced activity" and "mental fatigue" were significantly increased in the CFS group only (P <.04 and P <.02, respectively). CONCLUSIONS: Exercise challenge may be a valuable tool in the development of diagnostic criteria and tests for CFS. Establishment of a role for complement activation products as markers or participants in production of illness require further study.
Stenager EN, Svendsen MA, Stenager E.	Syddansk Universitet, Institut for Sundhedstjenesteforskning, Den Sociale Ankestyrelse, Kobenhavn.	[Disability retirement pension for patients with syndrome diagnoses. A registry study on the basis of data from the Social Appeal Board] [Article in Danish]	Ugeskr Laeger. 2003 Jan 27;165(5):469-74.	INTRODUCTION: Since the early 1990s, disability retirement pension may be granted on the basis of a syndrome diagnosis. Before the pension can be granted, local public authorities collect information on health and social matters and report to The Social Appeal Board. In 1998, a new diagnostic tool was introduced based on the International Statistical Classification of Diseases and Related Health Problems (ICD-10) diagnoses. The information available in The Social Appeal Board has made it possible to study the social consequences of a syndrome diagnosis. The purpose of the study was: 1) To estimate the incidence of patients granted disability retirement pension with the diagnoses whiplash, fibromyalgia, chronic pain disorder, chronic fatigue syndromee, chronic strain syndromee, and pelvic syndromee. 2) To estimate changes in the level of pension granted to patients with syndromee diagnosis. 3) To compare differences between patients with syndromee diagnosis granted disability retirement pension to patients with other diagnoses on the following parameters: sex, civil status, income when applying for pension, and attempts of rehabilitation. 4) To estimate comorbidity of psychiatric diagnosis in patients with syndromee diagnosis. MATERIAL AND METHODS: A register study of data on pension reported to The National Social Appeal Board in the period July 1st 1998 to December 31st, 2000. RESULTS: Of all patients granted pension in the period 8.3 per cent had a syndromee diagnosis, 11 per cent of the women and 5 per cent of the men. Both the relative and the absolute number of patients with syndromee diagnosis granted a pension were increasing. Comorbidity of psychiatric disorders was 3 per cent in the group with syndromee diagnosis. More patients with syndromee diagnosis than with other diagnoses had received sickness benefits and rehabilitation when pension was granted. DISCUSSION: The large number of patients with syndromee diagnosis granted pension calls for multidisciplinary prophylactic and treatment initiatives in order to reduce the number of patients in need of public support. The results are discussed in view of the new Pension's Act which will become effective as from January 1st, 2003.
Stewart CC, Cookfair DL, Hovey KM, Wende KE, Bell DS, Warner CL.	Laboratory of Flow Cytometry, Roswell Park Cancer Institute, Buffalo, New York.	Predictive immunophenotypes: Disease-related profile in chronic fatigue syndrome.	Cytometry. 2003 May;53B(1):26-33.	BACKGROUND: There is a growing body of evidence supporting the theory that problems with immune function play an important role in chronic fatigue syndrome (CFS). METHODS: We studied 90 CFS cases and 50 healthy controls from two different areas of upstate New York to determine whether there were differences in the absolute number and pattern of natural killer (NK) and cytotoxic T-cell phenotypes between CFS cases and healthy controls in the two regions. One group was from a small town where a cluster of cases existed; the other was from a large metropolitan area where there was not a known cluster. RESULTS: The number of CD56+CD3+CD8+ and CD56+CD3+CD8- cells in cases from the two areas were both significantly elevated over that of controls from the metropolitan area (P < 0.03). The number of CD56+CD3-CD8+ and CD56+CD3-CD8- cells was significantly reduced in the two case groups compared to that of controls from the metropolitan area (P = 0.04). However, controls who were from the

				same town as the cluster cases had numbers of CD56+CD3+CD8+, CD56+CD3+CD8-, and CD56+CD3-CD8- cells that were more like that of cases than controls. Only the number of CD56+CD3-CD8+ cells (an NK cell subset) was significantly different in cases versus controls from the cluster area (P = 0.022). CONCLUSIONS: These data suggest that differences in controls from cluster and noncluster areas may be responsible for some of the inconsistencies in results from other studies. Furthermore, they suggest the possibility that NK cell function may play an important role in preventing the development of CFS in individuals who live in a community where a cluster of cases have been identified. Cytometry Part B (Clin. Cytometry) 53B:26-33, 2003. Copyright 2003 Wiley-Liss, Inc.
Sullivan PF, Kovalenko P, York TP, Prescott CA, Kendler KS.	Virginia Institute for Psychiatric and Behavioral Genetics, Virginia Commonwealth University, Richmond, VA 23298-0126, USA.	Fatigue in a community sample of twins.	Psychol Med. 2003 Feb;33(2):263-81. Comment in: Psychol Med. 2003 Feb;33(2):197-201	BACKGROUND: Fatigue is a complex symptom associated with many physiological, psychological and pathological processes. Its correlates and typology remain inadequately understood. METHOD: These data were from two large, longitudinal twin studies. Trained interviewers enquired as to the presence of a > or = 5 day period in the previous year of fatigue or tiredness that interfered with daily activities. A range of potential correlates was assessed in a structured interview: demography; health beliefs; the presence of nine physical disorders; mood, anxiety and addictive disorders; neuroticism and extraversion; recollections of parental rearing; and nine stressful life events. Statistical analyses included logistic regression, CART, MARS, latent class analysis and univariate twin modelling. RESULTS: Data were available for interfering fatigue (IF) on 7740 individual twins (prevalence 9.9% in the previous year). IF was significantly associated with 42 of 52 correlates (most strongly with major depression, generalized anxiety disorder, reported major health problems and neuroticism). Multivariate analyses demonstrated that IF is a highly complex construct with different sets of correlates in its subtypes. There were two broad clusters of correlates of IF: (a) major depression, generalized anxiety disorder and neuroticism; and (b) beliefs of ill health coexisting with alcoholism and stressful life events. Twin analyses were consistent with aetiological heterogeneity--genetic effects may be particularly important in women and shared environmental effects in men. CONCLUSIONS: IF is a complex and common human symptom that is highly heterogeneous. More precise understanding of the determinants of IF may lead to a fuller understanding of more extreme conditions like chronic fatigue syndrome.
Szyndler JE, Towns S, Hoffman RC, Bennett DL.	Department of Adolescent Medicine, Children's Hospital at Westmead, Locked Bag 4001, Westmead NSW 2145, Australia.	Clinical assessment, management and outcomes of a group of adolescents presenting with complex medico-psychosocial conditions.	Ann Acad Med Singapore. 2003 Jan;32(1):51-7.	BACKGROUND: Adolescents with complex medico-psychosocial presentations are often seen as a management challenge. The Medical Family Therapy model provides a useful framework for working with these patients in the context of a multidisciplinary approach to treatment. MATERIALS AND METHODS: A retrospective case analysis of 38 patients referred over a two-year period to the Department of Adolescent Medicine was carried out. These patients met DSM-IV criteria for somatoform disorder or had a diagnosis of chronic fatigue syndrome (CFS). Duration of symptomatology, diagnosis, the presence of psychiatric conditions in the young person and their immediate family and the type and duration of the intervention were examined in relation to outcome. Two case presentations illustrate the complexity of the assessment and treatment process. RESULTS: Clinicians rated 47% of patients who engaged with the service as improved. There was no relationship between diagnosis, length of intervention and outcome. No significant

				differences emerged between the group of young people diagnosed with CFS and those with somatoform disorders in terms of outcome. Nine patients presented with symptoms which were similar or identical to those of one of their parents. Physical illness was more likely to be reported as a precipitating factor in the CFS group. Poor school attendance and psychiatric morbidity were linked to poor outcome. CONCLUSIONS: A comprehensive evaluation of presenting symptomatology and focussed intervention with measurable outcomes are important aspects of the clinical approach to complex medico-psychosocial conditions in adolescents. Families' beliefs about the presenting symptomatology and experiences of illness should be explored.
Tahmaz N, Soutar A, Cherrie JW.	Department of Environmental and Occupational Medicine, University of Aberdeen, Foresterhill Road, Aberdeen AB25 2ZP.	Chronic Fatigue and Organophosphate Pesticides in Sheep Farming: A Retrospective Study Amongst People Reporting to a UK Pharmacovigilance Scheme.	Ann Occup Hyg. 2003 Jun;47(4):261-7.	The Department of Health has recently published a report from the CFS/ME Working Group which concluded that chronic fatigue syndrome (CFS) should be recognized as a chronic illness. Symptoms consistent with CFS are often reported by people who consider their health has been affected by exposure to pesticides, but the Working Group concluded that this type of exposure is not a common trigger for the syndrome. The Veterinary Medicines Directorate (VMD) collects self-assessed reports of ill health in humans associated with veterinary medicines under their Suspected Adverse Reaction Surveillance Scheme. The reporters have mainly been sheep farmers. These reports were used to investigate the possible relationship between chronic fatigue (CF) and exposure to organophosphate pesticides in sheep farming. The overall aim of the study was to investigate a possible association between exposure to organophosphates and the development of CF amongst people who consider their health has been affected by pesticides in sheep farming. The hypothesis investigated was that repeated exposure to organophosphate pesticides in sheep dip may increase the probability of developing CF. A group of mostly sheep farmers who had reported to the VMD surveillance scheme were identified. We planned to use a retrospective case-control study design but the initial symptoms reports were not sufficiently reliable to enable this. The study population was asked to complete two questionnaires. The first questionnaire was designed to identify the history of exposure of subjects to organophosphate pesticides, and their exposure was then reconstructed using a metric specifically developed for this purpose. The second questionnaire collected detailed information to identify whether the subjects had CF when they originally reported to the VMD and at the time of the survey. The questionnaire was sent to a total of 206 subjects, of whom 28 had moved home. A total of 37% of the remaining 178 subjects participated. There was a high prevalence of CF amongst those who completed the questionnaire and this has generally persisted since the subjects reported to the VMD. Higher CF scores were associated with higher exposure to organophosphate pesticides. CF is very common amongst those who consider their health was affected by pesticides and we have shown there is limited evidence of an association between exposure to organophosphates and CF. Further research is needed to investigate the cause of this syndrome amongst farmers exposed to pesticides.
Taillefer SS, Kirmayer LJ, Robbins JM, Lasry JC.	Department of Psychology, Universite de Montreal, Montreal,	Correlates of illness worry in chronic fatigue syndrome.	J Psychosom Res. 2003 Apr;54(4):331-7.	BACKGROUND: Anxiety about illness leading to restriction of activity and physical deconditioning has been hypothesized to contribute to the chronicity of fatigue. Pathological symptom attributions, personality traits, and depression have all been hypothesized to contribute to illness worry. METHODS: We compared 45 chronic fatigue syndrome (CFS) and 40 multiple sclerosis

	Quebec, Canada			(MS) outpatients using a battery of psychometric instruments comprising the 12-item Illness Worry scale, the Symptom Interpretation Questionnaire (SIQ), the NEO Five-Factor Inventory (NEO-FFI), and a modified version of the SCL-90R Depression scale. RESULTS: There was no difference between the two diagnostic groups on neuroticism, depressive symptoms, as well as the three scales of the SIQ. On the illness worry index, the CFS group had significantly higher scores than the MS group. This difference was due to items tapping vulnerability to illness and the perception that others are not taking their illness seriously. Somatic attributional style, neuroticism, depressive symptoms, and age were all significant predictors of illness worry in both CFS and MS patients. CONCLUSIONS: Somatic attributions, neuroticism, and depression all contribute to illness worry in chronic illness. However, these factors do not account for the higher levels of illness worry in CFS as opposed to MS, which may be due to other specific cognitive and social interactional processes.
Tanaka S, Kuratsune H, Hidaka Y, Hakariya Y, Tatsumi KI, Takano T, Kanakura Y, Amino N.	Department of Laboratory Medicine, Osaka University Graduate School of Medicine (D2), Suita-shi, Osaka 565-0871, Japan. tanaka@labo.med.osaka-u.ac.jp	Autoantibodies against muscarinic cholinergic receptor in chronic fatigue syndrome.	Int J Mol Med. 2003 Aug;12(2):225-30.	The disturbance of the central nervous system and immunological abnormalities have been suggested in patients with chronic fatigue syndrome (CFS). We focused on immunological abnormalities against neurotransmitter receptors in CFS. Using a sensitive radioligand assay, we examined serum autoantibodies to recombinant human muscarinic cholinergic receptor 1 (CHRM1), mu-opioid receptor (OPRM1), 5-hydroxytryptamine receptor 1A (HTR1A), and dopamine receptor D2 (DRD2) in patients with CFS (n=60) and results were compared with those in patients with autoimmune disease (n=33) and in healthy controls (n=30). The mean anti-CHRM1 antibody index was significantly higher in patients with CFS ($p<0.0001$) and autoimmune disease ($p<0.05$) than that in healthy controls, and positive reaction was found in 53.3% of patients with CFS. Anti-OPRM1 antibodies, anti-HTR1A antibodies, and anti-DRD2 antibodies were found in 15.2, 1.7, and 5.0% of patients with CFS, respectively. Anti-nuclear antibodies were found in 56.7% (34/60) of patients with CFS, but anti-nuclear antibody titers did not correlate with the activities of the above four autoantibodies. The patients with positive autoantibodies to CHRM1 had a significantly higher mean score (1.81) of 'feeling of muscle weakness' than negative patients (1.18) among CFS patients ($p<0.01$). Higher scores on 'painful node', 'forgetfulness', and 'difficulty thinking' were also found in CFS patients with anti-CHRM1 antibodies but did not reach statistical significance. In conclusion, autoantibodies to CHRM1 were detected in a large number of CFS patients and were related to CFS symptoms. Our findings suggested that subgroups of CFS are associated with autoimmune abnormalities of CHRM1.
Tarello W.	Clinica Veterinaria Airone of Nus, Aosta, Italy. wtarello@yahoo.it	Immunological anomalies and thrombocytopenia in 117 dogs and cats diagnosed with chronic fatigue syndrome (CFS).	Acta Vet Hung. 2003;51(1):61-72.	Retrospective analysis of immune dysfunctions found in 55 dogs and 62 cats diagnosed with Chronic Fatigue Syndrome (CFS), revealed leukopenia in 11% of dogs (n = 6) and 22.5% of cats (n = 14), lymphopenia in 14.5% of dogs (n = 8) and 10% of cats (n = 6), hypogammaglobulinaemia in 9% of dogs (n = 5) and 13% of cats (n = 8) and thrombocytopenia in 20% of dogs (n = 11) and 68% of cats (n = 42). All patients had creatine kinase enzyme levels above the normal range (CK = 5-100 IU/L) and carried micrococcus-like organisms on erythrocytes. Blood cultures proved positive for Staphylococcus spp. in 16 cases. After low-dosage arsenic-based therapy (thiacetarsamide sodium) all animals experienced complete clinical remission. Subsequent controls demonstrated immune restoration in 4 representative FIV-FeLV negative cats, previously diagnosed with CFS

				associated with leukopenia, lymphopenia, hypogammaglobulinaemia and thrombocytopenia. The main conclusion is that a CFS-like disease in dogs and cats, characterised by the common hallmarks of high CK levels, absence of known causes of chronic fatigue in animals and presence of micrococcus-like organisms in the blood, can be associated with humoral and/or cellular immune deficiencies in 9-22.5% of cases and with thrombocytopenia in 20-68% of cases. Considerations are made on the possible role of micrococci in the aetiology of the condition and on the similarities with CFS in humans.
Terr AI.	Department of Medicine, University of California San Francisco Medical School, 450 Sutter Street, #2534, San Francisco, CA 94108, USA. abbaterrmed@attglobal.net	Environmental sensitivity.	Immunol Allergy Clin North Am. 2003 May;23(2):311-28.	The concept of environmental sensitivity is popular among a small group of physicians who believe that exposure to low levels of numerous environmental chemicals can cause a disease with numerous symptoms but no objective physical or laboratory abnormalities. The condition lacks a clear definition. Numerous theories that have been offered to explain the condition encompass immunotoxic, allergic, autoimmune, neurotoxic, cytotoxic, metabolic, behavioral, psychiatric, iatrogenic, and sociologic mechanisms. Environmental sensitivity has many features in common with other controversial syndromes, such as the chronic fatigue syndrome. Patients with environmental sensitivity frequently are subjected to unproven and unnecessary diagnostic tests and therapeutic modalities. In spite of the lack of physical illness and absence of pathology, patients often experience extreme disability, because their symptoms are triggered by common environmental exposures. The phenomenon of environmental sensitivity needs to be evaluated critically using scientifically sound methods. The practice of clinical ecology encompasses the practices of environmental sensitivity and its theories. Most methods of diagnosis and treatment have been disproved, and the concepts underlying these theories are not scientific. Alternative means of diagnosis and management are presented.
The GK, Prins J, Bleijenberg G, van der Meer JW.	University Medical Centre Nijmegen, Department of Internal Medicine, PO Box 9101, 6500 HB Nijmegen, The Netherlands. g.the@aig.umcn.nl	The effect of granisetron, a 5-HT3 receptor antagonist, in the treatment of chronic fatigue syndrome patients--a pilot study.	Neth J Med. 2003 Sep;61(9):285-9.	OBJECTIVE: To explore the effect of granisetron, a 5-HT3 antagonist, on fatigue and functional impairment in patients with chronic fatigue syndrome (CFS). METHODS: Five female patients were eligible to receive oral granisetron for one month (1 mg a day for the first two weeks and 2 mg a day for the second two weeks). The patients had to be between 18 and 65 years of age and suffering from CFS according to the CDC criteria. The effect was assessed by pre- and post-testing, using validated instruments designed to assess the different dimensions of CFS. Treatment response was also evaluated by visual analogue scales (VAS) for fatigue. Analysis was based on intention to treat. RESULTS: Treatment with granisetron resulted in significant improvement in fatigue severity and functional impairment. Activity level showed no significant increase. CONCLUSION: The promising results of this study have encouraged us to perform a placebo-controlled, double-blind study to evaluate the efficacy of 5-HT3 receptor antagonists in the treatment of CFS.
Tiersky LA, Matheis RJ, Deluca J, Lange G, Natelson BH.	Fairleigh Dickinson University, School of Psychology, Williams Hall (T-WH1-01), 1000 River Road, Teaneck, NJ 07666,	Functional status, neuropsychological functioning, and mood in chronic fatigue syndrome (CFS): relationship to	J Nerv Ment Dis. 2003 May;191(5):324-31.	Individuals with chronic fatigue syndrome (CFS) face chronic physical debilitation, reduced neuropsychological functioning, and changes in emotional well-being that significantly detract from quality of life. The role of psychiatric disturbance in reducing quality of life in CFS remains unclear. In the current investigation, the role of psychiatric status in reducing health-related quality of life in CFS was examined. Four subject groups were compared on measures of functional well-being, mood, and neuropsychological status: individuals with CFS and no history

	USA.	psychiatric disorder.		of psychiatric illness, individuals who had current symptoms of psychiatric illness that began after their CFS diagnosis, individuals who had current symptoms of psychiatric illness that began before their CFS diagnosis, and a healthy sedentary control group. Overall, it was found that individuals with CFS suffer from profound physical impairment. Concurrent psychiatric illness, however, did not adversely affect physical functional capacity. Physical functional capacity was not worse in individuals with a concurrent psychiatric illness. As expected, concurrent psychiatric illness was found to reduce emotional well-being. Moreover, individuals with a psychiatric illness that predated the onset of CFS suffered the greatest emotional distress. Thus, an individual's psychiatric history should be considered when attempting to understand the factors maintaining disability in CFS.
Tiev KP, Demettre E, Ercolano P, Bastide L, Lebleu B, Cabane J.	Service de Medecine Interne, Hopital Saint Antoine, 75571 Paris Cedex 12. UMR 5124 CNRS, Universite Montpellier 2, 34293 Montpellier Cedex 5, France.	RNase L Levels in Peripheral Blood Mononuclear Cells: 37-Kilodalton/83-Kilodalton Isoform Ratio Is a Potential Test for Chronic Fatigue Syndrome.	Clin Diagn Lab Immunol. 2003 Mar;10(2):315-6.	Chronic fatigue syndrome (CFS) is a disorder characterized by debilitating fatigue associated with immunological abnormalities. The etiology remains unclear. A low-molecular-mass (37 kDa) isoform of RNase L has been described in peripheral blood mononuclear cell (PBMC) extracts, and the ratio of two isoforms of RNase L (37 kDa/83 kDa) has been proposed as a potential biochemical marker of CFS. In a prospective case-control study, we tested whether the RNase L 37-kDa/83-kDa ratio could discriminate a SFC population. We compared the ratio of RNase L isoforms in PBMCs from 11 patients with CFS (6 women and 5 men; mean age +/- standard deviation, 43.2 +/- 13.8 years) and PBMCs from 14 healthy well-matched volunteers (10 women and 4 men; age, 39.1 +/- 11.6 years). A ratio of RNase L of 0.4 used as a threshold allowed diagnosis of CFS with high sensitivity (91%; 95% confidence interval [CI], 57 to 99%) and specificity (71%; 95% CI, 41 to 90%). The positive and negative prognostic values were 71% (95% CI, 41 to 90%) and 91% (95% CI, 57 to 99%), respectively. In the absence of acute infection or chronic inflammation, a high RNase L ratio could distinguish CFS patients from healthy volunteers. Additional large studies and follow-up studies are required to confirm the stability of this high ratio of RNase L isoforms in a CFS group.
van Gelder T, Smits P.		Pilot studies: one swallow does not make a summer...	Neth J Med. 2003 Sep;61(9):270-2.	What should we expect from pilot studies, done in small series of patients? In the literature there are many examples of small studies with very promising results, that in subsequent larger or better controlled studies proved to be much less promising, or even disastrous. In some instances the initial favourable outcome was due to selection bias. In others the use of nonvalidated methods of measuring outcome made the reproducibility of promising observations problematic. However, we have to start somewhere. In ths issue The et al. report favourable results of granisetron treatment in four out of five patients with chronic fatigue syndrome. A prospective, randomised, placebo-controlled, double-blind clinical trial with granisetron in patients with chronic fatigue syndrome is now ongoing.
Van Hoof E, Cluydts R, De Meirleir K.	Department of Human Physiology, Vrije Universiteit Brussel, Brussel, Belgium	Atypical depression as a secondary symptom in chronic fatigue syndrome.	Med Hypotheses. 2003 Jul;61(1):52-5.	Chronic fatigue syndrome (CFS) has gained prominence since 1988 and a substantial amount of research has been done in this domain. However, it is still regarded as a controversial condition. Moreover, most of the symptoms of CFS itself are non-specific, occurring in many illnesses; some of the symptoms are also common in depression. Indeed, an area of continued controversy and debate involves the diagnostic overlap between CFS and psychiatric disorders. Through anecdotal evidence, atypical depression appears to be common in CFS. Recent developments in

				psychobiology underscore the role of the acute phase response and its associated sickness behavior in affective disorders. Thus, we hypothesize that atypical depression is sickness behavior rather than an affective disorder as shown by anecdotal evidence in CFS.
Van Hoof E, De Meirleir K, Cluydts R, Coomans D		The Symptoms and Psychiatric Status of the Bijlmermeer Plane Crash Disaster: Similarities with Chronic Fatigue Syndrome and Gulf War Syndrome	Journal of Chronic Fatigue Syndrome 2003; 11 (3): 3-23	On October 4, 1992, the El Al Boeing crashed in the residential quarter 'Bijlmermeer' in Amsterdam (The Netherlands). In the years after the plane crash, local residents and assistance personnel began reporting a variety of unusual symptoms not unlike those reported by patients with chronic fatigue syndrome (CFS) and Gulf War Syndrome (GWS). The aim of this study was to define the symptom constellations reported by the patients and assess the possible causes of the illness. Standardized psychological questionnaires (MMPI-II, SCL-90, KPS and a complaints checklist) were used to screen for psychological changes and to describe the symptoms reported by the patients. Differences between local residents and assistance personnel, gender differences, Mycoplasma-infected and Mycoplasma non-infected patients were monitored. The major symptoms reported were extreme fatigue, non-restorative sleep, concentration-problems, memory problems and muscle and joint pains. There were no changes in the SCL-90 responses that indicated any alteration of psychological distress. Assessment using the MMPI-II revealed a profile typically seen in chronic physical illness and assessment of the Harris-Lingoes scales revealed no elevations in pathogenic scales. Twelve subjects (67%) had a positive Mycoplasma PCR response. Victims of the Bijlmermeer plane crash disaster had increases in symptoms similar to patients with Gulf War Syndrome and CFS and no evidence of somatoform disorder, anxiety or depression. Similar to patients with Gulf War Syndrome and CFS, a deregulation of the immune-competence through a combination of toxic material exposure and psychological stressors associated with increased opportunistic infections may be the most likely etiological hypothesis.
Van Hoof, Elke Danny Coomans Pascale De Becker Romain Meeusen Raymond Cluydts Kenny De Meirleir		Hyperbaric Therapy in Chronic Fatigue Syndrome	Journal of Chronic Fatigue Syndrome 2003; 11 (3): 37-51	The aim of this study was to determine if hyperbaric oxygen treatment (HBOT) could be used as adjunctive therapy and if HBOT could increase the quality of life in such a way that the functional status would improve in patients with an infection. A randomized, controlled trial was conducted on 15 Mycoplasma sp. infected CFS (CDC 1994) patients and 14 CFS (CDC 1994) patients with no evidence of a Mycoplasma infection were enrolled in a convenience randomization sample from our referral clinic. No statistical differences were found by use of univariate repeated measures although Bodily Pain as measured by the SF-36 seems to decrease after hyperbaric therapy (Greenhouse-Geisser: p = .010). Trends were found using paired t-testing for Mycoplasma infected CFS patients. The general perceived fatigue seemed to decrease after hyperbaric therapy (General Fatigue: p = .06). Directly after one week of hyperbaric therapy general fatigue improved (p = .03) but there was a reduction of activity (reduced activity: p = .05) and general perceived health (general health: p = .04). One month later the physical role increased (Role-Physical: p = .07). Although more data is required to make firm conclusions, trends were found. Reduced fatigue, increased levels of activity and an improved reaction time improved significantly their quality of life and therefore, enhanced also their functional status and thus could be used as an adjunctive therapy.

van Hout MS, Wekking EM, Berg IJ, Deelman BG.	Medical Spectrum Twente Hospital, Enschede, The Netherlands. MSEvanHout@ziekenhuis-mst.nl	Psychological treatment of patients with chronic toxic encephalopathy: lessons from studies of chronic fatigue and whiplash.	Psychother Psychosom. 2003 Sep-Oct;72(5):235-44.	BACKGROUND: Chronic toxic encephalopathy (CTE), which can result from long-term exposure to organic solvents, is characterized by problems of attention and memory, fatigue and affective symptoms. There is little experience with (neuro)psychological treatment in this patient group. We reviewed treatment outcome studies of CTE and comparable syndromes, namely, chronic whiplash-associated disorder (WAD) and chronic fatigue syndrome (CFS), with a view to providing recommendations for the psychological treatment of patients with CTE. METHODS: PubMed and PsychLIT were systematically searched and reference lists of retrieved articles were studied. The articles were classified according to study design and level of evidence. RESULTS: The studies of CFS provided high-level evidence for the effectiveness of cognitive-behavior therapy (CBT) in challenging dysfunctional cognitions regarding the effectiveness of rest and in stimulating graded activity. The studies of WAD were methodologically weaker, and most evaluated a combination of CBT and graded activity training. There was some evidence that changing fatigue- or pain-related behaviors may result in cognitive improvement. Two uncontrolled studies of CTE evaluated cognitive rehabilitation techniques but yielded inconsistent findings. CONCLUSIONS: CBT techniques focusing on changing illness attributions and on stimulating graded activity might be useful for patients with CTE, diminishing fatigue-related problems of concentration and memory. Future studies should evaluate whether cognitive deficits of CTE patients as a result of neurotoxic effects of exposure should be treated by cognitive rehabilitation. Copyright 2003 S. Karger AG, Basel
Vanness JM, Snell CR, Strayer DR, Dempsey L 4th, Stevens SR.	University of the Pacific, Department of Sport Sciences, Stockton, CA 95211, USA. mvanness@uop.edu	Subclassifying chronic fatigue syndrome through exercise testing.	Med Sci Sports Exerc. 2003 Jun;35(6):908-13.	PURPOSE: The purpose of this study was to examine physiological responses of persons with chronic fatigue syndrome (CFS) to a graded exercise test. METHODS: Cardiopulmonary exercise tests were performed on 189 patients diagnosed with CFS. Based on values for peak oxygen consumption, patients were assigned to one of four impairment categories (none, mild, moderate, and severe), using American Medical Association (AMA) guidelines. A one-way MANOVA was used to determine differences between impairment categories for the dependent variables of age, body mass index, percentage of predicted [OV0312]O(2), resting and peak heart rates, resting and peak systolic blood pressure, respiratory quotient (RQ), and rating of perceived exertion. RESULTS: Significant differences were found between each impairment level for percentage of predicted [OV0312]O(2) and peak heart rate. Peak systolic blood pressure values for the "moderate," and "severe" groups differed significantly from each other and both other

				groups. The more impaired groups had lower values. The no impairment group had a significantly higher peak RQ than each of the other impairment levels (all P < 0.001). Peak [OV0312]O(2) values were less than predicted for all groups. Compared with the males, the women achieved actual values for peak [OV0312]O(2) that were closer to their predicted values. CONCLUSION: Despite a common diagnosis, the functional capacity of CFS patients varies greatly. Stratifying patients by function allows for a more meaningful interpretation of the responses to exercise and may enable differential diagnosis between subsets of CFS patients.
Vecchiet J, Cipollone F, Falasca K, Mezzetti A, Pizzigallo E, Bucciarelli T, De Laurentis S, Affaitati G, De Cesare D, Giamberardino MA.	Department of Medicine and Science of Aging, G. D'Annunzio University of Chieti, Italy.	Relationship between musculoskeletal symptoms and blood markers of oxidative stress in patients with chronic fatigue syndrome.	Neurosci Lett. 2003 Jan 2;335(3):151-4.	In 21 patients with chronic fatigue syndrome (CFS) versus 20 normal subjects, we investigated the oxidant/antioxidant balance and its correlation with muscle symptoms. Patients versus controls showed significantly: lower Lag Phase and Vitamin E (Vit E) concentrations in plasma and low-density lipoproteins (LDL), higher LDL thiobarbituric acid reactive substances (TBARS), higher fatigue and lower muscle pain thresholds to electrical stimulation. A significant direct linear correlation was found between fatigue and TBARS, thresholds and Lag Phase, thresholds and Vit E in plasma and LDL. A significant inverse linear correlation was found between fatigue and Lag Phase, fatigue and Vit E, thresholds and TBARS. Increased oxidative stress and decreased antioxidant defenses are related to the extent of symptomatology in CFS, suggesting that antioxidant supplementation might relieve muscle symptoms in the syndrome.
Velanovich V.	Division of General Surgery, Henry Ford Hospital, Detroit, Michigan 48202-2689, USA. vvelanol@hfhs.org	The effect of chronic pain syndromes and psychoemotional disorders on symptomatic and quality-of-life outcomes of antireflux surgery.	J Gastrointest Surg. 2003 Jan;7(1):53-8.	Psychoemotional disorders (PED) and chronic pain syndromes (CPS) are common problems. Many patients with these disorders also suffer from gastroesophageal reflux disease (GERD). It is unclear how PED/CPS affect outcomes of antireflux surgery; therefore, the purpose of this study was to determine if PED/CPS adversely affects the results of surgical therapy for GERD. All patients referred for surgical therapy for GERD completed both the GERD-HRQL symptom severity instrument and the SF-36 generic quality-of-life instrument prior to surgery. To be candidates for surgery, patients must have symptomatic GERD and objective evidence of pathologic reflux by upper endoscopy, esophageal manometry and 24-hour pH monitoring. Patients underwent either laparoscopic or open Nissen or Toupet fundoplication. Six to 24 months postoperatively, patients were evaluated for satisfaction and quality-of-life. Ninety-three percent of control patients compared to 25% of PED/CPS patients were satisfied with surgery (P < 0.001). Dissatisfaction in PED/CPS patients was generally due to persistent or new somatic complaints. Median total GERD-HRQL scores improved for both groups, although postoperative scores were worse in the PED/CPS group. PED/CPS patients had significantly worse SF-36 scores both preoperatively and postoperatively compared to control patients. SF-36 scores improved in four of eight domains in control patients and none in the PED/CPS patients. In conclusion, PED/CPS patients are generally dissatisfied with antireflux surgery. Although some patients do benefit from surgery, careful patient selection is required. Copyright 2003 The Society for Surgery of the Alimentary Tract, Inc.
Vermeulen RC, Scholte HR.	Chronic Pain and Fatigue Research Centre, Waalstraat 25, 1078 BR	Rupture of silicone gel breast implants and symptoms of pain and fatigue.	J Rheumatol. 2003 Oct;30(10):2263-7.	OBJECTIVE: To compare symptoms of women with silicone gel breast implants and women with chronic fatigue syndrome (CFS), and to study the effect of rupture of the silicone implant. METHODS: Five hundred readers of the Dutch silicone breast implant support group magazine were asked to respond if they had been informed by the surgeon about the silicone implant

	Amsterdam, The Netherlands. rcwvermeulen@cfsccentrumamsterdam.nl			status at operation, and to answer questions about symptoms of CFS. Their complaints were compared with those of 100 female patients with CFS and 40 female controls. RESULTS: The questionnaires were returned by 319 women. Of these, 227 had symptoms of debilitating chronic fatigue. The patterns of symptoms differed from those in patients with CFS. An analysis of the relation between integrity of the implants and the symptoms could be carried out in 176 women, and 74% of these latter women reported ruptured implants. Significantly more women with ruptured implants than those with intact implants had debilitating chronic fatigue (75% vs 51%), postexertional malaise > 24 h (77% vs 51%), impaired short term memory (58% vs 38%), and multi-joint pain (77% vs 60%). CONCLUSION: Women with silicone breast implants often report severe pain and chronic fatigue. Rupture of the implant is associated with an increase in symptoms of pain and chronic fatigue.

Watson NF, Kapur V, Arguelles LM, Goldberg J, Schmidt DF, Armitage R, Buchwald D.	Department of Neurology and Sleep Disorders Center, University of Washington, Seattle 98104-2499, USA. nwatson@u.washington.edu	Comparison of subjective and objective measures of insomnia in monozygotic twins discordant for chronic fatigue syndrome.	Sleep. 2003 May 1;26(3):324-8.	STUDY OBJECTIVES: To examine the objective and subjective measures of insomnia in chronic fatigue syndrome (CFS). DESIGN: Monozygotic co-twin control study. SETTING: Academic medical center. PATIENTS OR PARTICIPANTS: Twenty-two pairs of monozygotic twins where 1 member of the pair had CFS and the other did not. INTERVENTIONS: N/A. MEASUREMENTS AND RESULTS: Twenty-two CFS-discordant twin pairs completed a Sleep Disorders Questionnaire, overnight polysomnography, and a postpolysomnography sleep survey. Mean and percent differences in the sleep measures were compared between the CFS and healthy twins using matched-pair methods of analysis. Compared with their healthy co-twins, the CFS twins more frequently endorsed 8 subjective measures of insomnia and poor sleep (all p < or = 0.05). However, the CFS and healthy twins did not differ in objective polysomnographic measures of insomnia, including sleep latency, total sleep time, sleep efficiency, arousal number, arousal index, hypnogram

				awakenings, rapid eye movement (REM)-sleep latency, and percent stages 1, 2, and 3-4 (delta). Percent stage REM sleep was increased in the CFS twins compared with the healthy twins (27.7% vs. 24.4%, p < or = 0.05). On the postpolysomnography survey, CFS twins reported that they had slept fewer hours (6.2 vs. 6.7; p < or = 0.05), and were less well rested (p < or = 0.001) compared to their co-twins. CONCLUSIONS: CFS patients had worse subjective sleep than their co-twins despite little objective data supporting this discrepancy, suggesting they suffer from an element of sleep-state misperception. The higher percentage of REM sleep in the CFS twins implies that REM sleep may play a role in this illness.
Weinbacher BS.		[Persistent fatigue despite sufficient sleep] [Article in German]	Schweiz Rundsch Med Prax. 2003 Feb 19;92(8):356-9.	Medizinische Universitatspoliklinik, Departement Innere Medizin, Kantonsspital Basel.
Westropp JL, Welk KA, Buffington CA.	Department of Veterinary Clinical Sciences, College of Veterinary Medicine, Ohio State University, Columbus 43210-1089, USA.	Small adrenal glands in cats with feline interstitial cystitis.	J Urol. 2003 Dec;170(6 Pt 1):2494-7.	PURPOSE: We documented the uncoupling of sympathetic nervous system activity from the hypothalamic-pituitary-adrenal axis in cats with feline interstitial cystitis (FIC). Altered hypothalamic-pituitary-adrenal activity was recently suggested in some humans with interstitial cystitis (IC) but to our knowledge no information exists on adrenal gland size and histopathology in this disease. To investigate further adrenal function in cats with FIC we determined cortisol responses to 125 microg synthetic adrenocorticotropic hormone (ACTH) as well as adrenal size and histology. MATERIALS AND METHODS: ACTH stimulation studies were performed in 11 healthy cats and 20 with FIC. Adrenal glands obtained at autopsy in 8 healthy cats and 13 with FIC were weighed, measured and examined histologically. RESULTS: Cats with FIC had significantly decreased responses to ACTH (2-way repeated measures ANOVA p <0.05). Mean weight +/- SD (58 +/- 50 vs 241 +/- 60 mg) and volume (264 +/- 72 vs 410 +/- 115 mm3) of adrenal glands were significantly smaller in cats with FIC than in healthy cats (p <0.05). CONCLUSIONS: These results suggest that cats with FIC may have mild primary adrenal insufficiency. Decreased adrenal size has been observed in patients with chronic fatigue syndrome, which can be a co-morbid condition in some patients with IC. If these abnormalities are confirmed in humans with IC, hormone replacement therapy may be indicated in select patients.
Whistler T, Unger ER, Nisenbaum R, Vernon SD.	Viral Exanthems and Herpes Virus Branch, Division of Viral and Rickettsial Diseases, National Centre for Infectious Diseases, Centres for Disease Control and Prevention, 1600 Clifton Rd, Atlanta, Georgia. sdv2@cdc.gov	Integration of gene expression, clinical, and epidemiologic data to characterize Chronic Fatigue Syndrome.	J Transl Med. 2003 Dec 1;1(1):10. Epub 2003 Dec 01.	BACKGROUND: Chronic fatigue syndrome (CFS) has no diagnostic clinical signs or diagnostic laboratory abnormalities and it is unclear if it represents a single illness. The CFS research case definition recommends stratifying subjects by co-morbid conditions, fatigue level and duration, or functional impairment. But to date, this analysis approach has not yielded any further insight into CFS pathogenesis. This study used the integration of peripheral blood gene expression results with epidemiologic and clinical data to determine whether CFS is a single or heterogeneous illness. RESULTS: CFS subjects were grouped by several clinical and epidemiological variables thought to be important in defining the illness. Statistical tests and cluster analysis were used to distinguish CFS subjects and identify differentially expressed genes. These genes were identified only when CFS subjects were grouped according to illness onset and the majority of genes were involved in pathways of purine and pyrimidine metabolism, glycolysis, oxidative phosphorylation, and glucose metabolism. CONCLUSION: These results provide a

				physiologic basis that suggests CFS is a heterogeneous illness. The differentially expressed genes imply fundamental metabolic perturbations that will be further investigated and illustrates the power of microarray technology for furthering our understanding CFS.

Whitehead J, Matsushita T.	Medical and Pharmaceutical Statistics Research Unit, The University of Reading, Reading, UK. j.r.whitehead@reading.ac.uk	Stopping clinical trials because of treatment ineffectiveness: a comparison of a futility design with a method of stochastic curtailment.	Stat Med. 2003 Mar 15;22(5):677-87.	This paper introduces a simple futility design that allows a comparative clinical trial to be stopped due to lack of effect at any of a series of planned interim analyses. Stopping due to apparent benefit is not permitted. The design is for use when any positive claim should be based on the maximum sample size, for example to allow subgroup analyses or the evaluation of safety or secondary efficacy responses. A final frequentist analysis can be performed that is valid for the type of design employed. Here the design is described and its properties are presented. Its advantages and disadvantages relative to the use of stochastic curtailment are discussed. Copyright 2003 John Wiley & Sons, Ltd.
Wiesmuller GA, Ebel H, Hornberg C, Kwan O, Friel J.	Institute of Hygiene and Environmental Medicine, University Hospital Aachen, Aachen, Germany.	Are syndromes in environmental medicine variants of somatoform disorders?	Med Hypotheses. 2003 Oct;61(4):419-30.	To date, relatively little is known about the etiology, pathophysiology, diagnosis, therapy, prevention and prognosis of environment-related syndromes like multiple chemical sensitivity (MCS), idiopathic environmental intolerance (IEI), sick building syndrome (SBS), chronic fatigue syndrome (CFS), candida syndrome (CS) and burnout syndrome (BS). Part of the reason is that these syndromes have not been clearly defined and classified in scientific categories distinct from each other, and that they show clinical similarities to classified somatoform disorders. Furthermore, there are at least three possible explanations for the existence of these syndromes: (1) The syndromes may result from the interaction of environmental factors, individual susceptibility and psychological factors (i.e., how they are perceived and seen by the patient); (2) they may reflect socially and culturally accepted methods of expressing distress; and/or (3) they may be iatrogenic. Despite all the uncertainties in evaluation of environmental syndromes, physicians have the duty to take the affected person's problems seriously. A comprehensive systematic classification which better accounts for these complex clinical manifestations is long overdue. Until these syndromes are well defined, the terms used for them should definitely not be applied to connote a specific disease process.
Yamamoto Y, LaManca JJ, Natelson BH.	Department of Neurosciences, New Jersey Medical	A measure of heart rate variability is sensitive to	Exp Biol Med (Maywood). 2003 Feb;228(2):167-74.	The use of symptoms generated by head up tilt (HUT) is not a useful tool in identifying chronic fatigue syndrome (CFS). We investigated whether heart rate variability (HRV) assessed early during HUT might be useful. A sample of 46 female subjects (24 with CFS and 22 sedentary, age-

	School, East Orange, New Jersey 07018-1095, USA.	orthostatic challenge in women with chronic fatigue syndrome.		matched healthy controls; CON) who had exhibited no difference in time to syncope during tilt was examined for HRV responses to 10 min of 70 degrees HUT after 5 min of baseline in the supine position. HRV data were analyzed by the method of coarse graining spectral analysis. Variables compared between groups included mean and standard deviation (SD(RRI)) of RR intervals (RRI), amplitudes of low- (A(LF); 0.04-0.15 Hz) and high-frequency (A(HF); >0.15 Hz) harmonic as well as aperiodic, fractal (A(FR); 1/f(beta)) spectral components, the spectral exponent beta, and the difference in these values between baseline and HUT for each subject. In the supine baseline, only mean RRI was significantly ($P < 0.01$) lower in CFS than in CON. During HUT, however, mean RRI ($P < 0.01$), SD(RRI) ($P < 0.01$), A(HF) ($P < 0.05$), and A(FR) ($P < 0.01$) were significantly lower in CFS than in CON. When the difference in values between baseline and HUT for each subject was examined, only the difference for A(FR) (deltaA(FR)) was significantly ($P < 0.01$) lower in CFS than in CON, suggesting that A(FR)is a disease-specific response of HRV to HUT. When a cut-off level was set to deltaA(FR) = -2.7 msec, the sensitivity and the specificity in differentiating CFS from controls were 90% and 72%, respectively. The data suggest that a decrease in aperiodic fractal component of HRV in response to HUT can be used to differentiate patients with CFS from CON.
Zavestoski S, Brown P, McCormick S, Mayer B, D'Ottavi M, Lucove JC.	Department of Sociology, University of San Francisco, 2130 Fulton Street, 94117-1080, San Francisco, CA, USA	Patient activism and the struggle for diagnosis: Gulf War illnesses and other medically unexplained physical symptoms in the US.	Soc Sci Med. 2004 Jan;58(1):161-75.	We examine Gulf War illnesses-which include the fatigue, joint pain, dermatitis, headaches, memory loss, blurred vision, diarrhea, and other symptoms reported by Gulf War veterans-in relation to other medically unexplained physical symptoms such as multiple chemical sensitivity, chronic fatigue syndrome, and fibromyalgia. Our intent is to examine the diagnosis negotiations involved in these mysterious diseases, by showing the different forms of legitimacy involved in such interactions. Factors involved in diagnostic legitimacy are: diagnostic legitimacy in the medical community, lay acceptance of the diagnosis, uncertainty in looking for causes, and social mobilization. We conclude by noting that research may not be able to find any cause for these diseases/conditions; hence, it may be necessary to embrace medical uncertainty, and also to accept patient experience in order to facilitate diagnosis, treatment, and recovery process. Such a change can alter patients' expectations and taken-for-granted assumptions about medicine, and perhaps in turn reduce the frequency with which dissatisfied individuals form illness groups that mobilize to challenge what they see as an unresponsive medical system.
[No authors listed]		[Article in Russian]	Vestn Oftalmol. 2003 Mar-Apr;119(2):45-7.	218 patients were examined and the chronic fatigue syndrome (CFS) was diagnosed in them on the basis of clinical-and-immunologic data. 126 somatically healthy persons of the same age and sex were in the control group. Vascular pathology of the vision organ was found in 153 (70.2%) persons, and dystrophic pathology was found in 115 (52.8%) persons. A combination of vascular and dystrophic pathologies of the vision organ was diagnosed in 46 (21.1%) patients. The detection of vision pathology in the CFS patients essentially exceeded the morbidity of similar pathology in the controls. No reliable differences of refraction anomalies were found between the CFS patients and the controls.

Department of Oral Medicine, University of Washington, Seattle, Washington 98195, USA. laaron@u.washington.edu	Health and functional status of twins with chronic regional and widespread pain.	J Rheumatol. 2002 Nov;29(11):2426-34. Erratum in: J Rheumatol. 2002 Dec;29(12):2667. Buchwald Dedra [corrected to Buchwald Debra]	OBJECTIVE: To examine the independent effects of chronic regional and widespread pain syndromes on health and functional status after accounting for comorbid chronic fatigue using a co-twin control design. METHODS: We identified 95 twin pairs discordant for pain in which one twin had chronic regional or widespread pain and the other denied chronic pain. Demographic data, functional and psychological status, health behaviors, and symptoms based on the 1994 criteria for chronic fatigue syndrome (CFS) were assessed by questionnaire. Psychiatric diagnoses were based on structured interview. Random effects regression modeling estimated associations between chronic regional and widespread pain and each health measure with and without adjustment for CFS. RESULTS: Significant differences ($p </= 0.05$) were found within twin pairs discordant for chronic regional and widespread pain, for general health perception, and physical and mental health functioning as measured by summary scores from the Short Form-36. In addition, differences were observed within pain discordant pairs in psychological distress as measured by the General Health Questionnaire as well as the number of psychiatric diagnoses. Adjustment for CFS eliminated the association between chronic pain and mental health, but the association between chronic pain and poor general health, physical functioning, and sleep quality persisted ($p </= 0.01$). Only the intra-pair difference in physical functioning distinguished twins with regional vs widespread pain ($p </= 0.05$). CONCLUSION: Both chronic regional and widespread pain exact debilitating effects on perceived general health, physical functioning, and sleep quality independent of CFS. However, the psychological and psychiatric influence of chronic pain appears closely tied to CFS. Research should examine the additive role of CFS-like illnesses in patients with chronic pain, and its influence on treatment and outcome.

Heberden Rehabilitation Unit,	Characteristics of patients with	J Neurol Neurosurg Psychiatry. 2002	This study audited 25 patients (21 female) from Oxfordshire who had been referred to either the liaison psychiatry or the neurological disability service between 1992 and 1998, reported a

	Amersham Hospital, Amersham, Buckinghamshire HP7 0JD, UK. allanson@doctors.org.uk	persistent severe disability and medically unexplained neurological symptoms: a pilot study.	Sep;73(3):307-9.	Barthel activities of daily living index score < 20 or a global assessment of functioning score of < or = 30, and had no pathology to explain their neurological disability. Levels of motor impairment, disability, mood, and cognitive status were assessed using standardised scales, and all patients were assigned a psychiatric diagnosis according to the International classification of diseases, 10th revision. Of the 25 patients, 13 had a motor conversion disorder, 8 had diverse somatoform disorders, and 3 had chronic fatigue syndrome. Nine had extensive previous contact with psychiatric services and 11 had experienced physical or sexual abuse. In 6 patients cessation of repeated self harm was closely associated with the onset of wheelchair use. Seven were receiving treatment for depression. The commonest putative diagnoses were multiple sclerosis (6) and epilepsy (5). Twelve were unable to walk and 20 owned a wheelchair but only 3 had formal care packages. The mean (SD) Barthel score was 14.1 (3.3) and the mean (SD) Frenchay activity index score was 12.9 (7.5). All were unemployed and receiving a disability living allowance, and some had benefits of up to pound 1815 a month. This small but significant group of disabled patients had a variety of psychiatric and neurological diagnoses and used considerable health care resources.
Anderson LS, Beverly WT, Corey LA, Murrelle L.	Virginia Institute for Psychiatric and Behavioral Genetics, Department of Human Genetics, Virginia Commonwealth University, Richmond, VA 23298-0003, USA. lsanders@hsc.vcu.edu	The Mid-Atlantic Twin Registry.	Twin Res. 2002 Oct;5(5):449-55.	The Mid-Atlantic Twin Registry (MATR) is a population-based registry of twin pairs ascertained from birth records and school system records of Virginia, North Carolina, and South Carolina. The MATR was formed in 1997 with the merging of the Virginia and North Carolina Twin Registries, and it expanded to include South Carolina when access to twin birth records in that state was granted in 1998. Registered twins ("participants") number more than 51,000, with approximately 46,000 of these individuals representing complete pairs. Roughly two-thirds of MATR participants are over age 18, with a mean age of approximately 35 years. These participants have primarily been drawn from the more than 170,000 identical and fraternal twin pairs born in the three states between 1913 and 2000. Twins and their family members have participated in numerous research projects, ranging from general health surveys to studies on specific health topics such as cardiovascular disease; depression and anxiety; seizures; behavioral development; pregnancy complications; conduct disorder; drug use, abuse, and dependence; cleft lip/palate; obesity; and chronic fatigue syndrome. The MATR has established a privacy policy and strict standard operating procedures to protect the confidentiality of participant data. The MATR considers a limited number of qualified requests per year from investigators interested in recruiting MATR participants into their research studies.

Arnold MC, Papanicolaou DA, O'Grady JA, Lotsikas A, Dale JK, Straus SE, Grafman J.	National Institute of Neurological Disorders and Stroke, National Institute of Child Health and Human Development and National Institute of Allergy and Infectious Diseases, National Institutes of Health, Bethesda, Maryland 20892-1440, USA.	Using an interleukin-6 challenge to evaluate neuropsychological performance in chronic fatigue syndrome.	Psychol Med. 2002 Aug;32(6):1075-89.	BACKGROUND: Individuals with acute infections experience a range of symptoms including fatigue, malaise, muscle aches, and difficulties with concentration and memory that are usually self-limited. This cluster of symptoms is otherwise, similar to those that characterize chronic fatigue syndrome (CFS). The goal of the present study was to evaluate the cognitive and psychological functioning of CFS patients and normal controls (NCs) when they both were experiencing acute influenza-like symptoms. To induce influenza-like symptoms, we administered interleukin-6 (IL-6), a cytokine that temporarily activates the acute phase immunological and endocrine responses. METHODS: Nineteen patients who met the 1994 International CFS Study Group Criteria and ten normal controls (NCs) completed routine clinical evaluations, neuropsychological tests of short-term memory, selective attention, and executive control, and self-ratings of somatic symptoms and psychological mood before, shortly following, and 1 day after IL-6 administration. RESULTS: CFS patients consistently reported more somatic symptoms, even when both groups perceived that they were ill. Both groups somatic symptoms increased during the IL-6 challenge, but the CFS patients symptoms increased more rapidly than controls. In general, the CFS patients performed similarly to NCs on the cognitive measures before, during, and after the IL-6. In contrast to predictions, IL-6 provocation did not impair the cognitive performance of either CFS patients or NCs. CONCLUSIONS: The IL-6 provocation exacerbated the patients self-reported symptoms but did not reveal notable cognitive impairments between patients and controls during cytokine-induced acute influenza-like symptoms.
Asbring P, Narvanen AL.	Centre for Development of Health Services, Department of Public Health Sciences at Karolinska Institutet in Stockholm, Sweden.	Women's experiences of stigma in relation to chronic fatigue syndrome and fibromyalgia.	Qual Health Res. 2002 Feb;12(2):148-60. Comment in: Evid Based Ment Health. 2002 Nov;5(4):127.	Chronic fatigue syndrome and fibromyalgia are characterized by being difficult to diagnose and having an elusive etiology and no clear-cut treatment strategy. The question of whether these illnesses are stigmatizing was investigated through interviews with 25 women with these illnesses. The women experienced stigmatization primarily before receiving a diagnosis, and the diffuse symptomatology associated with the illnesses were significant for stigmatization. Stigma consisted of questioning the veracity, morality, and accuracy of patient symptom descriptions and of psychologizing symptoms. Coping with stigma was also explored and found to comprise both withdrawal and approach strategies, depending on the individual's circumstances and goals.
Ax S, Gregg VH, Jones D.	School of Health, Liverpool John Moores University, 79 Tithebarn Street, Liverpool L2 2ER,	Caring for a relative with chronic fatigue syndrome: difficulties, cognition and acceptance over	J R Soc Health. 2002 Mar;122(1):35-42.	The present study explored the difficulties experienced by carers of chronic fatigue syndrome (CFS) sufferers, their cognitions, and their efforts to accept the illness. Semi-structured interviews were conducted with 17 carers to study these issues, retrospectively, over three stages: before the diagnosis of CFS, shortly after the diagnosis, and at present. Surprisingly, the results suggested that carers, several of them absent from home during the day, felt that their lives were

	England. heasax@yahoo.com	time.		only minimally constrained by the illness. Nevertheless, all carers reported specific coping efforts to manage both the illness and their own distress, and indicated that they learned to accept the illness over time. However, acceptance appeared to be a form of resignation rather than a positive appreciation of the illness. In light of the uncertainties surrounding the origin of CFS and carers' apparent confusion, the results obtained in the present study are significant in that they increase our understanding of CFS carers' quality of life, their efforts to cope with the illness, and the physical and emotional help they may provide to the sufferer. Such information can be usefully employed in the increasing development of counselling interventions and instrumental support networks that involve both sufferers and their carers.
Ayres JG, Wildman M, Groves J, Ment J, Smith EG, Beattie JM.	Department of Respiratory Medicine, Birmingham Heartlands Hospital, Birmingham, UK. ayresj@heartsol.wmids.nhs.uk	Long-term follow-up of patients from the 1989 Q fever outbreak: no evidence of excess cardiac disease in those with fatigue.	QJM. 2002 Aug;95(8):539-46. Comment in: QJM. 2002 Aug;95(8):491-2.	BACKGROUND: In 1989, an outbreak of Q fever (C. burnetii infection) with 147 confirmed cases occurred in Solihull, West Midlands. Three patients developed cardiomyopathy in the subsequent 10 years. The cohort has been followed up with respect to the development of fatigue and, in this instance, cardiac effects after the original infection. AIM: To determine whether persisting fatigue after Q fever represented sub-clinical cardiomyopathy. DESIGN: Prospective follow-up study. METHODS: All traceable subjects from the original outbreak, and community age-, sex- and smoking-matched controls, were studied. Questionnaires for idiopathic fatigue, 12-lead ECG, echocardiography, spirometry and shuttle walk distance were undertaken, and a subset with CDC-defined chronic fatigue syndrome had gated cardiac scans. RESULTS: Of the original cohort, 19 had died, three had emigrated and 10 were untraceable. Of the remaining 115, 108 responded to a mailed questionnaire and 87 were investigated further, of whom 85 provided complete data. Two developed aortic valve vegetations, one of whom died. Chronic fatigue syndrome was found in 20% of cases and 5.3% of controls (including those with co-morbidities), falling to 8.2% and 0 when excluding those with co-morbidities. There were no significant differences in ECG and echocardiographic investigations or shuttle-walk distance between those with fatigue and those without. Six of the seven patients with CFS had gated cardiac scans: all were within normal limits. CONCLUSIONS: These findings do not support the existence of a sub-clinical cardiomyopathy in the patients in this cohort who suffer from fatigue after acute Q fever, although endocarditis can occur after acute infection.

Joint hypermobility is more common in children with chronic fatigue syndrome than in healthy controls.	J Pediatr. 2002 Sep;141(3):421-5.	OBJECTIVE: To determine whether children with chronic fatigue syndrome (CFS) have a higher prevalence of joint hypermobility than gender-matched controls.Study design: Matched case-control study comparing the Beighton joint hypermobility scores in 58 consecutive children with CFS (incident cases) with 58 otherwise healthy controls referred to a dermatology clinic for evaluation of common skin problems. A second group of 58 patients previously diagnosed with CFS (prevalent cases) was matched by gender to the incident cases to evaluate temporal changes in referral patterns. RESULTS: Of the 58 patients in each group, 71% were female. The median Beighton scores were higher in incident CFS cases than in healthy controls (4 vs 1, P <.001). More incident CFS cases had Beighton scores >/=4 (consistent with joint hypermobility), 60% versus 24%, P <.0001. Incident and prevalent CFS cases had similar Beighton scores. The odds ratio for hypermobility in all patients with CFS versus healthy controls was 3.5 (P <.001; 95% CI, 1.6-7.5). CONCLUSIONS: Joint hypermobility is more common in patients with CFS than in otherwise healthy children with common skin disorders. The etiologic significance of the observed association remains to be defined.

Beck-Friis J.	j.beck-friis@telia.com	[Diagnosis of depressive disorder and so-called exhaustion	Lakartidningen. 2002 Feb 7;99(6):512-7.	Depressive disorders can be recognized by the loss of self-esteem; this contrasts with mourning and neurasthenic reactions, in which self-esteem remains intact. Just as depression can result from the gradual reduction and eventual loss of self-esteem, mourning and neurasthenic reactions can evolve into true depressive states. "Exhaustion depression", a new diagnostic

		depression. Self-esteem--a central concept] [Article in Swedish]		category connected to "burnout" situations, should be applied only when criteria for depressive disorder are fulfilled, including loss of self-esteem. When these criteria are lacking we should refer only to an exhaustion state provoked by stress. Neurotic mechanisms may represent a special class of relevant stress factors, but are not seen in manifest neurasthenic reactions and exhaustion depression.
Bentall RP, Powell P, Nye FJ, Edwards RH.	Department of Psychology, University of Manchester, Coupland I Building, Oxford Road, Manchester M13 9PL, UK.	Predictors of response to treatment for chronic fatigue syndrome.	Br J Psychiatry. 2002 Sep;181:248-52.	BACKGROUND: Controlled trials have shown that psychological interventions designed to encourage graded exercise can facilitate recovery from chronic fatigue syndrome. AIMS: To identify predictors of response to psychological treatment for chronic fatigue syndrome. METHOD: Of 114 patients assigned to equally effective treatment conditions in a randomised, controlled trial, 95 completed follow-up assessments. Relationships between variables measured prior to randomisation and changes in physical functioning and subjective handicap at 1 year were evaluated by multiple regression. RESULTS: Poor outcome was predicted by membership of a self-help group, being in receipt of sickness benefit at the start of treatment, and dysphoria as measured by the Hospital Anxiety and Depression scale. Severity of symptoms and duration of illness were not predictors of response. CONCLUSIONS: Poor outcome in the psychological treatment of chronic fatigue syndrome is predicted by variables that indicate resistance to accepting the therapeutic rationale, poor motivation to treatment adherence or secondary gains from illness.
Berner I, Gaubitz M, Jackisch C, Pfleiderer B.	Institute for Clinical Radiology, Universitat Munster, Albert-Schweitzer-Street 33, D-48129 Munster, Germany.	Comparative examination of complaints of patients with breast-cancer with and without silicone implants.	Eur J Obstet Gynecol Reprod Biol. 2002 Apr 10;102(1):61-6.	OBJECTIVE: To measure the relationship between silicone breast implants and various symptoms using a control group. STUDY DESIGN: A matched-pair-analysis of 96 women with breast-cancer (32 with silicone implants (K I); 64 without implants (K II)) was performed with help of a standardized questionnaire in respect to 50 single criteria. The condition of implants was monitored by MR-imaging. RESULTS: Athralgias and myalgias were not significantly more frequent in K I. Only six symptoms were reported significantly more often in patients with implants. Positive correlation with implant rupture was given only for the numb feeling/tingling sensation in extremities (P=0.02). There was no correlation between silicone implants and the symptoms of the "chronic-fatigue syndrome" nor any other described silicone-induced disease. CONCLUSIONS: According to our analysis many of the symptoms examined here are present in middle-aged women regardless of silicone implants and underlying disease.

Brage S.	Utredningsavdelingen Rikstrygdeverket 0241 Oslo. brage@ryggnett.no	[Utilization of national insurance in connection with functional somatic	Tidsskr Nor Laegeforen. 2002 May 30;122(14):1397-	BACKGROUND: Functional somatic disorders are often seen in medical practice. This study describes their financial consequences for the national insurance scheme. MATERIAL AND METHODS: National Insurance Administration data for the year 2000 were collected on sickness leave and disability pensions for fibromyalgia, whiplash injuries, chronic fatigue syndrome,

		disorders] [Article in Norwegian]	401.	dissociative and somatoform disorders, functional gastrointestinal disorders, chronic pelvic pain, and non-cardiac chest pain. RESULTS: Functional somatic disorders caused 2.9% of all sick leave among employees. Most of these were caused by fatigue/exhaustion or fibromyalgia. 6.3% of all new disability pensioners had a functional disorder, two thirds of them fibromyalgia. Functional disorders were more frequent in women, and in the 25-59 age group. INTERPRETATION: Functional disorders, fibromyalgia especially, are a great concern for the national insurance system. More focus on individual functioning rather than the disorder might contribute to better follow-up for these patients.
Brimacombe M, Helmer DA, Natelson BH.		Birth order and its association with the onset of chronic fatigue syndrome.	Hum Biol. 2002 Aug;74(4):615-20.	Chronic fatigue syndrome (CFS) is a medically unexplained illness that is diagnosed on the basis of a clinical case definition; so it probably is an illness with multiple causes producing the same clinical picture. One way of dealing with this heterogeneity is to stratify patients based on illness onset. We hypothesized that either the whole group of CFS patients or that group which developed CFS gradually would show a relation with birth order, while patients who developed CFS suddenly, probably due to a viral illness, would not show such a relation. We hypothesized the birth order effect in the gradual onset group because those patients have more psychological problems, and birth order effects have been shown for psychological characteristics. We compared birth order in our CFS patients to that in a comparison group derived from U.S. demographic data. We found a tendency that did not reach formal statistical significance for a birth order effect in the gradual onset group, but not in either the sudden onset or combined total group. However, the birth order effect we found was due to relatively increased rates of CFS in second-born children; prior birth order studies of personality characteristics have found such effects to be skewed toward first-born children. Thus, our data do support a birth order effect in a subset of patients with CFS. The results of this study should encourage a larger multicenter study to further explore and understand this relation.
Brimacombe M, Zhang Q, Lange G, Natelson BH.	Department of Preventive Medicine, University of Medicine and Dentistry - New Jersey Medical School, Newark, NJ 070718, USA.	Immunological variables mediate cognitive dysfunction in gulf war veterans but not civilians with chronic fatigue syndrome.	Neuroimmunomodulation. 2002-2003;10(2):93-100.	We explored the relationship between a set of immunological variables and a set of cognitive and functional status measures and a diagnosis of chronic fatigue syndrome (CFS) in civilians and veterans using various regression and factor analytic methods. Our approach emphasized the extraction of a few distinct factors in order to limit statistical problems associated with doing large numbers of multiple comparisons. This approach led to our finding cytokine data grouping into type 1 and type 2 clusters. A type 2 cluster plus a T and B cell factor predicted CFS caseness for Gulf War veterans but not for civilians with CFS. When a cognitive variable, reaction time, was added into the model, both immunological factors lost statistical significance; this indicates that the cognitive variable reaction time moderated the effects of the immunological factors in predicting patient status. We did a similar analysis on the roles of the immunological and cognitive variables in functional status using SF-36 data. Higher levels of these same two immunological factors predicted poorer general health as well as poorer physical and social functioning in Gulf War veterans but not in civilians with CFS. When the reaction time factor was added, only the lymphocyte factor remained significant. This implies that lymphocytes are directly related to functional status in Gulf War veterans with CFS, but the Th2 factor produces its effect on functional status via changes in cognitive abilities. Bron D.	Service d'Hematologie, Institut Jules Bordet, U.L.B.	[Fatigue and quality of life in cancer patients] [Article in French]	Rev Med Brux. 2002 Sep;23(4):A294-8.	Fatigue is the most frequent adverse event encountered in cancer patients and often underestimated by oncologists. This fatigue results in a deterioration of the quality of life physically, psychologically and socio-professionally. We have to distinguish various degrees of fatigue and identify "acute" fatigue from "chronic" fatigue. The acute fatigue appears normal after a physical or psychological effort and requires less than a week of rest to recover; the impact on quality of life is thus minimal. Chronic fatigue is more insidious; the causes are multiple. The patient feels that this fatigue is abnormal and disproportionate. It last several weeks and has a severe impact on the quality of life. Somatic mechanisms of fatigue related to the tumour and/or treatment are: vitaminic or proteic deficiencies due to malnutrition, accumulation of toxic metabolites, infections and septicemia, the abuse of sleeping tablets or antalgics, insomnias, immobilisation, organic insufficiencies or ionic disturbances. Anemia--observed in more than 50% of the cancerous patients--deserves a particular attention. The causes of this anemia are also multiple. It is obvious that anemia interferes with quality of life of the patient, decreases his physical performances and leads to a lack of motivation or energy. Patients with an hemoglobin level higher than 12 g/dl describe significantly less complaints and a higher physical and functional well being. To better assess the treatment of fatigue, it is important to first evaluate if the cause is organic, psychologic or mixed. Among the somatic causes, nutritious deficiencies, pain and anemia, . all these complications can be treated with appropriate medications. This fatigue is often recognized by the patient as a progression of the tumour or as a treatment failure. Therefore, it is important to inform the patients of the possibility of that adverse event so that it does not generate additional stress and anxiety during the treatment.
Brouwers FM, Van Der Werf S, Bleijenberg G, Van Der Zee L, Van Der Meer JW.	Departments of. General Internal Medicine and. Medical Psychology, University Medical Center Nijmegen, The Netherlands.	The effect of a polynutrient supplement on fatigue and physical activity of patients with chronic fatigue syndrome: a double-blind randomized controlled trial.	QJM. 2002 Oct;95(10):677-83.	BACKGROUND:The efficacy of dietary supplements in chronic fatigue syndrome (CFS) is uncertain, with conflicting evidence. Aim: To assess the effect of a polynutrient supplement on fatigue and physical activity of patients with CFS. DESIGN:Prospective randomized placebo-controlled, double-blind trial. METHODS:Fifty-three patients (16 males, 37 females) fulfilling the CDC criteria of CFS. The entry criteria were a score on the Checklist Individual Strength subscale fatigue severity (CIS fatigue) >or=40 and a weighted sum score of >or=750 for the eight subscales of the Sickness Impact Profile (SIP8) and no use of nutritional supplements in the 4 weeks prior to entry. The exclusion criteria were pregnancy and lactose intolerance. The intervention-a polynutrient supplement containing several vitamins, minerals and (co)enzymes, or placebo, twice daily for 10 weeks-was preceded by 2 weeks of baseline measurements. Outcome measurements took place in week 9 and 10 of the intervention. Five participants dropped out (4 supplement, 1 placebo). The main outcome measures were CIS fatigue score, number of CDC symptoms and SIP8 score. Efficacy analyses were performed on an intention-to-treat basis. RESULTS:No significant differences were found between the placebo and the treated group on any of the outcome measures: CIS fatigue +2.16 (95%CI -4.3 to +4.39, p=0.984); CDC symptoms +0.42 (95%CI -0.61 to +1.46, p=0.417); SIP8 +182 (95%CI -165 to +529, p=0.297). No patient reported full recovery. DISCUSSION:The findings do not support the use of a broad-spectrum nutritional supplement in treating CFS-related symptoms.

Liaudet AP, Cozon GJ.	Infectieuses, Hopital de la Croix-Rousse, Lyon, France.	delayed-type hypersensitivity in chronic fatigue syndrome: importance of the evaluation of lymphocyte activation by flow cytometry and the measurement of urinary neopterin] [Article in French]	(Paris). 2002 Feb;34(2):38-44.	and investigated. Although numerous immunological abnormalities have been linked with the syndrome, none have been found to be specific. This article describes the detection of delayed-type hypersensitive responses to certain common environmental antigens in almost fifty per cent of patients with this syndrome. Such hypersensitivity can be detected by the intradermal administration of antigens derived from commensal organisms like the yeast Candida albicans, and then monitoring for a systemic reaction over the following six to forty eight hours. This approach can be consolidated by performing lymphocyte activation tests in parallel and measuring in vitro T-cell activation by Candida albicans antigens by three-colour flow cytometry based on CD3, CD4 and either CD69 or CD25. Another useful parameter is the kinetics of neopterin excretion in the urine over the course of the skin test. The results showed that the intensity of the DTH response correlated with the number of T-cells activated in vitro. Various factors have been implicated in the fatigue of many patients, notably lack of sleep. However, it remains difficult to establish causality in either one direction or the other. This work is in the spirit of a multifactorial approach to the group of conditions referred to as "chronic fatigue syndrome".
Candy B, Chalder T, Cleare AJ, Wessely S, White PD, Hotopf M.	Department of Psychological Medicine, Guy's, King's and St. Thomas' School of Medicine, London.	Recovery from infectious mononucleosis: a case for more than symptomatic therapy? A systematic review.	Br J Gen Pract. 2002 Oct;52(483):844-51.	Infectious mononucleosis is usually an acute, transiently incapacitating condition, but for some sufferers it precipitates chronic illness. It is unclear which patients are at risk of a prolonged state of illness following onset of infectious mononucleosis and if there are any useful preventive measures that would facilitate recovery. The aim of this study was to review all cohort studies and intervention trials that provide information on: (a) the longitudinal course of ill health subsequent to the onset of infectious mononucleosis; (b) the relationship between psychosocial and clinical factors and recovery rate; and (c) the effect of interventions on recovery. A systematic review was conducted, based on a search of the PSYCHINFO, MEDLINE, EMBASE and CINHAL databases up to October 2001, and ISI Science and Social Sciences Citation Indices up to 22 November 2001. Eight papers were identified that gave data on illness following onset of infectious mononucleosis. The best evidence concluded that there is a distinct fatigue syndrome after infectious mononucleosis. Eight papers explored risk factors for prolonged illness following acute infectious mononucleosis. Results varied on the association of acute illness characteristics and psychological features with prolonged ill health. Poor physical functioning, namely lengthy convalescence and being less fit or active, consistently predicted chronic ill health. Three trials reported on interventions that aimed to shorten the time taken to resolve symptoms after uncomplicated infectious mononucleosis. None of the drug trials found any evidence that drug therapy shortens recovery time. The trial that compared the effect of activity with imposed bed rest, found that those patients allowed out of bed as soon as they felt able reported a quicker recovery. More information is needed on the course of ill health subsequent to the onset of infectious mononucleosis. Certain risk factors associated with delay may be amenable to a simple intervention in primary care.

Arch Dis Child. 2002 Feb;86(2):95-7.	AIM: To examine the efficacy of family focused cognitive behaviour therapy for 11-18 year olds with chronic fatigue syndrome. METHODS: Twenty three patients were offered family focused cognitive behaviour therapy. The main outcome was a fatigue score of less than 4 and attendance at school 75% of the time. RESULTS: Twenty patients completed treatment. Eighteen had completed all measures at six months follow up; 15 of these (83%) improved according to our predetermined criterion. Substantial improvements in social adjustment, depression, and fear were noted. CONCLUSIONS: Family focused cognitive behaviour therapy was effective in improving functioning and reducing fatigue in 11-18 year olds. Gains were maintained at six months follow up.

Cheng JS, Nash J, Meyer GA.	Section of Spinal Surgery, Vanderbilt University Medical Center, Nashville, Tennessee.	Chiari type I malformation revisited: diagnosis and treatment.	Neurolog. 2002 Nov;8(6):357-62.	BACKGROUND: Chiari type I malformations (Chiari I) are congenital deformities where caudal migration of the cerebellar tonsils through the foramen magnum compresses the cerebellum and cervicomedullary junction (lower brainstem and upper cervical spinal cord). Associations with chronic fatigue syndrome, fibromyalgia, orthostatic intolerance, and other neurologic syndromes have been proposed along with the current plethora of known symptoms of this disease process. In advanced cases, Chiari I malformations can lead to significant neurologic deficit and be the cause of permanent nervous system damage. REVIEW SUMMARY: This article focuses on the clinical diagnosistreatment of patients with Chiari I, including a discussion on the possible mechanisms of Chiari I with a review of present diagnostic tests, indications for treatment, and appraisal of surgical outcome. CONCLUSIONS: Future radiological advances and research will undoubtedly be directed to better understanding of the pathology of the Chiari malformation and more effective medical and surgical treatment.

Craig T, Kakumanu S.	Department of Medicine, Pennsylvania State University College of Medicine, Hershey 17033, USA. tcraig@psu.edu	Chronic fatigue syndrome: evaluation and treatment.	Am Fam Physician. 2002 Mar 15;65(6):1083-90. Comment in: Am Fam Physician. 2002 Nov 15;66(10):1838-9; author reply 1839. Am Fam Physician. 2003 Jan 15;67(2):252; author reply 252.	Severe fatigue is a common complaint among patients. Often, the fatigue is transient or can be attributed to a definable organic illness. Some patients present with persistent and disabling fatigue, but show no abnormalities on physical examination or screening laboratory tests. In these cases, the diagnosis of chronic fatigue syndrome (CFS) should be considered. CFS is characterized by debilitating fatigue with associated myalgias, tender lymph nodes, arthralgias, chills, feverish feelings, and postexertional malaise. Diagnosis of CFS is primarily by exclusion with no definitive laboratory test or physical findings. Medical research continues to examine the many possible etiologic agents for CFS (infectious, immunologic, neurologic, and psychiatric), but the answer remains elusive. It is known that CFS is a heterogeneous disorder possibly involving an interaction of biologic systems. Similarities with fibromyalgia exist and concomitant illnesses include irritable bowel syndrome, depression, and headaches. Therefore, treatment of CFS may be variable and should be tailored to each patient. Therapy should include exercise, diet, good sleep hygiene, antidepressants, and other medications, depending on the patient's presentation.
Creswell C, Chalder T.	Sub-Department of Clinical Health Psychology, University College London, Gower Street, London WC1E 6BT, UK. c.creswell@ucl.ac.uk	Underlying self-esteem in chronic fatigue syndrome.	J Psychosom Res. 2002 Sep;53(3):755-61.	OBJECTIVE: It has been suggested that people with chronic fatigue syndrome (CFS) have low self-esteem; however, this is not necessarily apparent when self-esteem is measured overtly. This study is the first to investigate underlying self-esteem using information-processing measures and overtly administered measures of self-esteem with this population. METHODS: The study comprised 68 participants (24 CFS, 24 healthy volunteers, and 20 chronic illness volunteers). A Self-Statements Questionnaire (SSQ) and an Emotional Stroop Test (EST) using neutral, positive, and negative trait words were administered. RESULTS: Participants with CFS reported lower self-esteem than the two comparison groups on overt measures. Overt responses, however, did not fully account for the full extent of the interference effect from the negative word Stroop compared to the positive word Stroop. CONCLUSION: In contrast to previous studies, participants with CFS reported lower levels of self-esteem on overt measures than two comparison groups. It is suggested, however, that the extent to which participants reported low self-esteem did not fully reflect their underlying low self-esteem and that this may result from the use of rigidly held defence mechanisms. Further use of information-processing measures, in contrast to relying only on self-report measures, is advocated for future research. Copyright 2002 Elsevier Science Inc.

Cullen W, Kearney Y, Bury G.	Department of General Practice, University College Dublin, Ireland. walter.cullen@ucd.ie	Prevalence of fatigue in general practice.	Ir J Med Sci. 2002 Jan-Mar;171(1):10-2.	BACKGROUND: Fatigue is an important symptom in general practice due to its association with physical, psychological and social problems. AIM: To determine the prevalence of fatigue as an unsolicited symptom during general practice consultations. METHODS: A random sample of GPs practising in Ireland was invited to provide data on consultations held over one day. Data were recorded on the presence of fatigue as a main or supporting symptom, social and demographic characteristics. RESULTS: Data were recorded by 89 GPs on 1,428 consultations. The prevalence of fatigue was 25%. It was the main reason for attending the doctor in 6.5% and a secondary reason in 19%. Sixty-two per cent of patients were female and 48% were eligible for free GP services. The mean age was 47.1 years. The presence of fatigue was associated with: attending a female GP, being female, attending a GP who had been qualified for fewer years and attending the GP frequently. CONCLUSION: The prevalence of fatigue reported in this study is over three times higher than that reported in earlier work. Doctor characteristics appear to be as important as patient characteristics in determining fatigue.
De Becker P, McGregor N, De Meirleir K.		Possible Triggers and Mode of Onset of Chronic Fatigue Syndrome	Journal of Chronic Fatigue Syndrome 2002; 10(2): 3 - 18	To identify the possible triggering events of CFS, we collected data on 1546 CFS patients and 309 excluded fatigued patients. Using extensive present and past medical history and lab reports as close as possible to the date of onset, an attempt was made to identify the agents that could play a role in the disease process. Significant differences were found between the events at onset, between the Fukuda or Holmes definitions and a sudden as distinct from a gradual onset. We further found a series of subgroups of events that occurred at onset of CFS. Each of these onset event clusters was associated with an infectious event, blood transfusion or hepatitis B vaccination. In a large percentage of our study group an infectious event was combined with a non-infectious event. In summary, we can conclude that a number of different stressors and consequent immunological and neuroendocrinological changes can contribute to the onset of CFS.
De Meirleir K, Suhadolnik RJ, Lebleu B, Englebienne P.	Antiviral pathway activation in chronic fatigue syndrome and acute infection.		Clin Infect Dis. 2002 May 15;34(10):1420-1; author reply 1421-2. Comment on: Clin Infect Dis. 2001 Dec 15;33(12):2080-1.	
De Sanctis V, Mangiagli A, Campisi S, Raiola G.	UO di Pediatria ed Adolscentologia, Arcispedale S. Anna, Ferrara, Italy.	[Chronic fatigue syndrome in adolescent] [Article in Italian]	Minerva Pediatr. 2002 Dec;54(6):631-7.	Fatigue is defined as a subjective sensation of tiredness or weariness that occurs at rest. The perception of fatigue among 12-15 years-old Italian adolescents in a school survey was about 70%. Generally the symptoms are reported after a viral illness or an infection. In adolescents with persistent or severe fatigue a selected screening evaluation to look for an underlying organic disorder is warranted. A practical diagnostic approach is given and a brief description of chronic fatigue syndrome is reported according to CDC revised diagnostic criteria published in 1997.
Demettre E, Bastide L, D'Haese A, De Smet K, De Meirleir K, Tiev KP,	UMR 5124 CNRS, Universite Montpellier 2, 34293 Montpellier, France.	Ribonuclease L proteolysis in peripheral blood mononuclear cells of	J Biol Chem. 2002 Sep 20;277(38):35746-51. Epub 2002 Jul 12.	A 37-kDa binding polypeptide accumulates in peripheral blood mononuclear cell (PBMC) extracts from chronic fatigue syndrome (CFS) patients and is being considered as a potential diagnostic marker (De Meirleir, K., Bisbal, C., Campine, I., De Becker, P., Salehzada, T., Demettre, E., and Lebleu, B. (2000) Am. J. Med. 108, 99-105). We establish here that this low molecular weight 2-

Englebienne P, Lebleu B.		chronic fatigue syndrome patients.		5A-binding polypeptide is a truncated form of the native 2-5A-dependent ribonuclease L (RNase L), generated by an increased proteolytic activity in CFS PBMC extracts. RNase L proteolysis in CFS PBMC extracts can be mimicked in a model system in which recombinant RNase L is treated with human leukocyte elastase. RNase L proteolysis leads to the accumulation of two major fragments with molecular masses of 37 and 30 kDa. The 37-kDa fragment includes the 2-5A binding site and the N-terminal end of native RNase L. The 30-kDa fragment includes the catalytic site in the C-terminal part of RNase L. Interestingly, RNase L remains active and 2-5A-dependent when degraded into its 30- and 37-kDa fragments by proteases of CFS PBMC extract or by purified human leukocyte elastase. The 2-5A-dependent nuclease activity of the truncated RNase L could result from the association of these digestion products, as suggested in pull down experiments.

Questions on the etiology, dynamics, diagnostics and treatment of this complex condition are briefly discussed.
Ducobu J.	Service de Medecine Interne, C.H.U. Tivoli, U.L.B.	[Chronic fatigue: introduction] [Article in French	Rev Med Brux. 2002 Sep;23(4):A279-82.	Chronic fatigue is frequent in primary care practice. After exclusion of medical causes, psychosocial factors and chronic fatigue syndrome (CFS) must be searched. The differential diagnosis is long and difficult, but it depends more of good clinical evaluation than of extensive laboratory investigation.
Durlach J, Pages N, Bac P, Bara M, Guiet-Bara A, Agrapart C.	SDRM, Universite Pierre et Marie Curie Paris V, F-75252 Paris, France. Jean.Durlach@wanadoo.fr	Chronopathological forms of magnesium depletion with hypofunction or with hyperfunction of the biological clock.	Magnes Res. 2002 Dec;15(3-4):263-8.	The main mechanisms of the chronopathological forms of magnesium depletion associate a low Mg intake with various dysregulating biorhythms. The differentiation between forms with hyperfunction and forms with hypofunction of the biological clock is seminal and the main marker is the production of melatonin (MT). The clinical forms of the various patterns of the chronopathological forms of Mg depletion may be central or peripheral. The clinical forms with hyperfunction of the biological clock (marker: increase in MT) may associate diverse expressions of nervous hypoexcitability: depression (i.e. Seasonal affective disease); cephalalgias nocturnal, without photophobia (i.e. cluster headaches); dyssomnia LASPS (advanced sleep phase syndrome) particularly]; asthenia and myalgias (i.e. fibromyalgia, chronic fatigue syndrome). The main comorbidity is found with depressive states. The therapy relies on classical bright light phototherapy, sometimes associated with psychoanaleptics. The clinical forms with hypofunction of biological clock (marker: decrease in MT) may associate various signs of nervous hyperexcitability (HEN): anxiety (from generalized anxiety to panic attacks); cephalalgias diurnal with photophobia (mainly migraine); dyssomnia [DSPS (delayed sleep phase syndrome) particularly, jet lag, night work disorders, age related insomnia, sometimes with inappropriate behaviour; photogenic epilepsia, generalized or focal; some clinical forms of chronic fatigue syndrome and fibromyalgia. The main comorbidity is between migraine and epilepsia. The treatment relies on the diverse forms of darkness therapy, possibly with the help of some psycholeptics: anxiolytics and anticonvulsants. The indications of chromatotherapy remain to be validated.

Durlach J, Pages N, Bac P, Bara M, Guiet-Bara A.	SDRM, Univ P et M Curie, Paris VI, France. Jean.Durlach@wanadoo.fr	Biorhythms and possible central regulation of magnesium status, phototherapy, darkness therapy and chronopathological forms of magnesium depletion.	Magnes Res. 2002 Mar;15(1-2):49-66.	Biological clock and magnesium status are linked. Central magnesium regulation may be hypothetized. Balanced magnesium status is requested to obtain efficiency of suprachiasmatic nuclei and of pineal gland. Conventional bright light therapy appears as a speedy and efficient antidepressant medication useful for the treatment of various types of depression, and of non migrainous headaches also. Although decrease in melatonin production seems accessory, increases of serotonergy and perhaps of Reactive Oxygen Species constitute the main mechanisms of action. Chromatotherapy emphazizes the effects of short exposure to specific colors. Although the increased production of melatonin constitutes the best marker of darkness, it is only an accessory mechanism of its action. The psycholeptic sedative effects of darkness, like those of magnesium, rely on direct membraneous and oxidant actions, neural mediated effects (i.e. stimulation of inhibitory neuromodulators such as GABA and taurine), and on antagonism of neuroactive gases (CO and NO). Darkness therapyper se, partial substitutive therapy with melatonin and with their mimicking agents (Mg, L-Tryptophan,Taurine) apply to all the chronopathological forms of magnesium depletion with decreased production of melatonin: sleep disorders, migraine, chronic fatigue syndrome, fibromyalgia, some forms of asthma and of sudden infant death syndrome. Further research should assess the importance of the chronopathological forms of magnesium depletion in the physiopathology of these disorders.

Egg R, Hogl B, Glatzl S, Beer R, Berger T.	Department of Neurology, University Hospital Innsbruck, Austria.	Autonomic instability, as measured by pupillary unrest, is not associated with multiple sclerosis fatigue severity.	Mult Scler. 2002 May;8(3):256-60.	Multiple sclerosis (MS) fatigue is one of the most common symptoms in MS, but its pathophysiology is still not understood Sympathovagal imbalance was suggested as a reason for fatigue in chronic fatigue syndrome. We examined the role of an imbalance in the central autonomic nervous system (ANS) as a cause of MS fatigue in 51 MS patients and a control group of 22 healthy volunteers. Fatigue was assessed with the revised MS Fatigue Severity Scale (FSS) and the Modified Fatigue Impact Scale (MFIS). Depression was evaluated with the Beck Depression Inventory (BDI). Disintegration of the central ANS expressed by pupillary fatigue waves was measured with pupillography and documented in the pupillary unrest index (PUI). All subjects had less than five points on the seven-point Stanford Sleepiness Scale and were therefore not sleepy. MS patients had significant higher mean FSS scores (p=0.001) and mean

				MFIS scores (p=0.003) than our control group. Mean BDI scores were significant higher (p=0.001) in the MS group, but were in the lowest score range (0-10 points) in both groups. Surprisingly, we found a statistically significant inverse correlation between PUI values and either FSS scores (p=0.001; r=-0.521) or MFIS scores (p=0.002; r=-0.423) in the MS group, but not in healthy participants. We therefore conclude that autonomic instability, as measured by pupillary unrest is not associated with MS fatigue severity.
Endicott NA.		Chronic Fatigue Syndrome in Psychiatric Patients: Exposure to Potentially Toxic Substances	Journal of Chronic Fatigue Syndrome 2002; 10 (1): 37 - 53	Several investigators have suggested that environmental chemicals or "pollutants" play a significant role in the pathogenesis of chronic fatigue syndrome (CFS). This study compares the reported exposures to environmental chemicals and other potentially toxic environmental factors of psychiatric patients with CFS and two sets of controls fom the same practice who did not meet the criteria for CFS. All comparisons found the CFS patients reported significantly more exposures to potentially toxic substances than any of the control groups. The extensive scientific literature on chemical intolerance and sensitization to generally non-toxic levels of potentially toxic substances, and its possible relevance to the investigation of CFS, is discussed.
Engel CC Jr, Adkins JA, Cowan DN.	Deployment Health Clinical Center, Walter Reed Army Medical Center, Washington, DC, USA. cengel@usuhs.mil	Caring for medically unexplained physical symptoms after toxic environmental exposures: effects of contested causation.	Environ Health Perspect. 2002 Aug;110 Suppl 4:641-7.	Medically unexplained physical symptoms (MUPS) are persistent idiopathic symptoms that drive patients to seek medical care. MUPS syndromes include chronic fatigue syndrome, fibromyalgia syndrome, and multiple chemical sensitivities. When MUPS occur after an environmental exposure or injury, an adversarial social context that we call "contested causation" may ensue. Contested causation may occur publicly and involve media controversy, scientific disagreement, political debate, and legal struggles. This adversarial social context may diminish the effectiveness of the provider-patient relationship. Contested causation also may occur privately, when disagreement over the causes of MUPS takes place in the patient-provider context. These patient-provider disagreements over causation often occur because of the enigmatic nature of MUPS. We suggest that a context of contested causation may have serious negative effects on healthcare for individuals with MUPS. Context plays a larger role in MUPS care than it does for most medical care because of the uncertain nature of MUPS, the reliance of standard MUPS therapies on a potentially tenuous patient-provider partnership, and the clinical need to rely routinely on subjective MUPS assessments that often yield discordant patient and provider conclusions. Contested causation may erode patient-provider trust, test the provider's self-assurance and capacity to share power with the patient, and raise problematic issues of compensation, reparation, and blame. These issues may distract patients and providers from therapeutic goals. In occupational and military settings, the adverse impact of contested causation on the patient-provider partnership may diminish therapeutic effectiveness to a greater degree than it does in other medical settings. Contested causation therefore raises questions regarding generalizability of standard therapies for MUPS and related syndromes to these settings. Future research is needed to learn whether intuitively sensible and evidence-based MUPS therapies benefit occupational and military medical patients who are afforded care in the context of contested causation.
Evengard B, Klimas N.	Department of Immunology,	Chronic fatigue syndrome: probable	Drugs. 2002;62(17):2433-	Chronic fatigue syndrome (CFS) belongs in the medically unexplained illnesses. It affects approximately 0.2-0.7% of the population in Western countries. It is characterised by unexplained

	Microbiology and Pathology, Karolinska Institutet at Huddinge University Hospital, Stockholm, Sweden. birgitta.evengard@infect.hs.sll.se	pathogenesis and possible treatments.	46.	fatigue, lasting 6 months or more, impairment of neurocognitive functions and quality of sleep, and of somatic symptoms, such as recurrent sore throat, muscle aches, arthralgias, headache and postexertional malaise. No link between infections and CFS has been clearly established but the immune system is activated, there are aberrations in several hypothalamic-pituitary axes and involvement of other parts of the central nervous system. No specific treatment has been found. Cognitive behavioural therapy is established to be of value to improve quality of life. More effective treatment should result, as advances in biomedical as well as psychological research continue.
Farquhar WB, Hunt BE, Taylor JA, Darling SE, Freeman R.	Center for Autonomic and Peripheral Nerve Disorders, Department of Neurology, Beth Israel Deaconess Medical Center, Harvard Medical School, Boston, MA 02215, USA.	Blood volume and its relation to peak O(2) consumption and physical activity in patients with chronic fatigue.	Am J Physiol Heart Circ Physiol. 2002 Jan;282(1):H66-71.	Individuals with chronic fatigue syndrome (CFS) experience a number of somatic complaints including severe, disabling fatigue, and exercise intolerance. We hypothesized that hypovolemia, through its interaction with central hemodynamics, would contribute to the exercise intolerance associated with this disorder. We examined blood volume, peak aerobic power, habitual physical activity, fatigue level, and their interrelations to understand the physiological basis of this disorder. Seventeen patients who met the Centers for Disease Control criteria for CFS and 17 age-matched controls participated in the study. Blood volume was assessed using a single bolus injection of Evans blue dye. Peak oxygen consumption was measured during exercise on an upright cycle ergometer. Supine cardiac output and stroke volumes were measured using CO(2) rebreathing. Questionnaires were used to assess habitual physical activity and fatigue. Patients displayed a trend for a 9% lower blood volume (58.3 +/- 2.1 vs. 64.2 +/- 2.5 ml/kg, P = 0.084) and had a 35% lower peak oxygen consumption (22.0 +/- 1.2 vs. 33.6 +/- 1.9 ml/kg, P < 0.001). These two variables were highly related within the patients (r = 0.835, P < 0.001) and the controls (r = 0.850, P < 0.001). Peak ventilation and habitual physical activity were significantly lower in the patients. Fatigue level was not related to any of the measured physiological parameters within the CFS group. In conclusion, individuals with CFS have a significantly lower peak oxygen consumption and an insignificant trend toward lower blood volume compared with controls. These variables were highly related in both subject groups, indicating that blood volume is a strong physiological correlate of peak oxygen consumption in patients with CFS.
Ferreira AC, de Marchena E.		Grading autonomic dysfunction in chronic fatigue syndrome.	Semin Arthritis Rheum. 2002 Dec;32(3):137-8 Comment on: Semin Arthritis Rheum. 2002 Dec;32(3):141-8.	Review Review, Tutorial
Fisher M, Krilov LR, Ovadia M.	Division of Adolescent Medicine, Division of Pediatric Infectious Diseases, Division of Pediatric Cardiology,	Chronic fatigue syndrome and eating disorders: concurrence or coincidence?	Int J Adolesc Med Health. 2002 Oct-Dec;14(4):307-16.	In this report we present four patients who were found to have both an eating disorder and the chronic fatigue syndrome (CFS). Two of the patients presented for evaluation of an eating disorder and also had CFS, while two of the patients presented for evaluation of CFS and also had an eating disorder. In all four patients the eating disorder preceded the CFS. We consider the question of whether the occurrence of these two disorders in the same patients is merely a coincidence; whether an eating disorder can act as a precipitant for CFS, perhaps through the

	North Shore University Hospital, North Shore-Long Island Jewish Health System, Manhasset, NY, USA. Fisher@nshs.edu			exacerbation of an underlying vascular instability; and whether overlapping etiologies may predispose some adolescents to develop both disorders. We also discuss similarities (including diagnostic dilemmas, cultural influences, psychological correlates, demographic similarities, perceptual biases, and cardiovascular effects) encountered in the management of both of these disorders.

Fortune DG, Richards HL, Main CJ, Griffiths CE.	Dermatology Centre, University of Manchester School of Medicine, Hope Hospital, Salford, UK.	Patients' strategies for coping with psoriasis.	Clin Exp Dermatol. 2002 May;27(3):177-84.	There is a paucity of research on the types of strategies that patients with psoriasis use to cope with the impact of their condition. By contrast there are a number of studies assessing coping by patients with nondermatological disease. The purpose of the present study was to examine strategies for coping in patients with psoriasis and investigate whether they differ as compared with normal controls and patients with other major medical diseases. Two hundred and fifty patients with a definite dermatologist-confirmed diagnosis of psoriasis participated in this cross-sectional study. Patients were assessed by psoriasis area severity index and all patients completed the COPE questionnaire and psoriasis disability index. Sixty healthy, control participants completed the COPE questionnaire for comparison purposes. Mean COPE scores from patients with psoriasis were also compared with published COPE scores from other medical diseases. The coping strategies most frequently used by patients with psoriasis were acceptance, planning, active coping and positive reinterpretation. The least frequently used were alcohol and nonprescription drugs, religion, and denial of their condition. Despite reporting greater disability, patients with severe psoriasis did not significantly differ from those with mild/moderate disease in their use of particular forms of coping strategies. Patients with psoriasis as a whole tended to use significantly less active coping strategies, planning, positive reinterpretation and humour when compared with normal controls. There was marked similarity in the frequency of use of particular coping strategies between patients with psoriasis and patients with other medical conditions. Similar types of coping strategies are utilized by patients regardless of whether their illness is visible (psoriasis) invisible (chronic fatigue syndrome, atrial fibrillation), has significant physical impairment (spinal cord injury), or is life-threatening (cancer, and myocardial infarction). It appears that illness brings with it a generic form of coping that may require shaping to fit the individual demands of diseases such as psoriasis.

Friedberg F.	Department of Psychiatry and Behavioral Science, Putnam Hall/South Campus, State University of New York at Stony Brook, PO Box 616, Stony Brook, NY 11794-8790, USA. fred.friedberg@stonybrook.edu	Does graded activity increase activity? A case study of chronic fatigue syndrome.	J Behav Ther Exp Psychiatry. 2002 Sep-Dec;33(3-4):203-15.	The reliance on self-report outcome measures in clinical trials of graded activity-oriented cognitive-behavior therapy in chronic fatigue syndrome (CFS) makes it difficult to draw definitive conclusions about actual behavioral change. The participant in this case study was a 52-year-old married male with CFS who was working full-time. Outcome measures included a step counter to objectively measure physical activity as well as a daily diary measure of exercise activity and in vivo ratings of perceived energy, fatigue, and affect. The following psychometric instruments were also used: the CFS Symptom Inventory, the SF-36, the Beck Depression Inventory, and the Beck Anxiety Inventory. The 26-session graded activity intervention involved gradual increases in physical activity. From baseline to treatment termination, the patient's self-reported increase in walk time from 0 to 155 min a week contrasted with a surprising 10.6% decrease in mean weekly step counts. The final follow-up assessment revealed a "much improved" global rating, substantial increases in patient-recorded walk time and weight lifting intensity, yet a relatively modest increment in weekly step counts. It appeared that improvement was associated with mood-enhancing, stress-reducing activities that were substituted for stress-exacerbating activities. Copyright 2003 Elsevier Science Ltd.
Gaab J, Huster D, Peisen R, Engert V, Heitz V, Schad T, Schurmeyer TH, Ehlert U.	Center for Psychobiological and Psychosomatic Research, University of Trier, Trier, Germany. jgaab@klipsy.unizh.ch	Hypothalamic-pituitary-adrenal axis reactivity in chronic fatigue syndrome and health under psychological, physiological, and pharmacological stimulation.	Psychosom Med. 2002 Nov-Dec;64(6):951-62.	OBJECTIVES: Subtle alterations of the hypothalamic-pituitary-adrenal (HPA) axis in chronic fatigue syndrome (CFS) have been proposed as a shared pathway linking numerous etiological and perpetuating processes with symptoms and observed physiological abnormalities. Because the HPA axis is involved in the adaptive responses to stress and CFS patients experience a worsening of symptoms after physical and psychological stress, we tested HPA axis functioning with three centrally acting stress tests. METHODS: We used two procedures mimicking real-life stressors and compared them with a standardized pharmacological neuroendocrine challenge test. CFS patients were compared with healthy control subjects regarding their cardiovascular and endocrine reactivity in a psychosocial stress test and a standardized exercise test, and their endocrine response in the insulin tolerance test (ITT). RESULTS: Controlling for possible confounding variables, we found significantly lower ACTH response levels in the psychosocial stress test and the exercise test, and significantly lower ACTH responses in the ITT, with no differences in plasma total cortisol responses. Also, salivary-free cortisol responses did not differ between the groups in the psychosocial stress test and the exercise test but were significantly higher for the CFS patients in the ITT. In all tests CFS patients had significantly reduced baseline ACTH levels. CONCLUSIONS: These results suggest that CFS patients are capable of mounting a sufficient cortisol response under different types of stress but that on a central level subtle

				dysregulations of the HPA axis exist.
Gaab J, Huster D, Peisen R, Engert V, Schad T, Schurmeyer TH, Ehlert U.	Center for Psychobiological and Psychosomatic Research, University of Trier, Trier, Germany. jgaab@klipsy.unizh.ch	Low-dose dexamethasone suppression test in chronic fatigue syndrome and health.	Psychosom Med. 2002 Mar-Apr;64(2):311-8.	OBJECTIVE: Subtle dysregulations of the hypothalamus-pituitary-adrenal axis in chronic fatigue syndrome have been described. The aim of this study was to examine the negative feedback regulations of the hypothalamus-pituitary-adrenal axis in chronic fatigue syndrome. METHODS: In 21 patients with chronic fatigue syndrome and 21 healthy control subjects, awakening and circadian salivary free cortisol profiles were assessed over 2 consecutive days and compared with awakening and circadian salivary free cortisol profiles after administration of 0.5 mg of dexamethasone at 11:00 PM the previous day. RESULTS: Patients with chronic fatigue syndrome had normal salivary free cortisol profiles but showed enhanced and prolonged suppression of salivary free cortisol after the administration of 0.5 mg of dexamethasone in comparison to the control subjects. CONCLUSIONS: Enhanced negative feedback of the hypothalamus-pituitary-adrenal axis could be a plausible explanation for the previously described alterations in hypothalamus-pituitary-adrenal axis functioning in chronic fatigue syndrome. Because similar changes have been described in stress-related disorders, a putative role of stress in the pathogenesis of the enhanced feedback is possible.
Gaby AR.		Intravenous nutrient therapy: the "Myers' cocktail".	Altern Med Rev. 2002 Oct;7(5):389-403.	Building on the work of the late John Myers, MD, the author has used an intravenous vitamin-and-mineral formula for the treatment of a wide range of clinical conditions. The modified "Myers' cocktail," which consists of magnesium, calcium, B vitamins, and vitamin C, has been found to be effective against acute asthma attacks, migraines, fatigue (including chronic fatigue syndrome), fibromyalgia, acute muscle spasm, upper respiratory tract infections, chronic sinusitis, seasonal allergic rhinitis, cardiovascular disease, and other disorders. This paper presents a rationale for the therapeutic use of intravenous nutrients, reviews the relevant published clinical research, describes the author's clinical experiences, and discusses potential side effects and precautions.

Garralda ME, Rangel L.	Academic Unit of Child and Adolescent Psychiatry, Imperial College School of Medicine, London, UK. e.garralda@ic.ac.uk	Annotation: Chronic Fatigue Syndrome in children and adolescents.	J Child Psychol Psychiatry. 2002 Feb;43(2):169-76.	BACKGROUND: Over the past two decades Chronic Fatigue Syndrome (CFS) of childhood has gained increasing prominence. A number of clinical reports and case-control studies have examined the nature of the disorder, its associations, response to treatment and outcome. METHOD: A review of publications on childhood CFS was undertaken and reference to work on adult CFS made. Most studies on childhood CFS have been on markedly affected children attending specialist pediatric clinics and very little is known about the condition as it presents in the community or to general medical services. RESULTS: The main symptom is fatigue in association with a variety of physical symptoms and with marked and prolonged functional impairment. CFS is commonly reported as being brought on by acute infections. Co-morbid psychiatric (usually mood) disorders are present in at least a half. Personality problems and health attitudes have been described as possible predisposing and maintaining factors. Clinical

				reports indicate that family work focused on engagement and on a rehabilitation programme (including graded increasing activity and treatment of psychiatric co-morbidity) can help even the more severely impaired children. Recovery may be expected in over two-thirds. CONCLUSIONS: CFS presents as a distinct, markedly impairing disorder of childhood. In its severe form, it is often associated with mood disorders. Further research into milder forms and into the efficacy of different treatment interventions is specially needed.
Geraghty J.	dr.geraghty@virgin.net	Homeopathic treatment of Chronic Fatigue Syndrome: three case studies using Jan Scholten's methodology.	Homeopathy. 2002 Apr;91(2):99-105.	This paper explores the treatment of Chronic Fatigue Syndrome following a viral infection in young people. The methodology is based on that of Dr Jan Scholten, Holland, who has systematically described the homeopathic themes of all elements in the periodic table. Three case studies are presented, Cobaltum Phosphoricum, Calcium Phosphoricum and Cadmium Phosphoricum were prescribed. The common themes and the differentiating features of these Phosphate salts are described in detail to show how the homeopathic similimum is found and cure achieved.
Gerrity TR, Bates J, Bell DS, Chrousos G, Furst G, Hedrick T, Hurwitz B, Kula RW, Levine SM, Moore RC, Schondorf R.	Georgetown University Medical Center, Washington, DC, USA.	Chronic fatigue syndrome: what role does the autonomic nervous system play in the pathophysiology of this complex illness?	Neuroimmunomodulation. 2002-2003;10(3):134-41.	Chronic fatigue syndrome (CFS) is a serious health concern affecting over 800000 Americans of all ages, races and socioeconomic groups and both genders. The etiology and pathophysiology of CFS are unknown, yet studies have suggested an involvement of the autonomic nervous system (ANS). A symposium was organized in December 2000 to explore the possibility of an association between ANS dysfunction and CFS, with special emphasis on the interactions between ANS dysfunction and other abnormalities noted in the immune and endocrine systems of individuals with CFS. This paper represents the consensus of the panel of experts who participated in this meeting. Copyright 2002 S. Karger AG, Basel

Goldstein DS, Robertson D, Esler M, Straus SE, Eisenhofer G.	Clinical Neurocardiology Section, National Institute of Neurological Disorders and Stroke, National Institutes of Health, Building 10, Room	Dysautonomias: clinical disorders of the autonomic nervous system.	Ann Intern Med. 2002 Nov 5;137(9):753-63.	The term dysautonomia refers to a change in autonomic nervous system function that adversely affects health. The changes range from transient, occasional episodes of neurally mediated hypotension to progressive neurodegenerative diseases; from disorders in which altered autonomic function plays a primary pathophysiologic role to disorders in which it worsens an independent pathologic state; and from mechanistically straightforward to mysterious and controversial entities. In chronic autonomic failure (pure autonomic failure, multiple system atrophy, or autonomic failure in Parkinson disease), orthostatic hypotension reflects sympathetic neurocirculatory failure from sympathetic denervation or deranged reflexive regulation of sympathetic outflows. Chronic orthostatic intolerance associated with postural tachycardia can

	6N252, 10 Center Drive MSC-1620, Bethesda, MD 20892-1620, USA.			arise from cardiac sympathetic activation after "patchy" autonomic impairment or blood volume depletion or, as highlighted in this discussion, from a primary abnormality that augments delivery of the sympathetic neurotransmitter norepinephrine to its receptors in the heart. Increased sympathetic nerve traffic to the heart and kidneys seems to occur as essential hypertension develops. Acute panic can evoke coronary spasm that is associated with sympathoneural and adrenomedullary excitation. In congestive heart failure, compensatory cardiac sympathetic activation may chronically worsen myocardial function, which rationalizes treatment with beta-adrenoceptor blockers. A high frequency of positive results on tilt-table testing has confirmed an association between the chronic fatigue syndrome and orthostatic intolerance; however, treatment with the salt-retaining steroid fludrocortisone, which is usually beneficial in primary chronic autonomic failure, does not seem to be beneficial in the chronic fatigue syndrome. Dysautonomias are an important subject in clinical neurocardiology.

Graffelman AW, Neven AK, Nagelkerken L, Petri H, Springer MP.		Subjective Sleep Quality and Depressive Symptoms in Patients with the Chronic Fatigue Syndrome	Journal of Chronic Fatigue Syndrome 2002; 10(2): 19 - 28	Objectives: To evaluate subjective quality of sleep and depressive symptoms of patients with chronic fatigue syndrome (CFS). Methods: Adult patients, who met the criteria for CFS, were recruited by general practitioners in the Leiden area, The Netherlands. Age and sex-matched controls were recruited. Questionnaires were handed out to 59 patients and 56 controls. Results: CFS patients had a significant higher mean score than controls on the Groningen Sleep Quality Score (GSQS) and the Zung-index, i.e., worse sleep and depression scores. In the multivariate logistic regression model, the GSQS had an OR of 1.35 per unit score (CI: 1.07-1.70), and the Zung-index had an OR of 1.21 per unit score (CI: 1.10-1.33). Conclusions: In our study, CFS patients report more subjective sleep impairment and depressive symptoms than controls but these factors appear to be independent. The fact that only a minority of the CFS patients have depressive symptoms suggests it is unlikely that depression is the cause of CFS.
Gray GC, Reed RJ, Kaiser KS, Smith TC, Gastanaga VM.	Department of Defense Center for Deployment Health Research, Naval Health Research Center, San Diego, CA, USA. gregory-	Self-reported symptoms and medical conditions among 11,868 Gulf War-era veterans: the Seabee Health Study.	Am J Epidemiol. 2002 Jun 1;155(11):1033-44.	US Navy Seabees have been among the most symptomatic Gulf War veterans. Beginning in May 1997, the authors mailed Gulf War-era Seabees a health survey in serial mailings. As of July 1, 1999, 68.6% of 17,559 Seabees contacted had returned the questionnaire. Compared with other Seabees, Gulf War Seabees reported poorer general health, a higher prevalence of all 33 medical problems assessed, more cognition difficulties, and a higher prevalence of four physician-diagnosed multisymptom conditions: chronic fatigue syndrome, posttraumatic stress disorder, multiple chemical sensitivity, and irritable bowel syndrome. Because the four multisymptom

	gray@uiowa.edu			conditions were highly associated with one another, the authors aggregated them into a working case definition of Gulf War illness. Among the 3,831 (22% cases) Gulf War Seabee participants, multivariable modeling revealed that female, Reserve, and enlisted personnel and participants belonging to either of two particular Seabee units were most likely to meet the case definition. Twelve of 34 self-reported Gulf War exposures were mildly associated with meeting the definition of Gulf War illness, with exposure to fumes from munitions having the highest odds ratio (odds ratio = 1.9, 95% confidence interval: 1.5, 2.4). While these data do not implicate a specific etiologic exposure, they demonstrate a strong association and a high prevalence of self-reported multisymptom conditions in a large group of symptomatic Gulf War veterans.
Green B.	University of Liverpool, UK. ben@priory.com	Focus on amisulpride.	Curr Med Res Opin. 2002;18(3):113-7.	Amisulpride is a second-generation antipsychotic, a substituted benzamide. It appears to be an effective agent in treating schizophrenia for what are characterised as positive and negative symptoms. The recommended doses are between 400 mg/day and 800 mg/day. Amisulpride demonstrates a good global safety profile, particularly when compared with first-generation antipsychotics, such as haloperidol. There are interesting studies that point towards amisulpride's antidepressant effect in dysthymia speculative on possible roles in affective psychoses and chronic fatigue syndrome.
Gupta A.	Robinson College, University of Cambridge, Cambridge CB3 9AN, UK. ashok@harleystressclinic.com	Unconscious amygdalar fear conditioning in a subset of chronic fatigue syndrome patients.	Med Hypotheses. 2002 Dec;59(6):727-35.	Here, a novel hypothesis for chronic fatigue syndrome (CFS) is proposed. CFS may be a neurophysiological disorder focussing on the amygdala. During a 'traumatic' neurological event often involving acute psychological stress combined with a viral infection or other chemical or physiological stressor, a conditioned network or 'cell assembly' may be created in the amygdala. The unconscious amygdala may become conditioned to be chronically sensitised to negative symptoms arising from the body. Negative signals from the viscera or physiological, chemical and dietary stressors, become conditioned stimuli and the conditioned response is a chronic sympathetic outpouring from the amygdala via various brain pathways including the hypothalamus. This cell assembly then produces the CFS vicious circle, where an unconscious negative reaction to symptoms causes immune reactivation/dysfunction, chronic sympathetic stimulation, leading to sympathetic dysfunction, mental and physical exhaustion, and a host of other distressing symptoms and secondary complications. And these are exactly the symptoms that the amygdala and associated limbic structures are trained to monitor and respond to, perpetuating a vicious circle. Recovery from CFS may involve projections from the medial prefrontal cortex to the amygdala, to control the amygdala's expressions. I shall firstly discuss predisposing, precipitating, and perpetuating factors involved in the possible etiology of chronic fatigue syndrome (CFS), followed by the patient's experience of the illness. Finally, I shall look at a suggested explanation for the symptoms of CFS. Copyright 2002 Elsevier Science Ltd.

Harrison S, Smith A, Sykes R.		Residential Rehabilitation Courses in the Self-Directed Management of Chronic Fatigue Syndrome: A Preliminary Evaluation	Journal of Chronic Fatigue Syndrome 2002; 10(2): 59 - 65	Residential rehabilitation courses in self-directed illness management offer a potentially useful patient-centered and multidiscipliary therapeutic option for Chronic Fatigue Syndrome. A retrospective survey of the data from the courses run by Westcare UK between 1995 and 1998 was undertaken to give a preliminary evaluation of outcomes and acceptability. The outcome results, for 49 participants, show improvements, at 12 months, on the Fatigue and Emotional Distress subscales of the PFRS. (Fatigue: before course: mean 3.66, s.d. 1.14; 12 months later: mean 3.11, s.d. 1.57; $F(1,48) = 11.10$ $p < 0.005$. Emotional distress: before course: mean 2.53, s.d. 1.46; 12 months later: mean 2.04, s.d. 1.39; $F(1,48) = 5.96$ $p < 0.01$.) Participants also reported a high level of general satisfaction with the course: 89.4% gave a rating of five or six, out of six. These results describe both longand short-term benefits, and support the continued use of these courses and the implementation of a further more rigorous study.
Hartocollis P.		'Actual neurosis' and psychosomatic medicine: the vicissitudes of an enigmatic concept.	Int J Psychoanal. 2002 Dec;83(Pt 6):1361-73.	Out of the concept of neurasthenia, the main non-psychotic diagnosis of nineteenth-century psychiatry besides hysteria, and on the basis of psychophysiological problems of his own, self-diagnosed as neurasthenia, Freud developed the notion of 'actual neurosis', a 'contentless psychic state' manifested by various somatic symptoms and a depressive mood, which he attributed to a chemical factor associated with aberrant sexual practices and in particular masturbation. Rejected by post-Freudian analysts as such along with the diagnosis of neurasthenia, the concept of 'actual neurosis' has survived under various theoretical schemes that seek to explain psychosomatic illness and somatisation, in general, with its concomitant poverty of affects and dearth of fantasy life. In more recent years, the concept of 'actual neurosis' has resurfaced under the label of chronic fatigue syndrome, a medical entity thought to be an immunological deficiency, while in psychoanalysis Freud's idea of a contentless mental state has been replaced by that of unconscious fantasy and symbolisation at a pre-genital or pre-verbal level.

Aug;11(5):463-71.	substantial functional disability. A volunteer sample of twins discordant for fatigue was identified from throughout the US. Fatigued twins were classified using three increasingly stringent definitions: (1) > or = 6 months of fatigue (119 pairs); (2) CFS-like illness based on self-report of the Centers for Disease Control and Prevention CFS research definition criteria (74 pairs); and (3) CFS assessed by clinical examination (22 pairs). Twins with chronic fatigue were compared with their unaffected co-twins on the eight standard scales and two physical and mental component summary scales from the medical outcomes study short-form health survey (SF-36). Substantial impairment was observed for fatigued twins across all levels of fatigue, while scores in the healthy twins were similar to US population values. Mean scores among fatigued twins on the physical and mental component summary scales were below 97 and 77%, respectively, of the US population scores. Diminished functional status was found across increasingly stringent classifications of fatigue and was associated with a dramatic decrement in physical functioning. The symptom of fatigue has a pronounced impact on functional status, especially in the domain of physical functioning.

Hoffman R.	Hematology-Oncology Section, University of Illinois-Chicago College of Medicine, Chicago, IL 60607, USA.	Quality of life issues in patients with essential thrombocythemia and polycythemia vera.	Semin Oncol. 2002 Jun;29(3 Suppl 10):3-9.	Essential thrombocythemia and polycythemia vera are both chronic progressive myeloproliferative disorders of insidious onset. If the excessive production of red cells and/or platelets is controlled, patients with these disorders may have prolonged survival. However, the clinical course of these patients can be complicated by a variety of events, including thrombotic episodes, bleeding episodes, arthropathies, pruritis, weakness, weight loss, neurologic impairment, erythromelalgia, fever, abdominal pain, and the life-threatening consequences of progression to myelofibrosis and/or acute leukemia. Effective control of hematopoiesis by phlebotomy or a variety of therapeutic agents has resulted in a reduction or elimination of many of these clinical events, but has not altered the evolution to myelofibrosis or acute leukemia. Use of each of these therapeutic strategies is also associated with a range of adverse events. Monitoring overall survival or a reduction in the frequency of clinical events has previously served as a means of assessing the results of these therapeutic interventions. Quality-of-life instruments have not been applied in a systematic fashion to the evaluation of outcomes in patients with these chronic myeloproliferative disorders. Quality-of-life assessments evaluate not only the

				state of well-being of a patient that results from an assessment of the individual's ability to perform everyday activities, which are reflective of physical, psychological, and social well-being, but also patient satisfaction with the control of disease and/or treatment-related symptoms. Quality-of-life instruments have been used to assess the clinical course of patients suffering from a variety of disorders, ranging from cancer to renal failure to chronic fatigue syndrome. Information about quality-of-life outcomes can contribute to the evaluation of variations in dose and timing of administration of therapeutic agents. It is possible that the side effects of a particular therapy may outweigh the disease regression achieved with a particular therapy. In the future, quality-of-life instruments may prove useful in prospectively evaluating therapeutic end points in patients with essential thrombocythemia and polycythemia vera. Ikuta K, Ibrahim MS, Kobayashi T, Tomonaga K.	Department of Virology, Research Institute for Microbial Diseases, Osaka University, Suita, Osaka 565-0871, Japan. ikuta@biken.osaka-u.ac.jp	Borna disease virus and infection in humans.	Front Biosci. 2002 Feb 1;7:d470-95.	Borna disease virus (BDV) is a nonsegmented, negative-, single-stranded, highly neurotropic RNA virus with noncytolytic replication in the central nervous system. This virus causes neurological and behavioral disturbances primarily in horses and sheep, in addition to a variety of other vertebrate animal species and in laboratory animal models. BDV is now gaining much of the research attention, because the disturbances seen in animals resemble those of neuropsychiatric disorders in humans. These observations raise the possibility that BDV infection may be associated with certain human disorders. Serological and molecular studies on many samples from human patients with a variety of psychiatric disorders have been performed. Some reported the presence and elevated levels of serum antibodies to BDV. Others reported the presence of BDV-RNAs or BDV-antigens in the peripheral blood samples as well as in autopsied brains. Taken together these data support the possibility of human infection with BDV. On the contrary, others reported the complete absence of such BDV-markers from their samples, supporting the absence of a link between BDV infection and psychiatric disorders as well as excluding it as a human pathogen. Thus, BDV infection in humans is highly controversial. Further investigations are required to answer the question whether BDV is a human pathogen and moreover, to elucidate the possible role, if any, of BDV in the pathogeneses of these disorders.
Jackson E.	Shaw Heath Health Centre, Stockport, Cheshire. libb.jackson@ntlworld.com	An overview of chronic fatigue syndrome.	Nurs Stand. 2002 Dec 11-17;17(13):45-53; quiz 54-5.	This article provides an overview of the condition known as chronic fatigue syndrome, or myalgic encephalomyelitis. The author describes common symptoms and their treatment, and discusses a model of patient care, piloted in the community, which includes elements of a range of therapeutic strategies.
Jason LA, Taylor RR, Kennedy CL, Jordan	Department of Psychology, DePaul	A factor analysis of chronic fatigue	Soc Psychiatry Psychiatr Epidemiol.	BACKGROUND: This study examined characteristics of fatigue in individuals with chronic fatigue from a community-based study. Most studies of chronic fatigue have been based on patients

K, Huang CF, Torres-Harding S, Song S, Johnson D.	University, Chicago, IL 60614, USA. ljason@wppost.depaul.edu	symptoms in a community-based sample.	2002 Apr;37(4):183-9.	recruited from primary or tertiary care settings. Samples such as these might not be representative of patients within the general population. The purpose of this study was to determine the factor structure of participants' symptoms in a random community sample of individuals with chronic fatigue. METHOD: A random sample of 18,675 respondents in Chicago received a brief telephone questionnaire designed to identify individuals with chronic fatigue. A group of 780 (4.2%) with chronic fatigue received further interview via telephone questionnaire involving characteristics of their fatigue. The analyses for this study were based on those people identified with having chronic fatigue. A factor analysis was conducted on responses to questionnaire items, and a four-factor solution emerged. Mean factor scores were derived and analyzed in relation to sociodemographic characteristics and sample subgroups. RESULTS: The four factors were labeled: Lack of Energy, Physical Exertion, Cognitive Functioning, and Fatigue and Rest. CONCLUSIONS: Results indicated that individuals with chronic fatigue have symptoms that can be differentiated into theoretically distinct factors.
Jason LA, Taylor RR, Plioplys S, Stepanek Z, Shlaes J.	Center for Community Research, DePaul University, Chicago, Illinois 60614, USA. ljason@wppost.depaul.edu	Evaluating attributions for an illness based upon the name: chronic fatigue syndrome, myalgic encephalopathy and Florence Nightingale disease.	Am J Community Psychol. 2002 Feb;30(1):133-48.	In recent years, considerable discussion has occurred about stigma surrounding the name given to an illness currently known as chronic fatigue syndrome (CFS). Although patients and medical personnel have expressed varying opinions on this issue, no studies have evaluated how beliefs about the illness change based upon the type of name used for diagnostic purposes. Proposals have been put forth to rename the illness with an eponym (a famous patient's or researcher's name) or with a less trivial sounding, more medically based type of name. In this study, attributions about CFS were measured in three groups of medical trainees. All groups read the same case study of a person with classic symptoms of chronic fatigue syndrome, with the only difference being in the type of name given. Trainees then were asked to provide attributions about certain aspects of the illness, including its cause, severity, and prognosis. Results suggested that, across name conditions, most trainees appeared to consider the symptom complex of CFS a serious illness resulting in poor quality of life. In addition, findings indicated that the name, chronic fatigue syndrome, may be regarded less seriously than the Myalgic Encephalopathy name with respect to some important aspects of the illness. In this study, specialty of medical trainee also played a role in how the illness was perceived.
Jason LA, Torres-Harding SR, Carrico AW, Taylor RR.	DePaul University, Center for Community Research, 990 West Fullerton Road, Chicago, IL 60614, USA. Ljason@depaul.edu	Symptom occurrence in persons with chronic fatigue syndrome.	Biol Psychol. 2002 Feb;59(1):15-27.	This investigation compared differences in the occurrence of symptoms in participants with CFS, melancholic depression, and no fatigue (controls). The following Fukuda et al. [Ann. Intern. Med. 121 (1994) 953] criteria symptoms differentiated the CFS group from controls, but did not differentiate the melancholic depression group from controls: headaches, lymph node pain, sore throat, joint pain, and muscle pain. In addition, participants with CFS uniquely differed from controls in the occurrence of muscle weakness at multiple sites as well as in the occurrence of various cardiopulmonary, neurological, and other symptoms not currently included in the current case definition. Implications of these findings are discussed.

Kerr JR, Bracewell J, Laing I, Mattey DL, Bernstein RM, Bruce IN, Tyrrell DA.	Department of Microbiology, Royal Brompton Hospital, National Heart and Lung Institute, Imperial College School of Medicine, London, UK. j.kerr@ic.ac.uk	Chronic fatigue syndrome and arthralgia following parvovirus B19 infection.	J Rheumatol. 2002 Mar;29(3):595-602.	OBJECTIVE: To determine the incidence of arthralgia and fatigue complicating B19 infection, along with associated B19 markers and autoantibodies. METHODS: We studied patients with acute B19 infection (n = 51), patients followed from the time of acute B19 infection (mean 22.5 mo) (n = 39), and healthy controls (n = 50). Clinical details were collected using a questionnaire and blood was tested for B19 markers and autoantibodies. RESULTS: Acute B19 arthralgia occurred in 31 patients and was associated with female sex ($p = 0.007$) and age > 20 years ($p = 0.02$). Acute B19 fatigue occurred in 8 patients and was not significantly associated with any marker. At followup, symptoms consisted of arthralgia (n = 5), arthralgia and fatigue (n = 6), fatigue (n = 7), lymphadenopathy (n = 1), and purpura due to thrombocytopenia (n = 2). Chronic B19 arthralgia was associated with persistent B19 viremia ($p = 0.029$). Comparison of the B19 followup group with the controls revealed a significantly increased prevalence of arthralgia ($p = 0.0002$), fatigue ($p < 0.0001$), and all other markers. Chronic B19 arthralgia was associated with both acute B19 arthralgia ($p = 0.0168$) and positive ANA at acute infection ($p = 0.0043$). Chronic B19 fatigue was associated with acute B19 fatigue ($p = 0.011$). Five patients fulfilled the Centers for Disease Control criteria for a diagnosis of chronic fatigue syndrome (CFS) and one of these was negative for serum anti-B19 IgG at followup by both Western blot and immunofluorescence. However, there was no characteristic pattern of B19 markers/autoantibodies in patients with B19 associated chronic fatigue. CONCLUSION: CFS may follow acute parvovirus B19 infection; however, attribution of a case of CFS to B19 infection may be extremely difficult in the absence of serological confirmation of acute infection at fatigue onset.

Kipen HM, Fiedler N.	Environmental and Occupational Health Sciences Institute, University of Medicine and Dentistry-Robert Wood Johnson	The role of environmental factors in medically unexplained symptoms and related syndromes: conference summary	Environ Health Perspect. 2002 Aug;110 Suppl 4:591-5.	This monograph of peer-reviewed articles is based on presentations at the conference "Environmental Factors in Medically Unexplained Physical Symptoms and Related Syndromes" held 10-12 January 2001 in Piscataway, New Jersey, USA. The purpose of the conference was to determine research priorities for elucidating the role of environmental factors in medically unexplained symptoms and symptom syndromes. These include conditions such as chronic fatigue syndrome, multiple chemical sensitivities, sick building syndrome, Gulf War illness, and the like. Approximately 1 1/2 days were devoted to plenary talks and 1 day was devoted to break-

	Medical School, Piscataway, New Jersey 08854, USA. kipen@eohsi.rutgers.edu	and recommendations.		out sessions to discuss epidemiologic, psychosocial, and experimental research. Recommendations were made for a series of epidemiologic, psychosocial, and experimental research approaches, with acknowledgment that nosology issues are clearly fundamental to advancing understanding of these conditions.
Kipen HM, Fiedler N.	Environmental and Occupational Health Sciences Institute--Occupational Health Division, University of Medicine and Dentistry of New Jersey--Robert Wood Johnson Medical School, Piscataway, New Jersey 08854, USA. kipen@eohsi.rutgers.edu	Environmental factors in medically unexplained symptoms and related syndromes: the evidence and the challenge.	Environ Health Perspect. 2002 Aug;110 Suppl 4:597-9.	Symptoms, and especially those without clear underlying medical explanations, account for a large percentage of clinical encounters. Many unexplained symptoms have been organized by patients and practitioners into syndromes such as chronic fatigue syndrome, multiple chemical sensitivity, sick building syndrome, Gulf War syndrome, and the like. All these syndromes are defined solely on the basis of symptoms rather than by medical signs. Some of the above-described conditions overlap strongly with explained conditions such as asthma. The relationship of such symptoms and syndromes to environmental exposure is often sharply debated, as is the distinction between the various syndromes. This leads to problems of what type of research should be conducted and who should conduct it. It is time to develop a comprehensive research agenda to sort out nomenclature, epidemiology, and environmental causation for these conditions, moving toward comprehensive and effective public health and clinical approaches.
Kisely SR.	Primary Care Mental Health Center, University of Western Australia, Fremantle, WA, Australia. stephenk@cyllene.uwa.edu.au	Treatments for chronic fatigue syndrome and the Internet: a systematic survey of what your patients are reading.	Aust N Z J Psychiatry. 2002 Apr;36(2):240-5.	OBJECTIVE: To evaluate the type, quality, and focus of patient information on the treatment of chronic fatigue syndrome on the Internet using simple search techniques. DESIGN: The search phrase 'chronic fatigue syndrome' was entered into nine common Internet search engines. The 25 most highly ranked pages identified by each of the nine search engines were analysed using a standardized pro forma. The following outcome measures were used: balance of content, consistency of content with evidence-based practice, declared authorship with credentials, information sources including the presence of references, the declaration of any potential conflict of interest, and the need to clarify information with an appropriate health professional. RESULTS: Two hundred and twenty-five websites were reviewed during a 2-week period in September 2000. A further 15 sites (6.3%) were inaccessible. Agreement between websites and systematic reviews of treatment for chronic fatigue syndrome ranged from 4 to 68%, the greatest agreement being for recommendations for graded exercise and the avoidance of prolonged rest. Most sites (64%) had a named author. Only a quarter to a third contained a declaration of interest, advised readers to clarify information with an appropriate health professional, or avoided inaccurate statements. CONCLUSIONS: The Internet contains a great deal of information on chronic fatigue syndrome that is neither balanced nor consistent with evidence-based practice. Doctors individually, and as a profession, should provide guidance on which Internet sites to trust.

		chronic fatigue, says study.		
Kobayashi H, Demura S.	Fukui National College of Technology.	[Relationship between chronic fatigue and subjective symptoms of fatigue with performance status (P.S.) and subjective fatigue scale for young adults (SFS-Y)] [Article in Japanese	Nippon Koshu Eisei Zasshi. 2002 Oct;49(10):1062-9.	OBJECTIVE: Today, fatigue complaints in adolescence are regarded as an issue for young adults as they may progress to the chronic fatigue syndrome. The purpose of this study was to examine the relationships between chronic fatigue based on self-reported performance states (P.S.) and subjective symptoms of fatigue assessed with a fatigue scale for young adults (SFS-Y). METHOD: The SFS-Y consisted of 24 item questions represonting 6 sub-scales, for difficulty in concentrated thinking, languor, reduced activation, reduced motivation, drowsiness and feeling of physical disintegration. The SFS-Y and for assessing fatigue symptoms and P.S. for chronic fatigue were administered to 548 male and female students aged 15-18 yr and to 608 male students aged 16-18 yr, respectively. Discriminant analysis and a logistic analysis model were employed to define the relevance of subjective symptoms of fatigue to chronic fatigue. RESULTS: It was determined that the SFS-Y can discliminate P.S. with high probability (74.0-81.4%), with accuracy beyond a fixed level. In particular, the correlation with "difficulty in concentrated thinking" was high. CONCLUSION: It was judged that the SFS-Y is effective as an index for discrimination of chronic fatigue in young adults with a particularly high relationship between "difficulty in centrated thinking" and chronic fatigue.
Koelle DM, Barcy S, Huang ML, Ashley RL, Corey L, Zeh J, Ashton S, Buchwald D.	Department of Laboratory Medicine, University of Washington, Seattle, WA, USA. dedra@u.washington.edu	Markers of viral infection in monozygotic twins discordant for chronic fatigue syndrome.	Clin Infect Dis. 2002 Sep 1;35(5):518-25. Epub 2002 Jul 31. Comment in: Clin Infect Dis. 2003 Mar 1;36(5):671-2; author reply 672-3.	To estimate the prevalence of viruses associated with chronic fatigue syndrome (CFS) and to control for genetic and environmental factors, we conducted a co-twin control study of 22 monozygotic twin pairs, of which one twin met criteria for CFS and the other twin was healthy. Levels of antibodies to human herpesvirus (HHV)-8, cytomegalovirus, herpes simplex virus 1 and 2, and hepatitis C virus were measured. Polymerase chain reaction (PCR) assays for viral DNA were performed on peripheral blood mononuclear cell specimens to detect infection with HHV-6, HHV-7, HHV-8, cytomegalovirus, Epstein-Barr virus, herpes simplex virus, varicella zoster virus, JC virus, BK virus, and parvovirus B19. To detect lytic infection, plasma was tested by PCR for HHV-6, HHV-8, cytomegalovirus, and Epstein-Barr virus DNA, and saliva was examined for HHV-8 DNA. For all assays, results did not differ between the group of twins with CFS and the healthy twins.
Kowal K, Schacterele RS, Schur PH, Komaroff AL, DuBuske LM.	Department of Allergology and Internal Disease, University Medical School, Bialystok, Poland.	Prevalence of allergen-specific IgE among patients with chronic fatigue syndrome.	Allergy Asthma Proc. 2002 Jan-Feb;23(1):35-9.	The prevalence of atopy among patients having chronic fatigue syndrome (CFS) has been reported to be as high as 80% in published surveys of patients with this syndrome. However, many of the reports relied on self-assessment by patients for the presence of atopy or solely used total immunoglobulin E (IgE) levels to assess the likelihood of atopy. To more critically assess the presence of atopy among patients with CFS, testing was done for total IgE and allergen-specific IgE using the Pharmacia CAP system including 20 common allergens: trees (birch/oak/ash), grass (rye/blue), weeds (common/giant ragweed), molds (Penicillium/Aspergillus/Alternaria), dust mites (Dermatophagoides pteronyssinus/Dermatophagoides farinae), animal dander (cat/dog), and foods (egg white/milk/wheat/corn/peanut/shrimp). Testing of 50 patients having documented CFS indicated that 78% had total IgE < 100 IU/mL, among whom 26% had a positive test for allergen-specific IgE of class I or greater for one or more allergens. Among the 22% of CFS patients having a total IgE > 100 IU/mL, 73% had a positive test for allergen-specific IgE for one or more allergens. The most commonly positive allergens were dust mites (24-26%), whereas molds

				(0-6%) and foods (0-4%) were rarely positive. The overall frequency of positive results for the presence of allergen-specific IgE among CFS patients was 36%, not significantly different from the normal prevalence of these antibodies in the general population (20-35%). This assessment of the prevalence of allergen-specific IgE antibodies in patients with CFS fails to support a potential association between CFS and atopy.
Krueger GR, Brandt ME, Wang G, Berthold F, Buja LM.	Department of Pathology & Laboratory Medicine, University of Texas-Houston Medical School, 77030, USA. Gerhard.Krueger@uth.tmc.edu	A computational analysis of Canale-Smith syndrome: chronic lymphadenopathy simulating malignant lymphoma.	Anticancer Res. 2002 Jul-Aug;22(4):2365-71.	OBJECTIVE: The objective of this study was to simulate changes in the human T cell system representing Canale-Smith syndrome using a dynamic computer model of T cell development and comparing with available human data. STUDY DESIGN: Physiological stepwise maturation and function of T lymphocytes in the computer model is altered by introducing functional disturbances following lymphotropic virus infection. In the present model, acute and chronic persistent infection with the human herpesvirus-6 (HHV-6) was simulated, and ensuing changes in T cell populations were compared with those measured in human patients. RESULTS: Using our computer model we previously found that simulated acute HHV-6 infection produced T cell computer data, which resembled an infectious mononucleosis-like disease in patients. Simulated chronic persistent infection, instead, resulted in variable cell changes comparing well to patients with chronic fatigue syndrome. In one setting, however, persistent immature lymphocytosis was observed similar to what initial has been described in this journal as Canale-Smith syndrome. CONCLUSION: Using a computer model developed by us we were able to produce simulations that resemble the immune system features of Canale-Smith syndrome. Further understanding of these simulation results may possibly guide future investigations into this disorder.
Kuratsune H, Yamaguti K, Lindh G, Evengard B, Hagberg G, Matsumura K, Iwase M, Onoe H, Takahashi M, Machii T, Kanakura Y, Kitani T, Langstrom B, Watanabe Y.	Department of Molecular Medicine, Hematology and Oncology, Osaka University Graduate School of Medicine, C9, 2-2 Yamada-oka, Suita, Osaka 565-0871, Japan. kura@bldon.med.osaka-u.ac.jp	Brain regions involved in fatigue sensation: reduced acetylcarnitine uptake into the brain.	Neuroimage. 2002 Nov;17(3):1256-65.	Fatigue is an indispensable sense for ordering rest. However, the neuronal and molecular mechanisms of fatigue remain unclear. Chronic fatigue syndrome (CFS) with long-lasting fatigue sensation seems to be a good model for studying these mechanisms underlying fatigue sensation. Recently, we found that most patients with CFS showed a low level of serum acetylcarnitine, which well correlated with the rating score of fatigue, and that a considerable amount of acetyl moiety of serum acetylcarnitine is taken up into the brain. Here we show by metabolite analysis of the mouse brain that an acetyl moiety taken up into the brain through acetylcarnitine is mainly utilized for the biosynthesis of glutamate. When we studied the cerebral uptake of acetylcarnitine by using [2-(11)C]acetyl-L-carnitine in 8 patients with CFS and in 8 normal age- and sex-matched controls, a significant decrease was found in several regions of the brains of the patient group, namely, in the prefrontal (Brodmann's area 9/46d) and temporal (BA21 and 41) cortices, anterior cingulate (BA24 and 33), and cerebellum. These findings suggest that the levels of biosynthesis of neurotransmitters through acetylcarnitine might be reduced in some brain regions of chronic fatigue patients and that this abnormality might be one of the keys to unveiling the mechanisms of the chronic fatigue sensation.
Lacour M, Zunder T, Dettenkofer M, Schonbeck S, Ludtke R, Scheidt C.	Institute of Environmental Medicine and Hospital Epidemiology,	An interdisciplinary therapeutic approach for dealing with patients attributing chronic	Int J Hyg Environ Health. 2002 Feb;204(5-6):339-46.	Nonspecific symptoms and a general feeling of ill health that is difficult to objectify are the commonest health problems with which patients present to an Environmental Medicine Outpatient Department (OPD). Of this group, a great proportion meets the classification criteria for Chronic Fatigue Syndrome (CFS) or Functional Memory Disorders in association with Idiopathic Chronic Fatigue (FMD-ICF). This is a longitudinal study of the OPD of Environmental

	Freiburg University Hospital, Hugstetter Strasse 55, D-79106 Freiburg, Germany. mlac@iuk3.ukl.uni-freiburg.de	fatigue and functional memory disorders to environmental poisoning--a pilot study.		Medicine, Freiburg University Hospital, Germany, to determine the feasibility and impact of an interdisciplinary therapeutic approach (self-help program, acupuncture, psychosomatic support by group interventions) in 8 patients with CFS, FMD-ICF, or CFS in association with self-reported Multiple Chemical Sensitivities (sr-MCS). The intervention took into consideration the patients' need for treatment of physical aspects of their disease. This is an important step to motivate patients into required psychosomatic support. Although none of the patients was willing to accept psychosomatic support or psychotherapy at study outset, acceptance of psychosomatic group interventions was high during the study course. Additionally five patients started with personal counseling at the Psychosomatic Clinic, and, without feeling stigmatized, 4 patients started with specific psychotherapy. The patients' quality of life showed no increase after four months, but, as shown by the Sum-Score of SF-36, it had improved significantly at the end of the study, which covered eight months' treatment (p = 0.015). Two follow-up investigations showed that this improvement probably persisted in part (mainly in the dimensions mental health, social function, physical role function, and vitality). In conclusion our interdisciplinary therapeutic approach indicates successful treatment of patients attributing CFS, CFS/sr-MCS, and FMD-ICF to environmental poisoning. We now plan to conduct a randomized controlled trial in the future.
Larkins RG, Molesworth SR.	.	Chronic fatigue syndrome clinical practice guidelines	Med J Aust. 2002 Jul 1;177(1):51-2. Comment in: Med J Aust. 2002 Nov 4;177(9):525-7; author reply 526-7.	
Lehman AM, Lehman DR, Hemphill KJ, Mandel DR, Cooper LM.	Faculty of Medicine, University of British Columbia, Vancouver, BC, Canada	Illness experience, depression, and anxiety in chronic fatigue syndrome.	J Psychosom Res. 2002 Jun;52(6):461-5.	OBJECTIVE: Given the high rate of psychiatric comorbidity with chronic fatigue syndrome (CFS), we considered two possible correlates of anxiety and depression: lack of illness legitimization and beliefs about limiting physical activity. METHOD: A total of 105 people diagnosed with CFS reported on their experiences with medical professionals and their beliefs about recovery and completed the depression and anxiety subscales of the Brief Symptom Inventory. RESULTS: Those who said that their physician did not legitimize their illness (36%) had higher depression and anxiety scores (P's<.05) than their counterparts. Those who believed that limiting their physical exertion was the path to recovery (55%) had lower depression and anxiety scores (P's<.01) than their counterparts. CONCLUSION: Lack of illness legitimization ranked high as a source of dissatisfaction for CFS patients, and it may aggravate psychiatric morbidity. Many CFS patients believed that staying within what they felt to be their physical limits would improve their condition. This belief, and possibly an accompanying sense of control over their symptoms, may alleviate psychiatric morbidity.
Lerner AM, Beqaj SH, Deeter RG, Dworkin HJ, Zervos M, Chang CH, Fitzgerald JT,	School of Medicine, Wayne State University, Detroit, MI, USA. lerner@cdimed.com	A six-month trial of valacyclovir in the Epstein-Barr virus subset of chronic fatigue syndrome:	Drugs Today (Barc). 2002 Aug;38(8):549-61.	This study was designed to determine safety and efficacy of a 6-month trial of valacyclovir in single-virus Epstein-Barr virus (EBV) persistent infection. Phase I of this study used four specific criteria to define a subset of patients with chronic fatigue syndrome (CFS). In the second phase, myocardial dynamics were measured by MUGA rest/stress radionuclide ventriculographic (RVG) examinations pre- and posttreatment with valacyclovir. In phase I, a trial was performed in 19

Goldstein J, O'Neill W.		improvement in left ventricular function.		consecutive CFS patients with the following diagnostic conditions: patients met criteria for diagnosis of CFS; they had had CFS for less than 1 year. They demonstrated repetitively abnormal oscillating T waves (ischemic or flat) at 24-h Holter monitoring; and they had elevated serum IgM antibody titers to EBV viral capsid antigen and/or total diffuse early antigen as measured by the enzyme-linked immunosorbent assay method. The treatment group comprised 10 CFS patients with no serum antibodies to human cytomegalovirus, but the control group (nine CFS patients) had, additionally, high titers of serum antibodies (IgG) to conformational structural antigens of human cytomegalovirus. Both the parallel treatment and control CFS groups received valacyclovir 1.0-1.5 gm q.6.h. for 6 months. This valacyclovir dose achieved serum acyclovir C(max) of > 7 microm and high antiviral activity versus EBV (IC(50) of 4.4-13.3 m). In phase II, six additional CFS patients met the same four criteria as the 19 CFS patients in phase I. They had, however, been ill for a mean of 55.8 months. Thus, 25 CFS patients comprise this study. The studies were carried out at a single outpatient practice in Birmingham, MI, U.S.A. Before initiating valacyclovir, and after 6 months of treatment, clinical and laboratory observations were made. The CFS Energy Index point score (Table I) was used to record each CFS patient's functional capacity at baseline and after 1, 3 and 6 months of valacyclovir. Energy Index point scores, as well as EBV and human cytomegalovirus serum antibody titers were assessed. In the second phase, left ventricular dynamics were repeated after 6 months of treatment with valacyclovir. We concluded that the 16 CFS patients (included in both phases of this study) with EBV-persistent infection (EBV single-virus subset) are improved after 6 months of continuous pharmacokinetic dosing with valacyclovir. Nine CFS patients with EBV/human cytomegalovirus co-infection did not benefit from 6 months of similar treatment. Valacyclovir is not an effective anti-human cytomegalovirus antiviral drug. Unimproved CFS patients with co-infections EBV and human cytomegalovirus may require combined treatment with valacyclovir and another drug more active against human cytomegalovirus. This preliminary trial, with a small number of patients, may be critical to an appropriately designed larger, double-blind, placebo-controlled trial. Copyright 2002 Prous Science
Lerner MA, Beqaj SH, Deeter RG, Fitzgerald JT.	Department of Medicine, William Beaumont Hospital, Wayne State University School of Medicine, Royal Oak, Michigan, USA. lerner@cdimed.com	IgM serum antibodies to human cytomegalovirus nonstructural gene products p52 and CM2(UL44 and UL57) are uniquely present in a subset of patients with chronic fatigue syndrome.	In Vivo. 2002 May-Jun;16(3):153-9.	Human cytomegalovirus (HCMV) IgM serum antibodies to two nonstructural gene products UL44 and UL57 (p52 and CM2) were assayed in patients with the diagnosis of the chronic fatigue syndrome (CFS) according to criteria established by the US Centers for Disease Control and Prevention. A subset of 16 CFS patients demonstrated HCMV IgG, but no HCMV IgM serum antibodies to conformational structural HCMV antigens (designated, V). By convention, these findings are interpreted to indicate only a remote HCMV infection. However, HCMV IgM p52 and CM2 antibodies were uniquely present in these 16 CFS patients. Other CFS patients with similar HCMV (V) IgG antibodies (18 patients), non-fatigued HCMV (V) IgG-positive control patients (18 patients), random HCMV (V) IgG-positive control patients from a clinical laboratory (26 patients), and non-fatigued HCMV (V) IgG-negative control patients (15 patients) did not have HCMV, IgM p52 or CM2 serum antibodies ($p < 0.05$). Control HCMV (V) IgG-positive patients had no serum IgM HCMV (V) antibodies to conventional structural HCMV (V) antigen. Thus, 77 various control patients did not contain IgM p52 or CM2 serum antibodies. The presence of IgM p52 and/or CM2

				HCMV serum antibodies in this subset of CSF-specific patients may detect incomplete HCMV multiplication in which a part of the HCMV protein-coding content of the HCMV genome is processed, but remains unassembled. These findings suggest that the presence of HCMV IgM p52 and CM2 serum antibodies may be a specific diagnostic test for the diagnosis of a subset of CFS patients. Further, these data suggest an etiologic relationship for HCMV infection in this group of CFS patients.
Lim A, Lubitz L.	Department of Paediatrics, Austin and Repatriation Medical Centre, Melbourne, Victoria, Australia.	Chronic fatigue syndrome: successful outcome of an intensive inpatient programme.	J Paediatr Child Health. 2002 Jun;38(3):295-9.	OBJECTIVE: To study the outcome of adolescents with chronic fatigue syndrome (CFS) following an intensive multi-disciplinary inpatient programme. METHODS: A follow-up questionnaire was distributed to all 57 adolescents who had completed the CFS inpatient programme at the Austin and Repatriation Medical Centre. RESULTS: Forty-two adolescents (74%) returned follow-up questionnaires. Immediately following the programme and up to five years after the programme, the majority of participants had returned to school and were functioning better in terms of physical activity and social interactions as compared with before the programme. Before the programme, 94% of adolescents were attending school half-time or less. Up to 5 years after the programme, 78% of adolescents were attending school full-time or with occasional absences only. CONCLUSIONS: A multidisciplinary inpatient programme for CFS was successful in helping to rehabilitate this group of adolescents who were significantly incapacitated prior to entering the inpatient programme.
Lindal E, Stefansson JG, Bergmann S.	Department of Psychiatry, Landspitalinn University Hospital, IS-101 Reykjavik, Iceland. elindal@landspitali.is	The prevalence of chronic fatigue syndrome in Iceland - a national comparison by gender drawing on four different criteria.	Nord J Psychiatry. 2002;56(4):273-7.	The study was carried out to estimate the prevalence of chronic fatigue syndrome (CFS) in Iceland. No previous prevalence studies known to us have been undertaken in Iceland or in Scandinavia. A 95-item custom-made questionnaire was sent to 4000 randomly selected people. The response rate was 63%. The questionnaire was constructed to include questions on all the items found in the four most common criteria for diagnosing CFS; the criteria being Australian, British and American. Results show very different prevalences according to the criteria used. The prevalence ranged from 0 to 4.9%, with the most established criteria yielding a prevalence of 1.4%. Re-test validity of the questionnaire was good, the following results are based on the selection criteria by Fukuda et al. (Fukuda K, Straus SE, Hickie I, Sharpe MC, Dobbins JG, Komaroff A, et al. The chronic fatigue syndrome: a comprehensive approach to its definition and study. Ann Int Med 1994;121:953-9). Women were in a majority (78%); their mean age was 44, they were fully employed and worked long hours. They believed that the onset of their symptoms was stress related. The type of work was unskilled in the majority of cases. A significant proportion of the males felt a constant buzzing in their ears ($P < 0.05$). Food suppliants were used daily by significantly more women than men ($P < 0.01$). Men had more frequently phobic symptoms ($P < 0.001$) than did women. Differences were found in the prevalence of phobia and panic ($P < 0.001$) between women in the CFS group compared to healthy ones. A positive correlation was found in the prevalence of phobia between women in the CFS group and those with Iceland Disease.
Linder R, Dinser R, Wagner M, Krueger GR, Hoffmann A.	Institute of Medical Informatics, Medical University of Lubeck, Ratzeburger Allee	Generation of classification criteria for chronic fatigue syndrome using an	In Vivo. 2002 Jan-Feb;16(1):37-43.	OBJECTIVE: The definition of chronic fatigue syndrome (CFS) is still disputed and no validated classification criteria have been published. Artificial neural networks (ANN) are computer-based models that can help to evaluate complex correlations. We examined the utility of ANN and other conventional methods in generating classification criteria for CFS compared to other diseases

	160, 23538 Lubeck, Germany. linder@medinf.mu-luebeck.de	artificial neural network and traditional criteria set.		with prominent fatigue, systemic lupus erythematosus (SLE) and fibromyalgia syndrome (FMA). PATIENTS AND METHODS: Ninety-nine case patients with CFS, 41 patients with SLE and 58 with FMA were recruited from a generalist outpatient population. Clinical symptoms were documented with help of a predefined questionnaire. The patients were randomly divided into two groups. One group (n = 158) served to derive classification criteria sets by two-fold cross-validation, using a) unweighted application of criteria, b) regression coefficients, c) regression tree analysis, and d) artificial neural networks in parallel. These criteria were validated with the second group (n = 40). RESULTS: Classification criteria developed by ANN were found to have a sensitivity of 95% and a specificity of 85%. ANN achieved a higher accuracy than any of the other methods. CONCLUSION: We present validated criteria for the classification of CFS versus SLE and FMA, comparing different classification approaches. The most accurate criteria were derived with the help of ANN. We therefore recommend the use of ANN for the classification of syndromes with complex interrelated symptoms like CFS.
Lindh U, Hudecek R, Danersund A, Eriksson S, Lindvall A.	Department of Oncology, Radiology and Clinical Immunology, Rudbeck Laboratory, SE-751 85 Uppsala, Sweden. Ulf.Lindh@bms.uu.se	Removal of dental amalgam and other metal alloys supported by antioxidant therapy alleviates symptoms and improves quality of life in patients with amalgam-associated ill health.	Neuroendocrinol Lett. 2002 Oct-Dec;23(5-6):459-82.	OBJECTIVES: The purpose of this study was to evaluate treatment of patients suffering from chronic ill health with a multitude of symptoms associated with metal exposure from dental amalgam and other metal alloys. SETTING AND DESIGN: We included 796 patients in a retrospective study using a questionnaire about symptom changes, changes in quality of life as a consequence of treatment and assessment of care taking. METHODS: Treatment of the patients by removal of offending dental metals and concomitant antioxidant therapy was implemented according to the Uppsala model based on a close co-operation between physicians and dentists. RESULTS: More than 70% of the responders, remaining after exclusion of those who had not begun or completed removal, reported substantial recovery and increased quality of life. Comparison with similar studies showed accordance of the main results. Plasma concentrations of mercury before and after treatment supported the metal exposure to be causative for the ill health. MAIN FINDINGS: Treatment according to the Uppsala model proved to be adequate for more than 70% of the patients. Patients with a high probability to respond successfully to current therapy might be detected by symptom profiles before treatment. CONCLUSIONS: The hypothesis that metal exposure from dental amalgam can cause ill health in a susceptible part of the exposed population was supported. Further research is warranted to develop laboratory tests to support identification of the group of patients responding to current therapy as well as to find out causes of problems in the group with no or negative results.
Loder C, Allawi J, Horrobin DF.		Treatment of multiple sclerosis with lofepramine, L-phenylalanine and vitamin B(12): mechanism of action and clinical importance: roles of the locus coeruleus	Med Hypotheses. 2002 Nov;59(5):594-602.	In a randomized, placebo-controlled double-blind trial a combination of lofepramine, phenylalanine and vitamin B(12) was found to be effective in relieving the symptoms of multiple sclerosis (MS). The effect occurred within 2-4 weeks, and improved all types of symptoms in all types of MS. The combination was also effective in relieving symptoms in patients with chronic pain and chronic fatigue. We hypothesize that the action of this combined therapy may relate to activation of the noradrenergic locus coeruleus/lateral tegmentum (LC/LT) system which has the potential to influence the functioning of large areas of the brain and spinal cord.

		and central noradrenergic systems.		
Logan AC, Beaulne TM.	Integrative Care Centre, 3600 Ellesmere Road, Unit 4, Toronto, ON M1C 4Y8, Canada.	The treatment of small intestinal bacterial overgrowth with enteric-coated peppermint oil: a case report.	Altern Med Rev. 2002 Oct;7(5):410-7. Comment in: Altern Med Rev. 2003 Feb;8(1):3; author reply 4-5.	Recent investigations have shown that bacterial overgrowth of the small intestine is associated with a number of functional somatic disorders, including irritable bowel syndrome (IBS), fibromyalgia, and chronic fatigue syndrome. A number of controlled studies have shown that enteric-coated peppermint oil (ECPO) is of benefit in the treatment of IBS. However, despite evidence of strong antimicrobial activity, ECPO has not been specifically investigated for an effect on small intestinal bacterial overgrowth (SIBO). A case report of a patient with SIBO who showed marked subjective improvement in IBS-like symptoms and significant reductions in hydrogen production after treatment with ECPO is presented. While further investigation is necessary, the results in this case suggest one of the mechanisms by which ECPO improves IBS symptoms is antimicrobial activity in the small intestine.

Looper KJ, Kirmayer LJ.	Division of Social and Transcultural Psychiatry, McGill University, Montreal, Quebec, Canada. karl.looper@mcgill.ca	Behavioral medicine approaches to somatoform disorders.	J Consult Clin Psychol. 2002 Jun;70(3):810-27.	This article reviews the research evidence for the efficacy of cognitive-behavioral therapy (CBT) for somatoform disorders. Randomized controlled studies support the efficacy of individual CBT for the treatment of hypochondriasis, body dysmorphic disorder (BDD), and undifferentiated somatoform disorders including medically unexplained symptoms, chronic fatigue syndrome, and noncardiac chest pain, and group CBT for the treatment of BDD and somatization disorder. On the basis of this review of the existing research and a theoretical model of the processes involved in somatoform disorders, the authors offer suggestions for future research and effective treatment.

Marx JJ.	. Prevention of organ failure in hereditary haemochromatosis		Neth J Med. 2002 Dec;60(11):419-22. Comment on: Neth J Med. 2002	In this editorial the dominant sites of organ manifestations in hereditary haemochromatosis are discussed as well as conditions that can occur as a result of iron-mediated manifestations: liver disease, diabetes mellitus, arthritis, and cardiomyopathy. The incidences of these organ manifestations and their well-known typical symptomatology are mentioned, in order to

			Dec;60(11):429-33.	investigate hereditary haemochromatosis as a possible (missed?) cause of the chronic fatigue syndrome. In particular the limitations of most studies about the prevalence of hereditary haemochromatosis in patients with the chronic fatigue syndrome are clearly summarised.
Masuda A, Munemoto T, Yamanaka T, Takei M, Tei C.	First Department of Internal Medicine, Faculty of Medicine, Kagoshima University, 8-35-1, Sakuragaoka, Kagoshima 890-8520, Japan.	Psychosocial characteristics and immunological functions in patients with postinfectious chronic fatigue syndrome and noninfectious chronic fatigue syndrome.	J Behav Med. 2002 Oct;25(5):477-85.	Differences between patients with postinfectious chronic fatigue syndrome (CFS, n = 16) and noninfectious CFS (n = 20) were clarified. The noninfectious CFS group had problems in family and developmental history, and had chronic stresses. Members of the postinfectious CFS group were social extroverts while those in the noninfectious CFS group was neurotic and introspective. Natural killer cell activity was suppressed in both groups. These findings suggest that the postinfectious CFS group and the noninfectious CFS group differed in their pathogenesis until the onset of CFS. The latter group should be considered as a variant of psychiatric disorder and treated accordingly.
Masuda A, Nakayama T, Yamanaka T, Koga Y, Tei C.	First Department of Internal Medicine, Faculty of Medicine, Kagoshima University, 8-35-1, Sakuragaoka, Kagoshima 890-8520, Japan.	The prognosis after multidisciplinary treatment for patients with postinfectious chronic fatigue syndrome and noninfectious chronic fatigue syndrome.	J Behav Med. 2002 Oct;25(5):487-97.	The prognosis after multidisciplinary treatment for patients with postinfectious chronic fatigue syndrome (CFS, n = 9) and noninfectious CFS (n = 9) was clarified. After treatment, natural killer (NK) cell activity increased in the postinfectious CFS group but did not recover to within normal range in the noninfectious CFS group. In the postinfectious CFS group, physical and mental symptoms improved, and 8 patients returned to work. In the noninfectious CFS group, symptoms did not improve, and only 3 patients returned to work. The prognosis of postinfectious CFS group was better than that of noninfectious CFS group. Classification of CFS patients into postinfectious and noninfectious groups is useful for choosing the appropriate treatment in order to obtain better prognosis.

McCauley LA, Joos SK, Barkhuizen A, Shuell T, Tyree WA, Bourdette DN.	Center for Research on Occupational and Environmental Toxicology, Oregon Health & Science University Portland, Oregon 97201, USA. mccauley@ohsu.edu	Chronic fatigue in a population-based study of Gulf War veterans.	Arch Environ Health. 2002 Jul-Aug;57(4):340-8.	Fatigue has been associated with illness in veterans of the Gulf War; however, few studies have confirmed self-reported fatigue by using clinical evaluation, and symptomatic veterans have not been evaluated with established criteria for Chronic Fatigue Syndrome (CFS). The authors describe the frequency and clinical characteristics of CFS in a sample of veterans residing in the northwestern United States. The sample was selected randomly from U.S. Department of Defense databases of troops deployed to southwest Asia during the Gulf War. The selected individuals were invited to participate in a clinical case-control study of unexplained illness. Of 799 survey respondents eligible for clinical evaluation, 178 had fatigue symptoms. Of the 130 veterans who were evaluated clinically, 103 had unexplained fatigue, and 44 veterans met the 1994 U.S. Centers for Disease Control criteria for CFS. In this population, the authors estimated a minimum prevalence of any unexplained fatigue to be 5.1%, and of CFS to be 2.2%. The estimated prevalence was greater among females than among males. Cases were similar to

				healthy controls, as determined by laboratory tests and physical findings. In comparison to several clinical studies of CFS patients, the authors of this study found a lower proportion of veterans who reported a sudden onset of symptoms (19%) vs. a gradual onset (50%). Although it has previously been suggested that veterans of the Gulf War suffer from higher rates of chronic fatigue than the general population, the study results described herein--on the basis of clinical examination of a population-based sample of veterans-actually indicate that an increased rate may indeed exist. Gulf War veterans with unexplained fatigue should be encouraged to seek treatment so that the impact of these symptoms on overall quality of life can be reduced.
McCue P, Scholey AB, Herman C, Wesnes KA.	Human Cognitive Neuroscience Unit, University of Northumbria, Newcastle upon Tyne, UK.	Validation of a telephone cognitive assessment test battery for use in chronic fatigue syndrome.	J Telemed Telecare. 2002;8(6):337-43.	We compared a computerized version of the Cognitive Drug Research (CDR) cognitive assessment test battery and a completely automated telephone version of the same battery. These assessed aspects of attention, working memory and long-term memory. Both methods were used to assess the cognitive performance of a cohort of 30 people with confirmed chronic fatigue syndrome (CFS) and a group of 30 healthy controls matched for age and education. The CFS group had significantly slower reaction times on all four cognitive measures on both the computerized and telephone tests. The mood data followed similar patterns inthe computer and telephone assessments. The results from both forms of the test battery confirmed the pattern and severity of cognitive impairment in CFS. Furthermore, the two methods of testing were similarly sensitive in detecting cognitive deficits. The incapacitating nature of CFS may cause problems for researchers if the restrictions to mobility affect the representativeness of the study group. The findings of the present study support the use of a fully automated telephone cognitive testing system for detecting deficits in CFS.
Merz S.	susanne@merz.as	[Chronic fatigue syndrome. More and more differential diagnoses suggest a new view of this syndrome] [Article in Swedish]	Lakartidningen. 2002 Aug 22;99(34):3282-7.	The diagnosis of chronic fatigue syndrome (CFS) requires a number of symptoms beyond chronic fatigue, according to the criteria developed in 1994 by the US Centers for Disease Control (CDC) International CFS Study Group. CFS is thus no synonym for chronic fatigue but rather an unusual syndrome afflicting no more than 0.1% of the population. Several CFS definitions have been developed over the years, and it is common for investigators to erroneously compare studies based on different definitions, which nevertheless all use the term CFS. Much of our "understanding" of CFS does not apply to the small group of patients who fulfill the current (1994) CDC definition (above). Recent studies have shown that a number of somatic diseases can present with CFS symptoms and thus be misdiagnosed as CFS. This review presents a list of such differential diagnoses, mainly chronic infections, endocrine diseases, and allergies. In view of these differential diagnoses (1) investigation and therapy must be individualized, and (2) we should offer rehabilitation where different specialists work as a coordinated team.

Metzger FA, Denney DR.	Department of Psychology,	Perception of cognitive	Ann Behav Med. 2002	This study examined discrepancies between perceived and actual performance by patients with chronic fatigue syndrome (CFS) confronted with a challenging cognitive task. Before and after

	University of Kansas, Lawrence 66045-7556.	performance in patients with chronic fatigue syndrome.	Spring;24(2):106-12.	completing a modified version of the Stroop task, 40 patients and 40 healthy control participants estimated their own performance and the performance that would normally be achieved by someone of equal age and education level. After correcting for differences between the groups in depression, we found no differences in actual performance on the Stroop. However, patients with CFS consistently underestimated their performance relative to normal performance. This difference was observed for both depressed and nondepressed subgroups of patients, persisted after adjusting the results for depression, and correlated with patients' ratings of the mental effort and fatigue evoked by the task. The results are discussed in light of cognitive models of CFS that suggest the setting of impossibly high standards of personal performance may contribute to the dynamism of this disease.
Michalsen A, Weidenhammer W, Melchart D, Langhorst J, Saha J, Dobos G.	Abteilung fur Innere Medizin V, Naturheilkunde und Integrative Medizin, Kliniken Essen Mitte, Essen.	[Short-term therapeutic fasting in the treatment of chronic pain and fatigue syndromes--well-being and side effects with and without mineral supplements] [Article in German]	Forsch Komplementarmed Klass Naturheilkd. 2002 Aug;9(4):221-7.	BACKGROUND: Fasting followed by vegetarian diet has shown to be an effective treatment for rheumatoid arthritis, moreover fasting is frequently used as an adjunctive treatment in chronic pain and stress/exhaustion syndromes. Data on well-being and the frequency of side effects during fasting are mostly retrospective. Mineral supplements are frequently used in order to compensate for fasting-induced tissue acidosis and to reduce side effects. There are only limited data that support this practice. OBJECTIVE: To study the effects of oral mineral supplements on common side effects and well-being during short-term fasting. PATIENTS AND METHODS: 209 consecutive inpatients with chronic pain/exhaustion syndromes were recruited. In a controlled non-randomised study design all patients underwent fasting (250 kcal; 3 l fluid intake/day) over 7 days, in study phase 1 without (n = 103) and in study phase 2 with (n = 106) concomitant prescription of standardised oral mineral supplements (3 x 2 to 3 x 3 Bullrich's Vital). Weight, blood pressure and urinary pH were recorded daily. Well-being and mood as well as common side effects (i.e. fatigue, hunger, heart burn, headache) were assessed with standardised self-reports. RESULTS: Baseline characteristics of the 209 patients (mean age 54.7 +/- 10.5 years; 83.3% female) were balanced. Both groups showed a fasting-induced decrease of blood pressure, a slight decrease in mood and well-being on days 3 and 4 with consecutive increase and moderate hunger, i.e. in the evening. Side effects and general tolerability of fasting as well as well-being and mood were not different between the groups. There were no serious side effects in both groups. CONCLUSIONS: Short-term fasting in inpatients with pain and stress syndromes is safe and well tolerated, concomitant mineral supplements have no additive benefit. Copyright 2002 S. Karger GmbH, Freiburg
Miller RG.	Department of Neurology, California Pacific Medical Center, San Francisco, California 94115, USA.	Role of fatigue in limiting physical activities in humans with neuromuscular diseases.	Am J Phys Med Rehabil. 2002 Nov;81(11 Suppl):S99-107.	New methods of examining both central and peripheral fatigue are now available. A broader understanding of the mechanisms of fatigue in healthy human subjects has begun to emerge. The mechanisms of fatigue in patients with various neuromuscular diseases are even more complex than in healthy persons. Examples of both central and peripheral fatigue in various neuromuscular diseases and other disorders are presented, including metabolic myopathy, chronic fatigue syndrome, postpolio syndrome, and amyotrophic lateral sclerosis.
Morriss RK, Robson MJ, Deakin JF.	Department of Psychiatry, University of	Neuropsychological performance and noradrenaline	Psychopharmacology (Berl). 2002 Sep;163(2):166-73.	RATIONALE: Subjective and objective impairments in neuropsychological function have been reported in chronic fatigue syndrome (CFS) patients under conditions of high arousal. These impairments may reflect impaired central noradrenaline function such as impaired post-synaptic

	Liverpool, Royal Liverpool Hospital, Prescot Street, Liverpool L69 3GA, UK. r.k.morris@liverpool.ac.uk	function in chronic fatigue syndrome under conditions of high arousal.	Epub 2002 Jul 30.	alpha-2 adrenoceptor function. OBJECTIVES: To determine whether high-dose clonidine has greater agonist effects at central post-synaptic alpha-2 receptors in CFS patients than controls under conditions of high arousal. As a result clonidine may reverse neuropsychological deficits underlying symptoms of poor concentration and memory. METHODS: High-dose clonidine (2.5 mg/kg) and placebo challenge tests were given in random order to ten medication-free CFS patients without anxiety disorders, depressive disorders or migraine and ten matched healthy controls under the same stressors (timed neuropsychological testing, venous sampling, intravenous drug administration). Growth hormone, cortisol, blood pressure, pulse rate, visual analogue scales of subjective neuropsychological performance and the performance on several tests from a computerised neuropsychological battery were measured. RESULTS: In CFS patients versus controls, clonidine enhanced both growth hormone (P = 0.028) and cortisol release (P = 0.021) and increased speed in the initial stage of a planning task (P = 0.023). There were no other differences between CFS patients and controls on hormonal, physiological, symptomatic or neuropsychological measures. CONCLUSIONS: Under conditions of high arousal, CFS patients may display supersensitive central post-synaptic alpha-2 adrenoceptor function associated with the release of cortisol and growth hormone and initial thinking time in planning tasks.
Naranch K, Park YJ, Repka-Ramirez MS, Velarde A, Clauw D, Baraniuk JN.	Chronic Pain and Fatigue Research Center, Division of Rheumatology, Immunology and Allergy, Georgetown University, Washington, DC 20007-2097, USA.	A tender sinus does not always mean rhinosinusitis.	Otolaryngol Head Neck Surg. 2002 Nov;127(5):387-97.	BACKGROUND: Sinus tenderness has not been quantitatively assessed. OBJECTIVE: We sought to compare sinus and systemic tenderness in rhinosinusitis, allergic rhinitis, and chronic fatigue syndrome (CFS), and healthy (non-CFS) groups. METHODS: Cutaneous pressures (kg/cm(2)) causing pain at 5 sinus and 18 systemic sites were measured in acute and chronic rhinosinusitis, active allergic rhinitis, healthy non-CFS/no rhinosinusitis, and CFS subjects. RESULTS: Sinus thresholds differed significantly (P </= 10(-11), ANOVA) between non-CFS/no rhinosinusitis (1.59 +/- 0.14 kg/cm(2), mean +/- 95% CI, n = 117), allergic rhinitis (1.19 +/- 0.31, n = 30), exacerbations of chronic rhinosinusitis (1.25 +/- 0.26, n = 25), non-CFS/chronic rhinosinusitis (1.23 +/- 0.27, n = 23), acute rhinosinusitis (1.10 +/- 0.20, n = 22), CFS/no rhinosinusitis (0.98 +/- 0.15, n = 70), and CFS/chronic rhinosinusitis (0.78 +/- 0.12, n = 56). Systemic pressure thresholds were lower for CFS (1.46 +/- 0.15) than for non-CFS (2.67 +/- 0.22, P </= 10(-11)). CONCLUSIONS: The lower sinus thresholds of rhinosinusitis groups validated the sign of sinus tenderness. Sinus and systemic thresholds were both 44% lower in CFS than in non-CFS subjects, suggesting that systemic hyperalgesia contributed to CFS sinus tenderness and "rhinosinusitis" complaints.
Naranch K, Repka-Ramirez SM, Park Y-J, Velarde A, Finnegan R, Murray J, Pheiffer A, Hwang E, Clauw D, Baraniuk JN.		Differences in Baseline Nasal Secretions Between Chronic Fatigue Syndrome (CFS) and Control Subjects	Journal of Chronic Fatigue Syndrome 2002; 10 (1): 3 - 15	Objective: To assess potential mechanism(s) for the rhinitis found in Chronic Fatigue Syndrome (CFS) subjects. Methods: The concentration of mucus constituents were measured in basal nasal lavage fluids of 103 CFS and 92 non-CFS control subjects. Subjects were further characterized by their Rhinitis Score and allergy skin test results into nonallergic and allergic rhinitis, atopic, and negative subgroups to determine if differences were related to atopy. Other questionnaires of irritant sensitivity and medicine use were completed. Results: Mucin polysaccaride (p = 0.043, ANOVA), free hemoglobin (p = 0.0044), mucin/total protein (p = 0.039) and hemoglobin/total protein (p = 0.043) were much higher in CFS than controls. CFS subjects with positive Rhinitis Scores (p = 0.023) or skin tests (p = 0.047) had higher mucin levels than those with negative values. For all subjects, inceased mucin was correlated with total protein (Pearson's r2 = 0.188)

				and inhaled corticosteroid use (r2 = 0.082) and elevated Tobacco Scores (r2 = 0.061). Other correlations with demographic, medication, or questionnaire responses gave r2 < 0.05. Conclusions: CFS subjects have a higher level of complaints in many systems including the nose. They appear to have an irritant (nonallergic) rhinitis with increased mucin production and mucosal friability (epistaxis of hemoglobin). Nasal and systemic drugs do not explain these significant baseline changes.
Naschitz JE, Sabo E, Naschitz S, Rosner I, Rozenbaum M, Madelain F, Hillel I, Priselac RM, Gaitini L, Eldar S, Zukerman E, Yeshurun D.	Departments of Internal Medicine A, Rheumatology, Anesthesiology, and Surgery, Bnai Zion Medical Center and Bruce Rappaport Faculty of Medicine, Technion-Israel Institute of Technology, Haifa, Israel.	Hemodynamics instability score in chronic fatigue syndrome and in non-chronic fatigue syndrome.	Semin Arthritis Rheum. 2002 Dec;32(3):141-8 Comment in: Semin Arthritis Rheum. 2002 Dec;32(3):137-8.	OBJECTIVE: In studying patients with chronic fatigue syndrome (CFS) we developed a method that confers numerical expression to the degree of blood pressure and heart rate lability, ie, the 'hemodynamic instability score' (HIS). The HIS in CFS patients differed significantly from healthy subjects. The present investigation compares the HIS in CFS, non-CFS chronic fatigue and patients with recurrent syncope. METHODS: Patients with CFS (n = 21), non-CFS chronic fatigue (n = 24), syncope of unknown cause (n = 44), and their age and sex-matched healthy controls (n = 21) were evaluated with a standardized head-up tilt test (HUTT). Abnormal reactions (endpoints) on HUTT were classified 'clinical outcomes' (cardioinhibitory or vasodepressor reaction, orthostatic hypotension, postural tachycardia syndrome) and 'HIS endpoint', i.e. HIS >-0.98. RESULTS: The highest incidence of endpoints was noted in patients with CFS (79%), followed by patients with syncope of unknown cause (46%), non-CFS chronic fatigue (35%), and healthy subjects (14%). Presyncope or syncope during tilt occurred in 38% of CFS patients, 21% of patients with non-CFS chronic fatigue, and 43% of patients with recurrent syncope. The average HIS values were: CFS = +2.02 (SD 4.07), non-CFS chronic fatigue = -2.89 (SD 3.64), syncope = -3.2 (SD 3.0), healthy = -2.48 (4.07). The odds ratios for CFS patients to have HIS >-0.98 was 8.8 compared with non-CFS chronic fatigue patients, 14.6 compared with recurrent syncope patients, and 34.8 compared with healthy subjects. CONCLUSION: The cardiovascular reactivity in patients with CFS has certain features in common with the reactivity in patients with recurrent syncope or non-CFS chronic fatigue, such as the frequent occurrence of vasodepressor reaction, cardioinhibitory reaction, and postural tachycardia syndrome. Apart from to these shared responses, the large majority of CFS patients exhibit a particular abnormality which is characterized by HIS values >-0.98. Thus, HIS >-0.98 lends objective criteria to the assessment of CFS. Copyright 2002, Elsevier Science (USA). All rights reserved.
Naschitz JE, Sabo E, Naschitz S, Rosner I, Rozenbaum M, Priselac RM, Gaitini L, Zukerman E, Yeshurun D.	Department of Internal Medicine A, Bnai Zion Medical Center, Haifa 31048, P. O. Box 4940, Israel. naschitz@tx.technion.ac.il	Fractal analysis and recurrence quantification analysis of heart rate and pulse transit time for diagnosing chronic fatigue syndrome.	Clin Auton Res. 2002 Aug;12(4):264-72. Comment in: Clin Auton Res. 2002 Aug;12(4):228-30.	This study aimed to develop a method to distinguish between the cardiovascular reactivity in chronic fatigue syndrome (CFS) and other patient populations. Patients with CFS (n = 23), familial Mediterranean fever (n = 15), psoriatic arthritis (n = 10), generalized anxiety disorder (n = 12), neurally mediated syncope (n = 20), and healthy subjects (n = 20) were evaluated with a shortened head-up tilt test (HUTT). A 10-minute supine phase of the HUTT was followed by recording 600 cardiac cycles on tilt, i. e., 5 to 10 minutes. Beat-to-beat heart rate (HR) and pulse transit time (PTT) were acquisitioned. Data were processed by recurrence plot and fractal analysis. Fifty-two variables were calculated in each subject. On multivariate analysis, the best predictors of CFS were HR-tilt-R/L, PTT-tilt-R/L, HR-supine-DET, PTT-tilt-WAVE, and HR-tilt-SD. Based on these predictors, the 'Fractal & Recurrence Analysis-based Score' (FRAS) was calculated: FRAS = 76.2 + 0.04*HR-supine-DET - 12.9*HR-tilt-R/L - 0.31*HR-tilt-SD - 19.27*PTT-tilt-R/L - 9.42*

				PTT-tilt-WAVE. The best cut-off differentiating CFS from the control population was FRAS = + 0.22. FRAS > + 0.22 was associated with CFS (sensitivity 70 % and specificity 88 %). The cardiovascular reactivity received mathematical expression with the aid of the FRAS. The shortened HUTT was well tolerated. The FRAS provides objective criteria which could become valuable in the assessment of CFS.
Nash J, Cheng JS, Meyer GA, Remler BF.	Medical College of Wisconsin, Milwaukee, Wis., USA.	Chiari type I malformation: overview of diagnosis and treatment.	WMJ. 2002;101(8):35-40.	Chiari Type I malformation (Chiari I) is a congenital hindbrain anomaly characterized by downward displacement of the cerebellar tonsils through the foramen magnum. This can lead to compression of cerebellar components, the lower brainstem, and the upper cervical spinal cord. In turn, a variety of neurological deficits and permanent nervous system damage may evolve. This review article discusses the etiology, diagnosis, and treatment of patients with Chiari I malformation. Its protean manifestations cause significant overlap with multiple sclerosis, chronic fatigue syndrome, and numerous other conditions. Accordingly, the diagnosis of Chiari I is difficult to establish by clinical evaluation alone. Demonstration of the characteristic hindbrain abnormalities, however, is easily accomplished with magnetic resonance imaging. Neuroimaging should therefore be considered in patients with cerebellar, brainstem, and cervical cord dysfunction. Surgical treatment is indicated in symptomatic patients with radiographic evidence of hindbrain abnormalities. Posterior fossa decompression has also been performed in patients with fibromyalgia and chronic fatigue syndrome based solely on overlapping symptoms with Chiari I. This practice remains controversial. Appraisal of surgical outcome requires postoperative neuroimaging and long-term patient follow-up to assess the permanency of improvement. Preliminary study results of the impact of surgical technique on patient outcome are reported. Ongoing research is devoted to a better understanding of the pathophysiology of Chiari I malformation and the development of more effective medical and surgical treatments.
Natelson BH, Haghighi MH, Ponzio NM.	Departments of Neurosciences, University of Medicine and Dentistry-New Jersey Medical School, Newark, New Jersey 07018 USA. bhm@njneuromed.org	Evidence for the presence of immune dysfunction in chronic fatigue syndrome.	Clin Diagn Lab Immunol. 2002 Jul;9(4):747-52.	
Natelson BH, Lange G.	Department of Neurosciences, Chronic Fatigue Syndrome Cooperative Research Center, UMDNJ, Newark,	A status report on chronic fatigue syndrome.	Environ Health Perspect. 2002 Aug;110 Suppl 4:673-7.	Medical history has shown that clinical disease entities or syndromes are composed of many subgroups--each with its own cause and pathogenesis. Although we cannot be sure, we expect the same outcome for chronic fatigue syndrome (CFS), a medically unexplained condition characterized by disabling fatigue accompanied by infectious, rheumatological, and neuropsychiatric symptoms. Although the ailment clearly can occur after severe infection, no convincing data exist to support an infectious (or immunologic) process in disease maintenance. Instead, data point to several possible pathophysiological processes: a covert encephalopathy,

	USA. bhn@njneuromed.org			impaired physiological capability to respond to physical and mental stressors, and psychological factors related to concerns about effort exacerbating symptoms. Each of these is under intense investigation. In addition, some data do exist to indicate that environmental agents also can elicit a state of chronic fatigue. We expect data to accumulate to support the belief that CFS has multiple causes.
Nijs J, Nicolson GL, De Becker P, Coomans D, De Meirleir K.	Department of Human Physiology, Faculty of Physical Education and Physiotherapy, Vrije Universiteit Brussel, KRO Gebouw-1, Laarbeeklaan 101, 1090 Brussel, Belgium. jo.nijs@vub.ac.be	High prevalence of Mycoplasma infections among European chronic fatigue syndrome patients. Examination of four Mycoplasma species in blood of chronic fatigue syndrome patients.	FEMS Immunol Med Microbiol. 2002 Nov 15;34(3):209-14.	Prevalence of Mycoplasma species infections in chronic fatigue syndrome (CFS) has been extensively reported in the scientific literature. However, all previous reports highlighted the presence of Mycoplasmas in American patients. In this prospective study, the presence of Mycoplasma fermentans, M. penetrans, M. pneumoniae and M. hominis in the blood of 261 European CFS patients and 36 healthy volunteers was examined using forensic polymerase chain reaction. One hundred and seventy-nine (68.6%) patients were infected by at least one species of Mycoplasma, compared to two out of 36 (5.6%) in the control sample (P<0.001). Among Mycoplasma-infected patients, M. hominis was the most frequently observed infection (n=96; 36.8% of the overall sample), followed by M. pneumoniae and M. fermentans infections (equal frequencies; n=67; 25.7%). M. penetrans infections were not found. Multiple mycoplasmal infections were detected in 45 patients (17.2%). Compared to American CFS patients (M. pneumoniae>M. hominis>M. penetrans), a slightly different pattern of mycoplasmal infections was found in European CFS patients (M. hominis>M. pneumoniae, M. fermentansz.Gt;M. penetrans).
Nijs J, Vaes P, Van Hoof E, De Becker P, McGregor N, De Meirleir K.		Activity Limitations and Participation Restrictions in Patients with Chronic Fatigue Syndrome-Construction of a Disease Specific Questionnaire	Journal of Chronic Fatigue Syndrome Volume 2002; 10 (3/4): 3 - 23	Review of the literature indicated the lack of disease specific measures for assessing activity limitations and participation restriction in patients with Chronic Fatigue Syndrome. Retrospective analysis of Karnofsky Performance Status questionnaires and Activities of Daily Living questionnaires (a Dutch version of the Barthel index, modified for CFS) of 141 subjects was performed to create a new questionnaire. Data analysis resulted in the following item selection, based on most frequently reported activity limitations and participation restriction; cleaning, washing dishes and returning them to cupboard, iron, do the wash, gardening, replace light bulb, walking, climb one flight of stairs, stand one hour, sit two hours, doing groceries, thirty minutes of computer work, carrying heavy objects, write a full page letter, use a screwdriver, hammer a nail, make one bed, reading, social activities, doing sports, studying, driving a car, going to school/working, preparing meals and caring for a child. These data were used to create the CFS-Activities and Participation Questionnaire (CFS-APQ). The reliability and different aspects of validity of this new measure still need to be established.
Ohashi K, Yamamoto Y, Natelson BH.	Educational Physiology Laboratory, Graduate School of Education, The University of Tokyo, 7-3-1 Hongo, Bunkyo-ku, Tokyo	Activity rhythm degrades after strenuous exercise in chronic fatigue syndrome.	Physiol Behav. 2002 Sep;77(1):39-44.	Post-exertional exacerbation of symptoms is one of the major characteristics of chronic fatigue syndrome (CFS). In this study, we evaluated the hypothesis that disturbances in circadian chronobiological regulation may play a role in generating this phenomenon. We recorded physical activity for 6-day periods in 16 women (10 CFS and 6 sedentary healthy controls, CON) before and after performing a maximal treadmill test. We calculated activity rhythms by computing autocorrelation coefficients by cutting 1 day apart from the data as a template and sliding it sequentially through each of the other days; all of 6 days were used as the templates. The peak value of autocorrelation coefficient (R) and the time between peak R's (circadian

	113-0033, Japan.			period, CP) were calculated. CFS patients had a lengthening (P < .05) of mean circadian period (MCP) that was longer than 24 h (P < .05), while MCP in CON remained unchanged. No difference was found in the standard error of each subject's MCP (circadian period variability, CPV) before and after exercise for both groups. We interpret this increase in circadian rest-activity period seen in CFS patients following exercise to indicate that exhaustive exercise interferes with normal entrainment to 24-h zeitgeber(s). This effect may be associated in part with the common patient complaint of symptom worsening following exertion. Copyright 2002 Elsevier Science Inc.
Palaniappan R, Sirimanna T.	Royal National Throat Nose and Ear Hospital, Gray's Inn Road, London WC1X 8EE, UK. rudipal@hotmail.com	Peripheral vestibular dysfunction in chronic fatigue syndrome.	Int J Pediatr Otorhinolaryngol. 2002 May 31;64(1):69-72.	OBJECTIVE: To report left-sided peripheral vestibular failure as the cause of dizziness in a 12-year-old boy diagnosed as having chronic fatigue syndrome (CFS). DESIGN: Retrospective case report with review of literature and discussion. SETTING: Tertiary children's hospital. CONCLUSION: We recommend proper vestibular assessment for CFS patients presenting with dizziness, as effective treatment for peripheral vestibular disorder exists in the form of balance rehabilitation exercises.
Pall ML.	Chronic fatigue syndrome/myalgic encephalitis.		Br J Gen Pract. 2002 Sep;52(482):762; author reply 763-4. Comment on: Br J Gen Pract. 2002 May;52(478):355-6.	
Pall ML.		Levels of Nitric Oxide Synthase Product Citrulline Are Elevated in Sera of Chronic Fatigue Syndrome Patients	Journal of Chronic Fatigue Syndrome Volume 2002; 10 (3/4): 37 - 41	Serum levels of citrulline, a product of nitric oxide synthase activity, were measured in 36 CFS patients and 16 controls to determine whether synthase activity may be elevated in CFS patients. Serum citrulline levels were found to be significantly elevated in CFS patients and, in addition, there was a trend towards higher levels in CFS patients with stronger symptoms. These results provide support for the view that nitric oxide synthase activity tends to be elevated in CFS patients, thus supporting a prediction of the elevated nitric oxide/peroxynitrite theory of CFS etiology.
Panerai AE, Vecchiet J, Panzeri P, Meroni P, Scarone S, Pizzigallo E, Giamberardino MA, Sacerdote P.	Department of Pharmacology, Istituto di Ricerca e Cura a Carattere Scientifico, University of Milan, Italy.	Peripheral blood mononuclear cell beta-endorphin concentration is decreased in chronic fatigue syndrome and fibromyalgia but not in depression: preliminary report.	Clin J Pain. 2002 Jul-Aug;18(4):270-3.	OBJECTIVE: The aim of this study was to examine the possible role of the immune system in the pathophysiology of chronic fatigue syndrome and fibromyalgia syndrome and in the differential diagnosis of depression by investigating changes in peripheral blood mononuclear cell levels of beta-endorphin, an endogenous opioid known to be involved in regulation of the immune system function. DESIGN: Beta-endorphin concentrations were measured by radioimmunoassay in peripheral blood mononuclear cells from healthy controls (n = 8) and patients with chronic fatigue syndrome (n = 17), fibromyalgia syndrome (n = 5), or depression (n = 10). RESULTS: Beta-endorphin concentrations were significantly lower in patients with chronic fatigue syndrome or fibromyalgia syndrome than in normal subjects and depressed patients ($p < 0.001$ and $p < 0.01$, respectively). They were significantly higher in depressed patients than in controls ($p < 0.01$). CONCLUSIONS: Evaluation of peripheral blood mononuclear cell beta-endorphin concentrations could represent a diagnostic tool for chronic fatigue syndrome and fibromyalgia and help with differential diagnosis of these syndromes versus depression. The results obtained are also

				consistent with the hypothesis that the immune system is activated in both chronic fatigue syndrome and fibromyalgia syndrome.
Pastel RH.	Radiation Pathophysiology and Toxicology Department, Armed Forces Radiobiology Research Institute, 8901 Wisconsin Avenue, Bethesda, MD 20889-5603, USA.	Radiophobia: long-term psychological consequences of Chernobyl.	Mil Med. 2002 Feb;167(2 Suppl):134-6.	The primary health effect of Chernobyl has been widespread psychological distress in liquidators (workers brought in for cleanup), evacuees, residents of contaminated areas, and residents of adjacent noncontaminated areas. Several psychoneurological syndromes characterized by multiple unexplained physical symptoms including fatigue, sleep and mood disturbances, impaired memory and concentration, and muscle and/or joint pain have been reported in the Russian literature. These syndromes, which resemble chronic fatigue syndrome and fibromyalgia, are probably not due to direct effects of radiation because they do not appear to be dose related to radiation exposure and because they occur in areas of both high and low contamination.
Patarca-Montero R, Fletcher MA.		The Paul-Bunnell Heterophile Antibody Determinant in Epstein-Barr Virus-Associated Disease	Journal of Chronic Fatigue Syndrome Volume 2002; 10 (3/4): 51 - 86	Reactivation of latent herpes viruses (notably EpsteinBarr virus, human herpesvirus-6) is commonly seen in chronic fatigue syndrome and it is believed to contribute to symptom perpetuation. EpsteinBarr virus (EBV), which was first isolated by Epstein, Barr and Achong (1964) from a cultured Burkitt's lymphoma lymphoblast cell line, is the etiological agent for infectious mononucleosis (IM), polyclonal and oligoclonal lymphomas associated with primary and acquired immunodeficiencies, and the complications of X-linked lymphoproliferative syndrome (XLP) (Cantani and Mastrantoni, 1989; Englund, 1988; Ernberg et al., 1990; Jones and Straus, 1987; Okano et al., 1988; Purtilo, 1987; Purtilo et al., 1981; Rowe et al., 1986; Saemundsen et al., 1981) and nasopharyngeal cancer (Pearson et al., 1984). Furthermore, people who have had IM have higher rates of subsequent development of malignant lymphoproliferative disorders (Abo et al., 1982; Snydman et al., 1982) and Hodgkin's disease (Green et al., 1979; Mueller, 1987; Poppema et al., 1985; Weiss et al., 1989), while patients with XLP have a higher incidence of non-Hodgkin's malignant lymphoma (Harrington et al., 1987). The precise role of EBV in these diseases or in CFS is not well understood. Nonetheless, it is known that EBV infection triggers the formation of heterophile antibodies that, for many decades, have formed the basis for serologic diagnosis of IM. In this review, we discuss the discovery, species variation, and structure of the erythrocyte membrane-associated Paul-Bunnell (PB) heterophile antibody determinant, its implications to IM diagnosis, and its potential contribution to defective immune surveillance, such as that seen in chronic fatigue syndrome.
Patarca-Montero R, Fletcher MA.		Effects of Benzalkonium Salts on G-protein-Mediated Processes and Surface Membranes: Relevance to Microbial- and Chemical-Induced	Journal of Chronic Fatigue Syndrome Volume 2002; 10 (3/4): 87 - 168	Benzalkonium salts comprise a group of positively charged surface-active alkylamine biocides with the general formula alkyldimethylbenzylammonium chloride or bromide. They interact with guanine nucleotide triphosphate-binding proteins (G proteins), thereby affecting signal transduction in a variety of cell types and processes. The present report reviews the known and potential basic science research and clinical applications and manifestations of benzalkonium salts. Benzalkonium salts have antiproliferative effects on a variety of cells (including T cells) through G-protein-dependent pathways, affect cytokine gene expression (downregulate tumor necrosis factor expression), and are also effective bactericidal, fungicidal, and virucidal agents with multisite (direct and immunologically-mediated) inhibitory activity against many pathogens,

		Diseases		including the human immunodeficiency virus (HIV), papillomavirus, and herpesviruses. Therefore, benzalkonium salts not only appear to be effective as disinfectants and spermicides but may also prove useful in the prevention and treatment of several diseases, particularly those linked to viruses and originating at the skin or mucosal surface. The untoward effects of benzalkonium salts are also discussed as a paradigm for chemical-induced diseases.
Patarca-Montero R.		Cytolytic Cells and Their Function	Journal of Chronic Fatigue Syndrome 2002; 10(2): 29 - 58	Cytolytic cells play an important role in cellular immunity and their function is compromised in a subgroup of patients with chronic fatigue syndrome. This review summarizes historical, methodological, clinical, therapeutic, and basic immunology aspects of cytolytic cells.
Pedersen NL, Lichtenstein P, Svedberg P.	Department of Medical Epidemiology, Karolinska Institutet, Stockholm, Sweden. Nancy.Pedersen@mep.ki.se	The Swedish Twin Registry in the third millennium.	Twin Res. 2002 Oct;5(5):427-32.	Since the Swedish Twin Registry was first established in the late 1950s to study the importance of smoking and alcohol consumption on cancer and cardiovascular diseases, it has been expanded and updated on several occasions. The focus has similarly broadened to most common complex diseases. The content of the database is described, ongoing projects based on the registry are summarized, and we review some of the principal findings on aging, cancer and cardiovascular disease that have come from the registry. Ongoing efforts and future plans for the STR are discussed. Among others, we plan blood collection and genotyping to study the genetic bases of complex diseases, a first contact ever with the cohorts born after 1958, and in-depth studies of selected diseases, such as Parkinson's disease and chronic fatigue syndrome.
Peres MF, Zukerman E, Young WB, Silberstein SD.	Sao Paulo Headache Centre and Albert Einstein Hospital Sao Paulo, Brazil. marioperes@yahoo.com	Fatigue in chronic migraine patients.	Cephalalgia. 2002 Nov;22(9):720-4.	Fatigue is a common symptom frequently reported in many disorders including headaches, but little is known about its nature. The objective was to determine the prevalence of fatigue in chronic migraine (CM) patients, to define its subtypes and its relationship with other conditions comorbid with CM. Sixty-three CM patients were analysed. The Fatigue Severity Scale (FSS), the Chalder fatigue scale and the CDC diagnostic criteria for chronic fatigue syndrome (CFS) were used. Fifty-three (84.1%) patients had FSS scores greater than 27. Forty-two (66.7%) patients met the CDC criteria for CFS. Thirty-two patients (50.8%) met the modified CDC criteria (without headache). Beck depression scores correlated with FSS, mental and physical fatigue scores. Trait anxiety scores also correlated with fatigue scales. Women had higher FSS scores than men, $P < 0.05$. Physical fatigue was associated with fibromyalgia, $P < 0.05$. Fatigue as a symptom and CFS as a disorder are both common in CM patients. Therapeutic interventions include a graded aerobic exercise program, cognitive behavioural therapy and antidepressants. Identification of fatigue and its subtypes in headache disorders and recognition of headaches in CFS patients has implications for the pathophysiology, diagnosis and treatment of these disorders.
Perski A, Grossi G, Evengard B, Blomkvist V, Yilbar B, Orth-Gomer K.	Stressmottagningen, Institutet for psykosocial miljomedicin, Stockholm.	[Emotional exhaustion common among women in the public sector] [Article in Swedish]	Lakartidningen. 2002 May 2;99(18):2047-52.	This cross-sectional investigation aimed at assessing levels of emotional exhaustion among female employees within the Swedish public sector. Other aims were to study the associations between self-rated emotional exhaustion and psychosocial factors at work, as well as findings from medical examinations. Data was collected by means of questionnaires including the Maslach Burnout Inventory, among 183 women working in geriatric care and 143 employees at the National Social Insurance Office. We found high proportions of emotional exhaustion in both samples (geriatric care = 34%; Social Insurance Office = 26%). Participants with high scores for emotional exhaustion reported more job-strain, less social support at work and more somatic, emotional and cognitive complaints than those with low or intermediate scores. Medical

				examinations performed on 19 participants with low scores and 41 with high scores for emotional exhaustion revealed significantly more findings among participants with high emotional exhaustion, particularly fatigue, sleep disturbances and cognitive impairment. There were no group differences in terms of depression or other findings. This study shows that individuals at risk for stress-related disorders may be identified using simple questionnaires. Early interventions for stress in the workplace may prevent incapacitating conditions among a great proportion of women working in the public sector.

Price EJ, Venables PJ. Department of Rheumatology, Princess Margaret Hospital, Okus Road, Swindon SN1 4JU, UK.		Dry eyes and mouth syndrome--a subgroup of patients presenting with sicca symptoms.	Rheumatology (Oxford). 2002 Apr;41(4):416-22.	OBJECTIVE: To evaluate the characteristics of patients presenting with symptoms suggestive of Sjogren's syndrome (SS) but failing to satisfy diagnostic criteria. METHODS: Clinical, serological and histological data were collected on 34 patients presenting with dry eyes and/or mouth who did not satisfy the Vitali criteria for the diagnosis of SS. They were compared with 136 patients with primary SS, 38 patients with secondary SS, and 13 patients without SS. Questionnaires on symptoms from each group were compared with 43 healthy controls. RESULTS: The 34 patients who did not satisfy the diagnostic criteria for SS or any other connective tissue disease were designated dry eyes and mouth syndrome (DEMS). Their demography including age was similar to that of a primary SS group and there was no more atrophy seen on their biopsies compared with SS and non-SS controls. They scored highly on visual analogue scales of symptoms but had few objective signs. All were negative for anti-Ro and anti-La although the prevalence of antinuclear antibodies (19%) was increased compared with a normal population. There was no excess of SS-associated tissue types. CONCLUSION: There was no evidence that age, salivary gland atrophy or subclinical SS accounted for the symptoms in DEMS. Most of the patients fitted into a spectrum of disease which tended more towards fibromyalgia and/or chronic fatigue syndrome.
Prins JB, Bleijenberg G, van der Meer JW.	Chronic fatigue syndrome and myalgic encephalomyelitis.		Lancet. 2002 May 11;359(9318):1699. Comment on: Lancet. 2002 Jan 12;359(9301):97-8.	
Puri BK, Counsell SJ, Zaman R, Main J, Collins AG, Hajnal JV, Davey NJ.	MRI Unit, MRC Clinical Sciences Centre, Imperial College School of	Relative increase in choline in the occipital cortex in chronic fatigue	Acta Psychiatr Scand. 2002 Sep;106(3):224-6.	OBJECTIVE: To test the hypothesis that chronic fatigue syndrome (CFS) is associated with altered cerebral metabolites in the frontal and occipital cortices. METHOD: Cerebral proton magnetic resonance spectroscopy (1H MRS) was carried out in eight CFS patients and eight age- and sex-matched healthy control subjects. Spectra were obtained from 20 x 20 x 20 mm3 voxels in the

	Medicine, Hammersmith Hospital, London, UK. basant.puri@csc.mrc.ac.uk	syndrome.		dominant motor and occipital cortices using a point-resolved spectroscopy pulse sequence. RESULTS: The mean ratio of choline (Cho) to creatine (Cr) in the occipital cortex in CFS (0.97) was significantly higher than in the controls (0.76; P=0.008). No other metabolite ratios were significantly different between the two groups in either the frontal or occipital cortex. In addition, there was a loss of the normal spatial variation of Cho in CFS. CONCLUSION: Our results suggest that there may be an abnormality of phospholipid metabolism in the brain in CFS.
Quan N, Herkenham M.	Department of Oral Biology, Ohio State University, Columbus 43210, USA. quan.14@osu.edu	Connecting cytokines and brain: a review of current issues.	Histol Histopathol. 2002 Jan;17(1):273-88.	Cytokines have been a multi-disciplinary research focus for over 2 decades. To date, there have been more than 15,000 articles published concerning the relationship between cytokines and the central nervous system (CNS). Over half of these articles have been published in the last 5 years. From such vast number of studies, two major topics emerge as the critical issues: 1) how do cytokines modulate the functions of the CNS? 2) what is the role of cytokines in the pathogenesis of neurological diseases? Thus far, it has been clearly established that cytokines can alter the functions of the CNS in specific manners, invoking CNS-controlled autonomic, neuroendocrine, and behavioral responses. Induced expression of cytokines has also been found in the CNS during brain injury and infection, contributing to the immunological processes at this "immunologically privileged" site. Furthermore, increasing evidence points to the potential involvement of cytokines in the induction and modulation of an array of neurological diseases ranging from Alzheimer's disease to chronic fatigue syndrome. Despite such progress, however, substantial obstacles remain for both the basic understanding and the potential clinical exploitation of how cytokines interact with CNS. In this review, we will attempt to synopsize the current theories and evidence regarding the answers to the above-mentioned critical questions. These issues will be reviewed not only in isolation, as most of the original reports focused on only one of the questions, but also in parallel such that inter-issue insights may be gained.
Raine R, Haines A, Sensky T, Hutchings A, Larkin K, Black N.	Department of Public Health and Policy, London School of Hygiene and Tropical Medicine, London WC1E 7HT. rosalind.raine@lshtm.ac.uk	Systematic review of mental health interventions for patients with common somatic symptoms: can research evidence from secondary care be extrapolated to primary care?	BMJ. 2002 Nov 9;325(7372):1082. Comment in: Evid Based Ment Health. 2003 May;6(2):55	OBJECTIVES: To determine the strength of evidence for the effectiveness of mental health interventions for patients with three common somatic conditions (chronic fatigue syndrome, irritable bowel syndrome, and chronic back pain). To assess whether results obtained in secondary care can be extrapolated to primary care and suggest how future trials should be designed to provide more rigorous evidence. DESIGN: Systematic review. DATA SOURCES: Five electronic databases, key texts, references in the articles identified, and citations from expert clinicians. STUDY SELECTION: Randomised controlled trials including participants with one of the three conditions for which no physical cause could be found. Two reviewers screened sources and independently extracted data and assessed quality. RESULTS: Sixty one studies were identified; 20 were classified as primary care and 41 as secondary care. For some interventions, such as brief psychodynamic interpersonal therapy, little research was identified. However, results of meta-analyses and of randomised controlled trials suggest that cognitive behaviour therapy and behaviour therapy are effective for chronic back pain and chronic fatigue syndrome and that antidepressants are effective for irritable bowel syndrome. Cognitive behaviour therapy and behaviour therapy were effective in both primary and secondary care in patients with back pain, although the evidence is more consistent and the effect size larger for secondary care. Antidepressants seem effective in irritable bowel syndrome in both settings but ineffective in

				chronic fatigue syndrome. CONCLUSIONS: Treatment seems to be more effective in patients in secondary care than in primary care. This may be because secondary care patients have more severe disease, they receive a different treatment regimen, or the intervention is more closely supervised. However, conclusions of effectiveness should be considered in the light of the methodological weaknesses of the studies. Large pragmatic trials are needed of interventions delivered in primary care by appropriately trained primary care staff.

Repka-Ramirez S, Naranch K, Park YJ, Clauw D, Baraniuk JN.	Division of Rheumatology, Immunology, and Allergy, Center for Chronic Pain and Fatigue Research, Georgetown University, 3800 Reservoir Road, N.W., Washington, D.C. 20007-2197, USA.	Cytokines in nasal lavage fluids from acute sinusitis, allergic rhinitis, and chronic fatigue syndrome subjects.	Allergy Asthma Proc. 2002 May-Jun;23(3):185-90.	The aim of this study was to compare the degree of inflammation present in acute sinusitis, allergic rhinitis, chronic Fatigue Syndrome (CFS), and non-CFS control subjects by measuring cytokine concentrations in nasal lavage fluids. The concentrations of total protein (TP; Lowry assay), nerve growth factor (NGF), tumor necrosis factor (TNF) alpha, and interleukin (IL)-8 were measured by ELISA in nasal lavage fluids from acute sinusitis (n = 13), active allergic rhinitis (n = 16), CFS (n = 95), and non-CFS (n = 89) subjects. CFS and non-CFS groups were subdivided further using allergy skin test and rhinitis score results. Acute sinusitis subjects had significantly higher TP ($p = 0.011$, ANOVA), TNF-alpha ($p = 0.00071$), and IL-8 ($p = 0.0000027$) concentrations and IL-8/TP ratios ($p = 0.0030$) than the other three patient groups. There were no differences based on skin test or rhinitis score severity within either the CFS or non-CFS groups. The mucopurulent discharge of acute sinusitis contained significantly higher TNF-alpha and IL-8. Neutrophils were a likely source for these cytokines. There were no differences between CFS and non-CFS subjects, making it unlikely that the rhinitis of CFS has an inflammatory component.
Richardson A.		The symptoms and management of myalgic encephalomyelitis.	Nurs Times. 2002 May 7-13;98(19):32-5.	Myalgic encephalomyelitis (ME), which is also known as chronic fatigue syndrome, is a chronic, debilitating illness with varying symptoms and patterns of progression. Research has yet to establish its aetiology and pathogenesis, and there is no cure. A number of management strategies have proved effective, but these should always be tailored to the individual patient. Although no drug treatment has been developed specifically for ME, therapies used to manage the same symptoms in other conditions can provide some relief. Treatment and management should be planned in partnership with the patient.

		Guidelines for Doctors	2002; 10 (1): 65 - 80	
Richardson J.		Toxins and Immunity in Chronic Fatigue Syndrome	Journal of Chronic Fatigue Syndrome Volume 2002; 10 (3/4): 43 - 50	In this paper, Dr. Richardson illustrates links between exposure, absorption and effects of viruses, bacteria, and inorganic toxins, and their toll on the immune system, as potential causes of chronic symptomatology as seen in chronic fatigue syndrome.
Romans S, Belaise C, Martin J, Morris E, Raffi A.	Department of Psychological Medicine, Dunedin School of Medicine, Dunedin, New Zealand. sarah.romans@stonebow.otago.ac.nz	Childhood abuse and later medical disorders in women. An epidemiological study.	Psychother Psychosom. 2002 May-Jun;71(3):141-50.	BACKGROUND: There have been many studies documenting adverse psychiatric consequences for people who have experienced childhood and adult sexual and physical abuse. These include posttraumatic stress disorder, anxiety, depression, substance abuse, eating disorders and probably some personality disorders or trait abnormalities. Much less is known about the links between abuse and physical/psychosomatic conditions in adult life. Hints of causal links are evident in the literature discussing headache, lower back pain, pelvic pain and irritable bowel syndrome. These studies are not definitive as they use clinic-based samples. METHODS: This study used interview data with a random community sample of New Zealand women, half of whom reported childhood sexual abuse and half who did not. Details about childhood physical abuse and adult abuse were also collected in a two-phase study. RESULTS: Complex relationships were found, as abuses tended to co-occur. Seven of 18 potentially relevant medical conditions emerged as significantly increased in women with one or more types of abuse. These were chronic fatigue, bladder problems, headache including migraine, asthma, diabetes and heart problems. Several of these associations with abuse are previously unreported. CONCLUSIONS: In this random community sample, a number of chronic physical conditions were found more often in women who reported different types of sexual and physical abuse, both in childhood and in adult life. The causal relationships cannot be studied in a cross-sectional retrospective design, but immature coping strategies and increased rates of dissociation appeared important only in chronic fatigue and headache, suggesting that these are not part of the causal pathway between abuse experiences and the other later physical health problems. This finding and the low co-occurrence of the identified physical conditions suggest relative specificity rather than a general vulnerability to psychosomatic conditions in women who have suffered abuses. Each condition may require separate further study. Copyright 2002 S. Karger AG, Basel

Roy-Byrne P, Afari N, Ashton S, Fischer M, Goldberg J, Buchwald D.	Department of Psychiatry and Behavioral Sciences, University of Washington, Seattle, WA 98104, USA.	Chronic fatigue and anxiety/depression: a twin study.	Br J Psychiatry. 2002 Jan;180:29-34.	BACKGROUND: Up to three-quarters of patients with fatigue syndromes have comorbid mood or anxiety disorders, suggesting that chronic fatigue is a forme fruste of anxiety or depressive states. AIMS: To establish whether the association of chronic fatigue with psychological distress is causal or due to a common genetic or environmental factor. METHOD: 69 monozygotic (MZ) and 31 dizygotic (DZ) female twin pairs, with only one co-twin reporting at least 6 months of fatigue, completed questions on fatigue, the General Health Questionnaire (GHQ) and a structured psychiatric interview. We examined the effects of three progressively more stringent definitions of chronic fatigue on four GHQ sub-scales. RESULTS: Fatigued MZ and DZ twins by all definitions were significantly more depressed, anxious, somatically preoccupied and socially dysfunctional than their non-fatigued co-twins. Intrapair differences were similar in DZ and MZ twins, but non-significant differences were observed for the somatic symptoms and anxiety/insomnia sub-scales. CONCLUSIONS: In this sample, chronic fatigue and psychological distress are strongly associated without evidence for genetic covariation, implying that the association is environmental, or due to overlapping definitions. Any genetic covariation missed is likely to involve anxiety rather than depression.
Sabath DE, Barcy S, Koelle DM, Zeh J, Ashton S, Buchwald D.	Department of Laboratory Medicine, Chronic Fatigue Syndrome Cooperative Research Center, University of Washington, Seattle, Washington 98195-7110, USA. dsabath@u.washington.edu	Cellular immunity in monozygotic twins discordant for chronic fatigue syndrome.	J Infect Dis. 2002 Mar 15;185(6):828-32. Epub 2002 Feb 28.	Studies elsewhere have suggested that immune dysfunction may be common in patients with chronic fatigue syndrome (CFS). The objective of this study was to assess the nature and extent of abnormalities in lymphocyte cell surface markers and NK cell activity in patients with CFS while controlling for genetic factors. A co-twin control study of immune system parameters was conducted for 22 pairs of monozygotic twins discordant for CFS and 9 healthy pairs of twins. The CFS twins had greater numbers of CD62L(+) T cells in several T cell subsets, although these differences did not achieve statistical significance. Significantly greater variability was noted in twins discordant for CFS than in the concordant healthy twins for 20 of 48 variables examined. The monozygotic co-twin control design is of unique value because of its ability to control for genetic influences on CFS; however, additional studies will be required to further assess immune dysregulation in this illness.
Sargent C, Scroop GC, Nemeth PM, Burnet RB, Buckley JD.	Exercise Physiology Research Unit, Department of Physiology, University of Adelaide, South Australia 5005, Australia.	Maximal oxygen uptake and lactate metabolism are normal in chronic fatigue syndrome.	Med Sci Sports Exerc. 2002 Jan;34(1):51-6. Comment in: Med Sci Sports Exerc. 2002 Oct;34(10):1691-2; author reply 1692-3.	PURPOSE: Previous studies in chronic fatigue syndrome (CFS) have reported reductions in maximal oxygen uptake (VO(2max)), yet often the testing procedures have not followed accepted guidelines, and gender data have been pooled. The present study was undertaken to reevaluate exercise capacity in CFS patients by using "gold standard" maximal exercise testing methodology and stratifying results on a gender basis. METHODS: Sixteen male and 17 female CFS patients and their gender-, age-, and mass-matched sedentary controls performed incremental exercise to volitional exhaustion on a stationary cycle ergometer while selected cardiorespiratory and metabolic variables were measured. RESULTS: VO(2max) in male CFS patients was not different from control values (CFS: 40.5 +/- 6.7; controls: 43.3 +/- 8.6; mL x kg(-1) x min(-1)) and was 96.3 +/- 17.9% of the age-predicted value, indicating no functional aerobic impairment (3.7 +/- 17.9%).

				In female CFS patients, VO(2max) was lower than control values (CFS: 30.0 +/- 4.7; controls: 34.2 +/- 5.6; mL x kg(-1) x min(-1), P = 0.002), but controls were higher than the age-predicted value (112.6 +/- 15.4%, P = 0.008) whereas the CFS patients were 101.2 +/- 20.4%, indicating no functional aerobic impairment (-1.2 +/- 20.4%). Maximal heart rate (HR(max)) in male CFS patients was lower than their matched controls (CFS: 184 +/- 10; controls: 192 +/- 12; beats x min(-1); P = 0.016) but was 99.1 +/- 5.5% of their age-predicted value. In female CFS patients, HR(max) was not different from controls (CFS: 183 +/- 11; controls: 186 +/- 10; beats x min(-1)) and was 98.9 +/- 5.1% of the age-predicted value. The VO(2) at the lactate threshold (LT) in each gender group, whether expressed in mL x kg(-1) x min(-1) or as a percentage of VO(2max), was not different between CFS patients and controls. CONCLUSIONS: In contrast to most previous reports, the present study found that VO(2max), HR(max), and the LT in CFS patients of both genders were not different from the values expected in healthy sedentary individuals of a similar age.
Schafer ML.	Klinikum der Philipps-Universitat Marburg, Klinik fur Psychiatrie und Psychotherapie, Germany.	[On the history of the concept neurasthenia and its modern variants chronic-fatigue-syndrome, fibromyalgia and multiple chemical sensitivities] [Article in German	Fortschr Neurol Psychiatr. 2002 Nov;70(11):570-82.	This article deals with the history of the terminological and nosological development of the concept neurasthenia introduced in 1869 by George Miller Beard and in particular with its reappearance in western medicine in the 1980 s. Beginning with its predecessors in antiquity and continuing with hypochondria, which became a fashionable disease in the 18 th century, the concept neurasthenia reached a high point and world-wide medical acceptance at the end of the 19 th/beginning of the 20 th century. However, between the 1930 s and 1960 s it declined in popularity and gradually disappeared until finally it only had a rudimentary nosological role in the term "pseudoneurasthenia". In the countries of the Far East, on the contrary, the concept of neurasthenia has been in continual use since its importation in the first decades of the last century. In the 1980 s, when an interest in the symptoms of chronic fatigue was reawakened in western medicine, the concept neurasthenia reappeared, this time to define the particular form of a neurotic disorder. Parallel to these developments increasing importance was attached to clinical descriptions of illnesses which on account of their similarity to the symptoms of neurasthenia could be termed modern variants of the concept neurasthenia. These are "Chronic-Fatigue-Syndrome", "Fibromyalgia" and "Multiple Chemical Sensitivities" which have more or less adopted the organic inheritance of Beard's former concept of neurasthenia, despite the fact that so far the question of organicity could not be decisively answered in a single case. In order to clarify possible influences on the development of the concept neurasthenia and its variants, the theories and ideas of E. Shorter, medical historian at the University of Toronto, are discussed in the final part of the article, whereby the particular cultural background in each case has a decisive influence on the manifestation of the psychosomatic symptoms.
Senna G, Gani F, Leo G, Schiappoli M.	Unita Operativa di Allergologia, Ospedale Civile Maggiore, Verona. gianenrico.senna@mail.azosp.vr.it	[Alternative tests in the diagnosis of food allergies] [Article in Italian]	Recenti Prog Med. 2002 May;93(5):327-34.	In the last years an increase of allergic diseases has been observed whose prevalence is about 20-30% in general population of western countries. However there is a risk of an over diagnosis of allergic diseases as many different diseases (migraine, chronic urticaria, chronic inflammatory bowel diseases, chronic-fatigue syndrome etc.) are considered due to food allergy or intolerance. In many patients the diagnosis is based on the results of alternative diagnostic tests such as the cytotoxic test, the provocation/neutralization sublingual or subcutaneous test, the heart-ear

				reflex test, the kinesiology, the biorisonance, the electro-acupuncture, and the hair analysis, or on immunological tests (immunocomplex or specific food IgG). We reviewed the scientific evidences of these tests (specificity, sensibility, rationale, reproducibility). According to most studies none of them had to be recommended as useful for the diagnosis of food allergy or intolerance. Physicians should alert patients about the risk of an indiscriminate use of these test in the diagnosis of food allergy. In fact the use of an incorrect diet could be dangerous, particularly in childhood, as recently shown.
Servaes P, Prins J, Verhagen S, Bleijenberg G.	Netherlands Fatigue Research Group, Department of Medical Psychology (118), University Medical Centre Nijmegen, P.O. Box 9101, 6500 HB Nijmegen, The Netherlands. p.servaes@cksmps.azn.nl	Fatigue after breast cancer and in chronic fatigue syndrome: similarities and differences.	J Psychosom Res. 2002 Jun;52(6):453-9.	OBJECTIVE: Fatigue is investigated in 57 severely fatigued disease-free breast cancer patients and in 57 gender- and age-matched patients with chronic fatigue syndrome (CFS) using multidimensional and multimethod assessment. A comparison between these groups of patients is important to determine whether a cognitive behavioural intervention to reduce fatigue in CFS patients would be appropriate as well for severely fatigued disease-free breast cancer patients. METHODS: Measurement included computerised questionnaires and a standardised neuropsychological test. Furthermore, patients filled out a daily Self-Observation List (SOL) and wore an actometer during a period of 12 days. RESULTS: In comparison to severely fatigued disease-free breast cancer patients, CFS patients score more problematic with regard to the level of fatigue, functional impairment, physical activity, pain and self-efficacy. However, a subgroup of severely fatigued disease-free breast cancer patients reports the same amount of problems as CFS patients with regard to psychological well-being, sleep and concentration. Finally, CFS patients and severely fatigued breast cancer patients score equal on measures of social support. CONCLUSION: There seem to be some similarities but also many differences between severely fatigued breast cancer survivors and females with CFS. Therefore, cognitive behaviour therapy (CBT) to reduce fatigue after treatment for cancer should also differ in certain aspects from cognitive behaviour therapy as it has been developed for patients with CFS.

Sharpe M.	University of Edinburgh. michael.sharpe@ed.ac.uk	The report of the Chief Medical Officer's CFS/ME working group: what does it say and will it	Clin Med. 2002 Sep-Oct;2(5):427-9. Comment in: Clin Med. 2002 Sep-Oct;2(5):389-90.	Chronic fatigue syndrome (CFS) sometimes known as myalgic encephalomyelitis or encephalopathy (ME) has long been a controversial topic. This year has seen the publication of a report from an independent working party set up by the UK Chief Medical Officer (CMO) to make recommendations for the management of the condition. The report makes a number of general recommendations about the provision of appropriate care and services. The more controversial

		help?		issues of what to call the illness, the nature of the illness and what treatment should be recommended are all addressed, but in the form of compromise rather than resolution. To the extent that this report is a step towards highlighting the needs not only of patients with CFS but the larger group of patients with symptom-defined conditions, it is to be welcomed. As a guide to management it raises as many questions as it answers. Much remains to be resolved before guidance that is both evidence based and acceptable to all parties is achieved.

Crit Rev Immunol. 2002;22(3):165-82.	The present review examines the cytokine response to acute exercise stress, with particular emphasis on the balance between proinflammatory and anti-inflammatory mechanisms, and the release of IL-6. Prolonged endurance exercise induces a sequenced release of pro- and anti-inflammatory cytokines, and IL-6 plays a dominant role. The magnitude of this response bears a general relationship to the intensity of effort, but the duration of activity and many environmental factors also modulate cytokine release. Although many types of cells are capable of producing cytokines, the main source of the exercise-induced IL-6 production appears to be the exercising muscle. The primary function of the additional IL-6 may be to regulate the supply of carbohydrate as muscle reserves of glycogen become depleted. There is also a delayed release of cytokines following eccentric exercise that is related to the repair of muscle injury. Since the production of cytokines is greater with endurance than with resistance exercise, it seems unlikely that they play an important role in the hypertrophy of muscle and bone. More research is needed on a number of important clinical issues where the exercise-induced release of cytokines may have relevance. Exercise-induced cytokine secretion has the potential to provide a simple model of sepsis. Preliminary observations suggest it may also modulate the risk of type 2 diabetes mellitus. Cytokine concentrations are increased in chronic fatigue syndrome, although it is less dear that the cytokine secretion is responsible for fatigue in humans. Exercise-induced modulations in cytokine secretion may contribute to allergies, bronchospasm, and upper respiratory infections in the endurance athlete. Further, the cytokine cascade is involved in the process of atherogenesis, and exercise-induced changes in cytokine production may expose

				latent HIV to chemotherapeutic agents.

Shetzline SE, Martinand-Mari C, Reichenbach NL, Buletic Z, Lebleu B, Pfleiderer W, Charubala R, De Meirleir K, De Becker P, Peterson DL, Herst CV, Englebienne P, Suhadolnik RJ.	Department of Biochemistry and the Fels Institute for Cancer Research and Molecular Biology, Temple University School of Medicine, Philadelphia, PA 19140, USA.	Structural and functional features of the 37-kDa 2-5A-dependent RNase L in chronic fatigue syndrome.	J Interferon Cytokine Res. 2002 Apr;22(4):443-56.	A 2',5'-oligoadenylate (2-5A)-dependent 37-kDa form of RNase L has been reported in extracts of peripheral blood mononuclear cells (PBMC) from individuals with chronic fatigue syndrome (CFS). In the current study, analytic gel permeation FPLC, azido photoaffinity labeling, two-dimensional (2-D) gel electrophoresis, and matrix-assisted laser desorption/ionization mass spectrometry (MALDI-MS) have been used to examine the biochemical relationship between the 80-kDa RNase L in healthy control PBMC and the 37-kDa RNase L in PBMC from individuals with CFS. Like the 80-kDa RNase L, the 37-kDa RNase L is present as a catalytically inactive heterodimer complex with the RNase L inhibitor (RLI). Formation of a 37-kDa RNase L-RLI complex indicates that the 37-kDa RNase L is structurally similar to the 80-kDa RNase L at the N-terminus, which contains the 2-5A binding domain. The enzymatically active monomer form of 37-kDa RNase L resolved by 2-D gel electrophoresis has a pI of 6.1. RT-PCR and Southern blot analyses demonstrated that the 37-kDa RNase L is not formed by alternative splicing. In-gel tryptic digestion of the 37-kDa RNase L that was excised from 2-D gels and subsequent MALDI-MS analysis identified three peptide masses that are identical to three predicted peptide masses in the 80-kDa RNase L. The electrophoretic mobility of 2-5A azido photolabeled/immunoprecipitated 37-kDa RNase L was the same under reducing and nonreducing conditions. The results presented show that the 37-kDa form of RNase L in PBMC shares structural and functional features with the native 80-kDa RNase L, in particular in the 2-5A binding and catalytic domains.
Short K, McCabe M, Tooley G.	School of Psychology, Deakin University, 221 Burwood Highway, Victoria 3125, Burwood, Australia.	Cognitive functioning in chronic fatigue syndrome and the role of depression, anxiety, and fatigue.	J Psychosom Res. 2002 Jun;52(6):475-83.	OBJECTIVE: This study was designed to investigate the role of depression, anxiety, and fatigue in Chronic Fatigue Syndrome (CFS) sufferers' objective and subjective cognitive performance. METHODS: Twenty-three CFS sufferers and 23 healthy control participants were compared on objective and subjective assessments of cognitive performance. Depression, anxiety, and fatigue were also evaluated. RESULTS: CFS sufferers did not demonstrate any impairment in objective cognitive functioning compared to the control group, and objective performance was not related to their higher levels of depression or their level of fatigue. Depression scores only accounted for a small amount of the variance in CFS sufferers' lower subjective assessment of their cognitive performance compared to control participants. There were no differences between the groups on anxiety scores. CONCLUSION: The results are discussed in terms of the heterogeneity of the CFS population and the complex interaction of symptomatological factors that characterise CFS.
Sigal LH, Hassett AL.	Division of Rheumatology and Connective Tissue Research, Department of Medicine, Lyme Disease Center,	Contributions of societal and geographical environments to "chronic Lyme disease": the psychopathogenesis	Environ Health Perspect. 2002 Aug;110 Suppl 4:607-11. Comment in: Environ Health Perspect. 2003 Feb;111(2):A76;	Lyme disease is a relatively well-described infectious disease with multisystem manifestations. Because of confusion over conflicting reports, anxiety related to vulnerability to disease, and sensationalized and inaccurate lay media coverage, a new syndrome, "chronic Lyme disease," has become established. Chronic Lyme disease is the most recent in a continuing series of "medically unexplained symptoms" syndromes. These syndromes, such as fibromyalgia, chronic fatigue syndrome, and multiple chemical sensitivity, meet the need for a societally and morally acceptable explanation for ill-defined symptoms in the absence of objective physical and

	University of Medicine and Dentistry of New Jersey-Robert Wood Johnson Medical School, New Brunswick, New Jersey 08903-0019, USA. sigallh@umdnj.edu	and aporology of a new "medically unexplained symptoms" syndrome.	author reply A77. Environ Health Perspect. 2003 Feb;111(2):A77; author reply A77.	laboratory findings. We describe factors involved in the psychopathogenesis of chronic Lyme disease and focus on the confusion and insecurity these patients feel, which gives rise to an inability to adequately formulate and articulate their health concerns and to deal adequately with their medical needs, a state of disorganization termed aporia.
Silver A, Haeney M, Vijayadurai P, Wilks D, Pattrick M, Main CJ.	Department of Psychological Medicine, John Radcliffe Hospital, Headington, Oxford, UK. amysilver@appleonline.net	The role of fear of physical movement and activity in chronic fatigue syndrome.	J Psychosom Res. 2002 Jun;52(6):485-93.	OBJECTIVE: To examine beliefs in relation to avoidance of activity in chronic fatigue syndrome (CFS) patients. METHODS: The first phase consisted of modifying an existing chronic pain measure of kinesiophobia-fear of physical movement and activity-and validating it on the CFS population [Tampa Scale of Kinesiophobia-Fatigue (TSK-F); n=129; test-retest: r=.89, P<.001; alpha=.68]. Subscales of Illness Beliefs (alpha=.78) and Beliefs about Activity (alpha=.70) were identified. The second phase consisted of evaluating whether behavioural persistence was predicted by the TSK-F (n=33). Participants were asked to ride an exercise bike for as long as they felt able. RESULTS: Analyses indicated that behavioural persistence did not correlate with maximal heart rate or resting heart rate, level of tiredness, symptom severity, illness identity or emotional distress. However, the TSK-F did correlate highly with distance travelled and added a significant 15% of the variance in distance after adjustments for gender and physical functioning (PF). The TSK-F Beliefs about Activity subscale appears to be the predictive factor, explaining 12% of the variance in excise performance or rather 12% of the avoidance of exercise. CONCLUSION: Beliefs about Activity appear to be an important variable in predicting behaviour and avoidance of exercise. As avoidance has been suggested as a key to the maintenance of symptoms, disability and distress in CFS patients, this research has important theoretical, clinical and research implications.
Silver DS, Wallace DJ.	Division of Rheumatology, Cedars-Sinai Medical Center, UCLA School of Medicine, Los Angeles, CA 90048, USA. davids@omcresearch.org	The management of fibromyalgia-associated syndromes.	Rheum Dis Clin North Am. 2002 May;28(2):405-17.	Most of the six million Americans with fibromyalgia have at least one associated syndrome which mandates specialized attention in addition to traditional therapeutic approaches. These include localized procedures, regional blocks, antiinflammatory or antimicrobial regimens, attention to non soft tissue sources of psychosocial distress, and classes of medicines not usually prescribed for fibromyalgia. The successful treatment of fibromyalgia-associated syndromes improves the symptoms, quality of life, and prognosis of fibromyalgia.
Sinaii N, Cleary SD, Ballweg ML, Nieman LK, Stratton P.	Pediatric and Reproductive Endocrinology Branch, National Institute of Child	High rates of autoimmune and endocrine disorders, fibromyalgia, chronic fatigue syndrome	Hum Reprod. 2002 Oct;17(10):2715-24.	BACKGROUND: Women with endometriosis may also have associated disorders related to autoimmune dysregulation or pain. This study examined whether the prevalence of autoimmune, chronic pain and fatigue and atopic disorders is higher in women with endometriosis than in the general female population. METHODS AND RESULTS: A cross-sectional survey was conducted in 1998 by the Endometriosis Association of 3680 USA members with surgically diagnosed

	Health and Human Development, NIH, 10 Center Drive, Building 10, Room 9D42, MSC 1583, Bethesda, MD 20892-1583, USA. sinaiin@mail.nih.gov	and atopic diseases among women with endometriosis: a survey analysis.		endometriosis. Almost all responders had pain (99%), and many reported infertility (41%). Compared with published rates in the general USA female population, women with endometriosis had higher rates of hypothyroidism (9.6 versus 1.5%, P < 0.0001), fibromyalgia (5.9 versus 3.4%, P < 0.0001), chronic fatigue syndrome (4.6 versus 0.03%, P < 0.0001), rheumatoid arthritis (1.8 versus 1.2%, P = 0.001), systemic lupus erythematosus (0.8 versus 0.04%, P < 0.0001), Sjogren's syndrome (0.6 versus 0.03%, P < 0.0001) and multiple sclerosis (0.5 versus 0.07%, P < 0.0001), but not hyperthyroidism or diabetes. Allergies and asthma were more common among women with endometriosis alone (61%, P < 0.001 and 12%, P < 0.001 respectively) and highest in those with fibromyalgia or chronic fatigue syndrome (88%, P < 0.001 and 25%, P < 0.001 respectively) than in the USA female population (18%, P < 0.001 and 5%, P < 0.001 respectively). CONCLUSIONS: Hypothyroidism, fibromyalgia, chronic fatigue syndrome, autoimmune diseases, allergies and asthma are all significantly more common in women with endometriosis than in women in the general USA population.
Singh A, Garg V, Gupta S, Kulkarni SK.	Pharmacology Division, University Institute of Pharmaceutical Sciences, Panjab University, Chandigarh 160 014, India.	Role of antioxidants in chronic fatigue syndrome in mice.	Indian J Exp Biol. 2002 Nov;40(11):1240-4.	The present study was carried out using mice model of chronic fatigue syndrome (CFS) in which mice were forced to swim everyday for 7 days for a 6 min session. There was a significant increase in despair behavior (immobility period) in saline treated mice on successive days. Treatment with potent antioxidants carvedilol (5 mg/kg, i.p.) and melatonin (10 mg/kg, i.p.) produced a significant reduction in immobility period. Similar results were observed with herbal products St. John's Wort (Hypericum perforatum L) (10 mg/kg, p.o.) and GS-02 (20 mg/kg, p.o.). Fluoxetine, a selective serotonin reuptake inhibitor produced a significant effect only on first and second day of its treatment. Biochemical analysis revealed that chronic swim test significantly increased lipid peroxidation and catalase levels in whole brains of mice. There was a decrease in the levels of super oxide dismutase (SOD) and glutathione reductase (GSH) in the brain. Administration of carvedilol, melatonin, GS-02 and St. John's Wort restored the levels of lipid peroxidation and glutathione. The enzymes SOD and catalase were also restored. Fluoxetine affected the biochemical variables not to the same extent as other treatments. The findings of the present study suggest that oxidative stress might play a significant role in the pathophysiology of CFS. Thus antioxidants and herbal products like St. Johns wort and GS-02 could be useful in the treatment of CFS.
Skowera A, Stewart E, Davis ET, Cleare AJ, Unwin C, Hull L, Ismail K, Hossain G, Wessely SC, Peakman M.	Department of Immunology, Guy's, King's & St Thomas' School of Medicine, King's College London, London, UK.	Antinuclear autoantibodies (ANA) in Gulf War-related illness and chronic fatigue syndrome (CFS) patients.	Clin Exp Immunol. 2002 Aug;129(2):354-8.	It is established that veterans of the 1991 Gulf War have an increased frequency of experiencing multiple symptoms. The underlying mechanism of these ailments is unclear, although they do not correspond to any clearly defined syndrome. The most common symptoms overlap with those of chronic fatigue syndrome (CFS). CFS was recently associated with a novel subtype of antinuclear autoantibody (ANA) that reacts with nuclear envelope (NE) antigens. NE autoantibodies are not known to be linked with any distinct clinical condition, but have been observed in patients with unusual mixed chronic autoimmune disorders and connective tissue diseases. In this study we examined whether NE ANAs are a feature of patients with CFS and symptomatic Gulf War veterans (sGWV). We studied the prevalence of ANA in 130 sGWV, 90 well Gulf War veterans (wGWV), 128 symptomatic Bosnia and Era veterans (sBEV), 100 CFS patients, and 111 healthy control subjects matching for age and sex. We found no significant difference in the prevalence of

				ANAs between any of the groups. None of the patients/or veterans we studied had ANA of the NE type. Our results show that multisymptom illness due to CFS or related to Gulf War service is not associated with antinuclear autoimmunity.
Slavkin HC.	School of Dentistry, University of Southern California Los Angeles, California, USA.	Distinguishing Mars from Venus: emergence of gender biology differences in oral health and systemic disease.	Compend Contin Educ Dent. 2002 Oct;23(10 Suppl):29-31.	We are learning to appreciate and understand that men and women have different genes and gene products (proteins), biochemistry and physiology, body weights and distribution of fats, and a few different tissues and organs. In such comparisons, we discover that women have a different prevalence for many oral and systemic diseases and disorders, and often illustrate differences in responses to disease mechanisms as well as to drug therapy and treatments. For example, consider the milestones of development, such as puberty or menopause, the unique differences in the prevalence of autoimmune diseases and disorders (Sjogren's syndrome, Hashimoto's disease), differences in the onset and progression of osteoporosis and osteoarthritis, differences in response to radiation and chemotherapy, and the differences in chronic facial pain, chronic fatigue syndrome, and fibromyalgia. This article highlights many opportunities to enhance the quality of oral health care for women.
Smith RC.	Michigan State University, East Lansing, USA.	Review: behavioral interventions show the most promise for the chronic fatigue syndrome.	ACP J Club. 2002 Mar-Apr;136(2):61. Comment on: JAMA. 2001 Sep 19;286(11):1360-8.	
Smits MG, Van Rooy R, Nagtegaal JE.		Influence of Melatonin on Quality of Life in Patients with Chronic Fatigue and Late Melatonin Onset	Journal of Chronic Fatigue Syndrome Volume 2002; 10 (3/4): 25 - 32	Medical Outcome Study Short Form-36 (MOS SF-36) qualities of life scores were studied in 38 chronic fatigue patients with late melatonin onset before and after treatment with melatonin. Before start of the treatment, quality of life was assessed twice. Pre-treatment scores were compared with each other and with the scores of 43 patients with Delayed Sleep Phase Syndrome and of 1063 healthy subjects. Melatonin, 5 mg, was taken orally, 5 hours before baseline salivary endogenous dim light melatonin onset. After mean (SD) treatment of 13.7 (0.8) weeks, quality of life scores "physical functioning," "energy/vitality," "bodily pain," and "general health perception" improved (p values, respectively, 0.017, 0.002, 0.002 and 0.009). In the pre-treatment period (mean [SD] interval: 6.5 [0.6] weeks) "social functioning" and "general health perception" improved (p = 0.013 and 0.010, respectively). In the chronic fatigue patients the quality of life scores did not differ from those of the Delayed Sleep Phase Syndrome patients, except for "physical functioning," "energy/vitality" and "general health perception." These were significantly lower. All chronic fatigue patient's scores were significantly lower than those of the healthy subjects except for "health transition."
Snell CR, Vanness JM, Strayer DR, Stevens SR.	Department of Sport Sciences, University of the Pacific, 3601 Pacific Avenue, Stockton, CA 95211-0197, USA.	Physical performance and prediction of 2-5A synthetase/RNase L antiviral pathway activity in patients with chronic fatigue	In Vivo. 2002 Mar-Apr;16(2):107-9.	The elevated RNase L enzyme activity observed in some Chronic Fatigue Syndrome (CFS) patients may be linked to the low exercise tolerance and functional impairment that typify this disease. The purpose of this investigation was to determine if specific indicators of physical performance can predict abnormal RNase L activity in CFS patients. Seventy-three CFS patients performed a graded exercise test to voluntary exhaustion. Forty-six patients had elevated RNase L levels. This measure was employed as the dependent variable in a discriminant function analysis, with peak V02, exercise duration and Karnofsky Performance Scores (KPS) serving as the independent

		syndrome.		variables. All three variables entered the single significant function ($p < 0.001$). The elevated RNase L group had a lower peak V02 and duration than the normal group, but a higher KPS. The results suggest that both exercise testing and the RNase L biomarker have potential to aid in the diagnosis of CFS.

Sullivan PF, Smith W, Buchwald D.	Virginia Institute for Psychiatric and Behavioral Genetics, Virginia Commonwealth University,	Latent class analysis of symptoms associated with chronic fatigue syndrome and fibromyalgia.	Psychol Med. 2002 Jul;32(5):881-8.	BACKGROUND: Chronic fatigue syndrome and fibromyalgia continue to be perplexing conditions of unknown validity. Aetiological and symptomatic heterogeneity is likely and the distinctiveness of these disorders remains unclear. Our aims were to investigate empirically symptomatic heterogeneity in chronic fatigue syndrome and fibromyalgia. METHODS: Latent class analysis was applied to data from 646 patients who met accepted criteria for chronic fatigue syndrome and/or fibromyalgia who were systematically evaluated at a specialist fatigue clinic. Thirty-two

	Richmond 23298-0126, USA.			symptoms commonly found in chronic fatigue syndrome and fibromyalgia were entered into the latent class analysis. RESULTS: We chose to interpret a four class solution. The classes appeared to differ in a graded fashion (rather than qualitatively) for symptom endorsements, pre-morbid characteristics, and co-morbidity with panic disorder and major depression. CONCLUSIONS: These results were unexpected given the usual assumption of the distinctiveness of chronic fatigue syndrome and fibromyalgia. These results support a conceptualization of chronic fatigue syndrome and fibromyalgia as being characterized by greater similarities than differences.
Sundbom E, Henningsson M, Holm U, Soderbergh S, Evengard B.	Department of Psychology, Umea University, Sweden. elisabet.sundbom@psy.umu.se	Possible influence of defenses and negative life events on patients with chronic fatigue syndrome: a pilot study.	Psychol Rep. 2002 Dec;91(3 Pt 1):963-78.	13 patients with a diagnosis of chronic fatigue syndrome and two contrast groups of conversion disorder patients (n = 19) and healthy controls (n = 13) were assessed using the projective perceptual Defense Mechanism Test to investigate if specific defense patterns are associated with chronic fatigue syndrome. Another objective was to assess the possible influence of perceived negative life events prior the onset of the illness. The overall results showed significant differences in defensive strategies among groups represented by two significant dimensions in a Partial Least Squares analysis. Compared to the contrast groups the patients with chronic fatigue syndrome were distinguished by a defense pattern of different distortions of aggressive affect, induced by an interpersonal anxiety-provoking stimulus picture with short exposures. Their responses suggested the conversion group was characterized by a nonemotionally adapted pattern and specific constellations of defenses, associated with interior reality orientation compared to the patients with chronic fatigue syndrome and the healthy controls. Rated retrospectively, the group with chronic fatigue syndrome reported significantly more negative life events prior to the onset of their illness than healthy controls. For instance, 5 of the 13 patients reported sexual assault or physical battery as children or teenagers compared to none of the healthy controls. A significant association was found between defense pattern and frequency of reported negative life events. However, these retrospective reports might be confounded to some extent by the experience of the patients' illness; for example, the reports may be interpreted in terms of present negative affect.
Swinkels DW, Aalbers N, Elving LD, Bleijenberg G, Swanink CM, van der Meer JW.	Department of Clinical Chemistry 564, University Medical Centre St Radboud, PO Box 9101, 6500 HB Nijmegen, The Netherlands. D.Swinkels@CKCL.azn.nl	Primary haemochromatosis: a missed cause of chronic fatigue syndrome?	Neth J Med. 2002 Dec;60(11):429-33. Comment in: Neth J Med. 2002 Dec;60(11):419-22.	OBJECTIVE: To determine whether patients previously diagnosed as chronic fatigue syndrome (CFS) actually have primary haemochomatosis (PH). METHODS: The setting was a Dutch referral centre. Transferrin saturation (TS) was retrospectively evaluated in banked blood samples of 88 patients diagnosed as CFS. Patients with elevated TS values were asked to provide a new overnight fasting blood sample for a second determination of TS and measurement of serum ferritin. The DNA was investigated for mutations in the HFE gene when one of these iron parameters was elevated. RESULTS: For 19 out of 88 patients with CFS an elevated TS was found. A new blood sample was obtained from 11 of these 19: six had increased TS and two had elevated serum ferritin values. These eight patients were neither C282Y homozygotes nor compound C282Y-H63D heterozygotes. In the eight cases where no new blood samples could be obtained, the TS was > 50% for two of the five men and < 45% for the three female patients. CONCLUSION: In a group of 88 CFS patients we could exclude PH in all but two of them (prevalence 2.3%; 95% confidence interval 0-5.5%). In our population of CFS patients PH is not more common than in a control population of northern European descent (prevalence 0.25-

				0.50%).
Sykes R.	Chronic fatigue syndrome/myalgic encephalitis.		Br J Gen Pract. 2002 Sep;52(482):762-3; author reply 763-4. Comment on: Br J Gen Pract. 2002 May;52(478):355-6.	
Taillefer SS, Kirmayer LJ, Robbins JM, Lasry JC.	Department of Psychology, Universite de Montreal, Canada.	Psychological correlates of functional status in chronic fatigue syndrome.	J Psychosom Res. 2002 Dec;53(6):1097-106.	BACKGROUND: The present study was designed to test a cognitive model of impairment in chronic fatigue syndrome (CFS) in which disability is a function of severity of fatigue and depressive symptoms, generalized somatic symptom attributions and generalized illness worry. METHODS: We compared 45 CFS and 40 multiple sclerosis (MS) outpatients on measures of functional ability, fatigue severity, depressive symptoms, somatic symptom attribution and illness worry. RESULTS: The results confirmed previous findings of lower levels of functional status and greater fatigue among CFS patients compared to a group of patients with MS. Fatigue severity was found to be a significant predictor of physical functioning but not of psychosocial functioning in both groups. In CFS, when level of fatigue was controlled, making more somatic attributions was associated with worse physical functioning, and both illness worry and depressive symptoms were associated with worse psychosocial functioning. CONCLUSIONS: Our findings support the role of depression and illness cognitions in disability in CFS sufferers. Different cognitive factors account for physical and psychosocial disability in CFS and MS. The SF-36 may be sensitive to symptom attributions, suggesting caution in its interpretation when used with patients with ill-defined medical conditions.
Tamizi far B, Tamizi B.	Department of Research, Isfahan University of Medical Sciences, Shahrekord, Isfahan, Iran. babak360@yahoo.com	Treatment of chronic fatigue syndrome by dietary supplementation with omega-3 fatty acids--a good idea?	Med Hypotheses. 2002 Mar;58(3):249-50.	Minor alterations of immune, neuroendocrine, and autonomic function may be associated with the chronic fatigue syndrome. omega-3 fatty acids decrease the production of putative mediators of inflammation, including interleukin-1, and tumor necrosis factor. Since interleukin-1 and tumor necrosis factor are the principal polypeptide mediators of immunoregulation, reduced production of these cytokines by dietary supplementation with omega-3, may be a possible mechanism for the treatment of chronic fatigue syndrome. Tan EM, Sugiura K, Gupta S.	W.M. Keck Autoimmune Disease Center, The Scripps Research Institute, La Jolla, California 92037, USA.	The case definition of chronic fatigue syndrome.	J Clin Immunol. 2002 Jan;22(1):8-12.	The 1994 case definition of chronic fatigue syndrome is widely used not only for diagnosis but also for clinical and laboratory-based observations of this clinical entity. The criteria for the 1994 case definition are based primarily on symptoms and not on physical signs or chemical or immunological tests. This situation has resulted in conflicting clinical and laboratory observations that in all likelihood is due to different populations of patients being studied in different centers. Based on some of the recent publications, there appears to be an emerging picture of this disease entity that we propose could be used to subgroup chronic fatigue syndrome into four different subclasses. These subclasses would consist of chronic fatigue with primarily nervous system disorders such as impaired memory or concentration and headache, chronic fatigue with primarily endocrine system disorders such as unrefreshing sleep and postexertional malaise,

				chronic fatigue with musculoskeletal system disorders such as muscle pain and joint pain, and chronic fatigue with immune system/infectious disorders such as sore throat and tender lymph nodes. It is suggested that if clinical and laboratory-based studies on chronic fatigue syndrome were conducted on more homogeneous subgroups of patients, the data from one center to the other might not be as conflicting and more insights can be shed on the nature of this clinical condition.
Tanaka H, Matsushima R, Tamai H, Kajimoto Y.	Department of Pediatrics, Osaka Medical College, Takatsuki-shi, Japan.	Impaired postural cerebral hemodynamics in young patients with chronic fatigue with and without orthostatic intolerance.	J Pediatr. 2002 Apr;140(4):412-7. Comment in: J Pediatr. 2002 Apr;140(4):387-9. J Pediatr. 2003 Feb;142(2):217; author reply 217-8.	OBJECTIVES: To measure postural changes in cerebral hemodynamics in young patients with chronic fatigue with and without orthostatic intolerance. STUDY DESIGN: We studied 28 patients (age, 10 to 22 years) and 20 healthy control subjects (age, 6 to 27 years). Cerebral oxygenated hemoglobin (oxy-Hb) and deoxygenated Hb were noninvasively and continuously measured with near infrared spectroscopy during active standing. Beat-to-beat arterial pressure was monitored by Finapres. RESULTS: Orthostatic intolerance determined by cardiovascular responses to standing was observed in 16 of 28 patients: instantaneous orthostatic hypotension in 8, delayed orthostatic hypotension in 2, and postural orthostatic tachycardia in 6. A rapid recovery of oxy-Hb by near infrared spectroscopy at the onset of active standing was not found in 15 of 16 patients with chronic fatigue and orthostatic intolerance and in 6 of 12 patients with chronic fatigue without orthostatic intolerance but only in 2 of 20 control subjects. Thirteen of 16 patients with orthostatic intolerance showed prolonged reduction in oxy-Hb during standing. CONCLUSIONS: Impaired cerebral hemodynamics in patients with chronic fatigue syndrome and postural orthostatic tachycardia suggest a link between impaired cerebral oxygenation and chronic fatigue. However, this cannot explain the symptoms in patients meeting the criteria of chronic fatigue without orthostatic intolerance.
Taylor RR, Jason LA, Curie CJ.	Department of Psychology, DePaul University, 2219 North Kenmore Avenue, Chicago, IL 60614, USA.	Prognosis of chronic fatigue in a community-based sample.	Psychosom Med. 2002 Mar-Apr;64(2):319-27.	OBJECTIVE: This study examined predictors of fatigue severity and predictors of continued chronic fatigue status at wave 2 follow-up within a random, community-based sample of individuals previously evaluated in a wave 1 prevalence study of chronic fatigue and chronic fatigue syndrome that originally took place between 1995 and 1997. METHODS: Wave 1 data were from a larger community-based prevalence study of chronic fatigue syndrome. In the present study, a second wave of data were collected by randomly selecting a sample of participants from the wave 1 sample of 18,675 adults and readministering a telephone screening questionnaire designed to assess symptoms of chronic fatigue syndrome. RESULTS: Findings revealed that wave 1 fatigue severity was a predictor of fatigue severity at wave 2 in the overall sample of individuals with and without chronic fatigue. In the smaller sample of individuals with chronic fatigue, wave 1 fatigue severity, worsening of fatigue with physical exertion, and feeling worse for 24 hours or more after exercise significantly predicted continued chronic fatigue status (vs. improvement) at wave 2 follow-up. CONCLUSIONS: These findings underscore the prognostic validity of postexertional malaise in predicting long-term chronic fatigue and also highlight the importance of using population-based, representative random samples when attempting to identify long-term predictors of chronic fatigue at follow-up.
Taylor RR, Jason LA.	Department of Psychology, DePaul	Chronic fatigue, abuse-related	Soc Sci Med. 2002 Jul;55(2):247-56.	The relationship between sexual and physical abuse history and negative health effects has been well-documented in medical facility samples. Few studies have examined the role of abuse

	University, Chicago, IL 60614, USA. rtaylor@wppost.depaul.edu	traumatization, and psychiatric disorders in a community-based sample.		history and its relationship with chronic fatigue and psychiatric disorders in a diverse, randomly selected community-based sample. The present study compared rates of different types of abuse events in individuals with chronic fatigue and non-symptomatic controls. Relationships between specific types of abuse and psychiatric disorders commonly associated with chronic fatigue were also explored. A stratified random sample of 18,675 adults residing in ethnically and socioeconomically diverse neighborhoods in Chicago first completed a telephone screening questionnaire. A control group and a group of individuals with chronic fatigue symptomatology were identified and administered a semi-structured psychiatric interview assessing DSM-IV Axis I psychiatric disorders and a sexual and physical abuse history questionnaire. Controlling for sociodemographic differences, fatigue outcome was significantly predicted by childhood sexual abuse and the total number of different childhood abuse events. Within the chronic fatigue group, diagnosis of posttraumatic stress disorder (PTSD) was significantly predicted by childhood sexual abuse, childhood death threat, the total number of childhood abuse events, and lifetime abuse events. Sexual abuse during adolescence or adulthood significantly predicted other anxiety disorders among individuals with chronic fatigue. These findings suggest that a history of abuse, particularly during childhood, may play a role in the development and perpetuation of a wide range of disorders involving chronic fatigue. Among individuals with chronic fatigue, PTSD and other anxiety disorders appear to demonstrate the strongest association with abuse history. The implications of these findings are discussed.
Thorn A.	Karolinska Institutet, Department of Public Health Sciences, Stockholm, Sweden. ake.thorn@nll.se	Methodologic aspects of the study of modern-age diseases: the example of sick-building syndrome.	Int J Occup Environ Health. 2002 Oct-Dec;8(4):363-70.	In recent decades, variously identified nebulous disorders such as sick-building syndrome, electrical hypersensitivity, and chronic fatigue syndrome, characterized by combinations of nonspecific symptoms and absence of demonstrable signs have appeared. Their similar nonspecific etiologic attributions have given rise to generic names such as "modern-age disease" and "symptom-based conditions." The lack of demonstrable biological correlates as well as the vagueness of the etiologic attributions makes modern-age diseases unusually problematic to study with epidemiologic methods, potentially leading to serious biases. Case studies of sick-building syndrome demonstrate that qualitative methods can help to elucidate the dynamic processes involved in syndrome development.
Timmers HJ, Wieling W, Soetekouw PM, Bleijenberg G, Van Der Meer JW, Lenders JW.	Department of General Internal Medicine, University Medical Center St. Radboud, P. O. Box 9101, 6500 HB Nijmegen, The Netherlands.	Hemodynamic and neurohumoral responses to head-up tilt in patients with chronic fatigue syndrome.	Clin Auton Res. 2002 Aug;12(4):273-80.	BACKGROUND: Data on the prevalence of orthostatic intolerance (OI) in patients with chronic fatigue syndrome (CFS) are limited and controversial. We tested the hypothesis that a majority of CFS patients exhibit OI during head-up tilt. METHODS: Hemodynamic and neurohumoral responses to 40 minutes of head-up tilt were studied in 36 CFS patients and 36 healthy controls. Changes in stroke volume, cardiac output and peripheral vascular resistance were estimated from finger arterial pressure waveform analysis (Modelflow). Blood samples were drawn before and at the end of head-up tilt for measurement of plasma catecholamines. RESULTS: At baseline, supine heart rate was higher in CFS patients (CFS: 66.4 +/- 8.4 bpm; controls: 57.4 +/- 6.6 bpm; $p < 0.001$) as was the plasma epinephrine level (CFS: 0.11 +/- 0.07 nmol/l; controls: 0.08 +/- 0.07 nmol/l: $p = 0.015$). An abnormal blood pressure and/or heart rate response to head-up tilt was seen in 10 (27.8 %) CFS patients (6 presyncope, 2 postural tachycardia, 2 tachycardia and presyncope) and 6 (16.7 %, $p = 0.26$) controls (5 presyncope, 1 tachycardia, 2 tachycardia and presyncope). Head-up

				tilt-negative CFS patients showed a larger decrease in stroke volume during tilt (-46.9 +/- 10.6) than head-up tilt-negative controls (-40.3 +/- 13.6 %, p = 0.008). Plasma catecholamine responses to head-up tilt did not differ between these groups. CONCLUSION: Head-up tilt evokes postural tachycardia or (pre)syncope in a minority of CFS patients. The observations in head-up tilt-negative CFS patients of a higher heart rate at baseline together with a marked decrease in stroke volume in response to head-up tilt may point to deconditioning.
Torres-Harding SR, Jason LA, Cane V, Carrico A, Taylor RR.	DePaul University, USA. storres@depaul.edu	Physicians' diagnoses of psychiatric disorders for people with chronic fatigue syndrome.	Int J Psychiatry Med. 2002;32(2):109-24.	OBJECTIVE: To examine rates of psychiatric diagnoses given by patients' primary or regular physicians to persons with chronic fatigue syndrome (CFS), persons with psychiatrically explained fatigue, and a control group. Physicians' psychiatric diagnosis and participants' self-reported psychiatric diagnoses were compared to lifetime psychiatric diagnoses as measured by a structured psychiatric interview. METHOD: Participants were recruited as part of a community-based epidemiology study of chronic fatigue syndrome. Medical records of 23 persons with chronic fatigue syndrome, 25 persons with psychiatrically explained chronic fatigue, and 19 persons without chronic fatigue (controls) were examined to determine whether their physician had given a diagnosis of mood, anxiety, somatoform, or psychotic disorder. Lifetime psychiatric status was measured using the Structured Clinical Interview for the DSM-IV (SCID). Participants' self reports of specific psychiatric disorders were assessed as part of a detailed medical questionnaire. RESULTS: Physicians' diagnosis of a psychiatric illness when at least one psychiatric disorder was present ranged from 40 percent in the psychiatrically explained group, 50 percent in the control group, and 64.3 percent in the CFS group. Participants in the psychiatrically explained group were more accurate than physicians in reporting the presence of a psychiatric disorder, and in accurately reporting the presence of a mood or anxiety disorder. CONCLUSIONS: The present investigation found underrecognition of psychiatric illness by physicians, with relatively little misdiagnosis of psychiatric illness. Physicians had particular difficulty assessing psychiatric disorder in those patients whose chronic fatigue was fully explained by a psychiatric disorder. Results emphasized the importance of using participant self report as a screening for psychiatric disorder.
Tournier JN, Drouet E, Jouan A.	Departement de biologie des agents transmissibles, Centre de recherches du service de sante des armees, 24, avenue des maquis du Gresivaudan, BP 87, F38702 La Tronche. j.tournier@eudoramail.com	[The Gulf war syndrome] [Article in French]	Presse Med. 2002 Jan 12;31(1 Pt 1):3-9.	SPARSE DATA: The Gulf war syndrome remains a little know entity since its first appearance 10 years ago. The objective of our work was to synthesize the data published on the subject in the scientific literature. We analysed the results of American and English epidemiological surveys, from which it was difficult to distinguish the existence of a univocal syndrome. IMPRECISE DEFINITION: It is difficult to give a clear clinical definition of the syndrome, the signs of which fluctuate depending on the studies. Chronic fatigue is frequently associated with the Gulf war syndrome, although some studies have described electrophysiological neurological lesions. NUMEROUS HYPOTHESES: The role of stress, vaccinations and their adjuvants, exposition to neurotoxic substances and weak uranium have been incriminated. We propose that multiple factors be integrated in the research for the genesis of this atypic syndrome.

van der Werf SP, de Vree B, Alberts M, van der Meer JW, Bleijenberg G; Netherlands Fatigue Research Group Nijmegen.	Department of Medical Psychology, University Medical Centre, Post Box 9101, 6500 HB Nijmegen, The Netherlands. s.vanderwerf@cksmps.azn.nl	Natural course and predicting self-reported improvement in patients with chronic fatigue syndrome with a relatively short illness duration.	J Psychosom Res. 2002 Sep;53(3):749-53.	OBJECTIVE: To describe the course of fatigue in chronic fatigue syndrome (CFS) patients with a relatively short duration of complaints and to test which psychosocial factors predict spontaneous improvement 1 year later. METHODS: Seventy-nine patients with a complaint duration of less than 2 years were tested at baseline and 78 of the same group at 1-year follow-up. During this time period, no systematic intervention took place. Self-reported improvement and fatigue severity were the main outcome measures. RESULTS: Forty-six percent (95% confidence intervals, 95CI = 35-58%) of the patients with a short illness duration reported to be improved. This was a significantly (chi(2) = 20.3, P < .001) higher percentage compared to the 20% (95CI = 15-26%) self-reported improvement in a previously published natural-course study among 246 CFS patients with a longer illness duration. Persistence of complaints after 1-year follow-up was associated with high baseline levels of experienced concentration problems, less strong psychosocial causal explanations for the complaints, and higher levels of the experienced lack of social support. Baseline fatigue severity predicted fatigue severity at follow-up. CONCLUSION: The results showed that CFS patients with a relatively short duration of complaints had a more favourable outcome compared to patients with a long illness duration. The data also indicated that complete recovery only occurred in patients with a complaint duration of less than 15 months. This finding has important implications, since it suggests that after such a time period spontaneous recovery hardly occurs. Copyright 2002 Elsevier Science Inc.
van der Werf SP, de Vree B, van Der Meer JW, Bleijenberg G.	Department of Medical Psychology, University Medical Center Nijmegen, the Netherlands. S.vanderWerf@cksmps.AZN.NL	The relations among body consciousness, somatic symptom report, and information processing speed in chronic fatigue syndrome.	Neuropsychiatry Neuropsychol Behav Neurol. 2002 Mar;15(1):2-9.	OBJECTIVE: The aim of this study was to assess the potential influence of body consciousness and levels of somatic symptom report upon information processing speed in patients with chronic fatigue syndrome (CFS). BACKGROUND: According to a model of a fixed information processing capacity, it was predicted that in a group of patients with CFS, high body consciousness in combination with a high report of somatic symptoms would affect information-processing speed negatively. METHODS: Information- and motor-processing speed were simultaneously measured with a simple- and a choice-reaction time task, whereas cognitive complaints were rated with two questionnaires. The hypothesized influence of private body consciousness and somatic symptom report upon information-processing speed was tested in a model. A symptom-validity test was used to screen for possible illness behavior. RESULTS: Private body consciousness was directly related to information-processing speed and somatic symptom report. Somatic symptom report was related to both test performance and memory and concentration complaints. CONCLUSIONS: Levels of private body consciousness directly affected somatic symptom report and information-processing speed. This finding supports the role of attentive processes in CFS, and offers, besides possible cerebral dysfunction, an alternative explanation for slowing of information processing in CFS.
Van Heck GL, De Vries J.		Quality of Life of Patients with Chronic Fatigue Syndrome	Journal of Chronic Fatigue Syndrome 2002; 10 (1): 17 - 35	The purpose of this study was to compare quality of life between patients with Chronic Fatigue Syndrome (CFS; n = 73) and healthy controls (n = 147), using a broad and generic quality of life assessment instrument, the World Health Organization Quality of Life assessment (WHOQOL-100). Partricipants were assessed on the WHOQOL-100, a self-assessment instrument designed

				for quantifying 24 facets relating to quality of life. These facets are groups into six larger domains: physical health, psychological health, level of independence, social relationships, environment, and spirituality. The WHOQOL-100 also includes one facet examining the overall quality of life and general health perceptions. Analyses revealed that the CFS group reported significantly lower levels of quality of life than the control group on overall quality of life and general health perceptions and on 22 out of the 24 facets of quality of life. Compared to earlier studies that used health-status scales or rather limited quality of life measures, this study generated a more complete picture of the problems of patients with CFS. The results suggest that the impact of CFS on the patients' lives is very profound. CFS has a quality-of-life burden that affects a wide range of factors inherent to quality of life. Questions that must be addressed by future research are considered.
Van Houdenhove B, Neerinckx E, Onghena P, Vingerhoets A, Lysens R, Vertommen H.	Faculty of Medicine, K.U. Leuven, Leuven, Belgium. Boudewijn.VanHoudenhove@uz.kuleuven.ac.be	Daily hassles reported by chronic fatigue syndrome and fibromyalgia patients in tertiary care: a controlled quantitative and qualitative study.	Psychother Psychosom. 2002 Jul-Aug;71(4):207-13.	BACKGROUND: This study aimed at providing insight in the frequency, emotional impact and nature of daily hassles, experienced by patients suffering from chronic fatigue syndrome (CFS) and/or fibromyalgia (FM), compared with patients with a chronic organic disease. METHODS: One hundred and seventy-seven CFS/FM patients, 26 multiple sclerosis (MS) and 26 rheumatoid arthritis (RA) patients were investigated within 2-6 months after diagnosis. All patients completed a self-report questionnaire assessing daily hassles and associated distress, a visual analogue scale assessing fatigue and pain and a depression and anxiety questionnaire. RESULTS: CFS/FM patients show a higher frequency of hassles, higher emotional impact and higher fatigue, pain, depression and anxiety levels compared with MS/RA patients. Three hassle themes dominate in the CFS/FM group: dissatisfaction with oneself, insecurity and a lack of social recognition. In contrast, hassles reported by MS/RA patients show a much larger diversity and are not focused on person-dependent problems. CONCLUSIONS: Patients recently diagnosed as suffering from CFS and/or FM are highly preoccupied and distressed by daily hassles that have a severe impact on their self-image, as well as their personal, social and professional functioning. An optimal therapeutic approach of CFS and FM should take account of this heavy psychosocial burden, which might refer to core themes of these patients' illness experience. Copyright 2002 S. Karger AG, Basel

Vernon SD, Shukla SK, Conradt J, Unger ER, Reeves WC.	Division of Viral and Rickettsial Diseases, National Center for Infectious Diseases, Centers for Disease Control and Prevention, Atlanta, GA 30333, USA. svernon@cdc.gov	Analysis of 16S rRNA gene sequences and circulating cell-free DNA from plasma of chronic fatigue syndrome and non-fatigued subjects.	BMC Microbiol. 2002 Dec 23;2(1):39.	BACKGROUND: The association of an infectious agent with chronic fatigue syndrome (CFS) has been difficult and is further complicated by the lack of a known lesion or diseased tissue. Cell-free plasma DNA could serve as a sentinel of infection and disease occurring throughout the body. This type of systemic sample coupled with broad-range amplification of bacterial sequences was used to determine whether a bacterial pathogen was associated with CFS. Plasma DNA from 34 CFS and 55 non-fatigued subjects was assessed to determine plasma DNA concentration and the presence of bacterial 16S ribosomal DNA (rDNA) sequences. RESULTS: DNA was isolated from 81 (91%) of 89 plasma samples. The 55 non-fatigued subjects had higher plasma DNA concentrations than those with CFS (average 151 versus 91 ng) and more CFS subjects (6/34, 18%) had no

				detectable plasma DNA than non-fatigued subjects (2/55, 4%), but these differences were not significant. Bacterial sequences were detected in 23 (26%) of 89. Only 4 (14%) CFS subjects had 16S rDNA sequences amplified from plasma compared with 17 (32%) of the non-fatigued (P = 0.03). All but 1 of the 23 16S rDNA amplicon-positive subjects had five or more unique sequences present. CONCLUSIONS: CFS subjects had slightly lower concentrations or no detectable plasma DNA than non-fatigued subjects. There was a diverse array of 16S rDNA sequences in plasma DNA from both CFS and non-fatigued subjects. There were no unique, previously uncharacterized or predominant 16S rDNA sequences in either CFS or non-fatigued subjects.
Vernon SD, Unger ER, Dimulescu IM, Rajeevan M, Reeves WC.	Division of Viral and Rickettsial Diseases, National Center for Infectious Diseases, Centers for Disease Control and Prevention, Atlanta, GA 30333, USA.	Utility of the blood for gene expression profiling and biomarker discovery in chronic fatigue syndrome.	Dis Markers. 2002;18(4):193-9.	Chronic fatigue syndrome (CFS) is a debilitating illness lacking consistent anatomic lesions and eluding conventional laboratory diagnosis. Demonstration of the utility of the blood for gene expression profiling and biomarker discovery would have implications into the pathophysiology of CFS. The objective of this study was to determine if gene expression profiles of peripheral blood mononuclear cells (PMBCs) could distinguish between subjects with CFS and healthy controls. Total RNA from PBMCs of five CFS cases and seventeen controls was labeled and hybridized to 1764 genes on filter arrays. Gene intensity values were analyzed by various classification algorithms and nonparametric statistical methods. The classification algorithms grouped the majority of the CFS cases together, and distinguished them from the healthy controls. Eight genes were differentially expressed in both an age-matched case-control analysis and when comparing all CFS cases to all controls. Several of the diffrentially expressed genes are associated with immunologic functions (e.g., CMRF35 antigen, IL-8, HD protein) and implicate immune dysfunction in the pathophysiology of CFS. These results successfully demonstrate the utility of the blood for gene expression profiling to distinguish subjects with CFS from healthy controls and for identifying genes that could serve as CFS biomarkers.

Walach H, Bosch H, Haraldsson E, Marx A, Tomasson H, Wiesendanger H, Lewith G.	Institute of Environmental Medicine and Hospital Epidemiology, University Hospital Freiburg, Germany. walach@ukl.uni-freiburg.de	Efficacy of distant healing--a proposal for a four-armed randomized study (EUHEALS).	Forsch Komplementarmed Klass Naturheilkd. 2002 Jun;9(3):168-76.	BACKGROUND: Distant healing as a treatment modality is frequently used by patients and healers. Some preliminary evidence suggests possible effects. Since patients suffering from multiple chemical sensitivity and chronic fatigue syndrome have only few effective treatment options, distant healing will be offered as a treatment within a formal trial of distant healing. DESIGN AND METHOD: A four-armed randomized trial will include 400 patients with self-attributed, environmental problems who fulfil the diagnostic criteria of severe idiopathic chronic fatigue, chronic fatigue syndrome or multiple chemical sensitivity. Patients will be recruited by specialized general practitioners and environmental clinics. They will be treated by healers distributed all over Europe, coming from various healing traditions and nationalities. Each patient will be treated by 3 healers. Healers will have no contact with the patients and will only be

				provided with the patient's Christian name and a photograph. The patients will be randomized to one of 4 groups in a 2 x 2 factorial design. They will either receive (distant) healing or not, and either know or not know this decision. Thereby the effects of expectation and of time can be disentangled from the specific effects of healing. OUTCOME MEASURE: Primary outcome measure will be the mental health summary scale of the MOS SF-36. The measure will be taken at the beginning and at the end of a 6- month treating or waiting period, respectively. A variety of moderator variables will be considered to evaluate which of these may be predictive of outcome. Copyright 2002 S. Karger GmbH, Freiburg

Department of Psychological Medicine, Barts and the London, Queen Mary's School of Medicine and Dentistry, University of London, London EC1A 7BE, UK. p.d.white@qmul.ac.uk	A comparison of patients with chronic fatigue syndrome attending separate fatigue clinics based in immunology and psychiatry.	J R Soc Med. 2002 Sep;95(9):440-4.	Hospital clinics for patients with chronic unexplained fatigue are held in departments of various disciplines. This causes difficulties for referrers in choosing the appropriate clinic and for researchers in generalizing findings from one type of clinic to others. We randomly selected 37 outpatients attending an immunology fatigue clinic and 36 outpatients attending a psychiatry fatigue clinic, all of whom had chronic fatigue syndrome. We compared demographic factors, symptoms, disability, quality of life, psychological distress and illness attributions. The patients from the two clinics were closely similar in their specific symptoms, disability, quality of life, psychological distress and previous attendance to mental health professionals. Psychological distress was high and equal in the two samples. The proportion of men was greater among patients attending the immunology clinic. In a post-hoc analysis, 64% of immunology attenders attributed their fatigue to physical factors, compared with 31% of psychiatry clinic attenders (chi(2)=6.35, 1 d.f., P=0.01). These findings suggest that research data from one type of chronic fatigue clinic can be generalized to others. Clinically similar patients are referred to different

				clinics, and the choice of clinic may be influenced by the patients' illness beliefs. The high levels of emotional distress suggest that psychosocial management is as important as physical management in hospital outpatients with chronic fatigue syndrome, irrespective of its aetiology.

Whitehead L, Campion P.		Can General Practitioners Manage Chronic Fatigue Syndrome? A Controlled Trial	Journal of Chronic Fatigue Syndrome 2002; 10 (1): 55 - 64	Background: Chronic Fatigue Syndrome/Myalgic Encephalomyeltis (CFS/ME) is now recognised as a condition that results in substantial disability with a prevalence of around 0.6%. Aim: The study aimed to test the hypotheses that general practitioners could (a) diagnose and (b) treat patients with the Chronic Fatigue Syndrome (CFS). Method: All practices in two health authorities were contacted with a 35% uptake. Fifty percent of practices then entered a patient into the study. Practices were randomised to either intervention or control groups, and were encouraged to recruit patients. It was intended that the intervention practices would introduce a form of brief cognitive behavioural therapy. Control practices were invited to manage their patients as usual, which often included referral to secondary care. Results: The study suffered from both poor recruitment and high drop out. However, we were able to show that this intervention had no effect on the illness of the patients enrolled, and that patients with CFS remained highly disabled over the 12 month study period, whatever their treatment. Conclusion: The study suggests that general practitioners in this study were unable to effectively treat the condition. This accords with the Royal Colleges' report (1996), that the only evidence for effective treatment thus far has come from specialist units. The study suggests that general practitioners are unable to provide a management programme of this nature, and possibly effective treatment programmes for CFS in primary care.
Whitehead WE, Palsson O, Jones KR.	Division of Digestive Diseases and Center for Functional Gastrointestinal and Motility Disorders, University of North Carolina, Chapel Hill,	Systematic review of the comorbidity of irritable bowel syndrome with other disorders: what are the causes and implications?	Gastroenterology. 2002 Apr;122(4):1140-56.	BACKGROUND & AIMS: Comorbid or extraintestinal symptoms occur frequently with irritable bowel syndrome and account for up to three fourths of excess health care visits. This challenges the assumption that irritable bowel is a distinct disorder. The aims of this study were to (1) assess comorbidity in 3 areas: gastrointestinal disorders, psychiatric disorders, and nongastrointestinal somatic disorders; and (2) evaluate explanatory hypotheses. METHODS: The scientific literature since 1966 in all languages cited in Medline was systematically reviewed. RESULTS: Comorbidity with other functional gastrointestinal disorders is high and may be caused by shared

	North Carolina 27599, USA. Whitehd@unch.unc.edu			pathophysiological mechanisms such as visceral hypersensitivity. Psychiatric disorders, especially major depression, anxiety, and somatoform disorders, occur in up to 94%. The nongastrointestinal nonpsychiatric disorders with the best-documented association are fibromyalgia (median of 49% have IBS), chronic fatigue syndrome (51%), temporomandibular joint disorder (64%), and chronic pelvic pain (50%). CONCLUSIONS: Multivariate statistical analyses suggest that these are distinct disorders and not manifestations of a common somatization disorder, but their strong comorbidity suggests a common feature important to their expression, which is most likely psychological. Some models explain the comorbidity of irritable bowel with other disorders by suggesting that each disorder is the manifestation of varying combinations of interacting physiological and psychological factors. An alternative hypothesis is that the irritable bowel diagnosis is applied to a heterogeneous group of patients, some of whom have a predominantly psychological etiology, whereas others have a predominantly biological etiology, and that the presence of multiple comorbid disorders is a marker for psychological influences on etiology.

Wildman MJ, Ayres JG.	. Q fever: still a mysterious disease		QJM. 2002 Dec;95(12):833-4. Comment on: QJM. 2002 Aug;95(8):491-2.	
Wildman MJ, Smith EG, Groves J, Beattie JM, Caul EO, Ayres JG.	Department of Respiratory Medicine, Birmingham Heartlands Hospital, UK.	Chronic fatigue following infection by Coxiella burnetii (Q fever): ten-year follow-up of the 1989 UK outbreak cohort.	QJM. 2002 Aug;95(8):527-38. Comment in: QJM. 2002 Aug;95(8):491-2.	BACKGROUND: Some patients exposed to Q fever (Coxiella burnetii infection) may develop chronic fatigue. AIM: To determine whether subjects involved in the West Midlands Q fever outbreak of 1989 had increased fatigue, compared to non-exposed controls, 10 years after exposure. DESIGN: Matched cohort study comparing cases to age-, sex- and smoking-history-matched controls not exposed to Q fever. METHODS: A postal questionnaire was sent to subjects at home, followed by further assessment in hospital, including a physical examination and blood tests. RESULTS: Of 108 Q-exposed subjects, 70 (64.8%) had fatigue, 37 idiopathic chronic fatigue (ICF) (34.3%), vs. 29/80 (36.3%) and 12 (15.0%), respectively, in controls. In 77 matched pairs, fatigue was commoner in Q-exposed subjects than in controls: 50 (64.9%) vs. 27 (35.1%), p<0.0001. ICF was found in 25 (32.5%) of Q-exposed patients and 11(14.3%) of controls (p=0.01). There were 36 (46.8%) GHQ cases in Q-exposed subjects, vs. 18 (23.4%) controls (p=0.004). A matched analysis of those more intensively studied showed fatigue in 48 (66.7%) Q-exposed patients and 25 (34.7%) controls, (p<0.0001), ICF in 25 (34.7%) Q-exposed and 10 (13.9%) controls (p=0.004), and chronic fatigue syndrome (CFS) in 14 (19.4%) Q-exposed patients and three (4.2%) controls (p=0.003). Thirty-four (47.2%) Q-exposed patients were GHQ cases

				compared to 17 (23.6%) controls (p=0.004). DISCUSSION: Subjects who were exposed to Coxiella in 1989 had more fatigue than did controls, and some fulfilled the criteria for CFS. Whether this is due to ongoing antigen persistence or to the psychological effects of prolonged medical follow-up is uncertain.
Wilhelmsen I.	Institute of Medicine, University of Bergen, Norway. Ingvard.Wilhelmsen @med.uib.no	Somatization, sensitization, and functional dyspepsia.	Scand J Psychol. 2002 Apr;43(2):177-80.	Functional dysepsia (FD) is defined as persistent or recurrent pain or discomfort centered in the upper abdomen without evidence of organic disease likely to explain the symptoms. Visceral hypersensitivity, motor dysfunction, and impaired gastric accommodation are found in some patients with FD, and psychological factors like chronic stress, attention and perception bias are also likely to play a part in the symptom formation. There is considerable overlap of non-specific symptoms like fatigue, headache, abdominal discomfort, muscle pain, and sleep disturbance in patients with different functional disorders, in this article exemplified by FD, fibromyalgia, and chronic fatigue syndrome. This overlap of symptoms indicates a common underlying sensitization process, leading to somatization.
Williams G, Waterhouse J, Mugarza J, Minors D, Hayden K.	Diabetes and Endocrinology Research Group, Department of Medicine, University Hospital Aintree, Liverpool, UK. gareth@liv.ac.uk	Therapy of circadian rhythm disorders in chronic fatigue syndrome: no symptomatic improvement with melatonin or phototherapy.	Eur J Clin Invest. 2002 Nov;32(11):831-7.	BACKGROUND: Patients with chronic fatigue syndrome (CFS) show evidence of circadian rhythm disturbances. We aimed to determine whether CFS symptoms were alleviated by melatonin and bright-light phototherapy, which have been shown to improve circadian rhythm disorders and fatigue in jet-lag and shift workers. DESIGN: Thirty patients with unexplained fatigue for > 6 months were initially assessed using placebo and then received melatonin (5 mg in the evening) and phototherapy (2500 Lux for 1 h in the morning), each for 12 weeks in random order separated by a washout period. Principal symptoms of CFS were measured by visual analogue scales, the Shortform (SF-36) Health Survey, Mental Fatigue Inventory and Hospital Anxiety and Depression Scale. We also determined the circadian rhythm of body temperature, timing of the onset of melatonin secretion, and the relationship between these. RESULTS: Neither intervention showed any significant effect on any of the principal symptoms or on general measures of physical or mental health. Compared with placebo, neither body temperature rhythm nor onset of melatonin secretion was significantly altered by either treatment, except for a slight advance of temperature phase (0.8 h; P = 0.04) with phototherapy. CONCLUSION: Melatonin and bright-light phototherapy appear ineffective in CFS. Both treatments are being prescribed for CFS sufferers by medical and alternative practitioners. Their unregulated use should be prohibited unless, or until, clear benefits are convincingly demonstrated.

Youssefi M, Linkowski P.	Service de Psychiatrie, Hopital Erasme, U.L.B.	[Chronic fatigue syndrome: psychiatric perspectives] [Article in French]	Rev Med Brux. 2002 Sep;23(4):A299-304.	Chronic fatigue syndrome (CFS) is a common illness of unknown etiology and pathogenesis characterized by severe disabling fatigue and a variety of musculoskeletal, neurocognitive, mood symptoms and sleep disorders lasting at least six months. A significant proportion of patients fulfilling operative criteria for a diagnosis of CFS will also meet criteria for a psychiatric disorder such as depression, somatization or anxiety disorders. Premorbid lifestyle may play a predisposing, and/or perpetuating role in CFS. Some patients improve with time but most remain functionally impaired for several years. A variety of interventions have been used in the treatment and management of CFS. Interventions which have shown promising results include cognitive behavioural therapy and graded exercise therapy. Antidepressants can be useful particularly in the case of comorbid affective disorders. Development of good therapeutic doctor-patient alliance with empathic care is central to the effective management of CFS. In this article we overview the nature and definition of CFS. The prevalence, the prognosis and the psychopathological issues are presented. The management of this controversial syndrome is discussed.
Yunus MB.	Section of Rheumatology, University of Illinois College of Medicine at Peoria, 1 Illini Dr, PO Box 1649, Peoria, IL 61656, USA. yunus@uic.edu	Gender differences in fibromyalgia and other related syndromes.	J Gend Specif Med. 2002 Mar-Apr;5(2):42-7.	Fibromyalgia syndrome is characterized by widespread musculoskeletal pain, fatigue, poor sleep, and tenderness on palpation at multiple sites called tender points. It occurs mostly among women; only about 10% of patients are men. Two recent studies showed that women had significantly more common fatigue, morning fatigue, "hurt all over," a greater total number of symptoms, as well as a greater number of tender points. Gender differences have also been reported in other related syndromes such as tension headache, migraine, irritable bowel syndrome, chronic fatigue syndrome, and temporomandibular disorder. Although the mechanisms of gender differences in these illnesses are not fully understood, they are likely to involve an interaction between biology, psychology, and sociocultural factors.
Zachrisson O, Regland B, Jahreskog M, Jonsson M, Kron M, Gottfries CG.	Psychiatry Section, Institute of Clinical Neuroscience, Goteborg University, Goteborg, Sweden. olof.zachrisson@neuro.gu.se	Treatment with staphylococcus toxoid in fibromyalgia/chronic fatigue syndrome--a randomised controlled trial.	Eur J Pain. 2002;6(6):455-66.	We have previously conducted a small treatment study on staphylococcus toxoid in fibromyalgia (FM) and chronic fatigue syndrome (CFS). The aim of the present study was to further assess the efficacy of the staphylococcus toxoid preparation Staphypan Berna (SB) during 6 months in FM/CFS patients. One hundred consecutively referred patients fulfilling the ACR criteria for FM and the 1994 CDC criteria for CFS were randomised to receive active drug or placebo. Treatment included weekly injections containing 0.1 ml, 0.2 ml, 0.3 ml, 0.4 ml, 0.6 ml, 0.8 ml, 0.9 ml, and 1.0 ml SB or coloured sterile water, followed by booster doses given 4-weekly until endpoint. Main outcome measures were the proportion of responders according to global ratings and the proportion of patients with a symptom reduction of > or =50% on a 15-item subscale derived from the comprehensive psychopathological rating scale (CPRS). The treatment was well tolerated. Intention-to-treat analysis showed 32/49 (65%) responders in the SB group compared to 9/49 (18%) in the placebo group (P<0.001). Sixteen patients (33%) in the SB group reduced their CPRS scores by at least 50% compared to five patients (10%) in the placebo group (P< 0.01). Mean change score on the CPRS (95% confidence interval) was 10.0 (6.7-13.3) in the SB group

				and 3.9 (1.1-6.6) in the placebo group (P<0.01). An increase in CPRS symptoms at withdrawal was noted in the SB group. In conclusion, treatment with staphylococcus toxoid injections over 6 months led to significant improvement in patients with FM and CFS. Maintenance treatment is required to prevent relapse.
Zachrisson O, Regland B, Jahreskog M, Kron M, Gottfries CG.	Psychiatry Section, Institute of Clinical Neuroscience, Goteborg University, Goteborg, Sweden. olof.zachrisson@neuro.gu.se	A rating scale for fibromyalgia and chronic fatigue syndrome (the FibroFatigue scale).	J Psychosom Res. 2002 Jun;52(6):501-9.	OBJECTIVE: To construct an observer's rating scale sensitive to change for measuring severity and treatment outcome in fibromyalgia (FM) and chronic fatigue syndrome (CFS) patients. METHODS: A selection of items from the Comprehensive Psychopathological Rating Scale (CPRS) were repeatedly rated and used as outcome measure of a 24-week treatment study. In the study 100 women, fulfilling the criteria for both FM and CFS, received intermittent injections of a staphylococcus toxoid or placebo. Nine CPRS-items with high baseline incidence (cutoff 70%) were extracted and validated against global ratings and the Fibromyalgia Impact Questionnaire (FIQ). The fibromyalgia and chronic fatigue syndrome rating scale (the FibroFatigue scale) was thereafter formed based upon the extracted items and three supplemented ones. The interrater reliability was tested in 27 consecutive patients of both sexes. RESULTS: The FibroFatigue scale is an observer's rating scale with 12 items measuring pain, muscular tension, fatigue, concentration difficulties, failing memory, irritability, sadness, sleep disturbances, and autonomic disturbances (items derived from the CPRS) and irritable bowel, headache, and subjective experience of infection (new items). There was a statistically significant correlation between the CPRS-extracted items and global ratings as well as with the FIQ. The interrater reliability of the new scale was excellent (correlation coefficient.98), irrespective of the patients' gender. CONCLUSION: The FibroFatigue scale seems to be a reliable and valid measuring instrument with capacity to monitor symptom severity and change during treatment of FM/CFS patients.
Zeman K, Lewandowicz-Uszynska A.	Zaklad Immunologii Klinicznej Instytutu Centrum Zdrowia Matki Polki i Zaklad Immunologii Klinicznej WAM w lodzi. zeman@achilles.wam.lodz.pl		Postepy Hig Med Dosw. 2002;56 Suppl:91-102. [Article in Polish]	The research connects usefulness of intravenous preparates of immunoglobulins in patients with secondary immunodeficiencies. Basing on the data of literature there was discussed the using IVIG in patients with HIV infection and with the chronic fatigue syndrome. There was also discussed the matt of using IVIG after multiorgans traumas, burns and operations with high risk complications.

Aaron LA, Buchwald D.	Department of Medicine, Division of Internal Medicine, Harborview Medical Center, 325 Ninth Avenue, Box 359780, Seattle, WA 98104, USA. laaron@u.washington.edu	A review of the evidence for overlap among unexplained clinical conditions.	Ann Intern Med. 2001 May 1;134(9 Pt 2):868-81.	PURPOSE: Unexplained clinical conditions share features, including symptoms (fatigue, pain), disability out of proportion to physical examination findings, inconsistent demonstration of laboratory abnormalities, and an association with "stress" and psychosocial factors. This literature review examines the nature and extent of the overlap among these unexplained clinical conditions and the limitations of previous research. DATA SOURCES: English-language articles were identified by a search of the MEDLINE database from 1966 to January 2001 by using individual syndromes and their hallmark symptoms as search terms. STUDY SELECTION: Studies that assessed patients with at least one unexplained clinical condition and that included information on symptoms, overlap with other unexplained clinical conditions, or physiologic markers. Conditions examined were the chronic fatigue syndrome, fibromyalgia, the irritable bowel syndrome, multiple chemical sensitivity, temporomandibular disorder, tension headache, interstitial cystitis, and the postconcussion syndrome. DATA EXTRACTION: Information on authorship, patient and control groups, eligibility criteria, case definitions, study methods, and major findings. DATA SYNTHESIS: Many similarities were apparent in case definition and symptoms, and the proportion of patients with one unexplained clinical condition meeting criteria for a second unexplained condition was striking. Tender points on physical examination and decreased pain threshold and tolerance were the most frequent and consistent objective findings. A major shortcoming of all proposed explanatory models is their inability to account for the occurrence of unexplained clinical conditions in many affected patients. CONCLUSIONS: Overlap between unexplained clinical conditions is substantial. Most studies are limited by methodologic problems, such as case definition and the selection and recruitment of case-patients and controls.
Aaron LA, Buchwald D.	Department of Medicine, Harborview Medical Center, 325 Ninth Avenue, Box 359780, Seattle, WA 98104, USA. laaron@u.washington.edu.	Fibromyalgia and other unexplained clinical conditions.	Curr Rheumatol Rep. 2001 Apr;3(2):116-22.	Several unexplained clinical conditions frequently coexist with fibromyalgia; these include chronic fatigue syndrome, irritable bowel syndrome, temporomandibular disorder, tension and migraine headaches, and others. However, only recently have studies directly compared the physiological parameters of these conditions (eg, fibromyalgia vs irritable bowel syndrome) to elucidate underlying pathogenic mechanisms. This review summarizes data from comparative studies and discusses their implications for future research.
Aaron LA, Herrell R, Ashton S, Belcourt M, Schmaling K, Goldberg J, Buchwald D.	Division of General Internal Medicine, Department of Medicine, University of Washington, Seattle, WA 98104, USA.	Comorbid clinical conditions in chronic fatigue: a co-twin control study.	J Gen Intern Med. 2001 Jan;16(1):24-31.	OBJECTIVES: Chronically fatiguing illness, defined as fatigue for at least 6 months, has been associated with various physical health conditions. Our objective was to determine whether there is a significant relationship between chronically fatiguing illness and 10 clinical conditions that frequently appear to be associated with fatigue, adjusting for the potentially confounding effects of psychiatric illness. DESIGN: A co-twin control study controlling for genetic and many environmental factors by comparing chronically fatigued twins with their nonfatigued co-twins. SETTING: A nationally distributed volunteer twin

	laaron@u.washington.edu			registry. PARTICIPANTS: The study included 127 twin pairs in which one member of the pair experienced fatigue of at least 6 months' duration and the co-twin was healthy and denied chronic fatigue. Fatigued twins were classified into 3 levels using increasingly stringent diagnostic criteria. MEASUREMENTS AND MAIN RESULTS: Twins reported on a history of fibromyalgia, irritable bowel syndrome, multiple chemical sensitivities, temporomandibular disorder, interstitial cystitis, postconcussion syndrome, tension headache, chronic low back pain, chronic pelvic pain (women), and chronic nonbacterial prostatitis (men). The prevalence of these comorbid clinical conditions was significantly higher in the fatigued twins compared to their nonfatigued co-twins. Most notably, compared to their nonfatigued co-twins, the chronically fatigued twins had higher rates of fibromyalgia (> 70% vs < 10%) and irritable bowel syndrome (> 50% vs < 5%). The strongest associations were observed between chronic fatigue and fibromyalgia (odds ratios > 20), irritable bowel syndrome, chronic pelvic pain, multiple chemical sensitivities, and temporomandibular disorder (all with odds ratios > or = 4). Regression analysis suggested that the number of comorbid clinical conditions associated with chronic fatigue could not be attributed solely to psychiatric illness. CONCLUSIONS: Chronically fatiguing illnesses were associated with high rates of many other clinical conditions. Thus, patients with chronic fatigue may present a complex clinical picture that poses diagnostic and management challenges. Nonetheless, clinicians should assess such patients for the presence of comorbid clinical conditions. Future research should provide a better understanding of the temporal relationship of the onset of fatigue and these conditions, and develop strategies for early intervention.
Addington AM, Gallo JJ, Ford DE, Eaton WW.	Department of Mental Hygiene, School of Hygiene and Public Health, The Johns Hopkins University, Baltimore, MD 21205, USA.	Epidemiology of unexplained fatigue and major depression in the community: the Baltimore ECA follow-up, 1981-1994.	Psychol Med. 2001 Aug;31(6):1037-44.	BACKGROUND: Fatigue is a common, non-specific, subjective symptom associated with several medical and psychiatric illnesses. The purpose of this investigation was to explore further the epidemiology of unexplained fatigue in the general population and the relationship between fatigue and depression. METHODS: The design was a prospective population-based study. Subjects included community-dwelling adults who were participants of the Baltimore sample of the Epidemiologic Catchment Area Program in 1981 and who were reinterviewed 13 years later. Lay interviewers using the Diagnostic Interview Schedule interviewed subjects. RESULTS: Number of somatization symptoms and history of a dysphoric episode at baseline were the two strongest predictors of both new onset of fatigue as well as recurrent/chronic fatigue over the 13-year follow-up interval. In addition, individuals who reported a history of unexplained fatigue at baseline as well as during the follow-up, were at markedly increased risk for new onset major depression as compared to those who never reported such fatigue, (RR = 28.4, 95% CI) (11.7, 68.0). Similarly, respondents who developed new fatigue or had remitted fatigue after 1981 were also at increased risk for developing major depression. CONCLUSIONS: Somatization was the strongest predictor of both new and chronic fatigue with unknown cause. In addition, fatigue was both predictive and a consequence of the depression syndrome.
Akagi H, Klimes I,	Leeds General	Cognitive behavioral	Gen Hosp Psychiatry.	Cognitive behavior therapy (CBT) has been shown to be effective in recent randomized

Bass C.	Infirmary, Leeds, UK.	therapy for chronic fatigue syndrome in a general hospital--feasible and effective.	2001 Sep-Oct;23(5):254-60.	controlled trials for chronic fatigue syndrome (CFS). We examined the effectiveness of CBT in a general hospital setting in a retrospective questionnaire follow-up study of 94 patients offered CBT by liaison psychiatry services. The questionnaire response rate was 61%. Eighteen percent had returned to normal functioning at follow-up. For the group as a whole, there was a significant improvement in the functional and social impairment and the number of frequently experienced symptoms. Those in work or study at follow-up was 53% (29% pretreatment), and 65% of patients mentioned occupational stress as a contributory factor in their illness. There was a significant reduction in the frequency of attendance at primary care in the year after the end of CBT. We conclude that cognitive behavioral therapy is an acceptable treatment for most patients and can be used in a general hospital outpatient setting by a variety of trained therapists. However, a proportion of patients do not benefit and remain significantly disabled by the condition.
Altemus M, Dale JK, Michelson D, Demitrack MA, Gold PW, Straus SE.	Weill Medical College, Cornell University, Box 244, 1300 York Avenue, New York, NY 10021, USA. maltemus@mail.med.cornell.edu	Abnormalities in response to vasopressin infusion in chronic fatigue syndrome.	Psychoneuroendocrinology. 2001 Feb;26(2):175-88.	Several neuroendocrine studies have suggested hypoactivation of the hypothalamic-pituitary-adrenal axis in chronic fatigue syndrome. One possible determinant of this neuroendocrine abnormality, as well as the primary symptom of fatigue, is reduced hypothalamic secretion of corticotropin-releasing hormone (CRH). Because CRH and vasopressin secreted from the hypothalamus act synergistically at the pituitary to activate ACTH secretion, the ACTH response to peripheral infusion of vasopressin can provide an indirect measure of hypothalamic CRH secretion. We measured the ACTH and cortisol response to a one hour infusion of arginine vasopressin in 19 patients with chronic fatigue syndrome and 19 age and sex matched healthy volunteers. Patients with chronic fatigue syndrome had a reduced ACTH response to the vasopressin infusion and a more rapid cortisol response to the infusion. These results provide further evidence of reduced hypothalamic CRH secretion in patients with chronic fatigue syndrome.
Anderberg UM.	Centrum for miljorelaterad ohalsa och stress (CEOS), institutionen for folkhalso- och vardvetenskap, enheten for socialmedicin, Uppsala universitet, Akademiska sjukhuset, Uppsala. ullamaria.anderberg@socmed.uu.se	[Stress-related syndromes--contemporary illnesses] [Article in Swedish]	Lakartidningen. 2001 Dec 19;98(51-52):5860-3.	There are many indications that distress within the family as well as at work are strong predictors for developing stress-related disorders. The relatively new diagnoses burnout, chronic fatigue syndrome and fibromyalgia syndrome probably represent different ways of reacting to an overwhelming situation. The boundary between these diseases, on the one hand, and depression, heart disease or infarction on the other is often diffuse, and the new diagnoses may well delineate preliminary stages of more serious diseases such as angina pectoris or myocardial infarction. There is evidence that also other causes of death may be related to stress. These circumstances reflect not only considerable suffering on the part of individuals, but also a substantial economic burden for society.
Anon		DHEA. Monograph.	Altern Med Rev. 2001 Jun;6(3):314-8.	Dehydroepiandrosterone (DHEA) is a steroid hormone secreted primarily by the adrenal glands and to a lesser extent by the brain, skin, testes, and ovaries. It is the most abundant circulating steroid in humans and can be converted into other hormones, including

				estrogen and testosterone. It has been characterized as a pleiotropic "buffer hormone," with receptor sites in the liver, kidney, and testes, and has a key role in a wide range of physiological responses. Circulating levels of DHEA decline with age and a relationship has been suggested between lower DHEA levels and heart disease, cancer, diabetes, obesity, chronic fatigue syndrome, AIDS, and Alzheimer's disease. Other research suggests that autoimmune diseases such as systemic lupus erythematosus (SLE), rheumatoid arthritis, and multiple sclerosis might be associated with declining DHEA levels.

Asbring P.	Centre for Development of Health Services, Department of Public Health Sciences, Karolinska Institutet, Stockholm, Sweden. pia.asbring@smd.sll.se	Chronic illness -- a disruption in life: identity-transformation among women with chronic fatigue syndrome and fibromyalgia.	J Adv Nurs. 2001 May;34(3):312-9.	BACKGROUND: People with chronic illnesses often suffer from identity-loss. Empirical research concerning patients with chronic fatigue syndrome (CFS) or fibromyalgia has not, however, adequately addressed the consequences of these illnesses for identity. AIM: The aim of this article is to describe how women with CFS and fibromyalgia create new concepts of identity after the onset of illness, and how they come to terms with their newly arisen identities. I aim to illuminate the biographical work done by these individuals, which includes a re-evaluation of their former identity and life. This process is illustrated by the following themes: An earlier identity partly lost and Coming to terms with a new identity. METHOD: The study is based on interviews with 25 women in Sweden, 12 with the diagnosis of CFS and 13 diagnosed with fibromyalgia. A grounded theory orientated approach was used when collecting and analysing the data. FINDINGS: The main findings are that: (1) the illnesses can involve a radical disruption in the women's biography that has profound consequences for their identity, particularly in relation to work and social life, (2) biographical disruptions are partial rather than total, calling for different degrees of identity transformation, (3) many of the women also experience illness gains in relation to the new identity. CONCLUSIONS: Thus, the biographical disruption and illness experience comprised both losses and illness gains that had consequences for identity.
Ax S, Gregg VH, Jones D.	Liverpool John Moores University. heasax@yahoo.com	Coping and illness cognitions: chronic fatigue syndrome.	Clin Psychol Rev. 2001 Mar;21(2):161-82.	The chronic fatigue syndrome (CFS) is described, and research on coping with this illness reviewed and analysed. CFS is a severely disabling illness of unknown etiology, which has occurred in epidemic forms all over the world. However, the number of sufferers has dramatically increased over previous years. The heterogeneous symptomatology of CFS was reviewed, and diagnostic criteria were discussed. The difficulty in establishing causality was emphasized. An interaction of factors appears most likely to be associated with illness onset and maintenance. As the mediating factor could be sufferers' coping behavior, the

				existing coping literature was reviewed. There might be an association between coping and physical and psychological well-being. Finally, recommendations are made for longitudinal research on coping and coping effectiveness, and for the development of therapeutic interventions.
Banks J, Prior L.	Cardiff University School of Social Sciences, Cardiff CF10 3WT, UK.	Doing things with illness. The micro politics of the CFS clinic.	Soc Sci Med. 2001 Jan;52(1):11-23.	This paper focuses on lay and professional ideas about the nature of chronic fatigue syndrome (CFS), and in particular, the ways in which understandings of the disorder are developed in a clinical setting. Our data are drawn from observations of consultations between sufferers and physicians in a UK medical out-patients clinic. We treat the clinic as a political field. That is to say, as an arena in which 'problems' (about the management of illness) are constituted, and alternative approaches and solutions to such problems are pressed. We note that in the realms of symptoms, aetiology and treatment evaluation, lay people in the CFS clinic have quite distinct ideas about what their problems are and how they might be analysed and managed--ideas that are often in conflict with those of medical professionals. Thus, lay sufferers, for example, operate within a different conceptual terrain from that of many professional experts. They are more likely to refer to a disease (myalgic encephalomyelitis or ME), rather than a syndrome. They call upon different kinds of hypotheses to explain their symptoms. They hold to conflicting ideas about the order of causal sequences, and they give emphasis to different kinds of phenomena in their accounts of illness. As a consequence, clinical consultations can often take on the form of a political contest between physician and patient to define the true and real nature of the patient's disorder--a micro political struggle in which neurological symptoms can be re-framed as psychiatric symptoms, and psychiatric symptoms as neurological. In short, a contest in which the demarcation lines between mind and body are continually assessed and re-defined, and the tenets of 'biomedicine' are constantly challenged.

Bazelmans E, Bleijenberg G, Van Der Meer JW, Folgering H.	Department of Medical Psychology, University of Nijmegen, The Netherlands.	Is physical deconditioning a perpetuating factor in chronic fatigue syndrome? A controlled study on maximal exercise performance and relations with fatigue, impairment and physical activity.	Psychol Med. 2001 Jan;31(1):107-14.	BACKGROUND: Chronic fatigue syndrome (CFS) patients often complain that physical exertion produces an increase of complaints, leading to a greater need for rest and more time spent in bed. It has been suggested that this is due to a bad physical fitness and that physical deconditioning is a perpetuating factor in CFS. Until now, studies on physical deconditioning in CFS have shown inconsistent results. METHODS: Twenty CFS patients and 20 matched neighbourhood controls performed a maximal exercise test with incremental load. Heart rate, blood pressure, respiratory tidal volume, O2 saturation, O2 consumption, CO2 production, and blood-gas values of arterialized capillary blood were measured. Physical fitness was quantified as the difference between the actual and predicted ratios of maximal workload versus increase of heart rate. Fatigue, impairment and physical activity were assessed to study its relationship with physical fitness. RESULTS: There were no statistically significant differences in physical fitness between CFS patients and their controls. Nine CFS patients had a better fitness than their control. A negative relationship between physical fitness and fatigue was found in both groups. For CFS patients a negative correlation between fitness and impairment and a positive correlation between fitness and physical activity was found as well. Finally, it was found that more CFS patients than controls did not achieve a physiological limitation at maximal exercise. CONCLUSIONS: Physical deconditioning does not seem a perpetuating factor in CFS.
Bell DS, Jordan K, Robinson M.	Primary Care Pediatrics, Lyndonville, New York, USA.	Thirteen-year follow-up of children and adolescents with chronic fatigue syndrome.	Pediatrics. 2001 May;107(5):994-8.	OBJECTIVE: To describe the educational, social, and symptomatic outcome of children and adolescents with chronic fatigue syndrome 13 years after illness onset. METHODS: Between January 1984 and December 1987, 46 children and adolescents developed an illness suggestive of chronic fatigue syndrome. Follow-up questionnaires were obtained from 35 participants an average of 13 years after illness onset. Data were obtained concerning subsequent medical diagnoses, amount of school missed, presence and severity of current symptoms, and subjective assessment of degree of illness resolution. RESULTS: Of the 35 participants, 24 were female (68.6%) and 11 were male (31.4%). Average age at illness onset was 12.1 years. Eight participants (22.9%) had an acute onset

				of symptoms, 27 (77.1%) had a gradual onset. No participant received an alternative medical diagnosis that could have explained the symptom complex between illness onset and follow-up. Thirteen participants (37.1%) considered themselves resolved of illness at follow-up; 15 participants (42.9%) considered themselves well but not resolved; 4 (11.4%) considered themselves chronically ill; and 3 (8.6%) considered themselves more ill than during the early years of illness. Correlation with the Medical Outcomes Study Short Form Health Survey was good for current level of symptoms and degree of recovery. Eight participants (22.9%) missed >2 years of school, and 5 of these were still ill at follow-up. Amount of school missed correlated with both illness severity at follow-up and perceived social impact of the illness. CONCLUSIONS: These data demonstrate the presence of an illness consistent with the current definition of chronic fatigue syndrome. Eighty percent of children and adolescents affected had a satisfactory outcome from their fatiguing illness, although the majority of these participants had mild to moderate persisting symptoms. Twenty percent of participants remain ill with significant symptoms and activity limitation 13 years after illness onset. Chronic fatigue syndrome in children and adolescents may result in persistent somatic symptoms and disability in a minority of those affected.
Bell IR, Baldwin CM, Stoltz E, Walsh BT, Schwartz GER.		Concomitant Environmental Chemical Intolerance Modifies the Neurobehavioral Presentation of Women with Fibromyalgia	Journal of Chronic Fatigue Syndrome 2001; 9(1/2): 3	Background: This study compared personality, dietary, and psychophysiological characteristics of 3 groups of women: fibromyalgia (FM) with illness from low levels of environmental chemicals (chemical intolerance, CI), FM alone without CI, and normal controls. CI may be a marker for enhanced central nervous system response amplification (sensitization) in limbic and mesolimbic pathways, which play a role in hedonic responses to food and drugs and in pain. Method: Fibromyalgic women with (FM/CI, n = 11) and without CI (FM, n = 10) and normals (NORM, n = 10) participated in the study. Measures included psychological trait questionnaires, a food frequency questionnaire, a taste test for hedonic and sweetness ratings of different sucrose concentrations, pain self-ratings, and resting spectral electroencephalographic alpha over midline sites, averaged over four separate days. Results: FM with CI had the highest scores on the Harm Avoidance dimension of the Tridimensional Personality Questionnaire, Carbohydrate Addicts Test, Limbic Symptom sensory and behavior subscales, and SCL-90-R somatization and obsessiveness subscales. FM groups both had the highest mean pain ratings for 21 tender point sites. Groups did not differ for macronutrient intake or for sweetness and hedonic ratings for sucrose. The combined FM groups had greater EEG alpha activity towards posterior midline sites than did normals. Conclusion: The pattern of findings may reflect impaired serotonergic function and/or elevated dopaminergic receptor activation by endogenous and/or exogenous agents. The data could have implications for pharmacological and dietary interventions in different subsets of FM patients.
Bested AC, Saunders PR, Logan AC.	Environmental Health Clinic, Sunnybrook and Women's College, Health	Chronic fatigue syndrome: neurological findings may be related to	Med Hypotheses. 2001 Aug;57(2):231-7.	Despite volumes of international research, the etiology of chronic fatigue syndrome (CFS) remains elusive. There is, however, considerable evidence that CFS is a disorder involving the central nervous system (CNS). It is our hypothesis that altered permeability of the blood-brain barrier (BBB) may contribute to ongoing signs and symptoms found in CFS. To

	Sciences Centre, Toronto, Canada.	blood--brain barrier permeability.		support this hypothesis we have examined agents that can increase the blood-brain barrier permeability (BBBP) and those that may be involved in CFS. The factors which can compromise the normal BBBP in CFS include viruses, cytokines, 5-hydroxytryptamine, peroxynitrite, nitric oxide, stress, glutathione depletion, essential fatty acid deficiency, and N-methyl-D-aspartate overactivity. It is possible that breakdown of normal BBBP leads to CNS cellular dysfunction and disruptions of neuronal transmission in CFS. Abnormal changes in BBBP have been linked to a number of disorders involving the CNS; based on review of the literature we conclude that the BBB integrity in CFS warrants investigation. Binder LM, Storzbach D, Campbell KA, Rohlman DS, Anger WK; Members of the Portland Environmental Hazards Research Center.	Oregon Health Sciences University, Portland, USA. Larry_Binder@email.msn.com	Neurobehavioral deficits associated with chronic fatigue syndrome in veterans with Gulf War unexplained illnesses.	J Int Neuropsychol Soc. 2001 Nov;7(7):835-9.	Gulf War unexplained illnesses (GWUI) are a heterogeneous collection of symptoms of unknown origin known to be more common among veterans of the Gulf War than among nonveterans. In the present study we focused on one of these unexplained illnesses. We tested the hypothesis that in a sample of Persian Gulf War veterans chronic fatigue syndrome (CFS) was associated with cognitive deficits on computerized cognitive testing after controlling for the effects of premorbid cognitive differences. We obtained Armed Forces Qualification Test (AFQT) data acquired around the date of induction into the military on 94 veterans of the Gulf War, 32 with CFS and 62 healthy controls. Controls performed better than participants diagnosed with CFS on the AFQT. Cognitive deficits were associated with CFS on 3 of 8 variables after the effect of premorbid AFQT scores was removed with ANCOVA.
Bourdette DN, McCauley LA, Barkhuizen A, Johnston W, Wynn M, Joos SK, Storzbach D, Shuell T, Sticker D.	Portland Veterans Affairs Medical Center, Department of Neurology, Mailcode P-3-NEURO, 3710 SW US Veteran's Hospital Road, Portland, OR 97201, USA. Dennis.Bourdette@med.va.gov	Symptom factor analysis, clinical findings, and functional status in a population-based case control study of Gulf War unexplained illness.	J Occup Environ Med. 2001 Dec;43(12):1026-40.	Few epidemiological studies have been conducted that have incorporated clinical evaluations of Gulf War veterans with unexplained health symptoms and healthy controls. We conducted a mail survey of 2022 Gulf War veterans residing in the northwest United States and clinical examinations on a subset of 443 responders who seemed to have unexplained health symptoms or were healthy. Few clinical differences were found between cases and controls. The most frequent unexplained symptoms were cognitive/psychological, but significant overlap existed with musculoskeletal and fatigue symptoms. Over half of the veterans with unexplained musculoskeletal pain met the criteria for fibromyalgia, and a significant portion of the veterans with unexplained fatigue met the criteria for chronic fatigue syndrome. Similarities were found in the clinical interpretation of unexplained illness in this population and statistical factor analysis performed by this study group and others.
Brewer JH, Berg D.		Hypercoaguable State Associated with Active Human Herpesvirus-6 (HHV-6) Viremia in Patients with Chronic Fatigue Syndrome	Journal of Chronic Fatigue Syndrome 2001; 8(3/4): 111	Objectives: A subset of patients with Chronic Fatigue Syndrome (CFS) have been found to be hypercoaguable in small previous studies. We wanted to analyze the incidence of a hypercoaguable state and assess hereditary hypercoaguable risk factors in a group of patients with known CFS and HHV-6 viremia. Methods: Thirty patients diagnosed with CFS that had at least one prior positive blood culture for active HHV-6 by rapid culture method were studied. A hypercoaguable panel was obtained to assess activation of coagulation. Two or more positive tests were determined to represent activation of coagulation. Hereditary thrombosis risk panels were also performed which included eight different

				genetic tests to assess hereditary abnormalities. Results: Twenty-four of thirty (80%) patients had a hypercoaguable state, thus activation of coagulation. Twenty-five of thirty (83%) of patients had a hereditary abnormality. Conclusions: CFS patients with active HHV-6 infection (viremia) have activation of coagulation and are hypercoaguable. Hereditary thrombosis risk factors are very prevalent in these patients. These hereditary abnormalities increase the hypercoaguable tendencies. The hypercoaguable state associated with active HHV-6 infection may be a significant contributing factor to the symptoms seen in CFS patients.
Brunet JL, Liaudet AP, Later R, Peyramond D, Cozon GJ.	Infectious Diseases Department-Hopital de la Croix-Rousse-69317 Lyon, France.	Delayed-type hypersensitivity and chronic fatigue syndrome: the usefulness of assessing T-cell activation by flow cytometry--preliminary study.	Allerg Immunol (Paris). 2001 Apr;33(4):166-72.	Chronic fatigue syndrome or benign myalgic encephalomyelitis has been extensively described and investigated. Although numerous immunological abnormalities have been linked with the syndrome, none have been found to be specific. This article describes the detection of delayed-type hypersensitive responses to certain common environmental antigens in almost fifty per cent of patients with this syndrome. Such hypersensitivity can be detected by the intradermal administration of antigens derived from commensal organisms like the yeast Candida albicans albicans, and then monitoring for a systemic reaction over the following six to forty-eight hours. This approach can be consolidated by performing lymphocyte activation tests in parallel and measuring in vitro T-cell activation by Candida albicans albicans antigens by three-colour flow cytometry based on CD3, CD4 and either CD69 or CD25. Another useful parameter is the kinetics of neopterin excretion in the urine over the course of the skin test. The results showed that the intensity of the DTH response correlated with the number of T-cells activated in vitro. Various factors have been implicated in the fatigue of many patients, notably lack of sleep. However, it remains difficult to establish causality in either one direction or the other. This work is in the spirit of a multifactorial approach to the group of conditions referred to as "chronic fatigue syndrome".
Buchwald D, Herrell R, Ashton S, Belcourt M, Schmaling K, Sullivan P, Neale M, Goldberg J.	Department of Medicine, University of Washington, Seattle, WA, USA. dedra@u.washington.edu	A twin study of chronic fatigue.	Psychosom Med. 2001 Nov-Dec;63(6):936-43.	OBJECTIVE: The etiology of chronic fatigue syndrome is unknown, but genetic influences may be important in its expression. Our objective was to assess the role of genetic and environmental factors in unexplained chronic fatigue. METHODS: A classic twin study was conducted using 146 female-female twin pairs, of whom at least one member reported > or =6 months of fatigue. After completing questionnaires on symptoms, zygosity, physical health, and a psychiatric interview, twins were classified using three increasingly stringent definitions: 1) chronic fatigue for > or =6 months, 2) chronic fatigue not explained by exclusionary medical conditions, and 3) idiopathic chronic fatigue not explained by medical or psychiatric exclusionary criteria of the chronic fatigue syndrome case definition. Concordance rates in monozygotic and dizygotic twins were calculated for each fatigue definition along with estimates of the relative magnitude of genetic and environmental influences on chronic fatigue. RESULTS: The concordance rate was higher in monozygotic than dizygotic twins for each definition of chronic fatigue. For idiopathic chronic fatigue, the concordance rates were 55% in monozygotic and 19% in dizygotic twins (p =.042). The estimated heritability in liability was 19% (95% confidence interval = 0-56) for chronic

				fatigue > or =6 months, 30% (95% confidence interval = 0-81) for chronic fatigue not explained by medical conditions, and 51% (95% confidence interval = 7-96) for idiopathic chronic fatigue. CONCLUSIONS: These results provide evidence supporting the familial aggregation of fatigue and suggest that genes may play a role in the etiology of chronic fatigue syndrome.
Buskila D, Press J.	Rheumatic Disease Unit and Department of Medicine 'B', Soroka Medical Centre and Ben-Gurion University, Beer-Sheva, 84101, Israel.	Neuroendocrine mechanisms in fibromyalgia-chronic fatigue.	Best Pract Res Clin Rheumatol. 2001 Dec;15(5):747-58.	Fibromyalgia and chronic fatigue syndrome are poorly understood disorders that share similar demographic and clinical characteristics. Because of the clinical similarities between both disorders it was suggested that they share a common pathophysiological mechanism, namely, central nervous system dysfunction. This chapter presents data demonstrating neurohormonal abnormalities, abnormal pain processing and autonomic nervous system dysfunction in fibromyalgia and chronic fatigue syndrome. The possible contribution of the central nervous system dysfunction to the development and symptomatology of these conditions is discussed. The chapter concludes by reviewing the effect of current treatments and emerging therapeutic modalities in fibromyalgia and chronic fatigue syndrome. Copyright 2001 Harcourt Publishers Ltd.
Buskila D.	Ben Gurion University of the Negev, Faculty of Health Sciences, Soroka Medical Center, Beer Sheva, Israel.	Fibromyalgia, chronic fatigue syndrome, and myofascial pain syndrome.	Curr Opin Rheumatol. 2001 Mar;13(2):117-27.	The prevalence of chronic widespread pain in the general population in Israel was comparable with reports from the USA, UK, and Canada. Comorbidity with fibromyalgia (FM) resulted in somatic hyperalgesia in patients with irritable bowel syndrome. One sixth of the subjects with chronic widespread pain in the general population were also found to have a mental disorder. Mechanisms involved in referred pain, temporal summation, muscle hyperalgesia, and muscle pain at rest were attenuated by the N-methyl-D-aspartate (NMDA) antagonist, ketamine, in FM patients. Delayed corticotropin release, after interleukin-6 administration, in FM was shown to be consistent with a defect in hypothalamic corticotropin-releasing hormone neural function. The basal autonomic state of FM patients was characterized by increased sympathetic and decreased parasympathetic systems tones. The severity of functional impairment as assessed by the Medical Outcome Survey Short Form (SF-36) discriminated between patients with widespread pain alone and FM patients. Chronic fatigue syndrome (CFS) occurred in about 0.42% of a random community-based sample of 28,673 adults in Chicago, Illinois. A significant clinical overlap between CFS and FM was reported. Cytokine dysregulation was not found to be a singular or dominant factor in the pathogenesis of CFS. A favorable outcome of CFS in children was reported; two thirds recovered and resumed normal activities. No major therapeutic trials in FM and CFS were reported over the past year.
Butler JA, Chalder T, Wessely S.	Department of Psychological Medicine, Maudsley Hospital, London.	Causal attributions for somatic sensations in patients with chronic fatigue syndrome and their partners.	Psychol Med. 2001 Jan;31(1):97-105.	BACKGROUND: Patients with chronic fatigue syndrome (CFS) often make somatic attributions for their illness which has been associated with poor outcome. A tendency to make somatic attributions in general may be a vulnerability factor for the development of CFS. METHODS: This cross-sectional study based on self-report questionnaire data aimed to investigate the type of attributions for symptoms made by patients with CFS and to compare this to attributions made by their partners. It was hypothesized that patients with CFS would make more somatic attributions for their own symptoms than control subjects

				and that partners of patients with CFS would make more somatic attributions for their ill relative's symptoms but would be similar to controls regarding their own symptoms. Fifty patients with CFS were compared to 50 controls from a fracture clinic in the same hospital and 46 relatives living with the patients with CFS. A modified Symptom Interpretation Questionnaire was used to assess causal attributions. RESULTS: CFS patients were more likely to make somatic attributions for their symptoms. The relatives of patients with CFS made significantly more somatic attributions for symptoms in their ill relative. However, they were like the fracture clinic controls in terms of making predominantly normalizing attributions for their own symptoms. CONCLUSIONS: The data support modification of existing cognitive behavioural treatments for CFS to investigate whether addressing partners' attributions for patients' symptoms improves recovery in the patient. Furthermore, a tendency to make somatic attributions for symptoms may be a vulnerability factor for the development of CFS.
Caserta MT, Mock DJ, Dewhurst S.	Department of Pediatrics, University of Rochester Medical Center, Rochester, NY 14642, USA.	Human herpesvirus 6.	Clin Infect Dis. 2001 Sep 15;33(6):829-33. Epub 2001 Aug 10.	The development of techniques for the culture of lymphoid cells and the isolation of viruses that infect these cells led to the discovery of human herpesvirus (HHV) 6 in 1986. At the time, HHV-6 was the first new human herpesvirus to be discovered in roughly a quarter of a century, and its isolation marked the beginning of an era of discovery in herpesvirology, with the identification of HHV-7 and HHV-8 (Kaposi's sarcoma-associated herpesvirus) during the following decade. Like most human herpesviruses, HHV-6 is ubiquitous and capable of establishing a lifelong, latent infection of its host. HHV-6 is particularly efficient at infecting infants and young children, and primary infection with the virus is associated with roseola infantum (exanthem subitum) and, most commonly, an undifferentiated febrile illness. Viral reactivation in the immunocompromised host has been linked to a variety of diseases, including encephalitis, and HHV-6 has been tentatively associated with multiple sclerosis. This article discusses the major properties of HHV-6, its association with human disease, and the pathobiological significance of viral reactivation.

Clauw DJ.	Georgetown Chronic Pain and Fatigue	Potential mechanisms in chemical	Ann N Y Acad Sci. 2001 Mar;933:235-	The symptom of chemical intolerance may occur in isolation, but often occurs in conjunction with other chronic symptoms such as pain, fatigue, memory disturbances, etc.

	Research Center, Department of Medicine, Georgetown University Medical Center, Washington, District of Columbia 20007, USA.	intolerance and related conditions.	53.	This frequent clustering of symptoms in individuals has led to the definition of several chronic multisymptom syndromes, such as multiple chemical sensitivity, fibromyalgia, chronic fatigue syndrome, and Gulf War illnesses. The aggregate research into these syndromes has suggested some unifying mechanisms that contribute to symptomatology. Multiple lines of evidence suggest that there is aberrant function of numerous efferent neural pathways, such as the autonomic nervous system and hypothalamic-pituitary axes, in subsets of individuals with these conditions. There is perhaps the greatest evidence for abnormal sensory processing in these syndromes, with a low "unpleasantness threshold" for multiple types of sensory stimuli. Psychological and behavioral factors are known to play a significant role in initiating or perpetuating symptoms in some persons with these illnesses. In the field of pain research, the interrelationship between physiologic and psychologic factors in symptom expression has been well studied. Using both established and novel methodologies, studies have suggested that psychologic factors such as hypervigilance and expectancy are playing a relatively minor role in most individuals with fibromyalgia and that clear evidence exists of physiologic amplification of sensory stimuli. These studies need to be extended to more sensory tasks and to larger numbers of subjects with related conditions. It is of note, though, that existing data on this spectrum of illnesses would suggest that there may be greater psychologic contributions to symptomatology if an illness is defined in part by behavior (e.g., avoidance of chemical exposures) rather than on the basis of symptoms alone.
Claypoole K, Mahurin R, Fischer ME, Goldberg J, Schmaling KB, Schoene RB, Ashton S, Buchwald D.	Departments of Psychiatry and Behavioral Sciences, University of Washington, Seattle, Washington, USA.	Cognitive compromise following exercise in monozygotic twins discordant for chronic fatigue syndrome: fact or artifact?	Appl Neuropsychol. 2001;8(1):31-40.	This study examined the effects of exhaustive exercise on cognitive functioning among 21 monozygotic twin pairs discordant for chronic fatigue syndrome (CFS). The co-twin control design adjusts for genetic and family environmental factors not generally accounted for in more traditional research designs of neuropsychological function. Participants pedaled a cycle ergometer to exhaustion; maximum oxygen output capacity (VO2max) as well as perceived exertion were recorded. Neuropsychological tests of brief attention and concentration, speed of visual motor information processing, verbal learning and recognition memory, and word and category fluency were administered with alternate forms to participants pre- and postexercise. The preexercise neuropsychological test performance of CFS twins tended to be slightly below that of the healthy twin controls on all measures. However, twins with CFS did not demonstrate differential decrements in neuropsychological functioning after exercise relative to their healthy co-twins. Because exercise does not appear to diminish cognitive function, rehabilitative treatment approaches incorporating exercise are not contraindicated in CFS.
Cleare AJ, Blair D, Chambers S, Wessely S.	Department of Psychological Medicine, Guy's King's and St. Thomas' School of Medicine and the	Urinary free cortisol in chronic fatigue syndrome.	Am J Psychiatry. 2001 Apr;158(4):641-3.	OBJECTIVE: The authors measured 24-hour urinary free cortisol in a group of well-characterized patients with chronic fatigue syndrome. METHOD: They obtained 24-hour urine collections from 121 consecutive clinic patients with chronic fatigue syndrome and 64 comparison subjects without the syndrome. RESULTS: Urinary free cortisol was significantly lower in the subjects with chronic fatigue syndrome regardless of the presence or absence of current or past comorbid psychiatric illness. Lower levels of urinary free

	Institute of Psychiatry, 103 Denmark Hill, London SE5 8AZ, UK. a.cleare@iop.kcl.ac.uk			cortisol were not related to medication use, sleep disturbance, or disability levels. CONCLUSIONS: There is mild hypocortisolism in chronic fatigue syndrome. Whether a primary feature or secondary to other factors, hypocortisolism may be one factor contributing to the symptoms of chronic fatigue syndrome.
Cleare AJ, Miell J, Heap E, Sookdeo S, Young L, Malhi GS, O'Keane V.	Department of Psychological Medicine, Institute of Psychiatry and Guy's, King's and St Thomas' School of Medicine, London SE5 8AZ, United Kingdom. a.cleare@iop.kcl.ac.uk	Hypothalamo-pituitary-adrenal axis dysfunction in chronic fatigue syndrome, and the effects of low-dose hydrocortisone therapy.	J Clin Endocrinol Metab. 2001 Aug;86(8):3545-54.	These neuroendocrine studies were part of a series of studies testing the hypotheses that 1) there may be reduced activity of the hypothalamic-pituitary-adrenal axis in chronic fatigue syndrome and 2) low-dose augmentation with hydrocortisone therapy would improve the core symptoms. We measured ACTH and cortisol responses to human CRH, the insulin stress test, and D-fenfluramine in 37 medication-free patients with CDC-defined chronic fatigue syndrome but no comorbid psychiatric disorders and 28 healthy controls. We also measured 24-h urinary free cortisol in both groups. All patients (n = 37) had a pituitary challenge test (human CRH) and a hypothalamic challenge test [either the insulin stress test (n = 16) or D-fenfluramine (n = 21)]. Baseline cortisol concentrations were significantly raised in the chronic fatigue syndrome group for the human CRH test only. Baseline ACTH concentrations did not differ between groups for any test. ACTH responses to human CRH, the insulin stress test, and D- fenfluramine were similar for patient and control groups. Cortisol responses to the insulin stress test did not differ between groups, but there was a trend for cortisol responses both to human CRH and D-fenfluramine to be lower in the chronic fatigue syndrome group. These differences were significant when ACTH responses were controlled. Urinary free cortisol levels were lower in the chronic fatigue syndrome group compared with the healthy group. These results indicate that ACTH responses to pituitary and hypothalamic challenges are intact in chronic fatigue syndrome and do not support previous findings of reduced central responses in hypothalamic-pituitary-adrenal axis function or the hypothesis of abnormal CRH secretion in chronic fatigue syndrome. These data further suggest that the hypocortisolism found in chronic fatigue syndrome may be secondary to reduced adrenal gland output. Thirty-two patients were treated with a low-dose hydrocortisone regime in a double-blind, placebo-controlled cross-over design, with 28 days on each treatment. They underwent repeated 24-h urinary free cortisol collections, a human CRH test, and an insulin stress test after both active and placebo arms of treatment. Looking at all subjects, 24-h urinary free cortisol was higher after active compared with placebo treatments, but 0900-h cortisol levels and the ACTH and cortisol responses to human CRH and the insulin stress test did not differ. However, a differential effect was seen in those patients who responded to active treatment (defined as a reduction in fatigue score to the median population level or less). In this group, there was a significant increase in the cortisol response to human CRH, which reversed the previously observed blunted responses seen in these patients. We conclude that the improvement in fatigue seen in some patients with chronic fatigue syndrome during hydrocortisone treatment is accompanied by a reversal of the blunted

				cortisol responses to human CRH.
Cleare AJ, O'Keane V, Miell J.	Department of Psychological Medicine, Guy's, King's and St Thomas' School of Medicine, 103 Denmark Hill, London SE3 8AF, UK. a.cleare@iop.kcl.ac.uk	Plasma leptin in chronic fatigue syndrome and a placebo-controlled study of the effects of low-dose hydrocortisone on leptin secretion.	Clin Endocrinol (Oxf). 2001 Jul;55(1):113-9.	OBJECTIVE: Previous studies have suggested that chronic fatigue syndrome (CFS) is associated with changes in appetite and weight, and also with mild hypocortisolism. Because both of these features may be related to leptin metabolism, we undertook a study of leptin in CFS. DESIGN: (i) A comparison of morning leptin concentration in patients with CFS and controls and (ii) a randomized, placebo-controlled crossover study of the effects of hydrocortisone on leptin levels in CFS. PATIENTS: Thirty-two medication free patients with CFS but not comorbid depression or anxiety. Thirty-two age, gender, weight, body mass index and menstrual cycle matched volunteer subjects acted as controls. MEASUREMENTS: We measured basal 0900 h plasma leptin levels in patients and controls. All 32 patients were taking part in a randomized, placebo-controlled crossover trial of low dose (5 or 10 mg) hydrocortisone as a potential therapy for CFS. We measured plasma leptin after 28 days treatment with hydrocortisone and after 28 days treatment with placebo. RESULTS: At baseline, there was no significant difference in plasma leptin between patients [mean 13.8, median 7.4, interquartile range (IQR) 18.0 ng/ml] and controls (mean 10.2, median 5.5, IQR 11.3 ng/ml). Hydrocortisone treatment, for both doses combined, caused a significant increase in leptin levels compared to placebo. When the two doses were analysed separately, only 10 mg was associated with a significant effect on leptin levels. We also compared the hydrocortisone induced increase in leptin between those who were deemed treatment-responders and those deemed nonresponders. Responders showed a significantly greater hydrocortisone-induced rise in leptin than nonresponders. This association between a clinical response to hydrocortisone and a greater rise in leptin levels may indicate a greater biological effect of hydrocortisone in these subjects, perhaps due to increased glucocorticoid receptor sensitivity, which may be present in some patients with CFS. CONCLUSIONS: We conclude that, while we found no evidence of alterations in leptin levels in CFS, low dose hydrocortisone therapy caused increases in plasma leptin levels, with this biological response being more marked in those CFS subjects who showed a positive therapeutic response to hydrocortisone therapy. Increases in plasma leptin levels following low dose hydrocortisone therapy may be a marker of pretreatment physiological hypocortisolism and of response to therapy.

Cochran John W.		Effect of Modafinil on	Journal of Chronic	Fatigue is a common symptom of a variety of neurological illnesses, such as Alzheimer's

		Fatigue Associated with Neurological Illnesses	Fatigue Syndrome 2001; 8(2): 65	disease, chronic fatigue syndrome, multiple sclerosis, Parkinson's disease, and stroke. Fatigue severely impairs productivity, performance, social functioning, and quality of life. Modafinil (PROVIGIL®) has been shown to significantly improve fatigue associated with multiple sclerosis and depression. Here, a retrospective review of the medical charts of 25 patients treated with modafinil for fatigue associated with various neurological illnesses was conducted. Modafinil was effective for the treatment of fatigue in 21 of 25 patients (84%), and was well tolerated. Therefore, modafinil appears to be a potentially attractive candidate for the treatment of fatigue associated with neurological disorders.
Coetzer P, Lockyer I, Schorn D, Boshoff L.	Sanlam, Bellville, Republic of South Africa.	Assessing impairment and disability for syndromes presenting with chronic fatigue.	J Insur Med. 2001;33(2):170-82.	Many disability claims are based on the subjective symptom of fatigue, which can be caused by a wide spectrum of diagnoses including fibromyalgia, chronic fatigue syndrome and cardiopulmonary diseases. Chronic pain is very often a compounding problem. It is vital for every insurer to have fair and objective criteria to distinguish between invalid claims and those with merit. This review article proposes objective tools and parameters to achieve this goal.
Cohen H, Neumann L, Kotler M, Buskila D.	Anxiety and Stress Research Unit, Ministry of Health Mental Health Center, Faculty of Health Sciences, Ben-Gurion University of the Negev, Beer Sheva, Israel. hagitc@bgumail.bgu.ac.il	Autonomic nervous system derangement in fibromyalgia syndrome and related disorders.	Isr Med Assoc J. 2001 Oct;3(10):755-60.	Fibromyalgia syndrome is a chronic, painful musculoskeletal disorder of unknown etiology and/or pathophysiology. During the last decade many studies have suggested autonomic nervous system involvement in this syndrome, although contradictory results have been reported. This review focuses on studies of the autonomic nervous system in fibromyalgia syndrome and related disorders, such as chronic fatigue syndrome and irritable bowel syndrome on the one hand and anxiety disorder on the other, and highlights techniques of dynamic assessment of heart rate variability. It raises the potentially important prognostic implications of protracted autonomic dysfunction in patient populations with fibromyalgia and related disorders, especially for cardiovascular morbidity and mortality.
Cook DB, Lange G, DeLuca J, Natelson BH.	Department of Neurosciences, UMDNJ-New Jersey Medical School, Newark, NJ 07103, USA.	Relationship of brain MRI abnormalities and physical functional status in chronic fatigue syndrome.	Int J Neurosci. 2001 Mar;107(1-2):1-6.	Chronic Fatigue Syndrome (CFS) is an unexplained illness that is characterized by severe fatigue. Some have suggested that CFS is a "functional somatic syndrome" in which symptoms of fatigue are inappropriately attributed to a serious illness. However, brain magnetic resonance imaging (MRI) data suggest that there may be an organic abnormality associated with CFS. To understand further the significance of brain MRI abnormalities, we examined the relationship between MRI identified brain abnormalities and self-reported physical functional status in 48 subjects with CFS who underwent brain MR imaging and completed the Medical Outcomes Study SF-36. Brain MR images were examined for the presence of abnormalities based on 5 general categories previously shown to be sensitive to differentiating CFS patients from healthy controls. There were significant negative relationships between the presence of brain abnormalities and both the physical functioning (PF) (rho=-.31, p=.03), and physical component summary PCS (rho=-.32, p=.03) subscales of the SF-36. CFS patients with MRI identified brain abnormalities scored significantly lower on both PF (t(1,46) =2.3, p=.026) and the PCS (t(1,41) =2.4, p=.02) than CFS subjects without an identified brain abnormality. When adjusted for age differences

				only the PF analysis remained significant. However, the effect sizes for both analyses were large indicating meaningful differences in perceived functional status between the groups. These results demonstrate that the presence of brain abnormalities in CFS are significantly related to subjective reports of physical function and that CFS subjects with MRI brain abnormalities report being more physically impaired than those patients without brain abnormalities.
Cordingley L, Wearden A, Appleby L, Fisher L.	School of Psychiatry and Behavioural Sciences, University of Manchester, Room 704, Stopford Building, Oxford Road, M13 9PT, Manchester, UK. lis.cordingley@man.ac.uk	The Family Response Questionnaire: a new scale to assess the responses of family members to people with chronic fatigue syndrome.	J Psychosom Res. 2001 Aug;51(2):417-24.	OBJECTIVE: Family responses to patients with chronic fatigue syndrome (CFS) may influence the course of the disorder and family members themselves are likely to be adversely affected. However, the beliefs and responses of relatives of CFS patients have been under-researched. The aim of this study was to produce an easy-to-administer questionnaire to assess the responses of family members to people with CFS. METHODS: Seventy-eight people, all close relatives of (physician-diagnosed) CFS sufferers, completed the first version of the Family Response Questionnaire (FRQ). RESULTS: Examination of the correlation matrix and a cluster analysis of the items support four scales rather than the original five. The four response scales were labelled: sympathetic-empathic, active engagement, rejecting-hostile, and concern with self. Measures of test-retest and internal reliability were high. Participants found the items both comprehensible and relevant to their experiences of living with people with CFS. CONCLUSION: The new version of the FRQ will be useful in further examination of the responses of CFS on individuals and their families.
Coutts R, Weatherby R, Davie A.	School of Exercise Science and Sport Management, Southern Cross University, P.O. Box 157, New South Wales 2480, Lismore, Australia.rcoutts@scu.edu.au	The use of a symptom "self-report" inventory to evaluate the acceptability and efficacy of a walking program for patients suffering with chronic fatigue syndrome.	J Psychosom Res. 2001 Aug;51(2):425-9.	OBJECTIVES: The purpose of this research was to evaluate the effectiveness of the modality of walking as a management strategy for patients suffering with chronic fatigue syndrome (CFS). METHODS: Six males and fourteen females with medically diagnosed CFS (CDC, 1994), completed a 12-week walking program. Prior to starting the program subjects underwent an incremental walking exercise test to predetermine their walking intensity. The SCL-90-R symptom "self-report" questionnaire was administered prior to, and at the completion of, the walking program. RESULTS: At the completion of the 12 weeks of walking, changes in four of the nine SCL-90-R dimensions were significant (somatisation, paranoid ideation, phobic anxiety, and psychoticism). Also significant were the changes in the combination indices, the Global Indices of Distress (GID) and the Positive Symptom Total (PST). CONCLUSION: This group of CFS subjects, by way of "self-report", indicated the possibility of an exercise-induced decrease in psychological stress. The walking intervention may have evoked positive changes in their well-being and, furthermore, provided no evidence of any exacerbation in their symptoms.
Creswell C, Chalder T.	Sub-Department of Clinical Health Psychology, University College London, Gower Street, WC1E 6BT,	Defensive coping styles in chronic fatigue syndrome.	J Psychosom Res. 2001 Oct;51(4):607-10.	OBJECTIVE: The cognitive-behavioral model of chronic fatigue syndrome (CFS) proposes that rigidly held beliefs act to defend individuals against low self-esteem. This study is the first to investigate the prevalence of a potential mechanism, the Defensive High Anxious coping style, among individuals with CFS. METHODS: The study comprised 68 participants (24 CFS; 24 healthy volunteers; 20 chronic illness volunteers). Participants completed the Bendig short form of the Taylor Manifest Anxiety Scale (B-MAS) and the Marlowe-Crowne

	London, UK. c.creswell@ucl.ac.uk			Social Desirability Scale (MC) in order to ascertain the distribution of participants in each group within the four coping styles defined by Weinberger et al. [J. Abnorm. Psychol. 88 (1979) 369]. RESULTS: A greater number of participants in the CFS group (46%) were classified as Defensive High Anxious compared to the two comparison groups [chi(2)(2)=8.84, P=.012]. CONCLUSION: This study provides support for the existence of defensive coping mechanisms as described by the cognitive-behavioral model of CFS. Furthermore, it has been suggested that this particular coping style may impinge directly on physical well being through similar mechanisms as identified in CFS, and further research linking these areas of research is warranted.
Csef H.	Arbeitsbereich Psychosomatische Medizin und Psychotherapie, Medizinische Poliklinik, der Universitat, Klinikstrasse 8, 97070 Wurzburg.	[Chronic fatigue] [Article in German]	Internist (Berl). 2001 Nov;42(11):1495-502, 1504; quiz 1504-7.	
Curt GA.	National Cancer Institute, National Institutes of Health, Clinical Center, Oncology Program, Building 10, Room 12N214, 9000 Rockville Pike, Bethesda, Maryland 20892, USA.	[Fatigue syndrome caused by malignant tumor. An increasing priority in patient care] [Article in Italian	Recenti Prog Med. 2001 Jun;92(6):408-12.	As oncologists have become more effective in alleviating pain, nausea and depression, fatigue has emerged as the most important symptom suffered by cancer patients. Indeed, the current literature suggests that fatigue is currently the most important untreated symptom in cancer medicine. In recent surveys of patients and their caregivers, fatigue is more important for the quality of life than pain, nausea or depression. Yet these same surveys confirm that oncologists underestimate the importance of cancer related fatigue. This may be partly because patients often do not fully share the full nature of their concerns. When patients do raise the issue of fatigue, the physicians' recommendations are often non specific. However, recent research has shown that fatigue is not inevitable and untreatable, but a symptom amenable to differential diagnosis and specific intervention. Like pain, fatigue is intrinsically a subjective problem where the doctor relies on the patient's reporting. Weakness, exhaustion, lethargy and asthenia are all used as functional descriptions of fatigue. While these are descriptive terms, clinical research in the measurement and alleviation of fatigue requires reproducible measurement tools. Several studies already exist and have begun to explore this important area of symptom management.

Daly E, Komaroff AL, Bloomingdale K, Wilson S, Albert MS.	Department of Psychiatry, Massachusetts General Hospital, 149 13th Street, Charlestown, MA 02129, USA. albert@psych.mgh.harvard.edu	Neuropsychological function in patients with chronic fatigue syndrome, multiple sclerosis, and depression.	Appl Neuropsychol. 2001;8(1):12-22.	Patients with chronic fatigue syndrome (CFS), multiple sclerosis (MS), and major depression were compared with controls and with each other on a neuropsychological battery that included standard neuropsychological tests and a computerized set of tasks that spanned the same areas of ability. A total of 101 participants were examined, including 29 participants with CFS, 24 with MS, 23 with major depressive disorder, and 25 healthy controls. There were significant differences among the groups in 3 out of 5 cognitive domains: memory, language, and spatial ability. Assessment of psychiatric symptoms indicated that all 3 patient groups had a higher prevalence of depression than the controls. A total measure of psychiatric symptomatology also differentiated the patients from the controls. After covarying the cognitive test scores by a measure of depression, the patient groups continued to differ from controls primarily in the area of memory. The findings support the view that the cognitive deficits found in CFS cannot be attributed solely to the presence of depressive symptomatology in the patients.
Davey NJ, Puri BK, Nowicky AV, Main J, Zaman R.	Department of Sensimotor Systems, Division of Neuroscience and Psychological Medicine, Imperial College School of Medicine, Charing Cross Hospital, Fullham Palace Road, W6 8RF, London, UK. n.davey@ic.ac.uk	Voluntary motor function in patients with chronic fatigue syndrome.	J Psychosom Res. 2001 Jan;50(1):17-20.	INTRODUCTION: The pathogenesis of chronic fatigue syndrome (CFS) remains unknown. In particular, little is known of the involvement of the motor cortex and corticospinal system. METHODS: Transcranial magnetic stimulation (TMS) was used to assess corticospinal function in terms of latency and threshold of motor-evoked potentials (MEPs) in thenar muscles. Reaction times and speed of movement were assessed using button presses in response to auditory tones. RESULTS: Patients had higher (P<.05) self-assessed indices of fatigue (7/10) than for pain (5/10), anxiety (4/10) or depression (3/10). Mean (+/-S.E.M.) simple reaction times (SRTs) were longer (P<.05) in the patients (275+/-19 ms) than in the controls (219+/-9 ms); choice reaction times (CRTs) were not significantly longer in the patients. Movement times, once a reaction task had been initiated, were longer (P<.05) in the patients in both SRTs (patients, 248+/-13 ms; controls, 174+/-9 ms) and CRTs (patients, 269+/-13 ms; controls, 206+/-12 ms). There was no difference (P>.05) in threshold or latency of MEPs in hand muscles between the patients (threshold, 54.5+/-2.2% maximum stimulator output [% MSO]; latency 22+/-0.3 ms) and controls (threshold 54.6+/-3.6% MSO; latency 22.9+/-0.5 ms). Regression analysis showed no correlation (P>.05) of SRTs with either threshold for MEPs or fatigue index. CONCLUSION: Corticospinal conduction times and excitability were within the normal range despite a slower performance time for motor tasks and an increased feeling of fatigue. This suggests that the feeling of fatigue and the slowness of movement seen in CFS are manifest outside the corticospinal system.
De Becker P, McGregor N, De Meirleir K.	VUB, Vakgroep Interne Geneeskunde, KRO gebouw niv.-1, Laarbeeklaan 101,	A definition-based analysis of symptoms in a large cohort of patients with chronic	J Intern Med. 2001 Sep;250(3):234-40.	OBJECTIVE: The Holmes and Fukuda criteria are widely used criteria all over the world, yet a specific European study regarding chronic fatigue syndrome (CFS) patient symptomatology has not been conducted so far. This study was performed to answer the need to assess the homogeneity of a large CFS population in relationship to the Fukuda or

	1090 Brussels, Belgium. pdbeck@minf.vub.ac.be	fatigue syndrome.		Holmes definitions and to assess the importance of a symptom severity scale. DESIGN: Multivariate analyses were performed to assess the symptom presentation within a fatigued population and the differences between the Fukuda and Holmes definitions compared with an excluded chronic fatigued group in a large cohort of fatigued patients. SETTING: An outpatient tertiary care setting fatigue clinic in Brussels. MAIN OUTCOME MEASURES: Prevalence and severity of symptoms and signs in a CFS population and in a chronic fatigued population. SUBJECTS AND METHODS: A total of 2073 consecutive patients with major complaints of prolonged fatigue participated in this study. Multivariate analyses were performed to assess the symptom presentation and severity and the differences between the Fukuda and Holmes definitions. RESULTS: Of the 2073 patients complaining of chronic fatigue (CF), 1578 CFS patients fulfilled the Fukuda criteria (100% of CFS group) and 951 (60.3% of the CFS group) fulfilled the Holmes criteria. Discriminant function analysis revealed that the Fukuda and Holmes definitions can be differentiated by symptom severity and prevalence. The Holmes definition was more strongly associated than the Fukuda definition with the symptoms that differentiated the CFS patients from the patients that did not comply with the CFS definitions. The inclusion of 10 additional symptoms was found to improve the sensitivity/specificity and accuracy for selection of CFS patients. CONCLUSIONS: The CFS patients fulfilling the Holmes criteria have an increased symptom prevalence and severity of many symptoms. Patients fulfilling the Fukuda criteria were less severely affected patients which leads to an increase in clinical heterogeneity. Addition of certain symptoms and removal of others would strengthen the ability to select CFS patients.

De Vries M, Soetekouw PM, Van Der Meer JW, Bleijenberg G.	Department of Medical Psychology, University Medical Centre St Radboud, Nijmegen, The Netherlands.	Natural course of symptoms in Cambodia veterans: a follow-up study.	Psychol Med. 2001 Feb;31(2):331-8.	BACKGROUND: Dutch (ex-)servicemen were deployed in the 1992-3-peace operation UNTAC in Cambodia. Since their return, they have voiced concerns about the health consequences of their service and they have reported symptoms such as fatigue and cognitive problems. The natural course of symptoms in Dutch Cambodia veterans was evaluated in a prospective study. METHODS: At 18-months follow-up, a questionnaire was sent to 354 veterans who met a set case definition for symptoms in Cambodia veterans or who had sub-threshold scores. Initial measurement of fatigue severity, psychological well-being, depression, post-traumatic stress disorder, trait-anxiety, self-efficacy and causal attributions, was used to evaluate predictors for self-reported improvement and low levels of fatigue at follow-up. RESULTS: At follow-up, 19% of the respondents reported complete recovery, 20% felt much better, 57% had the same complaints and 4% had become worse compared with their initial assessment. Self-reported improvement and less severe fatigue

				at follow-up were predicted by less severe fatigue at initial assessment and more perceived control over symptoms. CONCLUSIONS: Self-reported improvement was reported in a considerable percentage of Cambodia veterans, whereas another substantial percentage of Cambodia veterans continued to suffer with severe levels of fatigue and related symptoms. Predictors of improvement in Cambodia veterans and patients with chronic fatigue syndrome show similarities and also seem to bear importance for Gulf War veterans.
Deale A, Husain K, Chalder T, Wessely S.	Academic Department of Psychological Medicine, Guy's, King's, and St. Thomas's School of Medicine, London, UK. a.deale@iop.kcl.ac.uk	Long-term outcome of cognitive behavior therapy versus relaxation therapy for chronic fatigue syndrome: a 5-year follow-up study.	Am J Psychiatry. 2001 Dec;158(12):2038-42.	OBJECTIVE: This study evaluated the long-term outcome of cognitive behavior therapy versus relaxation therapy for patients with chronic fatigue syndrome. METHOD: Sixty patients who participated in a randomized controlled trial of cognitive behavior therapy versus relaxation therapy for chronic fatigue syndrome were invited to complete self-rated measures and participate in a 5-year follow-up interview with an assessor who was blind to treatment type. RESULTS: Fifty-three patients (88%) participated in the follow-up study: 25 received cognitive behavior therapy and 28 received relaxation therapy. A total of 68% of the patients who received cognitive behavior therapy and 36% who received relaxation therapy rated themselves as "much improved" or "very much improved" at the 5-year follow-up. Significantly more patients receiving cognitive behavior therapy, in relation to those in relaxation therapy, met criteria for complete recovery, were free of relapse, and experienced symptoms that had steadily improved or were consistently mild or absent since treatment ended. Similar proportions were employed, but patients in the cognitive behavior therapy group worked significantly more mean hours per week. Few patients crossed the threshold for "normal" fatigue, despite achieving a good outcome on other measures. Cognitive behavior therapy was positively evaluated and was still used by over 80% of the patients. CONCLUSIONS: Cognitive behavior therapy for chronic fatigue syndrome can produce some lasting benefits but is not a cure. Once therapy ends, some patients have difficulty making further improvements. In the future, attention should be directed toward ensuring that gains are maintained and extended after regular treatment ends.
Deale A, Wessely S.	Academic Department of Psychological Medicine, Guy's, King's and St Thomas's School of Medicine, Kings College, University of London, UK. alicia.deale@kcl.ac.uk	Patients' perceptions of medical care in chronic fatigue syndrome.	Soc Sci Med. 2001 Jun;52(12):1859-64.	This study investigated perceptions of medical care among patients with chronic fatigue syndrome (CFS) referred to a specialist clinic. Sixty-eight patients completed a questionnaire survey on their overall satisfaction with medical care received since the onset of their illness, and their views on specific aspects of care. Two-thirds of patients were dissatisfied with the quality of medical care received. Dissatisfied patients were significantly more likely to describe delay, dispute or confusion over diagnosis; to have received and rejected a psychiatric diagnosis; to perceive doctors as dismissive, skeptical or not knowledgeable about CFS and to feel that the advice given was inadequate or conflicting. Satisfied patients were significantly more likely to perceive doctors as caring, supportive and interested in their illness; to state that they did not expect their doctors to cure CFS and to perceive their GP or hospital doctor as the source of greatest help during their illness. Many patients were critical of the paucity of treatment, but this was not

				associated with overall satisfaction. The findings suggest that medical care was evaluated less on the ability of doctors to treat CFS, and more on their interpersonal and informational skills. Dissatisfaction with these factors is likely to impede the development of a therapeutic doctor-patient alliance, which is central to the effective management of CFS. The findings suggest a need for better communication and better education of doctors in the diagnosis and management of CFS.
Dendy C, Cooper M, Sharpe M.	Isis Education Centre, Warneford Hospital, Oxford, UK.	Interpretation of symptoms in chronic fatigue syndrome.	Behav Res Ther. 2001 Nov;39(11):1369-80.	Chronic fatigue syndrome (CFS) is an illness characterised by fatigue and other symptoms. Both psychological and biological aetiological factors have been proposed, but the disorder is of uncertain origin. The aetiology of the symptoms is therefore ambiguous. It has been suggested (a) that patients with CFS tend to interpret their symptoms as indicating physical illness and (b) they tend not to interpret these symptoms in terms of negative emotion. In order to test these hypotheses we developed a self-report questionnaire to assess the interpretation of symptoms in patients with CFS. It was administered to patients with CFS, patients with depression, patients with multiple sclerosis (MS), and normal controls. Preliminary results suggest that the measure has acceptable psychometric properties. Patients with CFS were more likely than either depressed patients or normal controls to interpret symptoms (characteristic of CFS) in terms of physical illness, but did not differ in this from the MS patients. When compared with all three other groups (including the MS patients), the patients with CFS were least likely to interpret symptoms in terms of negative emotional states. The theoretical and clinical implications of the findings are discussed.
DiClementi JD, Schmaling KB, Jones JF.	Department of Psychology, University of Colorado at Denver, Denver, CO, USA. diclemej@ipfw.edu	Information processing in chronic fatigue syndrome: a preliminary investigation of suggestibility.	J Psychosom Res. 2001 Nov;51(5):679-86.	This study examines the effects of certain types of information processing on the subjective experience of cognitive deficits in persons with chronic fatigue syndrome (CFS). Two groups of participants, persons with CFS and a group of healthy controls, were administered a symptom inventory and measures of intellectual functioning, memory, automatic processing, and suggestibility. The groups differed significantly on number and severity of reported symptoms and on measures of global suggestibility and automatic processing, but not on measures of intellectual functioning and memory. Suggestibility was related to number and severity of reported symptoms, as well as the inability to inhibit the automatic processing of information. Implications of these findings are discussed, as well as directions for future research and treatment of symptoms associated with CFS.
Dinan TG, Scott LV, Thakore J, Naesdal J, Keeling PW.	Department of Pharmacology and Therapeutics, University College Cork, The Cork Clinic, Western Road, Cork, Ireland. tdinan@indigo.ie	Impact of cortisol on buspirone stimulated prolactin release: a double-blind placebo-controlled study.	Psychoneuroendocrinology. 2001 Oct;26(7):751-6.	Buspirone is known to stimulate prolactin release. Clinical studies (e.g. in chronic fatigue syndrome) suggest that the response may be influenced by baseline cortisol levels. We conducted a double-blind placebo-controlled study to examine the relationship between the prolactin response to buspirone challenge and baseline cortisol level. Fifty healthy volunteers took part in the study. Buspirone was found to consistently elevate PRL levels above those seen following placebo administration. The PRL response as measured by area under the curve was highly correlated with the baseline cortisol level.
Dobbs BM, Dobbs	Department of	Working memory	J Int Neuropsychol	Cognitive impairments are among the most frequently reported and least investigated

AR, Kiss I.	Psychology, University of Alberta, Edmonton, Canada. bdobbs@ualberta.ca	deficits associated with chronic fatigue syndrome.	Soc. 2001 Mar;7(3):285-93.	components of the chronic fatigue syndrome (CFS). As part of a multifaceted study of the CFS, the present study investigated the cognitive functioning of chronic fatigue patients. The performance of 20 CFS patients was compared to that of controls (N = 20) on 4 tests of working memory (WM). Digit Span Forward was used to assess the storage capacity of WM. Multiple aspects of central executive functioning were assessed using several standard measures: Digit Span Backward, and Trails A and Trails B. More recently developed measures of WM were used to assess control of processing under temporal demands (working memory task) and resistance to interference (a sustained attention task). Deficits were restricted to more demanding tasks, requiring resistance to interference and efficient switching between processing routines. The overall results clearly implicate deficits in the control aspects of central executive function in CFS.
Edwards R, Suresh R, Lynch S, Clarkson P, Stanley P.	Division of Psychiatry and Behavioural Sciences, University of Leeds, LS9 7TF, Leeds, UK.	Illness perceptions and mood in chronic fatigue syndrome.	J Psychosom Res. 2001 Feb;50(2):65-8.	BACKGROUND: Individual beliefs and cognitions may affect adjustment to chronic fatigue syndrome (CFS) and illness perceptions, in particular, have been reported to correlate with both disability and psychological adjustment to CFS in self-diagnosed cases. OBJECTIVES: The aim of the present study was to examine these relationships in a clinic sample of CFS patients assessed by both a physician and psychiatrist. METHOD: A sample of 173 patients referred to a multidisciplinary CFS clinic and fulfilling current operational criteria for CFS [Ann Intern Med 121 (1994) 953; J R Soc Med 84 (1991) 118.] were randomly selected from the clinic database and surveyed with the Hospital Anxiety and Depression scale, Fatigue Questionnaire and Illness Perceptions Questionnaire [J Psychosom Res 37 (1993) 147; Psychol Health 11 (1996) 431; Acta Psychiatr Scand 67 (1983) 361.]. RESULTS: A total of 126 patients responded (73% response rate). The illness perception components studied were consequences (of illness), illness identity, causes (of illness), the ability to control/cure the illness and (expected) timeline of the illness. These components accounted for 15%, 28% and 30% of the variance in levels of fatigue, depression and anxiety, respectively. Two of the illness perception components (consequences and illness identity) were stronger predictors of fatigue score than mood scores. CONCLUSIONS: These findings confirmed in a clinical sample that illness perceptions are associated with variation in both disability and psychological adjustment in CFS. Illness perceptions may have an important and long-lasting effect on adaptation to CFS, and it is necessary to have a greater understanding of their role in order to tailor effective interventions for the condition.
Ehlert U, Gaab J, Heinrichs M.	Department of Clinical Psychology, University of Zurich, Zurichbergstrasse 43, CH-8044, Zurich, Switzerland. ehlertu@klipsy.unizh.ch	Psychoneuroendocrinological contributions to the etiology of depression, posttraumatic stress disorder, and stress-related bodily disorders: the role of the hypothalamus-	Biol Psychol. 2001 Jul-Aug;57(1-3):141-52.	Following the assumption that stressors play an important part in the etiology and maintenance of psychiatric disorders, it is necessary to evaluate parameters reflecting stress-related physiological reactions. Results from these examinations may help to deepen the insight into the etiology of psychiatric disorders and to elucidate diagnostic uncertainties. One of the best-known stress-related endocrine reactions is the hormonal release of the hypothalamic-pituitary-adrenal (HPA) axis. Dysregulations of this axis are associated with several psychiatric disorders. Profound hyperactivity of the HPA-axis has been found in melancholic depression, alcoholism, and eating disorders. In contrast, posttraumatic stress disorder, stress-related bodily disorders like idiopathic pain

		pituitary-adrenal axis.		syndromes, and chronic fatigue syndrome seem to be associated with diminished HPA activity (lowered activity of the adrenal gland). Hypotheses referring to (a) the psychophysiological meaning and (b) the development of these alterations are discussed.
Englebienne P, Herst CV, Smet K, D'Haese A, De Meirleir K.		Interactions Between RNase L Ankyrin-Like Domain and ABC Transporters as a Possible Origin for Pain, Ion Transport, CNS and Immune Disorders of Chronic Fatigue Immune Dysfunction Syndrome	Journal of Chronic Fatigue Syndrome 2001; 8(3/4): 83	Low molecular weight (LMW) ribonuclease L (RNase L) forms have been identified in peripheral blood mononuclear cells (PBMC) of patients with chronic fatigue immune dysfunction syndrome (CFIDS). Data from our laboratory indicate that these LMW RNase L proteins are produced by proteolytic cleavage of the native monomeric enzyme and we have identified calpain as one of the possible proteases involved. Using human recombinant RNase L (r-hRNase L) His-tagged at the N-terminus, we show here at the one hand that both calpain and PBMC extracts from CFIDS patients cleave the protein in fragments of identical sizes containing ankyrin-like repeat sequences. At the other hand, the activity of RNase L is modulated by its interaction with a specific inhibitor (RLI), a member of the ATP binding cassette (ABC) superfamily. RLI interacts with the ankyrin domain of RNase L, which results in a blockade of the 2N,5N-oligoadenylate (2-5A)-binding site of the enzyme. We show that RLI contains a small ankyrin-interacting peptide cluster through which it interacts with the first two ?-hairpin coils of the RNase L ankyrin domain. A similarity search performed at the NCBI using RLI aminoacid sequence as the entry allowed to identify several other ABC transporter proteins sharing significant identities with RLI, including the ankyrin-interacting peptide. Taken together, these results show that upon pathological cleavage of RNase L, fragments containing the ankyrin domain are released, which could be capable of interacting with selected members of the human ABC superfamily, preventing their interaction with the normal cognate ankyrin protein and hence impairing their proper cellular function. This interaction constitutes a common physiological mechanism explaining numerous and currently unexplained symptoms experienced by patients with CFIDS, which are otherwise totally unrelated.

Ferguson E, Cassaday HJ.	School of Psychology, University of Nottingham, Nottingham, NG7 2RD, UK. eamonn.ferguson@nottingham.ac.uk	Theoretical accounts of Gulf War Syndrome: from environmental toxins to psychoneuroimmunology and neurodegeneration.	Behav Neurol. 2001-2002;13(3-4):133-47.	Non-specific illness includes a wide variety of symptoms: behavioural (e.g., reduced food and water intake), cognitive (e.g., memory and concentration problems) and physiological (e.g., fever). This paper reviews evidence suggesting that such symptoms can be explained more parsimoniously as a single symptom cluster than as a set of separate illnesses such as Gulf War Syndrome (GWS) and chronic fatigue syndrome (CFS). This superordinate syndrome could have its biological basis in the activity of pro-inflammatory cytokines (in particular interleukin-1: IL-1), that give rise to what has become known as the 'sickness response'. It is further argued that the persistence of non-specific illness in chronic conditions like GWS may be (in part) attributable to a bio-associative mechanism (Ferguson

				and Cassaday, 1999). In the case of GWS, physiological challenges could have produced a non-specific sickness response that became associated with smells (e.g., petrol), coincidentally experienced in the Persian Gulf. On returning to the home environment, these same smells would act as associative triggers for the maintenance of (conditioned) sickness responses. Such associative mechanisms could be mediated through the hypothalamus and limbic system via vagal nerve innervation and would provide an explanation for the persistence of a set of symptoms (e.g., fever) that should normally be short lived and self-limiting. We also present evidence that the pattern of symptoms produced by the pro-inflammatory cytokines reflects a shift in immune system functioning towards a (T-helper-1) Th1 profile. This position contrasts with other immunological accounts of GWS that suggest that the immune system demonstrates a shift to a Th2 (allergy) profile. Evidence pertaining to these two contrasting positions is reviewed.

Ann N Y Acad Sci. 2001 Mar;933:24-37.	Sensitivities to chemicals are characterized by symptoms in multiple organ systems in response to low-level chemical exposures. This paper reviews studies of controlled exposures to odorants and to mixtures of volatile organic compounds. Sensitive subgroups include subjects who met Cullen's 1987 criteria for multiple chemical sensitivity (MCS), Gulf War veterans with chronic fatigue syndrome and chemical sensitivity (CFS/CS), and subjects with specific self-reported sensitivities to methyl terbutyl ether (MTBE) in gasoline (MTBE-sensitive). All studies include comparison of age- and sex-matched healthy controls. Studies of olfaction did not support unusual sensitivity, defined as lower odor thresholds, among MCS subjects; however, a dose-response pattern of symptoms was observed in response to suprathreshold concentrations of phenyl ethyl alcohol. In blinded, controlled exposures to clean air, gasoline, gasoline/11% MTBE, and gasoline/15% MTBE, a threshold effect was observed with MTBE-sensitive subjects reporting significantly increased symptoms to gasoline/15% MTBE exposure. Autonomic arousal (heart and respiration rate; end-tidal CO2) in response to odor of chemical mixtures may mediate symptoms for subjects with generalized chemical sensitivities, but not for those whose sensitivities are confined to specific chemicals. For example, Gulf War veterans with CFS/CS experienced reduced end-tidal CO2 when exposed to diesel fumes, while exposure to MTBE did not produce any psychophysiologic changes in MTBE-sensitive subjects. Controlled olfactory and exposure studies reveal that significant responses can be observed in chemically sensitive subjects even when de-adaptation has not occurred. However, these studies suggest that symptoms are not necessarily accompanied by changes in physiologic arousal.

				Subject characteristics play a critical role in outcomes.
Forton DM, Allsop JM, Main J, Foster GR, Thomas HC, Taylor-Robinson SD.		Evidence for a cerebral effect of the hepatitis C virus.	Lancet. 2001 Jul 7;358(9275):38-9.	Patients with hepatitis C virus (HCV) infection frequently complain of symptoms akin to the chronic fatigue syndrome and score worse on health-related quality of life indices than matched controls. We address the hypothesis that HCV itself affects cerebral function. Using proton magnetic-resonance spectroscopy we have shown elevations in basal ganglia and white matter choline/creatine ratios in patients with histologically-mild hepatitis C, compared with healthy volunteers and patients with hepatitis B. This elevation is unrelated to hepatic encephalopathy or a history of intravenous drug abuse, and suggests that a biological process underlies the extrahepatic symptoms in chronic HCV infection.

Fuentes K, Hunter MA, Strauss E, Hultsch DF.	Department of Psychology, University of Victoria, Victoria, BC, Canada. kfuentes@uvic.ca	Intraindividual variability in cognitive performance in persons with chronic fatigue syndrome.	Clin Neuropsychol. 2001 May;15(2):210-27.	Studies of cognitive performance among persons with chronic fatigue syndrome (CFS) have yielded inconsistent results. We sought to contribute to findings in this area by examining intraindividual variability as well as level of performance in cognitive functioning. A battery of cognitive measures was administered to 14 CFS patients and 16 healthy individuals on 10 weekly occasions. Analyses comparing the two groups in terms of level of performance defined by latency and accuracy scores revealed that the CFS patients were slower but not less accurate than healthy persons. The CFS group showed greater intraindividual variability (as measured by intraindividual standard deviations and coefficients of variation)

				than the healthy group, although the results varied by task and time frame. Intraindividual variability was found to be stable across time and correlated across tasks at each testing occasion. Intraindividual variability also uniquely differentiated the groups. The present findings support the proposition that intraindividual variability is a meaningful indicator of cognitive functioning in CFS patients.
Gantz NM, Coldsmith EE.	Division of Infectious Diseases, Department of Medicine, Pinnacle Health System, Harrisburg, PA 17110, USA. ngantz@pinnaclehealth.org [corrected]	Chronic fatigue syndrome and fibromyalgia resources on the world wide web: a descriptive journey.	Clin Infect Dis. 2001 Mar 15;32(6):938-48. Epub 2001 Mar 09.	A wealth of information on chronic fatigue syndrome (CFS) and fibromyalgia is available on the World Wide Web for health care providers and patients. These illnesses have overlapping features, and their etiologies remain unknown. Multiple Web sites were reviewed, and selected sites providing useful information were identified. Sites were classified according to their content and target audience and were judged according to suggested standards of Internet publishing. Fifty-eight sites were classified into groups as follows: comprehensive and research Web sites for CFS and fibromyalgia, meetings, clinical trials, literature search services, bibliographies, journal, and CFS and fibromyalgia Web sites for the patient.
Garland EM, Robertson D.	Autonomic Dysfunction Center, Department of Medicine, Vanderbilt University, Nashville, Tennessee, USA.	Chiari I malformation as a cause of orthostatic intolerance symptoms: a media myth?	Am J Med. 2001 Nov;111(7):546-52.	There is much interest in a putative relationship between Chiari I malformation and symptoms of orthostatic intolerance. It has been reported at scientific meetings that a number of patients with chronic fatigue syndrome or fibromyalgia have Chiari I malformation, or hindbrain compression in the absence of Chiari, and that they experience improvement after decompression surgery. Many of these patients have symptoms of orthostatic intolerance. A connection between Chiari I malformation and these conditions has been discussed in newspaper articles and on national television programs. Patients have also had access to much information on this topic via the Internet. Unfortunately, the Chiari I malformation and orthostatic intolerance connection is almost entirely unsupported by peer-reviewed literature. The purpose of this article is to provide an objective review of the available information.

Gartner BC, Fischinger JM, Roemer K, Mak M, Fleurent B, Mueller-Lantzsch N.	Department of Virology, University of Homburg/Saar, Kirrbergerstr. Haus 47, D-66421 Hombury Saar, Germany.	Evaluation of a recombinant line blot for diagnosis of Epstein-Barr Virus compared with ELISA, using immunofluorescence as reference method.	J Virol Methods. 2001 Apr;93(1-2):89-96.	A commercial line blot using recombinant antigens was compared with a commercial ELISA and 'in-house' IFA (reference test). Two panels were evaluated: Panel A was selected to distinguish between primary infections (89), past infections (20) and seronegatives (8) in immunocompetent individuals. In panel B, patients with a high number of reactivations were included: immunosuppressed patients (37), lymphoma (19), nasopharyngeal carcinoma (10), chronic fatigue syndrome (14). Blood donors (43) and cross-reactive sera (29) were added as controls. Line blot and IFA were concordant in 94% of primary infections, 100% of seronegatives and 100% of past infections, similar to ELISA. Results differed significantly with regard to reactivations. When compared with IFA, the incidence of reactivations was overestimated by the blot, 24 and 58% in blood donors and cross-reactive sera, respectively. ELISA showed a similar problems with 21 and 34% indeterminate results, respectively. The line blot is easy to carry out, has a good concordance with the reference IFA for primary infections, and is, therefore, a sufficient

				choice for distinguishing primary infection from seronegative and past infection. EBV reactivation assessment will require other methods such as EBV viral load.
Gilhooly PE, Ottenweller JE, Lange G, Tiersky L, Natelson BH.	Veterans Administration, New Jersey Health Care System, 385 Tremont Avenue, East Orange, NJ 07018, USA. PEGMD6@aol.com	Chronic fatigue and sexual dysfunction in female Gulf War veterans.	J Sex Marital Ther. 2001 Oct-Dec;27(5):483-7.	Chronic fatigue (CF) is one of the most common conditions reported by Gulf War veterans. This study evaluated female sexual dysfunction (FSD) in veterans with or without complaints of CF. Subjects were screened for medical and psychiatric causes of CF. They included 22 healthy subjects and 26 with fatiguing symptoms. FSD was reported by 10% of controls and by 60% of the fatigued ($p < .002$) while 19% versus 81% ($p < .001$) noted decreased libido. FSD was more prevalent in fatigued veterans than in the controls. This relationship was not mediated by an Axis I diagnosis. This appears to be the first report of sexual dysfunction in CF.
Gorman D, Monigatti J, Glass B, Gronwall D, Beasley M.	University of Auckland, New Zealand. d.gorman@auckland.ac.nz	Assessment of pentachlorophenol-exposed timber workers using a test-of-poisoning model.	Int J Occup Environ Health. 2001 Jul-Sep;7(3):189-94.	Sixty-two former New Zealand timber workers who were exposed to pentachlorophenol (PCP) at work were interviewed, examined, and assessed both by laboratory investigations and psychometrically for clinical syndromes that could be related to PCP exposure. Three such syndromes were identified: an acute complex of fever, headaches, upper and lower respiratory tract and eye irritation, skin disease, and foul smelling and discolored sweat; a chronic fatigue syndrome, beginning while still at work and frequently persisting; and a delayed encephalopathy. Neither of the sustained syndromes was considered characteristic of PCP poisoning, and many confounders were identified. An exposure index and a test-of-poisoning score had a statistically insignificant correlation.

Gow JW, Simpson K, Behan PO, Chaudhuri A, McKay IC, Behan WM.	Department of Neurology, University of Glasgow, Scotland, United Kingdom.	Antiviral pathway activation in patients with chronic fatigue syndrome and acute infection.	Clin Infect Dis. 2001 Dec 15;33(12):2080-1. Epub 2001 Nov 06. Comment in: Clin Infect Dis. 2002 May 15;34(10):1420-1;	Gene expression of key enzymes in 2 antiviral pathways (ribonuclease latent [RNase L] and RNA-regulated protein kinase [PKR]) was compared in 22 patients with chronic fatigue syndrome (CFS), 10 patients with acute gastroenteritis, and 21 healthy volunteers. Pathway activation in the group of patients with infections differed significantly from that of the other 2 groups, in whom there was no evidence of upregulation. Therefore, assay of activation is unlikely to provide the basis for a diagnostic test for CFS.

Gray D, Parker-Cohen NY, White T, Clark ST, Seiner SH, Achilles J, McMahon WM.	Department of Psychiatry, University of Utah, Salt Lake City 84108, USA. Douglas.gray@hsc.utah.edu	A comparison of individual and family psychology of adolescents with chronic fatigue syndrome, rheumatoid arthritis, and mood disorders.	J Dev Behav Pediatr. 2001 Aug;22(4):234-42.	Chronic fatigue syndrome (CFS) is a controversial diagnosis with unknown cause. Adult studies indicate high rates of psychosocial dysfunction and psychiatric comorbidity. The authors compared three groups of pediatric patients selected by diagnosis-(1l) CFS (n = 15), (2) juvenile rheumatoid arthritis (n = 15), and (3) mood disorders (n = 15)-across many psychological measures. CFS subjects had dramatic elevation of the Somatic Complaints subscale (mean T score = 75), whereas the mood disorders group had higher externalizing scores (mean T score = 68) on the Child Behavior Checklist. The CFS subjects missed significantly more school compared with the two control groups. After the onset of CFS, 13 of 15 of the CFS patients required significant educational accommodation. Only 4 of the 15 CFS patients had an Axis I psychiatric diagnosis, as determined by the Computerized Diagnostic Interview for Children. Despite a low rate of psychiatric diagnosis in the CFS sample, these data attest to their psychosocial and school dysfunction.

Washington University School of Medicine, Division of Allergy and Immunology, Euclid Avenue, St Louis, Missouri, USA. dhamilos@im.wustl.edu	Circadian rhythm of core body temperature in subjects with chronic fatigue syndrome.	Clin Physiol. 2001 Mar;21(2):184-95.	The pathophysiological basis for chronic fatigue syndrome (CFS) remains poorly understood. Certain symptoms of CFS, namely fatigue, neurocognitive symptoms and sleep disturbance, are similar to those of acute jet lag and shift work syndromes thus raising the possibility that CFS might be a condition associated with disturbances in endogenous circadian rhythms. In this study, we tested this hypothesis by examining the circadian rhythm of core body temperature (CBT) in CFS and control subjects. Continuous recordings of CBT were obtained every 5 min over 48 h in a group of 10 subjects who met the Center for Disease Control (CDC) definition of CFS and 10 normal control subjects. Subjects in the two groups were age, sex and weight-matched and were known to have normal basal metabolic rates and thyroid function. CBT recordings were performed under ambulatory conditions in a clinical research centre with the use of an ingestible radio frequency transmitter pill and a belt-worn receiver-logger. CBT time series were analysed by a cosinor analysis and by a harmonic-regression-plus-correlated-noise model to estimate the mean,

				amplitude and phase angle of the rhythm. The goodness of fit of each model was also compared using the Akaike Information Criterion (AIC) and sigma2. Average parameters for each group were compared by Student's t-test. By cosinor analysis, the only significant difference between CFS and control groups was in the phase angle of the third harmonic (P=0.02). The optimal harmonic-regression-plus-correlated-noise models selected were ARMA(1,1): control 7, CFS 6; ARMA(2,0): control 1, CFS 4; and ARMA(2,1): control 2 subjects. The optimal fit ARMA model contained two harmonics in eight of 10 control subjects but was more variable in the CFS subjects (1 harmonic: 5 subjects; 2 harmonics: 1 subject; 3 harmonics: 4 subjects). The goodness of fit measures for the optimal ARMA model were also better in the control than the CFS group, but the differences were not statistically significant. We conclude that, measured under ambulatory conditions, the circadian rhythm of CBT in CFS is nearly indistinguishable from that of normal control subjects although there was a tendency for greater variability in the rhythm. Hence, it is unlikely that the symptoms of CFS are because of disturbance in the circadian rhythm of CBT.
Hamilton W..	Chronic fatigue syndrome		Br J Gen Pract. 2001 Dec;51(473):1015. Comment on: Br J Gen Pract. 2001 Jul;51(468):553-8. Br J Gen Pract. 2001 Sep;51(470):758.	
Hamilton WT, Hall GH, Round AP.	North and East Devon Health Authority, Exeter. w.hamilton@cwcom.net	Frequency of attendance in general practice and symptoms before development of chronic fatigue syndrome: a case-control study.	Br J Gen Pract. 2001 Jul;51(468):553-8. Comment in: Br J Gen Pract. 2001 Dec;51(473):1015. Br J Gen Pract. 2001 Sep;51(470):758.	BACKGROUND: Chronic fatigue syndrome (CFS) research has concentrated on infective, immunological, and psychological causes. Illness behaviour has received less attention, with most research studying CFS patients after diagnosis. Our previous study on the records of an insurance company showed a highly significant increase in illness reporting before development of CFS. AIM: To investigate the number and type of general practitioner (GP) consultations by patients with CFS for 15 years before they develop their condition. DESIGN OF STUDY: Case-control study in 11 general practices in Devon. SETTING: Forty-nine patients with CFS (satisfying the Centers for Disease Control criteria), 49 age, sex, and general practice matched controls, and 37 patients with multiple sclerosis (MS) were identified from the general practices' computerised databases. METHOD: The number of general practice consultations and symptoms recorded in three five-year periods (quinquennia) were counted before development of the patients' condition. RESULTS: The median number of consultations was significantly higher for CFS patients than that of matched controls in each of the quinquennia: ratios for first quinquennium = 1.88, P = 0.01; second quinquennium = 1.70, P = 0.005; last quinquennium = 2.25, P < 0.001. More CFS patients than controls attended for 13 of the 18 symptoms studied. Significant increases were found for upper respiratory tract infection (P < 0.001), lethargy (P < 0.001), and vertigo (P = 0.02). Similar results were found for CFS patients when

				compared with MS. CONCLUSIONS: CFS patients consulted their GP more frequently in the 15 years before development of their condition, for a wide variety of complaints. Several possibilities may explain these findings. The results support the hypothesis that behavioural factors have a role in the aetiology of CFS.
Hammond DC.	Department of Physical Medicine & Rehabilitation, University of Utah School of Medicine, Salt Lake City, UT, USA. D.C.Hammond@m.cc.utah.edu	Treatment of chronic fatigue with neurofeedback and self-hypnosis.	NeuroRehabilitation. 2001;16(4):295-300.	A 21 year old patient reported a relatively rapid onset of serious chronic fatigue syndrome (CFS), with her worst symptoms being cognitive impairments. Congruent with research on rapid onset CFS, she had no psychiatric history and specialized testing did not suggest that somatization was likely. Neuroimaging and EEG research has documented brain dysfunction in cases of CFS. Therefore, a quantitative EEG was done, comparing her to a normative data base. This revealed excessive left frontal theta brainwave activity in an area previously implicated in SPECT research. Therefore, a novel treatment approach was utilized consisting of a combination of EEG neurofeedback and self-hypnosis training, both of which seemed very beneficial. She experienced considerable improvement in fatigue, vigor, and confusion as measured pre-post with the Profile of Mood States and through collaborative interviews with both parents. Most of the changes were maintained at 5, 7, and 9 month follow-up testing.
Hanson SJ, Gause W, Natelson B.	Department of Psychology, Rutgers University, Newark, New Jersey 07102, USA. jose@kreizler.rutgers.edu	Detection of immunologically significant factors for chronic fatigue syndrome using neural-network classifiers.	Clin Diagn Lab Immunol. 2001 May;8(3):658-62.	Neural-network classifiers were used to detect immunological differences in groups of chronic fatigue syndrome (CFS) patients that heretofore had not shown significant differences from controls. In the past linear methods were unable to detect differences between CFS groups and non-CFS control groups in the nonveteran population. An examination of the cluster structure for 29 immunological factors revealed a complex, nonlinear decision surface. Multilayer neural networks showed an over 16% improvement in an n-fold resampling generalization test on unseen data. A sensitivity analysis of the network found differences between groups that are consistent with the hypothesis that CFS symptoms are a consequence of immune system dysregulation. Corresponding decreases in the CD19(+) B-cell compartment and the CD34(+) hematopoietic progenitor subpopulation were also detected by the neural network, consistent with the T-cell expansion. Of significant interest was the fact that, of all the cytokines evaluated, the only one to be in the final model was interleukin-4 (IL-4). Seeing an increase in IL-4 suggests a shift to a type 2 cytokine pattern. Such a shift has been hypothesized, but until now convincing evidence to support that hypothesis has been lacking.
Hardt J, Buchwald D, Wilks D, Sharpe M, Nix WA, Egle UT.	Department of Psychosomatic Medicine and Psychotherapy, University of Mainz, Untere Zahlbacher 8, D-55101, Mainz, Germany. hardt@mail.uni-	Health-related quality of life in patients with chronic fatigue syndrome: an international study.	J Psychosom Res. 2001 Aug;51(2):431-4.	OBJECTIVE: Chronic fatigue syndrome (CFS) has been reported worldwide. Our objectives were to determine if patients from different countries have similar profiles of impairments. METHODS: Health-related quality of life (HRQoL) was assessed in 740 CFS patients in the US, 82 in the UK, and 65 in Germany using the eight subscales of the Short-Form General Health Survey (SF-36). To examine the internal structure, factor analyses were performed. RESULTS: Overall, there was a remarkable similarity in HRQoL among all CFS patients, regardless of location. Patients scored two to three standard deviations below normal on six subscales and one standard deviation below normal on the other two subscales. Factor analysis suggested a two-factor model where the same six subscales constitute the first

	mainz.de			factor and the two others the second factor. CONCLUSION: HRQoL is poor in CFS patients from three countries. This study is a first step towards conducting further comparative cross-cultural and international studies.
Hausotter W.		[Modern illnesses from the critical viewpoint] [Article in German]	Versicherungsmedizin. 2001 Dec 1;53(4):177-81. Comment in: Versicherungsmedizin. 2002 Sep 1;54(3):149-50; discussion 150.	Psychosomatic illness as "modern diseases" are of increasing interest to the public. Environmental illnesses, for example assumed intoxication with organic solvents, multiple chemical sensitivity, sick building syndrome, chronic fatigue syndrome, fibromyalgia, the influence of amalgam or of electromagnetic waves and ozone are often causes of anxiety. There are many hypotheses about the origin of these diseases. Some scientists emphasize an organic basis; however, this is not generally accepted. Very often with good reason a psychological cause is supposed. Objective diagnostic criteria are not available, therefore these diagnoses may only be applied after sufficient exclusion of other known organic diseases. Mostly a psychological treatment is refused by the person affected, and a scientifically based somatic concept for the therapy does not exist. The medicolegal problems are important and often the reason for prolonged forensic confrontations.
Hickie IB, Bansal AS, Kirk KM, Lloyd AR, Martin NG.	School of Psychiatry, University of New South Wales, Sydney, Australia. i.hickie@unsw.edu.au	A twin study of the etiology of prolonged fatigue and immune activation.	Twin Res. 2001 Apr;4(2):94-102.	Risk factors to prolonged fatigue syndromes (PFS) are controversial. Pre-morbid and/or current psychiatric disturbance, and/or disturbed cell-mediated immunity (CMI), have been proposed as etiologic factors. Self-report measures of fatigue and psychologic distress and three in vitro measures of CMI were collected from 124 twin pairs. Crosstwin-crosstrait correlations were estimated for the complete monozygotic (MZ; 79 pairs) and dizygotic (DZ; 45 pairs) twin groups. Multivariate genetic and environmental models were fitted to explore the patterns of covariation between etiologic factors. For fatigue, the MZ correlation was more than double the DZ correlation (0.49 versus 0.16) indicating strong genetic control of familial aggregation. By contrast, for in vitro immune activation measures MZ and DZ correlations were similar (0.49-0.69 versus 0.42-0.53) indicating the etiologic role of shared environments. As small univariate associations were noted between prolonged fatigue and the in vitro immune measures (r = -0.07 to -0.12), multivariate models were fitted. Relevant etiologic factors included: a common genetic factor accounting for 48% of the variance in fatigue which also accounted for 4%, 6% and 8% reductions in immune activation; specific genetic factors for each of the in vitro immune measures; a shared environment factor influencing the three immune activation measures; and, most interestingly, unique environmental influences which increased fatigue but also increased markers of immune activation. PFS that are associated with in vitro measures of immune activation are most likely to be the consequence of current environmental rather than genetic factors. Such environmental factors could include physical agents such as infection and/or psychologic stress.
Hickie IB, Davenport TA, Hadzi-Pavlovic D, Koschera A, Naismith SL, Scott EM, Wilhelm KA.	School of Psychiatry, University of New South Wales, Sydney. ian.hickie@beyondblue.org.au	Development of a simple screening tool for common mental disorders in general practice.	Med J Aust. 2001 Jul 16;175 Suppl:S10-7. Comment in: Med J Aust. 2001 Jul 16;175 Suppl:S6-7	OBJECTIVE: To develop and validate a self-report screening tool for common mental disorders. DESIGN AND SETTING: Sequential development and validation studies in three cohorts of patients in general practice and one cohort of patients in a specialist psychiatry clinic. PARTICIPANTS: 1585 patients in general practice examined cross-sectionally and longitudinally; 46515 patients attending 386 general practitioners nationwide; 364 patients

				participating in a longitudinal study of psychiatric disorders in general practice; and 522 patients attending a specialist psychiatry clinic. MAIN OUTCOME MEASURES: Performance of the 12 items from the 34-item SPHERE questionnaire against DSM-III-R and DSM-IV diagnoses of psychiatric disorder, self-reported Brief Disability Questionnaire findings, GPs' ratings of patients' needs for psychological care and degree of risk resulting from mental disorder, and patients' and GPs' reports of reasons for presentation. RESULTS: Six somatic and six psychological questions identify two levels (and three types) of mental disorder: patients reporting both characteristic psychological and somatic symptoms (Level 1, Type 1), and patients reporting either psychological symptoms (Level 2, Type 2) or somatic symptoms (Level 2, Type 3). This classification system predicts disability ratings (Level 1, 8.2 "days out of role in the last month" and Level 2, 4.1 and 5.4 "days out of role in the last month" for Types 2 and 3, respectively), rates of lifetime psychiatric diagnoses (Level 1, 63% and Level 2, 59% and 48%, respectively), both patients' and GPs' report of reasons for presentation, and doctors' ratings of risk as a result of mental disorder. There are important and differing sociodemographic correlates for the three types of mental disorders. CONCLUSION: A classification system based on the 12 items from the 34-item SPHERE questionnaire can be used to identify common mental disorders. This system has acceptable validity and reliability, and is suited specifically for general practice settings.
Inbar O, Dlin R, Rotstein A, Whipp BJ.	Department of Life Sciences, Zinman College, Wingate Institute, Netania, Israel. inbar@macam98.ac.il	Physiological responses to incremental exercise in patients with chronic fatigue syndrome.	Med Sci Sports Exerc. 2001 Sep;33(9):1463-70.	PURPOSE: The purpose of this investigation was to characterize the physiological response profiles of patients with chronic fatigue syndrome (CFS), to an incremental exercise test, performed to the limit of tolerance. METHODS: Fifteen patients (12 women and three men) who fulfilled the case definition for chronic fatigue syndrome, and 15 healthy, sedentary, age- and sex-matched controls, performed an incremental progressive all-out treadmill test (cardiopulmonary exercise test). RESULTS: As a group, the CFS patients demonstrated significantly lower cardiovascular as well as ventilatory values at peak exercise, compared with the control group. At similar relative submaximal exercise levels (% peak VO(2)), the CFS patients portrayed response patterns (trending phenomenon) characterized, in most parameters, by similar intercepts, but either lower (VCO(2), HR, O(2pulse), V(E), V(T), PETCO(2)) or higher (B(f), V(E)/VCO(2)) trending kinetics in the CFS compared with the control group. It was found that the primary exercise-related physiological difference between the CFS and the control group was their significantly lower heart rate at any equal relative and at maximal work level. Assuming maximal effort by all (indicated by RER, PETCO(2), and subjective exhaustion), these results could indicate either cardiac or peripheral insufficiency embedded in the pathology of CFS patients. CONCLUSION: We conclude that indexes from cardiopulmonary exercise testing may be used as objective discriminatory indicators for evaluation of patients complaining of chronic fatigue syndrome.
Jason LA, Eisele H, Taylor RR.	DePaul University, USA.	Assessing attitudes toward new names for chronic fatigue	Eval Health Prof. 2001 Dec;24(4):424-35.	A questionnaire was distributed at the American Association of Chronic Fatigue Syndrome's biannual convention in Washington in January 2001 as well as through various Internet Web sites and listserves during early February and March of 2001. The sample

		syndrome.		consisted of 432 respondents. Most respondents (86%) indicated they wanted a name change, although more patients than scientists were in favor of this change. It was also apparent that the patients and physicians were clearly split between adopting a name such as myalgic encephalopathy versus one such as neuro-endocrine immune disorder. Also, among those respondents who selected either of these two choices for a new name, less than 30% of them supported the other name. Although the majority of respondents feel the name should be changed at this time, this survey suggests there are different stakeholders involved in the name-change process, each with strong and sometimes disparate feelings about changing the name.
Jason LA, Taylor RR, Carrico AW.	DePaul University, Department of Psychology, Chicago, IL 60614, USA. ljason@wppost.depaul.edu	A community-based study of seasonal variation in the onset of chronic fatigue syndrome and idiopathic chronic fatigue.	Chronobiol Int. 2001 Mar;18(2):315-9.	One proposed hypothesis regarding the etiology of chronic fatigue syndrome (CFS) is that there is a subgroup of patients in which symptom onset is precipitated by a viral infection. If this is indeed true, then one would anticipate a greater incidence of the emergence of CFS symptoms during months when viral infections occur with the greatest frequency. The current community-based epidemiology study examined the month of symptom onset for 31 patients with CFS and 44 others with idiopathic chronic fatigue (ICF). It was determined that the distribution of the month of illness onset for the CFS and ICF groups was nonrandom, with greater numbers of participants than expected reporting an onset of CFS and ICF during January.
Jason LA, Taylor RR, Kennedy CL, Harding ST, Song S, Johnson D, Chimata R.		Subtypes of Chronic Fatigue Syndrome: A Review of Findings	Journal of Chronic Fatigue Syndrome 2001; 8(3/4): 1	Most studies of Chronic Fatigue Syndrome (CFS) have been based on patients recruited from primary or tertiary care settings. Patients from such settings might not be typical of patients in the general population and may not accurately reflect the heterogeneity among individuals diagnosed with this condition. The current paper reviews four community-based studies that examined subtypes of individuals with CFS. Distinctions between subtype groups based on sociodemographics, illness onset and duration, stressful precipitating events, symptom frequency, and comorbidity characteristics are made with respect to outcome measures of fatigue and symptom severity, functional ability, and psychiatric comorbidity.
Jason LA, Taylor RR.		Measuring Attributions About Chronic Fatigue Syndrome	Journal of Chronic Fatigue Syndrome 2001; 8(3/4): 31	Three studies explored the effects of different diagnostic labels and different types of recommended treatments for Chronic Fatigue Syndrome upon attributions regarding its cause, nature, severity, contagion, prognosis, and treatment. Attributions for Chronic Fatigue Syndrome appear to change based upon the diagnostic label given for the syndrome and the type of t reatment recommended. Results suggest that, in comparison to the Chronic Fatigue Syndrome label, the Myalgic Encephalopathy label prompts attributions that this syndrome is a serious condition associated with a physiologically-based etiology, a poor prognosis, and decreased potential for organ donation. Results also suggest that, compared with cognitive coping skills treatment, treatment with ampligen appears to be associated with perceptions of chronic fatigue syndrome as an accurate diagnosis and as a severely disabling condition.

Johnson SK, Lange G, Tiersky L, DeLuca J, Natelson BH.		Health-Related Personality Variables in Chronic Fatigue Syndrome and Multiple Sclerosis	Journal of Chronic Fatigue Syndrome 2001; 8(3/4): 41	This study investigated personality variables in patients with Chronic Fatigue Syndrome (CFS) and Multiple Sclerosis (MS), with healthy, sedentary subjects as controls. CFS and MS groups were higher on alexithymia, characterized as difficulty in describing and differentiating emotions and marked externalization. CFS and MS groups reported a more depressive attributional style than healthy participants, reflecting beliefs that causes for good events are not diffused into other areas of life while causes for bad events will always be present. The CFS group was significantly lower on Doctors/Others locus of control indicating lack of trust in medical professionals. Results indicate that CFS and MS are similar to each other while different from the healthy group on certain personality variables that likely reflect the demoralizing effects of coping with a chronic, disabling illness marked by uncertainty.
Kaminaga T, Kunimatsu N, Chikamatsu T, Furui S.	Department of Radiology, Teikyo University School of Medicine, Tokyo, Japan. kami@med.teikyo-u.ac.jp	Validation of CBF measurement with non-invasive microsphere method (NIMS) compared with autoradiography method (ARG).	Ann Nucl Med. 2001 Feb;15(1):61-4.	The purpose of this study is to examine the correlation of measured regional cerebral blood flow (rCBF) by means of a new microsphere method (non-invasive microsphere method), to the autoradiography (ARG) method, which is an established quantification method for 123I-IMP brain SPECT. The non-invasive microsphere (NIMS) method and ARG method were simultaneously applied to 30 patients, and quantified rCBF maps were calculated with each method. A significant correlation ($r = 0.70$: $p < 0.001$) was detected between mCBF values calculated with the NIMS and ARG methods. This new method seems to reliably quantify rCBF with brain SPECT.

Kerr JR, Barah F, Mattey DL, Laing I, Hopkins SJ, Hutchinson IV, Tyrrell DA.	Department of Microbiology, Royal Brompton Hospital, National Heart and Lung Institute,	Circulating tumour necrosis factor-alpha and interferon-gamma are detectable during	J Gen Virol. 2001 Dec;82(Pt 12):3011-9.	To investigate whether cytokine responses may have a bearing on the symptoms and outcome of parvovirus B19 infection, circulating cytokines were measured during acute infection (n=51), follow-up of acute infection (n=39) and in normal healthy controls (n=50). At acute B19 virus infection (serum anti-B19 IgM-positive), patients ranged in age from 4 to 54 years, with a mean age of 28.2 years. The male:female ratio was 1:4.1 and symptoms

	Imperial College School of Medicine, Sydney Street, London SW3 6NP, UK. j.kerr@ic.ac.uk	acute and convalescent parvovirus B19 infection and are associated with prolonged and chronic fatigue.		were rash (n=15), arthralgia (n=31), fatigue (n=8), lymphadenopathy (n=4), foetal hydrops (n=3), transient aplastic crisis (n=2), neutropenia (n=2), myelodysplasia (n=1), thrombocytopenia (n=1) and pancytopenia (n=1). Of these patients, 39 were contacted after a follow-up period of 2-37 months (mean of 22.5 months). In comparison with normal controls, detectable IL-6 was associated with acute B19 virus infection (26%; P=0.0003), but not with follow-up (6%; P=0.16). Detection of interferon (IFN)-gamma was associated with acute B19 virus infection (67%; P<0.0001) and follow-up (67%; P<0.0001). Detection of tumour necrosis factor (TNF)-alpha was associated with acute B19 virus infection (49%; P<0.0001) and follow-up (56%; P<0.0001). IL-1beta was detected in acute infection (20%), but not at follow-up. At acute B19 virus infection, detection of serum/plasma IL-6 was associated with rheumatoid factor (P=0.038) and IFN-gamma (> or =7 pg/ml) was associated with fatigue in those patients of > or =15 years of age (P=0.022). At follow-up, fatigue was associated with IFN-gamma (> or =7 pg/ml) and/or TNF-alpha (> or =40 pg/ml) (P=0.0275). Prolonged upregulation of serum IFN-gamma and TNF-alpha appears to represent a consistent host response to symptomatic B19 virus infection.
Klimas NG, Patarca-Montero R, Maher K, Smith M, Bathe O, Fletcher MA.		Clinical and Immunologic Effects of Autologous Lymph Node Cell Transplant in Chronic Fatigue Syndrome	Journal of Chronic Fatigue Syndrome 2001; 8(1): 39	An open labeled, phase 1, safety and feasibility study using lymph node extraction, ex vivo lymph node cell expansion, followed by autologous cell reinfusion was evaluated as a potential immunomodulatory treatment strategy in patients with chronic fatigue syndrome (CFS). The experimental therapy utilized the cells of the lymph node, activated and grown in culture with defined media, interleukin-2 (IL-2) and anti-CD3 to activate and enhance cellular immunological functions. This procedure was designed to change the cytokine pattern of the lymph node lymphocytes to favor expression of T-helper (Th)1-type over Th2-type cytokines. The mixed population of ex vivo immune-enhanced cells were reinfused into the donor, who was carefully monitored for adverse events and possible clinical benefit. There were no adverse events. There were significant improvements in clinical status in association with a significant decrease in Th2-type cytokine production.
Kovaleva AI, Pyshnov GIu.		[Problems of chronic fatigue] [Article in Russian]	Med Tr Prom Ekol. 2001;(11):1-5.	The review covers some human pathologic conditions defined as chronic fatigue syndrome, caroshi, burnout. Concerning nonspecific manifestations, one could characterize these conditions as general overfatigue of human. The authors attempt to consider these conditions from the viewpoint of occupationally induced disorders.
Krueger GR, Koch B, Hoffmann A, Rojo J, Brandt ME, Wang G, Buja LM.	Department of Pathology & Laboratory Medicine, University of Texas-Houston Medical School, 6431 Fannin St, MSB 2.246, Houston, Texas 77030, USA. Gerhard.Krueger@ut	Dynamics of chronic active herpesvirus-6 infection in patients with chronic fatigue syndrome: data acquisition for computer modeling.	In Vivo. 2001 Nov-Dec;15(6):461-5.	Ten adult patients with persistent active HHV-6 variant A infection and clinical chronic fatigue syndrome (CFS) were studied over a period of 24 months after initial clinical diagnosis. CFS was diagnosed according to IIIP-revised CDC-criteria as defined by the CFS Expert Advisory Group to the German Federal Ministry of Health in 1994. Changes in HHV-6 antibody titer, viral DNA load, peripheral blood T lymphocytes and subpopulations, as well as CD4/CD8 cell ratio and cell death (apoptosis) were monitored. Data were collected for comparison with respective changes in acute HHV-6 infection and as a basis for future computer simulation studies. The results showed variable but slightly elevated numbers of HHV-6 DNA copies in the blood of patients with CFS, while PBL (peripheral blood lymphocyte) apoptosis rates were clearly increased. CD4/CD8 cell ratios varied from below

	htmcedu			1 up to values as seen in autoimmune disorders. Contrary to acute HHV-6 infection, T lymphocytes do not exhibit the usual response to HHV-6, that is elevation of mature and immature populations suggesting a certain degree of unresponsiveness. The data suggest that persistent low-dose stimulation by HHV-6 may favor imbalanced immune response rather than overt immune deficiency. This hypothesis requires confirmation through additional functional studies.

LaManca JJ, Peckerman A, Sisto SA, DeLuca J, Cook S, Natelson BH.	Chronic Fatigue Syndrome Cooperative Research Center, University of Medicine and Dentistry of New Jersey-New Jersey Medical School, Newark, New Jersey, USA.	Cardiovascular responses of women with chronic fatigue syndrome to stressful cognitive testing before and after strenuous exercise.	Psychosom Med. 2001 Sep-Oct;63(5):756-64.	OBJECTIVE: The purpose of this study was to compare the cardiovascular responses of patients with chronic fatigue syndrome (CFS) to healthy control subjects when performing stressful cognitive tasks before and after strenuous exercise. METHOD: Beat-by-beat blood pressure and electrocardiogram were recorded on 19 women with CFS and 20 healthy nonexercising (ie, sedentary) women while they performed cognitive tests before, immediately after, and 24 hours after incremental exercise to exhaustion. RESULTS: Diminished heart rate ($p < .01$) and systolic ($p < .01$) and diastolic ($p < .01$) blood pressure responses to stressful cognitive testing were seen in patients with CFS when compared with healthy, sedentary controls. This diminished stress response was seen consistently in patients with CFS across three separate cognitive testing sessions. Also, significant negative correlations between self-ratings of CFS symptom severity and cardiovascular responses were seen ($r = -0.62$, $p < .01$). CONCLUSIONS: Women with CFS have a diminished cardiovascular response to cognitive stress; however, exercise did not magnify this effect. Also, the data showed that the patients with the lowest cardiovascular reactivity had the highest ratings of CFS symptom severity, which suggests that the individual response of the patient with CFS to stress plays a role in the common complaint of symptoms worsening after stress.
Lange G, Holodny AI, DeLuca J, Lee HJ, Yan XH, Steffener J, Natelson BH.	Departments of Psychiatry and Radiology, University of Medicine and Dentistry of New Jersey, New Jersey Medical School, 30 Bergen Street, Newark, NJ 07107, USA. langegu@umdnj.edu	Quantitative assessment of cerebral ventricular volumes in chronic fatigue syndrome.	Appl Neuropsychol. 2001;8(1):23-30.	Previous qualitative volumetric assessment of lateral ventricular enlargement in chronic fatigue syndrome (CFS) has provided evidence for subtle structural changes in the brains of some individuals with CFS. The aim of this pilot study was to determine whether a more sensitive quantitative assessment of the lateral ventricular system would support the previous qualitative findings. In this study, we compared the total lateral ventricular volume, as well as the right and left hemisphere subcomponents in 28 participants with CFS and 15 controls. Ventricular volumes in the CFS group were larger than in control groups, a difference that approached statistical significance. Group differences in ventricular asymmetry were not observed. The results of this study provide further evidence of subtle pathophysiological changes in the brains of participants with CFS.
Lange G, Tiersky LA, Scharer JB, Policastro	Center for Environmental	Cognitive functioning in Gulf War Illness.	J Clin Exp Neuropsychol. 2001	A comprehensive neuropsychological battery was administered to 48 veterans with Gulf War Illness (GWI) characterized by severe fatigue (GV-F) and 39 healthy veterans (GV-H).

T, Fiedler N, Morgan TE, Natelson BH.	Hazards Research, DVA NJ Health Care System, East Orange, NJ, USA. langegu@umdnj.edu		Apr;23(2):240-9.	Subjects were matched on intelligence and did not differ on age, gender, race, and alcohol consumption. Compared to GVs-H, GVs-F were significantly impaired on four tasks: three attention, concentration, information processing tasks and one measure of abstraction and conceptualization. After considering the presence of post-war Axis I psychopathology, GWI remained a significant predictor of cognitive performance on one of the attention, concentration, and information processing tasks and one abstraction and conceptualization measure. Performance on the remaining two attention, concentration, and information processing tasks was only significantly predicted by Axis I psychopathology with post-war onset. The results suggest that Gulf War Illness is associated with some aspects of cognitive dysfunction in Gulf Veterans, over and above the contribution of psychopathology.

Levin AM.		Chronic Fatigue Syndrome: The Yeast Concept	Journal of Chronic Fatigue Syndrome 2001; 8(2): 71	Many theories abound as to the cause of CFS, but none have been proven conclusively. Because of the prevalence of the condition in many different countries throughout the world, it is becoming increasingly necessary to find a common link in the causative mechanism. The cause must be present at an international level. The overgrowth of bowel yeast and its infiltration through the bowel wall into the blood stream would appear to be the starting point in the development of CFS. This invasion of yeast can occur for different reasons. Therapeutic interventions based on the years of hypothesis are suggested.
Levin J, Steele L.		On the epidemiology of 'mysterious' phenomena.	Altern Ther Health Med. 2001 Jan;7(1):64-6.	In the field of epidemiology, research topics are favored or dismissed depending on whether respective variables under investigation are believed to exist according to current scientific theories. Unconventional independent variables or exposures, such as religiousness and spirituality, and controversial dependent variables or outcomes, such as chronic fatigue syndrome, may be considered unacceptable topics for researchers because they do not fit comfortably into the consensus clinical perspectives of mainstream medical scientists or physicians. Disapproval of research in these and other taboo areas is generally masked by claims that such studies are "pseudoscientific," despite hundreds or thousands of peer-reviewed publications on these topics. In reality, seemingly "mysterious" variables are equally as amenable to epidemiologic research as any other exposure or disease.

				Similarly, alternative therapies are able to be investigated using existing methods, despite claims to the contrary. Such research is vital for scientific understanding to be expanded into new areas of inquiry.
Levine PH, Klimas N, Armitage R, Fredericks R, Stewart J, Torch W, Schwartz S, Suhadolnik R, Reichenbach NL, Rhodes L.		Nevada Chronic Fatigue Syndrome Consensus Conference	Journal of Chronic Fatigue Syndrome 2001; 9(1/2): 53	
Levine S, Eastman H, Ablashi DV.		Prevalence of IgM and IgG Antibody to HHV-6 and HHV-8 and Results of Plasma PCR to HHV-6 and HHV-7 in a Group of CFS Patients and Healthy Donors	Journal of Chronic Fatigue Syndrome 2001; 9(1/2): 31	Human herpes virus-6 is a beta herpes virus that was first described in 1986 and which occurs in the form of at least two variants, A and B. Healthy donors in the general population are carriers for mainly the B variant, in whom 90% harbor the DNA of this type in their peripheral blood mononuclear cells (PBMNC). A higher prevalence of this virus has been detected by testing of plasma and PBMNCs by IFA, ELISA and by the nested PCR technique, in addition to direct culture for HHV-6 in certain groups of immunesuppressed patients such as those with multiple sclerosis and HIV. It has also been isolated to a greater degree using these techniques from patients who meet the case definition for the chronic fatigue syndrome (CFS). We determined IgG and IgM antibody titers to HHV-6; IgG to HHV-8 and performed PCR testing for HHV-6 on the plasma of 46 patients with CFS and on 7 healthy donors (HD). We also performed PCR testing for HHV-7 on 15 CFS patients and on 4 HD(s). We found a higher prevalence of IgM antibody in CFS patients 23/36 (50%) versus 2/7 (28.5%) of HD. The prevalence of IgG antibody to HHV-8 was zero among both CFS patients and HD. Three out of forty six (6.5%) of CFS patients demonstrated a positive plasma by PCR to HHV-6 compared to zero out of 7 HD(s). Finally, four out of fifteen (26.7%) CFS patients and zero out of four HD (s) demonstrated a positive plasma PCR to HHV-7. Our results were influenced by the presence of various subpopulations of CFS patients among our study group, in addition to our reliance on the results of single specimens as opposed to a series of multiple samples over time in individual subjects, and by methodological variability (decreasing our yield because of diminished viral shedding in cell-free samples or increasing it compared to other research groups who failed to co-culture the PBMNCs with indicator cells, e.g., PHA-stimulated human cord blood cells or human fibroblasts for short-term culture [15 day]). Nevertheless, it is clear that the study of plasma and perhaps other tissue samples, such as cerebral spinal fluid and gastric mucosa from patients with CFS in better defined subgroups, as well as defined population of HDs using a variety of methodological techniques will increase our knowledge about the role of HHV-6 in this complex disorder.
Levine S.		Prevalence in the Cerebrospinal Fluid of the Following	Journal of Chronic Fatigue Syndrome 2001; 9(1/2): 41	Over the last decade a wide variety of infectious agents has been associated with the chronic fatigue syndrome (CFS) as potential etiologies for this disorder by researchers from all over the world. Many of these agents are neurotrophic and have been linked previously

		Infectious Agents in a Cohort of 12 CFS Subjects: Human Herpes Virus-6 and 8; Chlamydia Species; Mycoplasma Species; EBV; CMV; and Coxsackievirus		to other diseases involving the central nervous system (CNS). Human herpes virus-6 (HHV-6), especially the B variant, has been found in autopsy specimens of patients who suffered from multiple sclerosis. Because patients with CFS manifest a wide range of symptoms involving the CNS as shown by abnormalities on brain MRIs, SPECT scans of the brain and results of tilt table testing we sought to determine the prevalence of HHV-6, HHV-8, Epstein-Barr virus (EBV), cytomegalovirus (CMV), Mycoplasma species, Chlamydia species, and Coxsackie virus in the spinal fluid of a group of 12 patients with CFS. Although we intended to search mainly for evidence of actively replicating HHV-6, a virus that has been associated by several researchers with this disorder, we found evidence of HHV-8, Chlamydia species, CMV and Coxsackie virus in 6/12 samples. Attempts were made to correlate the clinical presentations of each of these patients, especially the neurological exams and results of objective testing of the CNS, with the particular infectious agent isolated. It was also surprising to obtain such a relatively high yield of infectious agents on cell free specimens of spinal fluid that had not been centrifuged. Future research in spinal fluid analysis, in addition to testing tissue samples by polymerase chain reaction (PCR) and other direct viral isolation techniques will be important in characterizing subpopulations of CFS patients, especially those with involvement of the CNS.
Lewis DH, Mayberg HS, Fischer ME, Goldberg J, Ashton S, Graham MM, Buchwald D.	Departments of Radiology, University of Washington, Seattle, USA.	Monozygotic twins discordant for chronic fatigue syndrome: regional cerebral blood flow SPECT.	Radiology. 2001 Jun;219(3):766-73.	PURPOSE: To evaluate the relationship between regional cerebral blood flow (rCBF) and chronic fatigue syndrome (CFS) in monozygotic twins discordant for CFS. MATERIALS AND METHODS: The authors conducted a co-twin control study of 22 monozygotic twins in which one twin met criteria for CFS and the other was healthy. Twins underwent a structured psychiatric interview and resting technetium 99m-hexamethyl-propyleneamine oxime single photon emission computed tomography of the brain. They also rated their mental status before the procedure. Scans were interpreted independently by two physicians blinded to illness status and then at a blinded consensus reading. Imaging fusion software with automated three-dimensional matching of rCBF images was used to coregister and quantify results. Outcomes were the number and distribution of abnormalities at both reader consensus and automated quantification. Mean rCBF levels were compared by using random effects regression models to account for the effects of twin matching and potential confounding factors. RESULTS: The twins with and those without CFS were similar in mean number of visually detected abnormalities and in mean differences quantified by using image registration software. These results were unaltered with adjustments for fitness level, depression, and mood before imaging. CONCLUSION: The study results did not provide evidence of a distinctive pattern of resting rCBF abnormalities associated with CFS. The described method highlights the importance of selecting well-matched control subjects.
Lipschitz EL		Chronic fatigue syndrome and posttraumatic stress disorder.	JAMA. 2001 Aug 22-29;286(8):916-7. Comment on: JAMA. 2001 May 23-	

			30;285(20):2557-9.	
Logan AC, Wong C.	CFS/FM Integrative Care Centre, Toronto, ON, Canada. alancloganND@excite.com	Chronic fatigue syndrome: oxidative stress and dietary modifications.	Altern Med Rev. 2001 Oct;6(5):450-9.	Chronic fatigue syndrome (CFS) is an illness characterized by persistent and relapsing fatigue, often accompanied by numerous symptoms involving various body systems. The etiology of CFS remains unclear; however, a number of recent studies have shown oxidative stress may be involved in its pathogenesis. The role of oxidative stress in CFS is an important area for current and future research as it suggests the use of antioxidants in the management of CFS. Specifically, the dietary supplements glutathione, N-acetylcysteine, alpha-lipoic acid, oligomeric proanthocyanidins, Ginkgo biloba, and Vaccinium myrtillus (bilberry) may be beneficial. In addition, research on food intolerance is discussed, since food intolerance may be involved in CFS symptom presentation and in oxidation via cytokine induction. Finally, recent evidence suggests celiac disease can present with neurological symptoms in the absence of gastrointestinal symptoms; therefore, celiac disease should be included in the differential diagnosis of CFS.
Logan AC.		Nutritional strategies for treating chronic fatigue syndrome.	Altern Med Rev. 2001 Feb;6(1):4-6. Comment on: Altern Med Rev. 2000 Apr;5(2):93-108.	
Manuel y Keenoy B, Moorkens G, Vertommen J, De Leeuw I.	University Hospital, University of Antwerp, Belgium. begona@uia.ua.ac.be	Antioxidant status and lipoprotein peroxidation in chronic fatigue syndrome.	Life Sci. 2001 Mar 16;68(17):2037-49.	The aetiology and pathogenesis of the Chronic Fatigue Syndrome (CFS) are still largely unresolved. Accompanying metabolic disorders such as selective n-6 fatty acid depletion suggest that oxidative stress and more specifically lipid peroxidation might play a role in its pathogenesis. In order to investigate this hypothesis, oxidant-antioxidant status and its impact on lipoprotein peroxidation in vitro was examined in 61 patients with unexplained fatigue lasting more than 1 month. They were subdivided into 2 groups: group CFS+ (33 subjects) fulfilled the 1988 Center of Disease Control criteria for CFS and group CFS- did not but was similar as regards age, sex distribution and clinical characteristics. Antioxidant status was similar in the 2 groups except for lower serum transferrin in the CFS + (mean (95 % CI) 2.41 (2.28-2.54) versus 2.73 (2.54-2.92) g/L in the CFS-, p = 0.009) and higher lipoprotein peroxidation in vitro: 6630 (5949-7312) versus 5581 (4852-6310) nmol MDA/mg LDL and VLDL cholesterol x minutes, p = 0.035). CFS intensified the influence of LDL cholesterol (p = 0.012) and of transferrin (p = 0.045) on peroxidation in vitro, suggesting additional pro-oxidant effects. These results indicate that patients with CFS have increased susceptibility of LDL and VLDL to copper-induced peroxidation and that this is related both to their lower levels of serum transferrin and to other unidentified pro-oxidising effects of CFS.
Maquet D, Croisier JL, Crielaard JM.	Medecine de l'appareil locomoteur, CHU Sart Tilman, 4000 Liege, Belgique, France.	[What happens to the fibromyalgia syndrome?] [Article in French]	Ann Readapt Med Phys. 2001 Jul;44(6):316-25.	OBJECTIVE: To realize a clarification about fibromyalgia, attempting to consider diagnostic criteria, prevalence, pathophysiology and therapeutic approach. METHOD: A systematic literature search was conducted to select articles about fibromyalgia and connected diseases. The database are Premedline, Medline and Medlineplus. RESULTS: Fifty-eight articles about fibromyalgia and twelve articles about connected diseases were selected to

	d.maquet@belgacom.net			realize this review of literature. DISCUSSION: Fibromyalgia constitutes a syndrome characterized by widespread musculo-skeletal pain, present above the waist and below the waist and in the axial skeleton. Widespread pain must have been present for at least three months. "Spasmophilie", chronic fatigue syndrome and myofascial syndrome represent diseases connected with fibromyalgia: differential diagnosis must be established. Researches related to fibromyalgia suggest a reduction of muscular performances associated with histological and biochemical anomalies. Patients are characterized by shorter and nonrestorative sleep. Psychological, neuroendocrine and central alterations appear often associated with fibromyalgia. The reduction of pressure tolerance and pain thresholds may be linked to the alterations of neuroendocrine substances. Literature recommend a multidisciplinary therapeutic approach in management of fibromyalgia. CONCLUSION: The pathophysiologic mechanisms in fibromyalgia appear multiple and interdependent. With the aim to optimizing treatment, investigations are necessary to determine biochemical repercussions of various therapeutic approaches.
Martinez-Lavin M.	Rheumatology Department, Instituto Nacional de Cardiologia Ignacio Chavez, Juan Badiano 1., 14080 Mexico, D.F. Mexico. mmlavin@infosel.net.mx	Overlap of fibromyalgia with other medical conditions.	Curr Pain Headache Rep. 2001 Aug;5(4):347-50.	Fibromyalgia is a multisystem illness. One of its defining features, generalized pain, may also be present in other rheumatic entities. The diagnosis of fibromyalgia is not easy by any means, it requires a profound knowledge of internal medicine. This article discusses the different rheumatic and nonrheumatic diseases that overlap or are prone to be confused with fibromyalgia. It emphasizes the key points in the differential diagnosis.
Masuda A, Nakayama T, Yamanaka T, Hatsutanmaru K, Tei C.	First Department of Internal Medicine, Kagoshima University.	Cognitive behavioral therapy and fasting therapy for a patient with chronic fatigue syndrome.	Intern Med. 2001 Nov;40(11):1158-61.	Cognitive behavioral therapy temporarily alleviated symptoms of a chronic fatigue syndrome patient but the anxiety about rehabilitation into work became stronger and his symptoms worsened. This patient was successfully rehabilitated by fasting therapy. Natural killer cell activity and serum acylcarnitine levels recovered after fasting therapy. Though fasting therapy transiently increased physical and mental subjective symptoms, the patient gained self-confidence by overcoming difficulties after fasting therapy. A combination of cognitive behavioral therapy and fasting therapy is promising as a treatment for chronic fatigue syndrome.
Michiels V, Cluydts R. Department of Psychology, Free University of Brussels, Belgium.		Neuropsychological functioning in chronic fatigue syndrome: a review.	Acta Psychiatr Scand. 2001 Feb;103(2):84-93.	OBJECTIVE: In this paper we review critically the current status of neurocognitive studies in patients with chronic fatigue syndrome (CFS). METHOD: CFS literature was monitored as part of a large research project which involved several neuropsychological and psychopathological studies. The literature survey was the result of several consecutive searches on Medline and PsycInfo databases. RESULTS: The neurocognitive studies are reviewed in terms of scientificaly accepted aspects of attention and memory. In addition, we review possible explanations for cognitive dysfunction in CFS. This is preceded with a discussion of the methodological limitations that are considered to explain inconcistencies across neuropsychological studies in CFS. CONCLUSION: The current research shows that

				slowed processing speed, impaired working memory and poor learning of information are the most prominent features of cognitive dysfunctioning in patients with CFS. Furthermore, to this date no specific pattern of cerebral abnormalities has been found that uniquely characterizes CFS patients. There is no overwhelming evidence that fatigue is related to cognitive performance in CFS, and researchers agree that their performance on neuropsychological tasks is unlikely to be accounted solely by the severity of the depression and anxiety.
Miike T.	Department of Child Development, Kumamoto University School of Medicine.	[Chronic fatigue syndrome] [Article in Japanese]	Nippon Rinsho. 2001 Dec;59 Suppl 8:414-21.	
Miller CS.	Department of Family and Community Medicine, University of Texas Health Science Center at San Antonio, 7703 Floyd Curl Drive, San Antonio, Texas 78229-3900, USA. millercs@uthscsa.edu	Toxicant-induced loss of tolerance.	Addiction. 2001 Jan;96(1):115-37.	Drug addiction and multiple chemical intolerance (abdiction) appear to be polar opposites--the former characterized by craving and dependency, the latter by aversion. However, when the two are viewed in juxtaposition similarities emerge, revealing a common underlying dynamic, one which appears to be a new paradigm of disease. TILT, or toxicant-induced loss of tolerance, bridges the gap between addiction and abduction and has the potential to explain a variety of illnesses, including certain cases of asthma, migraine headaches and depression, as well as chronic fatigue syndrome, fibromyalgia and "Gulf War syndrome". This paper argues that both addiction and chemical intolerance involve a fundamental breakdown in innate tolerance, resulting in an amplification of various biological effects, particularly withdrawal symptoms. While addicts seek further exposures so as to avoid unpleasant withdrawal symptoms, chemically intolerant individuals shun their problem exposures, but for the same reason--to avoid unpleasant withdrawal symptoms. These observations raise critical questions: do addictive drugs and environmental pollutants initiate an identical disease process? Once this process begins, can both addictants and pollutants trigger symptoms and cravings? TILT opens a new window between the fields of addiction and environmental medicine, one that has the potential to transform neighboring realms of medicine, psychology, psychiatry and toxicology.
Morrison RE, Keating HJ 3rd.	Department of Medicine, Division of General Internal Medicine, University of Tennessee at Memphis, Memphis, Tennessee, USA.	Fatigue in primary care.	Obstet Gynecol Clin North Am. 2001 Jun;28(2):225-40, v-vi.	Fatigue is a common problem in primary care that may represent a reaction to life problems or be a component of a disease state. A careful history, physical examination, and a few directed laboratory tests can usually allow the physician to differentiate between fatigue caused by depression, situational stress, or physical causes such as postviral or drug-induced fatigue, endocrine disorders, sleep disorders, infectious diseases, autoimmune disorders, or neurologic disease. Uncommonly, patients may have otherwise unexplained fatigue lasting 6 months or more that fulfills the criteria of chronic fatigue syndrome. A range of diagnostic skills coupled with a therapeutic physician-patient relationship will usually be successful in treating women with symptoms of fatigue.
Moss-Morris R, Petrie KJ.	Health Psychology Research Group,	Discriminating between chronic	Psychol Med. 2001 Apr;31(3):469-79.	BACKGROUND: Chronic fatigue syndrome (CFS) and depression share a number of common symptoms and the majority of CFS patients meet lifetime criteria for depression.

	Faculty of Medical and Health Science, The University of Auckland, New Zealand.	fatigue syndrome and depression: a cognitive analysis.		While cognitive factors seem key to the maintenance of CFS and depression, little is known about how the cognitive characteristics differ in the two conditions. METHODS: Fifty-three CFS patients were compared with 20 depressed patients and 38 healthy controls on perceptions of their health, illness attributions, self-esteem, cognitive distortions of general and somatic events, symptoms of distress and coping. A 6 month follow-up was also conducted to determine the stability of these factors and to investigate whether CFS-related cognitions predict ongoing disability and fatigue in this disorder. RESULTS: Between-group analyses confirmed that the depressed group was distinguished by low self-esteem, the propensity to make cognitive distortions across all situations, and to attribute their illness to psychological factors. In contrast, the CFS patients were characterized by low ratings of their current health status, a strong illness identity, external attributions for their illness, and distortions in thinking that were specific to somatic experiences. They were also more likely than depressed patients to cope with their illness by limiting stress and activity levels. These CFS-related cognitions and behaviours were associated with disability and fatigue 6 months later. CONCLUSIONS: CFS and depression can be distinguished by unique cognitive styles characteristic of each condition. The documented cognitive profile of the CFS patients provides support for the current cognitive behavioural models of the illness.
Mouterde O.		Myalgic encephalomyelitis in children.	Lancet. 2001 Feb 17;357(9255):562. Comment in: Lancet. 2001 Jun 9;357(9271):1889.	
Mueller D.	Division of Neurosurgery, University of Missouri Hospital and Clinics, USA. muellerdm@health.missouri.edu	Brainstem conundrum: the Chiari I malformation.	J Am Acad Nurse Pract. 2001 Apr;13(4):154-9.	PURPOSE: To describe the Chairi I Malformation in relation to the anatomy of the brain and spinal cord, the common manifestations of the condition, diagnostic considerations, and management for the primary care provider. DATA SOURCES: Extensive review of the world-wide scientific literature on the condition, supplemented with actual case studies. CONCLUSIONS: The adult Chairi I Malformation is an insidious congenital brainstem anomaly that consists of caudal displacement of the cerebellar tonsils, brainstem and fourth ventricle into the upper cervical space, resulting in overcrowding of the posterior fossa. IMPLICATIONS FOR PRACTICE: Due to the vague, and often ambiguous presenting symptoms of Chiari I Malformation, many patients are misdiagnosed with conditions such as multiple sclerosis, fibromyalgia, chronic fatigue syndrome, or psychiatric disorders. Patients frequently experience symptoms months to years prior to accurate diagnosis and often incur irreversible neurologic deficits.
Mullington JM, Hinze-Selch D, Pollmacher T.	Department of Neurology, Beth Israel Deaconess Medical Center and Harvard Medical School,	Mediators of inflammation and their interaction with sleep: relevance for chronic fatigue	Ann N Y Acad Sci. 2001 Mar;933:201-10.	In humans, activation of the primary host defense system leads to increased or decreased NREM sleep quality, depending on the degree of early immune activation. Modest elevations of certain inflammatory cytokines are found during experimental sleep loss in humans and, in addition, relatively small elevations of cytokines are seen following commencement of pharmacological treatments with clozapine, a CNS active antipsychotic

	Boston, Massachusetts 02215, USA. jmulling@caregroup.harvard.edu	syndrome and related conditions.		agent, known to have immunomodulatory properties. Cytokines such as TNF-alpha, its soluble receptors, and IL-6, present in the periphery and the CNS, comprise a link between peripheral immune stimulation and CNS-mediated behaviors and experiences such as sleep, sleepiness, and fatigue. The debilitating fatigue experienced in chronic fatigue syndrome and related diseases may also be related to altered cytokine profiles.

Cardiovascular response to upright tilt in fibromyalgia differs from that in chronic fatigue syndrome.	J Rheumatol. 2001 Jun;28(6):1356-60.	OBJECTIVE: To compare the cardiovascular response during postural challenge of patients with fibromyalgia (FM) to those with chronic fatigue syndrome (CFS). METHODS: Age and sex matched patients were studied, 38 with FM, 30 with CFS, and 37 healthy subjects. Blood pressure (BP) and heart rate (HR) were recorded during 10 min of recumbence and 30 min of head-up tilt. Differences between successive BP values and the last recumbent BP, their average, and standard deviation (SD) were calculated. Time curves of BP differences were analyzed by computer and their outline ratios (OR) and fractal dimensions (FD) were measured. HR differences were determined similarly. Based on the latter measurements, each subject's discriminant score (DS) was computed. RESULTS: For patients and controls average DS values were: FM: -3.68 (SD 2.7), CFS: 3.72 (SD 5.02), and healthy controls: -4.62 (SD 2.24). DS values differed significantly between FM and CFS ($p < 0.0001$). Subgroups of FM patients with and without fatigue had comparable DS values. CONCLUSION: The DS confers numerical expression to the cardiovascular response during postural challenge. DS values in FM were significantly different from DS in CFS, suggesting that homeostatic responses in FM and CFS are dissimilar. This observation challenges the hypothesis that FM and CFS share a common derangement of the stress-response system.
Naschitz JE, Sabo E, Naschitz S, Shaviv N, Rosner I, Rozenbaum M, Gaitini L, Ahdoot A, Ahdoot M, Priselac RM, Eldar S, Zukerman E, Yeshurun D.	Department of Internal Medicine A, Bnai Zion Medical Center and Bruce Rappaport Faculty of Medicine, Technion-Israel Institute of Technology, Haifa, Israel.	Hemodynamic instability in chronic fatigue syndrome: indices and diagnostic significance.	Semin Arthritis Rheum. 2001 Dec;31(3):199-208.	OBJECTIVES: To evaluate the cardiovascular response to postural challenge in patients with chronic fatigue syndrome (CFS) and to determine whether the degree of instability of the cardiovascular response may aid in diagnosing CFS. METHODS: Patients with CFS (n = 25) and their age- and gender-matched healthy controls (n = 37), patients with fibromyalgia (n = 30), generalized anxiety disorder (n = 15), and essential hypertension (n = 20) were evaluated with the aid of a standardized tilt test. The blood pressure (BP) and heart rate (HR) were recorded during 10 minutes of recumbence and 30 minutes of head-up tilt. We designated BP changes as the differences between successive BP values and the last recumbent BP. The average and standard deviation (SD) were calculated. Time curves of BP differences were loaded into a computerized image analyzer, and their outline ratios and fractal dimensions were measured. HR changes were determined similarly. The average and SD of the parameters were calculated, and intergroup comparisons were performed. RESULTS: On multivariate analysis, the independent predictors of CFS patients versus healthy controls were the fractal dimension of absolute values of the systolic BP changes

				(SYST-FD.abs), the standard deviation of the current values of the systolic BP changes (SYST-SD.cur), and the standard deviation of the current values of the heart rate changes (HR-SD.cur). The following equation was deduced to calculate the hemodynamic instability score (HIS) in the individual patient: HIS = 64.3303 + (SYST-FD.abs x -68.0135) + (SYST-SD.cur x 111.3726) + (HR-SD.cur x 60.4164). The best cutoff differentiating CFS from the healthy controls was -0.98. HIS values >-0.98 were associated with CFS (sensitivity 97%, specificity 97%). The HIS differed significantly between CFS and other groups (P <.0001) except for generalized anxiety disorder. Group averages (SD) of HIS were CFS = +3.72 (5.02), healthy = -4.62 (2.26), fibromyalgia = -3.27 (2.63), hypertension = -5.53 (2.24), and generalized anxiety disorder = +1.08 (5.2). CONCLUSION: The HIS adds objective criteria confirming the diagnosis of CFS. Copyright 2001 by W.B. Saunders Company

Nelson JJ, Natelson BH, Peckerman A, Pollet C, Lange G, Tiersky L, Servatius RJ, Policastro T, Fiedler N, Ottenweller JE.	Center for Environmental Hazards Research, Department of Veterans Affairs Medical Center, East Orange, NJ 07018, USA.	Medical follow-up of Persian Gulf War Veterans with severe medically unexplained fatigue: a preliminary study.	Mil Med. 2001 Dec;166(12):1107-9.	An important question for researchers interested in long-term consequences of military service is the health outcome of symptomatic Persian Gulf War Veterans. From an original group of 76 Gulf War Veterans who received the diagnosis of severe fatiguing illness, we attempted to get 58 veterans to return to our center for a second evaluation. Thirteen returned. Two had recovered by the time of revisit, but the rest remained ill; however, only one was so ill as to be unable to work. The data suggest that the medical consequences of serving in the Persian Gulf are not transient. The difficulty in getting veterans to return to our center suggests potential problems in the proposed nation-wide longitudinal health outcome study of Persian Gulf War Veterans.
Nesher G, Margalit R, Ashkenazi YJ.	Department of Rheumatology Service, Hebrew University Medical School, Jerusalem, Israel. nesher@inter.net.il	Anti-nuclear envelope antibodies: Clinical associations.	Semin Arthritis Rheum. 2001 Apr;30(5):313-20.	OBJECTIVES: Characterization of the clinical associations and clinical implications of antibodies reacting with antigens of the nuclear envelope. METHODS: Description of an illustrative case and a MEDLINE search-assisted literature review of relevant cases. RESULTS: With indirect immunofluorescence, autoantibodies directed against various antigens of the nuclear envelope stain the nucleus in a ring-like (rim) pattern. Autoantibodies against 5 antigenic components of the nuclear envelope have been described: anti-gp210, p62, lamina, lamina-associated polypeptides, and lamin B receptor. Antibodies to antigens of the nuclear pore complex, such as gp210 and p62, are highly specific (> 95%) for primary biliary cirrhosis and may aid in the serologic diagnosis of this condition, especially in cases in which antimitochondrial antibodies are not detectable. In contrast, antilamin antibodies are not disease-specific but seem to be associated with lupus anticoagulant or anticardiolipin antibodies, antiphospholipid syndrome, thrombocytopenia, autoimmune liver diseases, and arthralgia. High-titered antilamin

				antibodies help to define a subset of lupus patients with antiphospholipid antibodies who are at a lower risk of developing thrombotic events. In addition, preliminary data suggest that the presence of antilamin antibodies may be helpful in the diagnosis of chronic fatigue syndrome. CONCLUSIONS: Each of the antibodies reacting with nuclear membrane antigens has its own spectrum of disease associations. RELEVANCE: Determination of anti-nuclear envelope antibody pattern by indirect immunofluorescence, with subsequent determination of the specific antibody, carries important diagnostic and prognostic implications in various autoimmune conditions.
Nishikai M, Tomomatsu S, Hankins RW, Takagi S, Miyachi K, Kosaka S, Akiya K.	National Tokyo Medical Center, Tokyo, Japan.	Autoantibodies to a 68/48 kDa protein in chronic fatigue syndrome and primary fibromyalgia: a possible marker for hypersomnia and cognitive disorders.	Rheumatology (Oxford). 2001 Jul;40(7):806-10.	OBJECTIVE: To identify antinuclear antibodies (ANA) specific for chronic fatigue syndrome (CFS), and in related conditions such as fibromyalgia (FM) or psychiatric disorders. METHODS: One hundred and fourteen CFS patients and 125 primary and secondary FM patients were selected based on criteria advocated by the Centers for Disease Control and Prevention and by the American College of Rheumatology, respectively. As controls, healthy subjects and patients with either various psychiatric disorders or diffuse connective tissue diseases were included. Autoantibodies were examined by immunoblot utilizing HeLa cell extracts as the antigen. RESULTS: Autoantibodies to a 68/48 kDa protein were present in 13.2 and 15.6% of patients with CFS and primary FM, respectively. In addition, autoantibodies to a 45 kDa protein were found in 37.1 and 21.6% of the patients with secondary FM and psychiatric disorders, respectively. Meanwhile, these two autoantibodies were not found at all in connective tissue disease patients without FM, nor in healthy subjects ($P<0.05$). As a group, the anti-68/48 kDa-positive CFS patients presented more frequently with hypersomnia ($P<0.005$), short-term amnesia ($P<0.07$) or difficulty in concentration ($P<0.05$) than those CFS patients without the antibodies. CONCLUSIONS: The presence of the anti-68/48 kDa protein antibodies in a portion of both CFS and primary FM patients suggests the existence of a common immunological background. These antibodies may find utility as possible markers for a clinicoserological subset of CFS/FM patients with hypersomnia and cognitive complaints.

Although it has been indicated that patients with lung cancer experience higher level of fatigue than patients with other cancers, few published studies have focused on the characteristics of this fatigue and how it interferes with daily activities. The purpose of this

Nishiwaki Y, Hosaka T, Uchitomi Y.	Research Institute East, Kashiwa, Japan.	cancer: prevalence, correlated factors, and screening.		study was to clarify fatigue prevalence and the factors correlated with fatigue, and to develop a screening method for fatigue in patients with advanced lung cancer. One hundred fifty-seven patients completed two fatigue scales (Cancer Fatigue Scale [CFS], and Fatigue Numerical Scale [FNS]) plus other measures, along with a self-administered questionnaire asking whether fatigue had interfered with any of 7 areas of daily activities. Fifty-nine percent of patients had experienced clinical fatigue, which was defined as fatigue that interfered with any daily activities. Logistic regression analysis demonstrated that symptoms of dyspnea on walking, appetite loss, and depression were significant correlated factors. Both CFS and FNS were found to have sufficient sensitivity and specificity for use as a screening tool. The results indicated that fatigue is a frequent and important symptom, which is associated with both physical and psychological distress in this population. The CFS and FNS were confirmed to have sufficient screening ability.
Ottenweller JE, Sisto SA, McCarty RC, Natelson BH.	Department of Neurosciences, New Jersey Medical School, University of Medicine and Dentistry of New Jersey, Newark, USA. jeo@nbunj.jvnc.net	Hormonal responses to exercise in chronic fatigue syndrome.	Neuropsychobiology. 2001 Jan;43(1):34-41.	Chronic fatigue syndrome (CFS) is a debilitating disease characterized by severe, unexplained fatigue and postexertional exacerbation of symptoms. We examined basal endocrine function in a group of CFS patients and a carefully matched group of sedentary controls. The subjects then completed a graded, maximal exercise test on a treadmill, and additional blood samples were drawn 4 min and a day after the end of exercise. There were no differences in basal hormone levels before exercise. Plasma adrenocorticotropin, epinephrine, prolactin and thyrotropin responses 4 min after exercise were lower in the CFS group, but the growth hormone response may have been exaggerated, and the plasma norepinephrine response was similar to that in controls. The next day, there were no differences in hormone levels between the groups, which suggests that long-term changes in endocrine function are unlikely to be a cause of the prolonged fatigue that occurs in CFS patients after a bout of exertion. Overstreet DH, Djuric V.	Department of Psychiatry and Center for Alcohol Studies, University of North Carolina at Chapel Hill, 27599-7178, USA. dhover@med.unc.edu	A genetic rat model of cholinergic hypersensitivity: implications for chemical intolerance, chronic fatigue, and asthma.	Ann N Y Acad Sci. 2001 Mar;933:92-102.	The fact that only some individuals exposed to environmental chemicals develop chemical intolerance raises the possibility that genetic factors could be contributing factors. The present communication summarizes evidence from a genetic animal model of cholinergic supersensitivity that suggests that an abnormal cholinergic system could be one predisposing genetic factor. The Flinders Sensitive Line (FSL) rats were established by selective breeding for increased responses to an organophosphate. It was subsequently found that these FSL rats were also more sensitive to direct-acting muscarinic agonists and had elevated muscarinic receptors compared to the selectively bred parallel group, the Flinders Resistant Line (FRL) rats, or randomly bred control rats. Increased sensitivity to cholinergic agents has also been observed in several human populations, including individuals suffering from chemical intolerance. Indeed, the FSL rats exhibit certain behavioral characteristics such as abnormal sleep, activity, and appetite that are similar to those reported in these human populations. In addition, the FSL rats have been reported to exhibit increased sensitivity to a variety of other chemical agents. Peripheral tissues, such as intestinal and airway smooth muscle, appear to be more sensitive to both cholinergic agonists and an antigen, ovalbumin. Hypothermia, a centrally mediated response, is more

				pronounced in the FSL rats after nicotine and alcohol, as well as agents that are selective for the dopaminergic and serotonergic systems. In some cases, the increased sensitivity has been detected in the absence of any changes in the receptors with which the drugs interact (dopamine receptors), while receptor changes have been seen in other cases (nicotine receptors). Therefore, there may be multiple mechanisms underlying the multiple chemical sensitivity-chemical intolerance of the FSL rats. An elucidation of these mechanisms may provide useful clues to those involved in chemical intolerance in humans.
Pall ML, Satterle JD.	School of Molecular Biosciences, Washington State University, Pullman 99164-4660, USA. martin_pall@wsu.edu	Elevated nitric oxide/peroxynitrite mechanism for the common etiology of multiple chemical sensitivity, chronic fatigue syndrome, and posttraumatic stress disorder.	Ann N Y Acad Sci. 2001 Mar;933:323-9.	Various types of evidence implicate nitric oxide and an oxidant, possibly peroxynitrite, in MCS and chemical intolerance (CI). The positive feedback loops proposed earlier for CFS may explain the chronic nature of MCS (CI) as well as several of its other reported properties. These observations raise the possibility that this proposed elevated nitric oxide/peroxynitrite mechanism may be the mechanism of a new disease paradigm, answering the question raised by Miller earlier: "Are we on the threshold of a new theory of disease?"
Pall ML.		Cobalamin Used in Chronic Fatigue Syndrome Therapy Is a Nitric Oxide Scavenger	Journal of Chronic Fatigue Syndrome 2001; 8(2): 39	Cobalamin (vitamin B12) in the form of hydroxocobalamin or cyanocobalamin injections has been widely used to treat chronic fatigue syndrome (CFS). Hydroxocobalamin is a nitric oxide scavenger and is proposed here to act as such a scavenger in CFS treatment. Its possible efficacy in CFS treatment, if further substantiated, may provide confirmation of a prediction of the elevated nitric oxide/peroxynitrite theory of CFS etiology. This interpretation of the possible role of cobalamin in CFS treatment suggests a useful perspective for confirming and optimizing this treatment.
Pall ML.	School of Molecular Biosciences and Program in Medical Sciences, Washington State University, Pullman, 99164-4660, USA. pall@mail.wsu.edu	Common etiology of posttraumatic stress disorder, fibromyalgia, chronic fatigue syndrome and multiple chemical sensitivity via elevated nitric oxide/peroxynitrite.	Med Hypotheses. 2001 Aug;57(2):139-45.	Three types of overlap occur among the disease states chronic fatigue syndrome (CFS), fibromyalgia (FM), multiple chemical sensitivity (MCS) and posttraumatic stress disorder (PTSD). They share common symptoms. Many patients meet the criteria for diagnosis for two or more of these disorders and each disorder appears to be often induced by a relatively short-term stress which is followed by a chronic pathology, suggesting that the stress may act by inducing a self-perpetuating vicious cycle. Such a vicious cycle mechanism has been proposed to explain the etiology of CFS and MCS, based on elevated levels of nitric oxide and its potent oxidant product, peroxynitrite. Six positive feedback loops were proposed to act such that when peroxynitrite levels are elevated, they may remain elevated. The biochemistry involved is not highly tissue-specific, so that variation in symptoms may be explained by a variation in nitric oxide/peroxynitrite tissue distribution. The evidence for the same biochemical mechanism in the etiology of PTSD and FM is discussed here, and while less extensive than in the case of CFS and MCS, it is nevertheless suggestive. Evidence supporting the role of elevated nitric oxide/peroxynitrite in these four disease states is summarized, including induction of nitric oxide by common apparent inducers of these disease states, markers of elevated nitric oxide/peroxynitrite in patients and evidence for an inductive role of elevated nitric oxide in animal models. This theory

				appears to be the first to provide a mechanistic explanation for the multiple overlaps of these disease states and it also explains the origin of many of their common symptoms and similarity to both Gulf War syndrome and chronic sequelae of carbon monoxide toxicity. This theory suggests multiple studies that should be performed to further test this proposed mechanism. If this mechanism proves central to the etiology of these four conditions, it may also be involved in other conditions of currently obscure etiology and criteria are suggested for identifying such conditions. Papp KK, Erokwu B, Decker M, Strohl KP.	Louis B. Stokes Cleveland V.A. Medical Center and Case Western Reserve University School of Medicine, Cleveland, Ohio, USA. kkp4@po.cwru.edu	Medical student competence in eliciting a history for "chronic fatigue".	Sleep Breath. 2001 Sep;5(3):123-9.	PURPOSE: We report an observational study of medical students' abilities in taking a complex history for which sleep disorders is one of several possible conditions. METHODS: Students are observed taking a focused history from a simulated patient whose chief complaint is "I am tired. I cannot get anything done." Nine groups of students (n = 360) completing the internal medicine core-clerkship were evaluated by one of three examiners. Students received full, partial, or no credit for each item on a uniform behavioral checklist, which included prompts for common medical and psychiatric disorders associated with chronic fatigue. RESULTS: Observed means were lowest for items pertaining to sleep behaviors and head trauma. Fewer than half of the students inquired about whether or not the person had difficulty falling asleep at night, family history of sleep apnea, and frequency and length of naps. In contrast, the majority of students inquired about heart disease, metabolic disorders, the use of illicit drugs, alcohol consumption, and the taking of medications. Examiners accounted for a significant source of variance in scores; yet the station discriminated among top and bottom students as measured by the Objective Structured Clinical Examination (OSCE) overall. No statistically significant differences were observed on the basis of clerkship site, primary care versus traditional-track students, time of year, or gender. CONCLUSION: A majority of students do not adequately cover issues relevant to sleep in contrast to other associated disorders when taking a focused history for chronic fatigue.
Parker AJ, Wessely S, Cleare AJ.	Department of Psychological Medicine, Guy's, King's and St Thomas' School of Medicine and the Institute of Psychiatry, London.	The neuroendocrinology of chronic fatigue syndrome and fibromyalgia.	Psychol Med. 2001 Nov;31(8):1331-45.	BACKGROUND: Disturbance of the HPA axis may be important in the pathophysiology of chronic fatigue syndrome (CFS) and fibromyalgia. Symptoms may be due to: (1) low circulating cortisol; (2) disturbance of central neurotransmitters; or (3) disturbance of the relationship between cortisol and central neurotransmitter function. Accumulating evidence of the complex relationship between cortisol and 5-HT function, make some form of hypothesis (3) most likely. We review the methodology and results of studies of the HPA and other neuroendocrine axes in CFS. METHOD: Medline, Embase and Psychlit were searched using the Cochrane Collaboration strategy. A search was also performed on the King's College CFS database, which includes over 3000 relevant references, and a citation analysis was run on the key paper (Demitrack et al. 1991). RESULTS: One-third of the studies reporting baseline cortisol found it to be significantly low, usually in one-third of patients. Methodological differences may account for some of the varying results. More consistent is the finding of reduced HPA function, and enhanced 5-HT function on

				neuroendocrine challenge tests. The opioid system, and arginine vasopressin (AVP) may also be abnormal, though the growth hormone (GH) axis appears to be intact, in CFS. CONCLUSIONS: The significance of these changes, remains unclear. We have little understanding of how neuroendocrine changes relate to the experience of symptoms, and it is unclear whether these changes are primary, or secondary to behavioural changes in sleep or exercise. Longitudinal studies of populations at risk for CFS will help to resolve these issues.
Patarca R.	Department of Medicine, University of Miami School of Medicine, Florida 33101, USA. rpatarca@pol.net	Cytokines and chronic fatigue syndrome.	Ann N Y Acad Sci. 2001 Mar;933:185-200.	Chronic fatigue syndrome (CFS) patients show evidence of immune activation, as demonstrated by increased numbers of activated T lymphocytes, including cytotoxic T cells, as well as elevated levels of circulating cytokines. Nevertheless, immune cell function of CFS patients is poor, with low natural killer cell cytotoxicity (NKCC), poor lymphocyte response to mitogens in culture, and frequent immunoglobulin deficiencies, most often IgG1 and IgG3. Immune dysfunction in CFS, with predominance of so-called T-helper type 2 and proinflammatory cytokines, can be episodic and associated with either cause or effect of the physiological and psychological function derangement and/or activation of latent viruses or other pathogens. The interplay of these factors can account for the perpetuation of disease with remission/exacerbation cycles. A T-helper type 2 predominance has been seen among Gulf War syndrome patients and this feature may also be present in other related disorders, such as multiple chemical sensitivity. Therapeutic intervention aimed at induction of a more favorable cytokine expression pattern and immune status appears promising.
Patarca-Montero R, Antoni M, Fletcher MA, Klimas NG.	E. M. Papper Laboratory of Clinical Immunology, Center for Behavioral Medicine Research, Miami Veterans Administration Medical Center, University of Miami School of Medicine, P.O. Box 016960, Miami, FL 33101, USA.	Cytokine and other immunologic markers in chronic fatigue syndrome and their relation to neuropsychological factors.	Appl Neuropsychol. 2001;8(1):51-64.	The literature is reviewed and data are presented that relate to a model we have developed to account for the perpetuation of the perplexing disorder currently termed chronic fatigue syndrome (CFS). In patients with CFS there is chronic lymphocyte overactivation with cytokine abnormalities that include perturbations in plasma levels of proinflammatory cytokines and decrease in the ratio of Type 1 to Type 2 cytokines produced by lymphocytes in vitro following mitogen stimulation. The initiation of the syndrome is frequently sudden and often follows an acute viral illness. Our model for the subsequent chronicity of this disorder holds that the interaction of psychological factors (distress associated with either CFS-related symptoms or other stressful life events) and the immunologic dysfunction contribute to (a) CFS-related physical symptoms (e.g., perception of fatigue and cognitive difficulties, fever, muscle and joint pain) and increases in illness burden and (b) impaired immune surveillance associated with cytotoxic lymphocytes with resulting activation of latent herpes viruses.
Patarca-Montero R, Klimas NG, Fletcher MA.		Immunotherapy of Chronic Fatigue Syndrome: Therapeutic Interventions Aimed at Modulating the	Journal of Chronic Fatigue Syndrome 2001; 8(1): 3	Based on the postulates of viral and autoimmune etiologies of CFS, several interventions have been designed and tested by different research groups around the world, including the United States, Sweden, United Kingdom, Italy, and Japan. This review addresses those interventions aimed at altering the balance of certain cytokines, the mediators of immune responses. Patients with CFS who show evidence of activation of the immune system have poor immune cell function and a predominance of what is called a T-helper (Th)2-type

		Th1/Th2 Cytokine Expression Balance		cytokine response when their lymphocytes are activated. A Th2-type response, which is characterized by production of cytokines such as interleukin (IL)-4, -5, and -10, favors the function of B lymphocytes, the cellular factories of immunoglobulins. A predominance of a Th2-type response is therefore consistent with pathologies, such as autoimmunity and atopy, which are based on inappropriate production of immunoglobulins. Many of the CFS therapies discussed decrease the Th2-type predominance seen at baseline in CFS patients, thereby allowing a greater predominance of a Th1-type response, which favors the function of macrophages and natural killer cells. The function of the latter cells, which have the natural ability of directly destroying invading microbes and cancer cells, is defective in untreated CFS patients. Typical Th1-type cytokines include IL-2 and interferon-gamma, and some of the therapies induce their production. The interventions discussed in this review cover a wide spectrum of therapeutic tools ranging from lymph node cell immunotherapy, herbal products, and small molecules to vaccines. Despite the controversies on the etiology of CFS, immunotherapy research is useful and necessary.
Patarca-Montero R.		Fibromyalgia: Literature in Review (1999-2000)	Journal of Chronic Fatigue Syndrome 2001; 9(1/2): 63	Definition of Fibromyalgia, Disability and Functional Status Assessments, Endocrinology, Epidemiology, Immunology, Microbiology, Neurology, Pathophysiology, Pediatrics, Psychiatry, Psychology, Related Disorders and Complications, Treatment.
Patarca-Montero R.		Fibromyalgia	Journal of Chronic Fatigue Syndrome 2001; 9(3/4): 21 - 161	Although much has been learned over the last decade about fibromyalgia, much remains to be learned about its causes, nosology, treatment, and overlap with a variety of rheumatic and nonrheumatic conditions. Advances in rheumatology, cardiovascular medicine, endocrinology, epidemiology, immunology, infectious diseases, neurology, psychiatry, and psychology have served as the basis for the formulation of new lines of research and novel therapeutic interventions. The purpose of this review is to summarize the knowledge gained and published mainly within the last decade.

Paul LM, Wood L, Maclaren W.	Department of Physiotherapy, Podiatry and Radiography, Glasgow Caledonian University, City Campus, Cowcaddens Road, Scotland G4 OBA, Glasgow, UK. l.paul@gcal.ac.uk	The effect of exercise on gait and balance in patients with chronic fatigue syndrome.	Gait Posture. 2001 Jul;14(1):19-27.	This study investigated anecdotal reports of gait and balance abnormalities in subjects with Chronic Fatigue Syndrome (CFS) by examining the effects of a light exercise test on postural sway and various gait parameters. Tests were performed on 11 CFS patients and 11 age- and sex-matched sedentary controls. Results demonstrated that postural sway was not significantly different in both groups before or after the exercise test. There were, however, significant differences in gait parameters between the two groups confirming anecdotal evidence, but these differences were not exacerbated by the exercise test. Heart rate responses demonstrated that both groups were exercising at similar loads, although this was perceived to be higher by the CFS group.

Health Psychology Research Group, Faculty of Medicine and Health Sciences, The University of Auckland, Auckland, New Zealand. kj.petrie@auckland.ac.nz	Thoroughly modern worries: the relationship of worries about modernity to reported symptoms, health and medical care utilization.	J Psychosom Res. 2001 Jul;51(1):395-401.	OBJECTIVE: There is now greater public concern about how features of modern life pose threats to personal health. In two studies, we investigated the relationship between individuals' worries about modernity affecting health to symptom reports, perceptions of health and health care utilization. METHODS: In the first study, 526 University students completed a questionnaire measuring modern health worries (MHW), symptom reports and health perceptions. A second study utilized an existing national survey database of 7869 New Zealanders. Part of the survey examined people's concerns of modernity affecting their health in the past 12 months, as well as the use of conventional medical and alternative health care. RESULTS: We found concerns about modernity affecting health were made up of four major components: environmental pollution, toxic interventions, tainted food and radiation. MHW were significantly associated with somatic complaints and ratings of the importance of health to the individual. We also found individuals with high levels of MHW had a higher rate of food intolerance and chronic fatigue syndrome (CFS). In the second study, we found MHW to be associated with medical care utilization, particularly of alternative health practitioners. CONCLUSIONS: The results of these studies suggest concerns about modernity do cause changes in the way individuals interpret somatic information and may play a role in undermining perceptions of health. The area of MHW is worthy of study and may hold importance for understanding aspects of functional disorders.
Powell P, Bentall RP, Nye FJ, Edwards RH.	Regional Infectious Diseases Unit, University Hospital Aintree, Liverpool L9 7AL.	Randomised controlled trial of patient education to encourage graded exercise in chronic fatigue syndrome.	BMJ. 2001 Feb 17;322(7283):387-90. Comment in: ACP Journal Club 2001 Sep-Oct;135(2):46. BMJ. 2001 Jun 23;322(7301):1545-6.	OBJECTIVE: To assess the efficacy of an educational intervention explaining symptoms to encourage graded exercise in patients with chronic fatigue syndrome. DESIGN: Randomised controlled trial. SETTING: Chronic fatigue clinic and infectious diseases outpatient clinic. SUBJECTS: 148 consecutively referred patients fulfilling Oxford criteria for chronic fatigue syndrome. INTERVENTIONS: Patients randomised to the control group received standardised medical care. Patients randomised to intervention received two individual treatment sessions and two telephone follow up calls, supported by a comprehensive educational pack, describing the role of disrupted physiological regulation in fatigue symptoms and encouraging home based graded exercise. The minimum intervention group had no further treatment, but the telephone intervention group received an additional seven follow up calls and the maximum intervention group an additional seven face to face sessions over four months. MAIN OUTCOME MEASURE: A score of >/=25 or an increase of >/=10 on the SF-36 physical functioning subscale (range 10 to 30) 12 months after randomisation. RESULTS: 21 patients dropped out, mainly from the

				intervention groups. Intention to treat analysis showed 79 (69%) of patients in the intervention groups achieved a satisfactory outcome in physical functioning compared with two (6%) of controls, who received standardised medical care (P<0.0001). Similar improvements were observed in fatigue, sleep, disability, and mood. No significant differences were found between the three intervention groups. CONCLUSIONS: Treatment incorporating evidence based physiological explanations for symptoms was effective in encouraging self managed graded exercise. This resulted in substantial improvement compared with standardised medical care.
Prins JB, Bleijenberg G, Bazelmans E, Elving LD, de Boo TM, Severens JL, van der Wilt GJ, Spinhoven P, van der Meer JW.	Department of Medical Psychology, University Medical Centre, Nijmegen, The Netherlands. j.prins@cksmps.azn.nl	Cognitive behaviour therapy for chronic fatigue syndrome: a multicentre randomised controlled trial.	Lancet. 2001 Mar 17;357(9259):841-7.	BACKGROUND: Cognitive behaviour therapy (CBT) seems a promising treatment for chronic fatigue syndrome (CFS), but the applicability of this treatment outside specialised settings has been questioned. We compared CBT with guided support groups and the natural course in a randomised trial at three centres. METHODS: Of 476 patients diagnosed with CFS, 278 were eligible and willing to take part. 93 were randomly assigned CBT (administered by 13 therapists recently trained in this technique for CFS), 94 were assigned the support-group approach, and 91 the control natural course. Multidimensional assessments were done at baseline, 8 months, and 14 months. The primary outcome variables were fatigue severity (on the checklist individual strength) and functional impairment (on the sickness impact profile) at 8 and 14 months. Data were analysed by intention to treat. FINDINGS: 241 patients had complete data (83 CBT, 80 support groups, 78 natural course) at 8 months. At 14 months CBT was significantly more effective than both control conditions for fatigue severity (CBT vs support groups 5.8 [2.2-9.4]; CBT vs natural course 5.6 [2.1-9.0]) and for functional impairment (CBT vs support groups 263 [38-488]; CBT vs natural course 222 [3-441]). Support groups were not more effective for CFS patients than the natural course. Among the CBT group, clinically significant improvement was seen in fatigue severity for 20 of 58 (35%), in Karnofsky performance status for 28 of 57 (49%), and self-rated improvement for 29 of 58 (50%). Prognostic factors for outcome after CBT were a higher sense of control predicting more improvement, and a passive activity pattern and focusing on bodily symptoms predicting less improvement. INTERPRETATION: CBT was more effective than guided support groups and the natural course in a multicentre trial with many therapists. Our study showed a lower proportion of patients with improvement than CBT trials with a few highly skilled therapists.
Proctor SP, Heaton KJ, White RF, Wolfe J.	Boston Environmental Hazards Center (116B-4), 150 South Huntington Avenue, Boston, MA 02130-4893, USA. sproctor@bu.edu	Chemical sensitivity and chronic fatigue in Gulf War veterans: a brief report.	J Occup Environ Med. 2001 Mar;43(3):259-64.	The foci of this brief report are to (1) describe the prevalence of chemical sensitivity (CS) and chronic fatigue (CF) symptomatology and of presumptive multiple CS and CF syndrome diagnoses, and (2) explore the potential overlap between one purported case definition (i.e., chronic multi-symptom illness) and these unexplained symptom syndromes in a well-characterized group of Gulf War veterans. The number of subjects with CS and CF symptomatology and presumptive multiple CS and CF syndrome diagnoses was higher in the Gulf War-deployed group compared with a group deployed to Germany during the Gulf War. However, the percent differences were not significant when comparing the presumptive diagnoses of multiple CS and CF syndrome. The characteristic differences

				between the groups and the overlap with chronic multi-symptom illness are also discussed.
Racciatti D, Guagnano MT, Vecchiet J, De Remigis PL, Pizzigallo E, Della Vecchia R, Di Sciascio T, Merlitti D, Sensi S.	Clinic of Infectious Diseases, University of Chieti, Chieti, Italy.	Chronic fatigue syndrome: circadian rhythm and hypothalamic-pituitary-adrenal (HPA) axis impairment.	Int J Immunopathol Pharmacol. 2001 Jan-Apr;14(1):11-15.	Chronic Fatigue Syndrome (CFS) is a clinical condition characterized by a persistent or relapsing debilitating fatigue at rest, lasting more than 6 months, and made worse by exercise. At the present moment, there are three potential etiopathogenic factors: immunologic, viral and neuroendocrine. The purpose of our study was to evaluate possible alterations of the hypothalamic-pituitary-adrenal (HPA) axis in our CFS patients by studying the circadian rhythms of prolactin (PRL), thyrotropic hormone (TSH), adrenocorticotropic hormone (ACTH), and cortisol (CS). A total of 36 patients were enrolled according to the Centers for Disease Control and Prevention case-definition criteria. Twenty healthy subjects were included as controls. Blood samples were taken every 4 hours during a single 24-hour period. We performed a fluorometric enzyme immunoassay with serum PRL, cortisol and TSH, and an immunoradiometric assay with plasma ACTH. The circadian rhythms of PRL, TSH, ACTH and CS were statistically significant in both CFS and control groups. At 24:00 and 04:00 hrs the CFS patients showed lower ACTH levels than healthy subjects (p < 0.001); the PRL levels were higher at 04.00 h in CFS patients than in healthy subjects.
Racciatti D, Vecchiet J, Ceccomancini A, Ricci F, Pizzigallo E.	Department of Infectious Diseases, G. D'Annunzio University, Chieti Scalo, Italy. racciatt@unich.it	Chronic fatigue syndrome following a toxic exposure.	Sci Total Environ. 2001 Apr 10;270(1-3):27-31.	Chronic fatigue syndrome (CFS) is a clinical entity characterized by severe fatigue lasting more than 6 months and other well-defined symptoms. Even though in most CFS cases the etiology is still unknown, sometimes the mode of presentation of the illness implicates the exposure to chemical and/or food toxins as precipitating factors: ciguatera poisoning, sick building syndrome, Gulf War syndrome, exposure to organochlorine pesticides, etc. In the National Reference Center for CFS Study at the Department of Infectious Diseases of 'G. D'Annunzio' University (Chieti) we examined five patients (three females and two males, mean age: 37.5 years) who developed the clinical features of CFS several months after the exposure to environmental toxic factors: ciguatera poisoning in two cases, and exposure to solvents in the other three cases. These patients were compared and contrasted with two sex- and age-matched subgroups of CFS patients without any history of exposure to toxins: the first subgroup consisted of patients with CFS onset following an EBV infection (post-infectious CFS), and the second of patients with a concurrent diagnosis of major depression. All subjects were investigated by clinical examination, neurophysiological and immunologic studies, and neuroendocrine tests. Patients exposed to toxic factors had disturbances of hypothalamic function similar to those in controls and, above all, showed more severe dysfunction of the immune system with an abnormal CD4/CD8 ratio, and in three of such cases with decreased levels of NK cells (CD56+). These findings may help in understanding the pathogenetic mechanisms involved in CFS.
Redelmeier DA, Tu JV, Schull MJ, Ferris LE, Hux JE.	Department of Medicine, University of Toronto, Toronto, Ont. dar@ices.on.ca	Problems for clinical judgement: 2. Obtaining a reliable past medical history.	CMAJ. 2001 Mar 20;164(6):809-13.	Ordinary human reasoning may lead patients to provide an unreliable history of past experiences because of errors in comprehension, recall, evaluation and expression. Comprehension of a question may change depending on the definition of periods of time and prior questions. Recall fails through the loss of relevant information, the fabrication of misinformation and distracting cues. Evaluations may be mistaken because of the "halo

				effect" and a reluctance to change personal beliefs. Expression is influenced by social culture and the environment. These errors can also occur when patients report a history of present illness, but they tend to be more prominent with experiences that are more remote. An awareness of these specific human fallibilities might help clinicians avoid some errors when eliciting a patient's past medical history.
Regland, Zachrisson O, Stejskal V, Gottfries C-G.		Nickel Allergy Is Found in a Majority of Women with Chronic Fatigue Syndrome and Muscle Pain-And May Be Triggered by Cigarette Smoke and Dietary Nickel Intake	Journal of Chronic Fatigue Syndrome 2001; 8(1): 57	Two hundred and four women with chronic fatigue and muscle pain, with no signs of autoimmune disorder, received immune stimulation injections with a Staphylococcus vaccine at monthly intervals over 6 months. Good response was defined as a decrease by at least 50% of the total score on an observer's rating scale. Nickel allergy was evaluated as probable if the patient had a positive history of skin hypersensitivity from cutaneous exposure to metal objects. The patient's smoking habits were recorded. Fifty-two percent of the patients had a positive history of nickel contact dermatitis. There were significantly more good responders among the non-allergic non-smokers (39%) than among the allergic smokers (6%). We also present case reports on nickel-allergic patients who apparently improved after cessation of cigarette smoking and reducing their dietary nickel intake. Our observations indicate that exposure to nickel, by dietary intake or inhalation of cigarette smoke, may trigger systemic nickel allergy and contribute to syndromes of chronic fatigue and muscle pain.
Reid S, Hotopf M, Hull L, Ismail K, Unwin C, Wessely S.	Academic Department of Psychiatry, Guy's King's and St. Thomas' School of Medicine and Institute of Psychiatry, London, United Kingdom.	Multiple chemical sensitivity and chronic fatigue syndrome in British Gulf War veterans.	Am J Epidemiol. 2001 Mar 15;153(6):604-9.	The objective of this study was to measure the prevalence of multiple chemical sensitivity (MCS) and chronic fatigue syndrome (CFS) in British Gulf War veterans and to investigate their association with reported exposures and psychologic morbidity. In 1997--1998, the authors undertook a cross-sectional survey of three cohorts of British military personnel comprising Gulf veterans (n = 3,531), those who had served in Bosnia (n = 2,050), and those serving during the Gulf War but not deployed there (Era cohort, n = 2,614). MCS and CFS were defined according to operational criteria. The prevalence of MCS in the Gulf, Bosnia, and Era cohorts was 1.3%, 0.3%, and 0.2%, respectively. For CFS, the prevalence was 2.1% (Gulf cohort), 0.7% (Bosnia cohort), and 1.8% (Era cohort). In Gulf veterans, MCS was strongly associated with exposure to pesticides (adjusted odds ratio = 12.3, 95% confidence interval: 5.1, 30.0). Both syndromes were associated with high levels of psychologic morbidity. These findings suggest that CFS and MCS account for some of the medically unexplained illnesses reported by veterans after deployment to the Gulf. MCS was particularly associated with Gulf deployment and self-reported exposure to pesticides, findings that merit further exploration given the controversial status of this diagnosis and the potential for recall bias in a questionnaire survey.
Reinhart WH, Fleisch F.	Departement Innere Medizin, Kantonsspital Chur. walter.reinhart@ksc.gr.ch	[Fatigue] [Article in German	Schweiz Rundsch Med Prax. 2001 Nov 15;90(46):2015-8.	Fatigue is one of the most frequent symptoms in medicine. A detailed history must include sleeping habits, other diseases, drugs, and concomitant symptoms. A physical examination is necessary, followed by laboratory tests and imaging techniques, which must be used in a cost-effective manner. When underlying diseases are excluded, a chronic fatigue syndrome may be present. Its pathogenesis is largely unknown. Established treatment options in chronic fatigue syndrome are graded exercise, antidepressants in case of depression and

				anxiety, and cognitive behaviour treatment. The large number of other treatments including diets have no proven value. Fatigue remains a diagnostic and therapeutic challenge to the physician.
Repka-Ramirez MS, Naranch K, Park YJ, Velarde A, Clauw D, Baraniuk JN.	Department of Medicine, Georgetown University, Washington, DC 20007-2197, USA.	IgE levels are the same in chronic fatigue syndrome (CFS) and control subjects when stratified by allergy skin test results and rhinitis types.	Ann Allergy Asthma Immunol. 2001 Sep;87(3):218-21.	BACKGROUND: Chronic fatigue syndrome (CFS) has an uncertain pathogenesis. Allergies have been suggested as one cause. OBJECTIVE: The aim of this study was to compare serum immunoglobulin (Ig)E in CFS and control subjects to determine whether IgE levels were elevated in CFS. This would be suggestive of increased atopy in CFS. METHODS: IgE was measured by quantitative ELISA (sandwich) immunoassay in 95 CFS and 109 non-CFS control subjects. Subjects were classified by positive or negative allergy skin tests (AST) and rhinitis questionnaires (rhinitis score, RhSc) into four rhinitis types: nonallergic rhinitis (NAR with positive RhSc and negative AST); allergic rhinitis (AR with positive AST and RhSc); atopic/no rhinitis (AST positive/RhSc negative); and nonatopic/no rhinitis (both AST and RhSc negative) subjects. RESULTS: IgE was not significantly different between control (128 +/- 18 IU/mL, mean +/- SEM) and CFS (133 +/- 43 IU/mL) groups, or between control and CFS groups classified into the four rhinitis types. IgE was significantly higher in subjects with positive AST whether or not they had positive RhSc or CFS symptoms. CONCLUSIONS: Elevated IgE and positive AST indicate allergen sensitization, but are not necessarily indicators of symptomatic allergic diseases. There was no association between IgE levels and CFS, indicating that atopy was probably not more prevalent in CFS. Therefore, TH2-lymphocyte and IgE-mast cell mechanisms are unlikely causes of CFS.
Richardson J.		Viral Isolation from Brain in Myalgic Encephalomyelitis	Journal of Chronic Fatigue Syndrome 2001; 9(3/4): 15 - 19	
Ridsdale L, Godfrey E, Chalder T, Seed P, King M, Wallace P, Wessely S; Fatigue Trialists' Group.	Department of General Practice, Guy's, King's and St Thomas's School of Medicine, King's College, 5 Lambeth Walk, London SE11 6SP. L.Ridsdale@iop.kcl.ac.uk	Chronic fatigue in general practice: is counselling as good as cognitive behaviour therapy? A UK randomised trial.	Br J Gen Pract. 2001 Jan;51(462):19-24. Comment in: Br J Gen Pract. 2001 Apr;51(465):316-7. Br J Gen Pract. 2001 Apr;51(465):317-8.	BACKGROUND: Fatigue is a common symptom for which patients consult their doctors in primary care. With usual medical management the majority of patients report that their symptoms persist and become chronic. There is little evidence for the effectiveness of any fatigue management in primary care. AIM: To compare the effectiveness of cognitive behaviour therapy (CBT) with counselling for patients with chronic fatigue and to describe satisfaction with care. DESIGN OF STUDY: Randomised trial with parallel group design. SETTING: Ten general practices located in London and the South Thames region of the United Kingdom recruited patients to the trial between 1996 and 1998. Patients came from a wide range of socioeconomic backgrounds and lived in urban, suburban, and rural areas. METHOD: Data were collected before randomisation, after treatment, and six months later. Patients were offered six sessions of up to one hour each of either CBT or counselling. Outcomes include: self-report of fatigue symptoms six months later, anxiety and depression, symptom attributions, social adjustment and patients' satisfaction with care. RESULTS: One hundred and sixty patients with chronic fatigue entered the trial, 45 (28%) met research criteria for chronic fatigue syndrome; 129 completed follow-up. All patients met Chalder et al's standard criteria for fatigue. Mean fatigue scores were 23 on entry (at baseline) and 15 at six months' follow-up. Sixty-one (47%) patients no longer met

				standard criteria for fatigue after six months. There was no significant difference in effect between the two therapies on fatigue (1.04 [95% CI = -1.7 to 3.7]), anxiety and depression or social adjustment outcomes for all patients and for the subgroup with chronic fatigue syndrome. Use of antidepressants and consultations with the doctor decreased after therapy but there were no differences between groups. CONCLUSION: Counselling and CBT were equivalent in effect for patients with chronic fatigue in primary care. The choice between therapies can therefore depend on other considerations, such as cost and accessibility.
Robertson-Ritchie H.		Toward a new definition of chronic fatigue syndrome.	West J Med. 2001 Apr;174(4):241.	
Robinson GL, McGregor NR, Roberts TK, Dunstan RH, Butt H.	Special Education Centre, University of Newcastle, Callaghan, New South Wales, Australia.	A biochemical analysis of people with chronic fatigue who have Irlen Syndrome: speculation concerning immune system dysfunction.	Percept Mot Skills. 2001 Oct;93(2):486-504.	This study investigated the biological basis of visual processing disabilities in adults with Chronic Fatigue Syndrome. The study involved 61 adults with symptoms of Chronic Fatigue Syndrome who were screened for visual processing problems (Irlen Syndrome) and divided into two groups according to the severity of symptoms of Irlen Syndrome. Significant variations were identified in blood lipids and urine amino and organic acids of the two groups, which may be indicative of activation of the immune system due to some infective agent. It was suggested that metabolic profiling may help the development of more valid diagnostic categories and allow more investigation of immune system dysfunction as a possible causal factor in a range of learning and behaviour disorders.
Roelens S, Herst CV, D'Haese A, De Smet K, Frémont M, De Meirleir K, Englebienne P.		G-Actin Cleavage Parallels 2-5A-Dependent RNase L Cleavage in Peripheral Blood Mononuclear Cells-Relevance to a Possible Serum-Based Screening Test for Dysregulations in the 2-5A Pathway	Journal of Chronic Fatigue Syndrome 2001; 8(3/4): 63	A dysregulation in the 2N,5N-oligoadenylate (2-5A)-dependent RNase L antiviral pathway has been detected in peripheral blood mononuclear cells (PBMC) of chronic fatigue syndrome (CFS) patients, which is characterized by an unregulated RNase L activity and the presence of a low molecular weight (LMW) 2-5A-binding protein (37-kDa 2-5A-BP). This study was undertaken to test the possibility that the 37-kDa 2-5A-BP of CFS is produced by proteolytic cleavage of the 80-kDa monomeric enzyme. Incubation of the 80-kDa human recombinant RNase L (r-hRNase L) with PBMC extracts either positive or negative for the presence of 37-kDa 2-5A-BP, respectively, demonstrates that the LMW protein is produced by the former, not the latter, and that the size of the fragment generated from the recombinant protein matches the 37-kDa size of the fragment observed in the original PBMC. Digestion of r-hRNase L with calpain generated the same 37-kDa 2-5A-BP observed in PBMC extracts, and calpain immunoprecipitation from PBMC extracts reduced their proteolytic activity, an observation that suggests that calpain may be involved in the cleavage. We further examined G-actin, a known calpain substrate, for possible cleavage in PBMC. Actin fragments were observed of which the presence correlated with the presence of 37-kDa 2-5-BP. Since G-actin is cleared by serum transport, we further screened serum samples for the presence of LMW forms. A single LMW actin fragment could be detected in serum, the presence of which correlated significantly with the presence of both G-actin and RNase L fragments in PBMC. This latter observation offers the opportunity to screen large populations of patients for dysregulations in the RNase L pathway by a serum-based

				assay.
Rosenqvist P.	Psykiatriska kliniken, Kalmar, per.rosenqvist@ltblekinge.se	[Stress-related fatigue--some therapeutic experiences] [Article in Swedish]	Lakartidningen. 2001 Nov 28;98(48):5549-50, 5553.	
Ross S, Fantie B, Straus SF, Grafman J.	Department of Psychology, American University, Washington, DC, USA.	Divided attention deficits in patients with chronic fatigue syndrome.	Appl Neuropsychol. 2001;8(1):4-11.	Chronic fatigue syndrome (CFS) patients and controls were compared on a variety of mood state, personality, and neuropsychological measures, including memory, word finding, and attentional tasks that required participants to focus, sustain, or divide their attention, or to perform a combination of these functions. CFS patients demonstrated a selective deficit on 3 measures of divided attention. Their performance on the other neuropsychological tests of intelligence, fluency, and memory was no different than that of normal controls despite their reports of generally diminished cognitive capacity. There was an inverse relation between CFS patient fatigue severity and performance on 1 of the divided attention measures. Given these findings, it is probable that CFS patients will report more cognitive difficulties in real-life situations that cause them to divide their effort or rapidly reallocate cognitive resources between 2 response channels (vision and audition).
Rowe PC, Calkins H, DeBusk K, McKenzie R, Anand R, Sharma G, Cuccherini BA, Soto N, Hohman P, Snader S, Lucas KE, Wolff M, Straus SE.	Departments of Pediatrics and Medicine, Johns Hopkins Hospital, 600 N Wolfe St, Baltimore, MD 21287, USA.	Fludrocortisone acetate to treat neurally mediated hypotension in chronic fatigue syndrome: a randomized controlled trial.	JAMA. 2001 Jan 3;285(1):52-9. Comment in: JAMA. 2001 Mar 21;285(11):1441-2; discussion 1443. JAMA. 2001 Mar 21;285(11):1442-3. JAMA. 2001 Mar 21;285(11):1442; discussion 1443.	CONTEXT: Patients with chronic fatigue syndrome (CFS) are more likely than healthy persons to develop neurally mediated hypotension (NMH) in response to prolonged orthostatic stress. OBJECTIVE: To examine the efficacy of fludrocortisone acetate as monotherapy for adults with both CFS and NMH. DESIGN: Randomized, double-blind, placebo-controlled trial conducted between March 1996 and February 1999. SETTING: Two tertiary referral centers in the United States. PATIENTS: One hundred individuals aged 18 to 50 years who satisfied Centers for Disease Control and Prevention criteria for CFS and had NMH provoked during a 2-stage tilt-table test. Eighty-three subjects had adequate outcome data to assess efficacy. INTERVENTION: Subjects were randomly assigned to receive fludrocortisone acetate, titrated to 0.1 mg/d (n = 50) or matching placebo (n = 50) for 9 weeks, followed by 2 weeks of observation after discontinuation of therapy. MAIN OUTCOME MEASURE: Proportion of subjects in each group with at least a 15-point improvement on a 100-point global wellness scale. RESULTS: Baseline demographic and illness characteristics between the groups were similar; CFS had been present for at least 3 years in 71%. Using an intention-to-treat analysis, 7 subjects (14%) treated with fludrocortisone experienced at least a 15-point improvement in their wellness scores compared with 5 (10%) among placebo recipients (P =.76). No differences were observed in several other symptom scores or in the proportion with normal follow-up tilt test results at the end of the treatment period. CONCLUSIONS: In our study of adults with CFS, fludrocortisone as monotherapy for NMH was no more efficacious than placebo for amelioration of symptoms. Failure to identify symptomatic improvement with fludrocortisone does not disprove the hypothesis that NMH could be contributing to some of the symptoms of CFS. Further studies are needed to determine whether other

				medications or combination therapy are more effective in treating orthostatic intolerance in patients with CFS.
Ruchko VM, Makhlai LI, Borisevich SV, Makhlai AA.		[Chronic fatigue and immune dysfunction syndrome] [Article in Russian]	Vopr Virusol. 2001 May-Jun;46(3):46-8.	
Sachs L.	Department of Communication Studies, Linkoping University, Sweden. lisbeth.sachs@swipnet.se	From a lived body to a medicalized body: diagnostic transformation and chronic fatigue syndrome.	Med Anthropol. 2001;19(4):299-317. Comment in: Med Anthropol. 2001;19(4):411-3.	This paper addresses the diagnostic dilemma posed by chronic illness that offers no demonstrable evidence of serious physical disorders or pathology. Is a diagnosis such as chronic fatigue syndrome (CFS) disabling because it encourages people to identify with it? Does it become a self-fulfilling prophecy? In providing people with a name, and thus allowing them to confirm the legitimacy of their suffering, a diagnosis of CFS may help them to relate to their world and, hence, facilitate their recovery. One of the most relevant questions pertaining to a diagnosis of CFS concerns how people deal with suffering when it does not come with a biomedically established pathology. I draw upon material provided by 21 men and women diagnosed with CFS. My analysis concerns the ambivalence involved in the diagnostic process and its implications for the relationship between self-identity and chronicity.
Sakaino H.	Department of Oral Surgery, Kurume University School of Medicine, Kurume 830-0011, Japan.	The biochemical study of intermaxillary fixation (IMF) stress in oral surgery inpatients.	Kurume Med J. 2001;48(1):71-7.	Although intermaxillary fixation (IMF) is performed to treat the patients with maxillary fracture, this procedure is very stressful to the patients. IMF has been reported to increase noradrenaline (NA) release in the brain and elevate plasma corticosterone contents in the rat. These changes were significantly attenuated by diazepam, an anxiolytic of the benzodiazepine family. These results suggest that IMF could greatly affect the pituitary-adrenal system as a stress. In the present study, in order to examine the influence of IMF on the human body function, we measured levels of 17-hydrocorticosteroids (17-OHCS) and 17-ketosteroid (17-KS), which are metabolites of the adreno-cortical hormone cortisol, in the urine of inpatients undergoing IMF. The subjects were requested to fill out a questionnaire on irritableness caused by IMF. In these patients, urinary 17-OHCS levels were significantly increased after IMF and well correlated to the results of the questionnaire. The finding suggested that urinary 17-OHCS levels reflect stress related to IMF, and that such stress mainly causes an irritated feeling. Natural killer cell activity (NK activity), which is considered to be related to stress, was measured in these patients. The relationship between 17-OHCS levels and NK activity was examined in reference to the results of the questionnaire. Questionnaire showed that most patients noted insomnia and an irritated feeling during IMF. To examine the influence of anxiolytic agents on stress related to IMF, an anxiolytic agent, ethyl loflazepate, was administered during IMF, and urinary 17-OHCS levels were measured. There was no correlation between 17-OHCS levels and NK activity in the patients. Furthermore, no correlation was observed between visual analogue scale (VSA) and NK activity. Increases in 17-OHCS levels in the group treated with ethyl loflazepate, an anxiolytic of the benzodiazepine family, were significantly lower than in the untreated group. This suggests that ethyl loflazepate reduced stress responses to

				IMF. It has been reported that NK activity is reduced inpatients with depression or chronic fatigue syndrome. However, NK activity may not be affected by mechanical stress such as IMF. The finding that an anxiolytic agent, ethyl loflazepate, inhibited stress responses to IMF further suggests that anxiolytic drugs are very useful for treatment of irritated feeling of the patients undergoing IMF.
Schacterle RS, Conti Fabrizio, Magrini L, Komaroff AL, Valesini G.		Increased Eosinophil Protein X Levels in Chronic Fatigue Syndrome	Journal of Chronic Fatigue Syndrome 2001; 9(1/2): 21	Chronic fatigue syndrome is a condition of unknown etiology characterized by severe fatigue and accompanied by symptoms including cognitive difficulties, myalgias, and headaches. Studies of this illness have found chronic activation of the immune system, including one reporting elevated levels of eosinophil cationic protein, considered an eosinophil activation marker. The aim of this study was to measure serum levels of eosinophil protein X, a cationic protein not measured previously in this illness. Measurements are reported on serum samples from 29 patients meeting the Centers for Disease Control and Prevention criteria for chronic fatigue syndrome, and 30 healthy controls of similar age and gender. The median serum eosinophil protein X level in patients was higher than controls: 37.9 vs. 25.3 µg/L (p = 0.037). Forty-eight percent of patients versus 23% of controls had levels above the normal range. The marked increase in serum levels of eosinophil protein X in chronic fatigue syndrome patients could reflect eosinophil activation in this illness.

Servaes P, van der Werf S, Prins J, Verhagen S, Bleijenberg G.	Dutch Fatigue Research Group, Department of Medical Psychology (118), University Hospital Nijmegen, P.O. Box 9101, 6500 HB Nijmegen, The Netherlands. P.Servaes@cksmps.azn.nl	Fatigue in disease-free cancer patients compared with fatigue in patients with chronic fatigue syndrome.	Support Care Cancer. 2001 Jan;9(1):11-7.	The goal of our work was to assess fatigue in disease-free cancer patients with help of a validated fatigue questionnaire. Furthermore, we wished to analyse the relationship between severe fatigue and former treatment modalities, problems of concentration and motivation, physical activity, functional impairment, depression and anxiety and finally, to compare severely fatigued disease-free cancer patients and patients with Chronic Fatigue Syndrome (CFS). The participants were 85 adult cancer patients and 16 patients with CFS. The cancer patients were all disease-free and had been off treatment for a minimum of 6 months. They were asked to participate in this study by their physician when they came to the hospital for control visits. Patients who were willing to participate completed four questionnaires. The Checklist Individual Strength was used to measure fatigue. In addition, the Beck Depression Inventory, the Spielberger Trait Anxiety Inventory and the Nottingham Health Profile were used. Results indicate that 19% of the disease-free cancer patients were severely fatigued. Their fatigue experience is comparable to that of patients with CFS. Severe fatigue is associated with problems of concentration and motivation, reduced physical activity, emotional health problems and pain. Furthermore, a relation was found between fatigue and depression and anxiety. No relation was found between fatigue and

				type of cancer, former treatment modalities, duration of treatment and time since treatment ended. In conclusion, for one fifth of a group of disease-free cancer patients fatigue is a severe problem long after treatment. In addition to fatigue, these patients experience several psychological and physical problems.

Shephard RJ.	Defence & Civil Institute of Environmental Medicine, and Faculty of Physical Education & Health, University of Toronto, Ontario, Canada. royjshep@mountain-inter.net	Chronic fatigue syndrome: an update.	Sports Med. 2001;31(3):167-94.	The chronic fatigue syndrome is characterised by a fatigue that is disproportionate to the intensity of effort that is undertaken, has persisted for 6 months or longer, and has no obvious cause. Unless there has been a long period of patient- or physician-imposed inactivity, objective data may show little reduction in muscle strength or peak aerobic power, but the affected individual avoids heavy activity. The study of aetiology and treatment has been hampered by the low disease prevalence (probably <0.1% of the general population), and (until recently) by a lack of clear and standardised diagnostic criteria. It is unclear how far the aetiology is similar for athletes and nonathletes. It appears that in top competitors, overtraining and/or a negative energy balance can be precipitating factors. A wide variety of other possible causes and/or precipitating factors have been cited in the general population, including psychological stress, disorders of personality and affect, dysfunction of the hypothalamic-pituitary-adrenal axis, hormonal imbalance, nutritional deficits, immune suppression or activation and chronic infection. However, none of these factors have been observed consistently. The prognosis is poor; often disability and impairment of athletic performance are prolonged. Prevention of overtraining by careful monitoring seems the most effective approach in athletes. In those where the condition is established, treatment should aim at breaking the vicious cycle of effort avoidance, deterioration in physical condition and an increase in fatigue through a combination of encouragement and a progressive exercise programme.
Shepherd C.		Cognitive behaviour therapy for chronic fatigue syndrome.	Lancet. 2001 Jul 21;358(9277):239; author reply 240-1. Comment on: Lancet. 2001 Mar 17;357(9259):841-7

Upregulation of key components of the 2',5'-oligoadenylate (2-5A) synthetase/RNase L pathway has been identified in extracts of peripheral blood mononuclear cells from

	Fels Institute for Cancer Research and Molecular Biology, Temple University School of Medicine, Philadelphia, Pennsylvania 19140, USA.	(2-5A)-dependent 37-kDa RNase L: azido photoaffinity labeling and 2-5A-dependent activation.	Epub 2001 Apr 25. Erratum in: J Biol Chem 2001 Aug 24;276(34):32392.	individuals with chronic fatigue [corrected] syndrome, including the presence of a low molecular weight form of RNase L. In this study, analysis of 2',5'-Oligoadenylate (2-5A) binding and activation of the 80- and 37-kDa forms of RNase L has been completed utilizing photolabeling/immunoprecipitation and affinity assays, respectively. Saturation of photolabeling of the 80- and the 37-kDa RNase L with the 2-5A azido photoprobe, [(32)P]pApAp(8-azidoA), was achieved. Half-maximal photoinsertion of [(32)P]pApAp(8-azidoA) occurred at 3.7 x 10(-8) m for the 80-kDa RNase L and at 6.3 x 10(-8) m for the 37-kDa RNase L. Competition experiments using 100-fold excess unlabeled 2-5A photoaffinity probe, pApAp(8-azidoA), and authentic 2-5A (p(3)A(3)) resulted in complete protection against photolabeling, demonstrating that [(32)P]pApAp(8-azidoA) binds specifically to the 2-5A-binding site of the 80- and 37-kDa RNase L. The rate of RNA hydrolysis by the 37-kDa RNase L was three times faster than the 80-kDa RNase L. The data obtained from these 2-5A binding and 2-5A-dependent activation studies demonstrate the utility of [(32)P]pApAp(8-azidoA) for the detection of the 37-kDa RNase L in peripheral blood mononuclear cell extracts.
Sirois DA, Natelson B.	Department of Oral Medicine, New York University College of Dentistry, New York, USA.	Clinicopathological findings consistent with primary Sjogren's syndrome in a subset of patients diagnosed with chronic fatigue syndrome: preliminary observations.	J Rheumatol. 2001 Jan;28(1):126-31.	OBJECTIVE: Some patients diagnosed with chronic fatigue syndrome (CFS) have symptoms commonly observed in Sjogren's syndrome (SS), particularly xerophthalmia and xerostomia, leading to speculation that some patients with CFS might have primary SS or that the 2 disorders share common pathophysiological features. We investigated the prevalence of symptoms of mucosal dryness, salivary gland pathology, lacrimal hyposecretion, and autoantibodies (antinuclear antibody, SSA/SSB) among patients diagnosed with CFS. METHODS: Twenty-five subjects with CFS and 18 healthy control subjects were interviewed and examined, had a Schirmer test and fluorescein tear dilution, and underwent minor salivary gland (MSG) biopsy. Antibody to nuclear antigen as well as anti-La (SSA) and anti-Ro (SSB) antibody were available for subjects with CFS. Pathologists unaware of the subject group assignment examined labial salivary gland biopsy specimens and calculated a standard MSG score for each specimen. RESULTS: Mucosal dryness was reported by 13/25 (52%) subjects with CFS, of which 8 (32%) also had MSG score, low Schirmer test value, and symptoms consistent with primary SS (p = 0.05). No control subject met diagnostic criteria for primary SS. MSG focus scores < or =1 were common among both groups (CFS 14/25; controls 15/18). MSG results without pathological alteration were rare, seen in only one control and no CFS patients. Low Schirmer values were found in 10/25 (40%) CFS patients and 1/18 (6%) control (p = 0.01). CONCLUSION: A subset of patients with CFS may have primary SS.
Skowera A, Peakman M, Cleare A, Davies E, Deale A, Wessely S.		High prevalence of serum markers of coeliac disease in patients with chronic fatigue syndrome.	J Clin Pathol. 2001 Apr;54(4):335-6.	
Snell CR, Stevens SR,		Chronic Fatigue	Journal of Chronic	The purpose of this investigation was to identify significant quality-of-life issues for two

VanNess JM.		Syndrome, Ampligen, and Quality of Life: A Phenomenological Perspective	Fatigue Syndrome 2001; 8(3/4): 117	women previously diagnosed with chronic fatigue syndrome (CFS), and their families. Both women were participants in a cost-recovery, clinical trial of the antiviral and immunomodulatory drug, Ampligen. A qualitative, case study approach was adopted to access information not normally available from clinical trials. Specifically, semi-structured, in-depth interviews were conducted with the CFS patients, and their spouses, to discover if these families perceived any changes in their patterns of daily living contingent with participation in the Ampligen trial. Patient diaries were also analyzed for the purpose of triangulation. Content analysis of the interview transcripts and diary entries revealed a number of significant quality of life improvements for the women and their families, for which they perceived the drug therapy responsible. After an initial acclimation period, and with the exception of the day when the drug was administered, both women reported a reduction in pain, increased energy levels, and improved cognitive functioning. They each cited numerous cases to illustrate their improvement.
Soderberg S, Evengard B.	Huddinge University Hospital, M42, SE-141 86 Huddinge, Sweden. stina.soderberg@hs.sll.se	Short-term group therapy for patients with chronic fatigue syndrome.	Psychother Psychosom. 2001 Mar-Apr;70(2):108-11.	BACKGROUND: This study presents experiences of focused short-term group therapy for patients with chronic fatigue syndrome (CFS). METHODS: Fourteen women diagnosed as CFS patients were randomly placed into two groups. The control group received group therapy 5 months after the first group. The project consisted of 10 group sessions of 1.5 h per week. Sense of coherence (SOC) was used for measuring coping resources, and self-rating scales of quality of life and of fatigue were compared before and after group therapy. RESULTS: The most valuable aspect was the sharing of experiences. More than half of the patients also felt that the sessions had improved psychological well-being through adjustment of ambitions and improved coping with symptoms. CONCLUSION: The study encourages further research. If group therapy is chosen as treatment for these patients, a longer period is recommended. A possible alternative is individualized short-term therapy adapted to each patient's needs, problems and circumstances. Copyright 2001 S. Karger AG, Basel

St Clair Gibson A, Lambert ML, Noakes TD.	The Medical Research Council, Department of Human Biology,	Neural control of force output during maximal and	Sports Med. 2001;31(9):637-50.	A common belief in exercise physiology is that fatigue during exercise is caused by changes in skeletal muscle metabolism. This 'peripheral' fatigue results either from substrate depletion during submaximal exercise or metabolite accumulation during maximal exercise

	University of Cape Town, South Africa. agibson@sports.uct.ac.za	submaximal exercise.		in the exercising muscles. However, if substrate depletion alone caused fatigue, intracellular ATP levels would decrease and lead to rigor and cellular death. Alternatively, metabolite accumulation would prevent any increase in exercise intensity near the end of exercise. At present, neither of these effects has been shown to occur, which suggests that fatigue may be controlled by changes in efferent neural command, generally described as 'central' fatigue. In this review, we examine neural efferent command mechanisms involved in fatigue, including the concepts of muscle wisdom during short term maximal activity, and muscle unit rotation and teleoanticipation during submaximal endurance activity. We propose that neural strategies exist to maintain muscle reserve, and inhibit exercise activity before any irreparable damage to muscles and organs occurs. The finding that symptoms of fatigue occur in the nonexercising state in individuals with chronic fatigue syndrome indicates that fatigue is probably not a physiological entity, but rather a sensory manifestation of these neural regulatory mechanisms.

Stein E.		Chronic Fatigue Syndrome: Overcoming the Attitudinal Impasse	Journal of Chronic Fatigue Syndrome 2001; 8(3/4): 53	Context: Patients with Chronic Fatigue Syndrome and their physicians are often in conflict about the etiology and treatment of CFS. Objectives: 1. Survey the literature regarding physician's attitudes towards CFS; 2. Examine the contributing factors to physician's attitude towards the disorder; and 3. Suggest solutions. Data Sources: The relevant medical and psychological literature (years 1988- 2000) was searched using the search term "Chronic Fatigue Syndrome." This was supplemented with papers from the bibliographies of the retrieved papers, additional related literature, and clinical experience. Data Synthesis: Forty-six to ninty percent of GPs accept CFS as a discrete clinical entity and 30-82% are willing to make the diagnosis in qualifying patients. Conclusions: CFS is a heterogeneous, multifactorial host response disorder that is inadequately described by the biomedical model. Despite substantial evidence of multisystemic physical abnormality in CFS, the lack of pathognomic tests and the female gender predominance cause some physicians to continue to treat CFS as a psychosocial disorder. This leads to conflict between patients and physicians. CFS challenges physicians to think beyond current disease models, to tolerate diagnostic and therapeutic uncertainty, and to work collaboratively with patients rather than taking the role of expert.

Stewart JM.		Orthostatic Intolerance: A Review with Application to the Chronic Fatigue Syndrome	Journal of Chronic Fatigue Syndrome 2001; 8(2): 45	The symptoms of the chronic fatigue syndrome closely match those of chronic orthostatic intolerance and research suggests that orthostatic intolerance plays a role in the symptomatology of CFS. Recent investigations support the hypothesis that findings in CFS patients result at least in part from impaired blood pressure and heart rate regulation. Orthostatic intolerance has been implicated. Effective and specific treatment for chronic orthostatic intolerance can only be developed when a specific etiology or etiologies are discovered.
Streeten DH.	Department of Medicine, SUNY Upstate Medical University, Syracuse, New York 13210, USA.	Role of impaired lower-limb venous innervation in the pathogenesis of the chronic fatigue syndrome.	Am J Med Sci. 2001 Mar;321(3):163-7.	BACKGROUND: In patients with acute orthostatic hypotension, there is excessive pooling of blood in the legs, which may result from the strikingly subnormal compliance that is demonstrable in the pedal veins during norepinephrine infusion. The common occurrence of delayed orthostatic hypotension and/or tachycardia in the chronic fatigue syndrome (CFS) led to the present studies of foot vein compliance in CFS patients with a linear variable differential transformer. METHODS: Seven patients with CFS were compared with 7 age- and gender matched healthy control subjects in their blood pressure, heart-rate, and plasma norepinephrine responses to prolonged standing and in measurements of their foot vein contractile responses to intravenous norepinephrine infusions with the linear variable differential transformer. RESULTS: Excessive, delayed (usually after 10 min) orthostatic reductions in systolic and diastolic blood pressure ($P < 0.01$) and inconsistently excessive increases in heart rate were found in the CFS patients, in whom venous compliance in response to infused norepinephrine was significantly reduced ($P < 0.05$). CONCLUSIONS: In these patients with CFS, delayed orthostatic hypotension was clearly demonstrable, and, as in previously reported patients with orthostatic hypotension of acute onset, this was associated with reduced pedal vein compliance during norepinephrine infusion, implying impaired sympathetic innervation of foot veins. The rapid symptomatic improvement demonstrated in previous studies of CFS patients during correction of orthostatic venous pooling by inflation of military antishock trousers (MAST) to 35 mm Hg may suggest that excessive lower body venous pooling, perhaps by reducing cerebral perfusion, is involved in the orthostatic component of fatigue in these patients.
Strickland PS, Levine PH,. Peterson DL, O'Brien K, Fears T.		Neuromyasthenia and Chronic Fatigue Syndrome (CFS) in Northern Nevada/California: A Ten-Year Follow-Up of an Outbreak	Journal of Chronic Fatigue Syndrome 2001; 9(3/4): 3 - 14	In 1984-87, an outbreak of debilitating fatigue was reported by two physicians in the private practice of internal medicine in Incline Village, Nevada. Follow-up questionnaires were sent in 1995 to the 259 patients in this outbreak. The results were analyzed to determine how many patients met the latest Centers for Disease Control and Prevention (CDC) case definition for Chronic Fatigue Syndrome (CFS), Idiopathic Chronic Fatigue (ICF), or Prolonged Fatigue (PF). Data were analyzed separately for those living in the Lake Tahoe area and those referred from other locales. Of those returning questionnaires (123/259),

				41% met the CDC case definition for CFS, 56% met the criteria for inclusion in the subgroup ICF, and 3% experienced PF. In the populationbased Lake Tahoe group, symptomatic women were more likely to have CFS than ICF whereas symptomatic men were likely to fit ICF criteria. Also in this group, full recovery was reported more often among Lake Tahoe participants classified as having ICF (43%) than participants classified as having CFS (15%).
Tarello W.	Veterinary Surgeon, Castiglione del Lago, Perugia, Italy.	Chronic fatigue syndrome in horses: diagnosis and treatment of 4 cases.	Comp Immunol Microbiol Infect Dis. 2001 Jan;24(1):57-70.	A report from England has suggested that Chronic Fatigue Syndrome exists in equines and constitutes an emerging veterinary problem. Preliminary epidemiological studies seem to confirm the zoonotic implications of CFS. An arsenical drug, sodium thiacetarsamide, was administered to four horses with a diagnosis of Chronic Fatigue Syndrome (CFS), already treated unsuccessfully with different medications. The CFS-like lethargy, with accompanying symptoms and signs, of the four animals obtained a complete remission after intravenous treatment with this drug at low dosage (0.1 mg/kg/day). No adverse side effects were ever noticed. This clinical response was associated with recovery from anaemia and decrease of muscular enzyme values in two of the four horses. In all patients, micrococci-like bacteria found before treatment adhering to the outer surface of many red blood cells, disappeared at post-treatment controls. Considerations are made on the possible action of an arsenical drug, used in isolation, in the treatment of CFS.
Tarello W.	tarello@iol.it	Chronic Fatigue Syndrome (CFS) in 15 dogs and cats with specific biochemical and microbiological anomalies.	Comp Immunol Microbiol Infect Dis. 2001 Jul;24(3):165-85.	A great deal of controversy and speculation surrounds the etiology of Chronic Fatigue Syndrome (CFS) in human patients and the existence of a similar illness in animals. To evaluate the association with a presumptive staphylococcal infection and bacteremia, seven dogs and eight cats diagnosed with CFS (two meeting the CDC working case definition) were submitted to rapid blood cultures and fresh blood smears investigations. Nine out of 15 blood cultures proved Staph-positive and four isolates were specified as S. xilosus (3) and S. intermedius (1). The presence of micrococci-like organisms in the blood was of common observation among these subjects, in association with fatigue/pain-related symptoms and biochemical abnormalities suggestive of a myopathy. Following treatment with a low dosage arsenical drug (thiacetarsamide sodium, Caparsolate, i.v., 0.1 ml/kg/day) all patients experienced complete remission. Micrococci disappeared from the blood at post-treatment controls made 10-30 days later. The outcomes were compared with those of five healthy controls and five 'sick with other illness' patients showing significant difference.
Tarello W.	wtarello@supereva.it	Chronic fatigue syndrome (CFS) associated with Staphylococcus spp. bacteremia, responsive to potassium arsenite 0.5% in a veterinary surgeon and his	Comp Immunol Microbiol Infect Dis. 2001 Oct;24(4):233-46.	Chronic fatigue syndrome (CFS) in human patients remain a controversial and perplexing condition with emerging zoonotic aspects. Recent advances in human medicine seem to indicate a bacterial etiology and the condition has already been described in horses, dogs, cats and birds of prey in association with micrococci-like organisms in the blood. To evaluate the possibility of a chronic bacteremia, a veterinary surgeon (the author) and his coworking wife, both diagnosed with CFS and meeting the CDC working case definition, were submitted to rapid blood cultures and fresh blood smears investigations. Blood cultures proved Staph-positive and micrococci-like organisms in the blood were repeatedly observed in the 3-year period preceding the arsenical therapy, during which several

		coworking wife, handling with CFS animal cases.		medicaments, including antibiotics, proved unsuccessful. Following treatment with a low dosage arsenical drug (potassium arsenite 0.5%, im., 1 ml/12 h, for 10 days) both patients experienced complete remission. At the post-treatment control made 1 month later, micrococci had disappeared from the blood, and the CD4/CD8 ratio was raising.
Taylor RR, Jason LA.	Department of Occupational Therapy, University of Illinois at Chicago, 60612, USA.	Sexual abuse, physical abuse, chronic fatigue, and chronic fatigue syndrome: a community-based study.	J Nerv Ment Dis. 2001 Oct;189(10):709-15.	Using a randomly selected community-based sample, this investigation examined whether histories of childhood sexual, physical, and death threat abuse predicted adulthood outcomes of specific medical and psychiatric conditions involving chronic fatigue. This study also tested prior suggestions that most individuals with chronic fatigue syndrome report a past history of interpersonal abuse. Multinomial logistic regression was used to examine the relationship between abuse history and chronic fatigue group outcomes while controlling for the effects of sociodemographics. Compared with healthy controls, childhood sexual abuse was significantly more likely to be associated with outcomes of idiopathic chronic fatigue, chronic fatigue explained by a psychiatric condition, and chronic fatigue explained by a medical condition. None of the abuse history types were significant predictors of chronic fatigue syndrome. A closer examination of individuals in the chronic fatigue syndrome group revealed that significantly fewer individuals with CFS reported abuse as compared with those who did not. The implications of these findings are discussed.
Teitelbaum JE, Bird B, Greenfield RM, Weiss A, Muenz L, Gould L.		Effective Treatment of Chronic Fatigue Syndrome and Fibromyalgia–A Randomized, Double-Blind, Placebo-Controlled, Intent-To-Treat Study	Journal of Chronic Fatigue Syndrome 2001; 8(2): 3	Background: Hypothalamic dysfunction has been suggested in fibromyalgia (FMS) and chronic fatigue syndrome (CFS). This dysfunction may result in disordered sleep, subclinical hormonal deficiencies, and immunologic changes. Our previously published open trial showed that patients usually improve by using a protocol which treats all the above processes simultaneously. The current study examines this protocol using a randomized, double-blind design with an intent-to-treat analysis. Methods: Seventy-two FMS patients (38 active:34 placebo; 69 also met CFS criteria) received all active or all placebo therapies as a unified intervention. Patients were treated, as indicated by symptoms and/or lab testing, for: (1) subclinical thyroid, gonadal, and/or adrenal insufficiency, (2) disordered sleep, (3) suspected neurally mediated hypotension (NMH), (4) opportunistic infections, and (5) suspected nutritional deficiencies. Results: At the final visit, 16 active patients were "much better," 14 "better," 2 "same," 0 "worse," and 1 "much worse" vs. 3, 9, 11, 6, and 4 in the placebo group ($p < .0001$, Cochran-Mantel-Haenszel trend test). Significant improvement in the FMS Impact Questionnaire (FIQ) scores (decreasing from 54.8 to 33.2 vs. 51.4 to 47.7) and Analog scores (improving from 176.1 to 310.3 vs. 177.1 to 211.9) (both with $p < .0001$ by random effects regression), and Tender Point Index (TPI) (31.7 to 15.5 vs. 35.0 to 32.3, $p < .0001$ by baseline adjusted linear model) were seen. Long term follow-up (mean 1.9 years) of the active group showed continuing and increasing improvement over time, despite patients being able to discontinue most treatments. Conclusions: Significantly greater benefits were seen in the active group than in the placebo group for all primary outcomes. An integrated treatment approach appears effective in the treatment of FMS/CFS.

Tiersky LA, DeLuca J, Hill N, Dhar SK, Johnson SK, Lange G, Rappolt G, Natelson BH.	School of Psychology, Fairleigh Dickinson University, 1000 River Road, Mail Stop T-WH1-01, Teaneck, NJ 07666, USA.	Longitudinal assessment of neuropsychological functioning, psychiatric status, functional disability and employment status in chronic fatigue syndrome.	Appl Neuropsychol. 2001;8(1):41-50.	The longitudinal course of subjective and objective neuropsychological functioning, psychological functioning, disability level, and employment status in chronic fatigue syndrome (CFS) was examined. The relations among several key outcomes at follow-up, as well as the baseline characteristics that predict change (e.g., improvement), were also evaluated. The study sample consisted of 35 individuals who met the 1988 and 1994 CFS case definition criteria of the Centers for Disease Control (CDC) at intake. Participants were evaluated a mean of 41.9 (SEM = 1.7) months following their initial visit (range = 24-63 months). Results indicated that objective and subjective attention abilities, mood, level of fatigue, and disability improve over time in individuals with CFS. Moreover, improvements in these areas were found to be interrelated at follow-up. Finally, psychiatric status, age, and between-test duration were significant predictors of outcome. Overall, the prognosis for CFS appears to be poor, as the majority of participants remained functionally impaired over time and were unemployed at follow-up, despite the noted improvements.
Ting JY, Brown AF.	Department of Emergency Medicine, Princess Alexandra Hospital, Brisbane, Queensland, Australia.	Ciguatera poisoning: a global issue with common management problems.	Eur J Emerg Med. 2001 Dec;8(4):295-300.	Ciguatera poisoning, a toxinological syndrome comprising an enigmatic mixture of gastrointestinal, neurocutaneous and constitutional symptoms, is a common food-borne illness related to contaminated fish consumption. As many as 50000 cases worldwide are reported annually, and the condition is endemic in tropical and subtropical regions of the Pacific Basin, Indian Ocean and Caribbean. Isolated outbreaks occur sporadically but with increasing frequency in temperate areas such as Europe and North America. Increase in travel between temperate countries and endemic areas and importation of susceptible fish has led to its encroachment into regions of the world where ciguatera has previously been rarely encountered. In the developed world, ciguatera poses a public health threat due to delayed or missed diagnosis. Ciguatera is frequently encountered in Australia. Sporadic cases are often misdiagnosed or not medically attended to, leading to persistent or recurrent debilitating symptoms lasting months to years. Without treatment, distinctive neurologic symptoms persist, occasionally being mistaken for multiple sclerosis. Constitutional symptoms may be misdiagnosed as chronic fatigue syndrome. A common source outbreak is easier to recognize and therefore notify to public health organizations. We present a case series of four adult tourists who developed ciguatera poisoning after consuming contaminated fish in Vanuatu. All responded well to intravenous mannitol. This is in contrast to a fifth patient who developed symptoms suggestive of ciguatoxicity in the same week as the index cases but actually had staphylococcal endocarditis with bacteraemia. In addition to a lack of response to mannitol, clinical and laboratory indices of sepsis were present in this patient. Apart from ciguatera, acute gastroenteritis followed by neurological symptoms may be due to paralytic or neurotoxic shellfish poisoning, scombroid and pufferfish toxicity, botulism, enterovirus 71, toxidromes and bacteraemia. Clinical aspects of ciguatera toxicity, its pathophysiology, diagnostic difficulties and epidemiology are discussed.
Tomita K, Sakurada S, Minami S.	Department of Chemistry, College of	Enzymatic determination of	J Pharm Biomed Anal. 2001 Mar;24(5-	An enzymatic method was proposed for determination of acetylcarnitine (AcCar), even when carnitine (Car), non-acetylated form, co-exists. The method is consisted of four

	Engineering, Kanto Gakuin University, 4834 Mutsuura, Kanazawa-ku, Yokahama 236-8501, Japan. tomitak@kanto-gakuin.ac.jp	acetylcarnitine for diagnostic applications.	6):1147-50.	enzymatic reactions: First, AcCar is hydrolysed by acylcarnitine hydrolase to yield acetate; followed by the other three reactions coupled with three enzymes, respectively, acetate kinase, pyruvate kinase and lactate dehydrogenase; finally, the acetate formation causes a decrease in NADH. The amount of AcCar is then evaluated as the change in absorbance at 340 nm. The reagent composition of the reaction mixture was determined, and the characteristics of the method were investigated. The dilution test showed a good linearity over a wide range. The precision and accuracy tests produced satisfactory results. The co-existence of Car gave no effect on the measurement. The present method was found to be used easily, simply and rapidly for the selective determination of AcCar.
Tomoda, Jhodoi T, Miike T.		Chronic Fatigue Syndrome and Abnormal Biological Rhythms in School Children	Journal of Chronic Fatigue Syndrome 2001; 8(2): 29	Chronic fatigue syndrome occurring in previously healthy children and adolescents is one of the most vexing problems encountered by pediatric practitioners. To investigate the biological rhythms in the pediatric patients with CFS, we examined sleep pattern, and the circadian rhythm of core body temperature (CBT), and plasma cortisol in 41 patients, aged between 10 and 19 years, who did not have any physical or psychiatric disorders, but had non-specific complaints, and were suspected to have a circadian rhythm disturbance. They were diagnosed as having CFS on the basis of published criteria. Circadian variation of CBT in the CFS patients did not present a clear rhythm, and appearance time of their lowest CBT was significantly delayed compared to healthy subjects. Amplitude of circadian CBT changes, fitted to a cosinor curve by the least square method, was significantly smaller in the patients than in healthy subjects. Moreover, circadian rhythm of plasma cortisol in the patients appeared to be quite different, compared to healthy subjects. These findings suggest that their clinical psychosomatic symptoms (e.g., fatigue and sleep disturbance) might be closely related to the desynchronization of their biorhythms, particularly the circadian rhythm of body temperature and cortisol rhythm.
Tomonaga K, Kobayashi T, Ikuta K.	Department of Virology, Research Institute for Microbial Diseases, Osaka University.	[The neuropathogenesis of Borna disease virus infection] [Article in Japanese]	Nippon Rinsho. 2001 Aug;59(8):1605-13.	Borna disease virus(BDV) is a noncytolytic, neurotropic RNA virus that causes a disease of the central nervous system(CNS) in several vertebrate species, including horses, sheep, cats and ostriches. Epidemiological studies using peripheral blood or brain samples revealed that BDV can infect humans and that it may be related with certain neuropsychiatric disorders. The unique genetic and biological properties of BDV indicate that BDV develops a persistent infection in the CNS. Furthermore, a line of recent evidences suggests that BDV infection causes direct effects on brain functions in the absence of immunopathology-related brain damage. In this review, we discuss about recent data regarding neuropathogenesis of BDV infections in animals and humans.
Torpy DJ, Bachmann AW, Grice JE, Fitzgerald SP, Phillips PJ, Whitworth JA, Jackson RV.	Department of Medicine, University of Queensland, Greenslopes Private Hospital, Brisbane, Queensland 4120, Australia.	Familial corticosteroid-binding globulin deficiency due to a novel null mutation: association with fatigue and relative hypotension.	J Clin Endocrinol Metab. 2001 Aug;86(8):3692-700.	Corticosteroid-binding globulin is a 383-amino acid glycoprotein that serves a hormone transport role and may have functions related to the stress response and inflammation. We describe a 39-member Italian-Australian family with a novel complete loss of function (null) mutation of the corticosteroid-binding globulin gene. A second, previously described, mutation (Lyon) segregated independently in the same kindred. The novel exon 2 mutation led to a premature termination codon corresponding to residue -12 of the procorticosteroid-binding globulin molecule (c.121G-->A). Among 32 family members there

				were 3 null homozygotes, 19 null heterozygotes, 2 compound heterozygotes, 3 Lyon heterozygotes, and 5 individuals without corticosteroid-binding globulin mutations. Plasma immunoreactive corticosteroid-binding globulin was undetectable in null homozygotes, and mean corticosteroid-binding globulin levels were reduced by approximately 50% at 18.7 +/- 1.3 microg/ml (reference range, 30-52 microg/ml) in null heterozygotes. Morning total plasma cortisol levels were less than 1.8 microg/dl in homozygotes and were positively correlated to the plasma corticosteroid-binding globulin level in heterozygotes. Homozygotes and heterozygote null mutation subjects had a high prevalence of hypotension and fatigue. Among 19 adults with the null mutation, the systolic blood pressure z-score was 12.1 +/- 3.5; 11 of 19 subjects (54%) had a systolic blood pressure below the third percentile. The mean diastolic blood pressure z-score was 18.1 +/- 3.4; 8 of 19 subjects (42%) had a diastolic blood pressure z-score below 10. Idiopathic chronic fatigue was present in 12 of 14 adult null heterozygote subjects (86%) and in 2 of 3 null homozygotes. Five cases met the Centers for Disease Control criteria for chronic fatigue syndrome. Fatigue questionnaires revealed scores of 25.1 +/- 2.5 in 18 adults with the mutation vs. 4.2 +/- 1.5 in 23 healthy controls ($P < 0.0001$). Compound heterozygosity for both mutations resulted in plasma cortisol levels comparable to those in null homozygotes. Abnormal corticosteroid-binding globulin concentrations or binding affinity may lead to the misdiagnosis of isolated ACTH deficiency. The mechanism of the association between fatigue and relative hypotension is not established by these studies. As idiopathic fatigue disorders are associated with relatively low plasma cortisol, abnormalities of corticosteroid-binding globulin may be pathogenic.
Underhill JA, Mahalingam M, Peakman M, Wessely S.	Institute of Liver Studies, Department of Immunology, and Department of Psychological Medicine, Guy's, King's & St Thomas' School of Medicine, London, UK.	Lack of association between HLA genotype and chronic fatigue syndrome.	Eur J Immunogenet. 2001 Jun;28(3):425-8.	Although the aetiology of chronic fatigue syndrome is controversial, evidence that infective agents including viruses may have a role in the development of the condition has led to studies seeking an association with the immunomodulatory HLA genes. In the present study, we sought to extend previous work using a well-characterized patient group and modern HLA genotyping techniques. Fifty-eight patients were phenotyped for HLA A and B by microcytotoxicity and genotyped for HLA DRB, DQB and DPB by PCR oligoprobing, and the frequencies of antigens so assigned were compared with those from a control group of 134. No significant differences in HLA frequencies were found between patient and control groups. Thus, this study does not confirm previous findings of an HLA association with chronic fatigue syndrome, suggesting that neither presentation of viral antigen by HLA class I nor antigen processing genes in the HLA region is a major contributory factor in the development of the disease.
Underwood M, Eldridge S.		Chronic fatigue in general practice.	Br J Gen Pract. 2001 Apr;51(465):317-8. Comment on: Br J Gen Pract. 2001 Jan;51(462):19-24.

	Biological and Medical Psychology, University of Bergen, Norway.	subjective health complaints, and sustained arousal.	2001 Mar;933:119-29.	psychobiological mechanism underlying not only multiple chemical sensitivity (MCS), but a much more general cluster of illness, referred to as "subjective health complaints". Sustained arousal, or sustained "stress" responses, may be an important factor for the development of these conditions. Patients with subjective complaints without objective changes are sometimes referred to as having "fashionable diagnoses" or "unexplained symptoms". They may be given diagnoses like MCS, epidemic fatigue, chronic fatigue syndrome, burnout, stress, a variety of intoxications, environmental illness, radiation, multiple chemical hypersensitivity, food intolerance, functional dyspepsia, irritable bowel, myalgic encephalitis, postviral syndrome, yuppie flu, fibromyalgia, or vital exhaustion. One issue is whether this is one general condition or separate entities. Another issue is whether sensitization may be the psychobiological mechanism for most or all of these conditions. Finally, is it likely that sustained arousal may facilitate the development of sensitization in some or many neural circuits? In this review, the main emphasis will be on musculoskeletal pain. This is the most frequent and most expensive condition for sickness compensation and disability. The comorbidity of other complaints, however, will also be taken into account.
Valentine AD, Meyers CA.	Department of Neuro-Oncology, The University of Texas M. D. Anderson Cancer Center, Houston, Texas 77030, USA.	Cognitive and mood disturbance as causes and symptoms of fatigue in cancer patients.	Cancer. 2001 Sep 15;92(6 Suppl):1694-8.	Fatigue, cognitive dysfunction, and depression are very common in cancer patients. A relationship among the three entities is recognized but poorly understood. Factors that contribute to this poor understanding are the subjective nature of the symptoms, multiple potential causes, and a lack of reliable assessment tools. An understanding of fatigue in cancer patients may benefit from studies of chronic fatigue syndrome (CFS) and other nonmalignant diseases indicating that cognitive impairment varies with physical and mental fatigue, and that symptoms of depression experienced by patients with physical illnesses and primary mood disorders are qualitatively different. The multidimensional nature of fatigue suggests that interventions should be patient-specific. They could be related to lifestyle or involve the use of specific behavioral or pharmacologic therapies. As is the case with depression and cognitive disorders, targeted interventions against cancer-related fatigue will benefit from a better understanding of its potential biologic causes. Consideration of cognitive dysfunction and depression complicates the understanding of cancer-related fatigue; however, it provides opportunities to assist patients who must deal with this serious problem. Van Houdenhove B, Neerinckx E, Lysens R, Vertommen H, Van Houdenhove L, Onghena P, Westhovens R, D'Hooghe MB.	Department of Psychosomatic Rehabilitation, Katholieke Universiteit Leuven, Belgium. dewijn.VanHoudenhove@uz.kuleuven.ac.be	Victimization in chronic fatigue syndrome and fibromyalgia in tertiary care: a controlled study on prevalence and characteristics.	Psychosomatics. 2001 Jan-Feb;42(1):21-8.	The authors studied the prevalence and characteristics of different forms of victimization in 95 patients suffering from chronic fatigue syndrome (CFS) or fibromyalgia (FM) compared with a chronic disease group, including rheumatoid arthritis (RA) and multiple sclerosis (MS) patients, and a matched healthy control group. The authors assessed prevalence rates, nature of victimization (emotional, physical, sexual), life period of occurrence, emotional impact, and relationship with the perpetrator by a self-report questionnaire on burdening experiences. CFS and FM patients showed significantly higher prevalences of emotional neglect and abuse and of physical abuse, with a considerable subgroup experiencing lifelong victimization. The family of origin and the partner were the

				most frequent perpetrators. With the exception of sexual abuse, victimization was more severely experienced by the CFS/FM group. No differences were found between healthy control subjects or RA/MS patients, and between CFS and FM patients. These findings support etiological hypotheses suggesting a pivotal role for chronic stress in CFS and FM and may have important therapeutic implications.
Van Houdenhove B, Neerinckx E, Onghena P, Lysens R, Vertommen H.	Faculty of Medicine, K.U. Leuven, Leuven, Belgium. boudewijn.vanhoudenhove@uz.kuleuven.ac.be	Premorbid "overactive" lifestyle in chronic fatigue syndrome and fibromyalgia. An etiological factor or proof of good citizenship?	J Psychosom Res. 2001 Oct;51(4):571-6.	OBJECTIVE: In a former study, we have shown that patients suffering from chronic fatigue syndrome (CFS) or chronic pain, when questioned about their premorbid lifestyle, reported a high level of "action-proneness" as compared to control groups. The aim of the present study was to control for the patients' possible idealisation of their previous attitude towards action. METHODS: A validated Dutch self-report questionnaire measuring "action-proneness" (the HAB) was completed by 62 randomly selected tertiary care CFS and fibromyalgia (FM) patients, as well as by their significant others (SOs). RESULTS: HAB scores of the patients and those of the SOs were very similar and significantly higher than the norm values. Whether or not the SO showed sympathy for the patient's illness did not influence the results to a great extent. SOs with a negative attitude towards the illness even characterized the patients as more "action-prone." CONCLUSIONS: These results provide further support for the hypothesis that a high level of "action-proneness" may play a predisposing, initiating and/or perpetuating role in CFS and FM.
van Houdenhove B.		Does myalgic encephalomyelitis exist?	Lancet. 2001 Jun 9;357(9271):1889. Comment on: Lancet. 2001 Feb 17;357(9255):562.	
van Middendorp H, Geenen R, Kuis W, Heijnen CJ, Sinnema G.	Department of Pediatric Psychology, University Medical Center Utrecht, Wilhelmina Children's Hospital, The Netherlands.	Psychological adjustment of adolescent girls with chronic fatigue syndrome.	Pediatrics. 2001 Mar;107(3):E35.	OBJECTIVE: To examine psychosocial problems and adaptation of adolescent girls with chronic fatigue syndrome (CFS). METHODOLOGY: Thirty-six adolescent girls with CFS (mean age: 15.2 years; mean syndrome duration: 19.7 months) who fulfilled the criteria of the Centers for Disease Control and Prevention were examined by interviews regarding premorbid problems and by questionnaires regarding psychosocial functioning and distress, psychological attitudes, and coping resources. Data were compared with normative data. RESULTS: Of the adolescents, 86.1% reported 1 or more premorbid problems (58.3% physical, 38.9% psychological, and 52.8% familial). Normal adjustment was reported for psychosocial self-esteem, social abilities, and attentional abilities. High adjustment to adult social standards of behavior was found, but low perceived competence in specific adolescent domains, such as athletic ability, romance, and participation in recreational activities. The girls reported predominantly internalizing problems. Normal achievement motivation, no debilitating fear of failure, and high internal locus of control were observed. Palliative reaction patterns and optimism were predominantly used as coping strategies. CONCLUSIONS: The large number of premorbid problems suggests a possible contributing factor to the onset of the syndrome, although there were no reference data of healthy adolescents. In distinct domains of psychosocial

				adjustment, the adolescent girls with CFS showed strengths such as adequate self-esteem and scholastic and social abilities, and weaknesses such as low competence in adolescent-specific tasks and internalizing distress, which may partly be explained by syndrome-specific somatic complaints. The use of optimistic and palliative reaction patterns as coping strategies in this patient group indicates that the patients with CFS seem to retain an active and positive outlook on life, which may result in a rather adequate psychological adaptation to the syndrome, but also in maintenance of the syndrome by exceeding the physical limits brought about by the CFS. Our results on adjustment and coping strategies may be helpful to implement (individual) rehabilitation programs.
van Rensburg SJ, Potocnik FC, Kiss T, Hugo F, van Zijl P, Mansvelt E, Carstens ME, Theodorou P, Hurly PR, Emsley RA, Taljaard JJ.	Department of Chemical Pathology, University of Stellenbosch Medical School, Tygerberg Hospital, Tygerberg, South Africa. sjvr@gerga.sun.ac.za	Serum concentrations of some metals and steroids in patients with chronic fatigue syndrome with reference to neurological and cognitive abnormalities.	Brain Res Bull. 2001 May 15;55(2):319-25.	Chronic fatigue syndrome is defined by the Atlanta Centers for Disease Control (Atlanta, GA, USA) as debilitating fatigue lasting for longer than 6 months. Symptoms include disturbances of cognition. Certain factors have in the past been shown to influence cognition, including metals such as aluminum, iron, and zinc; and steroids such as dehydroepiandrosterone. In the present study, concentrations of these factors were determined in the serum and plasma of patients and their age- and gender-matched healthy controls (10 women and 5 men in each group). In addition, copper, dehydroepiandrosterone sulphate, cortisol, cholesterol, hemoglobin, ferritin and transferrin concentrations, as well as transferrin genetic subtypes were determined in both groups. The results indicate that patients had significantly increased serum aluminum and decreased iron compared to controls. In the females, serum iron and dehydroepiandrosterone sulphate were significantly decreased and correlated. Total cholesterol was significantly increased, and significantly negatively correlated with dehydroepiandrosterone sulphate. There were no differences in zinc, copper, cortisol, hemoglobin, transferrin and ferritin concentrations, or in transferrin genetic subtypes.
VanNess JM, Snell CR, Fredrickson DM, Strayer DR, Stevens SR.		Assessment of Functional Impairment by Cardiopulmonary Exercise Testing in Patients with Chronic Fatigue Syndrome	Journal of Chronic Fatigue Syndrome 2001; 8(3/4): 103	Functional impairment in a population of patients with chronic fatigue syndrome (CFS) was determined by exercise testing. The criteria established by Weber and Janicki were employed because impairment levels are based on maximal oxygen consumption. Oxygen consumption was obtained by cardiopulmonary exercise testing and was used to classify subjects according to the severity of impairment. All the subjects in this study met the CDC case definition for CFS. All patients underwent at least two maximal graded exercise tests in which expired air was collected for assessment of VO2max. Data are included for eighty-seven CFS patients, the highest VO2 was used for determining impairment. Although all patients met the CDC case definition for CFS, only 35 (40%) would be classified as having greater than "Mild" functional impairment. The highest VO2 of any of the patients in this study was 29.5 ml/kg/min, very close to what normative data predicts to be the average maximal value for the entire group. Without a sedentary control group it is unclear if the low VO2 in this population is due to the pathology of CFS or results from the inactivity that accompanies the disease. However, use of maximal VO2 during exercise can clearly discriminate between levels of functional impairment and may be efficacious for diagnosis of CFS. Additionally, in cases where cardiopulmonary analysis is unavailable, exercise

				duration on a standardized test may also be employed.
Vassallo CM, Feldman E, Peto T, Castell L, Sharpley AL, Cowen PJ.	University Department of Psychiatry, Warneford Hospital, Oxford.	Decreased tryptophan availability but normal post-synaptic 5-HT2c receptor sensitivity in chronic fatigue syndrome.	Psychol Med. 2001 May;31(4):585-91.	BACKGROUND: Chronic fatigue syndrome (CFS) has been associated with increased prolactin (PRL) responses to the serotonin (5-HT) releasing agent fenfluramine. It is not known whether this abnormality is due to increased 5-HT release or heightened sensitivity of post-synaptic 5-HT receptors. METHODS: We measured the increase in plasma PRL produced by the directly acting 5-HT receptor agonist, m-chlorophenylpiperazine (mCPP), in patients with CFS and healthy controls. We also compared the ability of mCPP to lower slow wave sleep (SWS) in the sleep polysomnogram of both subject groups. Finally, we measured plasma amino-acid levels to determine whether tryptophan availability differed between CFS subjects and controls. RESULTS: mCPP elevated plasma PRL equivalently in patients with CFS and controls. Similarly, the decrease in SWS produced by mCPP did not differ between the two subject groups. Plasma-free tryptophan was significantly decreased in CFS. CONCLUSIONS: The sensitivity of post-synaptic 5-HT2c receptors is not increased in patients with CFS. This suggests that the increased PRL response to fenfluramine in CFS is due to elevated activity of pre-synaptic 5-HT neurones. This change is unlikely to be due to increased peripheral availability of tryptophan.
Vermeulen RC, Scholte HR, Bezemer PD.		Cognitive behaviour therapy for chronic fatigue syndrome.	Lancet. 2001 Jul 21;358(9277):238; author reply 240-1. Comment on: Lancet. 2001 Mar 17;357(9259):841-7	
Visser J, Graffelman W, Blauw B, Haspels I, Lentjes E, de Kloet ER, Nagelkerken L.	Division of Immunological and Infectious Diseases, TNO Prevention and Health, P.O. Box 2215, 2301 CE, Leiden, The Netherlands.	LPS-induced IL-10 production in whole blood cultures from chronic fatigue syndrome patients is increased but supersensitive to inhibition by dexamethasone.	J Neuroimmunol. 2001 Oct 1;119(2):343-9.	Several causes have been held responsible for the chronic fatigue syndrome (CFS), including an altered hypothalamus-pituitary-adrenal gland (HPA)-axis activity, viral infections and a reduced Th1 activity. Therefore, it was investigated whether the regulation of IL-10 is different in CFS. LPS-induced cytokine secretion in whole blood cultures showed a significant increase in IL-10 and a trend towards a decrease in IL-12 as compared with healthy controls. In patients and controls, IL-12 secretion was equally sensitive to suppression by dexamethasone, whereas IL-10 secretion appeared more sensitive in CFS-patients. In controls, IL-10 and IL-12 secretion were inversely correlated with free serum cortisol ($r=-0.492$, $p<0.02$ and $r=-0.434$, $p<0.05$, respectively). In CFS, such an inverse correlation was found for IL-12 ($r=-0.611$, $p<0.02$) but not for IL-10 ($r=-0.341$, ns). These data are suggestive for a disturbed glucocorticoid regulation of IL-10 in CFS.
Visser J, Lentjes E, Haspels I, Graffelman W, Blauw B, de Kloet R, Nagelkerken L.	Division of Immunological and Infectious Diseases, TNO Prevention and Health, Leiden, The Netherlands.	Increased sensitivity to glucocorticoids in peripheral blood mononuclear cells of chronic fatigue syndrome patients, without evidence for	J Investig Med. 2001 Mar;49(2):195-204.	BACKGROUND: In this study we tested the hypothesis that the increased sensitivity to glucocorticoids in chronic fatigue syndrome (CFS)-patients can be attributed to an altered functioning of their glucocorticoid receptors (GR). METHODS: For this purpose, affinity and distribution of the GR were studied in purified, peripheral blood mononuclear cells (PBMC) of 10 CFS patients and 14 controls along with the responsiveness of these cells to glucocorticoids in vitro. RESULTS: Affinity (Kd) and number of GR was not different in PBMC of CFS patients when compared with the controls (Kd, 12.9 +/- 8.9 nmol vs 18.8 +/- 16.2

		altered density or affinity of glucocorticoid receptors.		nmol and GR number, 4,839 +/- 2,824/ cell vs 4,906 +/- 1,646/cell). Moreover, RT-PCR revealed no differences in GR messenger RNA expression. Nevertheless, PBMC from CFS patients showed an increased sensitivity to glucocorticoids in vitro. In CFS patients 0.01 micromol dexamethasone suppressed PBMC proliferation by 37%, whereas the controls were only suppressed by 17% (P < 0.01). Addition of phorbol 12-myristate 13-acetate to the cultures rendered the cells resistant to dexamethasone with regard to proliferation and IL-10 and IFN-gamma production, but not to IL-2 and TNF-alpha production in both patients and controls. No difference between patients and controls was observed in this respect CONCLUSIONS: In conclusion, PBMC of CFS patients display an increased sensitivity to glucocorticoids, which cannot be explained by number or affinity of the GR but should rather be attributed to molecular processes beyond the actual binding of the ligand to the GR.
Vives-Bauza C, Gamez J, Roig M, Briones P, Cervera C, Solano A, Montoya J, Andreu AL.	Research Centre for Biochemistry and Molecular Biology, Universitary Hospital Vall d'Hebron, Barcelona, Spain.	Exercise intolerance resulting from a muscle-restricted mutation in the mitochondrial tRNA(Leu (CUN)) gene.	Ann Med. 2001 Oct;33(7):493-6.	BACKGROUND: Some patients presenting with isolated lifelong exercise intolerance and ragged-red fibres, harbour skeletal-muscle restricted mutations in their mitochondrial DNA. AIM: To identify the molecular defect in a patient presenting with lifelong exercise intolerance, ragged-red fibres and deficiencies of complexes III and IV in skeletal muscle. METHODS: The muscle biopsy was studied for activities of the respiratory chain, histochemical stains, and sequencing the tRNA genes of mitochondrial DNA. RESULTS: The patient had a heteroplasmic mutation in the tRNA(Leu (CUN)) gene of mitochondrial DNA (G12334A). Clinical and morphological data as well as restriction fragment length polymorphism (RFLP) and single-fibre polymerase chain reaction (PCR) analyses strongly indicate that this molecular defect is the primary cause of the myopathy. CONCLUSION: Mutations in any mitochondrial gene should be considered in the differential diagnosis of patients with lifelong exercise intolerance, even when the neurological examination is normal.
Walsh CM, Zainal NZ, Middleton SJ, Paykel ES.	University Department of Psychiatry, Addenbrooke's Hospital, Cambridge, UK.	A family history study of chronic fatigue syndrome.	Psychiatr Genet. 2001 Sep;11(3):123-8.	Chronic fatigue syndrome (CFS) is characterized by unexplained, disabling fatigue and is associated with high rates of comorbid depression. While the aetiology is unknown, findings from recent twin surveys suggest that genetic factors may be relevant to prolonged fatigue states (> 1 month). To date, however, there has been no exploration of the role of familial/genetic factors in operationally defined CFS. The aims of the present study were: (i) to examine whether CFS is familial by comparing the rates of CFS in the first-degree relatives of CFS cases and medical control subjects; and (ii) to determine whether the high rate of comorbid depression in CFS is reflected in a greater familial loading for affective disorder. Twenty-five CFS cases and 36 medical control subjects were assessed for fatigue symptoms based on the Centre for Disease Control (CDC) criteria for CFS, and for lifetime psychiatric symptoms using the Schedule for Schizophrenia and Affective Disorders-Lifetime Version. Informant family history was obtained regarding first-degree relatives using the CDC criteria and the Family History Research Diagnostic Criteria. In addition, informant history was supplemented by sending a questionnaire to first-degree relatives. There were significantly higher rates of CFS in the relatives of CFS cases

				compared with the relatives of control subjects. The rate of depression in the CFS cases was similar to previous studies but did not appear to reflect a greater familial loading for depression when compared with control subjects. However, these analyses were complicated by higher than expected rates of depression in the control group. These findings suggest that familial factors are important in the aetiology of chronic fatigue syndrome.
Wessely S.	Guy's, King's, and St Thomas's School of Medicine and Institute of Psychiatry, London, United Kingdom. s.wessely@iop.kcl.ac.uk	Chronic fatigue: symptom and syndrome.	Ann Intern Med. 2001 May 1;134(9 Pt 2):838-43.	Chronic fatigue is common, is difficult to measure, can be associated with considerable morbidity, and is rarely a subject of controversy. The chronic fatigue syndrome also presents problems in definition and measurement, is associated with even more morbidity than chronic fatigue itself, and is often controversial. Particularly unclear is the way in which chronic fatigue and the chronic fatigue syndrome relate to each other: Is one the severe form of the other, or are they qualitatively and quantitatively different? We know that many things can cause chronic fatigue, and this is probably true for the chronic fatigue syndrome, too. We can anticipate that discrete causes of the chronic fatigue syndrome will be found in the future, even if these causes are unlikely to fall neatly along the physical-psychological divide that some expect. The causes of chronic fatigue are undoubtedly many, both in a population and in any individual person, even when a discrete cause, such as depression or cancer, is identified. Social, behavioral, and psychological variables are important in both chronic fatigue and the chronic fatigue syndrome. Interventions that address these general variables can be successful, and currently they are often more successful than interventions directed at specific causes.

White PD, Thomas JM, Kangro HO, Bruce-Jones WD, Amess J, Crawford DH, Grover SA, Clare AW.	Department of Psychological Medicine, St Bartholomew's and the Royal London School of Medicine and Dentistry, London, UK. P.D. White@qmul.ac.uk	Predictions and associations of fatigue syndromes and mood disorders that occur after infectious mononucleosis.	Lancet. 2001 Dec 8;358(9297):1946-54.	BACKGROUND: Certain infections can trigger chronic fatigue syndromes (CFS) in a minority of people infected, but the reason is unknown. We describe some factors that predict or are associated with prolonged fatigue after infectious mononucleosis and contrast these factors with those that predicted mood disorders after the same infection. METHODS: We prospectively studied a cohort of 250 primary-care patients with infectious mononucleosis or ordinary upper-respiratory-tract infections until 6 months after clinical onset. We sought predictors of both acute and chronic fatigue syndromes and mood disorders from clinical, laboratory, and psychosocial measures. FINDINGS: An empirically defined fatigue syndrome 6 months after onset, which excluded comorbid psychiatric disorders, was most

				reliably predicted by a positive Monospot test at onset (odds ratio 2.1 [95% CI 1.4-3.3]) and lower physical fitness (0.35 [0.15-0.8]). Cervical lymphadenopathy and initial bed rest were associated with, or predicted, a fatigue syndrome up to 2 months after onset. By contrast, mood disorders were predicted by a premorbid psychiatric history (2.3 [1.4-3.9]), an emotional personality score (1.21 [1.11-1.35]), and social adversity (1.7 [1.0-2.9]). Definitions of CFS that included comorbid mood disorders were predicted by a mixture of those factors that predicted either the empirically defined fatigue syndrome or mood disorders. INTERPRETATION: The predictors of a prolonged fatigue syndrome after an infection differ with both definition and time, depending particularly on the presence or absence of comorbid mood disorders. The particular infection and its consequent immune reaction may have an early role, but physical deconditioning may also be important. By contrast, mood disorders are predicted by factors that predict mood disorders in general.
Whiting P, Bagnall AM, Sowden AJ, Cornell JE, Mulrow CD, Ramirez G.	National Health Service Centre for Reviews and Dissemination, University of York, York, England, YO10 5DD. pfw2@york.ac.uk	Interventions for the treatment and management of chronic fatigue syndrome: a systematic review.	JAMA. 2001 Sep 19;286(11):1360-8. Erratum in: JAMA 2002 Mar 20;287(11):1401.	CONTEXT: A variety of interventions have been used in the treatment and management of chronic fatigue syndrome (CFS). Currently, debate exists among health care professionals and patients about appropriate strategies for management. OBJECTIVE: To assess the effectiveness of all interventions that have been evaluated for use in the treatment or management of CFS in adults or children. DATA SOURCES: Nineteen specialist databases were searched from inception to either January or July 2000 for published or unpublished studies in any language. The search was updated through October 2000 using PubMed. Other sources included scanning citations, Internet searching, contacting experts, and online requests for articles. STUDY SELECTION: Controlled trials (randomized or nonrandomized) that evaluated interventions in patients diagnosed as having CFS according to any criteria were included. Study inclusion was assessed independently by 2 reviewers. Of 350 studies initially identified, 44 met inclusion criteria, including 36 randomized controlled trials and 8 controlled trials. DATA EXTRACTION: Data extraction was conducted by 1 reviewer and checked by a second. Validity assessment was carried out by 2 reviewers with disagreements resolved by consensus. A qualitative synthesis was carried out and studies were grouped according to type of intervention and outcomes assessed. DATA SYNTHESIS: The number of participants included in each trial ranged from 12 to 326, with a total of 2801 participants included in the 44 trials combined. Across the studies, 38 different outcomes were evaluated using about 130 different scales or types of measurement. Studies were grouped into 6 different categories. In the behavioral category, graded exercise therapy and cognitive behavioral therapy showed positive results and also scored highly on the validity assessment. In the immunological category, both immunoglobulin and hydrocortisone showed some limited effects but, overall, the evidence was inconclusive. There was insufficient evidence about effectiveness in the other 4 categories (pharmacological, supplements, complementary/alternative, and other interventions). CONCLUSIONS: Overall, the interventions demonstrated mixed results in terms of effectiveness. All conclusions about effectiveness should be considered together with the methodological inadequacies of the studies. Interventions which have shown

				promising results include cognitive behavioral therapy and graded exercise therapy. Further research into these and other treatments is required using standardized outcome measures.
Wiesmuller GA, Ebel H, Hornberg C.	Institut fur Hygiene und Umweltmedizin, Universitatsklinikums, RWTH Aachen. GA.Wiesmueller@post.rwth-aachen.de	[Syndromes in environmental medicine: variants of somatoform disorders] [Article in German]	Fortschr Neurol Psychiatr. 2001 Apr;69(4):175-88.	Concerning the syndromes in environmental medicine, like Multiple Chemical Sensitivities (MCS), Idiopathic Environmental Intolerances (IEI), Sick Building Syndrome (SBS), Chronic Fatigue Syndrome (CFS), Candida Syndrome (CS), and Burnout Syndrome (BS), scientific knowledge in etiology, pathology, pathophysiology, diagnosis, therapy, prevention and prognosis is still lacking until now. A critical comparison shows that it is still impossible to find a scientifically satisfying delimitation. Syndromes in environmental medicine show clinical similarities to somatoform disorders. Furthermore, there are the following possible explanations for the existence of these syndromes: Firstly, they may be a complex interaction of environmental impacts, individual predispositions, psychological influences, as well as processes of mental perception and interpretation. Secondly, they may be an effect of distress influenced by culture and social structures and/or thirdly, they may be an latrogenic determination. A more comprehensive characterisation which better considers the complex clinical manifestations is overdue. Although there are neither scientifically validated procedures for diagnosis or therapy nor prophylactic measures, a hardly comprehensible number of partly unvalidated methods is in practical use. Until the syndromes are not finally defined the terms for the syndromes should not be applied to a certain disease. Despite all uncertainities in the evaluation of syndromes in environmental medicine, physicians have the duty to take the affected persons' problems seriously.

Wilson A, Hickie I, Hadzi-Pavlovic D, Wakefield D, Parker G, Straus SE, Dale J, McCluskey D, Hinds G, Brickman A, Goldenberg D, Demitrack M, Blakely T, Wessely S, Sharpe	University of New South Wales, Sydney, Australia.	What is chronic fatigue syndrome? Heterogeneity within an international multicentre study.	Aust N Z J Psychiatry. 2001 Aug;35(4):520-7.	OBJECTIVE: We sought to compare the characteristics of patients presenting with chronic fatigue (CF) and related syndromes in eight international centres and to subclassify these subjects based on symptom profiles. The validity of the subclasses was then tested against clinical data. METHOD: Subjects with a clinical diagnosis of CF completed a 119-item self-report questionnaire to provide clinical symptom data and other information such as illness course and functional impairment. Subclasses were generated using a principal components-like analysis followed by latent profile analysis (LPA). RESULTS: 744 subjects returned complete data sets (mean age 40.8 years, mean length of illness 7.9 years, female to male ratio 3:1). Overall, the subjects had a high rate of reporting typical CF symptoms

M, Lloyd A.				(fatigue, neuropsychological dysfunction, sleep disturbance). Using LPA, two subclasses were generated. Class one (68% sample) was characterized by: younger age, lower female to male ratio; shorter episode duration; less premorbid, current and familial psychiatric morbidity; and, less functional disability. Class two subjects (32%) had features more consistent with a somatoform illness. There was substantial variation in subclass prevalences between the study centres (Class two range 6-48%). CONCLUSIONS: Criteria-based approaches to the diagnosis of CF and related syndromes do not select a homogeneous patient group. While substratification of patients is essential for further aetiological and treatment research, the basis for allocating such subcategories remains controversial.
Yunus MB.	College of Medicine at Peoria, University of Illinois, One Illini Drive, PO Box 1649, Peoria, IL 61656, USA. Yunus@uic.edu	The role of gender in fibromyalgia syndrome.	Curr Rheumatol Rep. 2001 Apr;3(2):128-34.	Fibromyalgia syndrome (FMS), characterized by widespread pain and tenderness on palpation (tender points), is much more common in women than in men in a proportion of 9:1. Two recent studies have shown important gender differences in various clinical characteristics of FMS. In a community and a clinic sample, women experienced significantly more common fatigue, morning fatigue, hurt all over, total number of symptoms, and irritable bowel syndrome. Women had significantly more tender points. Pain severity, global severity and physical functioning were not significantly different between the sexes, nor were psychologic factors, eg, anxiety, stress, and depression. Gender differences have also been observed in other related syndromes, eg, chronic fatigue syndrome, irritable bowel syndrome, and headaches. The mechanisms of gender differences in these illnesses are not fully understood, but are likely to involve an interaction between biology, psychology, and sociocultural factors.
Zaman R, Puri BK, Main J, Nowicky AV, Davey NJ.	Division of Neuroscience and Psychological Medicine, Imperial College School of Medicine, Charing Cross Hospital, London W6 8RF, UK.	Corticospinal inhibition appears normal in patients with chronic fatigue syndrome.	Exp Physiol. 2001 Sep;86(5):547-50.	The pathogenesis of chronic fatigue syndrome (CFS) remains unknown. Thresholds and latencies of motor evoked potentials (MEPs) in response to transcranial magnetic stimulation (TMS) are normal but intracortical inhibition has not been investigated. Eleven patients with CFS were compared with 11 control subjects. Each patient completed a questionnaire using visual analogue indices of pain, fatigue, anxiety and depression. Subjects released a button to initiate simple (SRTs) and choice reaction time (CRTs) tasks; for each task, movement times were measured between release of the initiation button and depression of a second button 15 cm away. Subjects held a 10 % maximum voluntary contraction in the thenar muscles of their dominant hand while TMS was applied to the motor cortex; the duration and extent of inhibition of surface electromyographic (EMG) activity were assessed at stimulus strengths above and below the threshold for MEPs. Patients had significantly ($P < 0.05$) higher mean indices of fatigue than of pain, anxiety or depression. Mean (+/- S.E.M.) SRTs (but not CRTs) were longer in patients (309 +/- 45 ms) than in controls (218 +/- 9 ms). Movement times were longer in patients for both SRTs and CRTs. TMS thresholds, expressed as a percentage of the maximum stimulator output, were not significantly ($P > 0.05$) different in both groups for both MEPs (patients, 34 +/- 3%; controls, 36 +/- 3%) and inhibition of voluntary contraction (patients, 29 +/- 2%; controls, 34 +/- 4%). The duration and extent of inhibition did not differ significantly between

				groups at any stimulus strength. The pattern of change in duration and extent of inhibition with increasing stimulus intensity was no different in the two groups. The duration and extent of corticospinal inhibition in patients with CFS did not differ from controls, adding further evidence to the notion that the feeling of fatigue and the slowness of movement seen in CFS is not manifest in corticospinal output pathways.

Aaron LA, Buchwald D.	Seattle, Wash.	Tobacco use and chronic fatigue syndrome, fibromyalgia, and temporomandibular disorder	Arch Intern Med 2000 Aug 14;160(15):2398-401	
Aaron LA, Burke MM, Buchwald D.	Department of Medicine, University of Washington, Seattle, USA. laaron@u.washington.edu	Overlapping conditions among patients with chronic fatigue syndrome, fibromyalgia, and temporomandibular disorder.	Arch Intern Med 2000 Jan 24;160(2):221-7Comment in: Arch Intern Med. 2000 Aug 14-28;160(15):2398, 2401	BACKGROUND: Patients with chronic fatigue syndrome (CFS), fibromyalgia (FM), and temporomandibular disorder (TMD) share many clinical illness features such as myalgia, fatigue, sleep disturbances, and impairment in ability to perform activities of daily living as a consequence of these symptoms. A growing literature suggests that a variety of comorbid illnesses also may commonly coexist in these patients, including irritable bowel syndrome, chronic tension-type headache, and interstitial cystitis. OBJECTIVE: To describe the frequency of 10 clinical conditions among patients with CFS, FM, and TMD compared with healthy controls with respect to past diagnoses, degree to which they manifested symptoms for each condition as determined by expert-based criteria, and published diagnostic criteria. METHODS: Patients diagnosed as having CFS, FM, and TMD by their physicians were recruited from hospital-based clinics. Healthy control subjects from a dermatology clinic were enrolled as a comparison group. All subjects completed a 138-item symptom checklist and underwent a brief physical examination performed by the project physicians. RESULTS: With little exception, patients reported few past diagnoses of the 10 clinical conditions beyond their referring diagnosis of CFS, FM, or TMD. In contrast, patients were more likely than controls to meet lifetime symptom and diagnostic criteria for many of the conditions, including CFS, FM, irritable bowel syndrome, multiple chemical sensitivities, and headache. Lifetime rates of irritable bowel syndrome were particularly striking in the patient groups (CFS, 92%; FM, 77%; TMD, 64%) compared with controls (18%) (P<.001). Individual symptom analysis revealed that patients with CFS, FM, and TMD share common symptoms, including generalized pain sensitivity, sleep and concentration difficulties, bowel complaints, and headache. However, several symptoms also distinguished the patient groups. CONCLUSIONS: This study provides preliminary evidence that patients with CFS, FM, and TMD share key symptoms. It also is apparent that other localized and systemic conditions may frequently co-occur with CFS, FM, and TMD. Future research that seeks to identify the temporal relationships and other pathophysiologic mechanism(s) linking CFS, FM, and TMD will likely advance our understanding and treatment of these chronic, recurrent conditions.
Ablashi DV, Eastman HB, Owen CB, Roman	Department of Microbiology,	Frequent HHV-6 reactivation in multiple	J Clin Virol 2000 May;16(3):179-91	BACKGROUND: HHV-6 is a ubiquitous virus and its infection usually occurs in childhood and then becomes a latent infection. HHV-6 reactivation has been shown

MM, Friedman J, Zabriskie JB, Peterson DL, Pearson GR, Whitman JE.	Georgetown University, School of Medicine, Washington, DC, USA. dablashi@abionline.com	sclerosis (MS) and chronic fatigue syndrome (CFS) patients.		to play a role in the pathogenesis of AIDS and several other diseases. OBJECTIVES: To determine what role HHV-6 infection or reactivation plays in the pathogenesis of multiple sclerosis (MS) and chronic fatigue syndrome (CFS). RESULTS: Twenty-one MS and 35 CFS patients were studied and followed clinically. In these patients, we measured HHV-6 IgG and IgM antibody levels and also analyzed their peripheral blood mononuclear cells (PBMCs) for the presence of HHV-6, using a short term culture assay. In both MS and CFS patients, we found higher levels of HHV-6 IgM antibody and elevated levels of IgG antibody when compared to healthy controls. Seventy percent of the MS patients studied contained IgM antibodies for HHV-6 late antigens (capsid), while only 15% of the healthy donors (HD) and 20% of the patients with other neurological disorders (OND) had HHV-6 IgM antibodies. Higher frequency of IgM antibody was also detected in CFS patients (57.1%) compared to HD (16%). Moreover, 54% of CFS patients exhibited antibody to HHV-6 early protein (p41/38) compared to only 8.0% of the HD. Elevated IgG antibody titers were detected in both the MS and the CFS patients. PBMCs from MS, CFS and HD were analyzed in a short term culture assay in order to detect HHV-6 antigen expressing cells and to characterize the viral isolates obtained as either Variant A or B. Fifty-four percent of MS patients contained HHV-6 early and late antigen producing cells and 87% of HHV-6 isolates were Variant B. Isolates from CFS, patients were predominately Variant A (70%) and isolates from HD were predominately Variant B (67%). Moreover, one isolate from OND was also Variant B. Persistent HHV-6 infection was found in two CFS patients over a period of 2.5 years and HHV-6 specific cellular immune responses were detected in PBMCs from ten CFS patients. CONCLUSION: In both MS and CFS patients, we found increased levels of HHV-6 antibody and HHV-6 DNA. A decrease in cellular immune responses was also detected in CFS patients. These data suggest that HHV-6 reactivation plays a role in the pathogenesis of these disorders.
Addington JW.		Chronic Fatigue Syndrome: A Dysfunction of the Hypothalamic-Pituitary-Adrenal Axis	Journal of Chronic Fatigue Syndrome 2000; 7(2): 63	Chronic fatigue syndrome is a severe, often disabling disorder with prevalence as high as 422 cases per 100,000 in the United States. Aside from the adverse effects to patients' quality of life, sequela of the disorder include a negative impact on the economy as well as a burden on public health care costs. Some avenues of current research into the possible genesis of the syndrome are neurally mediated hypotension, viral pathogen, immunological disorders, lymphocyte enzyme system abnormalities, or a purely psychological root. This paper is a review of the literatures as to a neuroendocrinologic cause, namely dysfunction of the hypothalamic-pituitary-adrenal axis.
Afari N, Eisenberg DM, Herrell R, Goldberg J, Kleyman E, Ashton S, Buchwald D.	Department of Medicine, University of Washington, Seattle, WA, USA	Use of alternative treatments by chronic fatigue syndrome discordant twins.	1096-2190 2000 Mar 21;2(2):97-103	Background: Patients with chronic fatigue syndrome (CFS) have been faced with difficulties in diagnosis and lack of effective treatments. Anecdotal evidence suggests that use of alternative treatments may be common in these patients. Our primary objective was to compare the prevalence and patterns of alternative medicine use among twins who met the Centers for Disease Control and Prevention (CDC) CFS

				criteria to that of their non-CFS co-twins. Secondary goals were to assess how often alternative medicine use was discussed with physicians and the perceived benefit of these therapies. Methods: Sixty-three twin pairs discordant for CFS completed a survey about their use of 22 alternative therapies. Matched pair odds ratios and 95% confidence intervals were used to examine differences in the use between CFS twins and their non-CFS co-twins. Results: 91% of twins with CFS and 71% of non-CFS twins had used at least 1 alternative treatment in their lifetime. Twins with CFS were more likely to use homeopathy, mega-vitamins, herbal therapies, biofeedback, relaxation/meditation, guided imagery, massage therapy, energy healing, religious healing by others, and self-help groups than their non-CFS counterparts. A large proportion of all twins found alternative therapies helpful; however, only 42% of those with CFS and 23% of those without CFS discussed their use of alternative medicine with a physician. Conclusions: Individuals with CFS frequently used alternative medical treatments yet rarely communicated this use to their medical doctor. Future research should ascertain the usefulness of alternative practices in the management of CFS.
Afari N, Schmaling KB, Herrell R, Hartman S, Goldberg J, Buchwald DS.	Department of Medicine, University of Washington, Seattle, WA 98104, USA. afari@u.washington.edu	Coping strategies in twins with chronic fatigue and chronic fatigue syndrome.	J Psychosom Res 2000 Jun;48(6):547-54	OBJECTIVES: Individuals with chronic fatigue and chronic fatigue syndrome (CFS) face debilitating symptoms as well as stressful life situations that may result from their condition. The goal of this study was to examine the coping strategies used by fatigue-discordant twin pairs. METHODS: We utilized a co-twin design to assess how twin pairs discordant for chronic fatigue and CFS cope with stress. All twin pairs were administered the Revised Ways of Coping Checklist. RESULTS: Overall, the pattern of coping strategies was similar for fatigued and non-fatigued twins. However, twins with chronic fatigue or CFS utilized more avoidance strategies than their non-fatigued counterparts; those with chronic fatigue also used more avoidance relative to problem-focused coping than their co-twins. CONCLUSIONS: These results suggest that while fatigue-discordant twins generally exhibit similar behavior patterns in order to cope with stress, there may be an association between fatigue and avoidance coping. Future research should focus on the role of avoidance and its relationship to fatiguing illnesses.

Asa PB, Cao Y, Garry RF.	Department of Microbiology, Tulane Medical School, 1430 Tulane Avenue, New Orleans, Louisiana, 70112, USA. PMBA@aol.com	Antibodies to squalene in Gulf War syndrome.	Exp Mol Pathol 2000 Feb;68(1):55-64	Gulf War Syndrome (GWS) is a multisystemic illness afflicting many Gulf War-era veterans. The molecular pathological basis for GWS has not been established. We sought to determine whether the presence of antibodies to squalene correlates with the presence of signs and symptoms of GWS. Participants in this blinded cohort study were individuals immunized for service in Desert Shield/Desert Storm during 1990-1991. They included 144 Gulf War-era veterans or military employees (58 in the blinded study), 48 blood donors, 40 systemic lupus erythematosus patients, 34 silicone breast implant recipients, and 30 chronic fatigue syndrome patients. Serum antibodies to squalene were measured. In our small cohort, the substantial majority (95%) of overtly ill deployed GWS patients had antibodies to squalene. All (100%) GWS patients immunized for service in Desert Shield/Desert Storm who did not deploy, but had the same signs and symptoms as those who did deploy, had antibodies to squalene. In contrast, none (0%) of the deployed Persian Gulf veterans not showing signs and symptoms of GWS have antibodies to squalene. Neither patients with idiopathic autoimmune disease nor healthy controls had detectable serum antibodies to squalene. The majority of symptomatic GWS patients had serum antibodies to squalene. Ax S.		Coping Differences Between Chronic Fatigue Syndrome Sufferers and Their Carers	Journal of Chronic Fatigue Syndrome 2000; 5(2): 27	The main objective of the present study is to describe the extent to which CFS sufferers and their carers reported to have used a number of coping strategies over the course of the illness, and to find out if reports of coping differ between groups of these. In addition, associations between married sufferers and carers were investigated. From a methodological point of view, the factorial structure and the usefulness of the Ways of Coping Questionnaire (Folkman & Lazarus, 1988) in CFS was studied. The results indicate no gender differences. There are also no differences between sufferers supported and not supported by a carer. However, the results indicate reduced coping responses of carer husbands. From a methodological point of view, the emergence of comparable factors for sufferers and carers, which were also closely related to the original emotion and problem-focused factors, suggested that the use of the questionnaire was appropriate. The importance of these findings for coping research and therapy are discussed.
Axe E, Satz P.	Departments of Epidemiology and Neuropsychology, University of California-Los Angeles, Los Angeles, CA, USA	Psychiatric correlates in chronic fatigue syndrome.	Ann Epidemiol 2000 Oct 1;10(7):458	PURPOSE: This study presents psychiatric correlates in Chronic Fatigue Syndrome (CFS) that emerged from the CDC's Surveillance Study. It seeks to determine the time of onset and rates of syndromal psychiatric disorders and identify the predominant disorder. Other goals are to ascertain whether depression is associated with CFS symptomatology, compare syndromal to self- reported depression, and test for the specificity of the 1988 CDC case definition for CFS.METHODS: All 565 enrolled subjects had fatiguing illnesses and were evaluated for CFS. They completed the Diagnostic Interview Schedule for the DSM-III-R and the Beck Depression Inventory.

				Prevalence estimates for current syndromal psychiatric disorders were calculated. CFS symptoms were compared by depression status. Syndromal and self-reported depression were contrasted. Groups that did and did not meet the case definition were compared by three outcome variables.RESULTS: Rates of current psychiatric disorders were high in CDC subjects compared to the community. The predominant disorder was depression. Although prior disorders tended to persist (75%), many disorders were incident to the fatiguing illness (57%). Depression was not associated with increased CFS symptomatology. There was only weak agreement between measures of syndromal and self-reported depression (kappa = 0.3219). Subjects designated as CFS had similar rates of syndromal psychiatric disorders, syndromal depression, and self-reported depression as did non-CFS subjects.CONCLUSIONS: Current syndrome; psychiatric disorders appear associated with fatiguing illnesses. While prior psychiatric disorders are risk factors for current, the onset was largely concurrent with the fatiguing illnesses. The BDI should probably not be used as a measure for psychiatric morbidity in CFS subjects. Regardless of outcome, there was no evidence of specificity of psychiatric features to the CDC case definition.
Azpiroz F, Dapoigny M, Pace F, Muller-Lissner S, Coremans G, Whorwell P, Stockbrugger RW, Smout A.	Digestive System Research Unit, Hospital General Vall d'Hebron, Barcelona, Spain.	Nongastrointestinal disorders in the irritable bowel syndrome.	Digestion 2000;62(1):66-72	A large proportion of irritable bowel syndrome (IBS) patients also complain of other functional disorders, such as headache, noncardiac chest pain, low back pain, and dysuria. Some of these features, particularly headache, may have a negative influence on the outcome of IBS. In a large proportion of female IBS patients, sexual intercourse triggers the symptoms, and frequently IBS symptoms exacerbate during menses. These gynecological-type symptoms often mislead the patients to the gynecological clinic, which may imply unnecessary investigations and inappropriate treatments. The diagnostic criteria of the fibromyalgia syndrome include IBS, and hence, the apparent relationship of both syndromes is difficult to analyze. On the other hand, no convincing evidence has been produced to date to sustain an association between IBS and the chronic fatigue syndrome. Copyright 2000 S. Karger AG, Basel
Baraniuk JN, Naranch K, Maibach H, Clauw DJ.		Irritant Rhinitis in Allergic, Nonallergic, Control and Chronic Fatigue Syndrome Populations	Journal of Chronic Fatigue Syndrome 2000; 7(2): 3	Background: Irritation symptoms after exposure to ``nonspecific'' stimuli are often attributed to nonallergic rhinitis (vasomotor rhinitis). This is a heterogeneous syndrome of exclusion based on nasal symptoms with negative allergy skin tests. Method: Control (n = 114) and Chronic Fatigue Syndrome (CFS, n = 120) subjects scored the severity of nasal congestion and rhinorrhea sensations that they attributed to 9 irritants. The sum was the ``Irritant Rhinitis Score'' (IRS, maximum 72). A positive IRS of w 19 defined ``Irritant Rhinitis.'' Demographic, allergy skin test and other assessments were done to characterize the Irritant Rhinitis population. Results: Irritant Rhinitis was present in 11% of Control and 47% of CFS subjects. In multivariate analysis, positive IRS was correlated with a history of rhinitis complaints, systemic complaints such as fatigue, sensations of congestion and rhinorrhea induced by meteorological conditions, tobacco smoke, odors, perfumes, and other volatile

				materials, and diagnoses of CFS and Multiple Chemical Sensitivity (MCS). Although atopy was not correlated to Irritant Rhinitis, 51% of allergic rhinitis subjects had a positive IRS. Conclusions: The Irritant Rhinitis Score defined a population with irritant-induced nasal congestion and rhinorrhea who also had significant systemic complaints. Similar neural mechanisms may underlie the spectrum of Irritant Rhinitis, CFS and MCS.
Baraniuk JN, Naranch K, Maibach H, Clauw DJ.		Tobacco Sensitivity in Chronic Fatigue Syndrome (CFS)	Journal of Chronic Fatigue Syndrome 2000; 7(2): 33	Background: Mechanisms responsible for sensitivity to irritants such as tobacco smoke are poorly understood. A Tobacco Score questionnaire was developed to identify and characterize subjects with this sensitivity. For this pilot study, scores were assessed in populations of self-selected controls and a group with irritant sensitivity (Chronic Fatigue Syndrome, CFS). Method: Subjects graded the severity of 21 symptoms associated with tobacco exposure. Results were compared with other instruments and a measure of pain sensitivity (dolorimetry) in 116 control and 103 CFS subjects. Results: The Tobacco Score was positive in 16% of control and 51% of CFS subjects. Significant correlations were found between Tobacco Score, Irritant Rhinitis Score, and history of sinusitis. Intermediate relationships were found with history of allergic rhinitis, Systemic Complaints Score, and Multiple Chemical Sensitivity. Factors having no influence included gender, the severity of CFS symptoms, pain thresholds, and allergy skin tests. Conclusions: Tobacco sensitivity was correlated with measures of upper airway irritation and nonallergic sensitivity to triggers such as weather changes. The spectrum of symptoms, high prevalence in CFS, and absence of a relationship to atopy suggest that these nonallergic irritant syndromes may share a common neuropathophysiology.

Behan WMH, Holt IJ, Kay DH, Moonie P.		In vitro Study of Muscle Aerobic Metabolism in Chronic Fatigue Syndrome	Journal of Chronic Fatigue Syndrome 2000; 5(1): 3	The purpose of this study was to establish if muscle aerobic metabolism is abnormal in chronic fatigue syndrome (CFS). Myoblast cultures from muscle biopsies of 16 patients with CFS and 10 healthy controls were established. Micromethods were used to determine the lactate/pyruvate (L/P) ratio, respiratory chain function and cytochrome oxidase and lactic dehydrogenase activities. Mitochondrial DNA (mtDNA) volume was measured and mtDNA rearrangements sought. The results showed that myoblasts from ten of 16 cases of CFS had defects in aerobic metabolism: two had

				increased L/P ratios, suggestive of a defect in oxidative phosphorylation while eight had decreased ratios, consistent with a deficiency in pyruvate dehydrogenase. There was a statistically significant broader range of L/P ratios in the patients' cultures, compared to controls (p = 0.011). No mtDNA rearrangements were present. This in vitro study confirms that there is convincing evidence of mild aerobic defects in skeletal muscle in some cases of CFS.
Bell IR, Bootzin RR, Schwartz GER, Baldwin CM, Ballesteros F.		Differing Patterns of Cognitive Dysfunction and Heart Rate Reactivity in Chemically-Intolerant Individuals With and Without Lifestyle Changes	Journal of Chronic Fatigue Syndrome 2000; 5(2): 3	The purpose of the present study was to compare specific neuropsychological, psychological, and family history patterns, as well as cardiovascular reactivity of three community-recruited groups of nonsmoking, nonalcoholic middle-aged individuals with and without the symptom of intolerance to low levels of environmental chemicals (CI). CI is a common symptom in chronic fatigue syndrome and fibromyalgia. The groups included: (i) CI who had made associated lifestyle changes because of the CI (CI/LSC); (ii) CI who had not made such changes (CI); and (iii) normals without CI (N). All subjects underwent an evaluation session followed by two laboratory cognitive and psychophysiological test sessions one week apart. The CI/LSC diverged from the other groups in exhibiting poorer performance on the Continuous Visual Memory Test (CVMT) in terms of more false alarms and fewer correct hits, but normal performance on a visuospatial test of divided attention (DAT). In contrast, the CI group showed progressively poorer performance on the DAT with practice, but were like the N on the CVMT. The CI group showed a complex sensitization (amplification) of heart rate response to the DAT over time. In addition, the CI/LSC had the highest rate of family histories of alcohol problems and of attention deficit disorder, as well as of antihypertensive medication treatment and self-reported past emotional/physical abuse. Taken together, the data suggest that individuals with CI comprise a heterogeneous population requiring careful definition of subtypes for future studies.
Bottero P.		Role of Rickettsiae and Chlamydiae in the Psychopathology of Chronic Fatigue Syndrome (CFS) Patients: A Diagnostic and Therapeutic Report	Journal of Chronic Fatigue Syndrome 2000; 6(3/4): 147	Objective: To demonstrate the probable role of intracellular bacteria like Rickettsiae and Chlamydiae in the development of certain chronic psychopathological conditions and according to the efficiency of antibiotic regimes (cyclines and/or macrolides). The latter aim is based on the fact that all the patients that I have seen since 1981 had a sera reaction positive for Rickettsiae and/or Chlamydiae using the micro-agglutination on blade technique of P. Giroud and M.L. Giroud (MAG) by Prof. J.B. Jadin of Antwerpen, Belgium with special antigens cultured on guinea pig lungs and chicken embryos. Methods: This is an open study which began in 1981 in a private medical practice, not versus placebo; but with random choice. Treatment was for a minimum of six months (cyclines and/or macrolides together with vasodilatory medication; chloroquine; warm baths). Group one: 98 CFS cases; women: 78, men: 20; for 67 cases, the ancientness of symptoms is more than 2 years. Group two: 59 psycho-somatic cases; 5 schizophrenia; 3 borderline; 10 children with agressivity, excitement; 1 autistic child; 1 delirium with relapses. Results: Group one: 79.5% good

				and very good results; 4.1% fairly good; 16.4% failed. Group two: 82.3% good and very good results; 2.5% fairly good; 15. 2% failed. Conclusion: This diagnostic and therapeutic study began in 1981. All of the Dr. Bottero's therapeutic results are confirmed since 1991 by Dr. Cecile Jadin of Randburg (South Africa) for more than 3000 CFS and other psychopathological states (300): Sydney 98 CFS Conference, Australia. We have shown that Rickettsiae and Chlamydiae are probably causative factors in many ``psychopathologies.''
Bottero P.		Chronic Psychopathologies Associated with Persistant Rickettsiae and/or Similar Germs (Chlamydiae)	Journal of Chronic Fatigue Syndrome 2000; 6(3/4): 163	For 60 cases of diseases that are called ``Psychic'' associated with persistent rickettsiae; we have: 55 good and excellent result, 5 failure, but we still have to wait a confirmation in course of time for many patients.
Brace MJ, Scott Smith M, McCauley E, Sherry DD.	Department of Psychiatry, University of Washington, Seattle, USA.	Family reinforcement of illness behavior: a comparison of adolescents with chronic fatigue syndrome, juvenile arthritis, and healthy controls.	J Dev Behav Pediatr 2000 Oct;21(5):332-9	Parental encouragement of illness behavior is hypothesized to correlate with psychosocial dysfunction in adolescents with chronic illness. To explore this hypothesis, adolescents aged 11 to 17 years with chronic fatigue syndrome (CFS) (n = 10), juvenile rheumatoid arthritis (JRA) (n = 16), and healthy adolescents (n = 14) were recruited for the study. Measures included the Achenbach parent and youth self report forms, the Family Adaptability and Cohesion Evaluation Scale-II (FACES II), the Children's Depression Rating Scale, and number of days absent from school. The Illness Behavior Encouragement Scale (IBES) generated measures of parental reinforcement of illness behavior. As predicted, the teens with CFS scored statistically higher on measures of depression, total competence, and number of days of school missed in the previous 6 months (mean = 40). Children with JRA scored significantly lower than the CFS group on the measure of parental reinforcement of illness behavior. The healthy group produced intermediate scores. Results and implications for future clinical and research activity are discussed.
Bradley LA, McKendree-Smith NL, Alarcon GS.	Division of Clinical Immunology and Rheumatology, University of Alabama at Birmingham, School of Medicine, 475 Boshell Diabetes Building, 1808 7th Avenue South, Birmingham, AL 35294, USA. larry.bradley@ccc.uab.edu	Pain complaints in patients with fibromyalgia versus chronic fatigue syndrome.	Curr Rev Pain 2000;4(2):148-57	Individuals with fibromyalgia (FM) and/or chronic fatigue syndrome (CFS) report arthralgias and myalgias. However, only persons with FM alone exhibit abnormal pain responses to mild levels of stimulation, or allodynia. We identify the abnormalities in the neuroendocrine axes that are common to FM and CFS as well as the abnormalities in central neuropeptide levels and functional brain activity that differentiate these disorders. These two sets of factors, respectively, may account for the similarities and differences in the pain experiences of persons with FM and CFS.

Brooks JC, Roberts N, Whitehouse G, Majeed T.	Magnetic Resonance and Image Analysis Research Centre, University of Liverpool, Pembroke Place, Liverpool L69 3BX, UK.	Proton magnetic resonance spectroscopy and morphometry of the hippocampus in chronic fatigue syndrome.	Br J Radiol 2000 Nov;73(875):1206-8	Seven patients with chronic fatigue syndrome (CFS) were matched with ten healthy control subjects of similar age. Hippocampal volume, obtained from magnetic resonance images using an unbiased method, showed no difference between the two groups, whereas proton magnetic resonance spectroscopy showed a significantly reduced concentration of N-acetylaspartate in the right hippocampus of CFS patients (p = 0.005).
Buskila D.	Ben Gurion University of the Negev, Faculty of Health Sciences, Soroka Medical Center, Beer Sheva, Israel.	Fibromyalgia, chronic fatigue syndrome, and myofascial pain syndrome.	Curr Opin Rheumatol 2000 Mar;12(2):113-23	Fibromyalgia and widespread pain were common in Gulf War veterans with unexplained illness referred to a rheumatology clinic. Increased tenderness was demonstrated in the postmenstrual phase of the cycle compared with the intermenstrual phase in normally cycling women but not in users of oral contraceptives. Patients with fibromyalgia had high levels of symptoms that have been used to define silicone implant-associated syndrome. Tender points were found to be a common transient finding associated with acute infectious mononucleosis, but fibromyalgia was an unusual long-term outcome. The common association of fibromyalgia with other rheumatic and systemic illnesses was further explored. A preliminary study revealed a possible linkage of fibromyalgia to the HLA region. Patients with fibromyalgia were found to have an impaired ability to activate the hypothalamic pituitary portion of the hypothalamic pituitary adrenal axis as well as the sympathoadrenal system, leading to reduced corticotropin and epinephrine response to hypoglycemia. Much interest has been expressed in the literature on the possible role of autonomic dysfunction in the development or exacerbation of fatigue and other symptoms in chronic fatigue syndrome. Mycoplasma genus and mycoplasma fermentans were detected by polymerase chain reaction in patients with chronic fatigue syndrome. It was reported that myofascial temporomandibular disorder does not run in families. No major therapeutic trials in fibromyalgia, chronic fatigue syndrome, or myofascial pain syndrome were reported over the past year. The effectiveness of cognitive behavioral therapy and behavior therapy for chronic pain in adults was emphasized. A favorable outcome of fibromyalgia and chronic fatigue syndrome in children and adolescents was reported.

University of Medicine and Dentistry of New Jersey, Robert Wood Johnson Medical School, Environmental and Occupational Health Sciences Institute, Piscataway 08854, USA.	Odor perception: multiple chemical sensitivities, chronic fatigue, and asthma.	J Occup Environ Med 2000 Jun;42(6):629-38	Patients with multiple chemical sensitivities (MCS) often report heightened sensitivity to odors. Odor detection thresholds to phenyl ethyl alcohol (PEA) and pyridine (PYR) were evaluated as a measure of odor sensitivity for 33 MCS subjects, 13 chronic fatigue syndrome subjects, 16 asthmatic subjects, and 27 healthy controls. Odor identification ability (based on University of Pennsylvania Smell Identification Test results) and ratings in response to four suprathreshold levels of PEA and PYR were also assessed. Odor detection thresholds for PEA and PYR and odor identification ability were equivalent for all groups; however, when exposed to suprathreshold concentrations of PEA, MCS subjects reported significantly more trigeminal symptoms and lower esthetic ratings of PEA. No group differences were found in response to suprathreshold concentrations of PYR. In summary, MCS subjects did not demonstrate lower olfactory threshold sensitivity or enhanced ability to identify odors accurately. Furthermore, they were differentiated from the other groups in their symptomatic and esthetic ratings of PEA, but not PYR.
Chaudhuri A, Behan PO.		Neurological Dysfunction in Chronic Fatigue Syndrome	Journal of Chronic Fatigue Syndrome 2000; 6(3/4): 51	Chronic fatigue syndrome (CFS), popularly known in Europe as myalgic encephalomyelitis (ME), is a common but not a new illness. CFS/ME was classified as a neurological disease by the World Health Organisation in 1993. Neurological dysfunction is considered the principal mechanism of both physical and mental fatigue in this condition. This article reviews the neurological symptoms of the epidemic and sporadic forms of the illness. Paroxysmal changes in the severity of symptoms (fatigue and neuropsychiatric) are the hallmark features in the natural history of this disease. Ion channel abnormality leading to neuronal instability in selective anatomical pathways (basal ganglia circuitry) is proposed as the possible mechanism of fluctuating fatigue and related symptoms in CFS.
Chaudhuri A, Watson WS, Pearn J, Behan PO.	University Department of Neurology, Institute of Neurological Sciences, Southern General Hospital, Glasgow, UK.	The symptoms of chronic fatigue syndrome are related to abnormal ion channel function	Med Hypotheses 2000 Jan;54(1):59-63Comment in: Med Hypotheses. 2000 Dec;55(6):524 Med Hypotheses. 2000 Nov;55(5):457.	The pathogenesis of chronic fatigue syndrome (CFS) is unknown but one of the most characteristic features of the illness is fluctuation in symptoms which can be induced by physical and/or mental stress. Other conditions in which fluctuating fatigue occurs are caused by abnormal ion channels in the cell membrane. These include genetically determined channelopathies, e.g. hypokalemic periodic paralysis, episodic ataxia type 2 and acquired conditions such as neuromyotonia, myasthenic syndromes, multiple sclerosis and inflammatory demyelinating polyneuropathies. Our hypothesis is that abnormal ion channel function underlies the symptoms of CFS and this is supported also by the finding of abnormal cardiac-thallium201 SPECT scans in CFS, similar to that found in syndrome X, another disorder of ion channels. CFS and syndrome X can have identical clinical symptoms. CFS may begin after exposure to specific toxins which are known to produce abnormal sodium ion channels. Finally, in CFS, increased resting energy expenditure (REE) occurs, a state influenced by transmembrane ion transport. The hypothesis that ion channels are abnormal in CFS

				may help to explain the fluctuating fatigue and other symptoms.
Cichon MJ, Farrell DL, Ganio SH, Sadler GM.		A Case Series Survey of Silicone Breast Implant Patients	Journal of Chronic Fatigue Syndrome 2000; 5(3/4): 119	Objective: To survey the symptoms of a large group of breast implant patients displaying illness and to determine if any clinical or serological features predominate. Design: A case series survey. Setting: A private internal medicine practice. Patients: A referred sample of 415 patients with fatigue of long duration, followed by muscle/joint pain, cognition problems, polyneuropathy, and localized breast pain. Conclusion: Silicone adjuvant breast disease may be a novel disorder, possibly autoimmune, producing atypical syndromes that do not fit within the classic diagnostic criteria of known conditions. Furthermore, the diversity and distinction of silicone adjuvant breast disease may require the medical community to accept it as a new entity, encompassing a neurological and connective tissue disorder.
Clarke JN.	Sociology Department, Wilfrid Laurier University, Waterloo, Ontario, Canada.	The search for legitimacy and the "expertization" of the lay person: the case of chronic fatigue syndrome.	Soc Work Health Care 2000;30(3):73-93	Some "diseases" appear to be recognized first by sufferers. At times these diseases may be disclaimed by medical doctors and elusive to scientific categorization and description. In these cases sufferers may organize themselves together in support groups and lobby for money to finance the discovery of diagnostic markers that would legitimate and medicalize the constellation of symptoms that they experience. Chronic fatigue syndrome is such a disease; and it is characterized by varied and changing symptomatology. Its diagnostic markers are in the process of being refined. Presently, its diagnosis primarily originates in reports of subjective experience of extreme fatigue. Often-times people diagnose themselves after attending a support group and find a doctor through a support group network who believes in the disease. Sometimes, people then return to their own family doctors with information and try to teach their doctors about what they believe to be the nature of their disease, its prognosis and treatment. Through such paths as described in the paper, patients become "experts": they may often know more about the illness than doctors and non-suffering others. This paper moves beyond the experience of chronic illness to describe the processes through which people seek confirmation and legitimation for the way that they feel and in a sense become the "experts."
Cleare AJ, Sookdeo SS, Jones J, O'Keane V, Miell JP.	Department of Psychological Medicine, Guy's King's and St. Thomas' School of Medicine, and the Institute of Psychiatry, London, United Kingdom. a.cleare@iop.kcl.ac.uk	Integrity of the growth hormone/insulin-like growth factor system is maintained in patients with chronic fatigue syndrome.	J Clin Endocrinol Metab 2000 Apr;85(4):1433-9	GH deficiency states and chronic fatigue syndrome (CFS) share several characteristics, and preliminary studies have revealed aspects of GH dysfunction in CFS. This study assessed indexes of GH function in 37 medication-free CFS patients without comorbid psychiatric illness and 37 matched healthy controls. We also assessed GH function before and after treatment with low dose hydrocortisone, which has been shown recently to reduce fatigue in CFS. We measured basal levels of serum insulin-like growth factor I (IGF-I), IGF-II, IGF-binding protein-1 (IGFBP-1), IGFBP-2 and IGFBP-3 together with 24-h urinary GH excretion. We also performed 2 dynamic tests of GH function: a 100-microg GHRH test and an insulin stress test using 0.15 U/kg BW insulin. There were no differences between patients and controls in basal levels of IGF/IGFBP or in urinary GH excretion. GH responses to both the GHRH test and the insulin stress test were no different in patients and controls. CFS patients did have a

				marginally reduced suppression of IGFBP-1 during the insulin stress test. Hydrocortisone treatment had no significant effect on any of these parameters. There is no evidence of GH deficiency in CFS. At the doses used, hydrocortisone treatment appears to have little impact on GH function.
Cocchetto AM, McNamara ME, Jordan EF.		Human Herpes Virus 6 (HHV-6) Infection in Patients with Chronic Fatigue Syndrome and Its Relationship to Activation-Induced Cell Death	Journal of Chronic Fatigue Syndrome 2000; 6(3/4): 41	Using evidence-based medical research techniques, current knowledge about the presence of active HHV-6 infections, in a sub-population of patients with chronic fatigue syndrome (CFS), has been reviewed and implications to activation-induced cell death are presented. Therapeutic intervention methods are also disclosed with a call for clinical studies to test the hypothesis presented.

Couper J.	Department of Psychiatry, St Vincent's Hospital, The University of Melbourne, Fitzroy, Victoria, Australia. couperjw@svhm.org.au	Chronic fatigue syndrome and Australian psychiatry: lessons from the UK experience.	Aust N Z J Psychiatry 2000 Oct;34(5):762-9	OBJECTIVE: The aim of this paper is to outline the opportunities and dangers the chronic fatigue syndrome (CFS) issue presents to Australian psychiatry. METHOD: The scientific literature of the last 50 years on CFS in adults was reviewed and samples of recent media portrayals of CFS in the UK and Australia were collected. The author has worked in both the UK and Australia managing adult CFS patients in specialist outpatient consultation-liaison (C-L) psychiatry settings. RESULTS: Chronic fatigue syndrome has been at the heart of an acrimonious debate in the UK, both within the medical profession and in the wider community. UK psychiatry has been drawn into the debate, at times being the target of strong and potentially damaging criticism, yet UK psychiatry, especially the C-L subspecialty, has played a crucial role in clarifying appropriate research questions and in devising management strategies. The issue has served to enhance and broaden psychiatry's perceived research and clinical role at the important medicine-psychiatry interface in that country. CONCLUSIONS: Handled properly, the CFS issue offers Australian psychiatry, especially C-L psychiatry, an opportunity to make a useful contribution to patient care in a clinically difficult and contentious area, while at the same time serving to help broaden psychiatry's scope in the Australian medical landscape.
Cox DL, Findley LJ.		Severe and Very Severe Patients with Chronic Fatigue Syndrome: Perceived Outcome Following an Inpatient	Journal of Chronic Fatigue Syndrome 2000; 7(3): 33	The Chronic Fatigue Syndrome (CFS) Service within the Essex Neuroscience's Centre has been developing since 1990. The service was established as a comprehensive diagnostic and management service in July 1994. From May 1990 to March 1998, 318 patients with CFS were admitted into the programme and since November 1994, 1189 patients seen as outpatients. A previous survey indicated a positive perceived

		Programme		change in level of ability following the inpatient programme for all levels of CFS from mild to very severe. Of those admitted since 1990, 14% (43/318) were severely affected (extremely restricted mobility) and 9% (29/318) very severely affected (totally bedbound). Most studies on CFS do not include the more severe expressions of the disease; therefore, this descriptive paper aims to show the perceived outcome of these more severely affected patients following the inpatient programme. In particular, the eventual diagnosis, the specific approach to treatment and management and grading of patients will be described and the potential influence of the programme presented. The patients not diagnosed with CFS on discharge appeared to do least well at follow up.
Cruess SE, Klimas N, Antoni MH, Helder L, Maher K, Keller R, Fletcher MA.		Immunologic Status Correlates with Severity of Physical Symptoms and Perceived Illness Burden in Chronic Fatigue Syndrome Patients	Journal of Chronic Fatigue Syndrome 2000; 7(1): 39	The purpose of the present study was to investigate the relationship between immunologic status and physical symptoms in Chronic Fatigue Syndrome (CFS) patients. Twenty-seven patients diagnosed with CFS were included. Participants completed a questionnaire including selected subscales of the Sickness Impact Profile, the Cognitive Difficulties Scale, and frequency and severity of CFS-related physical symptoms. Cellular immune markers measured included number and percent of T-helper/inducer cells (CD3+CD4+), T-cytotoxic/suppressor cells (CD3+CD8+), activated T-lymphocytes (CD26+CD2+ CD3+), activated T cytotoxic/suppressor cells (CD38+HLA-DR+CD8+), and CD4/CD8 ratio. Spearman's correlation coefficients revealed significant associations between a number of immunologic measures and severity of illness suggesting that the degree of cellular immune activation was associated with the severity of CFS-related physical symptoms, cognitive complaints, and perceived impairment secondary to CFS. Specifically, elevations in T-helper/inducer cells, activated T-cells, activated cytotoxic/suppressor T-cells, and CD4/CD8 ratio were associated with greater severity of several symptoms. Furthermore, reductions in T-suppressor/cytotoxic cells also appeared related to greater severity of some CFS-related physical symptoms and illness burden. Multiple regression analyses demonstrated that decreased percentage of CD3+CD8+ cells and increased number of CD38+HLA-DR+CD8+ cells were the strongest predictors of total illness burden and fatigue severity, accounting for almost 30% of the variance in these measures.
Cukor D, Tiersky L, Natelson BH.		Psychiatric Comorbidity and Somatic Distress in Sudden and Gradual Onset Chronic Fatigue Syndrome	Journal of Chronic Fatigue Syndrome 2000; 7(4): 33	The purpose of this study was to examine if type of Chronic Fatigue Syndrome (CFS) onset suggested two distinct illness patterns within CFS. One hundred and seventeen patients diagnosed with CFS by a multidisciplinary team were divided into two groups: sudden versus gradual onset of symptoms. These two subgroups were compared on the presence of lifetime comorbid Axis I diagnoses, the pattern of medically unexplained symptoms, and the number of patients who met criteria for Somatization Disorder (SD). The two subgroups did not differ in any of the experimental variables indicating that onset type is not distinguished by either comorbid psychopathology or medically unexplained symptoms. Implications of

				these findings are discussed.

Davis SD, Kator SF, Wonnett JA, Pappas BL, Sall JL.	Preventive Medicine, Evans US Army Community Hospital, Fort Carson, Colorado, USA. shirley.davis@med.va.gov	Neurally mediated hypotension in fatigued Gulf War veterans: a preliminary report.	Am J Med Sci 2000 Feb;319(2):89-95	BACKGROUND: Many patients with chronic fatigue syndrome (CFS) have neurally mediated hypotension when subjected to head-up tilt, suggesting autonomic nervous system dysfunction. Some Gulf War veterans have symptoms similar to CFS. Whether they also tend to have neurally mediated hypotension is unknown. METHODS: We performed 3-stage tilt-table testing on 14 Gulf War veterans with chronic fatigue, 13 unfatigued control Gulf War veterans, and 14 unfatigued control subjects who did not serve in the Gulf War. Isoproterenol was used in stages 2 and 3 of the tilt protocol. RESULTS: More fatigued Gulf War veterans than unfatigued control subjects had hypotensive responses to tilt ($P < 0.036$). A positive response to the drug-free stage 1 of the tilt was observed in 4 of 14 fatigued Gulf War veterans versus 1 of 27 unfatigued control subjects ($P < 0.012$). Heart rate and heart rate variation during stage 1 was significantly greater in the fatigued group ($P < 0.05$). CONCLUSION: We conclude that more fatigued Gulf War veterans have neurally mediated hypotension than unfatigued control subjects, similar to observations in CFS. Autonomic nervous system dysfunction may be present in some fatigued Gulf War veterans.
De Becker P, Roeykens J, Reynders M, McGregor N, De Meirleir K.	Human Performance Laboratory and Department of Internal Medicine, Faculty of Physical Education and Physical Therapy, Vrije Universiteit Brussel, LK-Third Floor, Pleinlaan 2, 1050 Brussels, Belgium. pdbeck@minf.vub.ac.be	Erratum in: Arch Intern Med 2001 Sep 10;161(16):2051-2 Exercise capacity in chronic fatigue syndrome.	Arch Intern Med 2000 Nov 27;160(21):3270-7	BACKGROUND: Patients with chronic fatigue syndrome (CFS) suffer from various symptoms, including debilitating fatigue, muscle pain, and muscle weakness. Patients with CFS can experience marked functional impairment. In this study, we evaluated the exercise capacity in a large cohort of female patients with CFS. METHODS: Patients with CFS and matched sedentary control subjects performed a maximal test with graded increase on a bicycle ergometer. Gas exchange ratio was continuously measured. In a second stage, we examined only those persons who achieved a maximal effort as defined by 2 end points: a respiratory quotient of at least 1.0 and an age-predicted target heart rate of at least 85%. Data were assessed using univariate and multivariate statistical methods. RESULTS: The resting heart rate of the patient group was higher, but the maximal heart rate at exhaustion was lower, relative to the control subjects. The maximal workload and maximal oxygen uptake attained by the patients with CFS were almost half those achieved by the control subjects. Analyzing only those persons who performed a maximal exercise test, similar findings were observed. CONCLUSIONS: When compared with healthy sedentary women, female patients with CFS show a significantly decreased exercise capacity. This could affect their physical abilities to a moderate or severe extent. Reaching the age-predicted target heart rate seemed to be a limiting factor of the patients with CFS in achieving maximal effort, which could be due to autonomic disturbances. Arch Intern Med. 2000;160:3270-3277.
De Meirleir K, Bisbal C,	Department of Human	A 37 kDa 2-5A binding	Am J Med 2000	PURPOSE: Recent studies have revealed abnormalities in the ribonuclease L pathway

Campine I, De Becker P, Salehzada T, Demettre E, Lebleu B.	Physiology and Medicine, Vrije Universiteit Brussels, Belgium.	protein as a potential biochemical marker for chronic fatigue syndrome	Feb;108(2):99-105Comment in: Am J Med. 2000 Aug 15;109(3):257-9 Am J Med. 2000 Dec 15;109(9):744 Am J Med. 2000 Feb;108(2):169-71 Am J Med. 2000 Feb;108(2):172-3.	in peripheral blood mononuclear cells of patients with the chronic fatigue syndrome. We conducted a blinded study to detect possible differences in the distribution of 2-5A binding proteins in the cells of patients with chronic fatigue syndrome and controls. PATIENTS AND METHODS: We studied 57 patients with chronic fatigue syndrome and 53 control subjects (28 healthy subjects and 25 patients with depression or fibromyalgia). A radioactive probe was used to label 2-5A binding proteins in unfractionated peripheral blood mononuclear cell extracts and to compare their distribution in the three groups. RESULTS: A 37 kDa 2-5A binding polypeptide was found in 50 (88%) of the 57 patients with chronic fatigue syndrome compared with 15 (28%) of the 53 controls ($P < 0.01$). When present, the amount of 37 kDa protein was very low in the control groups. When expressed as the ratio of the 37 kDa protein to the 80 kDa protein, 41 (72%) of the 57 patients with chronic fatigue syndrome had a ratio > 0.05, compared with 3 (11%) of the 28 healthy subjects and none of the patients with fibromyalgia or depression. CONCLUSION: The presence of a 37 kDa 2-5A binding protein in extracts of peripheral blood mononuclear cells may distinguish patients with chronic fatigue syndrome from healthy subjects and those suffering from other diseases.
Deale A, Wessely S.	Department of Psychological Medicine, King's College, London, UK. alicia.deale@kcl.ac.uk	Diagnosis of psychiatric disorder in clinical evaluation of chronic fatigue syndrome.	J R Soc Med 2000 Jun;93(6):310-2	The overlap of symptoms in chronic fatigue syndrome (CFS) and psychiatric disorders such as depression can complicate diagnosis. Patients often complain that they are wrongly given a psychiatric label. We compared psychiatric diagnoses made by general practitioners and hospital doctors with diagnoses established according to research diagnostic criteria. 68 CFS patients referred to a hospital fatigue clinic were assessed, and psychiatric diagnoses were established by use of a standardized interview schedule designed to provide current and lifetime diagnoses. These were compared with psychiatric diagnoses previously given to patients. Of the 31 patients who had previously received a psychiatric diagnosis 21 (68%) had been misdiagnosed: in most cases there was no evidence of any past or current psychiatric disorder. Of the 37 patients who had not previously received a psychiatric diagnosis 13 (35%) had a treatable psychiatric disorder in addition to CFS. These findings highlight the difficulties of routine clinical evaluation of psychiatric disorder in CFS patients. We advise doctors to focus on subtle features that discriminate between disorders and to use a brief screening instrument such as the Hospital Anxiety and Depression Scale.
Donnay A, Ziem G.		Prevalence and Overlap of Chronic Fatigue Syndrome and Fibromyalgia Syndrome Among 100 New Patients with Multiple Chemical Sensitivity Syndrome	Journal of Chronic Fatigue Syndrome 2000; 5(3/4): 71	Background: Several studies have reported on extensive two-way overlaps found among chronic fatigue syndrome (CFS), fibromyalgia syndrome (FMS) and multiple chemical sensitivity syndrome (MCS) but none have yet reported on the overlap of all three. This study assesses the prevalence of pure MCS, MCS-CFS, MCS-FMS and the overlap of all three among 100 consecutive new patients evaluated for MCS in a private practice specializing in occupational and environmental medicine. Methods: Sixty-eight females and 32 males diagnosed with MCS-based on a medical history of multiple chronic symptoms in multiple organs triggered by multiple chemical

				exposures at or below previously tolerated levels-were also evaluated for CFS and FMS using the diagnostic criteria of the US Centers for Disease Control and the American College of Rheumatology, respectively. Results: Eighty-eight percent of the 100 MCS patients met criteria for CFS, 49% met criteria for FMS, and 47% met both. Slightly more male than female MCS patients had CFS: 91% vs. 87%; while FMS was more than twice as common among female MCS patients: 59% vs. 28%. The majority of women, 56%, met criteria for all three disorders, and an additional 31% had both MCS and CFS. This pattern was reversed in men, only 28% of whom had all three, compared to 63% with MCS and CFS but no FMS. MCS alone was diagnosed in only 10% of the women and 9% of the men. Even rarer was the overlap of MCS and FMS without any CFS, found in just 2 women. Conclusions: At least in this clinic population, MCS seldom occurs alone. The enormous range of diagnostic overlaps reported here and in previous studies of various overlaps among CFS, FMS and MCS highlights the need to screen for all three disorders in studies of any one and to report results in these terms. We recommend this be made standard practice in both clinical settings and research protocols.
Duley JA, Garrick DP, Pratt DA.		Raised Plasma Adenosine Associated with Chronic Fatigue Syndrome: A Preliminary Study	Journal of Chronic Fatigue Syndrome 2000; 7(3): 77	Plasma adenosine levels were measured in a small trial study of eighteen volunteers, aged 36-85 years. Volunteers comprised nine with chronic fatigue syndrome (CFSs), four with `other fatigue' illnesses, and five with no history of fatigue illnesses but some of whom were related to chronic fatigue sufferers. Plasma adenosine was slightly raised above the minimum detectable level (approx. 1 micromole/L) in one healthy non-fatigued volunteer and grossly raised (greater than 5 micromoles/L) in two non-fatigued volunteers, both of whom were related to CFSs. Among the nine CFSs, all had plasma adenosine raised above baseline, and seven were grossly raised. High adenosine levels were also seen in two of the volunteers with `other fatigue.' Raised adenosine occurred among certain families, suggesting a genetic metabolic element. Instability of adenosine in frozen stored plasma was noted. High levels of adenosine probably do not exist freely within peripheral plasma but may be released from blood cells locally within tissues or in response to venipuncture stress or other factors. The results may be highly relevant to other pathologies such as heart disease.
Duncan RB.		Latency Immunity and Therapy: A Clinical Study of Latent Epstein Barr Virus Incidence in 297 Idiopathic Chronic Fatigue Patients with Plausible Hypotheses	Journal of Chronic Fatigue Syndrome 2000; 5(2): 77	Organ cells of the body retain an Immune Activity System comparable to protozoa. The cells' immunity memory templates are latent proteins, microbes, their toxins and chemicals (latentees). Excess latentees are detected and excreted by latency therapy. Their excretion induces immediate and/or delayed symptoms and signs recognized by the patient. Foreign latent materials (latentors) enter the body and bypass the Natural Immune System to be taken up selectively by organ cell groups. Active infection/disease and allergens (antigens) involve the Natural Immune System antibodies. Latent infection/disease and allergens (latentors) involve the Organ Cell Immunity as intracellular latentees. Clinical laboratory testing is inappropriate. This Clinical Anecdotal Study compiles 297 patients who obtained little or no relief from

				conventional and alternative medicine (duration: 63% > three years.) Patients provoked symptoms to two or more of 16 viruses, in particular Epstein Barr Virus. Latency therapy (heat, saunas, massage, tolerated exercise and sweating during sleep, the auto-sauna) dilutions stimulated excretion until symptoms/signs cleared. The principals were Epstein Barr Virus 67.3%, 200 patients; 13 individual viruses 30.0%, 89 patients; non-viral 2.6%, 8 patients. Latency therapy < 50% improvement = 16.5%; 50% to 80% = 26.6%; 80% to 100% = 46. 7%; failures = 11%. Fourteen patients gave positive Epstein Barr Virus serology. A latency immunity concept explains affected subjective symptoms and illnesses and offers a treatment which complements related medical therapies.
Dunstan RH, McGregor NR, Roberts T K, Butt H, Niblett SH, Rothkirch T.		The Development of Laboratory-Based Tests in Chronic Pain and Fatigue: 1. Muscle Catabolism and Coagulase Negative Staphylococci Which Produce Membrane Damaging Toxins	Journal of Chronic Fatigue Syndrome 2000; 7(1): 23	Background: The diagnosis of chronic fatigue syndrome (CFS) requires the exclusion of other known fatigue-related diseases because the core symptoms of CFS represent a general host response to many well-defined diseases. The patient set derived by this process is heterogeneous in their polysymptomatic presentation and has proved very difficult to study clinically and scientifically. Objectives: To investigate the alterations in urine excretion and microbiology in patients with CFS. Results: CFS patients had multiple anomalies in their amino and organic acid homeostasis. Sub-groups of CFS patients could be delineated on the basis of their urine excretion and their symptom presentation. The most common feature was an active muscle catabolism resulting in a depletion of amino acids and associated organic and keto-acids. The extent of muscle catabolism was directly correlated to pain severity. The carriage of toxin-producing coagulase negative staphylococci (MDT-CoNS) was strongly correlated with the catabolic response and pain severity. Conclusions: An hypothesis has been constructed where an occult pathogen, such as MDT-CoNS, may be an aetiological agent contributing to the sustenance of a chronic fatigue/pain disorder, a comorbid pathogen. Urine analysis offers an opportunity for assessment of muscle catabolism and sub-classification of chronic fatigue patients leading to a number of management options. The detection of MDT-CoNS identifies potentially treatable agents that contribute to the fatigue and pain condition.
Dunstan RH, McGregor NR, Roberts T K, Butt H, Niblett SH, Rothkirch T.		The Development of Laboratory-Based Tests in Chronic Pain and Fatigue: 1. Dunstan RH, McGregor NR, Roberts T K, Butt H, Taylor WG, Carter A.		The Development of Laboratory-Based Tests in Chronic Pain and Fatigue: 2. Essential Fatty Acids and Cholesterol	Journal of Chronic Fatigue Syndrome 2000; 7(2): 59	Objectives: To investigate fatty acid and sterol homeostasis in patients with CFS. Methods: Plasma samples were collected from CFS and control subjects and analyzed for lipid composition by GC-MS metabolic profiling techniques. Results: CFS patients had significantly different profiles of fatty acids and sterols compared with control subjects. The 1st and 2nd most important factors discriminating the CFS patients from the controls, were a decrease in elaidic acid (trans-9-octadecenoic acid) and an increase in stearic acid (octadecanoic acid), respectively. The CFS patients also had lower levels of cholesterol, which has potential impact on membrane integrity and function, steroid hormone synthesis, energy metabolism and bile production. The CFS patients could also be subdivided into subgroups based on their fatty acid and sterol composition. The results of cluster analyses and multivariate analyses revealed that several types of homeostasis exist in different types of CFS patients, whereas the control group was largely homogeneous. Viral infections can contribute to the nature of the lipid-based anomalies in CFS patients and lipid profiles from patients with prior viral infections could be differentiated from those without viral histories. Conclusions: The assessment of fatty acids and sterols in fasting plasma samples can indicate essential fatty acid deficits, suggest appropriate types of essential fatty acid oils for formulations, indicate potential cholesterol deficit-associated anomalies, provide evidence for mitochondrial dysfunction and categorize CFS patients into biochemical subgroups. These evaluations provide a basis for devising individually tailored patient management protocols.
Durstine JL, Painter P, Franklin BA, Morgan D, Pitetti KH, Roberts SO.	Department of Exercise Science, University of South Carolina, Columbia 29208, USA. ldurstine@sophe.sph.sc.edu	Physical activity for the chronically ill and disabled.	Sports Med 2000 Sep;30(3):207-19	Exercise prescription principles for persons without chronic disease and/or disability are based on well developed scientific information. While there are varied objectives for being physically active, including enhancing physical fitness, promoting health by reducing the risk for chronic disease and ensuring safety during exercise participation, the essence of the exercise prescription is based on individual interests, health needs and clinical status, and therefore the aforementioned goals do not always carry equal weight. In the same manner, the principles of exercise prescription for persons with chronic disease and/or disability should place more emphasis on the patient's clinical status and, as a result, the exercise mode, intensity, frequency and duration are usually modified according to their clinical condition. Presently, these exercise prescription principles have been scientifically defined for

				clients with coronary heart disease. However, other diseases and/or disabilities have been studied less (e.g. renal failure, cancer, chronic fatigue syndrome, cerebral palsy). This article reviews these issues with specific reference to persons with chronic diseases and disabilities.
Elenkov IJ, Wilder RL, Chrousos GP, Vizi ES.	Inflammatory Joint Diseases Section, Arthritis and Rheumatism Branch, National Institute of Arthritis and Musculoskeletal and Skin Diseases, National Institutes of Health, Bethesda, Maryland, USA.	The sympathetic nerve--an integrative interface between two supersystems: the brain and the immune system.	Pharmacol Rev 2000 Dec;52(4):595-638	The brain and the immune system are the two major adaptive systems of the body. During an immune response the brain and the immune system "talk to each other" and this process is essential for maintaining homeostasis. Two major pathway systems are involved in this cross-talk: the hypothalamic-pituitary-adrenal (HPA) axis and the sympathetic nervous system (SNS). This overview focuses on the role of SNS in neuroimmune interactions, an area that has received much less attention than the role of HPA axis. Evidence accumulated over the last 20 years suggests that norepinephrine (NE) fulfills the criteria for neurotransmitter/neuromodulator in lymphoid organs. Thus, primary and secondary lymphoid organs receive extensive sympathetic/noradrenergic innervation. Under stimulation, NE is released from the sympathetic nerve terminals in these organs, and the target immune cells express adrenoreceptors. Through stimulation of these receptors, locally released NE, or circulating catecholamines such as epinephrine, affect lymphocyte traffic, circulation, and proliferation, and modulate cytokine production and the functional activity of different lymphoid cells. Although there exists substantial sympathetic innervation in the bone marrow, and particularly in the thymus and mucosal tissues, our knowledge about the effect of the sympathetic neural input on hematopoiesis, thymocyte development, and mucosal immunity is extremely modest. In addition, recent evidence is discussed that NE and epinephrine, through stimulation of the beta(2)-adrenoreceptor-cAMP-protein kinase A pathway, inhibit the production of type 1/proinflammatory cytokines, such as interleukin (IL-12), tumor necrosis factor-alpha, and interferon-gamma by antigen-presenting cells and T helper (Th) 1 cells, whereas they stimulate the production of type 2/anti-inflammatory cytokines such as IL-10 and transforming growth factor-beta. Through this mechanism, systemically, endogenous catecholamines may cause a selective suppression of Th1 responses and cellular immunity, and a Th2 shift toward dominance of humoral immunity. On the other hand, in certain local responses, and under certain conditions, catecholamines may actually boost regional immune responses, through induction of IL-1, tumor necrosis factor-alpha, and primarily IL-8 production. Thus, the activation of SNS during an immune response might be aimed to localize the inflammatory response, through induction of neutrophil accumulation and stimulation of more specific humoral immune responses, although systemically it may suppress Th1 responses, and, thus protect the organism from the detrimental effects of proinflammatory cytokines and other products of activated macrophages. The above-mentioned immunomodulatory effects of catecholamines and the role of SNS are also discussed in the context of their clinical implication in certain infections, major injury and

				sepsis, autoimmunity, chronic pain and fatigue syndromes, and tumor growth. Finally, the pharmacological manipulation of the sympathetic-immune interface is reviewed with focus on new therapeutic strategies using selective alpha(2)- and beta(2)-adrenoreceptor agonists and antagonists and inhibitors of phosphodiesterase type IV in the treatment of experimental models of autoimmune diseases, fibromyalgia, and chronic fatigue syndrome.

Endicott NA.		Chronic Fatigue Syndrome in Psychiatric Patients: Evidence of Premorbid Anomalous Patterns of Brain Organization	Journal of Chronic Fatigue Syndrome 2000; 5(1): 29	Forty-six patients with chronic fatigue syndrome (CFS) were matched with two control groups: one chosen on the basis of relatively good physical health (N = 92) and the other without regard to physical health (N = 46). All patients were from the same psychiatric practice. The groups were compared on 20 anomalous brain conditions or phenomena (ABCP) used as markers of patterns of brain organization. The results suggest that psychiatric patients who subsequently develop CFS have a higher number of pre-CFS ABCP, of both childhood and adult onset, than psychiatric patients who have not developed this condition.

Ferrari R.		The biopsychosocial model--a tool for rheumatologists.	Baillieres Best Pract Res Clin Rheumatol 2000 Dec;14(4):787-95	Rheumatologists grapple in daily practice with many controversial syndromes including fibromyalgia, late whiplash syndrome, chronic fatigue syndrome, Gulf War syndrome, the adverse outcomes of silicon breast implants and so on. For decades, much of the debate surrounding, and the approach to these controversial syndromes has centred on a model creating two camps-organic versus non-organic. While each camp has its support, this model seems to have failed in achieving the desired understanding of these syndromes, most particularly in offering the rheumatologist a practical and coherent approach to effective treatment. This chapter will thus

				introduce the biopsychosocial model, its elements, its advantages over the traditional model and the practical application of this model. Examples will be given of how rheumatologists can approach the treatment of these syndromes through patient education and the implementation of a change in illness behaviour. Department of Environmental and Community Medicine, UMDNJ-Robert Wood Johnson Medical School, 170 Frelinghuysen Road, Piscataway, NJ 08854, USA. nfiedler@eohsi.rutgers.edu	Stressors, personality traits, and coping of Gulf War veterans with chronic fatigue.	J Psychosom Res 2000 Jun;48(6):525-35	OBJECTIVES: preliminary surveys of Persian Gulf veterans revealed a significant prevalence of self-reported symptoms consistent with chronic fatigue syndrome (CFS). The purpose of this study was to compare self-reported life stressors, combat, and chemical exposures, personality and coping between Gulf War veterans with CFS and healthy veterans. METHODS: following a complete physical, psychiatric, and neuropsychological evaluation, 45 healthy veterans, 35 veterans with CFS and co-morbid psychiatric disorder, and 23 veterans with CFS and no co-morbid psychiatric disorder completed questionnaires assessing war and non-war-related life stressors, self-reports of environmental exposure (e.g. oil well fires, pesticides), personality, and coping. RESULTS: measures of personality, self-reported combat and chemical exposures, and negative coping strategies significantly differentiated healthy veterans from those with CFS. CONCLUSION: a biopsychosocial model of veterans' illness was supported by the fact that personality, negative coping strategies, life stress after the war, and environmental exposures during the war were significant predictors of veterans' current physical function.
Fletcher MA, Maher K, Patarca-Montero R, Klimas N.		Comparative Analysis of Lymphocytes in Lymph Nodes and Peripheral Blood of Patients with Chronic Fatigue Syndrome	Journal of Chronic Fatigue Syndrome 2000; 7(3): 65	Blood and lymph node samples were obtained from patients with chronic fatigue syndrome (CFS) who had volunteered to undergo a lymph node biopsy while participating in a phase 1 clinical trial of a novel immunomodulatory therapy. The surface marker phenotypes of the peripheral blood and lymph node samples were examined using four-color flow cytometry and compared to published proportions of cells in peripheral blood and lymph nodes from control individuals. While a greater proportion of T lymphocytes from both lymph nodes and peripheral blood of control subjects are immunologically ``naive'' (CD45RA+), the proportions of lymphocytes with a ``memory'' phenotype predominate in lymph nodes and peripheral blood of CFS patients. CFS has been proposed to be a disease of autoimmune etiology and in this respect it is interesting to note that decreased proportions of CD45RA+ T (``naive'') cells are also seen in the peripheral blood of patients with autoimmune diseases.
Friedberg F, Dechene L, McKenzie MJ 2nd, Fontanetta R.	Department of Mathematics, Fitchburg State College, MA, USA.	Symptom patterns in long-duration chronic fatigue syndrome.	J Psychosom Res 2000 Jan;48(1):59-68	OBJECTIVE: Our objective was to evaluate symptom patterns in patients with chronic fatigue syndrome (CFS) who were ill for 10 or more years. METHODS: This cross-sectional self-report study compared patient groups with long-duration (median = 18 years; n = 258) and short-duration (median = 3 years; n = 28) CFS to a group of healthy significant others (n = 79) on symptomatic, neurocognitive, and psychological variables. Data were gathered from a 574-item postal questionnaire. RESULTS: A principal-components analysis of CFS symptom data yielded a three-factor solution:

				cognitive problems; flu-like symptoms; and neurologic symptoms. Compared with the short-duration CFS group, the long-duration group had significantly higher CFS symptom severity scores ($p < 0.04$), largely attributable to increased cognitive difficulties. A subgroup comparison of subjects ill for < 3 years versus those ill 4-7 years suggested that denial coping strategies were more likely in those participants with the shorter illness duration. Significant differences between both CFS groups and healthy controls were found in a number of comorbid disorders. Participants with CFS most often endorsed immune/viral abnormalities and persistent stress as important perceived causes of their illness. CONCLUSION: Participants with long-duration CFS reported a large number of specific cognitive difficulties that were greater in severity than those reported by participants with short-duration CFS. The pattern of comorbid disorders in the CFS groups was consistent with hypersensitivity and viral reactivation hypotheses.
Friedberg F.		A Subgroup Analysis of Cognitive-Behavioral Treatment Studies	Journal of Chronic Fatigue Syndrome 2000; 5(3/4): 149	Several studies of graded activity-oriented cognitive behavioral treatment for chronic fatigue syndrome (CFS), all conducted in England, have reported dramatic improvements in functioning and substantial reductions in symptomatology. On the other hand, cognitive behavioral intervention studies conducted in Australia and the United States have not found significant improvements in functioning or CFS symptoms. Based on a review and synthesis of data from these clinical trials, naturalistic outcome investigations, and illness comparison studies, this articles argues that two CFS subgroups, distinguished by functional status and symptom severity, may account, in part, for the differences in outcome in cognitive behavioral treatment studies. It is also argued that differences in treatment duration may have influenced clinical outcomes. This article concludes with recommendations for specific cognitive behavioral interventions in CFS.
