Schulte-van Maaren YW, Giltay EJ, van Hemert AM, Zitman FG, de Waal MW, Van Rood YR, Carlier IV.	(1)Department of Psychiatry, Leiden University Medical Center, P.O. Box 9600, 2300 RC Leiden, The Netherlands. Electronic address: Y.W.M.Schulte-van_Maaren@lumc.nl. (2)Department of Psychiatry, Leiden	Reference values for the Body Image Concern Inventory (BICI), the Whitely Index (WI), and the Checklist Individual Strength (CIS-20R): The Leiden Routine Outcome Monitoring Study.	J Affect Disord. 2014 Aug;164:82-9. doi: 10.1016/j.jad.2014.03.013. Epub 2014 Mar 24.	BACKGROUND: The Body Image Concern Inventory (BICI), the Whitely Index (WI), and the Checklist Individual Strength (CIS-20R) are three questionnaires often incorporated in routine outcome monitoring (ROM). Respectively, they assess symptom severity in patients with body dysmorphic disorder, hypochondriasis, and chronic fatigue syndrome. We aimed to generate reference values for a healthy population and for a population of patients fulfilling diagnostic criteria for at least one of BDD, hypochondriasis, and CFS, treated in specialized mental health care. METHODS: The healthy ROM reference-group (n=648) was recruited through general practitioners. These subjects were matched for age and sex with the ROM patient-group (n=823). To define limits (i.e., cut-off-values) for one-sided reference intervals (5th percentile [P5] for ROM patient-group and 95th percentile [P95] for

	University Medical Center, P.O. Box 9600, 2300 RC Leiden, The Netherlands. (3)Department of Public Health and Primary Care, Leiden University Medical Center, Leiden, The Netherlands.			ROM reference-group) the outermost 5% of observations were used. Discriminative powers were evaluated by receiver operating characteristics (ROC) analyses RESULTS: Cut-off-values (P95 ROM reference-group) were 55 for the BICI, 6 for the WI, and 92 for the CIS-20R. These values differed for men and women, being mostly higher for women. The discriminative power of all three somatoform questionnaires was very high. LIMITATIONS: Substantial non-response and limited generalizability. CONCLUSIONS: For the BICI, WI, and CIS-20R a comprehensive set of reference values was obtained. The reference values may support clinical decisions regarding adjusting or terminating therapy, and possible referral.
Sha S, Liang J, Chen M, Xu B, Liang C, Wei N, Wu K.	State Key Laboratory of Cancer Biology & Xijing Hospital of Digestive Diseases, Fourth Military Medical University, Xi'an, Shaanxi Province, China.	Systematic review: faecal microbiota transplantation therapy for digestive and nondigestive disorders in adults and children.	Aliment Pharmacol Ther. 2014 May;39(10):1003-32. doi: 10.1111/apt.12699. Epub 2014 Mar 18. Review. Comment in Aliment Pharmacol Ther. 2014 Jul;40(1):119. Aliment Pharmacol Ther. 2014 Jul;40(1):119-20.	BACKGROUND: There has been growing interest in the use of faecal microbiota transplantation (FMT) for the treatment of gastrointestinal and nongastrointestinal diseases. AIM: To review systematically the reported efficacy and safety of FMT in the management of gastrointestinal and nongastrointestinal disorders in adults and children. METHODS: The systematic review followed Cochrane and PRISMA recommendations. Available articles were identified using three electronic databases in addition to hand searching and contacting experts. Inclusion criteria were any reports of FMT therapy written in English. RESULTS: A total of 844 patients who had undergone FMT were identified from 67 published studies. The most common indications were refractory/relapsing Clostridium difficile infection (CDI) (76.3%) and inflammatory bowel disease (IBD) (13.2%). There has been only one placebo-controlled trial, a successful trial in 43 patients with recurrent CDI. Seven publications report FMT in paediatric patients with a total of 11 treated, 3 with chronic constipation and the remainder with recurrent CDI or ulcerative colitis (UC). 90.7% of patients with refractory/relapsing CDI were cured and 78.4% of patients with IBD were in remission after FMT. FMT therapy could also be effective in treatment of some nongastrointestinal disorders such as chronic fatigue syndrome. The only reported serious adverse event attributed to the therapy was a case of suspected peritonitis. CONCLUSIONS: Although more controlled trials are needed, faecal microbiota transplantation therapy shows promise in both adults and children with gastrointestinal diseases such as CDI and IBD.

Shimosako N, Kerr JR.	(1) CFS Group, Department of Cellular & Molecular Medicine, St George's University of London, London, UK. (2)CFS Group, Department of Cellular & Molecular Medicine, St George's University of London, London, UK Escuela de Medicina y Ciencias de Salud, Universidad del Rosario, Bogota, Colombia.	Use of single-nucleotide polymorphisms (SNPs) to distinguish gene expression subtypes of chronic fatigue syndrome/myalgic encephalomyelitis (CFS/ME).	J Clin Pathol. 2014 Dec;67(12):1078-83. doi: 10.1136/jclinpath-2014-202597. Epub 2014 Sep 19.	AIMS: We have reported gene expression changes in patients with chronic fatigue syndrome/myalgic encephalomyelitis (CFS/ME) and the fact that such gene expression data can be used to identify subtypes of CFS/ME with distinct clinical phenotypes. Due to the difficulties in using a comparative gene expression method as an aid to CFS/ME disease and subtype-specific diagnosis, we have attempted to develop such a method based on single-nucleotide polymorphism (SNP) analysis. METHODS: To identify SNP allele associations with CFS/ME and CFS/ME subtypes, we tested genomic DNA of patients with CFS/ME (n=108), patients with endogenous depression (n=17) and normal blood donors (n=68) for 504 human SNP alleles located within 88 CFS-associated human genes using the SNP Genotyping GoldenGate Assay (Illumina, San Diego, California, USA). 360 ancestry informative markers (AIM) were also examined. RESULTS: 21 SNPs were significantly associated with CFS/ME compared with depression and normal groups. 148 SNP alleles had a significant association with one or more CFS/ME subtypes. For each subtype, associated SNPs tended to be grouped together within particular genes. AIM SNPs indicated that 4 subjects were of Asian origin while the remainder were Caucasian. Hierarchical clustering of AIM data revealed the relatedness between 2 couples of patients with CFS only and confirmed the overall heterogeneity of all subjects. CONCLUSIONS: This study provides evidence that human SNPs located within CFS/ME associated genes are associated with particular genomic subtypes of CFS/ME. Further work is required to develop this into a clinically useful subtype-specific diagnostic test.
Shiraishi W, Une H, Iwanaga Y, Yamamoto A.	Department of Neurology, Kyushu Kosei Nenkin Hospital.	A case of post-transfusion posterior reversible encephalopathy syndrome with cerebral hemorrhage that may be associated with fat-soluble vitamin deficiency	Rinsho Shinkeigaku. 2014;54(6):518-21.	[Article in Japanese] A 36-year-old woman with a 4 year history of lower legs edema, hypermenorrhea and melena without medical treatment was admitted to our hospital. At 18 days before admission, anasarca and general fatigue appeared and she was admitted to another hospital. Her hemoglobin concentration was 1.4 g/dl and chest X-ray showed cardiomegaly. Heart failure with severe chronic anemia was diagnosed, and blood transfusion was performed. Her hemoglobin concentration increased to 10 g/dl and the anasarca disappeared. The day after discharge, she was referred to our hospital with generalized convulsion. We diagnosed posterior reversible encephalopathy syndrome (PRES) from the typical MRI imaging. We started treatment and her consciousness recovered steadily. At a week after admission, left hemiparesis appeared. Her brain imaging revealed multiple intracranial hemorrhages. In addition, her visual disturbance revealed vitamin A and vitamin K deficiency. PRES sometimes occur secondary to blood transfusion, but secondary brain hemorrhage is rare. Her fat-soluble vitamin deficiency, which resulted from a peculiar eating habit, may have contributed to the brain hemorrhage.

Shmygalev S, Dagtekin O, Gerbershagen HJ, Marcus H, JÃ¼bner M, Sabatowski R, Petzke F.	Department of Anaesthesiology and Intensive Care Medicine, University Hospital Dresden, Technische Universität Dresden, Dresden, Germany, sergey.shmygalev@uniklinikum-dresden.de.	Assessing Cognitive and Psychomotor Performance in Patients with Fibromyalgia Syndrome.	Pain Ther. 2014 Oct 25.	INTRODUCTION: Patients with fibromyalgia syndrome (FMS) generally present with chronic widespread pain, accompanied by a range of additional and non-specific symptoms, such as fatigue, disturbed sleep, and cognitive dysfunction, which tend to increase with overall severity. Previous studies have shown moderate cognitive impairment in patients with FMS, but there are few valid data explicitly assessing the relevance of these findings to everyday functions, such as driving ability. Therefore, we studied patients with FMS to assess the impact of FMS on tests that predict driving ability. METHODS: Female patients with FMS were prospectively compared to a historical control group of healthy volunteers. The test battery comprised assessments of visual orientation, concentration, attention, vigilance, motor coordination, performance under stress, and reaction time. RESULTS: A total of 43 patients were matched to 129 controls. The results indicated that the patients' psychomotor and cognitive performances were significantly non-inferior when compared to healthy controls (with 0.05% alcohol), with the exception of motor coordination. Patients and healthy controls showed an age-related decline in test performance. Correlations were smaller in patients and reversed for vigilance which was linked to a greater FMS symptom load in younger patients. CONCLUSION: The results of the present study demonstrate that, in general, the driving ability of patients with FMS was not inferior to that of healthy volunteers based on a standardized computer-based test battery. However, variables, such as younger age, depression, anxiety, fatigue, pain, and poor motor coordination, likely contribute to the subjective perception of cognitive dysfunction in FMS.
Sieminski M, Losy J, Partinen M.	Department of Adult Neurology, Medical University of Gdansk, Gdansk, Poland. Electronic address: msiem@wp.pl.	Restless legs syndrome in multiple sclerosis.	Sleep Med Rev. 2014 Oct 12. doi:pii: S1087-0792(14)00101-4. 10.1016/j.smrv.2014.10.002. Review.	Restless legs syndrome (RLS) is a sleep-related sensory-motor disorder characterized by an irresistible urge to move the legs accompanied by unpleasant sensations in the lower extremities. According to many recent studies patients with multiple sclerosis (MS) suffer frequently from symptoms of RLS. The prevalence of RLS in MS patients varies 13.3%-65.1%, which is higher than the prevalence of RLS in people of the same age in the general population. MS patients with RLS have higher scores in the Expanded Disability Status Scale compared to MS patients without RLS. Presence of RLS has a negative impact on sleep quality and fatigue of MS patients. Iron deficiency and chronic inflammation may be factors contributing to development of RLS in MS. The relationship between the course and treatment of MS and RLS requires further prospective studies.
Singh K, Gupta R, Kamal H, Silvestri NJ, Wolfe GI.	Department of Neurology, University at Buffalo School of Medicine and Biomedical Sciences, The State University of New York, 100 High	Posterior reversible encephalopathy syndrome secondary to blood transfusion.	J Clin Neurosci. 2014 Dec 23. doi:pii: S0967-5868(14)00627-4. 10.1016/j.jocn.2014.10.005.	The appearance of posterior reversible encephalopathy syndrome (PRES) after blood transfusion is rare and has only been reported in three patients to our knowledge. We report a fourth patient with PRES secondary to blood transfusion. A 36-year-old woman with a history of menorrhagia presented to the emergency department with severe fatigue. She had a hemoglobin of 1.7g/dl and received four units of red blood cells over 15hours. On day 6 post-transfusion she returned with confusion, headache and a generalized tonic-clonic seizure. The MRI of her brain

	Street, Building D, Buffalo, NY 14203-1126, USA. Electronic address: Karanbirsinghmd@gmail.com.			was consistent with PRES. The following day her confusion worsened, repeat MRI of the brain showed new T2-weighted lesions. Over next 10days her mental status gradually improved close to her baseline. A repeat MRI of the brain showed resolution of the T2-weighted lesions. The clinical presentation, radiological findings and disease progression in our patient was consistent with PRES. Other than the blood transfusions, there were no apparent risk factors for PRES. The prior three patients with post-transfusion PRES have been reported in middle-aged women with uterine fibroids. It is suspected that these patients have a subacute to chronic anemic state due to ongoing menorrhagia. It is interesting to note that no cases of PRES post-transfusion have been reported in the setting of acute blood loss, such as from trauma. It is postulated that an abrupt increase in hemoglobin causes a rapid rise in blood viscosity and loss of hypoxic vasodilation. Subsequent endothelial damage and brain capillary leakage results in PRES. This constellation of changes may not occur after transfusion in patients with more acute blood loss.

Slim M, Calandre EP, Rico-Villademoros F.	Cousins Center for Psychoneuroimmunology, University of California, Los Angeles.	An insight into the gastrointestinal component of fibromyalgia: clinical manifestations and potential underlying mechanisms.	Rheumatol Int. 2014 Aug 14.	Major life stressors, especially those involving interpersonal stress and social rejection, are among the strongest proximal risk factors for depression. In this review, we propose a biologically plausible, multilevel theory that describes neural, physiologic, molecular, and genomic mechanisms that link experiences of social-environmental stress with internal biological processes that drive depression pathogenesis. Central to this social signal transduction theory of depression is the hypothesis that experiences of social threat and adversity up-regulate components of the immune system involved in inflammation. The key mediators of this response, called proinflammatory cytokines, can in turn elicit profound changes in

				behavior, which include the initiation of depressive symptoms such as sad mood, anhedonia, fatigue, psychomotor retardation, and social-behavioral withdrawal. This highly conserved biological response to adversity is critical for survival during times of actual physical threat or injury. However, this response can also be activated by modern-day social, symbolic, or imagined threats, leading to an increasingly proinflammatory phenotype that may be a key phenomenon driving depression pathogenesis and recurrence, as well as the overlap of depression with several somatic conditions including asthma, rheumatoid arthritis, chronic pain, metabolic syndrome, cardiovascular disease, obesity, and neurodegeneration. Insights from this theory may thus shed light on several important questions including how depression develops, why it frequently recurs, why it is strongly predicted by early life stress, and why it often co-occurs with symptoms of anxiety and with certain physical disease conditions. This work may also suggest new opportunities for preventing and treating depression by targeting inflammation.
Smith C, Wessely S.	Department of Psychological Medicine, Institute of Psychiatry, Weston Education Centre, London, UK.	Unity of opposites? Chronic fatigue syndrome and the challenge of divergent perspectives in guideline development.	J Neurol Neurosurg Psychiatry. 2014 Feb;85(2):214-9. doi: 10.1136/jnnp-2012-303208. Epub 2012 Nov 17.	Guideline development by its nature is a process and method of integration and synthesis of information, be it originating from research, evidence-based medicine, clinical findings, patient experience and/or individual narratives of an illness or disease. In the majority of cases, it can be assumed that this information and these ideas are travelling in the same direction; however, it is possible that the objective and subjective cannot be synthesised, and appear mutually contradictory. In this commentary, an example of where this might be the case has been analysed: a report published by the Scottish Public Health Network, a Health Care Needs Assessment of Services for people living with myalgic encephalomyelitis (ME)/chronic fatigue syndrome (CFS). It appears from reflection and analysis of this document that this process may indeed have gone awry. We propose that, if followed, this document would lead to the adoption of dangerous diagnostic criteria for ME/CFS, as well as preventing patients from making informed decisions about treatment options, and discouraging clinicians from following evidence-based medicine and recommending proven treatments for ME/CFS, because of potential implications for future commissioning. This commentary seeks to highlight some of the problems, contradictions and unintended consequences of a divergence between patient perspectives and evidence-based medicine despite probably sharing the same aim, that of improving patient care and striving for better understanding and better treatments for disease.
Smith SC, Wagner MS.	No address given	Clinical endocannabinoid deficiency (CECD) revisited: can this concept explain the therapeutic benefits	Neuro Endocrinol Lett. 2014;35(3):198-201. Review.	OBJECTIVES: Ethan B. Russo's paper of December 1, 2003 explored the concept of a clinical endocannabinoid deficiency (CECD) underlying the pathophysiology of migraine, fibromyalgia, irritable bowel syndrome and other functional conditions alleviated by clinical cannabis. METHODS: Available literature was reviewed, including searches via the National Library of medicine database and other sources. RESULTS: A review of the literature indicates that significant progress has been

		of cannabis in migraine, fibromyalgia, irritable bowel syndrome and other treatment-resistant conditions?		made since Dr. Ethan B. Russo's landmark paper, just ten years ago (February 2, 2004). Investigation at that time suggested that cannabinoids can block spinal, peripheral and gastrointestional mechanisms that promote pain in headache, fibromyalgia, irritable bowel syndrome and muscle spasm. CONCLUSION: Subsequent research has confirmed that underlying endocannabinoid deficiencies indeed play a role in migraine, fibromyalgia, irritable bowel syndrome and a growing list of other medical conditions. Clinical experience is bearing this out. Further research and especially, clinical trials will further demonstrate the usefulness of medical cannabis. As legal barriers fall and scientific bias fades this will become more apparent.
Snekkevik H, Eriksen HR, Tangen T, Chalder T, Reme SE.	Friskvernklinikken, Asker, Norway	Fatigue and depression in sick-listed chronic low back pain patients.	Pain Med. 2014 Jul;15(7):1163-70. doi: 10.1111/pme.12435. Epub 2014 Apr 9.	OBJECTIVE: The relationship between fatigue and pain has been investigated previously, but little is known about the prevalence of substantial fatigue in patients sick-listed for chronic low back pain (CLBP) and about how fatigue is associated with depression, pain, and long-term disability. The aims of the study were to examine the prevalence of substantial fatigue; associations between fatigue, depression, and pain; and whether fatigue predicted long-term disability. METHODS: Five hundred sixty-nine patients participating in a randomized controlled trial and sick-listed 2-10 months for LBP were included in the study. Cross-sectional analyses were conducted to investigate the prevalence and independent associations between fatigue, depression, pain, and disability, while longitudinal analyses were done to investigate the association between fatigue and long-term disability. RESULTS: The prevalence of substantial fatigue was 69.7%. Women reported significantly more fatigue than men ($t = -3.6$, $df = 551$; $P < .001$). Those with substantial fatigue had higher pain intensity ($t = -3.3$, $df = 534$; $P = 0.01$), more depressive symptoms ($t = -10.9$, $df = 454$; $P < 0.001$), and more disability ($t = -7.6$, $df = 539$; $P < 0.001$) than those without substantial fatigue. Musculoskeletal pain and depression were independently associated with substantial fatigue. In the longitudinal analyses, fatigue predicted long-term disability at 3, 6, and 12 months' follow-up. After pain and depression were controlled for, fatigue remained a significant predictor of disability at 6 months' follow-up. CONCLUSIONS: The vast majority of the sick-listed CLBP patients reported substantial fatigue. Those with substantial fatigue had more pain and depressive symptoms and a significant risk of reporting more disability at 3, 6, and 12 months. Substantial fatigue is disabling in itself but also involves a risk of developing chronic fatigue syndrome and long-term disability.
Stahl D, Rimes KA, Chalder T.	(1)Department of Biostatistics, Institute of Psychiatry, King's College London, UK. (2)Department of	Mechanisms of change underlying the efficacy of cognitive behaviour therapy for chronic	Psychol Med. 2014 Apr;44(6):1331-44. doi: 10.1017/S0033291713002006. Epub 2013 Aug 12.	BACKGROUND: Several randomized controlled trials (RCTs) have shown that cognitive behavioural psychotherapy (CBT) is an efficacious treatment for chronic fatigue syndrome (CFS). However, little is known about the mechanisms by which the treatment has its effect. The aim of this study was to investigate potential mechanisms of change underlying the efficacy of CBT for CFS. We applied path

	Psychology, University of Bath, UK. (3)Department of Psychological Medicine, Institute of Psychiatry, King's College London, UK.	fatigue syndrome in a specialist clinic: a mediation analysis.		analysis and introduce novel model comparison approaches to assess a theoretical CBT model that suggests that fearful cognitions will mediate the relationship between avoidance behaviour and illness outcomes (fatigue and social adjustment). METHOD: Data from 389 patients with CFS who received CBT in a specialist service in the UK were collected at baseline, at discharge from treatment, and at 3-, 6- and 12-month follow-ups. Path analyses were used to assess possible mediating effects. Model selection using information criteria was used to compare support for competing mediational models. RESULTS: Path analyses were consistent with the hypothesized model in which fear avoidance beliefs at the 3-month follow-up partially mediate the relationship between avoidance behaviour at discharge and fatigue and social adjustment respectively at 6 months. CONCLUSIONS: The results strengthen the validity of a theoretical model of CBT by confirming the role of cognitive and behavioural factors in CFS.
Struyf F, Meeus M, Fransen E, Roussel N, Jansen N, Truijen S, Nijs J.	Department of Rehabilitation Sciences and Physiotherapy, Faculty of Medicine and Health Sciences, University of Antwerp, Belgium; Chronic Pain and Chronic Fatigue Research Group (Pain in Motion). Electronic address: Filip.struyf@uantwerpen.be.	Interrater and intrarater reliability of the pectoralis minor muscle length measurement in subjects with and without shoulder impingement symptoms.	Man Ther. 2014 Aug;19(4):294-8. doi: 10.1016/j.math.2014.04.005. Epub 2014 Apr 21.	Measuring the pectoralis minor muscle length (PML) is of clinical interest, as a short PML has been associated with a decrease of scapular posterior tilting and shoulder pain. However, as no reliability data are available at present, the objective of this study was to examine the inter- and intrarater reliability of the PML measurement in both subjects with and without shoulder impingement symptoms (SIS). Therefore, two assessors performed the PML measurement (3 times/shoulder) in 25 patients with SIS and 25 pain-free controls. Both assessors were blinded for each other's findings. For reliability testing, intra-class coefficients (ICCs; model 2,1) and standard errors of measurements were calculated. Intrarater reliability analysis resulted with ICCs ranging from 0.87 (Standard error of measurement (SEM) 0.21-0.27%) (symptomatic) to 0.93 (SEM 0.19-0.30%) (asymptomatic) in patients with SIS, representing excellent test-retest agreement. Healthy subjects presented with ICCs ranging from 0.76 (SEM 0.29-0.32%) (dominant side) to 0.87 (SEM 0.21-0.32%) (non-dominant side), representing good test-retest agreement. ICCs and SEMs on the symptomatic and asymptomatic side (0.48 and 0.46%; 0.56 and 0.61%) in SIS patients, and on the two sides (non-dominant; 0.47 and 0.45%, dominant; 0.53 and 0.38% respectively) in healthy subjects showed moderate interrater reliability and low dispersion of the measurement errors. We concluded that the PML measurement has good to excellent intrarater reliability and poor to moderate interrater reliability.
Sulheim D, Fagermoen E, Winger A, Andersen AM, Godang K, MÃ¼ller F, Rowe PC, Saul	Department of Paediatrics, Oslo University Hospital, Oslo, Norway, Department of Paediatrics,	Disease mechanisms and clonidine treatment in adolescent chronic fatigue syndrome: a combined cross-	JAMA Pediatr. 2014 Apr;168(4):351-60. doi: 10.1001/jamapediatrics.2013.4647.	IMPORTANCE: Chronic fatigue syndrome (CFS) is a disabling condition with unknown disease mechanisms and few treatment options. OBJECTIVE: To explore the pathophysiology of CFS and assess clonidine hydrochloride pharmacotherapy in adolescents with CFS by using a hypothesis that patients with CFS have enhanced sympathetic activity and that sympatho-inhibition by clonidine would improve symptoms and function. DESIGN, SETTING, AND PARTICIPANTS: Participants were

JP, Skovlund E, Ã˜ie MG, Wyller VB.	Lillehammer County Hospital, Lillehammer, Norway.	sectional and randomized clinical trial.		enrolled from a single referral center recruiting nationwide in Norway. A referred sample of 176 adolescents with CFS was assessed for eligibility; 120 were included (34 males and 86 females; mean age, 15.4 years). A volunteer sample of 68 healthy adolescents serving as controls was included (22 males and 46 females; mean age, 15.1 years). The CSF patients and healthy controls were assessed cross-sectionally at baseline. Thereafter, patients with CFS were randomized 1:1 to treatment with low-dose clonidine or placebo for 9 weeks and monitored for 30 weeks; double-blinding was provided. Data were collected from March 2010 until October 2012 as part of the Norwegian Study of Chronic Fatigue Syndrome in Adolescents: Pathophysiology and Intervention Trial. INTERVENTIONS: Clonidine hydrochloride capsules (25 µg or 50 µg twice daily for body weight <35 kg or >35 kg, respectively) vs placebo capsules for 9 weeks. MAIN OUTCOMES AND MEASURES: Number of steps per day. RESULTS: At baseline, patients with CFS had a lower number of steps per day (P < .001), digit span backward score (P = .002), and urinary cortisol to creatinine ratio (P = .001), and a higher fatigue score (P < .001), heart rate responsiveness (P = .02), plasma norepinephrine level (P < .001), and serum C-reactive protein concentration (P = .04) compared with healthy controls. There were no significant differences regarding blood microbiology evaluation. During intervention, the clonidine group had a lower number of steps per day (mean difference, -637 steps; P = .07), lower plasma norepinephrine level (mean difference, -42 pg/mL; P = .01), and lower serum C-reactive protein concentration (mean ratio, 0.69; P = .02) compared with the CFS placebo group. CONCLUSIONS AND RELEVANCE: Adolescent CFS is associated with enhanced sympathetic nervous activity, low-grade systemic inflammation, attenuated hypothalamus-pituitary-adrenal axis function, cognitive impairment, and large activity reduction, but not with common microorganisms. Low-dose clonidine attenuates sympathetic outflow and systemic inflammation in CFS but has a concomitant negative effect on physical activity; thus, sympathetic and inflammatory enhancement may be compensatory mechanisms. Low-dose clonidine is not clinically useful in CFS. TRIAL REGISTRATION: clinicaltrials.gov Identifier: NCT01040429.
Swenson ER.	VA Puget Sound Health Care System and Department of Medicine, University of Washington, Seattle, WA, USA, eswenson@u.washington.edu.	Carbonic anhydrase inhibitors and high altitude illnesses.	Subcell Biochem. 2014;75:361-86. doi: 10.1007/978-94-007-7359-2_18. Review.	Carbonic anhydrase (CA) inhibitors, particularly acetazolamide, have been used at high altitude for decades to prevent or reduce acute mountain sickness (AMS), a syndrome of symptomatic intolerance to altitude characterized by headache, nausea, fatigue, anorexia and poor sleep. Principally CA inhibitors act to further augment ventilation over and above that stimulated by the hypoxia of high altitude by virtue of renal and endothelial cell CA inhibition which oppose the hypocapnic alkalosis resulting from the hypoxic ventilatory response (HVR), which acts to limit the full expression of the HVR. The result is even greater arterial oxygenation than that driven by hypoxia alone and greater altitude tolerance. The severity of several additional diseases of high attitude may also be reduced by acetazolamide, including

				high altitude cerebral edema (HACE), high altitude pulmonary edema (HAPE) and chronic mountain sickness (CMS), both by its CA-inhibiting action as described above, but also by more recently discovered non-CA inhibiting actions, that seem almost unique to this prototypical CA inhibitor and are of most relevance to HAPE. This chapter will relate the history of CA inhibitor use at high altitude, discuss what tissues and organs containing carbonic anhydrase play a role in adaptation and maladaptation to high altitude, explore the role of the enzyme and its inhibition at those sites for the prevention and/or treatment of the four major forms of illness at high altitude.
SÃ¡ez-FrancÃ s N, Valero S, Calvo N, GomÃ -I-Freixanet M, Alegre J, de Sevilla TF, Casas M.	Dept of Psychiatry, Hospital Universitari Vall d'Hebron, Passeig de la Vall d'Hebron 119-129, 08035 Barcelona, Dept of Psychiatry and Legal Medicine, Universitat Autònoma de Barcelona, Catalonia, Spain. E- address: nasaez@vhebron.net.	Chronic fatigue syndrome and personality: a case-control study using the Alternative Five Factor Model.	Psychiatry Res. 2014 May 30;216(3):373-8. doi: 10.1016/j.psychres.2014.02.031 . Epub 2014 Mar 3.	Neuroticism is the personality dimension most frequently associated with chronic fatigue syndrome (CFS). Most studies have also shown that CFS patients are less extraverted than non-CFS patients, but results have been inconsistent, possibly because the facets of the extraversion dimension have not been separately analyzed. This study has the following aims: to assess the personality profile of adults with CFS using the Alternative Five-Factor Model (AFFM), which considers Activity and Sociability as two separate factors of Extraversion, and to test the discriminant validity of a measure of the AFFM, the Zuckerman-Kuhlman Personality Questionnaire, in differentiating CFS subjects from normal-range matched controls. The CFS sample consisted of 132 consecutive patients referred for persistent fatigue or pain to the Department of Medicine of a university hospital. These were compared with 132 matched normal population controls. Significantly lower levels of Activity and significantly higher levels of Neuroticism-Anxiety best discriminated CFS patients from controls. The results are consistent with existing data on the relationship between Neuroticism and CFS, and clarify the relationship between Extraversion and CFS by providing new data on the relationship of Activity to CFS.

(2)Department of Clinical Laboratory	Hepatitis B vaccination and associated oral manifestations: a non-systematic review of literature and case reports.	Ann Med Health Sci Res. 2014 Nov;4(6):829-36. doi: 10.4103/2141-9248.144870. Review.	Hepatitis B vaccine has been administered in children and adults routinely to reduce the incidence of the disease. Even though, hepatitis B vaccine is considered as highly safe, some adverse reactions have been reported. A literature search was carried out in PubMed, accessed via the National Library of Medicine PubMed interface, searching used the following keywords: Hepatitis B vaccine and complications from 1980 to 2014. A total of 1147 articles were obtained out of which articles, which discuss the complications occurring orally or occurring elsewhere in the body, which

	Sciences, King Saud University, Alfarabi College of Medicine, Riyadh, Saudi Arabia. (3)Department of Restorative Dentistry Sciences, Alfarabi College of Dentistry and Nursing, Saudi Arabia.			have the potential to manifest orally after hepatitis B vaccination were selected. A total of 82 articles were identified which included 58 case series or case reports, 15 review articles, 4 cross sectional studies, 3 prospective cohort studies, one retrospective cohort study and a case control study. After reviewing the literature, we observed that complications seen after Hepatitis B vaccination are sudden infant death syndrome, multiple sclerosis, chronic fatigue syndrome, idiopathic thrombocytopenic purpura, vasculititis optic neuritis, anaphylaxis, systemic lupus erytymatosus, lichen planus and neuro-muscular disorder. Of these complications, some are manifested orally or have the potential to manifest orally. Although, most of the complications are self-limiting, some are very serious conditions, which require hospitalization with immediate medical attention.

The GK, Verkes RJ, Fekkes D, Bleijenberg G, van der Meer JW, Buitelaar JK.	Department of General Internal Medicine, Nijmegen Expert Centre Chronic Fatigue, Radboud University Nijmegen Medical Centre, Reinier Postlaan 4, 6525 GC Nijmegen, The Netherlands. g.the@adrz.nl.	Tryptophan depletion in chronic fatigue syndrome, a pilot cross-over study.	BMC Res Notes. 2014 Sep 16;7:650. doi: 10.1186/1756-0500-7-650.	BACKGROUND: Chronic fatigue syndrome (CFS) is still an enigmatic disorder. CFS can be regarded as a complex disorder with tremendous impact on lives of CFS-patients. Full recovery without treatment is rare. A somatic explanation for the fatigue is lacking. There is clinical and experimental evidence implicating enhanced serotonergic neurotransmission in CFS. Genetic studies and imaging studies support the hypothesis of upregulated serotonin system in CFS. In line with the hypothesis of an increased serotonergic state in CFS, we performed a randomised clinical trial investigated the effect of 5-HT3 receptor antagonism in CFS. No benefit was found of the 5-HT3 receptor antagonist ondansetron compared to placebo.To further investigate the involvement of serotonin in CFS we performed a placebo controlled cross over pilot study investigating the effect of Acute Tryptophan Depletion. FINDINGS: Five female CFS-patients who met the US Center for Disease Control and Prevention criteria for CFS were recruited. There were two test days, one week apart. Each participant received placebo and ATD. To evaluate the efficacy of the ATD procedure tryptophan and the large neutral amino acids were measured. The outcome measures were fatigue severity, concentration and mood states. ATD resulted in a significant plasma tryptophan to large neutral amino acid ratio reduction of 96%. There were no significant differences in fatigue-, depression and concentration between the placebo- and ATD condition. CONCLUSIONS: These first five CFS-patients did not respond to the ATD procedure. However, a much larger sample size is needed to draw final conclusions on the hypothesis of an increased serotonergic state in the pathophysiology of CFS. TRIAL REGISTRATION:

Tiemensma J, Andela CD, Kaptein AA, Romijn JA, van der Mast RC, Biermasz NR, Pereira AM.	Department of Endocrinology and MetabolismC7-Q, Center for Endocrine Tumors Leiden (CETL), Leiden University Medical Center, PO Box 9600, 2300 RC Leiden, The NetherlandsPsychological	Psychological morbidity and impaired quality of life in patients with stable treatment for primary adrenal insufficiency: cross-sectional study and review of the literature.	Eur J Endocrinol. 2014 Aug;171(2):171-82. doi: 10.1530/EJE-14-0023. Epub 2014 May 6. Review.	CONTEXT: A high prevalence of psychological morbidity and maladaptive personality as well as impaired quality of life (QoL) is observed in patients with and without hydrocortisone dependency following (cured) Cushing's syndrome. However, it is currently unclear whether a similar pattern is present in patients with chronic glucocorticoid replacement for primary adrenal insufficiency (PAI). OBJECTIVE: To evaluate psychological functioning, personality traits, and QoL in patients with PAI. DESIGN AND SUBJECTS: A cross-sectional study including 54 patients with stable treatment for PAI and 54 healthy matched controls. Both patients and controls completed questionnaires on psychological functioning (Apathy Scale, Irritability Scale, Mood and Anxiety Symptoms Questionnaire short form, and Hospital Anxiety and Depression Scale), personality traits (Dimensional Assessment of Personality Pathology short form), and QoL (Multidimensional Fatigue Inventory, Short Form 36, EuroQoL-5D, Nottingham Health Profile, and Physical Symptom Checklist). RESULTS: Patients with PAI suffered from more psychological morbidity (i.e. irritability and somatic arousal) and QoL impairments compared with controls (all $P<0.01$). There were no differences regarding maladaptive personality traits between patients and controls. However, there was a strong and consistent positive association between the daily hydrocortisone dose and prevalence of maladaptive personality traits (i.e. identity problems, cognitive distortion, compulsivity, restricted expression, callousness, oppositionality, rejection, conduct problems, social avoidance, narcissism, and insecure attachment, all $P<0.05$). There was also a strong relation between the mean daily hydrocortisone dose and both psychological morbidity (i.e. depression, $P<0.05$) and QoL impairments (i.e. general health perception, several measures of physical functioning, and vitality, all $P<0.05$). CONCLUSION: Patients on stable glucocorticoid replacement therapy for PAI report psychological morbidity and impaired QoL. Psychological morbidity, impaired QoL, and maladaptive personality traits were all associated with higher dosages of hydrocortisone.
Tobback E, Mariman A, Heytens S, Declercq T, Bouwen A, Spooren D, Snoeck P, Van Dessel K, D'Hooghe S, Rimbaut S, Vogelaers D.	No address given	A multidisciplinary network for the care of abnormal fatigue and chronic fatigue syndrome in the provinces of East and West Flanders in Belgium.	Acta Clin Belg. 2014 Oct;69(5):327-34. doi: 10.1179/2295333714Y.0000000056. Epub 2014 Jul 24.	The organization of care for patients with the chronic fatigue syndrome (CFS) in tertiary care referral centres from 2002 onwards, was negatively evaluated by the Belgian Health Care Knowledge Centre on the endpoint of socio-professional reintegration. Subsequently, the federal health authorities asked for the elaboration of a new and innovative model of stepped care, aiming at improved integration of diagnosis and treatment into primary care and between levels of health care for patients with CFS. The reference centre of the University Hospital Ghent took the initiative of recruiting partners in the Belgian provinces of East and West Flanders to guarantee the care for patients with medically unexplained symptoms, in particular abnormal fatigue and CFS. A new and innovative care model, in which general

				practitioners play a central role, emphasizes the importance of early recognition of the patient 'at risk', correct diagnosis and timely referral. Early detection and intervention is essential in order to avoid or minimize illness progression towards chronicity, to safeguard opportunities for significant health improvement as well as to enhance successful socio-professional reintegration. This approach covers both the large sample of patients developing somatic complaints without obvious disease in an early phase as well as the more limited group of patients with chronic illness, including CFS. Cognitive behavioural therapy and graded exposure/exercise therapy are the evidence based main components of therapy in the latter. A biopsychosocial model underlies the proposed path of care.

(1)Departments of Psychology, Anesthesiology and Urology, Queen's University, Kingston, ON; (2)Department of Urology, Queen's University, Kingston, ON; (3)Psychology, Queen's University, Kingston, ON; (4)Alan Edwards Pain Management Unit, McGill University Health Centre, Montreal, QC; (5)School of Psychology, University of Ottawa, Ottawa, ON	A survey of cannabis (marijuana) use and self-reported benefit in men with chronic prostatitis/chronic pelvic pain syndrome.	Can Urol Assoc J. 2014 Nov;8(11-12):E901-5. doi: 10.5489/cuaj.2268.	INTRODUCTION: Chronic prostatitis/chronic pelvic pain syndrome (CP/CPPS) is a chronic pelvic pain condition largely refractory to treatment. Cannabis (marijuana) use has been reported for a wide variety of chronic pain conditions, but no study has examined prevalence of cannabis use, symptom benefit or side effects, or frequency in CP/CPPS. METHODS: Participants were recruited from an outpatient CP/CPPS urology clinic (n = 98) and online through the Prostatitis Foundation website (n = 244). Participants completed questionnaires (demographics, CP/CPPS, depression, cannabis). RESULTS: The clinic sample included Canadian patients and the online sample included primarily American patients. Due to differences, groups were examined separately. Almost 50% of respondents reported using cannabis (clinic n = 49; online n = 89). Of the cannabis users, 36.8% of clinic and 75% of online respondents reported that it improved their symptoms. Most of the respondents (from the clinic and online groups) reported that cannabis improved their mood, pain, muscle spasms, and sleep. However, they did not note any improvements for weakness, fatigue, numbness, ambulation, and urination. Overall, the effectiveness of cannabis for CP/CPPS was "somewhat/very effective" (57% clinic; 63% online). There were no differences between side effects or choice of consumption and most reported using cannabis rarely. CONCLUSIONS: These are the first estimates in men suffering from CP/CPPS and suggest that while cannabis use is prevalent, its medical use and benefit are unknown. This is an understudied area and the benefit or hazard for cannabis use awaits further study.

Tsai SY, Yang TY, Chen HJ, Chen CS, Lin WM, Shen WC, Kuo CN, Kao CH.	Department of Laboratory Medicine, Mackay Memorial Hospital, Taipei, Taiwan	Increased risk of chronic fatigue syndrome following herpes zoster: a population-based study.	Eur J Clin Microbiol Infect Dis. 2014 Sep;33(9):1653-9. doi: 10.1007/s10096-014-2095-x. Epub 2014 Apr 9. Erratum in: Eur J Clin Microbiol Infect Dis. 2014 Sep;33(9):1661.	Chronic fatigue syndrome (CFS) is a complex disorder accompanied by unexplainable persistent fatigue, in which several etiological factors exist, such as viral infections. Using the National Health Insurance Research Database (NHIRD) of Taiwan, this study evaluated the association between herpes zoster (HZ) infection and the risk of CFS, and examined the possibility of patients developing postviral fatigue effects, including the possibility of developing other unexplainable chronic fatigue conditions. In this prospective cohort study using the NHIRD, we identified 9,205 patients with HZ infection [ICD-9 (International Classification of Disease, Ninth Revision), code 053] and 36,820 patients without HZ infection (non-HZ) from 2005 to 2007, and followed up to the end of 2010. The incidence rate of CFS was higher in the HZ cohort than in the non-HZ cohort (4.56 vs. 3.44 per 1,000 person-years), with an adjusted hazard ratio of 1.29 [95 % confidence interval (CI) = 1.09-1.53]. It was shown that the risk of CFS without comorbidity for each patient increased from 1.25- to 1.36-fold between the CFS and non-CFS cohorts; with long-term follow-up, the HZ cohort showed a significantly higher cumulative incidence rate of developing CFS than the non-HZ patients. We propose that patients with chronic fatigue might exist in a subset of patients that would be associated with HZ infection. The actual mechanism of development of CFS that is attributed to HZ infection remains unclear. The findings of this population cohort study provide pivotal evidence of postviral fatigue among patients with HZ infection.
Tschudi-Madsen H, Kjeldsberg M, Natvig B, Ihlebaek C, Straand J, Bruusgaard D.	Department of General Practice, Institute of Health and Society, Faculty of Medicine, University of Oslo, PO Box 1130, Blindern, N-0318 Oslo	Medically unexplained conditions considered by patients in general practice.	Fam Pract. 2014 Apr;31(2):156-63. doi: 10.1093/fampra/cmt081. Epub 2013 Dec 24.	BACKGROUND: Patients frequently present with multiple and 'unexplained' symptoms, often resulting in complex consultations. To better understand these patients is a challenge to health care professionals, in general, and GPs, in particular. OBJECTIVES: In our research on symptom reporting, we wanted to explore whether patients consider that they may suffer from conditions commonly regarded as unexplained, and we explored associations between these concerns and symptom load, life stressors and socio-demographic factors. METHODS: Consecutive, unselected patients in general practice completed questionnaires addressing eight conditions commonly regarded as unexplained (amalgam poisoning, Candida syndrome, fibromyalgia, food intolerance, electromagnetic hypersensitivity, burnout syndrome, chronic fatigue syndrome and irritable bowel syndrome). With logistic regression, we analysed associations with symptom load, burden of life stressors with negative impact on present health and socio-demographic variables. RESULTS: Out of the 909 respondents (response rate = 88.8%), 863 had complete data. In total, 39.6% of patients had considered that they may suffer from one or more unexplained conditions (UCs). These concerns were strongly and positively associated with recent symptom load and number of life stressors. If we excluded burnout and food intolerance, corresponding associations were found. CONCLUSION: Patients frequently considered that they may suffer from UCs. The likelihood of such concerns strongly increased with an increasing symptom load and

				with the number of life stressors with negative impact on present health. Hence, the number of symptoms may be a strong indicator of whether patients consider their symptoms part of such often controversial multisymptom conditions.

A definition of recovery in myalgic encephalomyelitis and chronic fatigue syndrome should be based upon objective measures.	Qual Life Res. 2014 Nov;23(9):2417-8. doi: 10.1007/s11136-014-0737-1. Epub 2014 Jun 17.	Comment in Qual Life Res. 2014 Nov;23(9):2419. Comment on Qual Life Res. 2014 Nov;23(9):2407-16. INTRODUCTION: Adamowicz and colleagues recently proposed to use "a consistent definition of recovery that captures a broad-based return to health with assessments of both fatigue and function as well as the patients' perceptions of his/her recovery status" for patients with chronic fatigue syndrome (CFS). METHODS: A qualitative analysis of case definitions for Myalgic encephalomyelitis (ME) and CFS and methods to assess the symptoms and clinical status of ME and CFS patients objectively. RESULTS: The criteria of CFS define a heterogeneous disorder. ME, often used interchangeably with CFS, is principally defined by muscle weakness, cognitive impairment etc., but above all post-exertional "malaise": a long-lasting increase in symptoms, e.g. muscle pain and cognitive deficits, after a minor exertion. The principle symptom of CFS however is "chronic fatigue". Since post-exertional "malaise" is not obligatory for CFS, only part of the CFS patients meet the diagnostic criteria for ME, while not all ME patients qualify as CFS patients. There are several accepted methods to assess characteristic symptoms and the clinical status of ME and CFS patients using objective measures, e.g. (repeated) cardiopulmonary exercise tests. CONCLUSION: To resolve the debate about the clinical status,

				proposed effectiveness of therapies and recovery in ME and CFS, it is crucial to accurately diagnose patients using well-defined criteria for ME and CFS and an objective assessment of various typical symptoms, since subjective measures such as "fatigue" will perpetuate the debate.
Twisk FN.	ME-de-patiënten Foundation, The Netherlands. Electronic address: frank.twisk@hetnet.	Underperformance of myalgic encephalomyelitis (ME)/chronic fatigue syndrome (CFS) patients at neurocognitive tests should be assessed objectively without an a priori judgment about the etiology. Twisk FN.	ME-de-Patiënten Foundation Limmen, Netherlands.	The status of and future research into Myalgic Encephalomyelitis and Chronic Fatigue Syndrome: the need of accurate diagnosis, objective assessment, and acknowledging biological and clinical subgroups.	Front Physiol. 2014;5:109. doi: 10.3389/fphys.2014.00109.	Although Myalgic Encephalomyelitis (ME) and Chronic Fatigue Syndrome (CFS) are used interchangeably, the diagnostic criteria define two distinct clinical entities. Cognitive impairment, (muscle) weakness, circulatory disturbances, marked variability of symptoms, and, above all, post-exertional malaise: a long-lasting increase of symptoms after a minor exertion, are distinctive symptoms of ME. This latter phenomenon separates ME, a neuro-immune illness, from chronic fatigue (syndrome), other disorders and deconditioning. The introduction of the label, but more importantly the diagnostic criteria for CFS has generated much confusion, mostly because chronic fatigue is a subjective and ambiguous notion. CFS was redefined in 1994 into unexplained (persistent or relapsing) chronic fatigue, accompanied by at least four out of eight symptoms, e.g., headaches and unrefreshing sleep. Most of the research into ME and/or CFS in the last decades was based upon the multivalent CFS criteria, which define a heterogeneous patient group. Due to the fact that fatigue and other symptoms are non-discriminative, subjective experiences, research has been hampered. Various authors have questioned the physiological nature of the symptoms and qualified ME/CFS as somatization. However, various typical symptoms can be assessed objectively using standardized methods. Despite subjective and unclear criteria and measures, research has observed specific abnormalities in ME/CFS repetitively, e.g., immunological abnormalities, oxidative and nitrosative stress, neurological anomalies, circulatory deficits and mitochondrial dysfunction. However, to improve future research standards and patient care, it is crucial that patients with post-exertional malaise (ME) and patients without this odd phenomenon are

				acknowledged as separate clinical entities that the diagnosis of ME and CFS in research and clinical practice is based upon accurate criteria and an objective assessment of characteristic symptoms, as much as possible that well-defined clinical and biological subgroups of ME and CFS patients are investigated in more detail, and that patients are monitored before, during and after interventions with objective measures and biomarkers.
Tzanis G, Dimopoulos S, Agapitou V, Nanas S.	(1) 1st Critical Care Medicine Department, Cardiopulmonary Exercise Testing and Rehabilitation Laboratory, "Evgenidio Hospital", National & Kapodestrian University of Athens, Papadiamantopoulou str., 20, Athens, 11528, Greece.	Exercise intolerance in chronic heart failure: the role of cortisol and the catabolic state.	Curr Heart Fail Rep. 2014 Mar;11(1):70-9. doi: 10.1007/s11897-013-0177-1. Review.	Chronic heart failure (CHF) is a complex clinical syndrome leading to exercise intolerance due to muscular fatigue and dyspnea. Hemodynamics fail to explain the reduced exercise capacity, while a significant skeletal muscular pathology seems to constitute the main underlying mechanism for exercise intolerance in CHF patients. There have been proposed several metabolic, neurohormonal and immune system abnormalities leading to an anabolic/catabolic imbalance that plays a central role in the pathogenesis of the wasting process of skeletal muscle myopathy. The impairment of the anabolic axes is associated with the severity of symptoms and the poor outcome in CHF, whereas increased cortisol levels are predictive of exercise intolerance, ventilatory inefficiency and chronotropic incompetence, suggesting a significant contributing mechanism to the limited functional status. Exercise training and device therapy could have beneficial effects in preventing and treating muscle wasting in CHF. However, specific anabolic treatment needs more investigation to prove possible beneficial effects.
Udovika NO, Romanenko Ilu, Lieonov OO.	No address given	Effectiveness of medical rehabilitation of women of reproductive age with fatigue syndrome.	Lik Sprava. 2014 Mar-Apr;(3-4):78-82.	[Article in Ukrainian] Efficacy Erbisol in combination with Lymphomyosot and Echinacea compositum C in medical rehabilitation of women of reproductive age with fatigue syndrome and chronic gynecological pathology was studied. It was found that this complex of medications promotes faster and more effective reduction of the level of circulating immune complexes in the serum, achievement of persistent clinical remission of disease and liquidation of fatigue syndrome manifestations, what improves the quality of life of patients.
Van Cauwenbergh D, Nijs J, Kos D, Van Weijnen L, Struyf F, Meeus M.	(1)Pain in Motion Research Group, Departments of Human Physiology and Rehabilitation Sciences, Faculty of Physical Education & Physiotherapy, Vrije Universiteit Brussel, Brussel, Belgium; Pain in Motion Research	Malfunctioning of the autonomic nervous system in patients with chronic fatigue syndrome: a systematic literature review.	Eur J Clin Invest. 2014 May;44(5):516-26. doi: 10.1111/eci.12256. Review.	INTRODUCTION: It is hypothesised that the autonomic nervous system responds differently to various stressors in patients with chronic fatigue syndrome (CFS) compared with healthy controls. The goal is to systematically review the scientific literature addressing the functioning of the autonomic nervous system in patients with CFS. MATERIALS AND METHODS: All studies that were identified through electronic databases (PubMed and Web of Science) were screened for eligibility based on the selection criteria and assessed (two independent raters) for methodological quality using a methodological checklist for case-control studies. RESULTS: Twenty-seven case-control studies were included. The methodological quality varied between 50% and 71·4%. Some studies showed different responses to head-up tilt and other autonomous testing. CONCLUSION: Although comparison

	Group, Faculty of Medicine and Health Sciences, University of Antwerp, Antwerp, Belgium.			between the included case-control studies was difficult, we can conclude that there are differences in autonomous response between patients with CFS and healthy controls. The heart rate dynamic response during the head-up tilt test differs between patients with CFS and healthy controls, supporting the increased prevalence of postural orthostatic tachycardia syndrome. The autonomic response can be useful for the diagnosis of CFS.
Van den Bergh M, Bauer FA, Posteraro AF, Thumma S, Dasanu CA.	No address given	An unusual presentation of Kikuchi-Fujimoto disease.	Conn Med. 2014 Apr;78(4):225-8.	Kikuchi-Fujimoto disease (KFD), also known as histiocytic necrotizing lymphadenitis, is a rare, self-limited disease of unknown etiology. This condition is most commonly encountered in Asian and Caucasian females of childbearing age who usually present with cervical lymphadenopathy and fever. Though rarely, KFD has been described in younger African-American females as well. It often mimics more serious conditions such as lymphoma, metastatic solid malignancy, HIV infection, tuberculosis, sarcoidosis, or systemic lupus erythematosus. Although its etiopathogenesis has not been fully elucidated, literature suggests viral or possibly autoimmune components to play a role. We describe a 34-year-old African-American female who presented with constitutional symptoms and polyadenopathy on clinical examination and imaging, of which the portacaval and portahepatis lymph nodes were most prominent. An extensive workup was otherwise unremarkable, and biopsy showed histiocytic necrotizing lymphadenitis. Initially, her clinical condition improved spontaneously, and she required only a short course of oral steroids. Three months later, she relapsed with bilateral cervical adenopathy and constitutional symptoms and was successfully managed again with steroids. Our case is unique with respect to (a) portahepatis and portacaval node enlargement as the dominant adenopathy and (b) her underlying conditions of fibromyalgia and chronic fatigue syndrome.
van Leeuwen N, Bossema ER, Knoop H, Kruize AA, Bootsma H, Bijlsma JW, Geenen R.	Department of Clinical and Health Psychology, Utrecht University, Department of Rheumatology and Clinical Immunology, University Medical Center Utrecht, Utrecht,	Psychological profiles in patients with SjÃ¶gren's syndrome related to fatigue: a cluster analysis.	Rheumatology (Oxford). 2014 Oct 6. doi:pii: keu387.	OBJECTIVE: Fatigue is a highly prevalent and debilitating symptom in the autoimmune disease SS. Although the disease process plays a role in fatigue, psychological factors may influence fatigue and the ability to deal with its consequences. Profiles of co-occurring psychological factors may suggest potential targets for the treatment of fatigue. The aim of this study was to identify psychological profiles in patients with SS and the accompanying levels of fatigue. METHODS: Three hundred patients with primary SS (mean age 57 years, 93% female) completed questionnaires on fatigue (multidimensional fatigue inventory), physical activity cognitions (TAMPA-SK), illness cognitions, cognitive regulation, emotion processing and regulation [Toronto Alexithymia Scale 20, Emotion Regulation Questionnaire (ERQ), Berkeley Expressivity Questionnaire], coping strategies (Brief COPE) and social support. RESULTS: Principal axis factor analysis (oblimin rotation) yielded six psychological factors: social support, negative thinking, positive thinking, emotional expressivity, avoidance and alexithymia (i.e. the inability to differentiate emotions). Using cluster analyses, these factors were

				grouped in four psychological profiles: functional (39%), alexithymic (27%), self-reliant (23%) and dysfunctional (11%). Irrespective of the psychological profile, the level of fatigue was substantially higher in patients than in the general population. Patients with a dysfunctional or an alexithymic profile reported more fatigue than those with a self-reliant profile. CONCLUSION: Our study in SS yielded four psychological profiles that were differentially associated with fatigue. These profiles can be used to examine determinants and prognosis of fatigue as well as the possibility of customizing cognitive behavioural interventions for chronic fatigue.
van Tilburg MA, Zaki EA, Venkatesan T, Boles RG.	Center for Functional GI and Motility Disorders, University of North Carolina, 130 Mason Farm Rd #4106, Chapel Hill, NC, 27599-7080, USA, tilburg@med.unc.edu.	Irritable bowel syndrome may be associated with maternal inheritance and mitochondrial DNA control region sequence variants.	Dig Dis Sci. 2014 Jul;59(7):1392-7. doi: 10.1007/s10620-014-3045-2. Epub 2014 Feb 6.	BACKGROUND AND AIM: Mitochondrial dysfunction has been implicated in various functional disorders that are co-morbid to irritable bowel syndrome (IBS) such as migraine, depression and chronic fatigue syndrome. The aim of the current case-control pilot study was to determine if functional symptoms in IBS show a maternal inheritance bias, and if the degree of this maternal inheritance is related to mitochondrial DNA (mtDNA) polymorphisms. METHODS: Pedigrees were obtained from 308 adult IBS patients, 102 healthy controls, and 36 controls with inflammatory bowel disease (IBD), all from Caucasian heritage, to determine probable maternal inheritance. Two mtDNA polymorphisms (16519T and 3010A), which have previously been implicated in other functional disorders, were assayed in mtDNA haplogroup H IBS subjects and compared to genetic data from 344 published haplogroup H controls. RESULTS: Probable maternal inheritance was found in 17.5 % IBS, 2 % healthy controls and 0 % IBD controls ($p < .0001$). No difference was found between IBS and control for 3010A, and a trend was found for 16519T ($p = 0.05$). IBS with maternal inheritance were significantly more likely to have the 16519T than controls (OR 5.8; 95 % CI 1.5-23.1) or IBS without maternal inheritance (OR 5.2; 95 % CI 1.2-22.6). CONCLUSIONS: This small pilot study shows that a significant minority (1/6) of IBS patients have pedigrees suggestive of maternal inheritance. The mtDNA polymorphism 16519T, which has been previously implicated in other functional disorders, is also associated with IBS patients who display maternal inheritance. These findings suggest that mtDNA-related mitochondrial dysfunction may constitute a sub-group within IBS. Future replication studies in larger samples are needed.
Vasiadi M, Newman J, Theoharides TC.	No address given	Isoflavones inhibit poly(I:C)-induced serum, brain, and skin inflammatory mediators - relevance to chronic fatigue syndrome.	J Neuroinflammation. 2014 Oct 31;11(1):168.	BackgroundChronic Fatigue Syndrome (CFS) is a neuroimmunoendocrine disease affecting about 1% of the US population, mostly women. It is characterized by debilitating fatigue for six or more months in the absence of cancer or other systemic diseases. Many CFS patients also have fibromyalgia and skin hypersensitivity that worsen with stress. Corticotropin-releasing hormone (CRH) and neurotensin (NT), secreted under stress, activate mast cells (MC) necessary for allergic reactions to release inflammatory mediators that could contribute to CFS

				symptoms.ObjectiveTo investigate the effect of isoflavones on the action of polyinosinic:polycytidylic acid (poly(I:C)), with or without swim stress, on mouse locomotor activity and inflammatory mediator expression, as well as on human MC activation.MethodsFemale C57BL/6 mice were randomly divided into four groups: (a) control/no-swim, (b) control/swim, (c) poly(I:C)/no swim, and (d) poly(I:C)/swim. Mice were provided with chow low or high in isoflavones for 2 weeks prior to ip injection with 20 mg/kg poly(I:C) followed or not by swim stress for 15 minutes. Locomotor activity was monitored overnight and animals were sacrificed the following day. Brain and skin gene expression, as well as serum levels, of inflammatory mediators were measured. Data were analyzed using the non-parametric Mann-Whitney U-test.ResultsPoly(I:C)-treated mice had decreased locomotor activity over 24 hours, and increased serum levels of TNF-¿, IL-6, KC (IL-8/CXCL8 murine homolog), CCL2,3,4,5, CXCL10, as well as brain and skin gene expression of TNF, IL-6, KC (Cxcl1, IL8 murine homolog), CCL2, CCL4, CCL5 and CXCL10. Histidine decarboxylase (HDC) and NT expression were also increased, but only in the skin, over the same period. High isoflavone diet reversed these effects.Conclusion -Poly(I:C) treatment decreased mouse locomotor activity and increased serum levels and brain and skin gene expression of inflammatory mediators. These effects were inhibited by isoflavones that may prove useful in CFS.
Vergauwen K, Huijnen IP, Kos D, Van de Velde D, van Eupen I, Meeus M.	Faculty of Medicine and Health Sciences, Department of Occupational Therapy, Ghent University , Ghent , Belgium .	Assessment of activity limitations and participation restrictions with persons with chronic fatigue syndrome: a systematic review.	Disabil Rehabil. 2014 Nov 3:1-11.	Abstract Purpose: To summarize measurement instruments used to evaluate activity limitations and participation restrictions in patients with chronic fatigue syndrome (CFS) and review the psychometric properties of these instruments. Method: General information of all included measurement instruments was extracted. The methodological quality was evaluated using the COSMIN checklist. Results of the measurement properties were rated based on the quality criteria of Terwee et al. Finally, overall quality was defined per psychometric property and measurement instrument by use of the quality criteria by Schellingerhout et al. Results: A total of 68 articles were identified of which eight evaluated the psychometric properties of a measurement instrument assessing activity limitations and participation restrictions. One disease-specific and 37 generic measurement instruments were found. Limited evidence was found for the psychometric properties and clinical usability of these instruments. However, the CFS-activities and participation questionnaire (APQ) is a disease-specific instrument with moderate content and construct validity. Conclusion: The psychometric properties of the reviewed measurement instruments to evaluate activity limitations and participation restrictions are not sufficiently evaluated. Future research is needed to evaluate the psychometric properties of the measurement instruments, including the other properties of the CFS-APQ. If it is necessary to use a measurement instrument, the CFS-APQ is recommended. Implications for Rehabilitation Chronic fatigue syndrome (CFS). Chronic fatigue syndrome causes activity limitations and participation restrictions in one or more

				areas of life. Standardized, reliable and valid measurement instruments are necessary to identify these limitations and restrictions. Currently, no measurement instrument is sufficiently evaluated with persons with CFS. If a measurement instrument is needed to identify activity limitations and participation restrictions with persons with CFS, it is recommended to use the CFS-APQ in clinical practice and scientific research.
Vermeulen RC, Vermeulen van Eck IW.	CFS/ME Medical Centre Amsterdam, Waalstraat 25-31, Amsterdam 1078BR, Netherlands. rv@cvscentrum.nl.	Decreased oxygen extraction during cardiopulmonary exercise test in patients with chronic fatigue syndrome.	J Transl Med. 2014 Jan 23;12:20. doi: 10.1186/1479-5876-12-20.	BACKGROUND: The insufficient metabolic adaptation to exercise in Chronic Fatigue Syndrome (CFS) is still being debated and poorly understood. METHODS: We analysed the cardiopulmonary exercise tests of CFS patients, idiopathic chronic fatigue (CFI) patients and healthy visitors. Continuous non-invasive measurement of the cardiac output by Nexfin (BMEYE B.V. Amsterdam, the Netherlands) was added to the cardiopulmonary exercise tests. The peak oxygen extraction by muscle cells and the increase of cardiac output relative to the increase of oxygen uptake ($\Delta Q'/\Delta V'O_2$) were measured, calculated from the cardiac output and the oxygen uptake during incremental exercise. RESULTS: The peak oxygen extraction by muscle cells was 10.83 ± 2.80 ml/100ml in 178 CFS women, 11.62 ± 2.90 ml/100 ml in 172 CFI, and 13.45 ± 2.72 ml/100 ml in 11 healthy women (ANOVA: P=0.001), 13.66 ± 3.31 ml/100 ml in 25 CFS men, 14.63 ± 4.38 ml/100 ml in 51 CFI, and 19.52 ± 6.53 ml/100 ml in 7 healthy men (ANOVA: P=0.008).The $\Delta Q'/\Delta V'O_2$ was > 6 L/L (normal $\Delta Q'/\Delta V'O_2 \approx 5$ L/L) in 70% of the patients and in 22% of the healthy group. CONCLUSION: Low oxygen uptake by muscle cells causes exercise intolerance in a majority of CFS patients, indicating insufficient metabolic adaptation to incremental exercise. The high increase of the cardiac output relative to the increase of oxygen uptake argues against deconditioning as a cause for physical impairment in these patients.
Vishnu VY, Modi M, Prabhakar S, Bhansali A, Goyal MK.	Department of Neurology, Post Graduate Institute of Medical Education and Research, Chandigarh 160012, India. Electronic address: vishnuvy16@yahoo.com.	A" motor neuron disease."	J Neurol Sci. 2014 Jan 15;336(1-2):251-3. doi: 10.1016/j.jns.2013.10.003. Epub 2013 Oct 8.	IMPORTANCE: Allgrove syndrome is a rare autosomal recessive disorder characterised by achalasia, alacrima, adrenal insufficiency, autonomic dysfunction and amyotrophy. The syndrome has been described in childhood and adult presentation, as in our case, is very rare. There is a considerable delay in diagnosis due to lack of awareness about the syndrome. OBSERVATIONS: We report a single case of a 36 year old man who was initially diagnosed and treated for achalasia cardia in our institute 14 years before. After 8 years he presented again with weakness and wasting predominantly distally. He had tongue fasciculations, brisk reflexes and extensor plantar. After supportive electrophysiological studies he was diagnosed as Amyotrophic lateral sclerosis. After 5 years he presented with generalised fatigue without any significant worsening of his neurological status. On reevaluation he had alacrimia, autonomic dysfunction and mild ACTH resistance. CONCLUSIONS AND RELEVANCE: Allgrove syndrome may be an underdiagnosed cause of multisystem neurological disease due to the heterogeneous clinical presentation as well as for ignorance of clinician about the syndrome. Based on our

				case, we also believe that there does exist a subgroup of patients who follow a less severe and chronic course. Recognition of syndrome allows for treatment of autonomic dysfunction, adrenal insufficiency and dysphagia.

Walter SM.	West Virginia University School of Nursing, PO Box 9640, 6400 Health Sciences South, Morgantown, WV 26506-9640, USA.	Case Report: Ehlers-Danlos Syndrome in an adolescent presenting with Chronic Daily Headache.	Surg Neurol Int. 2014;5(Suppl 13):S475-8. doi: 10.4103/2152-7806.144629.	BACKGROUND: Classic Ehlers-Danlos syndrome (EDS) is a connective tissue disorder characterized by skin hyperextensibility, skin fragility as well as joint hypermobility. EDS has been associated with psychiatric disorders, fatigue, dizziness, musculoskeletal pain, and stomach pain that are common complaints associated with adolescent chronic daily headache (CDH). This case report discusses an adolescent who presents with CDH and is subsequently diagnosed with EDS based upon the presenting symptoms for headache including syncope and chronic musculoskeletal pain as well as a history of hypermobility. CASE DESCRIPTION: A 15-year-old female presented to an outpatient headache clinic with a 10-year history of headache, which had become daily over the past 3 months and awakened her in the middle of the night. Past history also revealed chronic musculoskeletal pain, syncope, fatigue, and hypermobility of joints. Subsequent referral to a geneticist confirmed mild classic EDS. CONCLUSION: Along with the major manifestation of EDS, other signs and symptoms that characterize this disorder include musculoskeletal pain, fatigue, dizziness/vertigo, depression, and anxiety, which are often associated with CDH in adolescents. Clinicians treating CDH need to be aware of the major clinical manifestations of EDS as well as the other signs and symptoms that characterize both of these chronic pain disorders. An understanding of this syndrome will lead not only to a diagnosis of EDS but also initiation of a treatment plan specific for an adolescent with CDH and EDS.

Wang C, Xie WJ, Liu M, Yan J, Zhang JL, Liu Z, Guo LN.	No address given	Effect of manual acupuncture stimulation of Baihui" (GV 20)	Zhen Ci Yan Jiu. 2014 Oct;39(5):387-9.	[Article in Chinese] OBJECTIVE: To observe the effect of manual acupuncture stimulation of "Baihui" (GV 20), etc. on serum IFN- gamma and IL-4 contents in rats with chronic fatigue syndrome (CFS). METHODS: A total of 24 male SD rats were equally randomized into control group, model group and acupuncture group. CFS model was established by bounding and forced swimming in cold water once daily for 14 days. Rats in the acupuncture group were treated by manual acupuncture stimulation of bilateral "Zusanli" (ST 36), "Baihui" (GV 20), and "Guanyuan" (CV 4), once daily for 14 days. Serum IFN-gamma and IL-4 contents were detected by ELISA. RESULTS: Compared with the control group, the contention of serum IFN-gamma and ratio of IFN-gamma/IL-4 were significant decreased in the model group (P<0.01). While in comparison with the model group, the contention of IFN-gamma and ratio of IFN-gamma/IL-4 were obviously increased in the acupuncture group (P<0.05). No significant differences were found among the three groups in serum IL-4 levels (P>0.05). CONCLUSION: Manual acupuncture can inhibit CFS induced reduction of serum IFN-gamma level and the ratio of IFN-gamma/IL-4 in CFS rats, suggesting a favorable adjustment of acupuncture intervention for CFS by balancing the ratio of IFN-gamma/IL-4.
Wang H, Liu X, Lv B, Yang F, Hong Y.	(1)College of Computer Science and Technology, Huaqiao University, Xiamen, China. (2)School of Information Science and Engineering, Xiamen University, Xiamen, China. (3)Department of traditional Chinese medicine, Xiamen University, Xiamen, China.	Reliable multi-label learning via conformal predictor and random forest for syndrome differentiation of chronic fatigue in traditional Chinese medicine.	PLoS One. 2014;9(6):e99565. doi: 10.1371/journal.pone.0099565.	OBJECTIVE: Chronic Fatigue (CF) still remains unclear about its etiology, pathophysiology, nomenclature and diagnostic criteria in the medical community. Traditional Chinese medicine (TCM) adopts a unique diagnostic method, namely 'bian zheng lun zhi' or syndrome differentiation, to diagnose the CF with a set of syndrome factors, which can be regarded as the Multi-Label Learning (MLL) problem in the machine learning literature. To obtain an effective and reliable diagnostic tool, we use Conformal Predictor (CP), Random Forest (RF) and Problem Transformation method (PT) for the syndrome differentiation of CF. METHODS AND MATERIALS: In this work, using PT method, CP-RF is extended to handle MLL problem. CP-RF applies RF to measure the confidence level (p-value) of each label being the true label, and then selects multiple labels whose p-values are larger than the pre-defined significance level as the region prediction. In this paper, we compare the proposed CP-RF with typical CP-NBC(Naïve Bayes Classifier), CP-KNN(K-Nearest Neighbors) and ML-KNN on CF dataset, which consists of 736 cases. Specifically, 95 symptoms are used to identify CF, and four syndrome factors are employed in the syndrome differentiation, including 'spleen deficiency', 'heart deficiency', 'liver stagnation' and 'qi deficiency'. THE RESULTS: CP-RF demonstrates an outstanding performance beyond CP-NBC, CP-KNN and ML-KNN under the general metrics of subset accuracy, hamming loss, one-error, coverage, ranking loss and average precision. Furthermore, the performance of CP-RF remains steady at the large scale of confidence levels from 80% to 100%, which indicates its

				robustness to the threshold determination. In addition, the confidence evaluation provided by CP is valid and well-calibrated. CONCLUSION: CP-RF not only offers outstanding performance but also provides valid confidence evaluation for the CF syndrome differentiation. It would be well applicable to TCM practitioners and facilitate the utilities of objective, effective and reliable computer-based diagnosis tool.
Wang J, Sun C, Zheng Y, Pan H, Zhou Y, Fan Y.	Jilin Province Key Laboratory on Chemistry and Biology of Changbai Mountain Natural Drugs School of Life Sciences, Northeast Normal University, Changchun, 130024, People's Republic of China.	The effective mechanism of the polysaccharides from Panax ginseng on chronic fatigue syndrome.	Arch Pharm Res. 2014 Apr;37(4):530-8. doi: 10.1007/s12272-013-0235-y. Epub 2013 Aug 21.	Ginseng acidic polysaccharide WGPA isolated from the root of Panax ginseng C. A. Meyer was fractionated into WGPA-A and WGPA-N by anion-exchange chromatography. The antifatigue activity of ginseng acidic polysaccharide WGPA has been reported in our previous research. This present study was designed to identify its active component and elucidate the mechanism for preventing chronic fatigue syndrome (CFS). WGPA, WGPA-A and WGPA-N were orally administered to mice once daily for 15 days. The effects of these compounds on physiological biomarkers of oxidative stress and on the morphology of the mitochondria in striated skeletal muscle were assessed. The results of forced swimming test-induced indicated that WGPA and WGPA-A could lengthen the swimming time, while WGPA-N could not. In addition, malondialdehyde and lactate dehydrogenase levels in serum were enhanced; while those of superoxide dismutase and glutathione peroxidase were lowered. Interestingly, the structural degeneration of mitochondria were all ameliorated. These findings suggested that WGPA-A is the active component of WGPA, it might have potential therapeutic effects for CFS and the oxidative stress might be involved in the pathogenesis. Our results also provided essential data for a better understanding of the antifatigue effects of P. ginseng extracts.
Wang W, Russell A, Yan Y; Global Health Epidemiology Reference Group (GHERG).	School of Medical Sciences, Edith Cowan University, Perth, Western Australia WA6027, Australia. wei.wang@ecu.edu.au.	Traditional Chinese medicine and new concepts of predictive, preventive and personalized medicine in diagnosis and treatment of suboptimal health.	EPMA J. 2014 Feb 13;5(1):4. doi: 10.1186/1878-5085-5-4. Erratum in: EPMA J. 2014;5(1):12.	BACKGROUND: The premise of disease-related phenotypes is the definition of the counterpart normality in medical sciences. Contrary to clinical practices that can be carefully planned according to clinical needs, heterogeneity and uncontrollability is the essence of humans in carrying out health studies. Full characterization of consistent phenotypes that define the general population is the basis to individual difference normalization in personalized medicine. Self-claimed normal status may not represent health because asymptomatic subjects may carry chronic diseases at their early stage, such as cancer, diabetes mellitus and atherosclerosis. Currently, treatments for non-communicable chronic diseases (NCD) are implemented after disease onset, which is a very much delayed approach from the perspective of predictive, preventive and personalized medicine (PPPM). A NCD pandemic will develop and be accompanied by increased global economic burden for healthcare systems throughout both developed and developing countries. This paper examples the characterization of the suboptimal health status (SHS) which represents a new PPPM challenge in a population with ambiguous health complaints such as general weakness, unexplained medical syndrome (UMS), chronic fatigue syndrome (CFS), myalgic encephalomyelitis (ME), post-viral fatigue syndrome (PVFS) and chronic

				fatigue immune dysfunction syndrome (CFIDS). METHODS: We applied clinical informatic approaches and developed a questionnaire-suboptimal health status questionnaire-25 (SHSQ-25) for measuring SHS. The validity and reliability of this approach were evaluated in a small pilot study and then in a cross-sectional study of 3,405 participants in China. RESULTS: We found a correlation between SHS and systolic blood pressure, diastolic blood pressure, plasma glucose, total cholesterol and high-density lipoprotein (HDL) cholesterol among men, and a correlation between SHS and systolic blood pressure, diastolic blood pressure, total cholesterol, triglycerides and HDL cholesterol among women. CONCLUSIONS: The SHSQ-25 is a self-rated questionnaire of perceived health complaints, which can be used as a new instrument for PPPM. An ongoing longitudinal SHS cohort survey (China Sub-optimal Health Cohort Study, COACS) consisting of 50,000 participants will provide a powerful health trial to use SHSQ-25 for its application to PPPM through patient stratification and therapy monitoring using innovative technologies of predictive diagnostics and prognosis: an effort of paradigm shift from reactive to predictive medicine.
Wang YY, Li XX, Liu JP, Luo H, Ma LX, Alraek T.	Center for Evidence-Based Medicine, Beijing University of Chinese Medicine, Beijing, China	Traditional Chinese medicine for chronic fatigue syndrome: a systematic review of randomized clinical trials.	Complement Ther Med. 2014 Aug;22(4):826-33. doi: 10.1016/j.ctim.2014.06.004. Epub 2014 Jun 30.	BACKGROUND: There is no curative treatment for chronic fatigue syndrome (CFS). Traditional Chinese medicine (TCM) is widely used in the treatment of CFS in China. OBJECTIVE: To evaluate the effectiveness and safety of TCM for CFS. METHODS: The protocol of this review is registered at PROSPERO. We searched six main databases for randomized clinical trials (RCTs) on TCM for CFS from their inception to September 2013. The Cochrane risk of bias tool was used to assess the methodological quality. We used RevMan 5.1 to synthesize the results. RESULTS: 23 RCTs involving 1776 participants were identified. The risk of bias of the included studies was high. The types of TCM interventions varied, including Chinese herbal medicine, acupuncture, qigong, moxibustion, and acupoint application. The results of meta-analyses and several individual studies showed that TCM alone or in combination with other interventions significantly alleviated fatigue symptoms as measured by Chalder's fatigue scale, fatigue severity scale, fatigue assessment instrument by Joseph E. Schwartz, Bell's fatigue scale, and guiding principle of clinical research on new drugs of TCM for fatigue symptom. There was no enough evidence that TCM could improve the quality of life for CFS patients. The included studies did not report serious adverse events. CONCLUSIONS: TCM appears to be effective to alleviate the fatigue symptom for people with CFS. However, due to the high risk of bias of the included studies, larger, well-designed studies are needed to confirm the potential benefit in the future.
Warren JW, Clauw DJ, Wesselmann U, Howard FM, Gallicchio L,	Department of Medicine, University of Maryland School of Medicine, United	Functional somatic syndromes as risk factors for hysterectomy in early	J Psychosom Res. 2014 Nov;77(5):363-7. doi: 10.1016/j.jpsychores.2014.09.004. Epub 2014 Sep 16.	OBJECTIVE: We tested the hypothesis that functional somatic syndromes (FSSs) are risk factors for hysterectomy in early bladder pain syndrome/interstitial cystitis (BPS/IC). METHODS: In 312 women with incident BPS/IC, we diagnosed seven pre-BPS/IC syndromes: chronic pelvic pain (CPP), fibromyalgia, chronic fatigue

Morozov V.	States; Department of Epidemiology and Public Health, University of Maryland School of Medicine, United States. Electronic address: jwarren@medicine.umaryland.edu.	bladder pain syndrome/interstitial cystitis.		syndrome, irritable bowel syndrome (IBS), sicca syndrome, migraine, and panic disorder. Each was defined as present before 12months (existing syndrome) or onset within 12months (new syndrome) prior to BPS/IC onset. Retrospectively, we sought associations between prior hysterectomy and existing FSSs. Prospectively we studied associations of existing and new syndromes with subsequent hysterectomy. Logistic regression analyses adjusted for age, race, menopause and education. RESULTS: The retrospective study showed prior hysterectomy (N=63) to be associated with existing CPP and the presence of multiple existing FSSs. The prospective study revealed that 30/249 women with a uterus at baseline (12%) underwent hysterectomy in early BPS/IC. This procedure was associated with new CPP (OR 6.0; CI 2.0, 18.2), new IBS (OR 5.4; CI 1.3, 22.3), and ≥3 existing FSSs (OR 3.9; CI 1.1, 13.9). CONCLUSION: Accounting for CPP and IBS, the presence of multiple FSSs (most without pelvic pain) was a separate, independent risk factor for hysterectomy in early BPS/IC. This suggests that patient features in addition to abdominopelvic abnormalities led to this procedure. Until other populations are assessed, a prudent approach to patients who are contemplating hysterectomy (and possibly other surgeries) for pain and who have IBS or numerous FSSs is first to try alternative therapies including treatment of the FSSs.
Warren JW.	Department of Medicine, University of Maryland School of Medicine, 10 South Pine Street, #900, Baltimore, MD 21201, United States; Department of Epidemiology and Public Health, University of Maryland School of Medicine, United States. Electronic address: jwarren@medicine.umaryland.edu.	Bladder pain syndrome/interstitial cystitis as a functional somatic syndrome.	J Psychosom Res. 2014 Dec;77(6):510-5. doi: 10.1016/j.jpsychores.2014.10.003. Epub 2014 Oct 14.	PURPOSE: To determine whether bladder pain syndrome/interstitial cystitis (BPS/IC) has the characteristics of a functional somatic syndrome (FSS). MATERIALS AND METHODS: There is no accepted definition of an FSS. Consequently, this paper reviewed the literature for common FSS characteristics and for reports that BPS/IC has these characteristics. RESULTS: Eleven articles met inclusion and exclusion criteria and yielded 18 FSS characteristics. BPS/IC patients manifest all but two: the exceptions were normal light microscopic anatomy (after hydrodistention under anesthesia, some BPS/IC bladders have Hunner's lesions and most have petechial hemorrhages) and normal laboratory tests (many BPS/IC patients have hematuria). Petechial hemorrhages and hematuria are probably related and may appear during naturally-occurring bladder distention. Without such distention, then, the 90% of BPS/IC patients without a Hunner's lesion have all the characteristics of an FSS. Comparisons in the opposite direction were consistent: several additional features of BPS/IC were found in FSSs. CONCLUSIONS: This systematic but untested method is consistent with but does not test the hypothesis that BPS/IC in some patients might best be understood as an FSS. Like most conditions, BPS/IC is probably heterogeneous; hence only a proportion of BPS/IC cases are likely to be manifestations of an FSS. This hypothesis has several implications. Explorations of processes that connect the FSSs might contribute to understanding the pathogenesis of BPS/IC. Patients with FSSs are at risk for BPS/IC and may benefit from future preventive strategies. Therapies that are useful in FSSs also may be useful in some cases of BPS/IC.

Weidner J, Check JH.	No address given	Marked improvement of the autoimmune syndrome associated with autoimmune hepatitis by treatment with sympathomimetic amines.	Clin Exp Obstet Gynecol. 2014;41(4):460-1.	PURPOSE: To evaluate the effect of sympathomimetic amine therapy for a life threatening autoimmune disorder. MATERIALS AND METHODS: Dextroamphetamine sulfate was used to treat edema, myalgia, and chronic fatigue associated with autoimmune hepatitis (AIH). RESULTS: Sympathomimetic amine therapy completely abrogated the symptoms associated with AIH. CONCLUSIONS: AIH should be added to the long list of chronic treatment-refractory conditions that respond quickly and effectively to treatment with sympathomimetic amines.
Werner R, Meindl-Fridez C, Zimmerli L.	No address given	Chronic fatigue.	Praxis (Bern 1994). 2014 Mar 12;103(6):305-11; quiz 312-3. doi: 10.1024/1661-8157/a001611. Review	[Article in German] No abstract available
Wiborg JF, Wensing M, Tummers M, Knoop H, Bleijenberg G.	Expert Centre for Chronic Fatigue, Radboud University Nijmegen Medical Centre, The Netherlands; Department of Psychosomatic Medicine and Psychotherapy, University Medical Center Hamburg-Eppendorf & Schön Klinik Hamburg-Eilbek, Hamburg, Germany.	Implementing evidence-based practice for patients with chronic fatigue syndrome.	Clin Psychol Psychother. 2014 Mar-Apr;21(2):108-14. doi: 10.1002/cpp.1827. Epub 2012 Dec 11.	The aim of our study was to explore whether community-based mental health care centres (MHCs) are able to implement and sustain cognitive behaviour therapy (CBT) for chronic fatigue syndrome (CFS) with the help of an implementation manual. We monitored the implementation process and treatment outcome data of three Dutch MHCs that implemented or sustained CBT for CFS, one in the context of a stepped care programme. We compared these data with findings of other treatment studies conducted in the context of CBT for CFS. All three MHCs included at least 40 patients with dropout rates between 15% and 35% from intention-to-treat to second assessment. Effect sizes ranged between 0.88 and 1.76 for changes in fatigue severity and 0.43 and 1.23 for changes in physical functioning. With one exception, these outcomes were within the range of our benchmark. Contrary to original expectations, we provided additional implementation support to the two MHCs new with CBT for CFS. We concluded that our implementation manual does not seem to substitute external support for team leaders and associated professions during initial implementation of CBT for CFS but may have the potential to make this assistance more efficient. Particular attention should be paid to challenges of implementing stepped care for CFS.KEY PRACTITIONERS MESSAGE: Implementation of CBT for CFS in community-based MHCs was monitored. External support was provided in addition to an implementation manual during initial implementation of CBT for CFS. Participating MHCs were generally capable of successfully implementing and delivering CBT for CFS. Implementation of low-intensity interventions for CFS might better be postponed until therapists have sufficient experience with conventional CBT for CFS.

Winger A, Ekstedt M, Wyller VB, Helseth S.	Faculty of Nursing, Oslo and Akershus University College of Applied Sciences, Oslo, Norway; Medical Faculty, Institute of Clinical Medicine, University of Oslo, Oslo, Norway.	'Sometimes it feels as if the world goes on without me': adolescents' experiences of living with chronic fatigue syndrome.	J Clin Nurs. 2014 Sep;23(17-18):2649-57. doi: 10.1111/jocn.12522. Epub 2013 Dec 20.	AIMS AND OBJECTIVES: To explore the experience of being an adolescent with chronic fatigue syndrome. BACKGROUND: Despite ample research, chronic fatigue syndrome is still poorly understood, and there are still controversies related to the illness. Adolescents with chronic fatigue syndrome are often unable to attend school and lose social relations with friends. The challenges they face will affect their quality of life. DESIGN: A qualitative, phenomenological hermeneutical design. METHOD: Six boys and twelve girls, aged 12-18, were interviewed, emphasising their own experiences living with chronic fatigue syndrome. Analyses were performed using a phenomenological hermeneutical method. RESULTS: The core theme, 'Sometimes it feels as if the world goes on without me', encompasses the feelings an adolescent living with chronic fatigue syndrome might have about life. The core theme was supported by four subthemes: 'On the side of life--locked in and shut out'; 'the body, the illness and me'; 'if the illness is not visible to others, does it exist?'; and 'handling life while hoping for a better future'. The subthemes reflect the experience of social isolation, their own and others' understanding of the illness and hope for the future. CONCLUSIONS: Not being able to be with friends, or attend school, made the adolescents feel different and forgotten. They felt alienated in their own bodies and were struggling to be visible to themselves and to their surroundings. Spending less time with friends and more time with their parents constituted a threat to independence and development. Yet they managed to envision a better future despite all the difficulties. RELEVANCE FOR CLINICAL PRACTICE: To provide effective support and constructive relations to adolescents with chronic fatigue syndrome, all health professions involved need insight from the persons who are themselves ill. Health centres could function as resource centres for patients and healthcare professionals.
Winger A, Kvarstein G, Wyller VB, Sulheim D, Fagermoen E, SmÃ¥stuen MC, Helseth S.	Faculty of Health Sciences, Institute of Nursing, Oslo and Akershus University College of Applied Sciences, Oslo, Norway.	Pain and pressure pain thresholds in adolescents with chronic fatigue syndrome and healthy controls: a cross-sectional study.	BMJ Open. 2014 Oct 6;4(9):e005920. doi: 10.1136/bmjopen-2014-005920.	OBJECTIVES: Although pain is a significant symptom in chronic fatigue syndrome (CFS), pain is poorly understood in adolescents with CFS. The aim of this study was to explore pain distribution and prevalence, pain intensity and its functional interference in everyday life, as well as pressure pain thresholds (PPT) in adolescents with CFS and compare this with a control group of healthy adolescents (HC). METHODS: This is a case-control, cross-sectional study on pain including 120 adolescents with CFS and 39 HCs, aged 12-18 years. We measured pain frequency, pain severity and pain interference using self-reporting questionnaires. PPT was measured using pressure algometry. Data were collected from March 2010 until October 2012 as part of the Norwegian Study of Chronic Fatigue Syndrome in Adolescents: Pathophysiology and Intervention Trial. RESULTS: Adolescents with CFS had significantly lower PPTs compared with HCs ($p<0.001$). The Pain Severity Score and the Pain Interference Score were significantly higher in adolescents with CFS compared with HCs ($p<0.001$). Almost all adolescents with CFS experienced headache, abdominal pain and/or pain in muscles and joints. Moreover, in all sites,

				the pain intensity levels were significantly higher than in HCs (p<0.001). CONCLUSIONS: We found a higher prevalence of severe pain among adolescents with CFS and lowered pain thresholds compared with HCs. The mechanisms, however, are still obscure. Large longitudinal population surveys are warranted measuring pain thresholds prior to the onset of CFS. TRIAL REGISTRATION NUMBER: Clinical Trials, NCT01040429; The Norwegian Study of Chronic Fatigue Syndrome in Adolescents: Pathophysiology and Intervention Trial (NorCAPITAL) http://www.clinicaltrials.gov.

Effect of intermittent vitamin D3 on vascular function and symptoms in chronic fatigue syndrome - A randomised controlled trial.	Nutr Metab Cardiovasc Dis. 2014 Oct 22. doi:pii: S0939-4753(14)00315-9. 10.1016/j.numecd.2014.10.007.	BACKGROUND AND AIMS: Low 25-hydroxyvitamin D levels are common in patients with chronic fatigue syndrome; such patients also manifest impaired vascular health. We tested whether high-dose intermittent oral vitamin D therapy improved markers of vascular health and fatigue in patients with chronic fatigue syndrome. METHODS AND RESULTS: Parallel-group, double-blind, randomised placebo-controlled trial. Patients with chronic fatigue syndrome according to the Fukuda (1994) and Canadian (2003) criteria were randomised to receive 100,000 units oral vitamin D3 or matching placebo every 2 months for 6 months. The primary outcome was arterial stiffness measured using carotid-femoral pulse wave velocity at 6 months. Secondary outcomes included flow-mediated dilatation of the brachial artery, blood pressure, cholesterol, insulin resistance, markers of inflammation and oxidative stress, and the Piper Fatigue scale. As many as 50 participants were randomised; mean age 49 (SD 13) years, mean baseline pulse wave velocity 7.8 m/s (SD 2.3), mean baseline office blood pressure 128/78 (18/12) mmHg and mean baseline 25-hydroxyvitamin D level 46 (18) nmol/L. 25-hydroxyvitamin D levels increased by 22 nmol/L at 6 months in the treatment group relative to placebo. There was no effect of treatment on pulse wave velocity at 6 months (adjusted treatment effect 0.0 m/s; 95% CI -0.6 to 0.6; p = 0.93). No improvement was seen in other vascular and metabolic outcomes, or in the Piper Fatigue scale at 6 months (adjusted treatment effect 0.2 points; 95% CI -0.8 to 1.2; p = 0.73). CONCLUSION: High-dose oral vitamin D3 did not improve markers of vascular health or fatigue in patients with chronic fatigue syndrome. Trial registration: www.controlled-trials.com, ISRCTN59927814.

Won CH, Kryger M.	Section of Pulmonary, Critical Care and Sleep Medicine, Yale University School of Medicine, PO BOX 208057, 333 Cedar Street, New Haven, CT 06520-8057, USA. Electronic address: christine.won@yale.edu.	Sleep in patients with restrictive lung disease.	Clin Chest Med. 2014 Sep;35(3):505-12. doi: 10.1016/j.ccm.2014.06.006. Epub 2014 Jul 24. Review.	Restrictive lung disease leads to ventilatory defects and diffusion impairments. These changes may contribute to abnormal nocturnal pathophysiology, including sleep architecture disruption and impaired ventilation and oxygenation. Patients with restrictive lung disease may suffer significant daytime fatigue and dysfunction. Hypercarbia and hypoxemia during sleep may impact progression of lung disease and related symptoms. Little is known about the impact of treatment of sleep disruption on sleep quality and overall prognosis in restrictive lung disease. This review discusses the pathophysiology of sleep and comorbid sleep disorders in restrictive lung diseases including interstitial lung disease, neuromuscular disease, and obesity hypoventilation syndrome.
Wyller VB, SÃ¸rensen Ã˜, Sulheim D, Fagermoen E, Ueland T, Mollnes TE.	Dept. of Paediatrics, Oslo University Hospital, Norway; Division of Medicine and Laboratory Sciences, Medical Faculty, University of Oslo, Norway; Dept. of Paediatrics, Akershus University Hospital, Nordbyhagen, Norway. Electronic address: brwylle@online.no	Plasma cytokine expression in adolescent chronic fatigue syndrome.	Brain Behav Immun. 2014 Dec 31. doi:pii: S0889-1591(14)00614-X. 10.1016/j.bbi.2014.12.025.	Chronic fatigue syndrome (CFS) is a prevalent and disabling condition among adolescents. The pathophysiology is poorly understood, but low-grade systemic inflammation has been suggested as an important component. This study compared circulating levels of individual cytokines and parameters of cytokine networks in a large set of adolescent CFS patients and healthy controls, and explored associations between cytokines and symptoms in the CFS group. CFS patients (12-18years old) were recruited nation-wide to a single referral center as part of the NorCAPITAL project (ClinicalTrials ID: NCT01040429). A broad case definition of CFS was applied, requiring three months of unexplained, disabling chronic/relapsing fatigue of new onset, whereas no accompanying symptoms were necessary. Thus, the case definition was broader than the Fukuda-criteria of CFS. Healthy controls having comparable distribution of gender and age were recruited from local schools. Twenty-seven plasma cytokines, including interleukins, chemokines and growth factors were assayed using multiplex technology. The results were subjected to network analyses using the ARACNE algorithm. Symptoms were charted by a questionnaire, and patients were subgrouped according to the Fukuda-criteria. A total of 120 CFS patients and 68 healthy controls were included. CFS patients had higher scores for fatigue ($p<0.001$) and inflammatory symptoms ($p<0.001$) than healthy controls. All cytokine levels and cytokine network parameters were similar, and none of the differences were statistically different across the two groups, also when adjusting for adherence to the Fukuda criteria of CFS. Within the CFS group, there were no associations between aggregate cytokine network parameters and symptom scores. Adolescent CFS patients are burdened by symptoms that might suggest low-grade systemic inflammation, but plasma levels of individual cytokines as well as cytokine network measures were not different from healthy controls, and there were no associations between symptoms and cytokine expression in the CFS group. Low-grade systemic inflammation does not appear to be a central part of adolescent CFS pathophysiology.

Wyller VB, Fagermoen E, Sulheim D, Winger A, Skovlund E, Saul JP.	Department of Pediatrics, Oslo University Hospital, N-1478 Oslo, Norway ; Division of Medicine and Laboratory Sciences, Medical Faculty, University of Oslo, Oslo, Norway ; Department of Pediatrics, Akershus University Hospital, Nordbyhagen, Norway.	Orthostatic responses in adolescent chronic fatigue syndrome: contributions from expectancies as well as gravity.	Biopsychosoc Med. 2014;8:22. doi: 10.1186/1751-0759-8-22.	BACKGROUND: Orthostatic intolerance is common in chronic fatigue syndrome (CFS), and several studies have documented an abnormal sympathetic predominance in the autonomic cardiovascular response to gravitational stimuli. The aim of this study was to explore whether the expectancies towards standing are contributors to autonomic responses in addition to the gravitational stimulus itself. METHODS: A total of 30 CFS patients (12-18 years of age) and 39 healthy controls underwent 20° head-up tilt test and a motor imagery protocol of standing upright. Beat-to-beat cardiovascular variables were recorded. RESULTS: At supine rest, CFS patients had significantly higher heart rate, diastolic blood pressure, and mean arterial blood pressure, and lower stroke index and heart rate variability (HRV) indices. The response to 20° head-up tilt was identical in the two groups. The response to imaginary upright position was characterized by a stronger increase of HRV indices of sympathetic predominance (power in the low-frequency range as well as the ratio low-frequency: high-frequency power) among CFS patients. CONCLUSIONS: These results suggest that in CFS patients expectancies towards orthostatic challenge might be additional determinants of autonomic cardiovascular modulation along with the gravitational stimulus per se.
Yasui M, Yoshimura T, Takeuchi S, Tokizane K, Tsuda M, Inoue K, Kiyama H.	Department of Functional Anatomy and Neuroscience, Graduate School of Medicine, Nagoya University, Nagoya, Aichi, Japan; Core Research for Evolutional Science and Technology (CREST) of the Japan Science and Technology Agency, Saitama, Japan.	A chronic fatigue syndrome model demonstrates mechanical allodynia and muscular hyperalgesia via spinal microglial activation.	Glia. 2014 Sep;62(9):1407-17. doi: 10.1002/glia.22687. Epub 2014 May 23.	Patients with chronic fatigue syndrome (CFS) and fibromyalgia syndrome (FMS) display multiple symptoms, such as chronic widespread pain, fatigue, sleep disturbance, and cognitive dysfunction. Abnormal pain sensation may be the most serious of these symptoms; however, its pathophysiology remains unknown. To provide insights into the molecular basis underlying abnormal pain in CFS and FMS, we used a multiple continuous stress (CS) model in rats, which were housed in a cage with a low level of water (1.5 cm in depth). The von Frey and Randall-Seritto tests were used to evaluate pain levels. Results showed that mechanical allodynia at plantar skin and mechanical hyperalgesia at the anterior tibialis (i.e., muscle pain) were induced by CS loading. Moreover, no signs of inflammation and injury incidents were observed in both the plantar skin and leg muscles. However, microglial accumulation and activation were observed in L4-L6 dorsal horn of CS rats. Quantification analysis revealed a higher accumulation of microglia in the medial part of Layers I-IV of the dorsal horn. To evaluate an implication of microglia in pain, minocycline was intrathecally administrated (via an osmotic pump). Minocycline significantly attenuated CS-induced mechanical hyperalgesia and allodynia. These results indicated that activated microglia were involved in the development of abnormal pain in CS animals, suggesting that the pain observed in CFS and FMS patients may be partly caused by a mechanism in which microglial activation is involved.

Zeineh MM, Kang J, Atlas SW, Raman MM, Reiss AL, Norris JL, Valencia I, Montoya JG.	From the Department of Radiology, Lucas Center for Imaging, Stanford University School of Medicine, 1201 Welch Rd, Room P271, Stanford, CA 94305-5488.	Right Arcuate Fasciculus Abnormality in Chronic Fatigue Syndrome.	Radiology. 2014 Oct 29:141079.	Purpose To identify whether patients with chronic fatigue syndrome (CFS chronic fatigue syndrome) have differences in gross brain structure, microscopic structure, or brain perfusion that may explain their symptoms. Materials and Methods Fifteen patients with CFS chronic fatigue syndrome were identified by means of retrospective review with an institutional review board-approved waiver of consent and waiver of authorization. Fourteen age- and sex-matched control subjects provided informed consent in accordance with the institutional review board and HIPAA. All subjects underwent 3.0-T volumetric T1-weighted magnetic resonance (MR) imaging, with two diffusion-tensor imaging (DTI diffusion-tensor imaging) acquisitions and arterial spin labeling (ASL arterial spin labeling). Open source software was used to segment supratentorial gray and white matter and cerebrospinal fluid to compare gray and white matter volumes and cortical thickness. DTI diffusion-tensor imaging data were processed with automated fiber quantification, which was used to compare piecewise fractional anisotropy (FA fractional anisotropy) along 20 tracks. For the volumetric analysis, a regression was performed to account for differences in age, handedness, and total intracranial volume, and for the DTI diffusion-tensor imaging FA fractional anisotropy was compared piecewise along tracks by using an unpaired t test. The open source software segmentation was used to compare cerebral blood flow as measured with ASL arterial spin labeling. Results In the CFS chronic fatigue syndrome population, FA fractional anisotropy was increased in the right arcuate fasciculus (P = .0015), and in right-handers, FA fractional anisotropy was also increased in the right inferior longitudinal fasciculus (ILF inferior longitudinal fasciculus) (P = .0008). In patients with CFS chronic fatigue syndrome, right anterior arcuate FA fractional anisotropy increased with disease severity (r = 0.649, P = .026). Bilateral white matter volumes were reduced in CFS chronic fatigue syndrome (mean ± standard deviation, 467 581 mm(3) ± 47 610 for patients vs 504 864 mm(3) ± 68 126 for control subjects, P = .0026), and cortical thickness increased in both right arcuate end points, the middle temporal (T = 4.25) and precentral (T = 6.47) gyri, and one right ILF inferior longitudinal fasciculus end point, the occipital lobe (T = 5.36). ASL arterial spin labeling showed no significant differences. Conclusion Bilateral white matter atrophy is present in CFS chronic fatigue syndrome . No differences in perfusion were noted. Right hemispheric increased FA fractional anisotropy may reflect degeneration of crossing fibers or strengthening of short-range fibers. Right anterior arcuate FA fractional anisotropy may serve as a biomarker for CFS chronic fatigue syndrome .

Zeller B, Ruud E, Havard Loge J, Kanellopoulos A, Hamre H, Godang K, Bruun Wyller V.	Department of Pediatric Medicine, Oslo University Hospital, Oslo, Norway. Electronic address: bzeller@ous-hf.no	Chronic fatigue in adult survivors of childhood cancer: associated symptoms, neuroendocrine markers, and autonomic cardiovascular responses.	Psychosomatics. 2014 Nov-Dec;55(6):621-9. doi: 10.1016/j.psym.2013.12.005. Epub 2013 Dec 8.	BACKGROUND: Chronic fatigue (CF) is a common late effect after childhood cancer. OBJECTIVE: Based on findings among patients with the chronic fatigue syndrome (CFS), this study explored symptoms, neuroendocrine markers, and autonomic cardiovascular responses associated with CFS in childhood cancer survivors. METHODS: Long-term survivors of childhood lymphoma and acute lymphoblastic leukemia reporting CF were compared with survivors without CF. Data included patient-reported outcomes, clinical examination, head-up tilt test, and neuroendocrine markers in the blood and the urine. RESULTS: Of 102 included survivors, 15 were excluded from comparative analyses because of significant co-morbidity or pregnancy. Of the remaining 87 participants (median age 33.0 years, follow-up time 25.2 years), 35 had CF and 52 did not have CF. Compared with non-CF controls, CF cases reported a significantly ($P < 0.01$) higher frequency of symptoms typical of the CFS (muscle or joint pain or both and feeling confused/disoriented) and symptoms of autonomic dysfunction (palpitations, feeling intermittently heat and cold, and watery diarrhea). CF cases and controls did not differ regarding autonomic cardiovascular responses to orthostatic stress, but the CF group had lower levels of plasma adrenocorticotrophic hormone ($P = 0.002$) and higher levels of urine norepinephrine ($P = 0.017$). CONCLUSIONS: Survivors with CF reported a high symptom-burden compared with controls. There were few differences between both the groups regarding biomarkers, but slight alterations of the hypothalamus-pituitary-adrenal axis and sympathetic nervous activity were detected. CF in cancer survivors has features in common with the CFS, but further efforts are required to clarify the pathophysiology.
Zeller B, Loge JH, Kanellopoulos A, Hamre H, Wyller VB, Ruud E.	Departments of Pediatric Medicine Oncology, National Resource Center for Late Effects after Cancer Treatment Department of Behavioural Sciences in Medicine, University of Oslo, Oslo, Norway.	Chronic fatigue in long-term survivors of childhood lymphomas and leukemia: persistence and associated clinical factors.	J Pediatr Hematol Oncol. 2014 Aug;36(6):438-44. doi: 10.1097/MPH.0000000000000051.	BACKGROUND: Chronic fatigue (CF) is an important late effect after childhood malignancies. Our aim was to assess CF persistence over time, concurrent comorbidities, and associations with clinical symptoms. PROCEDURE: A total of 102 long-term survivors of childhood lymphomas and acute lymphoblastic leukemia, 53 and 49 reporting CF and no CF, respectively, at time point (TP)1, were evaluated for CF at a second TP after a median interval of 2.7 years. At TP2 a survey, including self-reported and objectively measured variables, assessed depressive symptoms, pain, and physical activity. RESULTS: A total of 32 of the 53 reported CF cases at both TPs and 40/49 survivors had no CF at both TPs, whereas 30 had changed their fatigue status between first and second assessment (converters). Major somatic comorbidities were equally distributed among the groups. After exclusion of converters and survivors with major comorbidity/pregnancy, 27 persistent CF (PCF) cases and 35 controls were compared. PCF cases reported significantly more depression, sleeping problems, anxiety, pain, and reduced physical function. Further, they were less physically active than controls (steps/d; $P=0.009$). In a multiple regression analysis, depressive symptoms remained the only significant predictor of PCF. CONCLUSIONS: Long-term survivors of childhood cancer with PCF

				are characterized by more depressive symptoms, anxiety, pain, insomnia, and less physical activity.
Zhang L, Xu MM, Zeng L, Liu S, Liu X, Wang X, Li D, Huang RZ, Zhao LB, Zhan QL, Zhu D, Zhang YY, Xu P, Xie P.	Department of Neurology, The First Affiliated Hospital of Chongqing Medical University, No. 1 Youyi Road, Yuzhong District, 400016, Chongqing, People's Republic of China.	Evidence for Borna disease virus infection in neuropsychiatric patients in three western China provinces.	Eur J Clin Microbiol Infect Dis. 2014 Apr;33(4):621-7. doi: 10.1007/s10096-013-1996-4. Epub 2013 Oct 30.	Borna disease virus (BDV) is a non-cytolytic, neurotropic RNA virus that can infect a wide variety of vertebrate species from birds and primates to humans. Several studies have been carried out to investigate whether BDV is associated with neuropsychiatric diseases. However, this association is still inconclusive. Two panels of subjects consisting of 1,679 various neuropsychiatric patients and healthy people from three western China provinces were enrolled in this study. BDV p24 or p40 RNA in peripheral blood mononuclear cells (PBMCs) were detected in the first panel of 1,481 subjects using reverse transcription quantitative polymerase chain reaction (RT-qPCR) and cerebrospinal fluid (CSF) samples from the BDV RNA-positive individuals were subjected to BDV p24 antibodies testing by enzyme-linked immunosorbent assay (ELISA). BDV p24 or p40 RNA in PBMCs and p24 antibodies in plasma were detected in the second panel of 198 subjects by RT-qPCR and Western blot. A higher prevalence for BDV RNA was demonstrated in patients with viral encephalitis (6.70%), Guillain-Barré syndrome (6.70%), schizophrenia (9.90%) and chronic fatigue syndrome (CFS) (12.70%) compared to healthy controls in the first panel. CSF p24 antibodies were demonstrated in three viral encephalitis patients, two schizophrenia patients and two major depressive disorder (MDD) patients. The prevalences of p24 antibodies in plasma from patients with viral encephalitis (13.24%), multiple sclerosis (25.00%) and Parkinson's disease (22.73%) were significantly higher than healthy controls. This study demonstrates that BDV infection also exists in humans from three western China provinces, and suggests the involvement of the contribution of BDV in the aetiology of Chinese patients with some neuropsychiatric disorders, including viral encephalitis, schizophrenia, CFS, multiple sclerosis and Parkinson's disease.

Lipid Replacement Therapy: A natural medicine approach to replacing damaged lipids in cellular membranes and organelles and restoring function.	Biochim Biophys Acta. 2013 Nov 21. pii: S0005-2736(13)00407-0. doi: 10.1016/j.bbamem.2013.11.010. [Epub ahead of print]	Lipid Replacement Therapy, the use of functional oral supplements containing cell membrane phospholipids and antioxidants, has been used to replace damaged, usually oxidized, membrane glycerophospholipids that accumulate during aging and in various clinical conditions in order to restore cellular function. This approach differs from other dietary and intravenous phospholipid interventions in the composition of phospholipids and their defense against oxidation during storage, ingestion, digestion and uptake as well as the use of protective molecules that noncovalently complex with phospholipid micelles and prevent their enzymatic and bile disruption. Once the phospholipids have been taken in by transport processes, they are protected by several natural mechanisms involving lipid receptors, transport and carrier molecules and circulating cells and lipoproteins until their delivery to tissues and cells where they can again be transferred to intracellular membranes by specific and nonspecific transport systems. Once delivered to membrane sites, they naturally replace and stimulate removal of damaged membrane lipids. Various chronic clinical conditions are characterized by membrane damage, mainly oxidative but also enzymatic, resulting in loss of cellular function. This is readily apparent in mitochondrial inner membranes where oxidative damage to phospholipids like cardiolipin and other molecules results in loss of trans-membrane potential, electron transport function and generation of high-energy molecules. Recent clinical trials have shown the benefits of Lipid Replacement Therapy in restoring mitochondrial function and reducing fatigue in aged subjects and patients with a variety of clinical diagnoses that are characterized by loss of mitochondrial function and include fatigue as a major symptom. This article is part of a Special Issue entitled: Membrane structure and function: Relevance in the cell's physiology, pathology and therapy.

Abbi B, Natelson BH.	War Related Illness and Injury Study Center, DVA Medical Center, East Orange, NJ, USA.	Is chronic fatigue syndrome the same illness as fibromyalgia: evaluating the 'single syndrome' hypothesis.	QJM. 2013 Jan; 106(1):3-9. doi: 10.1093/qjmed/hcs156. Epub 2012 Aug 26.	Chronic fatigue syndrome (CFS) and fibromyalgia (FM) are medically unexplained syndromes that can and often do co-occur. For this reason, some have posited that the two are part of the same somatic syndrome--examples of symptom amplification. This hypothesis would suggest that few differences exist between the two syndromes. To evaluate this interpretation, we have searched the literature for articles comparing CFS to FM, reviewing only those articles which report differences between the two. This review presents data showing differences across a number of parameters--implying that the underlying pathophysiology in CFS may differ from that of FM. We hope that our review encourages other groups to look for additional differences between CFS and FM. By continuing to preserve the unique illness definitions of the

				two syndromes, clinicians will be able to better identify, understand and provide treatment for these individuals.
Ablin JN, Clauw DJ, Lyden AK, Ambrose K, Williams DA, Gracely RH, Glass JM.	Institute of Rheumatology, Sourasky Medical Center, and Tel Aviv University faculty of Medicine, Israel. ajacob@post.tau.ac.il.	Effects of sleep restriction and exercise deprivation on somatic symptoms and mood in healthy adults.	Clin Exp Rheumatol. 2013 Nov-Dec; 31(6 Suppl 79):53-9. Epub 2013 Nov 15.	OBJECTIVES: Exposure to acute 'stressors' (e.g. infections, pain, and trauma) often results in altered sleep habits and reductions in routine activity. In some individuals, these behavioural responses to acute stressors may contribute to the development of chronic somatic symptoms such as widespread pain, fatigue, memory difficulties and mood disturbances, much like those associated with 'functional somatic syndromes' (FSS) such as fibromyalgia or chronic fatigue syndrome. METHODS: Eighty-seven healthy young adults who reported sleeping between 7 and 9 hours nightly and exercising regularly were randomised to one of four groups: exercise cessation, sleep restriction (6 hours nightly), both, or neither. Symptoms of pain, fatigue, cognitive dysfunction and negative mood were measured before and after the 10-day restriction period. RESULTS: Sleep restriction was a potent contributor to the development of somatic symptoms. Exercise cessation was less influential leading only to fatigue. There were no significant interactions between exercise cessation and sleep restriction, except that males were much more likely to develop somatic symptoms when deprived of both sleep and exercise than one or the other. Women were generally much more likely to develop somatic symptoms than men. CONCLUSIONS: This study supports previous research suggesting that both sleep and exercise are critical in 'preventing' somatic symptoms among some individuals. Furthermore, to our knowledge, this is the first time there is data to suggest that women are much more sensitive to decrements in routine sleep and exercise than are men.
Afari N, Ahumada SM, Wright LJ, Mostoufi S, Golnari G, Reis V, Cuneo JG.	VA Center of Excellence for Stress and Mental Health (N.A., S.M.), San Diego, California; VA San Diego Healthcare System (N.A., S.M., J.G.C.), San Diego, California; Department of Psychiatry (N.A., G.G.) University of California, San Diego, San Diego, California; Institute of Child Development (S.M.A.) University of Minnesota,	Psychological Trauma and Functional Somatic Syndromes: A Systematic Review and Meta-Analysis.	Psychosom Med. 2013 Dec 12. [Epub ahead of print]	Objective: This meta-analysis systematically examined the association of reported psychological trauma and posttraumatic stress disorder (PTSD) with functional somatic syndromes including fibromyalgia, chronic widespread pain, chronic fatigue syndrome, temporomandibular disorder, and irritable bowel syndrome. Our goals were to determine the overall effect size of the association and to examine moderators of the relationship.MethodsLiterature searches identified 71 studies with a control or comparison group and examined the association of the syndromes with traumatic events including abuse of a psychological, emotional, sexual, or physical nature sustained during childhood or adulthood, combat exposure, or PTSD. A random-effects model was used to estimate the pooled odds ratio and 95% confidence interval. Planned subgroup analyses and meta-regression examined potential moderators.ResultsIndividuals who reported exposure to trauma were 2.7 (95% confidence interval = 2.27-3.10) times more likely to have a functional somatic syndrome. This association was robust against both publication bias and the generally low quality of the literature. The magnitude of the association with PTSD was significantly larger than that with sexual or physical abuse. Chronic fatigue syndrome had a larger association with reported trauma than did either irritable bowel

	Minneapolis, Minnesota; VA Northern California Health Care System (L.J.W.), Oakland, California; and VA Palo Alto Healthcare System (V.R.), Palo Alto, California.			syndrome or fibromyalgia. Studies using nonvalidated questionnaires or self-report of trauma reported larger associations than did those using validated questionnaires.ConclusionsFindings highlight the limitations of the existing literature and emphasize the importance of conducting prospective studies, further examining the potential similarities and differences of these conditions and pursuing hypothesis-driven studies of the mechanisms underlying the link between trauma, PTSD, and functional somatic syndromes.

Akarsu S, Tekin L, Ay H, Carli AB, Tok F, Simşek K, Kiralp MZ.	Gülhane Military Medical Academy Haydarpasa Training Hospital, Department of Physical Medicine and Rehabilitation, Istanbul, Turkey. selimakarsu@yahoo.com.tr	The efficacy of hyperbaric oxygen therapy in the management of chronic fatigue syndrome.	Undersea Hyperb Med. 2013 Mar-Apr; 40(2):197-200.	OBJECTIVE: Chronic fatigue syndrome (CFS) is a chronic disease with social components that ensue secondary to the incapacity of the person to fulfill work, social and family responsibilities. Currently, there is no consensus regarding its treatment. The aim of this study was to determine the efficacy of hyperbaric oxygen (HBO2) therapy in CFS. DESIGN: Sixteen patients included in the study were diagnosed with CFS according to the Fukuda criteria. Patients received 15 treatment sessions of HBO2 therapy over a period of three consecutive weeks (five days per week). The outcome measures (visual analog fatigue scale (VAFS). Fatigue Severity Scale (FSS) and Fatigue Quality of Life Score (FQLS) were assessed before the treatment and after completion of the 15 sessions. RESULTS: HBO2 therapy was well tolerated, with no complications. After treatment, patients' scores were found to have improved with respect to VAFS, FSS and FQLS (all $p<0.005$). CONCLUSIONS: We may infer that HBO2 therapy decreases the severity of symptoms and increases the life quality of CFS patients. It may be a new treatment modality for the management of CFS. However, further studies with larger sample sizes and control groups are definitely awaited.
Akkaya N, Atalay NS, Selcuk ST, Alkan H, Catalbas N, Sahin F.	Department of Physical Medicine and Rehabilitation, Medicine Faculty, University of Pamukkale, 20070, Kinikli-Denizli, Turkey. nrakkaya@gmail.com	Frequency of fibromyalgia syndrome in breast cancer patients.	Int J Clin Oncol. 2013 Apr;18(2):285-92. doi: 10.1007/s10147-012-0377-9. Epub 2012 Feb 10.	BACKGROUND: We aimed to determine the frequency of fibromyalgia syndrome (FM) in operated breast cancer patients and to research the relationship between FM and the severity of fatigue and quality of life in these breast cancer patients. METHODS: The demographic data of 101 operated breast cancer patients were recorded. The patients who had pain were then classified as having regional pain (RP), widespread pain without FM (WP), and widespread pain with FM (WFM). The FM diagnosis was based on the American College of Rheumatology (ACR) criteria. The severity of fatigue was evaluated with the Brief Fatigue Inventory, the disease impact was evaluated

				with the Fibromyalgia Impact Questionnaire (FIQ), and the quality of life was evaluated with the European Organization for Research on Treatment of Cancer questionnaire Quality of Life-C30 (EORTC-QoL-C30). RESULTS: There was no pain in 38 (37.6%) patients, whereas there was pain in 63 (62.4%) patients (N = 42, 41.6% had RP, N = 21, 20.8% had WP). Ten (9.9%) of the entire patient cohort were diagnosed as having FM according to the ACR criteria. There were no differences among the 3 groups in respect to demographic characteristics when patients were classified as RP (N = 42), WP (N = 11), and WFM (N = 10) groups. While there were negative correlations between the FIQ and EORTC-QoL-C30-function score (r = -0.727) and EORTC-QoL-C30-global score (r = -0.488), there was a positive correlation between the FIQ and EORTC-QoL-C30-symptom score (r = 0.726). CONCLUSION: We note that the frequency of FM in the operated breast cancer patients in this study was higher than that reported in normal populations in the literature. Also, we found that the presence of FM had negative effects on the quality of life of the breast cancer patients. Accordingly, in the evaluation of widespread pain and complaints of fatigue in long-surviving breast cancer patients, after metastatic disease is excluded, the probability of FM should be kept in mind, so that appropriate treatment can be initiated to improve their functional status and quality of life.
Alves Eda S, Ackel-D'Elia C, Luz GP, Cunha TC, Carneiro G, Tufik S, Bittencourt LR, de Mello MT.	Disciplina de Medicina e Biologia do Sono, Departamento de Psicobiologia, Universidade Federal de São Paulo-UNIFESP, São Paulo, CEP: 04020-050, Brazil.	Does physical exercise reduce excessive daytime sleepiness by improving inflammatory profiles in obstructive sleep apnea patients?	Sleep Breath. 2013 May; 17(2):505-10. doi: 10.1007/s11325-012-0729-8. Epub 2012 Jun 20.	INTRODUCTION: Obstructive sleep apnea syndrome (OSAS) is associated with a variety of long-term consequences such as high rates of morbidity and mortality, due to excessive diurnal somnolence as well as cardiovascular and metabolic diseases. Obesity, recurrent episodes of upper airway obstruction, progressive hypoxemia, and sleep fragmentation during sleep cause neural, cardiovascular, and metabolic changes. These changes include activation of peripheral sympathetic nervous system and the hypothalamic-pituitary-adrenal axis, insulin sensitivity, and inflammatory cytokines alterations, which predispose an individual to vascular damage. DISCUSSION: Previous studies proposed that OSAS modulated the expression and secretion of inflammatory cytokines from fat and other tissues. Independent of obesity, patients with OSAS exhibited elevated levels of C-reactive protein, tumor necrosis factor-α and interleukin-6, which are associated with sleepiness, fatigue, and the development of a variety of metabolic and cardiovascular diseases. OSAS and obesity are strongly associated with each other and share many common pathways that induce chronic inflammation. Previous studies suggested that the protective effect of exercise may be partially attributed to the anti-inflammatory effect of regular exercise, and this effect was observed in obese patients. Although some studies assessed the effects of physical exercise on objective and subjective sleep parameters, the quality of life, and mood in patients with OSAS, no study has evaluated the effects of this treatment on inflammatory profiles. In this review, we cited some studies that directed our opinion to believe that since OSAS causes increased inflammation and has excessive daytime sleepiness as a symptom and being

				that physical exercise improves inflammatory profiles and possibly OSAS symptoms, it must be that physical exercise improves excessive daytime sleepiness due to its improvement in inflammatory profiles.
Amr M, Lakhan SE, Sanhan S, Al-Rhaddad D, Hassan M, Thiabh M, Shams T.	Global Neuroscience Initiative Foundation, Beverly Hills, CA, USA. slakhan@gnif.org.	Efficacy and tolerability of quetiapine versus haloperidol in first-episode schizophrenia: a randomized clinical trial.	Int Arch Med. 2013 Dec 5;6 (1):47. doi: 10.1186/1755-7682-6-47.	BACKGROUND: Schizophrenia is a chronic disease of global importance. The second-generation antipsychotic quetiapine has a favorable side-effect profile, however, its clinical effectiveness has been called into question when compared with first-generation antipsychotics such as haloperidol. This study evaluates the efficacy and tolerability of quetiapine versus haloperidol for first-episode schizophrenia in the outpatient setting. METHODS: 156 adult patients with first-episode schizophrenia participated in an outpatient clinical trial and were randomized to quetiapine (200 mg/d; n = 78) or haloperidol (5 mg/d; n = 78). The study medications were titrated to a mean daily dose of 705 mg for quetiapeine and 14 mg for haloperidol. The patients were assessed at baseline, six weeks, and twelve weeks. The primary outcome measures were positive and negative scores of the Positive and Negative Syndrome Scale (PANSS). Secondary measures were Global Assessment of Functioning (GAF) scale for overall psychosocial functioning, and Simpson-Angus Scale (SAS) for extra-pyramidal symptoms. RESULTS: At twelve weeks, the quetiapine group had a greater decrease in PANSS positive (18.9 vs. 15.3, p = 0.013) and negative scores (15.5 vs. 11.6, p = 0.012), however, haloperidol showed a greater decrease in general psychopathology score (23.8 vs. 27.7, p = 0.012). No significant difference between groups were found for total PANSS (58.3 vs. 54.8, p = 0.24) and GAF (45.7 vs. 46.2, p = 0.79).ANOVA identified significant group interactions on PANSS positive (F = 18.72, df = 1.6,52.4, p < 0.0001), negative (F = 5.20, df = 1.1,35.7, p < 0.0001), depression/anxiety (F = 106.49, df = 1.14,37.8, p < 0.0001), and total scores (F = 7.51, df = 1.4,45.6, p = 0.001).SAS (8.62 vs. 0.26, p < 0.0001) and adverse events of akathisia (78% vs. 0%, p = 0.000), parkinsonism (66.6% vs. 0%, p < 0.0001), and fatigue (84.6% vs. 66.6%, p = 0.009) were greater in haloperidol compared to quetiapine, whereas headache was more common in quetiapine treated patients (11.5% vs. 35.9%, p < 0.0001). CONCLUSIONS: Quetiapine has greater efficacy for positive and negative symptoms with less extra-pyramidal symptoms than haloperidol when used for first-episode schizophrenia in the outpatient setting.
Anderson G, Berk M, Maes M.	CRC, Glasgow, UK.	Biological phenotypes underpin the physio-somatic symptoms of somatization, depression, and chronic fatigue syndrome.	Acta Psychiatr Scand. 2013 Aug 17. doi: 10.1111/acps.12182. [Epub ahead of print]	OBJECTIVE: Somatization is a symptom cluster characterized by 'psychosomatic' symptoms, that is, medically unexplained symptoms, and is a common component of other conditions, including depression and myalgic encephalomyelitis/chronic fatigue syndrome (ME/CFS). This article reviews the data regarding the pathophysiological foundations of 'psychosomatic' symptoms and the implications that this has for conceptualization of what may more appropriately be termed physio-somatic symptoms. METHOD: This narrative review used papers published in PubMed, Scopus, and Google Scholar electronic databases using the keywords: depression and chronic fatigue, depression and somatization, somatization and chronic fatigue syndrome,

				each combined with inflammation, inflammatory, tryptophan, and cell-mediated immune (CMI). RESULTS: The physio-somatic symptoms of depression, ME/CFS, and somatization are associated with specific biomarkers of inflammation and CMI activation, which are correlated with, and causally linked to, changes in the tryptophan catabolite (TRYCAT) pathway. Oxidative and nitrosative stress induces damage that increases neoepitopes and autoimmunity that contribute to the immuno-inflammatory processes. These pathways are all known to cause physio-somatic symptoms, including fatigue, malaise, autonomic symptoms, hyperalgesia, intestinal hypermotility, peripheral neuropathy, etc. CONCLUSION: Biological underpinnings, such as immune-inflammatory pathways, may explain, at least in part, the occurrence of physio-somatic symptoms in depression, somatization, or myalgic encephalomyelitis/chronic fatigue syndrome and thus the clinical overlap among these disorders.
Anderson VR, Jason LA, Hlavaty LE.	Department of Psychology, Michigan State University, East Lansing, Michigan, USA.	A Qualitative Natural History Study of ME/CFS in the Community.	Health Care Women Int. 2014 Jan; 35(1):3-26. doi: 10.1080/07399332.2012.684816. Epub 2013 Feb 27.	In previous qualitative research on Myalgic Encephalomyelitis/chronic fatigue syndrome (ME/CFS), researchers have focused on the experiences of patients with ME/CFS in tertiary care samples. This qualitative study examined the natural history of people with ME/CFS (n = 19) from a community-based sample. Findings highlighted multilayered themes involving the illness experience and the physical construction of ME/CFS. In addition, this study further illuminated unique subthemes regarding community response and treatment, which have implications for understanding the progression of ME/CFS as well as experiences of those within patient networks. There is a need for more longitudinal qualitative research on epidemiological samples of patients with ME/CFS.
Angeletti C, Guetti C, Piroli A, Angeletti PM, Paladini A, Ciccozzi A, Marinangeli F, Varrassi G.	Anesthesiology and Pain Medicine, Department of Health Sciences, University of L'Aquila, Italy.	Duloxetine and pregabalin for pain management in multiple rheumatic diseases associated with fibromyalgia.	Pain Pract. 2013 Nov; 13(8):657-62. doi: 10.1111/papr.12009. Epub 2012 Nov 5.	The fibromyalgia syndrome (FMS) is characterized by chronic and widespread musculoskeletal pain and soreness accompanied by sleep disorders, chronic fatigue and affective disorders. FMS is often associated with other forms of immuno-rheumatic diseases. Although FMS pathophysiology is still not fully understood, a number of neuroendocrine, neurotransmission and neurosensitive disorders might generate a mechanism for the elicitation of pain by "central sensitization," which is common to many other painful conditions. The present case describes the success of a therapeutic scheme, which associates two different pharmacological classes, anticonvulsants and new-generation antidepressants, when FMS complicates a rare pathology called Cogan's syndrome. The association of two drugs might noticeably affect the molecular mechanisms of difficult pain, thus solving painful conditions of multifactorial origin.
Antcliff D, Keeley P, Campbell M, Oldham J, Woby S.	Pennine Acute Hospitals NHS Trust, North Manchester General Hospital, Manchester, M8 5RB,	The development of an activity pacing questionnaire for chronic pain and/or fatigue: a Delphi	Physiotherapy. 2013 Sep; 99(3):241-6. doi: 10.1016/j.physio.2012.12.003. Epub 2013 Feb 8.	OBJECTIVE: Activity pacing is frequently advised as a coping strategy for the management of chronic conditions (such as chronic low back pain, chronic widespread pain and chronic fatigue syndrome/myalgic encephalomyelitis). Despite anecdotal support for activity pacing, there is limited and conflicting research evidence into the efficacy of this strategy. There is no consensus on the interpretation

	UK. Deborah.Antcliff@pat.nhs.uk	technique.		of 'pacing' due to diverse descriptions, including strategies that encourage both increasing and decreasing activities. Furthermore, at present, there are few validated scales to measure how patients pace their activities. The aim of this study was to undertake the first stage in the development of a comprehensive tool that assesses the multi-faceted nature of pacing among patients with chronic conditions. DESIGN: Three-round Delphi technique. PARTICIPANTS: Expert panel based in the UK including patients and clinicians. RESULTS: The 42 participants who completed three rounds of Delphi included 4 patients, 3 nurses, 26 physiotherapists and 9 occupational therapists. The 38 questions that reached consensus to be included in the questionnaire encompassed a number of different facets of pacing, for example, breaking down tasks, not over-doing activities, and gradually increasing activities. CONCLUSIONS: To our knowledge, this is the first study that has engaged both patients and clinicians in a Delphi technique to develop an activity pacing questionnaire. In contrast to existing pacing scales, our questionnaire appears to contain a number of distinct facets of pacing. Further study is being undertaken to engage patients in the exploration of the validity, reliability and acceptability of the questionnaire.
Aroniadis OC, Brandt LJ.	Division of Gastroenterology, Montefiore Medical Center, Bronx, New York 10467, USA. oaroniad@montefiore.org	Fecal microbiota transplantation: past, present and future.	Curr Opin Gastroenterol. 2013 Jan;29(1):79-84. doi: 10.1097/MOG.0b013e32835a4b3e.	PURPOSE OF REVIEW: Fecal microbiota transplantation (FMT) re-establishes a balanced intestinal flora with resultant cure of recurrent Clostridium difficile infection (RCDI). FMT has also been used to treat other gastrointestinal (GI) diseases including inflammatory bowel disease (IBD), irritable bowel syndrome (IBS), and chronic constipation and a variety of non-GI disorders. The purpose of this review is to discuss the intestinal microbiota and FMT treatment of GI and non-GI diseases. RECENT FINDINGS: It is known that an imbalanced intestinal microbiota predisposes to CDI, IBD and IBS. The complex role of intestinal microbiota to maintain health, however, is a newer concept that is being increasingly studied. The microbiome plays an important role in cellular immunity and energy metabolism and has been implicated in the pathogenesis of non-GI autoimmune diseases, chronic fatigue syndrome, obesity and even some neuropsychiatric disorders. SUMMARY: FMT is a highly effective cure for RCDI, but increased knowledge of the intestinal microbiota in health maintenance, as well as controlled trials of FMT in a wide range of disorders are needed before FMT can be accepted and applied clinically.
Arroll M, Arroll B.	The Optimum Health Clinic, Research Department, London, England. drarroll@theoptimumhealthclinic.com	Chronic fatigue syndrome-a patient centred approach to management.	Aust Fam Physician. 2013 Apr; 42(4):191-3.	BACKGROUND: Chronic fatigue syndrome (myalgic encephalomyelitis) is a diagnosis that can attract feelings of stigma in the patient due to the lack of a definite diagnostic biomarker. To ensure that the patient firstly understands the diagnosis, and subsequently is comfortable with the treatment suggested, a patient centred approach is advised within the consultation. OBJECTIVE: This article presents a hypothetical case and uses this to give guidance on methods for negotiating the diagnosis and treatment of chronic fatigue syndrome. DISCUSSION: It is important to reassure the patient that negative investigation results and the suggestion of

				treatment options that are also used for depressive illness (eg. antidepressants and cognitive behavioural therapy), does not mean that their illness experience is fabricated or that they are being treated for depression. Once red flag features are ruled out and any exclusory illnesses identified, a multidisciplinary pragmatic rehabilitation program can be implemented. This includes strategies for increasing social support, liaising with employers and graded return to activities in a 'What matters to you?' approach.
Arroll MA, Howard A.	The Optimum Health Clinic, London, UK. drarroll@theoptimumhealthclinic.com	'The letting go, the building up, [and] the gradual process of rebuilding': identity change and post-traumatic growth in myalgic encephalomyelitis/chronic fatigue syndrome.	Psychol Health. 2013; 28(3):302-18. doi: 10.1080/08870446.2012.721882. Epub 2012 Sep 11.	The aim of this study was to explore the phenomenon of identity change and subsequent post-traumatic growth (PTG) in individuals with myalgic encephalomyelitis/chronic fatigue syndrome (ME/CFS). Ten participants (average illness duration 7.4 years) were interviewed (average length, 79minutes) via a semi-structured interview schedule and verbatim transcriptions were analysed with interpretative phenomenological analysis. The four superordinate themes revealed were 'comparisons of past to present self: "you have to be someone else, and you have to live with that'", 'the effect of social isolation on identity and subsequent insights into others' behaviours', 'contemplation of future and identity: ''where do I go from here?"', and 'PTG: "the letting go, the building up, [and] the gradual process of rebuilding"'. These themes outlined the experiences of those with ME/CFS as they underwent changes in identity due to the limitations the condition imposed on activities and roles, understanding others behaviours after a period of isolation, the comparison of the past self with the present self and finally, the positive growth that was noted by two of the interviewees with regards to a new 'true' self. Despite the distressing and unpredictable nature of ME/CFS, it appears that individuals with this disorder can experience personal growth.
Arroll MA.	The Optimum Health Clinic, Head Office and Training Centre, Bickerton House, 25-27 Bickerton Road, London N19 5JT, United Kingdom. drarroll@theoptimumhealthclinic.com	Allostatic overload in myalgic encephalomyelitis/chronic fatigue syndrome (ME/CFS).	Med Hypotheses. 2013 Sep; 81(3):506-8. doi: 10.1016/j.mehy.2013.06.023. Epub 2013 Jul 11.	Myalgic encephalomyelitis/chronic fatigue syndrome (ME/CFS) is a debilitating condition characterised by diverse symptoms such as fatigue, pain, sleep disturbance and autonomic dysfunction. There remains to be a singular biomarker identified for this illness, hence numerous theories about its development and perpetuation have been posited in the literature. This brief report presents the model of 'allostasis' as a framework for understanding ME/CFS, specifically the notion that the physiological mechanisms employed in the body to deal with stress termed here as 'allostatic states' (e.g. elevation of inflammatory cytokines), may in and of themselves contribute to the perpetuation of the disorder. This theoretical assertion has important consequences for the understanding of ME/CFS and treatment; rather than searching for a singular pathogen responsible for this condition, ME/CFS can be conceptualised as a maladaptive stress disorder and interventions aimed at addressing the allostatic states may be incorporated into current symptom management programmes.

Bäckström T, Bixo M, Nyberg S, Savic I.	Umeå Neurosteroid Research Centre, Department of Clinical Science, Umeå University, Umeå, Sweden. torbjorn.backstrom@ogbyn.umu.se	Increased neurosteroid sensitivity--an explanation to symptoms associated with chronic work related stress in women?	Psychoneuroendocrinology. 2013 Jul;38(7):1078-89. doi: 10.1016/j.psyneuen.2012.10.014. Epub 2012 Nov 22.	Work related psychosocial stress can be accompanied by so called burnout syndrome with symptoms of mental exhaustion, physical fatigue, and cognitive dysfunction. Underlying mechanisms for acquiring burnout syndrome are not clear. Animal studies show that chronic stress is associated with altered release of GABA-A receptor modulating steroids (GAMS), altered composition of the GABA-A receptor and altered sensitivity to GAMS. In the present study we investigated if such changes occur in women with burnout syndrome. We further asked whether flumazenil (a benzodiazepine antagonist, but with positive modulating effects on GABA-A receptors with altered subunit composition) can block the effect of the GAMS allopregnanolone. Ten women with occupational psychosocial stress and burnout syndrome were compared with twelve healthy controls in an experimental setting. Saccadic eye velocity (SEV) was measured after an injection of allopregnanolone, followed by an injection of flumazenil and a second injection of allopregnanolone. The sensitivity to allopregnanolone was significantly higher in the patients compared to controls after the first injection (p=0.04) and the difference increased when the response per allopregnanolone concentration unit was compared (p=0.006). Following the flumazenil injection the burnout patients (p=0.016), but not controls, showed a decrease in SEV and flumazenil acted like a positive modulator that is agonistic. There was no significant difference between the groups after second allopregnanolone injection. In conclusion, patients with work related psychosocial stress and burnout syndrome show a different response to GABA-A receptor modulators than controls suggesting a changed GABA-A receptor function in these patients. More precisely we hypothesize that the α4 and delta subunits are up-regulated elevating the responsiveness to allopregnanolone and change the effect of flumazenil, which provides a potential explanation to the burnout syndrome. Flumazenil does not block the effect of allopregnanolone.
Badham SP, Hutchinson CV.	School of Psychology, College of Medicine, Biological Sciences and Psychology, University of Leicester, Leicester, UK, s.p.badham@warwick.ac.uk.	Badham SP, Hutchinson CV.	Graefes Arch Clin Exp Ophthalmol. 2013 Dec; 251(12):2769-76. doi: 10.1007/s00417-013-2431-3. Epub 2013 Aug 6.	BACKGROUND: People who suffer from myalgic encephalomyelitis/chronic fatigue syndrome (ME/CFS) often report that their eye movements are sluggish and that they have difficulties tracking moving objects. However, descriptions of these visual problems are based solely on patients' self-reports of their subjective visual experiences, and there is a distinct lack of empirical evidence to objectively verify their claims. This paper presents the first experimental research to objectively examine eye movements in those suffering from ME/CFS. METHODS: Patients were assessed for ME/CFS symptoms and were compared to age, gender, and education matched controls for their ability to generate saccades and smooth pursuit eye movements. RESULTS: Patients and controls exhibited similar error rates and saccade latencies (response times) on prosaccade and antisaccade tasks. Patients showed

				relatively intact ability to accurately fixate the target (prosaccades), but were impaired when required to focus accurately in a specific position opposite the target (antisaccades). Patients were most markedly impaired when required to direct their gaze as closely as possible to a smoothly moving target (smooth pursuit). CONCLUSIONS: It is hypothesised that the effects of ME/CFS can be overcome briefly for completion of saccades, but that continuous pursuit activity (accurately tracking a moving object), even for a short time period, highlights dysfunctional eye movement behaviour in ME/CFS patients. Future smooth pursuit research may elucidate and improve diagnosis of ME/CFS.
Baraniuk JN, Adewuyi O, Merck SJ, Ali M, Ravindran MK, Timbol CR, Rayhan R, Zheng Y, Le U, Esteitie R, Petrie KN.	Division of Rheumatology, Immunology and Allergy, Georgetown University Washington, DC, USA.	A Chronic Fatigue Syndrome (CFS) severity score based on case designation criteria.	Am J Transl Res. 2013; 5(1):53-68. Epub 2013 Jan 21.	BACKGROUND: Chronic Fatigue Syndrome case designation criteria are scored as physicians' subjective, nominal interpretations of patient fatigue, pain (headaches, myalgia, arthralgia, sore throat and lymph nodes), cognitive dysfunction, sleep and exertional exhaustion. METHODS: Subjects self-reported symptoms using an anchored ordinal scale of 0 (no symptom), 1 (trivial complaints), 2 (mild), 3 (moderate), and 4 (severe). Fatigue of 3 or 4 distinguished "Fatigued" from "Not Fatigued" subjects. The sum of the 8(Sum8) ancillary criteria was tested as a proxy for fatigue. All subjects had history and physical examinations to exclude medical fatigue, and ensure categorization as healthy or CFS subjects. RESULTS: Fatigued subjects were divided into CFS with ≥4 symptoms or Chronic Idiopathic Fatigue (CIF) with ≤3 symptoms. ROC of Sum8 for CFS and Not Fatigued subjects generated a threshold of 14 (specificity=0.934; sensitivity=0.928). CFS (n=256) and CIF (n=55) criteria were refined to include Sum8≥14 and ≤13, respectively. Not Fatigued subjects had highly skewed Sum8 responses. Healthy Controls (HC; n=269) were defined by fatigue≤2 and Sum8≤13. Those with Sum8≥14 were defined as CFS-Like With Insufficient Fatigue Syndrome (CFSLWIFS; n=20). Sum8 and Fatigue were highly correlated (R(2)=0.977; Cronbach's alpha=0.924) indicating an intimate relationship between symptom constructs. Cluster analysis suggested 4 clades each in CFS and HC. Translational utility was inferred from the clustering of proteomics from cerebrospinal fluid. CONCLUSIONS: Plotting Fatigue severity versus Sum8 produced an internally consistent classifying system. This is a necessary step for translating symptom profiles into fatigue phenotypes and their pathophysiological mechanisms.
Baraniuk JN, El-Amin S, Corey R, Rayhan R, Timbol C.	Division of Rheumatology, Immunology and Allergy, Georgetown University, Washington, DC 20007-2197, USA. baraniuj@georgetown.edu	Carnosine treatment for gulf war illness: a randomized controlled trial.	Glob J Health Sci. 2013 Feb 4; 5(3):69-81. doi: 10.5539/gjhs.v5n3p69.	About 25% of 1990-1991 Persian Gulf War veterans experience disabling fatigue, widespread pain, and cognitive dysfunction termed Gulf War illness (GWI) or Chronic Multisymptom Illness (CMI). A leading theory proposes that wartime exposures initiated prolonged production of reactive oxygen species (ROS) and central nervous system injury. The endogenous antioxidant L-carnosine (B-alanyl-L-histidine) is a potential treatment since it is a free radical scavenger in nervous tissue. To determine if nutritional supplementation with L-carnosine would significantly improve pain, cognition and fatigue in GWI, a randomized double blind placebo controlled 12 week dose escalation study involving 25 GWI subjects was employed. L-carnosine was given

				as 500, 1000, and 1500 mg increasing at 4 week intervals. Outcomes included subjective fatigue, pain and psychosocial questionnaires, and instantaneous fatigue and activity levels recorded by ActiWatch Score devices. Cognitive function was evaluated by WAIS-R digit symbol substitution test. Carnosine had 2 potentially beneficial effects: WAIS-R scores increased significantly, and there was a decrease in diarrhea associated with irritable bowel syndrome. No other significant incremental changes were found. Therefore, 12 weeks of carnosine (1500 mg) may have beneficial cognitive effects in GWI. Fatigue, pain, hyperalgesia, activity and other outcomes were resistant to treatment.
Bateman L, Spotila J.	[No address quoted]	Article on CFS does not reflect current best treatment practices.	Am Fam Physician. 2013 Apr 1; 87(7): Online.	Comment on Am Fam Physician. 2012 Oct 15; 86(8):741-6.
Bayliss K, Riste L, Fisher L, Wearden A, Peters S, Lovell K, Chew-Graham C.	1Research Associate, Institute of Population Health, University of Manchester, Manchester, UK.	Diagnosis and management of chronic fatigue syndrome/myalgic encephalitis in black and minority ethnic people: a qualitative study.	Prim Health Care Res Dev. 2013 May 23:1-13. [Epub ahead of print]	Aim This study aims to explore the possible reasons for the lower levels of diagnosis of chronic fatigue syndrome/myalgic encephalitis (CFS/ME) in the black and minority ethnic (BME) population, and the implications for management. BACKGROUND: Population studies suggest CFS/ME is more common in people from BME communities compared with the White British population. However, the diagnosis is made less frequently in BME groups. METHODS: Semi-structured qualitative interviews were conducted with 35 key stakeholders in NW England. Interviews were analysed using open explorative thematic coding. Findings There are barriers at every stage to the diagnosis and management of CFS/ME in people from BME groups. This begins with a lack of awareness of CFS/ME among BME respondents. Religious beliefs and the expectation of roles in the family and community mean that some people in BME groups may choose to manage their symptoms outside primary care using alternative therapies, prayer or spiritual healing. When accessing primary care, all participants recognised the possible influence of language barriers in reducing the likelihood of a diagnosis of CFS/ME. Stereotypical beliefs, including labels such as 'lazy' or 'work shy' were also believed to act as a barrier to diagnosis. Patients highlighted the importance of an on-going relationship with the general practitioner (GP), but perceived a high turnover of GPs in inner city practices, which undermined the holistic approach necessary to achieve a diagnosis. CONCLUSION: Training is required for health professionals to challenge inaccurate assumptions about CFS/ME in BME groups. The focus on the individual in UK primary care may not be appropriate for this group due to the role played by the family and community in how symptoms can be presented and managed. Culturally sensitive, educational resources for patients are also needed to explain symptoms and legitimise consultation.
Beasant L, Mills N, Crawley E.	1 School of Social & Community Medicine, Centre for Child &	Adolescents and mothers value referral to a	Prim Health Care Res Dev. 2013 Apr 25:1-9. [Epub ahead of print]	BACKGROUND: Paediatric chronic fatigue syndrome or myalgic encephalopathy (CFS/ME) is relatively common and disabling. Current guidance recommends referral to specialist services, although some general practitioners believe the label of CFS/ME

	Adolescent Health, University of Bristol, Oakfield Grove, UK.	specialist service for chronic fatigue syndrome or myalgic encephalopathy (CFS/ME).		is harmful and many are not confident about diagnosing CFS/ME. Aim Explore whether or not adolescents and their mothers value referral to a specialist service for young people with CFS/ME. METHODS: A qualitative study nested within a feasibility study of interventions for CFS/ME [Specialist Medical Intervention and Lightning Evaluation (SMILE)]. In-depth interviews were undertaken with 13 mothers and 12 adolescents participating in the SMILE study. Transcripts were systematically assigned codes using the qualitative data organisation package NVivo and analysed thematically using techniques of constant comparison. RESULTS: Gaining access to the specialist service was difficult and took a long time. Mothers felt that they needed to be proactive and persistent, partly because of a lack of knowledge in primary and secondary care. Having gained access, mothers felt the CFS/ME service was useful because it recognised and acknowledged their child's condition and opened channels of dialogue between health-care professionals and education providers. Adolescents reported that specialist medical care resulted in better symptom management, although some adolescents did not like the fact that the treatment approach limited activity. CONCLUSIONS: Adolescents and their mothers value receiving a diagnosis from a specialist service and making progress in managing CFS/ME. General practitioners should support adolescents with CFS/ME in accessing CFS/ME specialist services, consistent with current guidance.
Beatty L, Lambert S.	[No address quoted]	A systematic review of internet-based self-help therapeutic interventions to improve distress and disease-control among adults with chronic health conditions.	Clin Psychol Rev. 2013 Jun; 33(4):609-22.	The evidence base of internet-based self-help interventions has been rapidly growing for mental health conditions over the past decade. However, to date a systematic review of the application of this technology to chronic health conditions has not been reported. The objective of the present review was to therefore critically appraise the research on the efficacy of internet self-help interventions for distress and disease outcomes in adults with physical health complaints. Electronic searches were conducted in Embase, CINAHL, MEDLINE and PsychINFO, and reference lists were examined. Twenty four studies met inclusion criteria, covering 8 health conditions. Across health conditions, consistent evidence was obtained that online therapeutic interventions were efficacious in improving disease-symptoms and control, with the exception of diabetes. Mixed evidence was obtained for distress outcomes: 3 health conditions demonstrated consistent benefit (irritable bowel syndrome, tinnitus, and one heterogeneous chronic illness population); one condition obtained moderate support (chronic pain); while results were not promising for diabetes. The limited research conducted among epilepsy, cancer, and chronic fatigue precluded conclusions from being drawn. Few studies met all methodological quality criteria. This review demonstrates that internet-based self-help interventions hold guarded promise in the amelioration of distress and disease-control, and further research implications are discussed.
Belcaro G, Cornelli U, Luzzi R,	Irvine3 Circulation/Vascular	Improved management of	Panminerva Med. 2013 Nov 14. [Epub ahead of print]	Aim: The aim of this supplement study was to evaluate French oak wood extract (Robuvit®, Horphag Research Ltd) used as a supplement in association with a defined

Cesarone MR, Dugall M, Feragalli B, Hu S, Pellegrini L, Ippolito E.	Labs and San Val. Epidemiology Department of Biomedical Sciences, Chieti−Pescara University, Pescara, Italy - cardres@abol.it.	primary chronic fatigue syndrome with the supplement French oak wood extract (Robuvit®): a pilot, registry evaluation.		management plan for chronic fatigue syndrome (CFS) in healthy subjects with CFS, a condition that has, so far, no specific treatment or management standards. Methods: Robuvit® is a new proprietary and exclusive extract of oak wood with important antoxidant actions. The dosage of the supplementation was 200 mg/day for at least 6 months. The CFS questionnaire and the Brief Mood Introspection Scale (BMIS) questionnaire were used to evaluate mood variations associated with CFS patients. The CFS form includes an analogue scale to record the variations of single symptoms with a score range of 0-10. At inclusion into the registry study, at least 5 symptoms were present. All subjects (age range 35-44; BMI range 24-26) with CFS were tested for oxidative stress: 61 out of 91 subjects had an increased value of oxidative stress. The BMIS scale evaluating mood changes in time was also used. The evaluation was repeated at 3 and 6 months. Results: Out of 91 eligible subjects with CFS, 48 subjects (31 with increased oxidative stress) were accepted as part of the supplement registry study using Robuvit; 43 (30 with increased oxidative stress) were accepted as controls using only the management plan. In the Robuvit® group there were 3 drop outs; also 3 controls were lost. Oxidative stress was increased in 64.58% of subjects that used Robuvit and in 69.7% of controls. The average values of oxidative stress were expressed for the whole group. The average follow up was 199.3; 9.2 days in the Robuvit group and 202.2; 5.5 in the control group with a minimum of 6 months. Considering variations in oxidative stress, there was no significant average change in controls, but a significant decrease from the initial values was observed in Robuvit subjects after 3 and 6 months. The CFS questionnaire variations in score indicated that there was a significant improvement for most symptoms after 3 and 6 months in the Robuvit group. Positive variations were also present in controls, indicating the positive effect of an increased attention to CFS. The improvement in signs/symptoms was significantly more valuable in subjects using the oak wood extract considering the main 8 symptoms and the accessory symptoms. Considering the BMIS variations, the totals for positive and negative items were significantly more favourable for Robuvit subjects. Overall mood evaluation in the oak wood extract group improved from an inclusion average of -6.93;2.1 to +4.32;2.6 at 6 months; in contrast it changed from -6.5;2.5 to -3.4;1.5 in controls. No side effects were observed during the supplementation with Robuvit. The compliance was optimal with 93% of the capsules correctly used. Conclusion: This promising pilot supplement registry study indicates a new opportunity of management for these difficult and often neglected patients. Correlation between oxidative stress and CFS has to be better explored.
Berger JR, Pocoski J, Preblick R, Boklage S.	Department of Neurology, University of Kentucky College of Medicine, Lexington, KY, USA.	Fatigue heralding multiple sclerosis.	Mult Scler. 2013 Oct; 19(11):1526-32. doi: 10.1177/1352458513477924. Epub 2013 Feb 25.	BACKGROUND: Fatigue is a common symptom in multiple sclerosis (MS) and is an important determinant of overall well-being and disability. OBJECTIVE: To assess the frequency with which fatigue precedes the diagnosis of MS using a retrospective database analysis. METHODS: Between January 1, 2003 and September 30, 2008, patients diagnosed with fatigue with and without fatigue-related medications within a

				3-year period prior to newly diagnosed MS were identified from the MarketScan Databases. All statistical analysis was performed using SAS. RESULTS: Of the 16,976 patients with MS in the overall population, 5305 (31.3%) were newly diagnosed with MS and had three years of continuous healthcare coverage prior to MS diagnosis. Of these patients, 1534 (28.9%) were labeled with chronic fatigue syndrome (ICD9-780.71) or malaise or fatigue (ICD9-780.79) prior to the diagnosis of MS. One-third of these patients were labeled with fatigue one to two years before the diagnosis; 30.8% were diagnosed only with fatigue and had no other MS symptoms prior to their MS diagnosis. Among the patients diagnosed with fatigue, 10.4% were also prescribed medication for fatigue. CONCLUSION: This study demonstrates that fatigue may herald MS, often by years. A careful history for transient neurological symptoms and a physical examination is warranted in any patient presenting with fatigue.
Blankfield A.	[No address quoted]	Kynurenine Pathway Pathologies: do Nicotinamide and Other Pathway Co-Factors have a Therapeutic Role in Reduction of Symptom Severity, Including Chronic Fatigue Syndrome (CFS) and Fibromyalgia (FM).	Int J Tryptophan Res. 2013 Jul 21;6 (Suppl 1):39-45. doi: 10.4137/IJTR.S11193. Print 2013.	The definition of dual tryptophan pathways has increased the understanding of the mind-body, body-mind dichotomy. The serotonergic pathway highlights the primary (endogenous) psychiatric disorders. The up-regulation of the kynurenine pathway by physical illnesses can cause neuropathic and immunological disorders1 associated with secondary neuropsychiatric symptoms. Tryptophan and nicotinamide deficiencies fall within the protein energy malnutrition (PEM) spectrum. They can arise if the kynurenine pathway is stressed by primary or secondary inflammatory conditions and the consequent imbalance of available catabolic/anabolic substrates may adversely influence convalescent phase efficiency. The replacement of depleted or reduced NAD+ levels and other cofactors can perhaps improve the clinical management of these disorders. Chronic fatigue syndrome (CFS) and fibromyalgia (FM) appear to meet the criteria of a tryptophan-kynurenine pathway disorder with potential neuroimmunological sequelae. Aspects of some of the putative precipitating factors have been previously outlined.2,3. An analysis of the areas of metabolic dysfunction will focus on future directions for research and management.
Blazquez A, Ruiz E, Aliste L, García-Quintana A, Alegre J.	A Unity of CFS and Fibromyalgia, Vall Hebron Hospital, Internal Medicine, Barcelona, Spain.	The Impact of Fatigue and Fibromyalgia on Sexual Dysfunction in Women with Chronic Fatigue Syndrome.	J Sex Marital Ther. 2013 Nov 25. [Epub ahead of print]	ABSTRACT Sexual dysfunction in patients with chronic fatigue syndrome (CFS) is attracting growing interest but has been analyzed by few studies to date. For this reason we evaluate sexual dysfunction in women with CFS (GRISS) and explore correlations with fatigue and other symptoms. Sexual dysfunction was greater in CFS patients (n = 615) with a higher number of cognitive, neurological, and neurovegetative symptoms, concomitant fibromyalgia, Sjögren's syndrome, or myofascial pain syndrome, and more intense fatigue (P <0.05).
Bloom S, Ablin JN, Lebel D, Rath E, Faran Y, Daphna-Tekoah S, Buskila D.	Orthopedic Surgery Department, Soroka Medical Center, Beersheba, Israel.	Awareness of diagnostic and clinical features of fibromyalgia among orthopedic surgeons.	Rheumatol Int. 2013 Apr; 33(4):927-31. doi: 10.1007/s00296-012-2488-z. Epub 2012 Jul 22.	Fibromyalgia Syndrome (FMS) is a chronic pain syndrome characterized by widespread musculoskeletal pain and fatigue. The current study was designed to evaluate the awareness and skills of orthopedic surgeons (OS) regarding FMS diagnosis and treatment. For the examination of awareness and familiarity of OS in Israel to Fibromyalgia, a questionnaire-based survey was conducted. Two hundred and nineteen OS, residents and specialists, were asked anonymously about

				awareness, knowledge, and treatment of FM. Multivariable statistical analysis was performed. 91 % (199) of responders reported that they recognized the disease. Notwithstanding, the mean knowledge score was 7.6 out of 17. In addition, OS who were trained in the south of Israel were found to have a better degree of knowledge about FM (9.7 vs. 7.4; $p < 0.03$). The awareness and knowledge among OS regarding FM needs to be improved. OS who were trained in the south of Israel were found to have better degree of knowledge regarding FM.
Borsini A, Hepgul N, Mondelli V, Chalder T, Pariante CM.	Section of Stress, Psychiatry and Immunology and Perinatal Psychiatry, Department of Psychological Medicine, Institute of Psychiatry, King's College London, UK.	Childhood stressors in the development of fatigue syndromes: a review of the past 20 years of research.	Psychol Med. 2013 Oct 7:1-15. [Epub ahead of print]	BACKGROUND: Chronic fatigue syndrome (CFS) and fibromyalgia (FM) are both highly prevalent conditions associated with extreme disability and with the development of co-morbid psychiatric disorders, such as depression and anxiety. Childhood stressors have been shown to induce persistent changes in the function of biological systems potentially relevant to the pathogenesis of both CFS and FM, such as the inflammatory system and the hypothalamic-pituitary-adrenal (HPA) axis. In this review, we examined whether multiple forms of childhood stressors are contributing factors to the development of these disorders, and of the associated psychiatric symptoms. METHOD: Using PubMed, we identified 31 papers relevant to this narrative review. We included cohort studies and case-control studies, without any exclusion in terms of age and gender. No study characteristics or publication date restrictions were imposed. RESULTS: Most studies across the literature consistently show that there is a strong association between experiences of childhood stressors and the presence of CFS and FM, with rates of CFS/FM being two- to three-fold higher in exposed than in unexposed subjects. We also found evidence for an increased risk for the development of additional symptoms, such as depression, anxiety and pain, in individuals with CFS and FM with a previous history of childhood stressors, compared with individuals with CFS/FM and no such history. CONCLUSIONS: Our review confirms that exposure to childhood stressors is associated with the subsequent development of fatigue syndromes such as CFS and FM, and related symptoms. Further studies are needed to identify the mechanisms underlying these associations.
Bossuyt X, Cooreman S, De Baere H, Verschueren P, Westhovens R, Blockmans D, Mariën G.	Experimental Laboratory Immunology, Catholic University Leuven, Leuven, Belgium. xavier.bossuyt@uz.kuleuven.ac.be	Detection of antinuclear antibodies by automated indirect immunofluorescence analysis.	Clin Chim Acta. 2013 Jan 16; 415:101-6. doi: 10.1016/j.cca.2012.09.021. Epub 2012 Sep 28. Comment in Clin Chim Acta. 2013 Jun 5; 421:168-9.	BACKGROUND: Testing for antinuclear antibodies is useful for the diagnosis of systemic rheumatic diseases. Automated systems for image acquisition and interpretation of indirect immunofluorescence-based tests are increasingly used. The diagnostic performance of such automated approach in untreated patients has not been reported. METHODS: Antinuclear antibodies were measured by automated indirect immunofluorescence using Zenit G. Sight on HEp2 and HEp2000 substrate in 268 consecutive samples submitted to the laboratory for antinuclear antibody testing, and in 231 patients with a systemic rheumatic disease at the time of diagnosis, 143 blood donors, 134 patients with chronic fatigue syndrome, and 133 diseased controls. RESULTS: Image acquisition by G-Sight was of high quality. The accuracy of pattern assignment was limited. There was a significant correlation between automated estimation of fluorescence intensity (probability index of positivity) and end-point

				titer. Probability index interval specific likelihood ratios for systemic rheumatic disease increased with increasing level of positivity probability. With the HEp-2 substrate, the likelihood ratio for systemic lupus erythematosus was 0.06, 0.4, 6.8, 12.1, and 43.9 for a probability measure of positivity of ≤10, 11-≤30, 31-≤50, 51-≤85, and >85, respectively. CONCLUSION: Quantitative data generated by automated image acquisition facilitates standardized interpretation.
Bould H, Collin SM, Lewis G, Rimes K, Crawley E.	School of Social and Community Medicine, University of Bristol, Bristol, UK.	Depression in paediatric chronic fatigue syndrome.	Arch Dis Child. 2013 Jun; 98(6):425-8. doi: 10.1136/archdischild-2012-303396. Epub 2013 Apr 25.	OBJECTIVE: To describe the prevalence of depression in children with chronic fatigue syndrome (CFS)/myalgic encephalomyelitis (ME) and investigate the relationship between depression in CFS/ME and clinical symptoms such as fatigue, disability, pain and school attendance. DESIGN: Cross-sectional survey data using the Hospital Anxiety and Depression Scale (HADS) collected at assessment. SETTING: Specialist paediatric CFS/ME service in the South West. PATIENTS: Children aged 12-18 years with CFS/ME. MAIN OUTCOME MEASURE: Depression was defined as scoring >9 on the HADS depression scale. RESULTS: 542 subjects had complete data for the HADS and 29% (156/542) (95% CI 25% to 33%) had depression. In a univariable analysis, female sex, poorer school attendance, and higher levels of fatigue, disability, pain, and anxiety were associated with higher odds of depression. Age of child and duration of illness were not associated with depression. In a multivariable analysis, the factors most strongly associated with depression were disability, with higher scores on the physical function subscale of the 36 item Short Form (SF-36). CONCLUSIONS: Depression is commonly comorbid with CFS/ME, much more common than in the general population, and is associated with markers of disease severity. It is important to screen for, identify and treat depression in this population.
Bourke JH, Johnson AL, Sharpe M, Chalder T, White PD.	Centre for Psychiatry, Wolfson Institute for Preventive Medicine, Barts and The London School of Medicine and Dentistry, Queen Mary University of London, UK.	Pain in chronic fatigue syndrome: response to rehabilitative treatments in the PACE trial.	Psychol Med. 2013 Aug 23:1-8. [Epub ahead of print]	BACKGROUND: Pain is a common symptom of chronic fatigue syndrome (CFS). We investigated the effects of the treatments used in the PACE trial [cognitive behavioural therapy (CBT), graded exercise therapy (GET), adaptive pacing therapy (APT) and specialist medical care (SMC)] on pain in CFS. METHOD: We compared pain outcomes including individual painful symptoms, taken from the CDC criteria for CFS and co-morbid fibromyalgia. We modelled outcomes adjusting for baseline variables with multiple linear regression. RESULTS: Significantly less frequent muscle pain was reported by patients following treatment with CBT compared to SMC (mean difference = 0.38 unit change in frequency, p = 0.02), GET versus SMC (0.42, p = 0.01) and GET versus APT (0.37, p = 0.01). Significantly less joint pain was reported following CBT versus APT (0.35, p = 0.02) and GET versus APT (0.36, p = 0.02). Co-morbid fibromyalgia was less frequent following GET versus SMC (0.03, p = 0.03). The effect sizes of these differences varied between 0.25 and 0.31 for muscle pain and 0.24 and 0.26 for joint pain. Treatment effects on pain were independent of 'change in fatigue'. CONCLUSIONS: CBT and GET were more effective in reducing the frequency of both muscle and joint pain than APT and SMC. When compared to SMC, GET also reduced the frequency of co-morbid fibromyalgia; the size of this effect on

				pain was small.
Bradley AS, Ford B, Bansal AS.	Department of Immunology, St Helier University Hospital NHS Trust, Carshalton, Surrey, UK.	Altered functional B cell subset populations in patients with chronic fatigue syndrome compared to healthy controls.	Clin Exp Immunol. 2013 Apr; 172(1):73-80. doi: 10.1111/cei.12043.	Chronic fatigue syndrome (CFS) is a heterogeneous disorder of unknown aetiology characterized by disabling fatigue, headaches, sleep disturbance and several other symptoms. The onset of CFS may follow a viral infection or period of stress. Patients with CFS do not have hypogammaglobulinaemia, predisposition to recurrent bacterial infections or symptoms of autoimmunity. To date, defects in B cell numbers or function have not been shown in the literature. However, treatment with anti-B cell therapy using Rituximab has recently shown benefit to CFS patients. We therefore postulated that patients with CFS had a subtle humoral immune dysfunction, and performed extended B cell immunophenotyping. We undertook a detailed characterization of the proportions of the different B cell subsets in 33 patients with CFS fulfilling the Canadian and Fukada criteria for CFS and compared these with 24 age- and gender-matched healthy controls (HC). CFS patients had greater numbers of naive B cells as a percentage of lymphocytes: 6·3 versus 3·9% in HC (P=0·034), greater numbers of naive B cells as a percentage of B cells: 65 versus 47% in controls (P=0·003), greater numbers of transitional B cells: 1·8 versus 0·8% in controls (P=0·025) and reduced numbers of plasmablasts: 0·5 versus 0·9% in controls (P=0·013). While the cause of these changes is unclear, we speculate whether they may suggest a subtle tendency to autoimmunity.
Brenu EW, Huth TK, Hardcastle SL, Fuller K, Kaur M, Johnston S, Ramos SB, Staines DR, Marshall-Gradisnik SM.	School of Medical Science, Griffith University, Gold Coast, Australia.	The Role of Adaptive and Innate Immune Cells in Chronic Fatigue Syndrome/ Myalgic Encephalomyelitis.	Int Immunol. 2013 Dec 16. [Epub ahead of print]	Perturbations in immune processes are a hallmark of a number of autoimmune and inflammatory disorders. Chronic Fatigue Syndrome/ Myalgic Encephalomyelitis (CFS/ME) is an inflammatory disorder with possible autoimmune correlates, characterised by reduced Natural Killer (NK) cell activity, elevations in regulatory T cells (Tregs) and dysregulation in cytokine levels. The purpose of this paper is to examine innate and adaptive immune cell phenotypes and functional characteristics that have not been previously examined in CFS/ME patients. 30 patients with CFS/ME and 25 non-fatigued controls were recruited for this study. Whole blood samples were collected from all participants for the assessment of cell phenotypes, functional properties, receptors, adhesion molecules, antigens and intracellular proteins using flow cytometric protocols. The cells investigated included NK cells, dendritic cells (DCs), neutrophils, B cells, T cells, γδT cells and Tregs. Significant changes were observed in B cell subsets, Tregs, CD4(+)CD73(+)CD39(+) T cells, cytotoxic activity, granzyme B, neutrophil antigens, TNF-α and IFN-γ in the CFS/ME patients in comparison to the non-fatigued controls. Alterations in B cells, Tregs, NK cells and neutrophils suggest significant impairments in immune regulation in CFS/ME and these may have similarities to a number of autoimmune disorders.
Brewer JH, Thrasher JD, Straus DC, Madison RA, Hooper D.	Plaza Infectious Disease and St. Luke's Hospital, 4320 Wornall Road, Suite 440, Kansas	Detection of mycotoxins in patients with chronic fatigue syndrome.	Toxins (Basel). 2013 Apr 11; 5(4):605-17. doi: 10.3390/toxins5040605.	Over the past 20 years, exposure to mycotoxin producing mold has been recognized as a significant health risk. Scientific literature has demonstrated mycotoxins as possible causes of human disease in water-damaged buildings (WDB). This study was conducted to determine if selected mycotoxins could be identified in human urine

	City, MO 64111, USA. jbrewer@plazamedicine.com			from patients suffering from chronic fatigue syndrome (CFS). Patients (n = 112) with a prior diagnosis of CFS were evaluated for mold exposure and the presence of mycotoxins in their urine. Urine was tested for aflatoxins (AT), ochratoxin A (OTA) and macrocyclic trichothecenes (MT) using Enzyme Linked Immunosorbent Assays (ELISA). Urine specimens from 104 of 112 patients (93%) were positive for at least one mycotoxin (one in the equivocal range). Almost 30% of the cases had more than one mycotoxin present. OTA was the most prevalent mycotoxin detected (83%) with MT as the next most common (44%). Exposure histories indicated current and/or past exposure to WDB in over 90% of cases. Environmental testing was performed in the WDB from a subset of these patients. This testing revealed the presence of potentially mycotoxin producing mold species and mycotoxins in the environment of the WDB. Prior testing in a healthy control population with no history of exposure to a WDB or moldy environment (n = 55) by the same laboratory, utilizing the same methods, revealed no positive cases at the limits of detection.

Brimmer DJ, Maloney E, Devlin R, Jones JF, Boneva R, Nagler C, LeRoy L, Royal S, Tian H, Lin JM, Kasten J, Unger ER.	Division of High-Consequence Pathogens and Pathology, Centers for Disease Control and Prevention, 1600 Clifton Road, MS-G41, Atlanta, GA 30033, USA. dyv4@cdc.gov	A pilot registry of unexplained fatiguing illnesses and chronic fatigue syndrome.	BMC Res Notes. 2013 Aug 2; 6:309. doi: 10.1186/1756-0500-6-309.	BACKGROUND: Chronic fatigue syndrome (CFS) has no diagnostic clinical signs or biomarkers, so diagnosis requires ruling out conditions with similar signs and symptoms. We conducted a pilot registry of unexplained fatiguing illnesses and CFS to determine the feasibility of establishing and operating a registry and implementing an education outreach initiative. The pilot registry was conducted in Bibb County, Georgia. Patient referrals were obtained from healthcare providers who were identified by using various education outreach initiatives. These referrals were later supplemented with self-referrals by members of a local CFS support group. All patients meeting referral criteria were invited to participate in a screening interview to determine eligibility. If patients met registry criteria, they were invited to a one-day clinic for physical and laboratory evaluations. We classified patients based on the 1994 case definition. RESULTS: We registered 827 healthcare providers. Forty-two

				providers referred 88 patients, and 58 patients (66%) completed clinical evaluation. Of the 188 CFS support group members, 53 were self-referred and 46 (87%) completed the clinical evaluation. Of the 104 participants completing evaluation, 36% (n=37) met the criteria for CFS, 17% (n=18) had insufficient fatigue or symptoms (ISF), and 47% (n=49) were found to have exclusionary medical or psychiatric illnesses. Classification varied significantly by type of referral but not by previous history of CFS diagnosis. Healthcare providers referred more patients who were classified as CFS as compared to support group referrals in which more exclusionary conditions were identified. Family practice and internal medicine specialties made the most referrals and had the highest number of CFS cases. We conducted three CME events, held three "Meet and Greet" sessions, visited four large clinical health practices and health departments, mailed five registry newsletters, and conducted in-person office visits as part of education outreach, which contributed to patient referrals. CONCLUSIONS: Referrals from healthcare providers and self-referrals from the patient support group were important to registry enrollment. The number of potentially treatable conditions that were identified highlights the need for continued medical management in this population, as well as the limitations of registries formed without clinical examination. Education initiatives were successful in part because of partnerships with local organizations.
Broadbent S, Coutts R.	School of Health and Human Sciences, Southern Cross University, PO Box 157, Lismore, NSW 2480, Australia. suzanne.broadbent@scu.edu.au	The protocol for a randomised controlled trial comparing intermittent and graded exercise to usual care for chronic fatigue syndrome patients.	BMC Sports Sci Med Rehabil. 2013 Aug 30; 5(1):16. doi: 10.1186/2052-1847-5-16.	BACKGROUND: Chronic Fatigue Syndrome is a debilitating disorder with an unknown aetiology but suspected multifactorial origins. Common "triggers" include severe viral infections and emotional stress. Recent studies have also found evidence of immune dysfunction and elevated inflammatory cytokines in CFS patients, but there has been considerable variation in the outcome measures and magnitude of these studies. Currently, there is no cure for CFS but treatments include rest, specialist medical care, cognitive behavioural therapy, and graded (self-paced) exercise. To date, several studies have examined the efficacy of graded exercise with or without Cognitive Behavioural Therapy, with some success for patients. However, improvements in functional capacity have not necessarily correlated with improvements in immune function, fatigue or other symptoms. This 12-week pilot trial compares graded and intermittent exercise to normal care, measuring physiological outcomes, fatigue levels, immune function and wellness. METHODS/DESIGN: 90 patients aged between 16 to 60 years, who meet the diagnostic criteria for CFS and have been diagnosed by their medical practitioner, will be randomly recruited into groups consisting of Intermitent exercise, Graded exercise and usual care (Control). The outcomes will be measured pre-study (Week 0) and post-study (Week 13). Primary outcomes are VO2peak, anaerobic threshold, peak power, levels of fatigue, immune cell (CD3+CD4+, CD3+CD8+, CD19+, CD 16+CD56+) concentrations and activation. Secondary outcomes include onset of secondary CFS symptoms (e.g. fever, swollen lymph nodes), wellness, mood, and sleep patterns. Primary analysis will be based on intention to treat using

				logistic regression models to compare treatments. Quantitative data will be analysed using repeated measures ANOVA with a linear model, and Cohen's effect size. Qualitative data such as participants' responses (e.g. changes in mood and other reactions) following the exercise modalities will be read and sections demarcated. A code will be applied to each segment. A prevalence of codes will be considered thematically. DISCUSSION: The results of the trial will provide information about the efficacy of intermittent and graded exercise compared to usual care (rest and lifestyle recommendations), contributing to the evidence for best-practice CFS management. TRIAL REGISTRATION: Australia and New Zealand Clinical Trials Registry ACTRN12612001241820.
Broderick G, Ben-Hamo R, Vashishtha S, Efroni S, Nathanson L, Barnes Z, Fletcher MA, Klimas N.	Department of Medicine, University of Alberta, Edmonton, Canada. gordon.broderick@ualberta.ca	Altered immune pathway activity under exercise challenge in Gulf War Illness: an exploratory analysis.	Brain Behav Immun. 2013 Feb; 28: 159-69. doi: 10.1016/j.bbi.2012.11.007. Epub 2012 Nov 29.	Though potentially linked to the basic physiology of stress response we still have no clear understanding of Gulf War Illness (GWI), a debilitating illness presenting with a complex constellation of immune, endocrine and neurological symptoms. Here we compared male GWI (n=20) with healthy veterans (n=22) and subjects with chronic fatigue syndrome/myalgic encephalomyelitis (CFS/ME) (n=7). Blood was drawn during a Graded eXercise Test (GXT) prior to exercise, at peak effort (VO2 max) and 4-h post exercise. Affymetrix HG U133 plus 2.0 microarray gene expression profiling in peripheral blood mononuclear cells (PBMCs) was used to estimate activation of over 500 documented pathways. This was cast against ELISA-based measurement of 16 cytokines in plasma and flow cytometric assessment of lymphocyte populations and cytotoxicity. A 2-way ANOVA corrected for multiple comparisons (q statistic <0.05) indicated significant increases in neuroendocrine-immune signaling and inflammatory activity in GWI, with decreased apoptotic signaling. Conversely, cell cycle progression and immune signaling were broadly subdued in CFS. Partial correlation networks linking pathways with symptom severity via changes in immune cell abundance, function and signaling were constructed. Central to these were changes in IL-10 and CD2+ cell abundance and their link to two pathway clusters. The first consisted of pathways supporting neuronal development and migration whereas the second was related to androgen-mediated activation of NF-κB. These exploratory results suggest an over-expression of known exercise response mechanisms as well as illness-specific changes that may involve an overlapping stress-potentiated neuro-inflammatory response.
Brooks J, King N, Wearden A.	Centre for Applied Psychological Research, University of Huddersfield, UK.	Couples' experiences of interacting with outside others in chronic fatigue syndrome: a qualitative study.	Chronic Illn. 2013 Apr 12. [Epub ahead of print]	OBJECTIVES: Social isolation and stigma are frequently reported by patients with chronic fatigue syndrome/myalgic encephalomyelitis and relationships in the home environment with those close to the patients (their 'significant others') may thus be particularly important. Rather little attention has yet been paid to the beliefs and experiences of 'significant others' themselves in this context. This study sought to explore in-depth the beliefs and experiences of both patients and 'significant others' in relation to chronic fatigue syndrome/myalgic encephalomyelitis. METHODS: In-depth interviews using a semi-structured interview schedule designed around the

				core constructs of the Common-Sense Model of self-regulation were conducted with two patients with chronic fatigue syndrome/myalgic encephalomyelitis and their spouses. Interpretative Phenomenological Analysis was used to analyse interview data. RESULTS: Experiences of social interactions in relation to chronic fatigue syndrome/myalgic encephalomyelitis with others outside of the relationship dyad emerged as a key issue for all participants when reflecting on their experiences of living with the condition. These concerns are presented under two themes: interactions with healthcare professionals and interactions with the social world. CONCLUSIONS: It is evident that significant others play an important role in the lived experience of chronic fatigue syndrome/myalgic encephalomyelitis. For both patients and significant others, the wider social world and interactions with outside others may be important influences on dyadic coping in chronic fatigue syndrome/myalgic encephalomyelitis. Both future research and treatment interventions could usefully include a 'significant other' perspective.
Brooks JM, Daglish J, Wearden AJ.	University of Huddersfield, UK.	Attributions, distress and behavioural responses in the significant others of people with chronic fatigue syndrome.	J Health Psychol. 2013 Oct; 18(10):1288-95. doi: 10.1177/1359105312464670. Epub 2012 Nov 23.	To test an attribution-emotion model of reactions to chronic fatigue syndrome/myalgic encephalomyelitis, 30 significant others of 30 adult patients with chronic fatigue syndrome/myalgic encephalomyelitis were administered a semi-structured interview about their beliefs regarding the patient's illness and completed questionnaire measures of distress and behavioural responses to the patient. Spontaneous causal explanations (attributions) for illness events, symptom exacerbation and negative patient mood were extracted and coded. Significant others' distress and negative behavioural responses towards the chronic fatigue syndrome/myalgic encephalomyelitis patient were associated with attributing illness events to causes personal and internal to the patient. Our findings may inform the future family-based interventions for chronic fatigue syndrome/myalgic encephalomyelitis.
Brooks K, Carter J.	Department of Kinesiology, Texas A&M University, USA.	Overtraining, Exercise, and Adrenal Insufficiency.	J Nov Physiother. 2013 Feb 16;3 (125). pii: 11717.	Running, or any aerobic training in moderation, has a positive effect on health. There is a point of diminishing returns, where chronic stress from overtraining, which is common in runners, may be linked to problems in the adrenal gland. Overtraining Syndrome (OS) has been linked with adrenal insufficiency. There is a direct link between stress and the adrenal glands, and the physical stress of overtraining may cause the hormones produced in these glands to become depleted. Overtraining Syndrome (OS) has been described as chronic fatigue, burnout and staleness, where an imbalance between training/competition, versus recovery occurs. Training alone is seldom the primary cause. In most cases, the total amount of stress on the athlete exceeds their capacity to cope. A triggering stressful event, along with the chronic overtraining, pushes the athlete to start developing symptoms of overtraining syndrome, which is far worse than classic overtraining. Overtraining can be a part of healthy training, if only done for a short period of time. Chronic overtraining is what leads to serious health problems, including adrenal insufficiency. Severe overtraining

				over an extended period can result in adrenal depletion. An Addison-Type overtraining syndrome, where the adrenal glands are no longer able to maintain proper hormone levels and athletic performance is severely compromised has been described by researchers. The purpose of this review is to describe the relationship between overtraining, chronic fatigue, and adrenal insufficiency and to address the overlap in these conditions, as well as examine critical research on the relationship between the dysfunction of the adrenal axis in over trained and stressed athletes.
Brown AA, Evans MA, Jason LA.	Center for Community Research, DePaul University, Chicago, IL, USA.	Examining the energy envelope and associated symptom patterns in chronic fatigue syndrome: does coping matter?	Chronic Illn. 2013 Dec; 9(4):302-11. doi: 10.1177/1742395313478220. Epub 2013 Apr 12.	OBJECTIVE/Hypothesis The objective of this study was to examine sub-types of individuals with chronic fatigue syndrome based on variables that are associated with the energy envelope theory and to examine the role of coping strategies in explaining the differences found between the subtypes. METHODS Cluster analysis was used. Grouping variables included physical functioning, post-exertional malaise severity, and the extent to which an individual was outside of the energy envelope. These clusters were evaluated using discriminant function analysis to determine whether they could be differentiated based on coping styles. RESULTS Cluster analysis identified three groups. Clusters 1 and 2 were consistent with the energy envelope theory. However, Cluster 3 was characterized by patients with the most impairment, but they were to a lesser extent exceeding their energy envelope. Coping strategies explained a small percentage (10%) of the variance in differentiating the clusters. DISCUSSION Energy maintenance may be associated with improved functioning and less severe symptoms for some. However, patients in Cluster 3 were closer to remaining within their energy envelope and also used higher levels of adaptive coping but were more impaired than Cluster 2. This suggests that adaptive coping strategies were not associated with improved health, as members of Cluster 3 were severely limited in functioning.
Bullones Rodríguez MÁ, Afari N, Buchwald DS; National Institute of Diabetes and Digestive and Kidney Diseases Working Group on Urological Chronic Pelvic Pain. Collaborators Afari N, Buchwald DS, Clauw D, Dimitrakov J, Kusek J, Mullins C,	Department of Psychology, University Rey Juan Carlos, Madrid, Spain.	Evidence for overlap between urological and nonurological unexplained clinical conditions.	J Urol. 2013 Jan; 189 (1 Suppl):S66-74. doi: 10.1016/j.juro.2012.11.019.	PURPOSE: Unexplained clinical conditions share common features such as pain, fatigue, disability out of proportion to physical examination findings, inconsistent laboratory abnormalities, and an association with stress and psychosocial factors. We examined the extent of the overlap among urological and nonurological unexplained clinical conditions characterized by pain. We describe the limitations of previous research and suggest several possible explanatory models. MATERIALS AND METHODS: Using hallmark symptoms and syndromes as search terms a search of 12 databases identified a total of 1,037 full-length published articles in 8 languages from 1966 to April 2008. The search focused on the overlap of chronic pelvic pain, interstitial cystitis, painful bladder syndrome, chronic prostatitis/chronic pelvic pain syndrome or vulvodynia with fibromyalgia, chronic fatigue syndrome, temporomandibular joint and muscle disorders or irritable bowel syndrome. We abstracted information on authorship, type of case and control groups, eligibility criteria, case definitions, study methods and major findings. RESULTS: The literature suggests considerable comorbidity between urological and nonurological unexplained

Nyberg L, Payne C, Peñacoba C, Pezzone M, Pontari M, Potts J, Bullones Rodríguez MÁ, Warren J.				clinical conditions. The most robust evidence for overlap was for irritable bowel syndrome and urological unexplained syndromes with some estimates of up to 79% comorbidity between chronic pelvic pain and symptoms of irritable bowel syndrome. However, most studies were limited by methodological problems, such as varying case definitions and selection of controls. CONCLUSIONS: The overlap between urological and selected nonurological unexplained clinical conditions is substantial. Future research should focus on using standardized definitions, and rigorously designed, well controlled studies to further assess comorbidity, clarify the magnitude of the association and examine common pathophysiological mechanisms.
Caccamo D, Cesareo E, Mariani S, Raskovic D, Ientile R, Currò M, Korkina L, De Luca C.	Department of Biomedical Sciences and Morpho-Functional Imaging, Polyclinic University of Messina, 98125 Messina, Italy.	Xenobiotic sensor- and metabolism-related gene variants in environmental sensitivity-related illnesses: a survey on the Italian population.	Oxid Med Cell Longev. 2013; 2013:831969. doi: 10.1155/2013/831969. Epub 2013 Jul 7.	In the environmental sensitivity-related illnesses (SRIs), multiple chemical sensitivity (MCS), chronic fatigue syndrome (FCS), and fibromyalgia (FM), the search for genetic polymorphisms of phase I/II xenobiotic-metabolizing enzymes as suitable diagnostic biomarkers produced so far inconclusive results, due to patient heterogeneity, geographic/ethnic differences in genetic backgrounds, and different methodological approaches. Here, we compared the frequency of gene polymorphisms of selected cytochrome P450 (CYP) metabolizing enzymes and, for the first time, the frequency of the xenobiotic sensor Aryl hydrocarbon receptor (AHR) in the three cohorts of 156 diagnosed MCS, 94 suspected MCS, and 80FM/FCS patients versus 113 healthy controls. We found significantly higher frequency of polymorphisms CYP2C9∗*2, CYP2C9*3, CYP2C19*2, CYP2D6*4 and CYP2D6*41 in patients compared with controls. This confirms that these genetic variants represent a genetic risk factor for SRI. Moreover, the compound heterozygosity for CYP2C9*2 and *3 variants was useful to discriminate between either MCS or FM/CFS versus SMCS, while the PM *41/*41 genotype discriminated between MCS and either SMCS or FM/CFS. The compound heterozygosity for CYP2C9 *1/*3 and CYP2D6 *1/*4 differentiated MCS and SMCS cases from FM/CFS ones. Interestingly, despite the distribution of the AHR Arg554Lys variant did not result significantly different between SRI cases and controls, it resulted useful for the discrimination between MCS and SMCS cases when considered within haplotypes in combination with CYP2C19 *1/*2 and CYP2D6 *1/*4. Results allowed us to propose the genotyping for these specific CYP variants, together with the AHR Arg554Lys variant, as reliable, cost-effective genetic parameters to be included in the still undefined biomarkers' panel for laboratory diagnosis of the main types of environmental-borne SRI.
Cai Y, Tang L.	Department of Nephrology, the Second Affiliated Hospital, Chongqing Medical University, Yuzhong District, Chongqing, China.	Rare acute kidney injury secondary to hypothyroidism-induced rhabdomyolysis.	Yonsei Med J. 2013 Jan 1; 54(1):172-6. doi: 10.3349/ymj.2013.54.1.172.	PURPOSE: Acute kidney injury (AKI) caused by hypothyroidism-induced rhabdomyolysis is a rare and potentially life-threatening syndrome. The aim of this study was to investigate the clinical characteristics of such patients. MATERIALS AND METHODS: We retrospectively analyzed five patients treated at the Second Affiliated Hospital of Chongqing Medical University with AKI secondary to hypothyroidism-induced rhabdomyolysis from January 2006 to December 2010. RESULTS: Of the five cases reviewed (4 males, age range of 37 to 62 years), adult primary hypothyroidism

				was caused by amiodarone (1 case), chronic autoimmune thyroiditis (1 case), and by uncertain etiologies (3 cases). All patients presented with facial and lower extremity edema. Three patients presented with weakness, while two presented with blunted facies and oliguria. Only one patient reported experiencing myalgia and proximal muscle weakness, in addition to fatigue and chills. Creatine kinase, lactate dehydrogenase, and renal function normalized after thyroid hormone replacement, except in two patients who improved through blood purification. CONCLUSION: Hypothyroidism should be considered in patients presenting with renal impairment associated with rhabdomyolysis. Moreover, further investigation into the etiology of the hypothyroidism is warranted.
Carbonario F, Matsutani LA, Yuan SL, Marques AP.	Department of Speech Therapy, Physical Therapy and Occupational Therapy, Faculty of Medicine of the University of São Paulo, SP, Brazil. pasqual@usp.br	Effectiveness of high-frequency transcutaneous electrical nerve stimulation at tender points as adjuvant therapy for patients with fibromyalgia.	Eur J Phys Rehabil Med. 2013 Apr; 49(2):197-204. Epub 2013 Mar 13.	BACKGROUND: Fibromyalgia is a chronic pain syndrome associated with sleep disorders, fatigue and psychological symptoms. Combinations therapies, such as electrotherapy and therapeutic exercises have been used in the clinical practice. AIM: To assess the efficacy of high-frequency transcutaneous electrical nerve stimulation (TENS) as an adjuvant therapy to aerobic and stretching exercises, for the treatment of fibromyalgia. DESIGN: Controlled clinical trial. SETTING: Unit of rehabilitation of a public hospital. POPULATION: Twenty-eight women aged 52.4±7.5 years, with fibromyalgia. METHODS: A visual analogue scale measured pain intensity; tender points pain threshold, by dolorimetry; and quality of life, by the Fibromyalgia Impact Questionnaire. All subjects participated in an eight-week program consisting of aerobic exercises, followed by static stretching of muscle chains. In TENS group, high-frequency (150 Hz) was applied on bilateral tender points of trapezium and supraspinatus. RESULTS: TENS group had a greater pain reduction (mean change score=-2.0±2.9 cm) compared to Without TENS group (-0.7±3.7 cm). There was a difference between mean change scores of each group for pain threshold (right trapezium: 0.2±1 kg/cm² in TENS group and -0.2±1.2 kg/cm² in Without TENS group). In the evaluation of clinically important changes, patients receiving TENS had relevant improvement of pain, work performance, fatigue, stiffness, anxiety and depression compared to those not receiving TENS. CONCLUSION: It has suggested that high-frequency TENS as an adjuvant therapy is effective in relieving pain, anxiety, fatigue, stiffness, and in improving ability to work of patients with fibromyalgia. CLINICAL REHABILITATION IMPACT: High-frequency TENS may be used as a short-term complementary treatment of fibromyalgia.

Castori M, Morlino S, Celletti C, Ghibellini G, Bruschini M, Grammatico P, Blundo C, Camerota F.	Division of Medical Genetics, Department of Molecular Medicine, Sapienza University, San Camillo-Forlanini Hospital, Rome, Italy.	Re-writing the natural history of pain and related symptoms in the joint hypermobility syndrome/Ehlers-Danlos syndrome, hypermobility type.	Am J Med Genet A. 2013 Dec; 161(12):2989-3004. doi: 10.1002/ajmg.a.36315. Epub 2013 Nov 6.	Joint hypermobility syndrome (JHS) and Ehlers-Danlos syndrome, hypermobility type (EDS-HT) are two clinically overlapping connective tissue disorders characterized by chronic/recurrent pain, joint instability complications, and minor skin changes. Fatigue and headache are also common, although are not yet considered diagnostic criteria. JHS/EDS-HT is a unexpectedly common condition that remains underdiagnosed by most clinicians and pain specialists. This results in interventions limited to symptomatic and non-satisfactory treatments, lacking reasonable pathophysiologic rationale. In this manuscript the fragmented knowledge on pain, fatigue, and headache in JHS/EDS is presented with review of the available published information and a description of the clinical course by symptoms, on the basis of authors' experience. Pathogenic mechanisms are suggested through comparisons with other functional somatic syndromes (e.g., chronic fatigue syndrome, fibromyalgia, and functional gastrointestinal disorders). The re-writing of the natural history of JHS/EDS-HT is aimed to raise awareness among clinical geneticists and specialists treating chronic pain conditions about pain and other complications of JHS/EDS-HT. Symptoms' clustering by disease stage is proposed to investigate both the molecular causes and the symptoms management of JHS/EDS-HT in future studies.
Castro-Marrero J, Cordero MD, Sáez-Francas N, Jimenez-Gutierrez C, Aguilar-Montilla FJ, Aliste L, Alegre-Martin J.	1 CFS Unit, Institut de Recerca Vall d'Hebron, Hospital Universitari Vall d'Hebron, Universitat Autònoma de Barcelona, Barcelona, Spain .	Could mitochondrial dysfunction be a differentiating marker between chronic fatigue syndrome and fibromyalgia?	Antioxid Redox Signal. 2013 Nov 20; 19(15):1855-60. doi: 10.1089/ars.2013.5346. Epub 2013 May 29.	Chronic fatigue syndrome (CFS) and fibromyalgia (FM) are complex and serious illnesses that affect approximately 2.5% and 5% of the general population worldwide, respectively. The etiology is unknown; however, recent studies suggest that mitochondrial dysfunction has been involved in the pathophysiology of both conditions. We have investigated the possible association between mitochondrial biogenesis and oxidative stress in patients with CFS and FM. We studied 23 CFS patients, 20 FM patients, and 15 healthy controls. Peripheral blood mononuclear cell showed decreased levels of Coenzyme Q10 from CFS patients ($p<0.001$ compared with controls) and from FM subjects ($p<0.001$ compared with controls) and ATP levels for CFS patients ($p<0.001$ compared with controls) and for FM subjects ($p<0.001$ compared with controls). On the contrary, CFS/FM patients had significantly increased levels of lipid peroxidation, respectively ($p<0.001$ for both CFS and FM patients with regard to controls) that were indicative of oxidative stress-induced damage. Mitochondrial citrate synthase activity was significantly lower in FM patients ($p<0.001$) and, however, in CFS, it resulted in similar levels than controls. Mitochondrial DNA content (mtDNA/gDNA ratio) was normal in CFS and reduced in FM patients versus healthy controls, respectively ($p<0.001$). Expression levels of peroxisome proliferator-activated receptor gamma-coactivator 1-alpha and transcription factor A, mitochondrial by immunoblotting were significantly lower in FM patients ($p<0.001$) and were normal in CFS subjects compared with healthy controls. These data lead to the hypothesis that mitochondrial dysfunction-dependent

				events could be a marker of differentiation between CFS and FM, indicating the mitochondria as a new potential therapeutic target for these conditions.
Cella M, White PD, Sharpe M, Chalder T.	Institute of Psychiatry, King's College London, UK. matteo.cella@kcl.ac.uk	Cognitions, behaviours and co-morbid psychiatric diagnoses in patients with chronic fatigue syndrome.	Psychol Med. 2013 Feb; 43(2):375-80. doi: 10.1017/S0033291712000979 . Epub 2012 May 9.	BACKGROUND: Specific cognitions and behaviours are hypothesized to be important in maintaining chronic fatigue syndrome (CFS). Previous research has shown that a substantial proportion of CFS patients have co-morbid anxiety and/or depression. This study aims to measure the prevalence of specific cognitions and behaviours in patients with CFS and to determine their association with co-morbid anxiety or depression disorders. METHOD: A total of 640 patients meeting Oxford criteria for CFS were recruited into a treatment trial (i.e. the PACE trial). Measures analysed were: the Cognitive Behavioural Response Questionnaire, the Chalder Fatigue Scale and the Work and Social Adjustment Scale. Anxiety and depression diagnoses were from the Structured Clinical Interview for DSM-IV. Multivariate analysis of variance was used to explore the associations between cognitive-behavioural factors in patients with and without co-morbid anxiety and/or depression. RESULTS: Of the total sample, 54% had a diagnosis of CFS and no depression or anxiety disorder, 14% had CFS and one anxiety disorder, 14% had CFS and depressive disorder and 18% had CFS and both depression and anxiety disorders. Cognitive and behavioural factors were associated with co-morbid diagnoses; however, some of the mean differences between groups were small. Beliefs about damage and symptom focussing were more frequent in patients with anxiety disorders while embarrassment and behavioural avoidance were more common in patients with depressive disorder. CONCLUSIONS: Cognitions and behaviours hypothesized to perpetuate CFS differed in patients with concomitant depression and anxiety. Cognitive behavioural treatments should be tailored appropriately.
Celletti C, Castori M, La Torre G, Camerota F.	Physical Medicine and Rehabilitation, Department of Orthopaedics, Sapienza University, Umberto I Hospital, Rome, Italy. c_celletti@libero.it	Biomed Res Int. 2013;2013: 580460. doi: 10.1155/2013/580460. Epub 2013 Jul 14.	Evaluation of kinesiophobia and its correlations with pain and fatigue in joint hypermobility syndrome/Ehlers-Danlos syndrome hypermobility type.	Ehlers-Danlos syndrome hypermobility type a. k. a. joint hypermobility syndrome (JHS/EDS-HT) is a hereditary musculoskeletal disorder associating generalized joint hypermobility with chronic pain. Anecdotal reports suggest a prominent role for kinesiophobia in disease manifestations, but no study has systematically addressed this point.OBJECTIVE: To investigate the impact of kinesiophobia and its relationship with pain, fatigue, and quality of life in JHS/EDS-HT. DESIGN: Cross-sectional study. SUBJECTS/PATIENTS: 42 patients (40 female and 2 male) with JHS/EDS-HT diagnosis following standardized diagnostic criteria were selected. METHODS: Disease features were analyzed by means of specific questionnaires and scales evaluating kinesiophobia, pain, fatigue, and quality of life. The relationships among variables were investigated using the Spearman bivariate analysis. RESULTS: Kinesiophobia resulted predominantly in the patients' sample. The values of kinesiophobia did not correlate with intensity of pain, quality of life, and (or) the single component of fatigue. A strong correlation was discovered between kinesiophobia and general severity of fatigue. CONCLUSIONS: In JHS/EDS-HT, the onset of pain-avoiding strategies is related to the presence of pain but not to its intensity. The clear-cut

				correlation between kinesiophobia and severity of fatigue suggests a direct link between musculoskeletal pain and fatigue. In JHS/EDS-HT, the underlying mechanism is likely to be facilitated by primary disease characteristics, including hypotonia.
Cha YH, Cui Y, Baloh RW.	Department of Neurology, University of California Los Angeles, Los Angeles, California 90095, USA.	Repetitive transcranial magnetic stimulation for mal de debarquement syndrome.	Otol Neurotol. 2013 Jan; 34(1):175-9. doi: 10.1097/MAO.0b013e318278bf7c.	OBJECTIVE: Mal de debarquement syndrome (MdDS) is a chronic disorder of imbalance characterized by a feeling of rocking and swaying. The disorder starts after prolonged exposure to passive motion such as from a boat or plane. All medical treatment is palliative and symptoms that persist beyond 6 months show low likelihood of remission. This pilot study explored the feasibility and tolerability of repetitive transcranial magnetic stimulation (rTMS) as potential treatment for MdDS. PATIENTS/INTERVENTION: Ten subjects (8 women) with persistent MdDS lasting from 10 to 91 months were given 1 session each of 4 counterbalanced protocols: left 10 Hz (high frequency), left 1 Hz (low frequency), right 10 Hz, and right 1 Hz rTMS over the dorsolateral prefrontal cortex (DLPFC). MAIN OUTCOME MEASURE: Reduction of rocking sensation reported on a visual analogue scale. RESULTS: 1) Right-handers improved most with 10-Hz stimulation over the left DLPFC while left-handers improved most with 10 Hz stimulation over the right DLPFC; 2) low-frequency DLPFC stimulation was associated with symptom worsening in some subjects; 3) duration of symptoms was negatively correlated with treatment response; 4) rTMS was well tolerated in MdDS subjects, showing similar rates of headache (10 of 40 sessions) as for other studies; and 5) fatigue occurred after 6 sessions usually with low-frequency stimulation. CONCLUSION: rTMS was well tolerated in subjects with MdDS with promising short-term symptom improvement. Future studies of rTMS in MdDS may consider sequential days of stimulation, longer post-rTMS observation periods, formal measurement of post-TMS fatigue, and randomization with a sham condition.
Chan JS, Ho RT, Wang CW, Yuen LP, Sham JS, Chan CL.	Centre on Behavioral Health, The University of Hong Kong, Hong Kong.	Effects of qigong exercise on fatigue, anxiety, and depressive symptoms of patients with chronic fatigue syndrome-like illness: a randomized controlled trial.	Evid Based Complement Alternat Med. 2013; 2013:485341. doi: 10.1155/2013/485341. Epub 2013 Jul 31.	Background: Anxiety/depressive symptoms are common in patients with chronic fatigue syndrome- (CFS-) like illness. Qigong as a modality of complementary and alternative therapy has been increasingly applied by patients with chronic illnesses, but little is known about the effect of Qigong on anxiety/depressive symptoms of the patients with CFS-like illness. Purpose: To investigate the effects of Qigong on fatigue, anxiety, and depressive symptoms in patients with CFS-illness. Methods: One hundred and thirty-seven participants who met the diagnostic criteria for CFS-like illness were randomly assigned to either an intervention group or a waitlist control group. Participants in the intervention group received 10 sessions of Qigong training twice a week for 5 consecutive weeks, followed by home-based practice for 12 weeks. Fatigue, anxiety, and depressive symptoms were assessed at baseline and postintervention. Results: Total fatigue score [$F(1,135) = 13.888$, $P < 0.001$], physical fatigue score [$F(1,135) = 20.852$, $P < 0.001$] and depression score [$F(1,135) = 9.918$, $P = 0.002$] were significantly improved and mental fatigue score [$F(1,135) = 3.902$, $P = 0.050$] was marginally significantly improved in the Qigong group compared to controls. The anxiety score was not significantly improved in the Qigong group.

				Conclusion: Qigong may not only reduce the fatigue symptoms, but also has antidepressive effect for patients with CFS-like illness. Trial registration HKCTR-1200.
Chan W, Bosch JA, Jones D, Kaur O, Inston N, Moore S, McClean A, McTernan PG, Harper L, Phillips AC, Borrows R.	1- Department of Nephrology & Kidney Transplantation, Queen Elizabeth Hospital Birmingham, Birmingham, UK. 2 - Department of Nutrition & Dietetics, Queen Elizabeth Hospital Birmingham, Birmingham, UK. 3- School of Sport and Exercise Sciences, The University of Birmingham, Birmingham, UK. 4 - Division of Metabolic and Vascular Health, Clinical Sciences Research Institute, Warwick Medical School, University of Warwick, Coventry, UK. 5 - Centre for Translational Inflammation Research, University of Birmingham Research Laboratories, Queen Elizabeth Hospital Birmingham, Birmingham, UK. 6 - Address correspondence to: Richard Borrows, M.A., Department of Nephrology & Kidney Transplantation,	Predictors and consequences of fatigue in prevalent kidney transplant recipients.	Transplantation. 2013 Dec 15;96 (11):987-94. doi: 10.1097/TP.0b013e3182a2e88b.	BACKGROUND: Fatigue has been underinvestigated in stable kidney transplant recipients (KTRs). The objectives of this study were to investigate the nature, severity, prevalence, and clinical awareness of fatigue in medically stable KTRs, examine the impact of fatigue on quality of life (QoL), and explore the underlying causes of posttransplantation fatigue. METHODS: This single-center cross-sectional study enrolled 106 stable KTRs. Multi-dimensional Fatigue Inventory-20 was used to measure five fatigue dimensions: General Fatigue, Physical Fatigue, Reduced Activity, Reduced Motivation, and Mental Fatigue. Clinical awareness of fatigue was determined by reviewing medical records. QoL was assessed by Medical Outcomes Study Short Form-36 Questionnaire. Demographic, clinical, psychosocial, and behavioral parameters were evaluated as fatigue predictors. RESULTS: Fatigue was found in 59% of KTRs. Only 13% had this symptom documented in medical records. Fatigue in KTRs was in the same range as chronically unwell patients, with Physical Fatigue, Reduced Activity, and Reduced Motivation approached levels observed in chronic fatigue syndrome. All fatigue dimensions significantly and inversely correlated with QoL ($P<0.001$ for all associations). Demographic predictors were male, older age, and non-Caucasian ethnicity ($P\leq0.05$ for all associations). Clinical predictors included elevated highly sensitive C-reactive protein (inflammation), decreased estimated glomerular filtration rate (graft dysfunction), and reduced lean tissue index ($P\leq0.05$ for all associations). Psychosocial and behavioral predictors were inferior sleep quality, anxiety, and depression ($P<0.01$ for all associations). CONCLUSIONS: Fatigue is common and pervasive in clinically stable KTRs. It is strongly associated with reduced QoL. This study identified modifiable fatigue predictors and sets the scene for future interventional studies.

Chang FY, Lu CL.	Environmental Heath and Safety Office, Taipei Veterans General Hospital, National Yang-Ming University School of Medicine, Taipei, Taiwan.	Irritable bowel syndrome and migraine: bystanders or partners?	J Neurogastroenterol Motil. 2013 Jul;19(3):301-11. doi: 10.5056/jnm.2013.19.3.301. Epub 2013 Jul 8.	Irritable bowel syndrome (IBS) and migraine are distinct clinical disorders. Apart from the characteristics of chronic and recurrent pain in nature, these pain-related disorders apparently share many similarities. For example, IBS is female predominant with community prevalence about 5-10%, whereas that of migraine is 1-3% also showing female predominance. They are often associated with many somatic and psychiatric comorbidities in terms of fibromyaglia, chronic fatigue syndrome, interstitial cystitis, insomnia and depression etc., even the IBS subjects may have coexisted migraine with an estimated odds ratio of 2.66. They similarly reduce the quality of life of victims leading to the social, medical and economic burdens. Their pathogeneses have been somewhat addressed in relation to biopsychosocial dysfunction, heredity, genetic polymorphism, central/visceral hypersensitivity, somatic/cutaneous allodynia, neurolimbic pain network, gonadal hormones and abuses etc. Both disorders are diagnosed according to the symptomatically based criteria. Multidisciplinary managements such as receptor target new drugs, melantonin, antispasmodics, and psychological drugs and measures, complementary and alternatives etc. are recommended to treat them although the used agents may not be necessarily the same. Finally, the prognosis of IBS is pretty good, whereas that of migraine is less fair since suicide attempt and stroke are at risk. In conclusion, both distinct chronic pain disorders to share many similarities among various aspects probably suggest that they may locate within the same spectrum of a pain-centered disorder such as central sensitization syndromes. The true pathogenesis to involve these disorders remains to be clarified in the future.
Chen GL, Miller GM.	Harvard Medical School, New England Primate Research Center, Division of Neuroscience, One Pine Hill Drive, Southborough, MA 01772-9102, USA. guo-lin_chen@hms.harvard	Tryptophan hydroxylase-2: an emerging therapeutic target for stress disorders.	Biochem Pharmacol. 2013 May 1; 85(9):1227-33. doi: 10.1016/j.bcp.2013.02.018. Epub 2013 Feb 19.	Serotonin (5-HT) has been long recognized to modulate the stress response, and dysfunction of 5-HT has been implicated in numerous stress disorders. Accordingly, the 5-HT system has been targeted for the treatment of stress disorders. Tryptophan hydroxylase (TPH) is the rate-limiting enzyme in 5-HT synthesis, and the recent identification of a second, neuron-specific TPH isoform (TPH2) opened up a new area of research. With a decade of extensive investigation, it is now recognized that: (1) TPH2 exhibits a highly flexible gene expression that is modulated by an increasing number of internal and external environmental factors including the biological clock, stressors, endogenous hormones, and antidepressant therapies; and (2) genetically determined TPH2 activity is linked to a growing body of stress-related neuronal

	.edu			correlates and behavioral traits. These findings reveal an active role of TPH2 in the stress response and provide new insights into the long recognized but not yet fully understood 5-HT-stress interaction. As a major modulator of 5-HT neurotransmission and the stress response, TPH2 is of both pathophysiological and pharmacological significance, and is emerging as a new therapeutic target for the treatment of stress disorders. Given that numerous antidepressant therapies influence TPH2 gene expression, TPH2 is already inadvertently targeted for the treatment of stress disorders. With increased understanding of the regulation of TPH2 activity we can now purposely utilize TPH2 as a target to develop new or optimize current therapies, which are expected to greatly improve the prevention and treatment of a wide variety of stress disorders.

Chirilă EL, Postolache P.	Faculty of Medicine, University of Medicine and Pharmacy "Carol Davila"- Bucureşti.	Orthostatic intolerance and chronic fatigue syndrome--possible related conditions.	Rev Med Chir Soc Med Nat Iasi. 2013 Apr-Jun; 117 (2):388-93.	The connection between orthostatic intolerance and chronic fatigue syndrome was first introduced in 1995. It was demonstrated that many patients with chronic fatigue syndrome also had some form of orthostatic intolerance. Some studies suggested that dysautonomia may be the common problem in patients with these syndromes. Although these conditions affect an important number of people, especially younger adults, orthostatic intolerance and chronic fatigue syndrome are among the least understood of the autonomic disorders and sustained research is focused particularly on elucidating their pathogenesis and identifying the most effective methods of treatment.
Christley Y, Duffy T, Everall IP, Martin CR.	School of Health, Nursing and Midwifery, University of the West of Scotland, Ayr Campus, University Avenue, Ayr, KA8 0SX, UK. yvonne.christley@uws.ac.uk	The neuropsychiatric and neuropsychological features of chronic fatigue syndrome: revisiting the enigma.	Curr Psychiatry Rep. 2013 Apr; 15(4):353. doi: 10.1007/s11920-013-0353-8.	The aim of this article is to provide a comprehensive and updated review of the key neuropsychiatric and neuropsychological complaints associated with chronic fatigue syndrome (CFS). Neuropsychiatric and neuropsychological difficulties are common in CFS and are linked primarily to disorders of mood, affect and behaviour. The neuropsychiatric complaint most frequently encountered amongst CFS patients is depression and in particular major depressive disorder (MDD). Despite decades of research, the precise aetiological relationship between CFS and MDD remains poorly understood. This has resulted in the development of a number of interesting and polarised hypotheses regarding the aetiological nature of CFS. Recent scientific advances have however begun to unravel a number of interesting inflammatory and immunological explanations that suggest CFS and MDD are distinct yet interrelated

				conditions. The possibility that the overlap between CFS and MDD might be explained in terms of shared oxidative and nitrosative (IO&NS) pathways is an area of intense research interest and is reviewed in detail in this article. The overlap between CFS and MDD is further differentiated by variations in HPA axis activity between the two disorders. Important immunological differences between MDD and CFS are also reviewed with particular emphasis on antiviral RNase L pathways in CFS. In addition to the presence of neuropsychiatric complaints, CFS is also associated with neuropsychological symptoms such as impaired attention, memory and reaction time. The key neuropsychological problems reported by CFS patients are also included in the review in an effort to understand the significance of cognitive impairment in CFS.
Chung SD, Lin CC, Liu SP, Lin HC.	Division of Urology, Department of Surgery, Far Eastern Memorial Hospital, Ban Ciao, Taipei, Taiwan; School of Health Care Administration, Taipei Medical University, Taipei, Taiwan; Sleep Research Center, Taipei Medical University Hospital, Taipei, Taiwan.	Obstructive Sleep Apnea Increases the Risk of Bladder Pain Syndrome/Interstitial Cystitis: A Population-Based Matched-Cohort Study.	Neurourol Urodyn. 2013 Mar 28. doi: 10.1002/nau.22401. [Epub ahead of print]	AIMS: Previous studies indicated a possible association between bladder pain syndrome/interstitial cystitis (BPS/IC) and sleep disorders including sleep abnormalities with delayed onset of sleep, waking up before needed, and snoring. Nevertheless, no previous study has reported the association between obstructive sleep apnea (OSA) and BPS/IC. In this retrospective cohort study, we examined the risk of BPS/IC among subjects with OSA during a 3-year follow-up in Taiwan using a population-based dataset. METHODS: This study comprised 2,940 study subjects with OSA, and 29,400 randomly selected comparison subjects. We individually followed-up each sampled subject (n=32,340) for a 3-year period to identify those subjects who subsequently received a diagnosis of BPS/IC. A Cox proportional hazards regression model was constructed to estimate the risk of subsequent BPS/IC following a diagnosis of OSA. RESULTS: Incidences of BPS/IC during the 3-year follow-up period were 13.61 (95% confidence interval [CI]=7.37-23.13) and 3.60 (95% CI=2.06-4.39) for subjects with and those without OSA, respectively. After adjusting for diabetes, hypertension, coronary heart disease, obesity, hyperlipidemia, chronic pelvic pain, irritable bowel syndrome, fibromyalgia, chronic fatigue syndrome, depression, panic disorder, migraines, sicca syndrome, allergies, endometriosis, asthma, tobacco use disorder, and alcohol abuse, the stratified Cox proportional hazards regressions revealed that the hazard ratio for BPS/IC among subjects with OSA was 3.71 (95% CI=1.81-7.62, P<0.001) that of comparison subjects. CONCLUSIONS: This study provides epidemiological evidence of a link between OSA and a subsequent BPS/IC diagnosis. We suggest that clinical practitioners treating subjects with OSA be alert to urinary complaints in this population.
Chung SD, Liu SP, Lin CC, Li HC, Lin HC.	Division of Urology, Department of Surgery, Far Eastern Memorial Hospital, Banciao, Taipei, Taiwan.	Bladder pain syndrome/interstitial cystitis is associated with hyperthyroidism.	PLoS One. 2013 Aug 21; 8(8):e72284. doi: 10.1371/journal.pone.0072284.	BACKGROUND: Although the etiology of bladder pain syndrome/interstitial cystitis (BPS/IC) is still unclear, a common theme with BPS/IC patients is comorbid disorders which are related to the autonomic nervous system that connects the nervous system to end-organs. Nevertheless, no study to date has reported the association between hyperthyroidism and BPS/IC. In this study, we examined the association of IC/BPS with having previously been diagnosed with hyperthyroidism in Taiwan. DESIGN: Data in this study were retrieved from the Longitudinal Health Insurance Database. Our study

				consisted of 736 female cases with BPS/IC and 2208 randomly selected female controls. We performed a conditional logistic regression to calculate the odds ratio (OR) for having previously been diagnosed with hyperthyroidism between cases and controls. RESULTS: Of the 2944 sampled subjects, there was a significant difference in the prevalence of prior hyperthyroidism between cases and controls (3.3% vs. 1.5%, p<0.001). The conditional logistic regression analysis revealed that compared to controls, the OR for prior hyperthyroidism among cases was 2.16 (95% confidence interval (CI): 1.27~3.66). Furthermore, the OR for prior hyperthyroidism among cases was 2.01 (95% CI: 1.15~3.53) compared to controls after adjusting for diabetes, coronary heart disease, obesity, hyperlipidemia, chronic pelvic pain, irritable bowel syndrome, fibromyalgia, chronic fatigue syndrome, depression, panic disorder, migraines, sicca syndrome, allergies, endometriosis, and asthma. CONCLUSIONS: Our study results indicated an association between hyperthyroidism and BPS/IC. We suggest that clinicians treating female subjects with hyperthyroidism be alert to urinary complaints in this population.
Ciregia F, Giusti L, Da Valle Y, Donadio E, Consensi A, Giacomelli C, Sernissi F, Scarpellini P, Maggi F, Lucacchini A, Bazzichi L.	Department of Pharmacy, University of Pisa, Via Bonanno 6, Pisa, 56126, Italy. lucas@farm.unipi.it.	A multidisciplinary approach to study a couple of monozygotic twins discordant for the chronic fatigue syndrome: a focus on potential salivary biomarkers.	J Transl Med. 2013 Oct 2; 11:243. doi: 10.1186/1479-5876-11-243.	BACKGROUND: Chronic Fatigue Syndrome (CFS) is a severe, systemic illness characterized by persistent, debilitating and medically unexplained fatigue. The etiology and pathophysiology of CFS remains obscure, and diagnosis is formulated through the patient's history and exclusion of other medical causes. Thereby, the availability of biomarkers for CFS could be useful for clinical research. In the present study, we used a proteomic approach to evaluate the global changes in the salivary profile in a couple of monozygotic twins who were discordant for CFS. The aim was to evaluate differences of salivary protein expression in the CFS patient in respect to his healthy twin. METHODS: Saliva samples were submitted to two-dimensional electrophoresis (2DE). The gels were stained with Sypro, and a comparison between CFS subject and the healthy one was performed by the software Progenesis Same Spot including the Analysis of variance (ANOVA test). The proteins spot found with a ≥2-fold spot quantity change and p<0.05 were identified by Nano-liquid chromatography electrospray ionization tandem mass spectrometry. To validate the expression changes found with 2DE of 5 proteins (14-3-3 protein zeta/delta, cyclophilin A, Cystatin-C, Protein S100-A7, and zinc-alpha-2-glycoprotein), we used the western blot analysis. Moreover, proteins differentially expressed were functionally analyzed using the Ingenuity Pathways Analysis software with the aim to determine the predominant canonical pathways and the interaction network involved. RESULTS: The analysis of the protein profiles allowed us to find 13 proteins with a different expression in CFS in respect to control. Nine spots were up-regulated in CFS and 4 down-regulated. These proteins belong to different functional classes, such as inflammatory response, immune system and metabolism. In particular, as shown by the pathway analysis, the network built with our proteins highlights the involvement of inflammatory response in CFS pathogenesis. CONCLUSIONS: This study

				shows the presence of differentially expressed proteins in the saliva of the couple of monozygotic twins discordant for CFS, probably related to the disease. Consequently, we believe the proteomic approach could be useful both to define a panel of potential diagnostic biomarkers and to shed new light on the comprehension of the pathogenetic pathways of CFS.
Cockshell SJ, Mathias JL.	[No address quoted]	Cognitive Functioning in People With Chronic Fatigue Syndrome: A Comparison Between Subjective and Objective Measures.	Neuropsychology. 2013 Dec 23. [Epub ahead of print]	Objective: The purpose of this study was to examine the relationship between subjective and objective assessments of memory and attention in people with chronic fatigue syndrome (CFS), using tests that have previously detected deficits in CFS samples and measures of potential confounds. Method: Fifty people with CFS and 50 healthy controls were compared on subjective (memory and attention symptom severity, Cognitive Failures Questionnaire, Everyday Attention Questionnaires) and objective (California Verbal Learning Test, Rey-Osterreith Complex Figure Test, Paced Auditory Serial Addition Test, Stroop task) measures of memory and attention. Fatigue, sleep, depression, and anxiety were also assessed. Results: The CFS group reported experiencing more cognitive problems than the controls, but the two groups did not differ on the cognitive tests. Scores on the subjective and objective measures were not correlated in either group. Depression was positively correlated with increased severity of cognitive problems in both the CFS and control groups. Conclusions: There is little evidence for a relationship between subjective and objective measures of cognitive functioning for both people with CFS and healthy controls, which suggests that they may be capturing different constructs. Problems with memory and attention in everyday life are a significant part of CFS. Depression appears to be related to subjective problems but does not fully explain them.
Cockshell SJ, Mathias JL.	School of Psychology, The University of Adelaide, South Australia, Australia.	Cognitive deficits in chronic fatigue syndrome and their relationship to psychological status, symptomatology, and everyday functioning.	Neuropsychology. 2013 Mar; 27(2):230-42. doi: 10.1037/a0032084.	OBJECTIVE: To examine cognitive deficits in people with chronic fatigue syndrome (CFS) and their relationship to psychological status, CFS symptoms, and everyday functioning. METHOD: The current study compared the cognitive performance (reaction time, attention, memory, motor functioning, verbal abilities, and visuospatial abilities) of a sample with CFS (n = 50) with that of a sample of healthy controls (n = 50), all of whom had demonstrated high levels of effort and an intention to perform well, and examined the extent to which psychological status, CFS symptoms, and everyday functioning were related to cognitive performance. RESULTS: The CFS group showed impaired information processing speed (reaction time), relative to the controls, but comparable performance on tests of attention, memory, motor functioning, verbal ability, and visuospatial ability. Moreover, information processing speed was not related to psychiatric status, depression, anxiety, the number or severity of CFS symptoms, fatigue, sleep quality, or everyday functioning. CONCLUSION: A slowing in information processing speed appears to be the main cognitive deficit seen in persons with CFS whose performance on effort tests is not compromised. Importantly, this slowing does not appear to be the consequence of other CFS-related variables, such as depression and fatigue, or motor speed.

Collinge W, Yarnold P, Soltysik R.	Collinge and Associates, Eugene, OR, USA.	Fibromyalgia Symptom Reduction by Online Behavioral Self-monitoring, Longitudinal Single Subject Analysis and Automated Delivery of Individualized Guidance.	N Am J Med Sci. 2013 Sep;5 (9):546-53. doi: 10.4103/1947-2714.118920.	BACKGROUND: Fibromyalgia (FM) is a complex chronic pain condition that is difficult to treat. The prevailing approach is an integration of pharmacological, psycho-educational, and behavioral strategies. Information technology offers great potential for FM sufferers to systemically monitor symptoms as well as potential impacts of various management strategies. AIMS: This study aimed to evaluate effects of a web-based, self-monitoring and symptom management system (SMARTLog) that analyzes personal self-monitoring data and delivers data-based feedback over time. MATERIALS AND METHODS: Subjects were self-referred, anonymous, and recruited via publicity on FM advocacy websites. Standardized instruments assessed health status, self-efficacy, and locus of control at baseline and monthly during participation. Subjects were encouraged to complete the SMARTLog several times weekly. Within-subject, univariate, and multivariate analyses were used to derive classification trees for each user associating specific behavior variables with symptom levels over time. RESULTS: Moderate use (3 times weekly x 3 months) increased likelihood of clinically significant improvements in pain, memory, gastrointestinal problems, depression, fatigue, and concentration; heavy use (4.5 times weekly x five months) produced the above plus improvement in stiffness and sleep difficulties. CONCLUSIONS: Individualized, web-based behavioral self-monitoring with personally-tailored feedback can enable FM sufferers to significantly reduce symptom levels over time.
Cordero MD, Alcocer-Gómez E, Culic O, Carrión AM, de Miguel M, Díaz-Parrado E, Pérez-Villegas EM, Bullón P, Battino M, Sánchez-Alcazar JA.	1 Dpto. Citología e Histología Normal y Patológica, Facultad de Medicina, Universidad de Sevilla, Sevilla, Spain.	NLRP3 Inflammasome Is Activated in Fibromyalgia: The Effect of Coenzyme Q10.	Antioxid Redox Signal. 2013 Sep 19. [Epub ahead of print]	Abstract Aims: Fibromyalgia (FM) is a prevalent chronic pain syndrome characterized by generalized hyperalgesia associated with a wide spectrum of symptoms such as fatigue and joint stiffness. Diagnosis of FM is difficult due to the lack of reliable diagnostic biomarkers, while treatment is largely inadequate. We have investigated the role of coenzyme Q10 (CoQ10) deficiency and mitochondrial dysfunction in inflammasome activation in blood cells from FM patients, and in vitro and in vivo CoQ10 deficiency models. Results: Mitochondrial dysfunction was accompanied by increased protein expression of interleukin (IL)-1β, NLRP3 (NOD-like receptor family, pyrin domain containing 3) and caspase-1 activation, and an increase of serum levels of proinflammatory cytokines (IL-1β and IL-18). CoQ10 deficiency induced by p-aminobenzoate treatment in blood mononuclear cells and mice showed NLRP3 inflammasome activation with marked algesia. A placebo-controlled trial of CoQ10 in FM patients has shown a reduced NLRP3 inflammasome activation and IL-1β and IL-18 serum levels. Innovation: These results show an important role for the NLRP3 inflammasome in the pathogenesis of FM, and the capacity of CoQ10 in the control of inflammasome. Conclusion: These findings provide new insights into the pathogenesis of FM and suggest that NLRP3 inflammasome inhibition represents a new therapeutic intervention for the disease. Antioxid. Redox Signal. 00, 000-000.

Costantini A, Pala MI.	Department of Neurological Rehabilitation, Villa Immacolata, Viterbo, Italy. carapetata@libero.it	Thiamine and fatigue in inflammatory bowel diseases: an open-label pilot study.	J Altern Complement Med. 2013 Aug; 19(8):704-8. doi: 10.1089/acm.2011.0840. Epub 2013 Feb 4.	OBJECTIVES: To demonstrate that fatigue and other disorders related to ulcerative colitis and Crohn's disease are the manifestation of an intracellular mild thiamine deficiency and not due to malabsorbtion, augmented requirements, or nutritional factors, and that this dysfunction is curable with high doses of thiamine administered orally or parenterally. DESIGN: In this pilot study, we treated fatigue in eight patients with ulcerative colitis and four patients affected by Crohn's disease from January to April 2011. The patients were recruited through general practitioners' surveys and among personnel and affiliated personnel of the clinic Villa Immacolata. Fatigue was measured using the chronic fatigue syndrome scale, and the determination of thiamine and thiamine pyrophosphate levels in the blood was carried out through blood tests. The levels of thiamine and thiamine pyrophosphate in the blood were normal. All patients were assigned to receive high doses of thiamine orally. Depending upon the body weight of each patient, dosage ranged from 600mg/day (60kg) to 1,500mg/day (90kg). The chronic fatigue syndrome scale as well as thiamine and thiamine pyrophosphate levels in the blood were measured 20 days after the beginning of the therapy. RESULTS: Ten patients out of twelve showed complete regression of fatigue, while the remaining two patients showed nearly complete regression of fatigue compared to the chronic fatigue syndrome scale scores before therapy. CONCLUSIONS: The absence of blood thiamine deficiency and the efficacy of high-dose thiamine in our patients suggest that fatigue is the manifestation of a thiamine deficiency, likely due to a dysfunction of the active transport of thiamine inside the cells, or due to structural enzymatic abnormalities. The administration of large quantities of thiamine increases the concentration in the blood to levels in which the passive transport restores the normal glucose metabolism in all cells and leads to a complete regression of fatigue.

Crawley E, Collin SM, White PD, Rimes K, Sterne JA, May MT; CFS/ME National Outcomes Database.	Centre for Child & Adolescent Health, School of Social & Community Medicine, University of Bristol, Oakfield House, Oakfield Grove, Bristol BS8 2BN, UK. esther.crawley@bristol.ac.uk	Treatment outcome in adults with chronic fatigue syndrome: a prospective study in England based on the CFS/ME National Outcomes Database.	QJM. 2013 Jun; 106(6):555-65. doi: 10.1093/qjmed/hct061. Epub 2013 Mar 28. Erratum in QJM. 2013 Jun; 106(6):567.	BACKGROUND: Chronic fatigue syndrome (CFS) is relatively common and disabling. Over 8000 patients attend adult services each year, yet little is known about the outcome of patients attending NHS services. AIM: Investigate the outcome of patients with CFS and what factors predict outcome. DESIGN: Longitudinal patient cohort. METHODS: We used data from six CFS/ME (myalgic encephalomyelitis) specialist services to measure changes in fatigue (Chalder Fatigue Scale), physical function (SF-36), anxiety and depression (Hospital Anxiety and Depression Scale) and pain (visual analogue pain rating scale) between clinical assessment and 8-20 months of follow-up. We used multivariable linear regression to investigate baseline factors associated with outcomes at follow-up. Results: Baseline data obtained at clinical assessment were available for 1643 patients, of whom 834 (51%) had complete follow-up data. There were improvements in fatigue [mean difference from assessment to outcome: -6.8; 95% confidence interval (CI) -7.4 to -6.2; P < 0.001]; physical function (4.4; 95% CI 3.0-5.8; P < 0.001), anxiety (-0.6; 95% CI -0.9 to -0.3; P < 0.001), depression (-1.6; 95% CI -1.9 to -1.4; P < 0.001) and pain (-5.3; 95% CI -7.0 to -3.6; P < 0.001). Worse fatigue, physical function and pain at clinical assessment predicted a worse outcome for fatigue at follow-up. Older age, increased pain and physical function at assessment were associated with poorer physical function at follow-up. CONCLUSION: Patients who attend NHS specialist CFS/ME services can expect similar improvements in fatigue, anxiety and depression to participants receiving cognitive behavioural therapy and graded exercise therapy in a recent trial, but are likely to experience less improvement in physical function. Outcomes were predicted by fatigue, disability and pain at assessment.
Crawley E, Mills N, Beasant L, Johnson D, Collin SM, Deans Z, White K, Montgomery A.	Centre for Child & Adolescent Health, School of Social and Community Medicine, University of Bristol, Oakfield House, Oakfield Road, BS8	The feasibility and acceptability of conducting a trial of specialist medical care and the Lightning Process in children with chronic	Trials. 2013 Dec 5; 14:415. doi: 10.1186/1745-6215-14-415.	BACKGROUND: Chronic fatigue syndrome (CFS) or myalgic encephalomyelitis (ME) is relatively common in children with limited evidence for treatment. The Phil Parker Lightning Process (LP) is a trademarked intervention, which >250 children use annually. There are no reported studies investigating the effectiveness or possible side effects of LP. METHODS: The trial population was drawn from the Bath and Bristol NHS specialist paediatric CFS or ME service. The study was designed as a pilot randomized trial with children (aged 12 to 18 years) comparing specialist medical care

	2BN, Bristol, UK. esther.crawley@bristol.ac.uk.	fatigue syndrome: feasibility randomized controlled trial (SMILE study).		with specialist medical care plus the Lightning Process. Integrated qualitative methodology was used to explore the feasibility and acceptability of the recruitment, randomization and interventions. RESULTS: A total of 56 children were recruited from 156 eligible children (1 October 2010 to 16 June 2012). Recruitment, randomization and both interventions were feasible and acceptable. Participants suggested changes to improve feasibility and acceptability and we incorporated the following in the trial protocol: stopped collecting 6-week outcomes; introduced a second reminder letter; used phone calls to collect primary outcomes from nonresponders; informed participants about different approaches of each intervention and changed our recommendation for the primary outcome for the full study from school attendance to disability (SF-36 physical function subscale) and fatigue (Chalder Fatigue Scale). CONCLUSIONS: Conducting randomized controlled trials (RCTs) to investigate an alternative treatment such as LP is feasible and acceptable for children with CFS or ME. Feasibility studies that incorporate qualitative methodology enable changes to be made to trial protocols to improve acceptability to participants. This is likely to improve recruitment rate and trial retention. TRIAL REGISTRATION: Feasibility study first randomization: 29 September 2010.Trial registration: Current Controlled Trials ISRCTN81456207 (31 July 2012).Full trial first randomization: 19 September 2012.
Crawley E, Mills N, Hollingworth W, Deans Z, Sterne JA, Donovan JL, Beasant L, Montgomery A.	Centre for Child and Adolescent Health, School of Social and Community Medicine, Oakfield House, Oakfield Grove, Bristol, BS8 2BN, UK. Esther.crawley@bristol.ac.uk.	Comparing specialist medical care with specialist medical care plus the Lightning Process® for chronic fatigue syndrome or myalgic encephalomyelitis (CFS/ME): study protocol for a randomised controlled trial (SMILE Trial).	Trials. 2013 Dec 26; 14(1):444.	BACKGROUND: Chronic fatigue syndrome or myalgic encephalomyelitis (CFS/ME) is a relatively common and potentially serious condition with a limited evidence base for treatment. Specialist treatment for paediatric CFS/ME uses interventions recommended by National Institute for Health and Clinical Excellence (NICE) including cognitive behavioural therapy, graded exercise therapy and activity management. The Lightning Process® (LP) is a trademarked intervention derived from osteopathy, life-coaching and neuro-linguistic programming, delivered over three consecutive days as group sessions. Although over 250 children with CFS/ME attend LP courses each year, there are no reported studies on the effectiveness or cost-effectiveness. METHODS: This pragmatic randomised controlled trial is set within a specialist paediatric CFS/ME service in the south west of England. Children and young people with CFS/ME (n = 80 to 112), aged 12 to 18 years old will be randomised to specialist medical care (SMC) or SMC plus the LP. The primary outcome will be physical function (SF-36 physical function short form) and fatigue (Chalder Fatigue Scale). DISCUSSION: This study will tell us whether adding the LP to SMC is effective and cost-effective compared to SMC alone. This study will also provide detailed information on the implementation of the LP and SMC.
Crawley E.	[No address quoted]	The epidemiology of chronic fatigue syndrome/myalgic encephalitis in children.	Arch Dis Child. 2013 Oct 21. doi: 10.1136/archdischild-2012-302156. [Epub ahead of print]	Most paediatricians regularly see children with chronic fatigue syndrome or myalgic encephalitis (CFS/ME) in their clinics and yet we know little about how common it is, who is affected, whether there are risk factors and how likely a child is to recover (or what might predict recovery). Recent research suggests that this illness is more complicated than previously thought and that rather than being an illness found in

				middle class families, it is more common in those who are socially deprived. This article reviews what is currently known about this important but little understood condition.
Creed FH, Tomenson B, Chew-Graham C, Macfarlane GJ, Davies I, Jackson J, Littlewood A, McBeth J.	School of Community Based Medicine, University of Manchester, Oxford Road, Manchester, UK. francis.creed@manchester.ac.uk	Multiple somatic symptoms predict impaired health status in functional somatic syndromes.	Int J Behav Med. 2013 Jun; 20(2):194-205. doi: 10.1007/s12529-012-9257-y.	BACKGROUND: The relationship between functional somatic syndromes and multiple somatic symptoms is unclear. PURPOSE: We assessed whether the number of somatic symptoms is a predictor of health status in three functional somatic syndromes (FSS). METHODS: In a population-based study of 990 UK adults we assessed chronic widespread pain (CWP), chronic fatigue (CF) and irritable bowel syndrome (IBS) by questionnaire and medical record data. We assessed health status (Short Form 12 and EQ-5D), number of somatic symptoms (Somatic Symptom Inventory) and anxiety/depression (Hospital Anxiety and Depression Scale) both at baseline and at follow-up 1 year later. RESULTS: The proportion of people with an FSS who also have multiple somatic symptoms (52-55 %) was similar in the three functional syndromes. The presence of multiple somatic symptoms was associated with more impaired health status both at baseline and at follow-up. This finding was not explained by severity of FSS. In the absence of multiple somatic symptoms, the health status of the FSS was fair or good. In multiple regression analysis, the number of somatic symptoms, the presence of a functional syndrome (CWP or CF) and anxiety/depression were predictors of EQ-5D thermometer at follow-up after adjustment for confounders. CONCLUSIONS: Multiple somatic symptoms in people with an FSS are associated with impaired health status and this cannot be explained by more severe functional syndrome or the presence of anxiety and depression.
Crinion SJ, McNicholas WT.	Department of Respiratory and Sleep Medicine, Pulmonary and Sleep Disorders Unit, St. Vincent's University Hospital, Elm Park, Dublin, Ireland.	Sleep-related disorders in chronic obstructive pulmonary disease.	Expert Rev Respir Med. 2013 Dec 30. [Epub ahead of print]	Sleep may have several negative consequences in patients with chronic obstructive pulmonary disease (COPD). Sleep is typically fragmented with diminished slow wave and rapid-eye-movement sleep, which likely represents an important contributing factor to daytime symptoms such as fatigue and lethargy. Furthermore, normal physiological adaptations during sleep, which result in mild hypoventilation in normal subjects, are more pronounced in COPD, which can result in clinically important nocturnal oxygen desaturation. The co-existence of obstructive sleep apnea and COPD is also common, principally because of the high prevalence of each disorder, and there is little convincing evidence that one disorder predisposes to the other. Nonetheless, this co-existence, termed the overlap syndrome, typically results in more pronounced nocturnal oxygen desaturation and there is a high prevalence of pulmonary hypertension in such patients. Management of sleep disorders in patients with COPD should address both sleep quality and disordered gas exchange. Non-invasive pressure support is beneficial in selected cases, particularly during acute exacerbations associated with respiratory failure, and is particularly helpful in patients with the overlap syndrome. There is limited evidence of benefit from pressure support in the chronic setting in COPD patients without obstructive sleep apnea.
Curriu M, Carrillo	Institut de recerca de la	Screening NK-, B- and	J Transl Med. 2013 Mar 20;11:	BACKGROUND: Chronic Fatigue Syndrome (CFS) is a debilitating neuro-immune

J, Massanella M, Rigau J, Alegre J, Puig J, Garcia-Quintana AM, Castro-Marrero J, Negredo E, Clotet B, Cabrera C, Blanco J.	sida, IrsiCaixa-HIVACAT, Institut d'Investigació en Ciències de la Salut Germans Trias I Pujol|, Badalona, Spain.	T-cell phenotype and function in patients suffering from Chronic Fatigue Syndrome.	68. doi: 10.1186/1479-5876-11-68.	disorder of unknown etiology diagnosed by an array of clinical manifestations. Although several immunological abnormalities have been described in CFS, their heterogeneity has limited diagnostic applicability. METHODS: Immunological features of CFS were screened in 22 CFS diagnosed individuals fulfilling Fukuda criteria and 30 control healthy individuals. Peripheral blood T, B and NK cell function and phenotype were analyzed by flow cytometry in both groups. RESULTS: CFS diagnosed individuals showed similar absolute numbers of T, B and NK cells, with minor differences in the percentage of CD4+ and CD8+ T cells. B cells showed similar subset frequencies and proliferative responses between groups. Conversely, significant differences were observed in T cell subsets. CFS individuals showed increased levels of T regulatory cells (CD25+/FOXP3+) CD4 T cells, and lower proliferative responses in vitro and in vivo. Moreover, CD8 T cells from the CFS group showed significantly lower activation and frequency of effector memory cells. No clear signs of T-cell immunosenescence were observed. NK cells from CFS individuals displayed higher expression of NKp46 and CD69 but lower expression of CD25 in all NK subsets defined. Overall, T cell and NK cell features clearly clustered CFS individuals. CONCLUSIONS: Our findings suggest that alterations in T-cell phenotype and proliferative response along with the specific signature of NK cell phenotype may be useful to identify CFS individuals. The striking down modulation of T cell mediated immunity may help to understand intercurrent viral infections in CFS.
Datieva VK, Rosinskaia AV, Levin OS.	[No address quoted]	The use of melatonin in the treatment of chronic fatigue syndrome and circadian rhythm disorders in Parkinson's disease. [Article in Russian]	Zh Nevrol Psikhiatr Im S S Korsakova. 2013;113 (7 Pt 2):77-81.	Chronic fatigue syndrome (CFS), a specific asthenic condition, is identified in a half of patients with Parkinson's disease (PD). An aim of the study was to evaluate an effect of melatonin (melaxen) on the severity of CFS, affective disorders, quality of life and sleep disorders in 30 patients with early and late stages of PD. After treatment, there was a decrease by 21% (p<0,05) on the Parkinson fatigue scale. At the same time, the improvement of sleep, assessed by the PDSS, decrease in the state anxiety on the Spilberger's scale and improvement of quality of life on the PDQ-39 (p<0,05) were found. No significant differences in motor, cognitive autonomic disorders and depression level were noted compared to baseline. Therefore, melatonin, together with optimized antiparkinsonian treatment, can treat CFS improve sleep and quality of life of PD patients.
De Meirleir KL, Khaiboullina SF, Frémont M, Hulstaert J, Rizvanov AA, Palotás A, Lombardi VC.	Whittemore Peterson Institute for Neuro-Immune Disease, University of Nevada, Reno 1664 N Virginia Street MS 0552, Reno, NV 89557 USA.	Plasmacytoid dendritic cells in the duodenum of individuals diagnosed with myalgic encephalomyelitis are uniquely immunoreactive to antibodies to human	In Vivo. 2013 Mar-Apr; 27(2):177-87.	Myalgic encephalomyelitis (ME) is a debilitating illness of unknown etiology characterized by neurocognitive dysfunction, inflammation, immune abnormalities and gastrointestinal distress. An increasing body of evidence suggests that disruptions in the gut may contribute to the induction of neuroinflammation. Therefore, reports of human endogenous retroviral (HERV) expression in association with neuroinflammatory diseases prompted us to investigate the gut of individuals with ME for the presence of HERV proteins. In eight out of 12 individuals with ME, immunoreactivity to HERV proteins was observed in duodenal biopsies. In contrast, no immunoreactivity was detected in any of the eight controls. Immunoreactivity to

		endogenous retroviral proteins.		HERV Gag and Env proteins was uniquely co-localized in hematopoietic cells expressing the C-type lectin receptor CLEC4C (CD303/BDCA2), the co-stimulatory marker CD86 and the class II major histocompatibility complex HLA-DR, consistent with plasmacytoid dendritic cells (pDCs). Although the significance of HERVs present in the pDCs of individuals with ME has yet to be determined, these data raise the possibility of an involvment of pDCs and HERVs in ME pathology. To our knowledge, this report describes the first direct association between pDCs and HERVs in human disease.
Deák M, Szvetnik A, Balog A, Sohár N, Varga R, Pokorny G, Tóth G, Kiss M, Kovács L.	Department of Rheumatology, Faculty of Medicine, Albert Szent-Györgyi Health Centre, University of Szeged, Szeged, Hungary. drdeakmagdi@gmail.com	Neuroimmune interactions in Sjögren's syndrome: relationship of exocrine gland dysfunction with autoantibodies to muscarinic acetylcholine receptor-3 and mental health status parameters.	Neuroimmunomodulation. 2013; 20(2):79-86. doi: 10.1159/000345177. Epub 2012 Dec 12.	OBJECTIVES: Antimuscarinic acetylcholine receptor-3 (m3AChR) autoantibodies have been described in primary Sjögren's syndrome (pSS). The aim of this study was to compare various methods for their detection and to assess the contributions of anti-m3AChR and other immunological and psychosocial factors to the pathomechanism of secondary SS (sSS). METHODS: Sixty-five rheumatoid arthritis (RA) patients, 103 systemic lupus erythematosus (SLE) patients, 76 pSS patients and 50 controls were compared. Three immunodominant epitopes of m3AChR were synthesized and used in ELISA. Two extracellular epitopes were also prepared in fusion with glutathione-S-transferase and one in conjugation with bovine serum albumin. Mental health status was assessed with the 36-item Short-Form Health Survey and Functional Assessment of Chronic Illness Therapy fatigue scale. Correlations were evaluated between glandular function and anti-m3AChR positivities and specificities, features of SLE and RA, and mental health parameters. RESULTS: Fourteen RA and 27 SLE patients had sSS. The autoantibody levels to all epitopes of m3AChR were significantly higher in pSS and SLE patients than in the controls. The fusion protein forms discriminated RA from pSS and SLE; furthermore, the YNIP fusion protein also distinguished pSS from SLE. The prevalence and the mean levels of all autoantibodies did not differ statistically between sicca and non-sicca SLE or RA patients. Glandular dysfunction correlated with higher age in SLE and RA and an impaired health-related quality of life in SLE. CONCLUSIONS: The second and third extracellular loops of m3AChR are antigenic in pSS. Immunoassays with antigens as fusion peptides demonstrate the best performance. Sicca SLE patients have worse mental health status. Anti-m3AChR antibodies represent a peculiar example of neuroimmune interactions.
Dinan TG, Stanton C, Cryan JF.	Alimentary Pharmabiotic Centre, University College Cork and Teagasc Moorepark, Cork, Ireland. Electronic address: t.dinan@ucc.ie.	Psychobiotics: a novel class of psychotropic.	Biol Psychiatry. 2013 Nov 15; 74(10):720-6. doi: 10.1016/j.biopsych.2013.05.001. Epub 2013 Jun 10. Comment in Biol Psychiatry. 2013 Nov 15; 74(10):708-9.	Here, we define a psychobiotic as a live organism that, when ingested in adequate amounts, produces a health benefit in patients suffering from psychiatric illness. As a class of probiotic, these bacteria are capable of producing and delivering neuroactive substances such as gamma-aminobutyric acid and serotonin, which act on the brain-gut axis. Preclinical evaluation in rodents suggests that certain psychobiotics possess antidepressant or anxiolytic activity. Effects may be mediated via the vagus nerve, spinal cord, or neuroendocrine systems. So far, psychobiotics have been most extensively studied in a liaison psychiatric setting in patients with irritable bowel syndrome, where positive benefits have been reported for a number of organisms

				including Bifidobacterium infantis. Evidence is emerging of benefits in alleviating symptoms of depression and in chronic fatigue syndrome. Such benefits may be related to the anti-inflammatory actions of certain psychobiotics and a capacity to reduce hypothalamic-pituitary-adrenal axis activity. Results from large scale placebo-controlled studies are awaited.
Dixit R, Popescu A, Bagić A, Ghearing G, Hendrickson R.	University of Pittsburgh School of Medicine, Pittsburgh, PA, USA.	Medical comorbidities in patients with psychogenic nonepileptic spells (PNES) referred for video-EEG monitoring.	Epilepsy Behav. 2013 Aug; 28(2):137-40. doi: 10.1016/j.yebeh.2013.05.004. Epub 2013 Jun 5.	Differentiating between psychogenic nonepileptic spells (PNES) and epileptic seizures without video-EEG monitoring is difficult. The presence of specific medical comorbidities may discriminate the two, helping physicians suspect PNES over epilepsy earlier. A retrospective analysis comparing the medical comorbidities of patients with PNES with those of patients with epilepsy was performed in 280 patients diagnosed with either PNES (N = 158, 74.7% females) or epilepsy (N = 122, 46.7% females) in the Epilepsy Monitoring Unit (EMU) of the University of Pittsburgh Medical Center over a two-year period. Patients with PNES, compared to those with epilepsy, were mostly female, significantly more likely to have a history of abuse, had more functional somatic syndromes (fibromyalgia, chronic fatigue syndrome, chronic pain syndrome, tension headaches, and irritable bowel syndrome), and had more medical illnesses that are chronic with intermittent attacks (migraines, asthma, and GERD). The presence of at least of one these disorders may lead physicians to suspect PNES over epilepsy and expedite appropriate referral for video-EEG monitoring for diagnosis.
Djamshidian A, Lees AJ.	The National Hospital for Neurology and Neurosurgery, Queen Square and the Reta Lila Weston Institute of Neurological Studies, UCL, London, UK.	Can stress trigger Parkinson's disease?	J Neurol Neurosurg Psychiatry. 2013 Nov 20. doi: 10.1136/jnnp-2013-305911. [Epub ahead of print]	In this manuscript we summarize the role of chronic stress as a potential trigger factor for Parkinson's disease. Underlying mechanisms and stress-induced changes to the neuronal networks have been highlighted. Examples of stress induced reversible symptoms that resemble parkinsonism in humans and in animal models raise the question whether emotional stress can cause striatal degeneration in susceptible patients. A Pubmed literature review searching for the terms 'Stress', 'Distress and Parkinson's disease', 'Emotional Distress and Parkinson's disease', 'Stress and Parkinson's disease', 'Prodromal Parkinson's disease', 'Non motor symptoms and Parkinson's disease', 'Paradoxical kinesia', 'Psychogenic parkinsonism', 'Functional somatic syndromes', 'Chronic fatigue syndrome', 'Irritable bowel syndrome', 'Fibromyalgia', 'Dopamine and fibromyalgia', 'Dopamine and chronic fatigue syndrome' and 'Dopamine and irritable bowel syndrome' was carried out until April 2013. Articles were also identified through searches of the authors' own files. Only papers published in English were reviewed. The final reference list was generated on the basis of originality and relevance to the broad scope of this viewpoint.
Donegan K, Beau-Lejdstrom R, King B, Seabroke S, Thomson A, Bryan P.	Vigilance and Risk Management of Medicines, Medicines and Healthcare products Regulatory	Bivalent human papillomavirus vaccine and the risk of fatigue syndromes in girls in the UK.	Vaccine. 2013 Oct 9;31 (43):4961-7. doi: 10.1016/j.vaccine.2013.08.024. Epub 2013 Sep 1.	INTRODUCTION: Over 70% of cervical cancers are related to human papillomavirus types 16 and 18. In 2008, the vaccine Cervarix, protecting against these two strains, was introduced into the routine UK immunisation programme for girls aged 12-13 years, with a catch-up in girls aged up to 18 years. As part of the risk management planning for this new campaign, the Medicines and Healthcare products Regulatory

	Agency, London, UK.			Agency (MHRA) anticipated a range of conditions, including chronic fatigue syndrome, which might be reported as adverse events in temporal association with the vaccine. METHODS: Near-real time 'observed vs. expected' analyses were conducted comparing the number of reports of fatigue syndromes submitted via the MHRA's Yellow Card passive surveillance scheme to the expected number, using background rates calculated from the Clinical Practice Research Datalink (CPRD) and estimates of vaccination coverage. Subsequently, an ecological analysis and a self-controlled case series (SCCS), both using CPRD, compared the incidence rate of fatigue syndromes in girls before and after the start of the vaccination campaign and the risk in the year post-vaccination compared to other periods. RESULTS: The number of spontaneous reports of chronic fatigue following Cervarix vaccination was consistent with estimated background rates even assuming low reporting. Ecological analyses suggested that there had been no change in the incidence of fatigue syndromes in girls aged 12-20 years after the introduction of the vaccination despite high uptake (IRR: 0.94, 95% CI: 0.78-1.14). The SCCS, including 187 girls, also showed no evidence of an increased risk of fatigue syndromes in the year post first vaccination (IRR: 1.07, 95% CI: 0.57-2.00, p=0.84). DISCUSSION: The successful implementation of an enhanced pharmacovigilance plan provided immediate reassuring evidence that there was no association between vaccination with Cervarix and an increased risk of chronic fatigue syndromes. This has now also been further demonstrated in more comprehensive epidemiological studies.
Dörr J, Nater U.	Psychologie, Universität Marburg.	Fatigue syndromes--an overview of terminology, definitions and classificatory concepts. [Article in German]	Psychother Psychosom Med Psychol. 2013 Feb; 63(2):69-76. doi: 10.1055/s-0032-1327706. Epub 2013 Feb 13.	This article aims at giving a general view of fatigue syndromes, their description, and their differentiation. The syndromes neurasthenia, chronic fatigue syndrome/myalgic encephalomyelitis (CFS/ME), and burnout are discussed. First, the historical background of fatigue classification is shortly reviewed. Each syndrome is introduced in terms of definition and classification as well as differentiation from each other. The article discusses the differentiation of the syndromes from each other as well as differentiation of CFS/ME and burnout from depression. We conclude that it is difficult to differentiate criteria due to insufficient empirical evidence. More research is needed concerning integration of the diagnoses in classification systems as well as differentiation between syndromes. High comorbidity of depression with CFS and Burnout can be shown, but diagnoses also comprise distinct symptoms.

Efficace F, Baccarani M,	Italian Group for Adult Hematologic Diseases,	Chronic fatigue is the most important	Leukemia. 2013 Jul; 27(7):1511-9. doi:	Health-related quality of life (HRQOL) is an important goal of therapy for chronic myeloid leukemia (CML) patients treated with current molecular-targeted therapies.

Breccia M, Cottone F, Alimena G, Deliliers GL, Baratè C, Specchia G, Di Lorenzo R, Luciano L, Turri D, Martino B, Stagno F, Dabusti M, Bergamaschi M, Leoni P, Simula MP, Levato L, Fava C, Veneri D, Sica S, Rambaldi A, Rosti G, Vignetti M, Mandelli F.	Data Center and Health Outcomes Research Unit, Rome, Italy. f.efficace@gimema.it	factor limiting health-related quality of life of chronic myeloid leukemia patients treated with imatinib.	10.1038/leu.2013.51. Epub 2013 Feb 18.	The main objective of this study was to investigate factors associated with long-term HRQOL outcomes of CML patients receiving imatinib. Analysis was performed on 422 CML patients recruited in an observational multicenter study. HRQOL was assessed with the Medical Outcomes Study 36-Item Short-Form Health Survey (SF-36). Key socio-demographic and clinical data were investigated for their association with HRQOL outcomes. Chronic fatigue and social support were also investigated. Univariate and multivariate linear regression analyses were used to identify independent factors associated with HRQOL outcomes. Fatigue was the only variable showing an independent and consistent association across all physical and mental HRQOL outcomes ($P<0.01$). Differences between patients reporting low versus high fatigue levels were more than eight and seven times the magnitude of a clinically meaningful difference, respectively, for the role physical ($\Delta=70$ points) and emotional scale ($\Delta=63$ points) of the SF-36. Fatigue did not occur as an isolated symptom and was most highly correlated with musculoskeletal pain ($r=0.511$; $P\leq0.001$) and muscular cramps ($r=0.448$; $P\leq0.001$). Chronic fatigue is the major factor limiting HRQOL of CML patients receiving imatinib.
Elfaitouri A, Herrmann B, Bölin-Wiener A, Wang Y, Gottfries CG, Zachrisson O, Pipkorn R, Rönnblom L, Blomberg J.	Section of Clinical Microbiology, Department of Medical Sciences, Uppsala University, Uppsala, Sweden.	Epitopes of microbial and human heat shock protein 60 and their recognition in myalgic encephalomyelitis.	PLoS One. 2013 Nov 28; 8 (11):e81155. doi: 10.1371/journal.pone.0081155.	Myalgic encephalomyelitis (ME, also called Chronic Fatigue Syndrome), a common disease with chronic fatigability, cognitive dysfunction and myalgia of unknown etiology, often starts with an infection. The chaperonin human heat shock protein 60 (HSP60) occurs in mitochondria and in bacteria, is highly conserved, antigenic and a major autoantigen. The anti-HSP60 humoral (IgG and IgM) immune response was studied in 69 ME patients and 76 blood donors (BD) (the Training set) with recombinant human and E coli HSP60, and 136 30-mer overlapping and targeted peptides from HSP60 of humans, Chlamydia, Mycoplasma and 26 other species in a multiplex suspension array. Peptides from HSP60 helix I had a chaperonin-like activity, but these and other HSP60 peptides also bound IgG and IgM with an ME preference, theoretically indicating a competition between HSP60 function and antibody binding. A HSP60-based panel of 25 antigens was selected. When evaluated with 61 other ME and 399 non-ME samples (331 BD, 20 Multiple Sclerosis and 48 Systemic Lupus Erythematosus patients), a peptide from Chlamydia pneumoniae HSP60 detected IgM in 15 of 61 (24%) of ME, and in 1 of 399 non-ME at a high cutoff ($p<0.0001$). IgM to specific cross-reactive epitopes of human and microbial HSP60 occurs in a subset of ME, compatible with infection-induced autoimmunity.
Elgen I, Hikmat O, Aspevik TN, Hagen EM.	Department of Child and Adolescent Psychiatry, Haukeland University Hospital, 5021 Bergen, Norway; Department of Clinical Medicine, University of	CFS in Children and Adolescent: Ten Years of Retrospective Clinical Evaluation.	Int J Pediatr. 2013; 2013:270373. doi: 10.1155/2013/270373. Epub 2013 Jun 16.	Aim: To estimate number of children being diagnosed with chronic fatigue syndrome (CFS). Methods: For a period of 10 years (2002-2011) data from children being referred for fatigue symptoms were collected retrospectively. Results: Thirty-seven children were referred. Four were excluded due to incorrect coding. Six (18%) patients received other diagnoses at the end of evaluation time. Of the 27 who received the diagnosis G93.3, four had a previous chronic illness, while 23 patients were previously healthy. All patients reported onset of fatigue symptom in relation to

	Bergen, P.O Box 7804, 5020 Bergen, Norway.			an infection, and all tested positive for IgG to either Epstein-Barr virus, cytomegalovirus or borrelia, indicating previous infection. There were 16 (59%) boys among the 27 patients. The mean age at the debut of fatigue symptoms was 141 months (SD 30) for boys and 136 months (SD 31) for girls, respectively. Being underweight, defined as BMI < 17.5, was found in 12 (44%) patients. Conclusion: An increasing number of children and adolescents are evaluated for CFS. The clinical assessment of children and adolescents with possible CFS need systematically evaluation. Nutritional status, possible eating disorder, and psychosocial issues need to be addressed and evaluated carefully. A multidisciplinary approach is essential when assessing CFS in children and adolescents. There is a need for European guidelines.

Eriksen TE, Risør MB.	Department of Occupational and Environmental Medicine, University Hospital of North Norway, Box 6060, 9038, Tromsø, Norway, thor.eirik.eriksen@unn.no.	What is called symptom?	Med Health Care Philos. 2013 Jul 23. [Epub ahead of print]	There is one concept in medicine which is prominent, the symptom. The omnipresence of the symptom seems, however, not to be reflected by an equally prominent curiosity aimed at investigating this concept as a phenomenon. In classic, traditional or conventional medical diagnostics and treatment, the lack of distinction with respect to the symptom represents a minor problem. Faced with enigmatic conditions and their accompanying labels such as chronic fatigue syndrome, fibromyalgia, medically unexplained symptoms, and functional somatic syndromes, the contestation of the symptom and its origin is immediate and obvious and calls for further exploration. Based on a description of the diagnostic framework encompassing medically unexplained conditions and a brief introduction to how such symptoms are managed both within and outside of the medical clinic, we argue on one hand how unexplained conditions invite us to reconsider and re-think the concept we call a "symptom" and on the other hand how the concept "symptom" is no longer an adequate and necessary fulcrum and must be enriched by socio-cultural,

				phenomenological and existential dimensions. Consequently, our main aim is to expand both our interpretative horizon and the linguistic repertoire in the face of those appearances we label medically unexplained symptoms.
Evans M, Jason LA.	[No address quoted]	Effects of Time Frame on the Recall Reliability of CFS Symptoms.	Eval Health Prof. 2013 Sep 23. [Epub ahead of print]	This study serves as an investigation of the reliability of symptom data as reported by individuals with chronic fatigue syndrome (CFS), across three recall time frames (the past week, the past month, and the past 6 months), and at two assessment points (with 1 week in between each assessment). Multilevel model analyses were used to determine the optimal recall time frame, in terms of test -retest reliability, for each of the Fukuda et al. (1994) case defining symptoms. Results suggested that the optimal time frame for reliably reporting CFS symptoms was six months for sore throat, lymph node pain, muscle pain, post-exertional malaise, headaches, memory/concentration difficulties, and unrefreshing sleep. For joint pain, the optimal time frame was one month. Researchers who are interested in the assessment of CFS symptoms need to take recall time frame into account, especially when the intended goal is to standardize and improve the methods used to reliably and accurately diagnose this complex illness.
Finsterer J, Ahting U.	Krankenanstalt Rudolfstiftung, Vienna, Austria.	Mitochondrial depletion syndromes in children and adults.	Can J Neurol Sci. 2013 Sep; 40 (5):635-44.	To highlight differences between early-onset and adult mitochondrial depletion syndromes (MDS) concerning etiology and genetic background, pathogenesis, phenotype, clinical presentation and their outcome. MDSs most frequently occur in neonates, infants, or juveniles and more rarely in adolescents or adults. Mutated genes phenotypically presenting with adult-onset MDS include POLG1, TK2, TyMP, RRM2B, or PEO1/twinkle. Adult MDS manifest similarly to early-onset MDS, as myopathy, encephalo-myopathy, hepato-cerebral syndrome, or with chronic progressive external ophthalmoplegia (CPEO), fatigue, or only minimal muscular manifestations. Diagnostic work-up or treatment is not at variance from early-onset cases. Histological examination of muscle may be normal but biochemical investigations may reveal multiple respiratory chain defects. The outcome appears to be more favorable in adult than in early-onset forms. Mitochondrial depletion syndromes is not only a condition of neonates, infants, or juveniles but rarely also occurs in adults, presenting with minimal manifestations or manifestations like in the early-onset forms. Outcome of adult-onset MDS appears more favorable than early-onset MDS.
Fisher H, Crawley E.	Paediatric CFS/ME Service, Royal National Hospital for Rheumatic Diseases, UK.	Why do young people with CFS/ME feel anxious? A qualitative study.	Clin Child Psychol Psychiatry. 2013 Oct; 18(4):556-73. doi: 10.1177/1359104512460862. Epub 2012 Oct 23.	Young people with chronic fatigue syndrome or myalagic encephalopathy (CFS/ME) (CFS/ME) experience higher levels of psychological distress than healthy controls and young people with other chronic illnesses, and it was recently demonstrated that 38% of this population scored above the clinical cut-off on the Spence Child Anxiety Scale. Subscales of social and separation anxiety were consistently high across gender and age groups. In this study, we used qualitative methods to help us understand more about these two types of anxiety in young people with CFS/ME. Eleven young people (age 12-18) were interviewed. Interviews were self-directed by the participants and

				were wide ranging. The transcripts were analysed using interpretative phenomenological analysis. Five superordinate themes were identified: social loss and adjustment; introduction of uncertainty and unpredictability; the vulnerable self; individual differences; and contributions towards recovery. Many themes were identical to those described in young people coping with other chronic illnesses in adolescence. In addition, young people with CFS/ME describe experiences associated with the perceived illegitimacy of this condition, namely: feeling unable to explain their illness; bullying from peers; disbelief; and distrust from adults around them. This becomes an additional challenge for these young people. Clinicians need to be aware of these problems, and offer appropriate support.
Fitzcharles MA, Ste-Marie PA, Goldenberg DL, Pereira JX, Abbey S, Choinière M, Ko G, Moulin DE, Panopalis P, Proulx J, Shir Y; National Fibromyalgia Guideline Advisory Panel.	Division of Rheumatology, McGill University Health Centre, Montreal, Quebec, Canada. mary-ann.fitzcharles@muhc.mcgill.ca	2012 Canadian Guidelines for the diagnosis and management of fibromyalgia syndrome: executive summary.	Pain Res Manag. 2013 May-Jun; 18(3):119-26.	BACKGROUND: Recent neurophysiological evidence attests to the validity of fibromyalgia (FM), a chronic pain condition that affects >2% of the population. OBJECTIVES: To present the evidence-based guidelines for the diagnosis, management and patient trajectory of individuals with FM. METHODS: A needs assessment following consultation with diverse health care professionals identified questions pertinent to various aspects of FM. A literature search identified the evidence available to address these questions; evidence was graded according to the standards of the Oxford Centre for Evidence-Based Medicine. Drafted recommendations were appraised by an advisory panel to reflect meaningful clinical practice. RESULTS: The present recommendations incorporate the new clinical concepts of FM as a clinical construct without any defining physical abnormality or biological marker, characterized by fluctuating, diffuse body pain and the frequent symptoms of sleep disturbance, fatigue, mood and cognitive changes. In the absence of a defining cause or cure, treatment objectives should be patient-tailored and symptom-based, aimed at reducing global complaints and enhancing function. Healthy lifestyle practices with active patient participation in health care forms the cornerstone of care. Multimodal management may include nonpharmacological and pharmacological strategies, although it must be acknowledged that pharmacological treatments provide only modest benefit. Maintenance of function and retention in the workforce is encouraged. CONCLUSIONS: The new Canadian guidelines for the treatment of FM should provide health professionals with confidence in the complete care of these patients and improve clinical outcomes.
Fjorback LO, Arendt M, Ornbøl E, Walach H, Rehfeld E, Schröder A, Fink P.	The Research Clinic for Functional Disorders and Psychosomatics, Aarhus University Hospital, Denmark. lonefjor@rm.dk	Mindfulness therapy for somatization disorder and functional somatic syndromes: randomized trial with one-year follow-up.	J Psychosom Res. 2013 Jan;74(1):31-40. doi: 10.1016/j.jpsychores.2012.09.006. Epub 2012 Oct 1.	OBJECTIVE: To conduct a feasibility and efficacy trial of mindfulness therapy in somatization disorder and functional somatic syndromes such as fibromyalgia, irritable bowel syndrome, and chronic fatigue syndrome, defined as bodily distress syndrome (BDS). METHODS: We randomized 119 patients to either mindfulness therapy (mindfulness-based stress reduction and some cognitive behavioral therapy elements for BDS) or to enhanced treatment as usual (2-hour specialist medical care and brief cognitive behavioral therapy for BDS). The primary outcome measure was change in physical health (SF-36 Physical Component Summary) from baseline to 15-

				month follow-up. RESULTS: The study is negative as we could not demonstrate a different development over time for the two groups (F(3,2674)=1.51, P=.21). However, in the mindfulness therapy group, improvement was obtained toward the end of treatment and it remained present at the 15-month follow-up, whereas the enhanced treatment as usual group achieved no significant change until 15-month follow-up. The change scores averaged half a standard deviation which amounts to a clinically significant change, 29% changed more than 1 standard deviation. Significant between-group differences were observed at treatment cessation. CONCLUSION: Mindfulness therapy is a feasible and acceptable treatment. The study showed that mindfulness therapy was comparable to enhanced treatment as usual in improving quality of life and symptoms. Nevertheless, considering the more rapid improvement following mindfulness, mindfulness therapy may be a potentially useful intervention in BDS patients. Clinically important changes that seem to be comparable to a CBT treatment approach were obtained. Further research is needed to replicate or even expand these findings.
Fjorback LO, Carstensen T, Arendt M, Ornbøl E, Walach H, Rehfeld E, Fink P.	The Research Clinic for Functional Disorders and Psychosomatics, Aarhus University Hospital, Aarhus, Denmark. lonefjor@rm.dk	Mindfulness therapy for somatization disorder and functional somatic syndromes: analysis of economic consequences alongside a randomized trial.	J Psychosom Res. 2013 Jan; 74 (1):41-8. doi: 10.1016/j.jpsychores.2012.09. 010. Epub 2012 Oct 11.	OBJECTIVE: The objective of the present study is to estimate the economic consequences of somatization disorder and functional somatic syndromes such as fibromyalgia and chronic fatigue syndrome, defined as bodily distress syndrome (BDS), when mindfulness therapy is compared with enhanced treatment as usual. METHODS: A total of 119 BDS patients were randomized to mindfulness therapy or enhanced treatment as usual and compared with 5950 matched controls. Register data were analyzed from 10years before their inclusion to 15-month follow-up. The main outcome measures were disability pension at the 15-month follow-up and a reduction in total health care costs. Unemployment and sickness benefit prior to inclusion were tested as possible risk factors. RESULTS: At 15-month follow-up, 25% from the mindfulness therapy group received disability pension compared with 45% from the specialized treatment group (p=.025). The total health care utilization was reduced over time in both groups from the year before inclusion (mean $5325, median $2971) to the year after inclusion (mean $3644, median $1593) (p=.0001). This overall decline was seen in spite of elevated costs due to assessment and mindfulness therapy or enhanced treatment as usual. The BDS patients accumulated significantly more weeks of unemployment and sickness benefit 5 and 10years before inclusion (p<.0001) than the population controls. CONCLUSIONS: Mindfulness therapy may prevent disability pension and it may have a potential to significantly reduce societal costs and increase the effectiveness of care. Accumulated weeks of unemployment and sickness benefit are possible risk factors for BDS.
Flores S, Brown A, Adeoye S, Jason LA, Evans M.	DePaul University, Chicago, IL, USA. S.Flore10@DePaul.Edu	Examining the impact of obesity on individuals with chronic fatigue	Workplace Health Saf. 2013 Jul; 61(7):299-307. doi: 10.3928/21650799-20130617-12. Epub 2013 Jun	Chronic fatigue syndrome (CFS) is a complex disorder affecting multiple body systems. The most commonly used definition of CFS is 6 or more months of fatigue and the presence of at least four of eight minor symptoms. In addition, many health and psychological conditions, including severe obesity-body mass index (BMI) of 40

		syndrome.	24.	kg/m(2) or greater-exclude individuals from a diagnosis of CFS. Obesity has been correlated with fatigue, sleep problems, and less satisfaction with general health, functioning, and vitality. The current study investigated weight trends over time in a community-based sample of individuals with CFS and healthy controls. The study further investigated the impact of comorbid weight issues on several health and disability outcomes in a subset of overweight individuals. Overweight and obese individuals with CFS demonstrated poorer functioning than controls who were similarly weighted. One participant was excluded because she had gained weight at a monitoring visit and her BMI was greater than 40 kg/m(2). The implications of these findings for health care workers are discussed.
Frémont M, Coomans D, Massart S, De Meirleir K.	R.E.D Laboratories NV, Z-1 Researchpark 100, 1731 Zellik, Belgium. mfremont@redlabs.be	High-throughput 16S rRNA gene sequencing reveals alterations of intestinal microbiota in myalgic encephalomyelitis/chronic fatigue syndrome patients.	Anaerobe. 2013 Aug; 22:50-6. doi: 10.1016/j.anaerobe.2013.06.002. Epub 2013 Jun 19.	Human intestinal microbiota plays an important role in the maintenance of host health by providing energy, nutrients, and immunological protection. Intestinal dysfunction is a frequent complaint in myalgic encephalomyelitis/chronic fatigue syndrome (ME/CFS) patients, and previous reports suggest that dysbiosis, i.e. the overgrowth of abnormal populations of bacteria in the gut, is linked to the pathogenesis of the disease. We used high-throughput 16S rRNA gene sequencing to investigate the presence of specific alterations in the gut microbiota of ME/CFS patients from Belgium and Norway. 43 ME/CFS patients and 36 healthy controls were included in the study. Bacterial DNA was extracted from stool samples, PCR amplification was performed on 16S rRNA gene regions, and PCR amplicons were sequenced using Roche FLX 454 sequencer. The composition of the gut microbiota was found to differ between Belgian controls and Norwegian controls: Norwegians showed higher percentages of specific Firmicutes populations (Roseburia, Holdemania) and lower proportions of most Bacteroidetes genera. A highly significant separation could be achieved between Norwegian controls and Norwegian patients: patients presented increased proportions of Lactonifactor and Alistipes, as well as a decrease in several Firmicutes populations. In Belgian subjects the patient/control separation was less pronounced, however some abnormalities observed in Norwegian patients were also found in Belgian patients. These results show that intestinal microbiota is altered in ME/CFS. High-throughput sequencing is a useful tool to diagnose dysbiosis in patients and could help designing treatments based on gut microbiota modulation (antibiotics, pre and probiotics supplementation).
Friedberg F, Napoli A, Coronel J, Adamowicz J, Seva V, Caikauskaite I, Ngan MC, Chang J, Meng H.	Department of Psychiatry and Behavioral Science, Stony Brook University, Stony Brook, NY, USA. fred.friedberg@stonybrookmedicine.edu	Chronic fatigue self-management in primary care: a randomized trial.	Psychosom Med. 2013 Sep; 75(7):650-7. doi: 10.1097/PSY.0b013e31829dbed4. Epub 2013 Aug 6.	OBJECTIVE: To assess the efficacy of brief fatigue self-management (FSM) for medically unexplained chronic fatigue (UCF) and chronic fatigue syndrome (CFS) in primary care. METHODS: A randomized controlled design was used wherein 111 patients with UCF or CFS were randomly assigned to two sessions of FSM, two sessions of symptom monitoring support (attention control; AC), or a usual care control condition (UC). Participants were assessed at baseline and at 3 and 12 months after treatment. The primary outcome, the Fatigue Severity Scale, measured fatigue impact on functioning. Analysis was by intention to treat (multiple imputation) and

				also by per protocol. RESULTS: A group × time interaction across the 15-month trial showed significantly greater reductions in fatigue impact in the FSM group in comparison with the AC group ($p < .023$) and the UC group ($p < .013$). Medium effect sizes for reduced fatigue impact in the FSM group were found in comparison with the AC group ($d = 0.46$) and the UC group ($d = 0.40$). The per-protocol analysis revealed large effect sizes for the same comparisons. Clinically significant decreases in fatigue impact were found for 53% of participants in the FSM condition, 14% in the AC condition, and 17% in the UC condition. Dropout rates at the 12-month follow-up were high (42%-53%), perhaps attributable to the burden of monthly telephone calls to assess health care use. CONCLUSION: A brief self-management intervention for patients with UCF or CFS seemed to be clinically effective for reducing the impact of fatigue on functioning. Trial Registration clinicaltrials.gov Identifier: NCT00997451.
Fuchs CE, van Geelen SM, van Geel R, Sinnema G, van de Putte EM, Hermans HJ, Kuis W.	Division of Paediatric Psychology, University Medical Centre Utrecht, 3584 EA, Lundlaan 6, KE.04.133.1, Utrecht, The Netherlands. c.e.fuchs@umcutrecht.nl	Health and identity: Self-positioning in adolescent chronic fatigue syndrome and juvenile idiopathic arthritis.	Clin Child Psychol Psychiatry. 2013 Jul; 18(3):383-97. doi: 10.1177/1359104512455814. Epub 2012 Oct 11.	The aim of this study is to gain more insight into basic aspects of identity, in relation to adolescent chronic fatigue syndrome (CFS) and juvenile idiopathic arthritis (JIA). In dialogical self theory, identity is regarded as incorporating multiple self-positions, such as 'I as tired', 'I as pessimistic', or 'I as decisive'. Physical and psychosocial impairment might alter the organization of these self-positions. The Personal Position Repertoire procedure, a quantitative method to analyse the prominence of self-positions, the Child Health Questionnaire, assessing health-related functioning, and the Checklist Individual Strength, measuring fatigue, were completed by 42 adolescents with CFS, 37 adolescents with JIA and 23 healthy teenagers. Adolescents with JIA report impaired physical functioning and general health. However, they position themselves very similar to healthy teenagers - i.e. as strong and healthy. While this self-positioning approach might be adequate and sustainable in adolescence, it could prove too strenuous to maintain throughout adult life. Adolescents with CFS, besides indicating severe physical difficulties, also report more psychosocial problems. They position themselves as significantly less strong and more unwell. With this emphasis on positions relating to their illness, there seems to be little room left for stronger positions. It is regarded of clinical importance to address these issues in this crucial developmental period.
Fukuda S, Horiguchi M, Yamaguti K, Nakatomi Y, Kuratsune H, Ichinose H, Watanabe Y.	Department of Medical Science on Fatigue, Osaka City University, Graduate School of Medicine, Osaka, Japan.	Association of monoamine-synthesizing genes with the depression tendency and personality in chronic fatigue syndrome patients.	Life Sci. 2013 Feb 27; 92(3):183-6. doi: 10.1016/j.lfs.2012.11.016. Epub 2012 Dec 13.	AIMS: Tyrosine hydroxylase (TH) and GTP cyclohydrolase I (GCH) are the rate-limiting enzymes for the biosynthesis of catecholamines and tetrahydrobiopterin (BH4), respectively. Since catecholamines and BH4 are thought to be involved in the pathophysiology of CFS, we explored the genetic factors that influence CFS development and examined the possible association between the SNPs of the TH and GCH genes and the various characteristics of CFS patients. MAIN METHODS: After drawing venous blood from CFS patients and controls, genomic DNA was then extracted from whole blood in accordance with standard procedures. Digestion patterns of the PCR products were used for genotyping the SNPs of GCH (rs841; C+243T) and TH (rs10770141; C-824T). We also performed questionnaires consisting

				of fatigue-scale and temperament and character inventory scale (TCI) to CFS patients. KEY FINDINGS: Our results demonstrated that the allele differences for the GCH and TH SNPs were not associated with CFS patients. We did find that the GCH gene with the C+243T polymorphism affected harm avoidance, while the TH gene with the C-824T polymorphism affected persistence in the CFS patients. The concept of persistence has been linked to specific personality, such as perfectionism, in CFS. SIGNIFICANCE: Our results suggest that the biosynthetic pathways of the monoamine neurotransmitters that are mediated by TH and GCH might be associated with the CFS clinical findings, because persistence is one of the typical personality traits observed in CFS and patients with major depressive disorder exhibit a higher harm avoidance score.
Gao J, Gurbaxani BM, Hu J, Heilman KJ, Emanuele Ii VA, Lewis GF, Davila M, Unger ER, Lin JM.	PMB Intelligence LLC West Lafayette, IN, USA; Mechanical and Materials Engineering, Wright State University Dayton, OH, USA.	Multiscale analysis of heart rate variability in non-stationary environments.	Front Physiol. 2013 May 30; 4:119. doi: 10.3389/fphys.2013.00119. eCollection 2013.	Heart rate variability (HRV) is highly non-stationary, even if no perturbing influences can be identified during the recording of the data. The non-stationarity becomes more profound when HRV data are measured in intrinsically non-stationary environments, such as social stress. In general, HRV data measured in such situations are more difficult to analyze than those measured in constant environments. In this paper, we analyze HRV data measured during a social stress test using two multiscale approaches, the adaptive fractal analysis (AFA) and scale-dependent Lyapunov exponent (SDLE), for the purpose of uncovering differences in HRV between chronic fatigue syndrome (CFS) patients and their matched-controls. CFS is a debilitating, heterogeneous illness with no known biomarker. HRV has shown some promise recently as a non-invasive measure of subtle physiological disturbances and trauma that are otherwise difficult to assess. If the HRV in persons with CFS are significantly different from their healthy controls, then certain cardiac irregularities may constitute good candidate biomarkers for CFS. Our multiscale analyses show that there are notable differences in HRV between CFS and their matched controls before a social stress test, but these differences seem to diminish during the test. These analyses illustrate that the two employed multiscale approaches could be useful for the analysis of HRV measured in various environments, both stationary and non-stationary.
Gladwell PW, Pheby D, Rodriguez T, Poland F.	North Bristol NHS Trust, Bristol, UK .	Use of an online survey to explore positive and negative outcomes of rehabilitation for people with CFS/ME.	Disabil Rehabil. 2013 Jun 4. [Epub ahead of print]	Abstract Purpose: First, to explore the experiences of people with Chronic Fatigue Syndrome/Myalgic Encephalomyelitis (CFS/ME) of rehabilitation therapies so as to build an understanding of reasons for the discrepancy between the notably mixed experiences regarding effectiveness reported in patient surveys and the RCT evidence about the efficacy of Graded Exercise Therapy (GET). GET is a form of structured and supervised activity management that aims for gradual but progressive increases in physical activity. Second, to review patient experiences of two related rehabilitation approaches - Exercise on Prescription (EoP) and Graded Activity Therapy (GAT). Method: An online survey conducted by the charity Action for ME generated qualitative data about 76 patient experiences of rehabilitation undertaken during or

				after 2008, examined using thematic analysis. Results: Both positive and negative experiences of rehabilitation were reported. Positive themes included supportive communication, the benefits of a routine linked with baseline setting and pacing, the value of goal setting, and increasing confidence associated with exercise. Negative themes included poor communication, feeling pushed to exercise beyond a sustainable level, having no setback plan, and patients feeling blamed for rehabilitation not working. Conclusions: The negative themes may help explain the negative outcomes from rehabilitation reported by previous patient surveys. The negative themes indicate rehabilitation processes which contradict the NICE (National Institute for Health and Clinical Excellence) Guideline advice regarding GET, indicating that some clinical encounters were not implementing these. These findings suggest areas for improving therapist training, and for developing quality criteria for rehabilitation in CFS/ME. Implications for Rehabilitation The insensitive delivery of rehabilitation support for people with CFS/ME can explain negative outcomes reported in patient surveys. Therapist-patient collaboration, establishing a sustainable baseline and agreeing a setback plan are all examples of higher quality rehabilitation indicated by this research. Greater awareness of the positive and negative experiences of rehabilitation therapies should enable avoidance of the potential pitfalls identified in this research. Positive experiences of rehabilitation therapies include supportive communication with a therapist, treatment which included routines and goals, and value attached to baselines and controlled pacing. By contrast, factors leading to negative experiences include poor communication and support, conflict in beliefs about CFS/ME and rehabilitation, pressure to comply with treatment, worsening of symptoms, baselines experienced as unsustainable, and feeling blamed for rehabilitation not working.
Goedendorp MM, van der Werf SP, Bleijenberg G, Tummers M, Knoop H.	Department of Health Sciences, University Medical Center Groningen, University of Groningen, The Netherlands. m.m.goedendorp@umcg.nl	Does neuropsychological test performance predict outcome of cognitive behavior therapy for Chronic Fatigue Syndrome and what is the role of underperformance?	J Psychosom Res. 2013 Sep;75(3):242-8. doi: 10.1016/j.jpsychores.2013.07.011. Epub 2013 Jul 26.	OBJECTIVE: A subgroup of patients with Chronic Fatigue Syndrome (CFS) has cognitive impairments, reflected by deviant neuropsychological test performance. However, abnormal test scores can also be caused by suboptimal effort. We hypothesized that worse neuropsychological test performance and underperformance were related to each other and to a smaller reduction in fatigue, functional impairments, physical limitations and higher dropout rates following cognitive behavior therapy (CBT) for CFS. METHODS: Data were drawn from a previous trial, in which CFS patients were randomized to two conditions; 1) guided self-instruction and additional CBT (n=84) or 2) waiting period followed by regular CBT for CFS (n=85). Underperformance was assessed using the Amsterdam Short Term Memory Test (<84). To test neuropsychological test performance, the Symbol Digit Modalities Task, a simple reaction time task and a choice reaction time task were used. Interaction effects were determined between underperformance and neuropsychological test performance on therapy outcomes. RESULTS: Underperformance was associated to worse neuropsychological test performance, but there were no significant interaction effects

				of these two factors by therapy on fatigue severity, functional impairments and physical limitations, but there was a significant main effect of underperformance on functional impairments, physical limitations and dropout rates. CONCLUSION: Underperformance or neuropsychological test performance was not related to the change in fatigue, functional impairments, and physical limitations following CBT for CFS. However, underperforming patients did drop out more often. Therapists should pay attention to beliefs and behavioral or environmental factors that might maintain underperformance and increase the risk of dropout.
Goodwin L, White PD, Hotopf M, Stansfeld SA, Clark C.	Centre for Psychiatry, Barts and The London School of Medicine and Dentistry, Queen Mary University of London, Wolfson Institute of Preventive Medicine, Charterhouse Square, London EC1M 6BQ, UK. l.goodwin@qmul.ac.uk	Life course study of the etiology of self-reported irritable bowel syndrome in the 1958 British birth cohort.	Psychosom Med. 2013 Feb;75(2):202-10. doi: 10.1097/PSY.0b013e31827c351b. Epub 2013 Jan 16.	OBJECTIVE: Irritable bowel syndrome (IBS) is a common gastrointestinal disorder with unknown etiology. This is the first study to use a life course approach to examine premorbid risk markers for self-reported IBS in a UK birth cohort. METHODS: Cohort study using the 1958 British birth cohort, which included 98.7% of births in 1 week in England, Wales, and Scotland. The outcome was self-reported IBS by the age of 42 years, classified with onset after 24 years and onset after 34 years. Childhood psychopathology was assessed by the Rutter scales, and adulthood psychopathology was assessed by the Malaise Inventory. RESULTS: The prevalence of self-reported IBS in this cohort was 8.4% by 42 years (95% confidence interval [CI]=8.2-8.6). In multivariate analyses, being female (odds ratio [OR]=2.00, 95% CI=1.67-2.36), reporting 1 week to 1 month of school absence for ill health at 16 years (OR=1.27, 95% CI=1.03-1.56) and psychopathology at 23 years (OR=1.25, 95% CI=1.01-1.54) and 33 years (OR=2.20, 95% CI=1.74-2.76) were associated with an increased odds for IBS. Prospectively measured childhood adversity showed no significant association. CONCLUSIONS: This is the first study to show a long-term prospective link between premorbid psychopathology and later self-reported IBS, in agreement with previous findings on chronic fatigue syndrome. There is no evidence that prospective measures of childhood adversity are risk markers for IBS, and there is weak evidence that prospective measures of childhood illness at 16 years are risk markers for IBS, differing to results from the same cohort for psychopathology, chronic fatigue syndrome, and chronic widespread pain. This study also does not replicate the findings of retrospective studies examining the etiology of IBS.
Gotts ZM, Deary V, Newton J, Van der Dussen D, De Roy P, Ellis JG.	Northumbria Centre for Sleep Research, Department of Psychology, Northumbria University, Newcastle, UK.	Are there sleep-specific phenotypes in patients with chronic fatigue syndrome? A cross-sectional polysomnography analysis.	BMJ Open. 2013 Jun 20; 3(6). pii: e002999. doi: 10.1136/bmjopen-2013-002999.	OBJECTIVES: Despite sleep disturbances being a central complaint in patients with chronic fatigue syndrome (CFS), evidence of objective sleep abnormalities from over 30 studies is inconsistent. The present study aimed to identify whether sleep-specific phenotypes exist in CFS and explore objective characteristics that could differentiate phenotypes, while also being relevant to routine clinical practice. DESIGN: A cross-sectional, single-site study. SETTING: A fatigue clinic in the Netherlands. PARTICIPANTS: A consecutive series of 343 patients meeting the criteria for CFS, according to the Fukuda definition. MEASURES: Patients underwent a single night of polysomnography (all-night recording of EEG, electromyography, electrooculography, ECG and respiration) that was hand-scored by a researcher blind to diagnosis and

				patient history. RESULTS: Of the 343 patients, 104 (30.3%) were identified with a Primary Sleep Disorder explaining their diagnosis. A hierarchical cluster analysis on the remaining 239 patients resulted in four sleep phenotypes being identified at saturation. Of the 239 patients, 89.1% met quantitative criteria for at least one objective sleep problem. A one-way analysis of variance confirmed distinct sleep profiles for each sleep phenotype. Relatively longer sleep onset latencies, longer Rapid Eye Movement (REM) latencies and smaller percentages of both stage 2 and REM characterised the first phenotype. The second phenotype was characterised by more frequent arousals per hour. The third phenotype was characterised by a longer Total Sleep Time, shorter REM Latencies, and a higher percentage of REM and lower percentage of wake time. The final phenotype had the shortest Total Sleep Time and the highest percentage of wake time and wake after sleep onset. CONCLUSIONS: The results highlight the need to routinely screen for Primary Sleep Disorders in clinical practice and tailor sleep interventions, based on phenotype, to patients presenting with CFS. The results are discussed in terms of matching patients' self-reported sleep to these phenotypes in clinical practice.
Groeger D, O'Mahony L, Murphy EF, Bourke JF, Dinan TG, Kiely B, Shanahan F, Quigley EM.	Alimentary Health Ltd., Cork, Ireland.	Bifidobacterium infantis 35624 modulates host inflammatory processes beyond the gut.	Gut Microbes. 2013 Jul-Aug; 4(4):325-39. doi: 10.4161/gmic.25487. Epub 2013 Jun 21.	Certain therapeutic microbes, including Bifidobacteria infantis (B. infantis) 35624 exert beneficial immunoregulatory effects by mimicking commensal-immune interactions; however, the value of these effects in patients with non-gastrointestinal inflammatory conditions remains unclear. In this study, we assessed the impact of oral administration of B. infantis 35624, for 6-8 weeks on inflammatory biomarker and plasma cytokine levels in patients with ulcerative colitis (UC) (n = 22), chronic fatigue syndrome (CFS) (n = 48) and psoriasis (n = 26) in three separate randomized, double-blind, placebo-controlled interventions. Additionally, the effect of B. infantis 35624 on immunological biomarkers in healthy subjects (n = 22) was assessed. At baseline, both gastrointestinal (UC) and non-gastrointestinal (CFS and psoriasis) patients had significantly increased plasma levels of C-reactive protein (CRP) and the pro-inflammatory cytokines tumor necrosis factor α (TNF-α) and interleukin-6 (IL-6) compared with healthy volunteers. B. infantis 35624 feeding resulted in reduced plasma CRP levels in all three inflammatory disorders compared with placebo. Interestingly, plasma TNF-α was reduced in CFS and psoriasis while IL-6 was reduced in UC and CFS. Furthermore, in healthy subjects, LPS-stimulated TNF-α and IL-6 secretion by peripheral blood mononuclear cells (PBMCs) was significantly reduced in the B. infantis 35624-treated groups compared with placebo following eight weeks of feeding. These results demonstrate the ability of this microbe to reduce systemic pro-inflammatory biomarkers in both gastrointestinal and non-gastrointestinal conditions. In conclusion, these data show that the immunomodulatory effects of the microbiota in humans are not limited to the mucosal immune system but extend to the systemic immune system.
Grover S, Kate N.	Department of	Somatic symptoms in	Int Rev Psychiatry. 2013 Feb;	In medically ill patients the term 'somatic symptoms' is used to understand those

	Psychiatry, Postgraduate Institute of Medical Education and Research, Chandigarh 160012, India. drsandeepg2002@yahoo.com	consultation-liaison psychiatry.	25(1):52-64. doi: 10.3109/09540261.2012.727786.	symptoms which cannot be fully understood in the light of existing medical illness(es). These include a number of physical symptoms and also certain clinical syndromes such as irritable bowel syndrome, fibromyalgia, and chronic fatigue syndrome among others. However, it is increasingly recognized that such patients have larger degrees of psychological morbidities, especially depressive and anxiety disorders, and have disproportionately elevated rates of medical care utilization, including outpatient visits, hospitalizations and total healthcare costs. In view of this psychological morbidity, significant distress and functional impairment, the role of the consultation-liaison psychiatrist is prominent in the management of these patients. A consultation-liaison (CL) psychiatrist is expected to be part of the primary care team to manage patient with unexplained SS, and at the same time is expected to guide colleagues to practice a patient-centred approach to improve the outcome of patients with such symptoms. The clinical work of a CL psychiatrist involves evaluation of patients with medically unexplained symptoms for probable psychiatric disorders and treatment of psychiatric morbidity and also management of patients without psychiatric morbidity. Management strategies include reattribution, cognitive behaviour therapy and antidepressants, with each strategy showing varying degrees of success.
Haley RW, Charuvastra E, Shell WE, Buhner DM, Marshall WW, Biggs MM, Hopkins SC, Wolfe GI, Vernino S.	Epidemiology Division, Department of Internal Medicine, University of Texas Southwestern Medical Center, Dallas, TX 75390-8874, USA. robert.haley@UTSouthwestern.edu	Cholinergic autonomic dysfunction in veterans with Gulf War illness: confirmation in a population-based sample.	JAMA Neurol. 2013 Feb; 70(2):191-200. doi: 10.1001/jamaneurol.2013.596. Comment in JAMA Neurol. 2013 Feb; 70(2):158-9.	BACKGROUND: The authors of prior small studies raised the hypothesis that symptoms in veterans of the 1991 Gulf War, such as chronic diarrhea, dizziness, fatigue, and sexual dysfunction, are due to cholinergic autonomic dysfunction. OBJECTIVE: To perform a confirmatory test of this prestated hypothesis in a larger, representative sample of Gulf War veterans. DESIGN: Nested case-control study. SETTING: Clinical and Translational Research Center, University of Texas Southwestern Medical Center, Dallas. PARTICIPANTS: Representative samples of Gulf War veterans meeting a validated case definition of Gulf War illness with 3 variants (called syndromes 1-3) and a control group, all selected randomly from the US Military Health Survey. MAIN OUTCOME MEASURES: Validated domain scales from the Autonomic Symptom Profile questionnaire, the Composite Autonomic Severity Score, and high-frequency heart rate variability from a 24-hour electrocardiogram. RESULTS: The Autonomic Symptom Profile scales were significantly elevated in all 3 syndrome groups (P< .001), primarily due to elevation of the orthostatic intolerance, secretomotor, upper gastrointestinal dysmotility, sleep dysfunction, urinary, and autonomic diarrhea symptom domains. The Composite Autonomic Severity Score was also higher in the 3 syndrome groups (P= .045), especially in syndrome 2, primarily due to a significant reduction in sudomotor function as measured by the Quantitative Sudomotor Axon Reflex Test, most significantly in the foot; the score was intermediate in the ankle and upper leg and was nonsignificant in the arm, indicating a peripheral nerve length-related deficit. The normal increase in high-frequency heart rate variability at night was absent or blunted in all 3 syndrome groups (P< .001). CONCLUSION: Autonomic symptoms are associated with objective, predominantly

				cholinergic autonomic deficits in the population of Gulf War veterans.
Hannan LM, Dominelli GS, Chen YW, Darlene Reid W, Road J.	Institute for Breathing and Sleep, Austin Hospital, Heidelberg, Victoria, Australia; University of Melbourne, Medicine, Dentistry and Health Sciences, Melbourne, Victoria, Australia; University of British Columbia, Respiratory Division and Department of Medicine, Vancouver, British Columbia, Canada. Electronic address: liamhannan1@yahoo.com.au.	Systematic review of non-invasive positive pressure ventilation for chronic respiratory failure.	Respir Med. 2013 Nov 20. Pii: S0954-6111(13)00451-4. doi: 10.1016/j.rmed.2013.11.010. [Epub ahead of print]	BACKGROUND: This systematic review examined the effect of non-invasive positive pressure ventilation (NIPPV) on patient reported outcomes (PROs) and survival for individuals with or at risk of chronic respiratory failure (CRF). METHODS: Randomised controlled trials (RCTs) and prospective non-randomised studies in those treated with NIPPV for CRF were identified from electronic databases, reference lists and grey literature. Diagnostic groups included in the review were amyotrophic lateral sclerosis/motor neuron disease (ALS/MND), Duchenne muscular dystrophy (DMD), restrictive thoracic disease (RTD) and obesity hypoventilation syndrome (OHS). RESULTS: Eighteen studies were included and overall study quality was weak. Those with ALS/MND had improved somnolence and fatigue as well as prolonged survival with NIPPV. For OHS, improvements in somnolence and fatigue, dyspnoea and sleep quality were demonstrated, while for RTD, measures of dyspnoea, sleep quality, physical function and health, mental and emotional health and social function improved. There was insufficient evidence to form conclusions regarding the effect of NIPPV for those with DMD. CONCLUSIONS: This review has demonstrated that NIPPV influences PROs differently depending on the underlying cause of CRF. These findings may provide assistance to patients and clinicians to determine the relative costs and benefits of NIPPV therapy and also highlight areas in need of further research.
Häuser W, Urrútia G, Tort S, Uçeyler N, Walitt B.	Psychosomatic Medicine and Psychotherapy,Technische Universität München, München, Germany.whaeuser@klinikum-saarbruecken.de	Serotonin and noradrenaline reuptake inhibitors (SNRIs) for fibromyalgia syndrome.	Cochrane Database Syst Rev. 2013 Jan 31;1: CD010292. doi: 10.1002/14651858.CD010292.	BACKGROUND: Fibromyalgia syndrome (FMS) is a clinically well-defined chronic condition of unknown etiology characterized by chronic widespread pain that often co-exists with sleep disturbances, cognitive dysfunction and fatigue. Patients often report high disability levels and poor quality of life (QOL). Drug therapy focuses on reducing key symptoms and improving quality of life. OBJECTIVES: To assess the benefits and harms of serotonin and noradrenaline reuptake inhibitors (SNRIs) compared with placebo for treating FMS symptoms in adults. SEARCH METHODS: We searched the Cochrane Central Register of Controlled Trials (CENTRAL), (The Cochrane Library 2012, Issue 9), MEDLINE (1966 to September 2012), EMBASE (1980 to September 2012), www.clinicalstudyresults.org (U.S.-marketed pharmaceuticals) (to September 2012) and www.clinicaltrials.gov (to September 2012) for published and ongoing trials and examined the reference lists of reviewed articles. SELECTION CRITERIA: We selected randomized, controlled trials of any formulation of SNRIs against placebo for the treatment of FMS in adults. DATA COLLECTION AND ANALYSIS: Two review authors independently extracted the data from the included studies, and assessed the risks of bias of the studies. Discrepancies were resolved by discussion. MAIN RESULTS: Ten studies were included with a total of 6038 participants. Five studies investigated duloxetine against placebo, and five investigated milnacipran against placebo. A total of 3611 participants were included into duloxetine or

				milnacipran groups and 2427 participants into placebo groups. The studies had a low risk of bias in general. Duloxetine and milnacipran had a small incremental effect over placebo in reducing pain (standardized mean difference (SMD) -0.23; 95% confidence interval (CI) -0.29 to -0.18; 6.1% relative improvement). One-hundred and ninety-two participants per 1000 on placebo reported an at least 50% pain reduction compared to 280 per 1000 on SNRIs (Risk ratio (RR) 1.49, 95% CI 1.35 to 1.64; number needed to treat to benefit (NNTB) 11, 95% CI 9 to 15). Duloxetine and milnacipran did not reduce fatigue substantially (SMD -0.14; 95% CI -0.19 to -0.08; 2.5% relative improvement; NNTB 17, 95% CI 12 to 29), and did not improve QOL substantially (SMD -0.20; 95% CI -0.25 to -0.14; 4.6% relative improvement; NNTB 12, 95% CI 9 to 17) compared to placebo. There were no statistically significant differences between either duloxetine or milnacipran and placebo in reducing sleep problems (SMD -0.07; 95% CI -0.16 to 0.03; 2.5% relative improvement). One-hundred and seven participants per 1000 on placebo dropped out due to adverse events compared to 196 per 1000 on SNRIs. The dropout rate due to adverse events in the duloxetine and milnacipran groups was statistically significantly higher than in placebo groups (RR 1.83, 95% CI 1.53 to 2.18; number needed to treat to harm (NNTH) 11, 95% CI 9 to 13). There was no statistically significant difference in serious adverse events between either duloxetine or milnacipran and placebo (RR 0.78, 95% CI 0.55 to 1.12). AUTHORS' CONCLUSIONS: The SNRIs duloxetine and milnacipran provided a small incremental benefit over placebo in reducing pain. The superiority of duloxetine and milnacipran over placebo in reducing fatigue and limitations of QOL was not substantial. Duloxetine and milnacipran were not superior to placebo in reducing sleep problems. The dropout rates due to adverse events were higher for duloxetine and milnacipran than for placebo. The most frequently reported symptoms leading to stopping medication were nausea, dry mouth, constipation, headache, somnolence/dizziness and insomnia. Rare complications of both drugs may include suicidality, liver damage, abnormal bleeding, elevated blood pressure and urinary hesitation.
Hawkins RA.	Boonshoft School of Medicine at Wright State University in Dayton, Ohio, USA. bob.hawkins@khnetwork.org	Fibromyalgia: a clinical update.	J Am Osteopath Assoc. 2013 Sep; 113(9):680-9. doi: 10.7556/jaoa.2013.034.	Fibromyalgia is a common chronic syndrome defined by core symptoms of widespread pain, fatigue, and sleep disturbance. Other common symptoms include cognitive difficulty, headache, paresthesia, and morning stiffness. Fibromyalgia is increasingly understood as 1 of several disorders that are referred to as central sensitivity syndromes; these disorders share underlying causes and clinical features. Tender points are often detected in patients with fibromyalgia and were formerly required for diagnosis. Newly proposed criteria, however, rely on patients' reports of widespread pain and other somatic symptoms to establish the diagnosis of fibromyalgia. The management of fibromyalgia requires a multidimensional approach including patient education, cognitive behavioral therapy, exercise, and pharmacologic therapy. The present review provides an update on these various aspects of treating a patient with fibromyalgia.

He J, Hollingsworth KG, Newton JL, Blamire AM.	Institute of Cellular Medicine & Newcastle Magnetic Resonance Centre, Newcastle University, Newcastle upon Tyne, United Kingdom.	Cerebral vascular control is associated with skeletal muscle pH in chronic fatigue syndrome patients both at rest and during dynamic stimulation.	Neuroimage Clin. 2013 Jan 5; 2:168-73. doi: 10.1016/j.nicl.2012.12.006.	Cerebral blood flow (CBF) is maintained despite changing systemic blood pressure through cerebral vascular control, with such tight regulation believed to be under local tissue control. Chronic fatigue syndrome (CFS) associates with a wide range of symptoms, including orthostatic intolerance, skeletal muscle pH abnormalities and cognitive impairment. CFS patients are known to have reduced CBF and orthostatic intolerance associates with abnormal vascular regulation, while skeletal muscle pH abnormalities associate with autonomic dysfunction. These findings point to autonomic dysfunction as the central feature of CFS, and cerebral vascular control being influenced by factors outside of the brain, a macroscopic force affecting the stability of regional regulation. We therefore explored whether there was a physiological link between cerebral vascular control and skeletal muscle pH management in CFS. Seventeen consecutive CFS patients fulfilling the Fukuda criteria were recruited from our local CFS clinical service. To probe the static scenario, CBF and skeletal muscle pH were measured at rest using MRI and (31)P magnetic resonance spectroscopy ((31)P-MRS). To examine dynamic control, brain functional MRI was performed concurrently with Valsalva manoeuvre (VM), a standard autonomic function challenge, while (31) P-MRS was performed during plantar flexion exercise. Significant inverse correlation was seen between CBF and skeletal muscle pH at rest ($r = - 0.67$, $p < 0.01$). Prolonged cerebral vascular constriction during the sympathetic phase of VM was associated with higher pH in skeletal muscle after plantar flexion exercise ($r = 0.69$, $p < 0.008$). In conclusion, cerebral vascular control is closely related to skeletal muscle pH both at rest and after dynamic stimulation in CFS.
Heins M, Knoop H, Nijs J, Feskens R, Meeus M, Moorkens G, Bleijenberg G.	Expert Centre for Chronic Fatigue, Radboud University Nijmegen Medical Centre, Nijmegen, The Netherlands. m.heins@nkcv.umcn.nl	Influence of symptom expectancies on stair-climbing performance in chronic fatigue syndrome: effect of study context.	Int J Behav Med. 2013 Jun; 20(2):213-8. doi: 10.1007/s12529-012-9253-2.	BACKGROUND: In patients with chronic fatigue syndrome (CFS), performance of physical activities may be affected by an anticipated increase in symptoms after these activities. Nijs et al. previously studied the influence of symptom expectancies and related psychological processes on the performance of an isolated physical activity [Nijs J, Meeus M, Heins M, Knoop H, Moorkens G, Bleijenberg G. Kinesiophobia, catastrophizing and anticipated symptoms before stair climbing in chronic fatigue syndrome: an experimental study. Disabil Rehabil 2012. doi: 10.3109/09638288.2011.641661 .]. PURPOSE: We aimed to validate the previous findings in a larger group of patients in a different setting. We also extended the possible underlying psychological processes studied. METHOD: In 49 CFS patients, we measured performance (duration and increase in heart rate) during self-paced climbing and descending of two floors of stairs. Before this task, patients rated experienced fatigue and anticipated fatigue after stair climbing. In addition, kinesiophobia, catastrophising and focusing on bodily symptoms were measured. Using correlational and regression analyses, we tested whether performance during stair climbing could be explained by experienced and anticipated fatigue and psychological factors. RESULTS: Longer duration of stair climbing correlated with

				higher anticipated fatigue, independently of sex, age, body mass index and fatigue before stair climbing. Focusing on bodily symptoms and fatigue-related catastrophising were related to anticipated fatigue. CONCLUSION: Symptom expectations affect the performance of physical activity in CFS patients, possibly through focusing on bodily symptoms and catastrophising. These findings partially contradict the findings of the previous study, which stresses the importance of study context in conducting this type of experiments (i.e., patient characteristics, instructions).
Heins MJ, Knoop H, Bleijenberg G.	Expert Centre for Chronic Fatigue, Radboud University Nijmegen Medical Centre, 4628, PO Box 9101, 6500 HB Nijmegen, The Netherlands. m.heins@nkcv.umcn.nl	The role of the therapeutic relationship in cognitive behaviour therapy for chronic fatigue syndrome.	Behav Res Ther. 2013 Jul; 51(7):368-76. doi: 10.1016/j.brat.2013.02.001. Epub 2013 Apr	Cognitive behaviour therapy (CBT) for chronic fatigue syndrome (CFS) can reduce fatigue and impairment. Recently, it was found that changes in fatigue-perpetuating factors, i.e. focusing on symptoms, control over fatigue, perceived activity and physical functioning, are associated with and explain up to half of the variance in fatigue during CBT for CFS. The therapy relationship, e.g. outcome expectations and working alliance, may also contribute to treatment outcome. We aimed to examine the role of the therapy relationship in CBT and determine whether it exerts its effect independently of changes in fatigue-perpetuating factors. We used a cohort of 217 CFS patients in which the pattern of change in fatigue-perpetuating factors was examined previously. Fatigue, therapy relationship and fatigue-perpetuating factors were measured at the start of therapy, three times during CBT and at the end of therapy. Baseline outcome expectations and agreement about the content of therapy predicted post therapy fatigue. A large part of the variance in post-treatment fatigue (25%) was jointly explained by outcome expectations, working alliance and changes in fatigue-perpetuating factors. From this, we conclude that positive outcome expectations and task agreement seem to facilitate changes in fatigue-perpetuating factors during CBT for CFS. It is therefore important to establish a positive therapy relationship early in therapy.
Heins MJ, Knoop H, Burk WJ, Bleijenberg G.	Expert Centre for Chronic Fatigue, Radboud University Nijmegen Medical Centre, The Netherlands. m.heins@nkcv.umcn.nl	The process of cognitive behaviour therapy for chronic fatigue syndrome: which changes in perpetuating cognitions and behaviour are related to a reduction in fatigue?	J Psychosom Res. 2013 Sep;75(3):235-41. doi: 10.1016/j.jpsychores.2013.06.034. Epub 2013 Jul 19.	OBJECTIVE: Cognitive behaviour therapy (CBT) can significantly reduce fatigue in chronic fatigue syndrome (CFS), but little is known about the process of change taking place during CBT. Based on a recent treatment model (Wiborg et al. J Psych Res 2012), we examined how (changes in) cognitions and behaviour are related to the decrease in fatigue. METHODS: We included 183 patients meeting the US Centers for Disease Control criteria for CFS, aged 18 to 65 years, starting CBT. We measured fatigue and possible process variables before treatment; after 6, 12 and 18 weeks; and after treatment. Possible process variables were sense of control over fatigue, focusing on symptoms, self-reported physical functioning, perceived physical activity and objective (actigraphic) physical activity. We built multiple regression models, explaining levels of fatigue during therapy by (changes in) proposed process variables. RESULTS: We observed large individual variation in the patterns of change in fatigue and process variables during CBT for CFS. Increases in the sense of control over fatigue, perceived activity and self-reported physical functioning, and decreases in

				focusing on symptoms explained 20 to 46% of the variance in fatigue. An increase in objective activity was not a process variable. CONCLUSION: A change in cognitive factors seems to be related to the decrease in fatigue during CBT for CFS. The pattern of change varies considerably between patients, but changes in process variables and fatigue occur mostly in the same period.
Hempel HA, Burns KH, De Marzo AM, Sfanos KS.	Department of Pathology, Johns Hopkins University School of Medicine, Baltimore, MD, USA.	Infection of Xenotransplanted Human Cell Lines by Murine Retroviruses: A Lesson Brought Back to Light by XMRV.	Front Oncol. 2013 Jun 17; 3:156. doi: 10.3389/fonc.2013.00156. eCollection 2013.	Infection of xenotransplanted human cells by xenotropic retroviruses is a known phenomenon in the scientific literature, with examples cited since the early 1970s. However, arguably, until recently, the importance of this phenomenon had not been largely recognized. The emergence and subsequent debunking of Xenotropic Murine leukemia virus-Related Virus (XMRV) as a cell culture contaminant as opposed to a potential pathogen in several human diseases, notably prostate cancer and Chronic Fatigue Syndrome, highlighted a potential problem of murine endogenous gammaretroviruses infecting commonly used human cell lines. Subsequent to the discovery of XMRV, many additional cell lines that underwent xenotransplantation in mice have been shown to harbor murine gammaretroviruses. Such retroviral infection poses the threat of not only confounding experiments performed in these cell lines via virus-induced changes in cellular behavior but also the potential infection of other cell lines cultured in the same laboratory. Thus, the possibility of xenotropic retroviral infection of cell lines may warrant additional precautions, such as periodic testing for retroviral sequences in cell lines cultured in the laboratory.
Henningsen P, Martin A.	Klinik für Psychosomatische Medizin und Psychotherapie, Klinikum rechts der Isar der TU München. p.henningsen@tum.de	Chronic fatigue syndrome. [Article in German]	Dtsch Med Wochenschr. 2013 Jan;138(1-2):33-8. doi: 10.1055/s-0032-1327358. Epub 2012 Dec 18.	Enduring and disabling fatigue that cannot be explained by a known disease is the main characteristic of chronic fatigue syndrome. Several definitions do exist, and classification approaches vary regarding supplementary symptoms, time course, and by implicit concepts of aetiology. CFS can be considered as a functional somatic syndrome, e.g. supported by the high rates of comorbid bodily complaints and syndromes that lack clear medical explanation. Accordingly the diagnostic process should not be limited to the thorough physical examination, but also address additional somatic complaints, psychosocial factors (specifically subjective illness beliefs), and impairments. Recently German medical and psychological societies provided treatment guidelines for functional somatic syndromes. Cognitive behavioural therapy and graded activity are evidence based treatment methods for CFS.
Hossenbaccus Z, White PD.	Barts and The London School of Medicine and Dentistry, Queen Mary University London, London, UK.	Views on the nature of chronic fatigue syndrome: content analysis.	JRSM Short Rep. 2013 Jan; 4(1):4. doi: 10.1258/shorts.2012.012051. Epub 2013 Jan 14.	OBJECTIVES: Chronic fatigue syndrome (CFS), also known as myalgic encephalomyelitis (ME), has provoked much controversy and led to arguments between the medical profession and patient organizations. A particular focus for debate is the categorization of the condition as physical or psychological in its nature. The aim of this study was to compare how the written media, patient organizations and medical authorities regard the illness. DESIGN: Content analysis of newspaper articles, ME patient organization websites, and medical websites and textbooks were assessed by two independent assessors. SETTING: Three national UK newspapers, UK

				ME websites, and UK medical websites and textbooks, were accessed during 2010. PARTICIPANTS: 146 source files were scored from 36 patients' organizations, 72 media articles and 38 medical authorities. MAIN OUTCOME MEASURED: The overall opinion of an article or website was rated using a five point Likert scale, from 'extremely psychological' (scored as 1), 'moderately psychological' (2), 'both psychological and physical' (3), 'moderately physical' (4) or 'extremely physical' (5). RESULTS: Eighty-nine percent (32 of 36) of ME patient organizations considered the illness to be physical, compared with 58% (42/72) of newspaper articles, and 24% (9/38) of medical authorities. Sixty-three percent (24/38) of medical authorities regarded the illness as both physical and psychological. The inter-group differences of the Likert scores were statistically significant ($\chi(2) = 27.37$, 2 df, $P < 0.001$). CONCLUSION: The considerable disagreement, particularly between ME patient organizations and medical authorities, may help to explain the gulf in understanding between doctors and patients and the consequent reluctance of some patients to engage in behavioural treatments.

Attention processes in chronic fatigue syndrome: Attentional bias for health-related threat and the role of attentional control.	Behav Res Ther. 2014 Jan; 52:9-16. doi: 10.1016/j.brat.2013.10.005. Epub 2013 Oct 24.	Cognitive behavioural models of chronic fatigue syndrome (CFS) propose that attention processes, specifically, enhanced selective attention to health-threat related cues may play an important role in symptom maintenance. The current study investigated attentional bias towards health-threat stimuli in CFS. It also examined whether individuals with CFS have impaired executive attention, and whether this was related to attentional bias. 27 participants with CFS and 35 healthy controls completed a Visual Probe Task measuring attentional bias, and an Attention Network Test measuring executive attention, alerting and orienting. Participants also completed self-report measures of CFS and mood symptoms. Compared to the control group, the CFS group showed greater attentional bias for health-threat words than pictures; and the CFS group was significantly impaired in executive attention. Furthermore, CFS individuals with poor executive attention showed greater attentional bias to health-threat related words, compared not only to controls but also to CFS individuals with good executive attention. Thus, this study revealed a significant relationship between attentional bias and executive attention in CFS: attentional bias to threat was primarily evident in those with impaired executive attention control. Taking account of individual differences in executive attention control in current intervention models may be beneficial for CFS.

Hughes AM, Lucas RM, McMichael AJ, Dwyer T, Pender MP, van der Mei I, Taylor BV, Valery P, Chapman C, Coulthard A, Dear K, Kilpatrick TJ, Williams D, Ponsonby AL.	National Centre for Epidemiology and Population Health, Australian National University, Canberra, Australia. annmaree.hughes@anu.edu.au	Early-life hygiene-related factors affect risk of central nervous system demyelination and asthma differentially.	Clin Exp Immunol. 2013 Jun; 172(3):466-74. doi: 10.1111/cei.12077.	The increasing prevalence of immune-related diseases, including multiple sclerosis, may be partly explained by reduced microbial burden during childhood. Within a multi-centre case-control study population, we examined: (i) the co-morbid immune diseases profile of adults with a first clinical diagnosis of central nervous system demyelination (FCD) and (ii) sibship structure in relation to an autoimmune (FCD) and an allergic (asthma) disease. FCD cases (n=282) were aged 18-59 years; controls (n=558) were matched on age, sex and region. Measures include: history of doctor-diagnosed asthma; sibling profile (number; dates of birth); and regular childcare attendance. FCD cases did not differ from controls with regard to personal or family history of allergy, but had a greater likelihood of chronic fatigue syndrome [odds ratio (OR) = 3·11; 95% confidence interval (CI) 1·11, 8·71]. Having any younger siblings showed reduced odds of FCD (OR=0·68; 95% CI: 0·49, 0·95) but not asthma (OR = 1·47; 95% CI: 0·91, 2·38). In contrast, an increasing number of older siblings was associated with reduced risk of asthma (P trend = 0·04) but not FCD (P trend=0·66). Allergies were not over-represented among people presenting with FCD. Sibship characteristics influence both FCD and asthma risk but the underlying mechanisms differ, possibly due to the timing of the putative 'sibling effect'.
Hutchinson CV, Badham SP.	College of Medicine, Biological Sciences and Psychology, University of Leicester, Leicester, Leicestershire, United Kingdom. ch190@le.ac.uk	Patterns of abnormal visual attention in myalgic encephalomyelitis.	Optom Vis Sci. 2013 Jun; 90(6):607-14. doi: 10.1097/OPX.0b013e318294c232.	PURPOSE: To experimentally assess visual attention difficulties commonly reported by those with myalgic encephalomyelitis/chronic fatigue syndrome (ME/CFS). METHODS: Twenty-nine ME/CFS patients and 29 controls took part in the study. Performance was assessed using the Useful Field of View (UFOV), a spatial cueing task and visual search. RESULTS: Patients and controls performed similarly on the processing speed subtest of the UFOV. However, patients exhibited marginally worse performance compared with controls on the divided attention subtest and significantly worse performance on the selective attention subtest. In the spatial cueing task, they were slower than controls to respond to the presence of the target, particularly when cues were invalid. They were also impaired, relative to controls, on visual search tasks. CONCLUSIONS: We have provided experimental evidence for ME/CFS-related difficulties in directing visual attention. These findings support the subjective reports of those with ME/CFS and could represent a potential means to improve diagnosis.

Ickmans K, Clarys P, Nijs J, Meeus M, Aerenhouts D, Zinzen E, Aelbrecht S, Meersdom G, Lambrecht L, Pattyn N.	Pain in Motion Research Group (PIM), Department of Human Physiology, Vrije Universiteit Brussel, Brussels, Belgium	Association between cognitive performance, physical fitness, and physical activity level in women with chronic fatigue syndrome.	J Rehabil Res Dev. 2013;50 (6):795-810. doi: 10.1682/JRRD.2012.08.0156.	Limited scientific evidence suggests that physical activity is directly related to cognitive performance in patients with chronic fatigue syndrome (CFS). To date, no other study has examined the direct relationship between cognitive performance and physical fitness in these patients. This study examined whether cognitive performance and physical fitness are associated in female patients with CFS and investigated the association between cognitive performance and physical activity level (PAL) in the same study sample. We hypothesized that patients who performed better on cognitive tasks would show increased PALs and better performance on physical tests. The study included 31 women with CFS and 13 healthy inactive women. Participants first completed three cognitive tests. Afterward, they undertook a test to determine their maximal handgrip strength, performed a bicycle ergometer test, and were provided with an activity monitor. In patients with CFS, lower peak oxygen uptake and peak heart rate were associated with slower psychomotor speed ($p < 0.05$). Maximal handgrip strength was correlated with working memory performance ($p < 0.05$). Both choice and simple reaction time were lower in patients with CFS relative to healthy controls ($p < 0.05$ and $p < 0.001$, respectively). In conclusion, physical fitness, but not PAL, is associated with cognitive performance in female patients with CFS.
Ickmans K, Meeus M, De Kooning M, Lambrecht L, Nijs J.	Pain in Motion Research Group, Department of Human Physiology and Physiotherapy, Faculty of Physical Education & Physiotherapy, Vrije Universiteit Brussel, Brussel, Belgium; Pain in Motion Research Group, Division of Musculoskeletal Physiotherapy, Department of Health Care Sciences, Artesis University College Antwerp, Antwerp, Belgium; Pain in	Recovery of upper limb muscle function in chronic fatigue syndrome with and without fibromyalgia.	Eur J Clin Invest. 2013 Nov 11. doi: 10.1111/eci.12201. [Epub ahead of print]	BACKGROUND: Chronic fatigue syndrome (CFS) patients frequently complain of muscle fatigue and abnormally slow recovery, especially of the upper limb muscles during and after activities of daily living. Furthermore, disease heterogeneity has not yet been studied in relation to recovery of muscle function in CFS. Here, we examine recovery of upper limb muscle function from a fatiguing exercise in CFS patients with (CFS+FM) and without (CFS-only) comorbid fibromyalgia and compare their results with a matched inactive control group. DESIGN: In this case-control study, 18 CFS-only patients, 30 CFS+FM patients and 30 healthy inactive controls performed a fatiguing upper limb exercise test with subsequent recovery measures. RESULTS: There was no significant difference among the three groups for maximal handgrip strength of the non-dominant hand. A significant worse recovery of upper limb muscle function was found in the CFS+FM, but not in de CFS-only group compared with the controls ($P < 0{\cdot}05$). CONCLUSIONS: This study reveals, for the first time, delayed recovery of upper limb muscle function in CFS+FM, but not in CFS-only patients. The results underline that CFS is a heterogeneous disorder suggesting that reducing the heterogeneity of the disorder in future research is important to make progress towards a better understanding and uncovering of mechanisms regarding the nature of divers impairments in these patients.

Ickmans K, Meeus M, De Kooning M, Lambrecht L, Pattyn N, Nijs J.	K. Ickmans, PT, MSc, Pain in Motion Research Group, Department of Human Physiology and Physiotherapy, Faculty of Physical Education and Physiotherapy, Vrije Universiteit Brussel, Brussels, Belgium; Pain in Motion Research Group, Division of Musculoskeletal Physiotherapy, Department of Health Care Sciences, Artesis University College, Antwerp, Belgium; and Pain in Motion Research Group, Department of Physical Medicine and Physiotherapy, University Hospital Brussels, Brussels, Belgium.	Can Recovery of Peripheral Muscle Function Predict Cognitive Task Performance in Chronic Fatigue Syndrome With and Without Fibromyalgia?	Phys Ther. 2013 Dec 20. [Epub ahead of print]	BACKGROUND: Both good physical and cognitive functioning have a positive influence on the execution of activities of daily living. Patients with chronic fatigue syndrome (CFS) as well as patients with fibromyalgia (FM) have marked cognitive deficits. Furthermore, a good physical and functional health status may have a positive impact on a variety of cognitive skills. A link that has already been observed in young and old healthy individuals, but in patients with CFS evidence is limited. OBJECTIVE: To examine whether recovery of upper limb muscle function could be a significant predictor of cognitive performance in patients with CFS and CFS with comorbid FM. Furthermore, this study determined whether cognitive performance is different in CFS patients with and without comorbid FM. DESIGN: A case-control design. METHODS: Eighteen patients with CFS-only, 30 patients with CFS+FM, and 30 healthy inactive controls were studied. Participants first completed three performance-based cognitive tests designed to assess selective and sustained attention, cognitive inhibition, and working memory capacity. Seven days later, they performed a fatiguing upper limb exercise test with subsequent recovery measures. RESULTS: Recovery of upper limb muscle function was found to be a significant predictor of cognitive performance in patients with CFS. Patients with CFS+FM, but not patients with CFS-only showed significantly decreased cognitive performance compared with the controls. LIMITATIONS: The cross-sectional nature of this study does not allow for inferences of causation. CONCLUSIONS: The results suggest that a better physical health status could predict better mental health in patients with CFS. Furthermore, they underline disease heterogeneity, suggesting that reducing this in future research is important to better understand and uncover mechanisms regarding the nature of diverse impairments in these patients.
Ickmans K, Meeus M, Kos D, Clarys P, Meersdom G, Lambrecht L,	Pain in Motion Research Group (PIM), Department of Human Physiology, Faculty of	Cognitive performance is of clinical importance, but is unrelated to	Clin Rheumatol. 2013 Oct; 32(10):1475-85. doi: 10.1007/s10067-013-2308-1. Epub 2013 Jun 5.	In various chronic pain populations, decreased cognitive performance is known to be related to pain severity. Yet, this relationship has not been investigated in patients with chronic fatigue syndrome (CFS). This study investigated the relationship between cognitive performance and (1) pain severity, (2) level of fatigue, and (3) self-reported

Pattyn N, Nijs J.	Physical Education and Physiotherapy, Vrije Universiteit Brussel, Building L, Pleinlaan 2, 1050, Brussels, Belgium.	pain severity in women with chronic fatigue syndrome.		symptoms and health status in women with CFS. Examining the latter relationships is important for clinical practice, since people with CFS are often suspected to exaggerate their symptoms. A sample of 29 female CFS patients and 17 healthy controls aged 18 to 45 years filled out three questionnaires (Medical Outcomes Study 36-Item Short-Form Health Survey, Checklist Individual Strength (CIS), and CFS Symptom List) and performed three performance-based cognitive tests (psychomotor vigilance task, Stroop task, and operation span task), respectively. In both groups, pain severity was not associated with cognitive performance. In CFS patients, the level of fatigue measured with the CFS Symptom List, but not with the CIS, was significantly correlated with sustained attention. Self-reported mental health was negatively correlated with all investigated cognitive domains in the CFS group. These results provide evidence for the clinical importance of objectively measured cognitive problems in female CFS patients. Furthermore, a state-like measure (CFS Symptom List) appears to be superior over a trait-like measure (CIS) in representing cognitive fatigue in people with CFS. Finally, the lack of a significant relationship between cognitive performance and self-reported pain severity suggests that pain in CFS might be unique.
Ishii A, Tanaka M, Iwamae M, Kim C, Yamano E, Watanabe Y.	Department of Physiology, Osaka City University Graduate School of Medicine, 1-4-3 Asahimachi, Abeno-ku, Osaka, 545-8585, Japan. a.ishii@med.osaka-cu.ac.jp	Fatigue sensation induced by the sounds associated with mental fatigue and its related neural activities: revealed by magnetoencephalography.	Behav Brain Funct. 2013 Jun 13;9:24. doi: 10.1186/1744-9081-9-24.	BACKGROUND: It has been proposed that an inappropriately conditioned fatigue sensation could be one cause of chronic fatigue. Although classical conditioning of the fatigue sensation has been reported in rats, there have been no reports in humans. Our aim was to examine whether classical conditioning of the mental fatigue sensation can take place in humans and to clarify the neural mechanisms of fatigue sensation using magnetoencephalography (MEG). METHODS: Ten and 9 healthy volunteers participated in a conditioning and a control experiment, respectively. In the conditioning experiment, we used metronome sounds as conditioned stimuli and two-back task trials as unconditioned stimuli to cause fatigue sensation. Participants underwent MEG measurement while listening to the metronome sounds for 6 min. Thereafter, fatigue-inducing mental task trials (two-back task trials), which are demanding working-memory task trials, were performed for 60 min; metronome sounds were started 30 min after the start of the task trials (conditioning session). The next day, neural activities while listening to the metronome for 6 min were measured. Levels of fatigue sensation were also assessed using a visual analogue scale. In the control experiment, participants listened to the metronome on the first and second days, but they did not perform conditioning session. MEG was not recorded in the control experiment. RESULTS: The level of fatigue sensation caused by listening to the metronome on the second day was significantly higher relative to that on the first day only when participants performed the conditioning session on the first day. Equivalent current dipoles (ECDs) in the insular cortex, with mean latencies of approximately 190 ms, were observed in six of eight participants after the conditioning session, although ECDs were not identified in any participant before the

				conditioning session. CONCLUSIONS: We demonstrated that the metronome sounds can cause mental fatigue sensation as a result of repeated pairings of the sounds with mental fatigue and that the insular cortex is involved in the neural substrates of this phenomenon.
Iwata K, Shimada T, Kawabata H.	Division of Infectious Diseases, Kobe University Hospital.	A case of lyme disease requiring over 1 year to diagnose at an infectious-disease clinic. [Article in Japanese]	Kansenshogaku Zasshi. 2013 Jan; 87(1):44-8.	A 42-year-old woman presenting with years of fever and vague symptoms could not be satisfactorily diagnosed in physical examination or conventional workups. She was presumptively diagnosed with chronic fatigue syndrome and treated symptomatically. Fourteen months after the initial visit, she developed left facial palsy. Lyme disease serology was positive. Four weeks of oral amoxicillin ameliorated symptoms. Only 5 to 15 cases of Lyme disease are reported annually in Japan, mostly from the northeastern-most island of Hokkaido. It may occur anywhere in Japan, however; probably is underdiagnosed. Lyme disease may cause fevers of unknown origin. Astute clinical suspicion and appropriate workups are thus needed to diagnose this infection.
Jarjour IT.	Department of Pediatrics, Clinic for Autonomic Dysfunction, Texas Children's Hospital, Houston, TX 77030-2399, USA. jarjour@bcm.edu	Postural tachycardia syndrome in children and adolescents.	Semin Pediatr Neurol. 2013 Mar; 20(1):18-26. doi: 10.1016/j.spen.2013.01.001.	Postural tachycardia syndrome is a chronic condition with frequent symptoms of orthostatic intolerance or sympathetic activation and excessive tachycardia while standing, without significant hypotension. Orthostatic symptoms include dizziness, lightheadedness, blurring of vision, near faints, weakness in legs, poor concentration, nausea, and headaches. Somatic symptoms include fatigue, sleep disorder, widespread pain, abdominal pain, and menstrual irregularities. Psychological problems may overlap with physical complaints. This review discusses the normal physiology of orthostatic change, different pathophysiological mechanisms of postural tachycardia syndrome, including hypovolemia, venous pooling, autonomic neuropathy, and hyperadrenergic responses. In addition, an outline for management tailored to the patient's clinical syndrome is presented, along with concluding thoughts on future research needs.
Jason LA, Brown A, Evans M, Sunnquist M, Newton JL.	DePaul University.	Contrasting Chronic Fatigue Syndrome versus Myalgic Encephalomyelitis/Chronic Fatigue Syndrome.	Fatigue. 2013 Jun 1;1(3):168-183.	BACKGROUND: Much debate is transpiring regarding whether chronic fatigue syndrome (CFS) and myalgic encephalomyelitis (ME) are different illnesses. Several prior studies that compared the Fukuda et al. CFS criteria to the Canadian ME/CFS criteria found that the Canadian criteria identified patients with more functional impairments and greater physical, mental, and cognitive problems than those who met Fukuda et al. criteria.[3,4] These samples were located in the Chicago metropolitan area, so the results could not be generalized to other locations. In addition, past studies used a symptom questionnaire that was not specifically developed to tap the Canadian criteria. PURPOSE: The present comparative study of CFS and ME/CFS criteria was intended to correct the methodological problems of prior studies. METHODS: This article used data from three distinct samples to compare patients who met criteria for the ME/CFS Canadian clinical case definition [1] to those who met the Fukuda et al. CFS case definition.[2]. RESULTS: Findings indicated that fewer individuals met the Canadian criteria than the Fukuda et al.

				criteria. Those who met the Canadian criteria evidenced more severe symptoms and physical functioning impairment. CONCLUSIONS: Future research should continue to compare existing case definitions and determine which criteria best select for this illness.
Jason LA, Brown M, Brown A, Evans M, Flores S, Grant-Holler E, Sunnquist M.	Center for Community Research, DePaul University, Chicago, IL.	Center for Community Research, DePaul University, Chicago, IL.	Fatigue. 2013 Jan 14; 1(1-2):27-42. Epub 2012 Aug 8.	OBJECTIVES: Treatment approaches for patients with Myalgic Encephalomyelitis/chronic fatigue syndrome (ME/CFS) have been controversial. This paper provides the theoretical and conceptual background for the Energy Envelope Theory to assist patients with ME/CFS and reviews evidence of its treatment efficacy. METHODS: Over a 15-year period, efforts were directed to develop a non-pharmacologic intervention that endeavored to help patients with ME/CFS self-monitor and self-regulate energy expenditures and learn to pace activities and stay within their energy envelope. CONCLUSIONS: Studies show that the energy envelope approach, which involves rehabilitation methods, helps patients with ME/CFS pace activities and manage symptoms and can significantly improve their quality of life.
Jason LA, Brown MM.	Center for Community Research, DePaul University, Chicago, IL 60614, USA. ljason@depaul.edu	Sub-typing daily fatigue progression in chronic fatigue syndrome.	J Ment Health. 2013 Feb; 22(1):4-11. doi: 10.3109/09638237.2012.670879. Epub 2012 May 1.	BACKGROUND: Activity logs involve patients writing down their activities and symptoms over 1 or more days. Aims This study sought to classify daily fatigue patterns among patients with chronic fatigue syndrome (CFS) using activity logs. METHOD: Fatigue intensity was self-reported every 30 min in a sample of 90 patients with CFS over 1 day. A cluster analysis using fatigue intensity, variability and slope was conducted. RESULTS: Three clusters emerged involving patients with different trajectories. One group evidenced high fatigue intensity, low variability, and fatigue intensity stayed the same over time. A second group had moderate fatigue intensity, high variability, and fatigue intensity decreased over time. A third group had moderate fatigue intensity, high variability, but fatigue intensity increased over time. The three clusters of patients differed on measures of actigraphy, pain and immune functioning. CONCLUSIONS: Activity logs can provide investigators and clinicians with valuable sources of data for understanding patterns of fatigue and activity among patients with CFS.
Jenewein J.	Back pain and somatisation. [Article in German] Abstract available in German from the publisher	Klinik für Psychiatrie und Psychotherapie, Universitätsspital Zürich.	Ther Umsch. 2013 Sep; 70(9):537-41. doi: 10.1024/0040-5930/a000443.	Back pain is frequently found in patients with somatoform disorders, particularly in somatisation and somatoform pain disorders. About 10 % to 20 % of patients suffering from back pain can be diagnosed with somatoform pain disorders. Additionally, up to 50 % of back pain patients suffer from other psychiatric disorders like major depression or anxiety disorders. Diagnostically, somatoform pain disorders must be distinguished from other chronic widespread pain disorders like fibromaylgia and chronic fatigue syndrome. Treatment usually consists of psychological/behavioral interventions in combination with relaxation techniques, physical activation and antidepressants
Jhamb M, Liang K, Yabes J, Steel JL, Dew MA, Shah N,	Renal-Electrolyte Division, Department of Medicine, University	Prevalence and Correlates of Fatigue in Chronic Kidney	Am J Nephrol. 2013 Dec 10; 38 (6):489-495. [Epub ahead of print]	Background: Fatigue is an important symptom to patients with advanced chronic kidney disease (CKD). The aim of this study is to examine the prevalence and severity of fatigue among non-dialysis-dependent CKD and end-stage renal disease (ESRD)

Unruh M.	of Pittsburgh, Pittsburgh, Pa., USA.	Disease and End-Stage Renal Disease: Are Sleep Disorders a Key to Understanding Fatigue?		patients, to examine the association of fatigue with subjective and objective sleep quality, and to identify other modifiable factors associated with fatigue. Methods: A cross-sectional survey of 87 non-dialysis-dependent CKD (eGFR ≤45 ml/min/1.73 m(2)) and 86 ESRD patients was done using the Functional Assessment of Chronic Illness Therapy - Fatigue (FACIT-F) and 36-Item Short-Form (SF-36) vitality scale. Higher FACIT-F score denoted less fatigue. Objective sleep was assessed using in-home polysomnography. Predictors of fatigue were determined using a linear regression model. Results: The mean FACIT-F score among all participants was 34.5 ± 11.0. Mean scores were similar among CKD and ESRD groups (34.25 ± 11.28 vs. 34.73 ± 10.86; p = 0.73). On univariate analyses, patients with higher levels of fatigue were more likely to have cardiovascular disease, benzodiazepine use, depressive symptoms, and slightly lower hemoglobin and serum albumin levels. There was no significant association between severity of sleep apnea and level of fatigue (Apnea Hypopnea Index 20.1 ± 27.6 vs. 20.3 ± 22.0; p = 0.69). Presence of cardiovascular disease, low serum albumin, depressive symptoms, poor subjective sleep quality, excessive daytime sleepiness and restless legs syndrome were independently associated with greater fatigue in multivariable regression models. The FACIT-F score correlated closely with the SF-36 vitality score (r = 0.81, p < 0.0001). Conclusions: Patients with advanced CKD and ESRD experience profound fatigue. Depressive symptoms, restless legs syndrome, excessive daytime sleepiness, and low albumin levels may provide targets for interventions to improve fatigue in patients with advanced CKD.
Johnston S, Brenu EW, Staines D, Marshall-Gradisnik S.	Griffith Health Institute, School of Medical Sciences, National Centre for Neuroimmunology and Emerging Diseases, Griffith University, Parklands, QLD, Australia.	The prevalence of chronic fatigue syndrome/ myalgic encephalomyelitis: a meta-analysis.	Clin Epidemiol. 2013; 5:105-10. doi: 10.2147/CLEP.S39876. Epub 2013 Mar 26.	PURPOSE: To perform a meta-analysis to examine variability among prevalence estimates for CFS/ME, according to the method of assessment used. METHODS: Databases were systematically searched for studies on CFS/ME prevalence in adults that applied the 1994 Centers for Disease Control (CDC) case definition.1 Estimates were categorized into two methods of assessment: self-reporting of symptoms versus clinical assessment of symptoms. Meta-analysis was performed to pool prevalences by assessment using random effects modeling. This was stratified by sample setting (community or primary care) and heterogeneity was examined using the I (2) statistic. RESULTS: Of 216 records found, 14 studies were considered suitable for inclusion. The pooled prevalence for self-reporting assessment was 3.28% (95% CI: 2.24-4.33) and 0.76% (95% CI: 0.23-1.29) for clinical assessment. High variability was observed among self-reported estimates, while clinically assessed estimates showed greater consistency. CONCLUSION: The observed heterogeneity in CFS/ME prevalence may be due to differences in method of assessment. Stakeholders should be cautious of prevalence determined by the self-reporting of symptoms alone. The 1994 CDC case definition appeared to be the most reliable clinical assessment tool available at the time of these studies. Improving clinical case definitions and their adoption internationally will enable better comparisons of findings and inform health systems

				about the true burden of CFS/ME.
Johnston S, Brenu EW, Staines DR, Marshall-Gradisnik S.	Griffith Health Institute, School of Medical Sciences, National Centre for Neuroimmunology and Emerging Diseases, Griffith University, Parklands, QLD, Australia. samantha.johnston3@griffithuni.edu.au	The adoption of chronic fatigue syndrome/myalgic encephalomyelitis case definitions to assess prevalence: a systematic review.	Ann Epidemiol. 2013 Jun; 23(6):371-6. doi: 10.1016/j.annepidem.2013.04.003.	PURPOSE: Prevalence estimates have been based on several case definitions of chronic fatigue syndrome (CFS). The purpose of this work is to provide a rigorous overview of their application in prevalence research. METHODS: A systematic review of primary studies reporting the prevalence of CFS since 1990 was conducted. Studies were summarized according to study design, prevalence estimates, and case definition used to ascertain cases. RESULTS: Thirty-one studies were retrieved, and eight different case definitions were found. Early estimates of CFS prevalence were based on the 1988 Centers for Disease Control and Prevention, Australian, and Oxford. The 1994 Centers for Disease Control and Prevention, however, has been adopted internationally, as a general standard. Only one study has reported prevalence according to the more recent, Canadian Consensus Criteria. Additional estimates were also found according to definitions by Ho-Yen, the 2005 Centers for Disease Control and Prevention empirical definition, and an epidemiological case definition. CONCLUSIONS: Advances in clinical case definitions during the past 10 years such as the Canadian Consensus Criteria have received little attention in prevalence research. Future assessments of prevalence should consider adopting more recent developments, such as the newly available International Consensus Criteria. This move could improve the surveillance of more specific cases found within CFS.
Karabulut GS, Beşer OF, Erginöz E, Kutlu T, Cokuğraş FÇ, Erkan T.	Department of Pediatrics, Cerrahpaşa Medical Faculty, İstanbul University, İstanbul, Turkey.	The Incidence of Irritable Bowel Syndrome in Children Using the Rome III Criteria and the Effect of Trimebutine Treatment.	J Neurogastroenterol Motil. 2013 Jan;19(1):90-3. doi: 10.5056/jnm.2013.19.1.90. Epub 2013 Jan 8.	BACKGROUND/AIMS: Irritable bowel syndrome (IBS) is one of the most common functional gastrointestinal disorders and when compared to the vast knowledge pertaining to adults with IBS, very little is known about IBS in children and adolescents. We aimed to explore the prevalence of IBS, identify symptoms and contributing factors and also to examine the efficacy of trimebutine maleate in children and adolescents. METHODS: The study involved 345 children and adolescents (4-18 years) and parents were requested to fill in a questionnaire, Rome III criteria was used to diagnose IBS. To exclude organic disease, all patients underwent medical investigations. Half of the randomly selected IBS patients were treated with trimebutine maleate while the rest of IBS patients were not. The IBS patients were reevaluated at the end of 3 weeks. RESULTS: The prevalence of IBS according to Rome III criteria in children and adolescents was 22.6% and IBS with constipation was the predominant subtype. Back pain (OR, 6.68), headache (OR, 4.72) and chronic fatigue (OR, 3.74) were significantly higher in IBS group. The prevalence of IBS in both parents and depression in mothers was greater for the patient group than the healthy controls ($P < 0.0001$). The prevalence of functional dyspepsia in IBS group was 80.8% and was significantly higher than control group. Clinical recovery was seen in 94.9% of the trimebutine maleate group versus spontaneous recovery in 20.5% of the non-medicated group. The difference was significant ($P < 0.0001$). CONCLUSIONS: IBS is a common disorder in children and adolescents. IBS is closely associated with somatic

				and familial factors. Trimebutine maleate is effective for pediatric IBS patients.
Kartha GK, Kerr H, Shoskes DA.	Glickman Urological and Kidney Institute, Cleveland Clinic, Cleveland, Ohio, USA.	Clinical phenotyping of urologic pain patients.	Curr Opin Urol. 2013 Nov; 23 (6):560-4. doi: 10.1097/MOU.0b013e3283652a9d.	PURPOSE OF REVIEW: Urologic pain conditions such as chronic prostatitis/chronic pelvic pain syndrome, interstitial cystitis/bladder pain syndrome and chronic orchialgia are common, yet diagnosis and treatment are challenging. Current therapies often fail to show efficacy in randomized controlled studies. Lack of efficacy may be due to multifactorial causes and heterogeneity of patient presentation. Efforts have been made to map different phenotypes in patients with urologic pain conditions to tailor more effective therapies. This review will look at current literature on phenotype classification in urologic pain patients and their use in providing effective therapy. RECENT FINDINGS: There has been validation of the 'UPOINT' system (urinary symptoms, psychosocial dysfunction, organ specific findings, infection, neurologic/systemic and tenderness of muscle) to better categorize male chronic prostatitis/chronic pelvic pain syndrome and interstitial cystitis/bladder pain syndrome. Refinement of domain systems and recent cluster analysis has suggested possible central processes involved in urologic pain conditions similar to systemic pain syndromes such as fibromyalgia, chronic fatigue and irritable bowel syndrome. SUMMARY: Domain characterization of urologic pain conditions via phenotype mapping can be used to better understand causes of chronic pain and hopefully provide more effective, targeted and multimodal therapy.
Katz BZ, Jason LA.	Division of Infectious Diseases, Ann and Robert H. Lurie Children's Hospital of Chicago, Northwestern University Feinberg School of Medicine, Chicago, Illinois 60611, USA. bkatz@northwestern.edu	Chronic fatigue syndrome following infections in adolescents.	Curr Opin Pediatr. 2013 Feb; 25(1):95-102. doi: 10.1097/MOP.0b013e32835c1108.	PURPOSE OF REVIEW: To review the recent epidemiology, pathophysiology, and treatment of postinfectious chronic fatigue syndrome (CFS) in adolescents. RECENT FINDINGS: Thirteen percent of adolescents (mainly women) met the criteria for CFS 6 months following infectious mononucleosis; the figure was 7% at 12 months and 4% at 24 months. Peak work capacity, activity level, orthostatic intolerance, salivary cortisol, and natural killer cell number and function were similar between adolescents with CFS following infectious mononucleosis and recovered controls. Autonomic system, oxygen consumption, peak oxygen pulse, psychological and cytokine network differences were documented between those who recovered and those who did not. SUMMARY: The prognosis of CFS is better in adolescents than in adults. Activity level, exercise tolerance, and orthostatic testing could not distinguish patients with CFS from adolescents who have recovered from infectious mononucleosis (controls), while certain cytokine network analyses, life stress factors, and autonomic symptoms could.
Kawabata M, Ueno T, Tomita J, Kawatani J, Tomoda A, Kume S, Kume K.	[No address quoted]	Temporal organization of rest defined by actigraphy data in healthy and childhood chronic fatigue syndrome	BMC Psychiatry. 2013 Nov 4; 13(1):281. [Epub ahead of print]	BACKGROUND: Accumulating evidence has shown a universality in the temporal organization of activity and rest among animals ranging from mammals to insects. Previous reports in both humans and mice showed that rest bout durations followed long-tailed (i.e., power-law) distributions, whereas activity bouts followed exponential distributions. We confirmed similar results in the fruit fly, Drosophila melanogaster. Conversely, another report showed that the awakening bout durations, which were defined by polysomnography in bed, followed power-law distributions, while sleeping

		children.		periods, which may correspond to rest, followed exponential distributions. This apparent discrepancy has been left to be resolved. METHODS: Actigraphy data from healthy and disordered children were analyzed separately for two periods: time out of bed (UP period) and time in bed (DOWN period). RESULTS: When data over a period of 24 h were analyzed as a whole, rest bouts showed a power law distribution as previously reported. However, when UP and DOWN period data were analyzed separately, neither showed power law properties. Using a newly developed strict method, only 30% of individuals satisfied the power law criteria, even when the 24 h data were analyzed. The human results were in contrast to the Drosophila results, which revealed clear power-law distributions for both day time and night time rest through the use of a strict method. In addition, we analyzed the actigraphy data from patients with childhood type chronic fatigue syndrome (CCFS), and found that they showed differences from healthy controls when their UP and DOWN data were analyzed separately. CONCLUSIONS: These results suggested that the DOWN sleep, the bout distribution of which showed exponential properties, contributes to the production of long-tail distributions in human rest periods. We propose that separate analysis of UP and DOWN period data is important for understanding the temporal organization of activity.
Keijmel SP, Delsing CE, Sprong T, Bleijenberg G, van der Meer JW, Knoop H, Bleeker-Rovers CP.	Radboud Expertise Centre for Q fever, Department of Internal Medicine, Division of Infectious Diseases, Radboud University Nijmegen Medical Centre, P.O. Box 9101, 6500 HB, Nijmegen, The Netherlands. s.keijmel@aig.umcn.nl	The Qure study: Q fever fatigue syndrome--response to treatment; a randomized placebo-controlled trial.	BMC Infect Dis. 2013 Mar 27; 13:157. doi: 10.1186/1471-2334-13-157.	BACKGROUND: Q fever is a zoonosis that is present in many countries. Q fever fatigue syndrome (QFS) is one of the most frequent sequelae after an acute Q fever infection. QFS is characterized by persistent fatigue following an acute Q fever infection, leading to substantial morbidity and a high socio-economic burden. The occurrence of QFS is well-documented, and has been described in many countries over the past decades. However, a treatment with proven efficacy is not available. Only a few uncontrolled studies have tested the efficacy of treatment with antibiotics on QFS. These studies suggest a positive effect of long-term treatment with a tetracycline on performance state; however, no randomized controlled trials have been performed. Cognitive behavioral therapy (CBT) has been proven to be an effective treatment modality for chronic fatigue in other diseases, but has not yet been tested in QFS. Therefore, we designed a trial to assess the efficacy of long-term treatment with the tetracycline doxycycline and CBT in patients with QFS. METHODS/DESIGN: A randomized placebo-controlled trial will be conducted. One-hundred-eighty adult patients diagnosed with QFS will be recruited and randomized between one of three groups: CBT, long-term doxycycline or placebo. First, participants will be randomized between CBT and medication (ratio 1:2). A second double-blinded randomization between doxycycline and placebo (ratio 1:1) will be performed in the medication condition. Each group will be treated for six months. Outcome measures will be assessed at baseline and post intervention. The primary outcome measure is fatigue severity. Secondary outcome measures are functional impairment, level of psychological distress, and Coxiella burnetii PCR and serology. DISCUSSION: The Qure study is the first randomized

				placebo-controlled trial, which evaluates the efficacy of long-term doxycycline and of cognitive behavioral therapy in patients with QFS. The results of this study will provide knowledge about evidence-based treatment options for adult patients with QFS. TRIAL REGISTRATION: ClinicalTrials.gov: NCT01318356, and Netherlands Trial Register: NTR2797.
Keller J, Chen YK, Lin HC.	School of Public Health, Taipei Medical University, Taipei, Taiwan.	Association of bladder pain syndrome/interstitial cystitis with urinary calculus: a nationwide population-based study.	Int Urogynecol J. 2013 Apr; 24(4):565-71. doi: 10.1007/s00192-012-1917-6. Epub 2012 Aug 16.	INTRODUCTION AND HYPOTHESIS: Although one prior study reported an association between bladder pain syndrome/interstitial cystitis (BPS/IC) and urinary calculi (UC), no population-based study to date has been conducted to explore this relationship. Therefore, using a population-based data set in Taiwan, this study set out to investigate the association between BPS/IC and a prior diagnosis of UC. METHODS: This study included 9,269 cases who had received their first-time diagnosis of BPS/IC between 2006 and 2007 and 46,345 randomly selected controls. We used conditional logistic regression analysis to compute the odds ratio (OR) and its corresponding 95 % confidence interval (CI) for having been previously diagnosed with UC between cases and controls. RESULTS: There was a significant difference in the prevalence of prior UC between cases and controls (8.1 vs 4.3 %, $p < 0.001$). Conditional logistic regression analysis revealed that cases were more likely to have been previously diagnosed with UC than controls (OR = 1.70; 95 % CI = 1.56-1.84) after adjusting for chronic pelvic pain, irritable bowel syndrome, fibromyalgia, chronic fatigue syndrome, depression, panic disorder, migraine, sicca syndrome, allergy, endometriosis, and asthma. BPS/IC was found to be significantly associated with prior UC regardless of stone location; the adjusted ORs of kidney calculus, ureter calculus, bladder calculus, and unspecified calculus when compared to controls were 1.58 (95 % CI = 1.38-1.81), 1.73 (95 % CI = 1.45-2.05), 3.80 (95 % CI = 2.18-6.62), and 1.83 (95 % CI = 1.59-2.11), respectively. CONCLUSIONS: This work generates the hypothesis that UC may be associated with BPS/IC.
Keller JJ, Liu SP, Lin HC.	School of Public Health, Taipei Medical University, Taipei, Taiwan.	A case-control study on the association between rheumatoid arthritis and bladder pain syndrome/interstitial cystitis.	Neurourol Urodyn. 2013 Sep; 32(7):980-5. doi: 10.1002/nau.22348. Epub 2012 Nov 5.	AIM: While bladder pain syndrome/interstitial cystitis (BPS/IC) has been suggested by a number of studies to have autoimmune character, no population-based study to date has been conducted investigating its association with rheumatoid arthritis (RA). This study aimed to examine the association between IC/BPS and having previously been diagnosed with RA. METHODS: We conducted this study by using administrative claims data sourced from the Taiwan National Health Insurance Database. Our study included 9,269 cases with BPS/IC and 46,345 randomly selected controls. Conditional logistic regression was performed to calculate the odds ratio (OR) for the association between previously diagnosed RA and IC/BPS. RESULTS: RA was found among 202 (2.2%) cases and 504 (1.12%) controls. Conditional logistic regression analysis suggested that when compared with controls, the OR for prior RA among cases was 1.66 (95% CI=1.47-1.87, P<0.001) after adjusting for diabetes, hypertension, coronary heart disease, obesity, hyperlipidemia, chronic pelvic pain, irritable bowel syndrome, fibromyalgia, chronic fatigue syndrome, depression, panic disorder, migraine, sicca

				syndrome, allergy, endometriosis, asthma, overactive bladder, tobacco use disorder, and alcohol abuse. Additionally, BPS/IC was consistently and significantly associated with a previous diagnosis of RA regardless of prescription drug use; the OR for prior RA among groups prescribed ≤1 type of disease-modifying antirheumatic drug (DMARD), two types of DMARDs, and ≥3 types of DMARDs or TNF-alpha inhibitor when compared to controls were 1.49 (95% CI=1.28-1.72), 1.91 (95% CI=1.38-2.68), and 2.36 (95% CI=1.77-3.17), respectively. CONCLUSIONS: There is an association between RA and BPS/IC after adjusting for socio-demographic characteristics and medical co-morbidities.
Kempke S, Luyten P, Claes S, Goossens L, Bekaert P, Van Wambeke P, Van Houdenhove B.	Department of Psychology, University of Leuven, Belgium. stefan.kempke@ppw.kuleuven.be	Self-critical perfectionism and its relationship to fatigue and pain in the daily flow of life in patients with chronic fatigue syndrome.	Psychol Med. 2013 May; 43(5):995-1002. doi: 10.1017/S0033291712001936. Epub 2012 Aug 30.	BACKGROUND: Research suggests that the personality factor of self-critical or maladaptive perfectionism may be implicated in chronic fatigue syndrome (CFS). However, it is not clear whether self-critical perfectionism (SCP) also predicts daily symptoms in CFS. Method In the present study we investigated whether SCP predicted fatigue and pain over a 14-day period in a sample of 90 CFS patients using a diary method approach. After completing the Depressive Experiences Questionnaire (DEQ) as a measure of SCP, patients were asked each day for 14 days to complete Visual Analogue Scales (VAS) of fatigue, pain and severity of depression. Data were analysed using multilevel analysis. RESULTS: The results from unconditional models revealed considerable fluctuations in fatigue over the 14 days, suggesting strong temporal variability in fatigue. By contrast, pain was relatively stable over time but showed significant inter-individual differences. Congruent with expectations, fixed-effect models showed that SCP was prospectively associated with higher daily fatigue and pain levels over the 14-day period, even after controlling for levels of depression. CONCLUSIONS: This is the first study to show that SCP predicts both fatigue and pain symptoms in CFS in the daily course of life. Hence, therapeutic interventions aimed at targeting SCP should be considered in the treatment of CFS patients with such features.
Kempke S, Luyten P, Claes S, Van Wambeke P, Bekaert P, Goossens L, Van Houdenhove B.	Department of Psychology, University of Leuven, Leuven, Belgium. stefan.kempke@ppw.kuleuven.be	The prevalence and impact of early childhood trauma in Chronic Fatigue Syndrome.	J Psychiatr Res. 2013 May; 47(5):664-9. doi: 10.1016/j.jpsychires.2013.01.021. Epub 2013 Feb 16.	: Although some studies have found high rates of early childhood trauma in Chronic Fatigue Syndrome (CFS), the role of early trauma in this condition remains controversial. METHODS: This study examined the prevalence of early childhood trauma and its impact on daily fatigue and pain levels over a 14-day period in a sample of 90 carefully screened CFS patients using a diary method approach. Data were analyzed using multilevel analysis. RESULTS: More than half of the patients (54.4%) had experienced at least one type of early trauma, with the majority of these patients reporting multiple traumas. Prevalence rates were particularly high for emotional trauma (i.e., emotional abuse and/or emotional neglect) (46.7%). Moreover, total trauma scores and emotional abuse significantly predicted higher levels of daily fatigue and pain over the 14-day period, even when controlling for demographic features and depressed mood. CONCLUSIONS: This is the first study to demonstrate that early childhood trauma predicts increasing levels of core symptoms

				of CFS in the daily flow of life. Moreover, findings of this study suggest that emotional trauma may be particularly important in CFS.
Kempke S, Van Den Eede F, Schotte C, Claes S, Van Wambeke P, Van Houdenhove B, Luyten P.	Department of Psychology, University of Leuven, Tiensestraat 102, Leuven, Belgium. Stefan.Kempke@ppw.kuleuven.be	Prevalence of DSM-IV personality disorders in patients with chronic fatigue syndrome: a controlled study.	Int J Behav Med. 2013 Jun; 20(2):219-28. doi: 10.1007/s12529-012-9273-y.	BACKGROUND: It is not yet clear whether chronic fatigue syndrome (CFS) is associated with elevated levels of personality disorders. PURPOSE: This study aims to determine the prevalence of DSM-IV axis II personality disorders among patients with CFS. METHODS: We examined the prevalence of personality disorders in a sample of 92 female CFS patients and in two well-matched control groups, i.e., normal community individuals (N=92) and psychiatric patients (N=92). Participants completed the assessment of DSM-IV personality disorders questionnaire (ADP-IV), which yields a categorical and dimensional evaluation of personality disorder features. RESULTS: The prevalence of personality disorders in CFS patients (16.3 %) was significantly lower than in psychiatric patients (58.7 %) and was similar to that in the community sample (16.3 %). Similar results were found for dimensional and pseudodimensional scores, except for the Depressive (DE) and Obsessive-Compulsive Personality Disorder (O-C) subscales. Patients with CFS had significantly higher levels of DE features compared to normal controls and similar dimensional scores on the O-C scale compared to psychiatric controls. CONCLUSIONS: Although the CFS sample was characterized by depressive and obsessive-compulsive personality features, this study provides no evidence for the assumption that these patients generally show a higher prevalence of axis II pathology. Given the conflicting findings in this area, future studies using multiple measures to assess personality disorders in CFS are needed to substantiate these findings.
Kim EH, Pascua PN, Song MS, Baek YH, Kwon HI, Park SJ, Lim GJ, Kim SM, Decano A, Lee KJ, Cho WK, Ma JY, Choi YK.	College of Medicine and Medical Research Institute, Chungbuk National University, 12 Gaeshin-Dong Henugduk-Ku, Cheongju 361-763, Republic of Korea.	Immunomodulaton and attenuation of lethal influenza A virus infection by oral administration with KIOM-C.	Antiviral Res. 2013 Jun; 98(3):386-93. doi: 10.1016/j.antiviral.2013.04.006. Epub 2013 Apr 13.	Herbal medicine is used to treat many conditions such as asthma, eczema, premenstrual syndrome, rheumatoid arthritis, migraine, headaches, menopausal symptoms, chronic fatigue, irritable bowel syndrome, cancer, and viral infections such as influenza. In this study, we investigated the antiviral effect of KIOM-C for the treatment of influenza A virus infection. Our results show that oral administration of KIOM-C conferred a survival benefit to mice infected with the 2009 pandemic H1N1 [A(H1N1)pdm09] virus, and resulted in a 10- to 100-fold attenuation of viral replication in ferrets in a dose-dependent manner. Additionally, oral administration of KIOM-C increased the production of antiviral cytokines, including IFN-γ and TNF-α, and decreased levels of pro-inflammatory cytokines (IL-6) and chemokines (KC, MCP-1) in the Bronchoalveolar lavage fluid (BALF) of A(H1N1)pdm-infected mice. These results indicate that KIOM-C can promote clearance of influenza virus in the respiratory tracts of mice and ferrets by modulating cytokine production in hosts. Taken together, our results suggest that KIOM-C is a potential therapeutic compound mixture for the treatment of influenza virus infection in humans.
Kim JE, Hong KE, Kim HJ, Choi JB, Baek YH, Seo BK,	Department of Medical Research, Korea Institute of Oriental	An open-label study of effects of acupuncture on	Trials. 2013 May 21; 14:147. doi: 10.1186/1745-6215-14-147.	BACKGROUND: Even though chronic fatigue syndrome and idiopathic chronic fatigue are quite common, there are no clearly known causes. Most treatments are therefore symptomatic in nature, and chronic fatigue syndrome and idiopathic chronic fatigue

Lee S, Kang KW, Lee MH, Kim JH, Lee S, Jung SY, Jung HJ, Shin MS, Choi SM.	Medicine, Acupuncture, Moxibustion & Meridian Research Group, 1672 Yuseongdae-ro, Yuseong-gu, Daejeon, South Korea.	chronic fatigue syndrome and idiopathic chronic fatigue: study protocol for a randomized controlled trial.		patients are highly interested in using oriental medicine or complementary and alternative medicine treatment. Acupuncture, one of the major treatments used in oriental medicine, is effective in treating various diseases. This study will attempt to analyze the effectiveness and safety of acupuncture in the treatment of chronic fatigue by comparing the two treatment groups (body acupuncture, Sa-am acupuncture) and the control group (usual care). METHODS/DESIGN: This study consists of a four-center, three-arm, randomized, controlled, and open-label trial. One hundred and fifty participants are randomly divided into treatment groups A and B and a control group. The treatment groups will receive acupuncture treatments either two or three times per week for a total of 10 sessions over a period of 4 weeks. The control group will not receive acupuncture treatments and will continue their usual care during this period. The primary outcome variable is the Fatigue Severity Scale, which will be utilized 5 weeks after randomization. Secondary outcome variables are the Fatigue Severity Scale at 13 weeks, a short form of the Stress Response Inventory, the Beck Depression Inventory, the Numeric Rating Scale, and the EuroQol-5 Dimension at 5 and 13 weeks after randomization. DISCUSSION: This study will provide evidence with high external validity on the effectiveness and safety of acupuncture as a treatment for chronic fatigue syndrome and idiopathic chronic fatigue. TRIAL REGISTRATION: Clinical Research Information Service KCT0000508.

Kingma EM, Rosmalen JG, White PD, Stansfeld SA, Clark C.	University of Groningen, University Medical Center Groningen, Department of Psychiatry, Interdisciplinary Center Psychopathology and Emotion regulation (ICPE), Groningen, The Netherlands.	The prospective association between childhood cognitive ability and somatic symptoms and syndromes in adulthood: the 1958 British birth cohort.	J Epidemiol Community Health. 2013 Dec 1;67 (12):1047-53. doi: 10.1136/jech-2013-202850. Epub 2013 Sep 10.	BACKGROUND: Cognitive ability is negatively associated with functional somatic symptoms (FSS) in childhood. Lower childhood cognitive ability might also predict FSS and functional somatic syndromes in adulthood. However, it is unknown whether this association would be modified by subjective and objective measures of parental academic expectations. METHODS: 14 068 participants from the 1958 British birth cohort, whose cognitive ability was assessed at 11 years. Outcomes were somatic symptoms at 23, 33 and 42 years. Self-reported irritable bowel syndrome (IBS), chronic fatigue syndrome/myalgic encephalomyelitis (CFS/ME) and operationally defined CFS-like illness were measured at 42 years. RESULTS: Lower cognitive ability at age 11 years was associated with somatic symptoms at ages 23, 33 and 42 years. Adjusting for sex, childhood internalising problems, previous somatic symptoms and concurrent psychological symptoms, childhood cognitive ability remained negatively associated with somatic symptoms at age 23 years (β=-0.060, 95% CI -0.081 to -0.039, p<0.01), 33 years (β= -0.031, 95% CI -0.050 to -0.011, p<0.01), but not with somatic symptoms at 42 years. Overall, we found no clear association between lower childhood cognitive ability and CFS/ME, CFS-like illness and IBS. Associations between

				cognitive ability and somatic symptoms at 23 years were moderated by low parental social class, but not by subjective indicators of parental academic expectations. CONCLUSIONS: Lower childhood cognitive ability predicted somatic symptoms, but not CFS/ME, CFS-like illness and IBS in adulthood. While earlier research indicated an important role for high parental academic expectations in the development of early-life FSS, these expectations do not seem relevant for somatic symptoms or functional somatic syndromes in later adulthood.
Kir'iakov VA, Saarkoppel' LM, Krylova IV, Sukhova AV.	[No address quoted]	Chronic fatigue syndrome in patients with vibration disease. [Article in Russian]	Med Tr Prom Ekol. 2013; (2):28-32.	The article presents study results that demonstrate chronic fatigue syndrome in patients with vibration disease. Clinical manifestations of chronic fatigue syndrome are characterized by changes in the emotional-volitional and cognitive areas. Application of nootropic drug cortexin increases the efficiency of rehabilitation in patients with vibration disease with chronic fatigue syndrome.
Knight S, Harvey A, Lubitz L, Rowe K, Reveley C, Veit F, Hennel S, Scheinberg A.	Clinical Sciences, Murdoch Childrens Research Institute, Melbourne, Victoria, Australia; Victorian Paediatric Rehabilitation Service, Monash Children's, Melbourne, Victoria, Australia; Department of Paediatrics, University of Melbourne, Melbourne, Victoria, Australia; Melbourne School of Psychological Sciences, University of Melbourne, Melbourne, Victoria, Australia.	Paediatric chronic fatigue syndrome: Complex presentations and protracted time to diagnosis.	J Paediatr Child Health. 2013 Nov; 49(11):919-24. doi: 10.1111/jpc.12425. Epub 2013 Oct 31.	AIM: The diagnosis and management of paediatric chronic fatigue syndrome (CFS) remain ongoing challenges for paediatric clinicians, particularly given its unknown aetiology and the little research on effective treatments for this condition. The aim of this study was to describe the presenting features of new patients attending a specialist chronic fatigue clinic at a tertiary-level Australian children's hospital. METHOD: The medical records of all patients with an initial consultation at the chronic fatigue clinic over a 12-month period were reviewed using a standardised data collection template. Functional impact was based on school attendance and classified according to the National Institute of Health and Clinical Excellence guidelines (2007). RESULTS: A total of 99 patients attending the clinic were identified. Of these, 59 were diagnosed with CFS. Median age was 15.4 years with almost two-thirds of patients of female sex. Median time between symptom onset and diagnosis was 15.5 months. There was a high occurrence of fatigue, sleep disturbance, pain, postexertional malaise, and autonomic and cognitive symptoms in the group. The functional impact of CFS was classified as mild for 20%, moderate for 66% and severe for 14% of patients. CONCLUSIONS: Most young people diagnosed with CFS experience symptoms for a protracted period, with considerable functional impact prior to initial tertiary service consultation. This audit has identified important areas for research, practice development and education in relation to the management of patients with CFS.
Knight SJ, Scheinberg A, Harvey AR.	Murdoch Childrens Research Institute, Melbourne, Victoria, Australia. sarah.knight@mcri.edu	Interventions in pediatric chronic fatigue syndrome/myalgic encephalomyelitis: a	J Adolesc Health. 2013 Aug; 53(2):154-65. doi: 10.1016/j.jadohealth.2013.03.009. Epub 2013 May 1.	PURPOSE: A range of interventions have been used for the management of Chronic Fatigue Syndrome/Myalgic Encephalomyelitis (CFS/ME) in children and adolescents. Currently, debate exists as to the effectiveness of these different management strategies. The objective of this review was to synthesize and critically appraise the literature on interventions for pediatric CFS/ME. METHOD: CINAHL, PsycINFO and

	.au	systematic review.		Medline databases were searched to retrieve relevant studies of intervention outcomes in children and/or adolescents diagnosed with CFS/ME. Two reviewers independently selected articles and appraised the quality on the basis of predefined criteria. RESULTS: A total of 24 articles based on 21 studies met the inclusion criteria. Methodological design and quality were variable. The majority assessed behavioral interventions (10 multidisciplinary rehabilitation; 9 psychological interventions; 1 exercise intervention; 1 immunological intervention). There was marked heterogeneity in participant and intervention characteristics, and outcome measures used across studies. The strongest evidence was for Cognitive Behavioral Therapy (CBT)-based interventions, with weaker evidence for multidisciplinary rehabilitation. Limited information exists on the maintenance of intervention effects. CONCLUSIONS: Evidence for the effectiveness of interventions for children and adolescents with CFS/ME is still emerging. Methodological inadequacies and inconsistent approaches limit interpretation of findings. There is some evidence that children and adolescents with CFS/ME benefit from particular interventions; however, there remain gaps in the current evidence base.
Kossaify A, Kallab K.	Department of Syncope and Electrophysiology, ND Secours/USEK University Hospital, Byblos, Lebanon. antoinekossaify@yahoo.com.	Neurocardiogenic syncope and associated conditions: insight into autonomic nervous system dysfunction.	Turk Kardiyol Dern Ars. 2013 Jan; 41(1):75-83. doi: 10.5543/tkda.2013.44420.	Neurocardiogenic syncope is known to be associated with autonomic nervous system dysfunction, although the mechanism has not been entirely elucidated. In this study, we sought to highlight the pathogenic role of the autonomic nervous system in neurocardiogenic syncope and to review the associated co-morbidities known to have a dysautonomic basis. Herein we discuss migraine, orthostatic hypotension, postural orthostatic tachycardia syndrome, endothelial dysfunction, chronic fatigue syndrome, and carotid sinus hypersensitivity with a focus on the pathogenic role of the autonomic nervous system and any consecutive clinical implications. Other conditions, such as pre-syncopal heart rate acceleration and/or instability and pre-syncopal breathing instability, which occur during a tilt test, are discussed in the same perspective.
Kuemmerle-Deschner JB, Haug I.	Division of Pediatric Rheumatology, Department of Pediatrics, University Children's Hospital Tuebingen, Hoppe-Seyler-Strasse 1, 72076 Tuebingen, Germany.	Canakinumab in patients with cryopyrin-associated periodic syndrome: an update for clinicians.	Ther Adv Musculoskelet Dis. 2013 Dec; 5(6):315-29. doi: 10.1177/1759720X13502629.	The cryopyrin-associated periodic syndrome (CAPS) is a very rare disease. It is estimated that there are 1-2 cases for every 1 million people in the US and 1 in every 360,000 in France. However, many patients are diagnosed very late or not at all, meaning the real prevalence is likely to be higher. CAPS encompasses the three entities of familial cold auto-inflammatory syndrome (FCAS), Muckle-Wells syndrome (MWS), and neonatal-onset multisystem inflammatory disease (NOMID)/chronic infantile neurologic, cutaneous and articular (CINCA) syndrome. They have in common a causative mutation in the NLRP3 gene. The altered gene product cryopyrin leads to activation of the inflammasome which in turn is responsible for excessive production of interleukin (IL)-1β. IL-1β causes the inflammatory manifestations in CAPS. These appear as systemic inflammation including fever, headache or fatigue, rash, eye disease, progressive sensorineural hearing loss, musculoskeletal manifestations and central nervous system (CNS) symptoms (NOMID/CINCA only). With the advent of IL-1

				Inhibitors, safe and effective therapeutic options became available for this devastating disease. To prevent severe and possible life-threatening disease sequelae, early and correct diagnosis and immediate initiation of therapy are mandatory in most patients. Canakinumab is a fully human monoclonal IgG1 anti-IL-1β antibody. It provides selective and prolonged IL-1β blockade and has demonstrated a rapid (within hours), complete and sustained response in most CAPS patients without any consistent pattern of side effects. Long-term follow-up trials have demonstrated sustained efficacy, safety and tolerability. Canakinumab is approved by the US Food and Drug Administration for FCAS and MWS and by European Medicines Agency for treatment of all three phenotypes of CAPS.
Kutner NG, Zhang R.	[No address quoted]	Frailty in dialysis-dependent patients with end-stage renal disease.	JAMA Intern Med. 2013 Jan 14; 173(1):78-9. doi: 10.1001/2013.jamainternmed.750.	Comment in JAMA Intern Med. 2013 Jan 14; 173(1):79.
Lakhan SE, Schofield KL.	Global Neuroscience Initiative Foundation, Los Angeles, California, United States of America.	Mindfulness-based therapies in the treatment of somatization disorders: a systematic review and meta-analysis.	PLoS One. 2013 Aug 26;8(8):e71834. doi: 10.1371/journal.pone.0071834.	BACKGROUND: Mindfulness-based therapy (MBT) has been used effectively to treat a variety of physical and psychological disorders, including depression, anxiety, and chronic pain. Recently, several lines of research have explored the potential for mindfulness-therapy in treating somatization disorders, including fibromyalgia, chronic fatigue syndrome, and irritable bowel syndrome. METHODS: Thirteen studies were identified as fulfilling the present criteria of employing randomized controlled trials to determine the efficacy of any form of MBT in treating somatization disorders. A meta-analysis of the effects of mindfulness-based therapy on pain, symptom severity, quality of life, depression, and anxiety was performed to determine the potential of this form of treatment. FINDINGS: While limited in power, the meta-analysis indicated a small to moderate positive effect of MBT (compared to wait-list or support group controls) in reducing pain (SMD = -0.21, 95% CI: -0.37, -0.03; p<0.05), symptom severity (SMD = -0.40, 95% CI: -0.54, -0.26; p<0.001), depression (SMD = -0.23, 95% CI: -0.40, -0.07, p<0.01), and anxiety (SMD = -0.20, 95% CI: -0.42, 0.02, p = 0.07) associated with somatization disorders, and improving quality of life (SMD = 0.39, 95% CI: 0.19, 0.59; p<0.001) in patients with this disorder. Subgroup analyses indicated that the efficacy of MBT was most consistent for irritable bowel syndrome (p<0.001 for pain, symptom severity, and quality of life), and that mindfulness-based stress reduction (MBSR) and mindfulness-based cognitive therapy (MCBT) were more effective than eclectic/unspecified MBT. CONCLUSIONS: Preliminary evidence suggests that MBT may be effective in treating at least some aspects of somatization disorders. Further research is warranted.
Langhorst J, Klose P, Dobos GJ, Bernardy K,	Department of Internal and Integrative Medicine, University of	Efficacy and safety of meditative movement therapies	Rheumatol Int. 2013 Jan; 33(1):193-207. doi: 10.1007/s00296-012-2360-1.	A systematic review with meta-analysis of the efficacy and safety of meditative movement therapies (Qigong, Tai Chi and Yoga) in fibromyalgia syndrome (FMS) was carried out. We screened Clinicaltrials.Gov, Cochrane Library, PsycINFO, PubMed and

Häuser W.	Duisburg-Essen, Kliniken Essen-Mitte, 45276 Essen, Germany. j.langhorst@kliniken-essen-mitte.de	in fibromyalgia syndrome: a systematic review and meta-analysis of randomized controlled trials.	Epub 2012 Feb 15.	Scopus (through December 2010) and the reference sections of original studies for meditative movement therapies (MMT) in FMS. Randomized controlled trials (RCT) comparing MMT to controls were analysed. Outcomes of efficacy were pain, sleep, fatigue, depression and health-related quality of life (HRQOL). Effects were summarized using standardized mean differences (SMD [95% confidence interval]). Outcomes of safety were drop out because of adverse events and serious adverse events. A total of 7 out of 117 studies with 362 subjects and a median of 12 sessions (range 8-24) were included. MMT reduced sleep disturbances (-0.61 [-0.95, -0.27]; 0.0004), fatigue (-0.66 [-0.99, -0.34]; <0.0001), depression (-0.49 [-0.76, -0.22]; 0.0004) and limitations of HRQOL (-0.59 [-0.93, -0.24]; 0.0009), but not pain (-0.35 [-0.80, 0.11]; 0.14) compared to controls at final treatment. The significant effects on sleep disturbances (-0.52 [-0.97, -0.07]; 0.02) and HRQOL (-0.66 [-1.31, -0.01]; 0.05) could be maintained after a median of 4.5 (range 3-6) months. In subgroup analyses, only Yoga yielded significant effects on pain, fatigue, depression and HRQOL at final treatment. Drop out rate because of adverse events was 3.1%. No serious adverse events were reported. MMT are safe. Yoga had short-term beneficial effects on some key domains of FMS. There is a need for high-quality studies with larger sample sizes to confirm the results.
Lattie EG, Antoni MH, Fletcher MA, Czaja S, Perdomo D, Sala A, Nair S, Fu SH, Penedo FJ, Klimas N.	Department of Psychology, University of Miami.	Beyond Myalgic Encephalomyelitis/ Chronic Fatigue Syndrome (ME/CFS) Symptom Severity: Stress Management Skills are Related to Lower Illness Burden.	Fatigue. 2013; 1(4). doi: 10.1080/21641846.2013.843255.	BACKGROUND: The onset of Myalgic Encephalomyelitis/Chronic Fatigue Syndrome (ME/CFS) typically involves reductions in activities of daily living and social interactions (jointly referred to as "illness burden"). Emotional distress has been linked to increased reported symptoms, and stress management skills have been related to lower fatigue severity in CFS patients. Symptom severity and illness burden are highly correlated. The ability to manage stress may attenuate this relationship, allowing individuals to feel less burdened by the illness independent of the severity of their symptoms. PURPOSE: This study aimed to evaluate if perceived stress management skills affect illness burden via emotional distress, independent of ME/CFS symptom severity. METHODS: A total of 117 adults with ME/CFS completed measures of perceived stress management skills, emotional distress, ME/CFS symptom severity and illness burden. RESULTS: Regression analyses revealed that greater perceived stress management skills related to less social and fatigue-related illness burden, via lower emotional distress. This relationship existed independent of the association of symptom severity on illness burden, and was stronger among those not currently employed. CONCLUSIONS: Ability to manage stress is associated with a lower illness burden for individuals with ME/CFS. Future studies should evaluate the efficacy of psychosocial interventions in lowering illness burden by targeting stress management skills.
Lauche R, Cramer H, Dobos G, Langhorst J,	Department of Internal and Integrative Medicine, Kliniken	A systematic review and meta-analysis of mindfulness-based	J Psychosom Res. 2013 Dec;75(6):500-10. doi: 10.1016/j.jpsychores.2013.10.	OBJECTIVES: This paper presents a systematic review and meta-analysis of the effectiveness of mindfulness-based stress reduction (MBSR) for FMS. METHODS: The PubMed/MEDLINE, Cochrane Library, EMBASE, PsychINFO and CAMBASE databases

Schmidt S.	Essen-Mitte, Faculty of Medicine, University of Duisburg-Essen, Essen, Germany. Electronic address: r.lauche@kliniken-essen-mitte.de.	stress reduction for the fibromyalgia syndrome.	010. Epub 2013 Oct 26.	were screened in September 2013 to identify randomized and non-randomized controlled trials comparing MBSR to control interventions. Major outcome measures were quality of life and pain; secondary outcomes included sleep quality, fatigue, depression and safety. Standardized mean differences and 95% confidence intervals were calculated. RESULTS: Six trials were located with a total of 674 FMS patients. Analyses revealed low quality evidence for short-term improvement of quality of life (SMD=-0.35; 95% CI -0.57 to -0.12; P=0.002) and pain (SMD=-0.23; 95% CI -0.46 to -0.01; P=0.04) after MBSR, when compared to usual care; and for short-term improvement of quality of life (SMD=-0.32; 95% CI -0.59 to -0.04; P=0.02) and pain (SMD=-0.44; 95% CI -0.73 to -0.16; P=0.002) after MBSR, when compared to active control interventions. Effects were not robust against bias. No evidence was further found for secondary outcomes or long-term effects of MBSR. Safety data were not reported in any trial. CONCLUSIONS: This systematic review found that MBSR might be a useful approach for FMS patients. According to the quality of evidence only a weak recommendation for MBSR can be made at this point. Further high quality RCTs are required for a conclusive judgment of its effects.
Lauche R, Cramer H, Häuser W, Dobos G, Langhorst J.	Department of Internal and Integrative Medicine, Kliniken Essen-Mitte, Faculty of Medicine, University of Duisburg-Essen, 45276 Essen, Germany.	A systematic review and meta-analysis of qigong for the fibromyalgia syndrome.	Evid Based Complement Alternat Med. 2013;2013:635182. doi: 10.1155/2013/635182. Epub 2013 Oct 31.	Objectives: The fibromyalgia syndrome (FMS) is a chronic condition with only few evidence-based complementary and alternative therapies available. This paper presents a systematic review and meta-analysis of the effectiveness of Qigong for fibromyalgia syndrome. Methods: The PubMed/MEDLINE, Cochrane Library, Embase, PsycINFO, and Cambase databases were screened in December 2012 to identify randomized controlled trials comparing Qigong to control interventions. Major outcome measures were pain and quality of life; and secondary outcomes included sleep quality, fatigue, depression, and safety. Standardized mean differences (SMD) and 95% confidence intervals were calculated. Results: Seven trials were located with a total of 395 FMS patients. Analyses revealed low quality evidence for short-term improvement of pain, quality of life, and sleep quality and very low quality evidence for improvement of fatigue after Qigong for FMS, when compared to usual care. No evidence was found for superiority of Qigong compared to active treatments. No serious adverse events were reported. Discussion: This systematic review found that Qigong may be a useful approach for FMS patients. According to the quality of evidence, only a weak recommendation for Qigong can be made at this point. Further high quality RCTs are required for the conclusive judgment of its long-term effects.
Lehmann S, Milde-Busch A, Straube A, von Kries R, Heinen F.	Institute of Social Paediatrics and Adolescent Medicine, Medical Faculty of Ludwig-Maximilians-University Munich, Munich, Bavaria,	How specific are risk factors for headache in adolescents? Results from a cross-sectional study in Germany.	Neuropediatrics. 2013 Feb; 44(1):46-54. doi: 10.1055/s-0032-1333432. Epub 2013 Jan 10.	BACKGROUND: The identified preventable risk factors for primary headache in adolescents are smoking; consumption of coffee or alcoholic mixed drinks; physical inactivity; muscle pain in the head, neck, or shoulder region; and chronic stress. OBJECTIVE: To investigate the interrelation of headache with other health complaints and the specificity of the above-mentioned risk factors for headache in adolescents. METHODS: A total of 1,260 students (grades 10 and 11) filled in questionnaires on headache, dietary, and lifestyle factors. The type of headache and health complaints

	Germany. steffi.lehmann@med.uni-muenchen.de			such as dizziness, abdominal pain, musculoskeletal pains, symptoms of possible fatigue syndrome, and psychic complaints were assessed. RESULTS: Isolated headache was found in 18% of the headache sufferers; most frequently isolated tension-type headache (78.2%). Only among adolescents with a combination of headache (mainly migraine) and other health complaints, significant associations for almost all analyzed risk factors were found. The strength of the associations with the considered risk factors was very similar in all three analyzed strata except for considerably lower odds ratios for isolated headache. CONCLUSION: All analyzed risk factors are nonspecific for headache in adolescents because they also increase the risk for other health complaints. Interventions, therefore, should consider a holistic approach focusing not only on headache but also on a broader spectrum of health complaints.
Lenert P, Icardi M, Dahmoush L.	Department of Internal Medicine, Carver College of Medicine, The University of Iowa, 200 Hawkins Drive, Iowa City, IA, USA. petar-lenert@uiowa.edu	ANA (+) ANCA (+) systemic vasculitis associated with the use of minocycline: case-based review.	Clin Rheumatol. 2013 Jul; 32(7):1099-106. doi: 10.1007/s10067-013-2245-z. Epub 2013 Apr 21.	Minocycline is a synthetic tetracycline-derived antibiotic with significant anti-inflammatory properties that may benefit patients with rheumatoid arthritis. Surprisingly, chronic exposure to minocycline can also cause a breach in immunologic tolerance resulting in a variety of autoimmune syndromes such as drug-induced lupus or autoimmune hepatitis. Vasculitis, most commonly resembling cutaneous polyarteritis nodosa, has also been seen in patients taking this drug. Herein, we present a case of biopsy-proven systemic vasculitis presenting as an ANA (+) ANCA (+) polyarteritis nodosa-like syndrome in a male patient who was taking minocycline for his acne for approximately 2 years. Patient initially presented with constitutional symptoms such as profound weight loss and fatigue, along with myalgias, oligoarticular arthritis, and livedo reticularis. About 2 months later, he developed a severe left testicular pain. Biopsy showed vasculitis complicated with the infarction of the left testis. Angiography revealed microaneurysms in the renal and splenic circulation. Stopping the offending drug, along with the short course of prednisone and hydroxychloroquine, resulted in prompt resolution of his symptoms. We additionally present a comprehensive review of biopsy-proven cases of vasculitis associated with chronic minocycline treatment focusing on its pathogenesis and clinical manifestations.
Leone C, D Amico E, Cilia S, Nicoletti A, Di Pino L, Patti F.	[No address quoted]	Cognitive impairment and "invisible symptoms" are not associated with CCSVI in MS.	BMC Neurol. 2013 Jul 27; 13(1):97. [Epub ahead of print]	BACKGROUND: We investigated the association between chronic cerebrospinal venous insufficiency (CCSVI) and cognitive impairment (CI) in multiple sclerosis (MS). Moreover, we evaluated the association between CCSVI and other frequent self-reported MS symptoms. METHODS: We looked at the presence of CI in incident MS patients with CCVSI in a population-based cohort of Catania, Italy. All subjects were group-matched by age, sex, disease duration and EDSS score with MS patients without CCSVI, serving as controls. CI was assessed with the Brief Repeatable Battery (BRB) and the Stroop Test (ST) and it was defined by the presence of at least three impaired tests. Fatigue and depressive symptoms were assessed with Fatigue Severity Scale (FSS) and Hamilton Depressive Rating Scale (HDRS), respectively. Bladder and sexual symptoms were assessed with the respective items of the Italian version of

				Guy's Neurological Disability Scale (GNDS). Quality of life was evaluated with Multiple Sclerosis Quality of Life-54 Instrument (MSQOL-54). RESULTS: Out of 61 MS patients enrolled in the study, 27 were CCSVI positive and 34 were CCSVI negative. Of them, 43 were women (70.5%); the mean age was 43.9 +/- 11.8 years; the mean disease duration was 159.7 +/- 113.7 months; mean EDSS was 3.0 +/- 2.6. Of them, 36 (59.0%) were classified relapsing-remitting (RR), 12 (19.7%) secondary progressive (SP), seven (11.5%) primary progressive (PP) and six (9.3%) Clinically Isolated Syndrome (CIS). Overall, CI was detected in 29/61 (47.5%) MS patients; particularly 13/27 (48.1%) in the CCSVI positive group and 16/34 (47.0%) in the CCSVI negative group. Presence of CCSVI was not significantly associated with the presence of CI (OR 1.04; 95%CI 0.37-2.87; p-value = 0.9). Not significant differences were found between the two groups regarding the other MS symptoms investigated. CONCLUSIONS: Our findings suggest a lack of association between CCSVI and CI in MS patients. Fatigue, depressive, bladder/sexual symptoms and self-reported quality of life are not associated with CCSVI.
Lewis I, Pairman J, Spickett G, Newton JL.	Institute for Ageing & Health, Newcastle University, Newcastle upon Tyne, UK.	Is chronic fatigue syndrome in older patients a different disease? - a clinical cohort study.	Eur J Clin Invest. 2013 Mar; 43(3):302-8. doi: 10.1111/eci.12046. Epub 2013 Feb 9.	BACKGROUND: Chronic fatigue syndrome (CFS) is a disabling disorder characterised by persistent fatigue with a typical age of diagnosis of 35-50 years. CFS does present in those aged over 50 but whether this is a different disease in older age groups has not been considered. Therefore, we performed a clinical cohort study to examine and differentiate the clinical and autonomic features in CFS patients aged over 50. DESIGN: A total of 179 Fukuda diagnosed CFS patients were recruited, and 25 older CFS patients (50 + years) were matched case by case for gender and length of history to 25 younger CFS patients (16-29 years). A range of symptomatic-based questionnaires were used in addition to heart rate variability and baroreceptor sensitivity to assess autonomic function. RESULTS: Chronic fatigue syndrome can present for the first time in an older population. Older CFS patients demonstrate increased fatigue (Fatigue impact scale; 85 ± 33 vs. 107 ± 27, P = 0·02) (Chalder fatigue scale; 9 ± 3 vs. 11 ± 1, P = 0·002) and caseness for depression (Hospital Anxiety and Depression scale; 7 ± 3 vs. 10 ± 4; P = 0·005). There is a greater autonomic dysfunction in older CFS patients, with reduced parasympathetic function (HFnu; 49·1 ± 18 vs. 36·2 ± 18, P = 0·01, RR30: 15; ±, P = 0·02) and increased sympathetic function (LFnu; 51·5 ± 17 vs. 63·8 ± 18, P = 0·01). Baroreflex sensitivity was substantially reduced (BRS; 19·7 ± 12 vs. 9·9 ± 5, P = 0·0004), and left ventricular ejection time prolonged (LVET; 274·6 ± 16 vs. 285·8 ± 9, P = 0·004). CONCLUSIONS: Older CFS patients demonstrate a disease phenotype very different from younger patients. The combination of differing underlying pathogenic mechanisms and the physiological aspects of ageing result in a greater disease impact in older CFS patients.
Lewis I, Pairman J, Spickett G, Newton JL.	Institute for Ageing & Health, Newcastle University, Newcastle,	Clinical characteristics of a novel subgroup of	J Intern Med. 2013 May; 273(5):501-10. doi: 10.1111/joim.12022. Epub	OBJECTIVES: A significant proportion of patients with chronic fatigue syndrome (CFS) also have postural orthostatic tachycardia syndrome (POTS). We aimed to characterize these patients and differentiate them from CFS patients without POTS in

	UK.	chronic fatigue syndrome patients with postural orthostatic tachycardia syndrome.	2013 Jan 7. Comment in J Intern Med. 2013 May; 273(5):498-500.	terms of clinical and autonomic features. METHODS: A total of 179 patients with CFS (1994 Centers for Disease Control and Prevention criteria) attending one of the largest Department of Health-funded CFS clinical services were included in this study. Outcome measures were as follows: (i) symptom assessment tools including the fatigue impact scale, Chalder fatigue scale, Epworth sleepiness scale (ESS), orthostatic grading scale (OGS) and hospital anxiety and depression scale (HADS-A and -D, respectively), (ii) autonomic function analysis including heart rate variability and (iii) haemodynamic responses including left ventricular ejection time and systolic blood pressure drop upon standing. RESULTS: CFS patients with POTS (13%, n = 24) were younger (29 ± 12 vs. 42 ± 13 years, P < 0.0001), less fatigued (Chalder fatigue scale, 8 ± 4 vs. 10 ± 2, P = 0.002), less depressed (HADS-D, 6 ± 4 vs. 9 ± 4, P = 0.01) and had reduced daytime hypersomnolence (ESS, 7 ± 6 vs. 10 ± 5, P = 0.02), compared with patients without POTS. In addition, they exhibited greater orthostatic intolerance (OGS, 11 ± 5; P < 0.0001) and autonomic dysfunction. A combined clinical assessment tool of ESS ≤9 and OGS ≥9 identifies accurately CFS patients with POTS with 100% positive and negative predictive values. CONCLUSIONS: The presence of POTS marks a distinct clinical group of CFS patents, with phenotypic features differentiating them from those without POTS. A combination of validated clinical assessment tools can determine which CFS patients have POTS with a high degree of accuracy, and thus potentially identify those who require further investigation and consideration for therapy to control heart rate.
Light KC, Agarwal N, Iacob E, White AT, Kinney AY, Vanhaitsma TA, Aizad H, Hughen RW, Bateman L, Light AR.	Department of Anesthesiology, University of Utah Health Sciences Center, Salt Lake City, UT, USA. Electronic address: kathleen.c.light@hsc.utah.edu.	Differing leukocyte gene expression profiles associated with fatigue in patients with prostate cancer versus chronic fatigue syndrome.	Psychoneuroendocrinology. 2013 Dec;38(12):2983-95. doi: 10.1016/j.psyneuen.2013.08.008 Epub 2013 Sep 6.	BACKGROUND: Androgen deprivation therapy (ADT) often worsens fatigue in patients with prostate cancer, producing symptoms similar to chronic fatigue syndrome (CFS). Comparing expression (mRNA) of many fatigue-related genes in patients with ADT-treated prostate cancer versus with CFS versus healthy controls, and correlating mRNA with fatigue severity may clarify the differing pathways underlying fatigue in these conditions. METHODS: Quantitative real-time PCR was performed on leukocytes from 30 fatigued, ADT-treated prostate cancer patients (PCF), 39 patients with CFS and 22 controls aged 40-79, together with ratings of fatigue and pain severity. 46 genes from these pathways were included: (1) adrenergic/monoamine/neuropeptides, (2) immune, (3) metabolite-detecting, (4) mitochondrial/energy, (5) transcription factors. RESULTS: PCF patients showed higher expression than controls or CFS of 2 immune transcription genes (NR3C1 and TLR4), chemokine CXCR4, and mitochondrial gene SOD2. They showed lower expression of 2 vasodilation-related genes (ADRB2 and VIPR2), 2 cytokines (TNF and LTA), and 2 metabolite-detecting receptors (ASIC3 and P2RX7). CFS patients showed higher P2RX7 and lower HSPA2 versus controls and PCF. Correlations with fatigue severity were similar in PCF and CFS for only DBI, the GABA-A receptor modulator (r=-0.50, p<0.005 and r=-0.34, p<0.05). Purinergic P2RY1 was correlated only with PCF fatigue and pain severity (r=+0.43 and +0.59, p=0.025 and p=0.001). CONCLUSIONS: PCF patients

				differed from controls and CFS in mean expression of 10 genes from all 5 pathways. Correlations with fatigue severity implicated DBI for both patient groups and P2RY1 for PCF only. These pathways may provide new targets for interventions to reduce fatigue.
Lillestøl K, Bondevik H.	Avdeling for samfunnsmedisin, Institutt for helse og samfunn, Universitetet i Oslo, Norway. kristine.lillestol@medisin.uio.no	Neurasthenia in Norway 1880-1920. [Article in Norwegian]	Tidsskr Nor Laegeforen. 2013 Mar 19; 133(6):661-5. doi: 10.4045/tidsskr.12.1221.	Neurasthenia was introduced as a diagnostic category in America in 1869, and rapidly spread to Europe. Many have drawn parallels between the historical disease entity of neurasthenia and contemporary conditions such as chronic fatigue syndrome/myalgic encephalopathy and burn-out, but we have little knowledge about the early history of neurasthenia in Norway. On the basis of Norwegian medical journals from the period 1880-1920, we have sought to study the introduction, understanding and application of the concept of neurasthenia in Norwegian medical practice, with particular emphasis on symptoms, causes, treatment, prognosis and prevalence. Results show that the term was probably used in a Norwegian medical journal for the first time in 1876, and during the 1880s there followed an increasing number of reports of people who had been diagnosed with neurasthenia. The condition was defined as a weakness of the nervous system. The symptom picture was extensive, with exhaustion as the main symptom. The causes of the symptoms could not be objectively verified or located, and theories abounded. Overexertion was a common explanation, although traumas, infections, malnutrition, heredity and sexual excesses were also assumed to be causes. The recommended treatment focused on strengthening the nervous system, for example through rest and electrotherapy. The condition was described as typical of its time, as a response to the «Zeitgeist» and modern life.
Lind R, Berstad A, Hatlebakk J, Valeur J.	Department of Medicine, Haukeland University Hospital, Bergen.	Chronic fatigue in patients with unexplained self-reported food hypersensitivity and irritable bowel syndrome: validation of a Norwegian translation of the Fatigue Impact Scale.	Clin Exp Gastroenterol. 2013 Jul 4;6:101-7. doi: 10.2147/CEG.S45760. Print 2013.	BACKGROUND: Patients with unexplained self-reported food hypersensitivity and irritable bowel syndrome (IBS) suffer from several health complaints, including fatigue. The aim of the present study was to validate a Norwegian translation of the Fatigue Impact Scale (FIS), and to assess the impact of fatigue in patients with self-reported food hypersensitivity and IBS, as compared with healthy controls. METHODS: Thirty-eight patients with unexplained self-reported food hypersensitivity and IBS, who participated in the validation of the FIS completed the following additional questionnaires: the Short Form of Nepean Dyspepsia Index for assessment of quality of life, the Subjective Health Complaint Inventory, and questionnaires for diagnosis and severity of IBS. Impact of fatigue was studied in 43 patients with unexplained self-reported food hypersensitivity, 70% diagnosed with IBS, and 42 healthy controls. RESULTS: Cronbach's α for the FIS was 0.98, indicating excellent agreement between individual items. Scores on the FIS correlated with scores on the Short Form of Nepean Dyspepsia Index ($r = 0.50$, $P = 0.001$), indicating good convergent validity, and were higher in patients (median 85.0, interquartile range 36.8-105.3) than in controls (median 14.0, interquartile range 3.0-29.0, $P \leq 0.0001$). CONCLUSION: The Norwegian translation of the FIS performed excellently in patients with unexplained self-reported

				food hypersensitivity and IBS, with patients reporting significantly more impact of chronic fatigue than healthy controls.
Ljøstad U, Mygland Å.	Department of Neurology, Sørlandet Hospital, Kristiansand, Norway. unn.ljostad@sshf.no	Chronic Lyme; diagnostic and therapeutic challenges.	Acta Neurol Scand Suppl. 2013; (196):38-47. doi: 10.1111/ane.12048.	In this review, we aim to discuss the definition, clinical and laboratory features, diagnostics, and management of chronic Lyme. Chronic Lyme is a rare condition caused by long-lasting and ongoing infection with the spirochete Borrelia burgdorferi (Bb). The most common manifestations are progressive encephalitis, myelitis, acrodermatitis chronica atrophicans with or without neuropathy, and arthritis. Chronic Lyme is not considered to present with isolated subjective symptoms. Direct detection of Bb has low yield in most manifestations of chronic Lyme, while almost 100% of the cases are seropositive, that is, have detectable Bb IgG antibodies in serum. Detection of Bb antibodies only with Western blot technique and not with ELISA and detection of Bb IgM antibodies without simultaneous detection of Bb IgG antibodies should be considered as seronegativity in patients with long-lasting symptoms. Patients with chronic Lyme in the nervous system (neuroborreliosis) have, with few exceptions, pleocytosis and production of Bb antibodies in their cerebrospinal fluid. Strict guidelines should be applied in diagnostics of chronic Lyme, and several differential diagnoses, including neurological disease, rheumatologic disease, post-Lyme disease syndrome, chronic fatigue syndrome, and psychiatric disease, should be considered in the diagnostic workup. Antibiotic treatment with administration route and dosages according to current guidelines are recommended. Combination antimicrobial therapy or antibiotic courses longer than 4 weeks are not recommended. Patients who attribute their symptoms to chronic Lyme on doubtful basis should be offered a thorough and systematic diagnostic approach, and an open and respectful dialogue.

Lu Y (1), Liu Y(2), Li Y(1).	(1)Laboratory of Oral Biomedical Science and Translational Medicine, Department of Orthodontics, School of Stomatology, Tongji University, Shanghai, China. (2)Laboratory of Oral Biomedical Science and Translational Medicine, Department of	Comparison of natural estrogens and synthetic derivative on genioglossus function and estrogen receptors expression in rats with chronic intermittent hypoxia.	J Steroid Biochem Mol Biol. 2013 Dec 12; 140 C: 71-79. doi: 10.1016/j.jsbmb.2013.12.006. [Epub ahead of print]	The pathogenesis of obstructive sleep apnea-hypopnea syndrome (OSAHS) is summarized as the narrow anatomic structure of upper airway (UA) and the defective function of UA dilator muscles. Up to now, there have been no specific treatments for the UA dilator muscle deficiency. We previously found that some estrogen-like compounds exert protective effects on genioglossus, but this protection tends to be less satisfactory. A novel phytoestrogen derivative was synthesized in recent years and was verified to have some cytoprotective activity. This study was designed to compare the effects of natural estrogens and the synthetic resveratrol dimer on genioglossus contraction and expression of estrogen receptors (ERs) under chronic intermittent hypoxia (CIH) condition. Genioglossus myoblasts of rat were isolated and cultured in a culture medium with different agents (estradiol, genistein, resveratrol, and resveratrol dimer, respectively) under hypoxia condition, and ERs expressions

	Orthodontics, School of Stomatology, Tongji University, Shanghai, China. Electronic address: liuyuehua@tongji.edu.cn.			were detected. In vivo study, 48 ovariectomized female rats were randomized into six groups. After CIH exposure and agents injection, rats were tested for genioglossus contractile properties and further analysis of ERs expression. Estradiol up-regulated ERα level and exerted the best protective effect of fatigue resistance. Genistein, resveratrol and resveratrol dimer primarily up-regulated the expression of ERβ. Resveratrol dimer exhibited better protection of fatigue resistance than genistein and resveratrol, and expressed higher binding affinity for ERβ than for ERα. Besides estrogenic effects, there may be some other mechanisms for the fatigue resistance improvement contributed by phytoestrogens and their derivatives.
Lucas K, Maes M.	Sportzenkoppel 54, 22359, Hamburg, Germany.	Role of the Toll Like receptor (TLR) radical cycle in chronic inflammation: possible treatments targeting the TLR4 Pathway.	Mol Neurobiol. 2013 Aug; 48(1):190-204. doi: 10.1007/s12035-013-8425-7. Epub 2013 Feb 26.	Activation of the Toll-like receptor 4 (TLR4) complex, a receptor of the innate immune system, may underpin the pathophysiology of many human diseases, including asthma, cardiovascular disorder, diabetes, obesity, metabolic syndrome, autoimmune disorders, neuroinflammatory disorders, schizophrenia, bipolar disorder, autism, clinical depression, chronic fatigue syndrome, alcohol abuse, and toluene inhalation. TLRs are pattern recognition receptors that recognize damage-associated molecular patterns and pathogen-associated molecular patterns, including lipopolysaccharide (LPS) from gram-negative bacteria. Here we focus on the environmental factors, which are known to trigger TLR4, e.g., ozone, atmosphere particulate matter, long-lived reactive oxygen intermediate, pentachlorophenol, ionizing radiation, and toluene. Activation of the TLR4 pathways may cause chronic inflammation and increased production of reactive oxygen and nitrogen species (ROS/RNS) and oxidative and nitrosative stress and therefore TLR-related diseases. This implies that drugs or substances that modify these pathways may prevent or improve the abovementioned diseases. Here we review some of the most promising drugs and agents that have the potential to attenuate TLR-mediated inflammation, e.g., anti-LPS strategies that aim to neutralize LPS (synthetic anti-LPS peptides and recombinant factor C) and TLR4/MyD88 antagonists, including eritoran, CyP, EM-163, epigallocatechin-3-gallate, 6-shogaol, cinnamon extract, N-acetylcysteine, melatonin, and molecular hydrogen. The authors posit that activation of the TLR radical (ROS/RNS) cycle is a common pathway underpinning many "civilization" disorders and that targeting the TLR radical cycle may be an effective method to treat many inflammatory disorders.
Lukkahatai N, Saligan LN.	National Institute of Nursing Research, National Institutes of Health, Bethesda, MD 20892, USA. nada.lukkahatai@nih.gov	Association of catastrophizing and fatigue: a systematic review.	J Psychosom Res. 2013 Feb;74(2):100-9. doi: 10.1016/j.jpsychores.2012.11.006. Epub 2012 Dec 2.	OBJECTIVE: Catastrophizing is an exaggerated negative evaluation and attention to specific symptoms such as pain or fatigue. A number of studies consistently support the significant role of catastrophizing in pain. However, the role of catastrophizing in fatigue is less frequently investigated. This article provides a critical review of published studies investigating this association. METHODS: Using the keyword "Fatigue AND Catastrophizing", we performed a search in PubMed, SCOPUS, PsycINFO, and EMBASE. RESULTS: Fourteen studies were reviewed and all except one were found to provide empirical support for an association between high

				catastrophizing and high fatigue. Most of these reviewed articles also show the large impact of catastrophizing on fatigue severity. Two longitudinal studies found that fatigue catastrophizing level before cancer treatment is a significant predictor of post-treatment fatigue. Studies also demonstrated that persons who had higher scores for catastrophizing recalled fatigue more accurately than those with lower scores. CONCLUSION: In spite the differences of its definition and the measurements used, a similar significant association between catastrophizing and fatigue was reported. Because this observation was based on 14 studies with limited types of patients, further studies are recommended to examine the role of catastrophizing in fatigue from other clinical populations and to investigate its utility as a behavioral marker for central fatigue.
Maas ML, Wever PC, Plat AW, Hoogeveen EK.	Department of Internal Medicine, Jeroen Bosch Hospital's-Hertogenbosch, The Netherlands. martjemaas@hotmail.com	An uncommon cause of Staphylococcus aureus sepsis.	Scand J Infect Dis. 2013 Sep;45(9):722-4. doi: 10.3109/00365548.2013.795658. Epub 2013 Jun 9.	We describe a case of Staphylococcus aureus sepsis after acupuncture for chronic fatigue syndrome (CFS). Sepsis is a rare, but potentially fatal complication of acupuncture. The most common cause of bacterial infection after acupuncture is S. aureus. The effectiveness of acupuncture for the treatment of CFS is not proven, therefore the potential benefits should be weighed against the risks.
Maes M, Anderson G, Morris G, Berk M.	[No address quoted]	Diagnosis of myalgic encephalomyelitis: where are we now?	Expert Opin Med Diagn. 2013 May; 7(3):221-5. doi: 10.1517/17530059.2013.776039. Epub 2013 Feb 27.	INTRODUCTION: The World Health Organization has classified myalgic encephalomyelitis (ME) as a neurological disease since 1969 considering chronic fatigue syndrome (CFS) as a synonym used interchangeably for ME since 1969. ME and CFS are considered to be neuro-immune disorders, characterized by specific symptom profiles and a neuro-immune pathophysiology. However, there is controversy as to which criteria should be used to classify patients with "chronic fatigue syndrome." AREAS COVERED: The Centers for Disease Control and Prevention (CDC) criteria consider chronic fatigue (CF) to be distinctive for CFS, whereas the International Consensus Criteria (ICC) stresses the presence of post-exertion malaise (PEM) as the hallmark feature of ME. These case definitions have not been subjected to rigorous external validation methods, for example, pattern recognition analyses, instead being based on clinical insights and consensus. EXPERT OPINION: Pattern recognition methods showed the existence of three qualitatively different categories: (a) CF, where CF evident, but not satisfying full CDC syndrome criteria. (b) CFS, satisfying CDC criteria but without PEM. (c) ME, where PEM is evident in CFS. Future research on this "chronic fatigue spectrum" should, therefore, use the above-mentioned validated categories and novel tailored algorithms to classify patients into ME, CFS, or CF.
Maes M, Ringel K, Kubera M,	Maes Clinics @ TRIA, Bangkok, Thailand.	In myalgic encephalomyelitis/ch	J Affect Disord. 2013 Sep 5; 150 (2):223-30. doi:	BACKGROUND: Myalgic encephalomyelitis/chronic fatigue syndrome (ME/CFS) is accompanied by activation of immuno-inflammatory pathways, increased bacterial

Anderson G, Morris G, Galecki P, Geffard M.	dr.michaelmaes@hotmail.com	ronic fatigue syndrome, increased autoimmune activity against 5-HT is associated with immuno-inflammatory pathways and bacterial translocation.	10.1016/j.jad.2013.03.029. Epub 2013 May 10.	translocation and autoimmune responses to serotonin (5-HT). Inflammation is known to damage 5-HT neurons while bacterial translocation may drive autoimmune responses. This study has been carried out to examine the autoimmune responses to 5-HT in ME/CFS in relation to inflammation and bacterial translocation. METHODS: We examined 5-HT antibodies in 117 patients with ME/CFS (diagnosed according to the centers for disease control and prevention criteria, CDC) as compared with 43 patients suffering from chronic fatigue (CF) but not fulfilling the CDC criteria and 35 normal controls. Plasma interleukin-1 (IL-1), tumor necrosis factor (TNF) α, neopterin and the IgA responses to Gram-negative bacteria were measured. Severity of physio-somatic symptoms was measured using the fibromyalgia and chronic fatigue syndrome rating scale (FF scale). RESULTS: The incidence of positive autoimmune activity against 5-HT was significantly higher ($p<0.001$) in ME/CFS (61.5%) than in patients with CF (13.9%) and controls (5.7%). ME/CFS patients with 5-HT autoimmune activity displayed higher TNFα, IL-1 and neopterin and increased IgA responses against LPS of commensal bacteria than those without 5-HT autoimmune activity. Anti-5-HT antibody positivity was significantly associated with increased scores on hyperalgesia, fatigue, neurocognitive and autonomic symptoms, sadness and a flu-like malaise. DISCUSSION: The results show that, in ME/CFS, increased 5-HT autoimmune activity is associated with activation of immuno-inflammatory pathways and increased bacterial translocation, factors which are known to play a role in the onset of autoimmune reactions. 5-HT autoimmune activity could play a role in the pathophysiology of ME/CFS and the onset of physio-somatic symptoms. These results provide mechanistic support for the notion that ME/CFS is a neuro-immune disorder.
Maestú C, Blanco M, Nevado A, Romero J, Rodríguez-Rubio P, Galindo J, Bautista Lorite J, de Las Morenas F, Fernández-Argüelles P.	[No address quoted]	Reduction of pain thresholds in fibromyalgia after very low-intensity magnetic stimulation: A double-blinded, randomized placebo-controlled clinical trial.	Pain Res Manag. 2013 Nov-Dec; 18 (6):e101-6.	BACKGROUND: Exposure to electromagnetic fields has been reported to have analgesic and antinociceptive effects in several organisms. Objective: To test the effect of very low-intensity transcranial magnetic stimulation on symptoms associated with fibromyalgia syndrome. METHODS: A double-blinded, placebo-controlled clinical trial was performed in the Sagrado Corazón Hospital, Seville, Spain. Female fibromyalgia patients (22 to 50 years of age) were randomly assigned to either a stimulation group or a sham group. The stimulation group (n=28) was stimulated using 8 Hz pulsed magnetic fields of very low intensity, while the sham group (n=26) underwent the same protocol without stimulation. Pressure pain thresholds before and after stimulation were determined using an algometer during the eight consecutive weekly sessions of the trial. In addition, blood serotonin levels were measured and patients completed questionnaires to monitor symptom evolution. RESULTS: A repeated-measures ANOVA indicated statistically significant improvement in the stimulation group compared with the control group with respect to somatosensory pain thresholds, ability to perform daily activities, perceived chronic pain and sleep quality. While improvement in pain thresholds was apparent after the first stimulation session, improvement in the other three measures occurred after the

				sixth week. No significant between-group differences were observed in scores of depression, fatigue, severity of headaches or serotonin levels. No adverse side effects were reported in any of the patients. CONCLUSIONS: Very low-intensity magnetic stimulation may represent a safe and effective treatment for chronic pain and other symptoms associated with fibromyalgia.
Mantovani G, Madeddu C, Macciò A.	Department of Medical Oncology, University of Cagliari, Monserrato, Cagliari, Italy. mantovan@medicina.unica.it	Drugs in development for treatment of patients with cancer-related anorexia and cachexia syndrome.	Drug Des Devel Ther. 2013 Aug 12; 7:645-56. doi: 10.2147/DDDT.S39771. **Retraction** in Drug Des Devel Ther. 2013; 7:1385.	Cancer-related anorexia and cachexia syndrome (CACS) is a complex multifactorial condition, with loss of lean body mass, chronic inflammation, severe metabolic derangements, reduced food intake, reduced physical activity, and poor quality of life as key symptoms. Cachexia recognizes different phases or stages, moving from precachexia through overt cachexia to advanced or refractory cachexia. The purpose of this review is to describe currently effective approaches for the treatment of cachexia, moving forward to drugs and treatments already shown to be effective but needing further clinical trials to confirm their efficacy. We then introduce novel promising investigational drugs and approaches which, based on a strong rationale from the most recent data on the molecular targets/pathways driving the pathophysiology of cachexia, need to be tested either in currently ongoing or appropriate future clinical trials to confirm their clinical potential. Although different drugs and treatments have been tested, we can speculate that a single therapy may not be completely successful. Indeed, considering the complex clinical picture and the multifactorial pathogenesis of CACS, we believe that its clinical management requires a multidisciplinary and multitargeted approach. In our opinion, appropriate treatment for cachexia should target the following conditions: inflammatory status, oxidative stress, nutritional disorders, muscle catabolism, immunosuppression, quality of life, and above all, fatigue. A comprehensive list of the most interesting and effective multitargeted treatments is reported and discussed, with the aim of suggesting the most promising with regard to clinical outcome. A critical issue is that of testing therapies at the earliest stages of cachexia, possibly at the precachexia stage, with the aim of preventing or delaying the development of overt cachexia and thereby obtaining the best possible clinical outcome for patients.
Maresca T, Covini E, Márquez López Mato A.	Instituto de Psiquiatría Biológica Integral (IPBI). ipbi@ipbi.com.ar.	Conditions, controversies and contradictions between central sensitivity syndrome and depressive disorders. [Article in Spanish]	Vertex. 2013 Sep; 24 (111):373-91.	We present a description of the Central Sensitivity Syndrome (CSS) and some of its main components such as Multiple Chemical Sensitivity Syndrome, Chronic Fatigue Syndrome and Fibromyalgia. We review the changes in pain perception, describing the physiology and pathophysiology of the painful experience from the medulla horn to the CNS. We explain the theory of central sensitization as the basis to the syndrome. We refer to the differences between fibromyalgia and depressive disorders, is spite of their frequent presentation in comorbidity. We state the main clinical and neurobiological differences. We point out the main psychoneuroimmunoendocrinologic differences such as adrenal activity (hypoactivity vs. hyperactivity, DST hypersuppressive response vs. DST non suppression, hypersensitivity of central glucocorticoid receptors vs. desensitization of these,

				among others), thyroid (probable reverse T3 vs. flat stimuli TSH response curve) and growth hormone secretion (probable increase vs. disruption of normal circadian rhythm) that makes CSS resemble PTSD. We describe differential changes in sleep patterns (alpha-delta intrusion vs. altered sleep time, REM latency, and stage 3/4) and immunological disturbances almost opposite in each pathological entity. We finally argue which medical specialty should treat these complex syndromes.
Mariman A, Delesie L, Tobback E, Hanoulle I, Sermijn E, Vermeir P, Pevernagie D, Vogelaers D.	Department of General Internal Medicine, Infectious Diseases and Psychosomatic Medicine, University Hospital Ghent, Belgium; Center for Neurophysiologic Monitoring, University Hospital Ghent, Belgium. Electronic address: an.mariman@ugent.be.	Undiagnosed and comorbid disorders in patients with presumed chronic fatigue syndrome.	J Psychosom Res. 2013 Nov;75(5):491-6. doi: 10.1016/j.jpsychores.2013.07.010. Epub 2013 Aug 20.	OBJECTIVE: To assess undiagnosed and comorbid disorders in patients referred to a tertiary care center with a presumed diagnosis of chronic fatigue syndrome (CFS). METHODS: Patients referred for chronic unexplained fatigue entered an integrated diagnostic pathway, including internal medicine assessment, psychodiagnostic screening, physiotherapeutic assessment and polysomnography+multiple sleep latency testing. Final diagnosis resulted from a multidisciplinary team discussion. Fukuda criteria were used for the diagnosis of CFS, DSM-IV-TR criteria for psychiatric disorders, ICSD-2 criteria for sleep disorders. RESULTS: Out of 377 patients referred, 279 (74.0%) were included in the study [84.9% female; mean age 38.8years (SD 10.3)]. A diagnosis of unequivocal CFS was made in 23.3%. In 21.1%, CFS was associated with a sleep disorder and/or psychiatric disorder, not invalidating the diagnosis of CFS. A predominant sleep disorder was found in 9.7%, 19.0% had a psychiatric disorder and 20.8% a combination of both. Only 2.2% was diagnosed with a classical internal disease. In the total sample, a sleep disorder was found in 49.8%, especially obstructive sleep apnea syndrome, followed by psychophysiologic insomnia and periodic limb movement disorder. A psychiatric disorder was diagnosed in 45.2%; mostly mood and anxiety disorder. CONCLUSIONS: A multidisciplinary approach to presumed CFS yields unequivocal CFS in only a minority of patients, and reveals a broad spectrum of exclusionary or comorbid conditions within the domains of sleep medicine and psychiatry. These findings favor a systematic diagnostic approach to CFS, suitable to identify a wide range of diagnostic categories that may be subject to dedicated care.
Mariman AN, Vogelaers DP, Tobback E, Delesie LM, Hanoulle IP, Pevernagie DA.	Ghent University Hospital, Department of Internal Diseases, Infectious Diseases and Psychosomatic Medicine, 185 De Pintelaan, 9000 Ghent, Belgium. An.mariman@ugent.be	Sleep in the chronic fatigue syndrome.	Sleep Med Rev. 2013 Jun; 17(3):193-9. doi: 10.1016/j.smrv.2012.06.003. Epub 2012 Oct 6.	Chronic fatigue syndrome (CFS) is a disabling condition characterized by severe fatigue lasting for more than six months and the presence of at least four out of eight minor criteria. Sleep disturbance presenting as unrefreshing or nonrestorative sleep is one of these criteria and is very common in CFS patients. Biologically disturbed sleep is a known cause of fatigue and could play a role in the pathogenesis of CFS. However, the nature of presumed sleep impairment in CFS remains unclear. Whilst complaints of NRS persist over time, there is no demonstrable neurophysiological correlate to substantiate a basic deficit in sleep function in CFS. Polysomnographic findings have not shown to be significantly different between subjects with CFS and normal controls. Discrepancies between subjectively poor and objectively normal sleep suggest a role for psychosocial factors negatively affecting perception of sleep quality. Primary sleep disorders are often detected in patients who otherwise qualify for a CFS

				diagnosis. These disorders could contribute to the presence of daytime dysfunctioning. There is currently insufficient evidence to indicate that treatment of primary sleep disorders sufficiently improves the fatigue associated with CFS. Therefore, primary sleep disorders may be a comorbid rather than an exclusionary condition with respect to CFS.
Marković I, Culo MI, Gudelj-Gracanin A, Morović-Vergles J.	Opća bolnica Dr. Ivo Pedisić, Sisak. imarkoviczg@gmail.com	Gluten-sensitive enteropathy: a disease to take into consideration - a case report. [Article in Croatian]	Reumatizam. 2013; 60(1):32-6.	Gluten-sensitive enteropathy or celiac disease is a chronic small intestinal immune-mediated enteropathy precipitated by exposure to dietary gluten in genetically predisposed individuals. Although the disease may manifest itself at any age, it occurs mostly in either early childhood or in the third or fourth decade of life. Malabsorption syndrome as a typical clinical feature is commonly absent. Patients may exhibit minor gastrointestinal complaints, as well as numerous extraintestinal manifestations. We report a 43-year-old female patient with mi gratory arthralgias as the leading symptom, fatigue, sideropenic anemia and mild intermittent diarrhoea, who was diagnosed with gluten-sensitive enteropathy. Four months after introduction of gluten-free diet the patient reported no arthralgias, and complete clinical response was achieved. The aim of our case-report was to show that migratory arthralgias can be an extraintestinal manifestation of gluten-sensitive enteropathy. Unexplained articular complaints should raise clinical suspicion of celiac disease.
Marques M, De Gucht V, Leal I, Maes S.	Health Psychology, Leiden University, Wassenaarseweg 52, Leiden, The Netherlands. mmarques@ispa.pt	A cross-cultural perspective on psychological determinants of chronic fatigue syndrome: a comparison between a Portuguese and a Dutch patient sample.	Int J Behav Med. 2013 Jun; 20(2):229-38. doi: 10.1007/s12529-012-9265-y.	BACKGROUND: Few studies focus on cross-cultural differences in Chronic fatigue syndrome (CFS). PURPOSE: This study aimed to (1) compare fatigue severity and impairment, somatic complaints, psychological distress, and quality of life (QoL) in a population of Portuguese and Dutch patients; (2) explore the differential contribution of behavioral and cognitive determinants of fatigue severity; and (3) investigate the relation between fatigue severity and somatic complaints on one hand and QoL on the other in both populations. METHOD: Eighty-five female patients from Portugal (Mean age=47.54) and 167 female CFS patients from The Netherlands (Mean age=44.93) participated in the study. All participants were surveyed for demographic and clinical characteristics, fatigue severity, somatic symptoms, psychological distress, (physical and psychological) QoL, physical activity, behavior regulation patterns, and illness representations. RESULTS: Cross-cultural differences were found in relation to working status, duration of fatigue symptoms, psychological distress, somatic complaints, and psychological QoL. Although behavioral characteristics and illness representations were significantly associated with fatigue severity in both Portuguese and Dutch patients, there were important differences in the determinants of CFS. Moreover, higher levels of fatigue and severity of other somatic complaints were related to poor QoL. CONCLUSIONS: These findings show cross-cultural similarities and differences in clinical characteristics and psychological determinants of CFS that are important in view of diagnosis and treatment.

Mascarelli PE, Maggi RG, Hopkins S, Mozayeni BR, Trull CL, Bradley JM, Hegarty BC, Breitschwerdt EB.	Intracellular Pathogens Research Laboratory, Center for Comparative Medicine and Translational Research, College of Veterinary Medicine, North Carolina State University, Raleigh, NC 27607, USA.	Bartonella henselae infection in a family experiencing neurological and neurocognitive abnormalities after woodlouse hunter spider bites.	Parasit Vectors. 2013 Apr 15; 6:98. doi: 10.1186/1756-3305-6-98.	BACKGROUND: Bartonella species comprise a group of zoonotic pathogens that are usually acquired by vector transmission or by animal bites or scratches. METHODS: PCR targeting the Bartonella 16S-23S intergenic spacer (ITS) region was used in conjunction with BAPGM (Bartonella alpha Proteobacteria growth medium) enrichment blood culture to determine the infection status of the family members and to amplify DNA from spiders and woodlice. Antibody titers to B. vinsonii subsp. berkhoffii (Bvb) genotypes I-III, B. henselae (Bh) and B. koehlerae (Bk) were determined using an IFA test. Management of the medical problems reported by these patients was provided by their respective physicians. RESULTS: In this investigation, immediately prior to the onset of symptoms two children in a family experienced puncture-like skin lesions after exposure to and presumptive bites from woodlouse hunter spiders. Shortly thereafter, the mother and both children developed hive-like lesions. Over the ensuing months, the youngest son was diagnosed with Guillain-Barre (GBS) syndrome followed by Chronic Inflammatory Demyelinating Polyradiculoneuropathy (CIDP). The older son developed intermittent disorientation and irritability, and the mother experienced fatigue, headaches, joint pain and memory loss. When tested approximately three years after the woodlouse hunter spider infestation, all three family members were Bartonella henselae seroreactive and B. henselae DNA was amplified and sequenced from blood, serum or Bartonella alpha-proteobacteria (BAPGM) enrichment blood cultures from the mother and oldest son. Also, B. henselae DNA was PCR amplified and sequenced from a woodlouse and from woodlouse hunter spiders collected adjacent to the family's home. CONCLUSIONS: Although it was not possible to determine whether the family's B. henselae infections were acquired by spider bites or whether the spiders and woodlice were merely accidental hosts, physicians should consider the possibility that B. henselae represents an antecedent infection for GBS, CIDP, and non-specific neurocognitive abnormalities.

Matsuo K, Saburi M, Ishikawa H, Tei K, Hosokawa Y, Fujii C, Mizuno T, Nakagawa M.	Division of Neurology, Ohmihachiman Community Medical Center, Japan. matsuo@pb4.so-net.ne.jp	Sjögren syndrome presenting with encephalopathy mimicking Creutzfeldt-Jakob disease.	J Neurol Sci. 2013 Mar 15;326(1-2):100-3. doi: 10.1016/j.jns.2013.01.005. Epub 2013 Jan 18.	A 61-year-old man developed subacute progressive dementia, general fatigue, a tonic-clonic seizure, and a decreased level of consciousness. He had a past history of chronic hepatitis type C and was diagnosed as having hepatic encephalopathy due to hyperammonemia. His level of consciousness did not improve even though the serum ammonia level improved. In addition, he had repeated general myoclonic seizures. Head MRI (diffusion-weighted imaging) showed high signal intensities in the right thalamus and the cerebral cortices in the frontal, temporal and parietal lobes (predominantly on the right side). An electroencephalogram (EEG) showed periodic lateralized epileptic discharges (PLEDs). Cerebrospinal fluid analysis revealed high total tau protein and 14-3-3 protein levels. This case was diagnosed as Creutzfeldt-Jakob disease (CJD) based on these clinical data. However, the patient gradually improved without specific treatment. The differential diagnosis was reconsidered, and an increased erythrocyte sedimentation rate and positive serum anti-SS-A and anti-SS-B antibodies were noted. A diagnosis of Sjögren syndrome (SjS) was finally made based on a biopsy of a minor salivary gland showing infiltration of lymphocytes around the gland ducts. Steroid therapy (prednisolone 40mg/day orally) was given, and his clinical condition improved. The lesions on the head MRI decreased, and the EEG findings normalized. This case suggests that SjS has a wide spectrum, including neurological disorders, and that SjS should be considered in the differential diagnosis of CJD.

Epub 2012 Nov 8.	increase to plateau. Reactive oxygen species (ROS) modulate the heat plateau in healthy controls. The initial peak, due to C-fiber nociceptor-mediated axon reflexes, is blunted with local anesthetics and may serve as a surrogate for the cutaneous response to peripheral heat. Chronic fatigue syndrome (CFS) subjects report increased perception of pain. To determine the role of ROS in this neurally mediated response, we evaluated changes in cutaneous blood flow from local heat in nine CFS subjects (16-22 yr) compared with eight healthy controls (18-26 yr). We heated skin to 42°C and measured local blood flow as a percentage of maximum cutaneous vascular conductance (%CVC(max)). Although CFS subjects had significantly lower baseline flow [8.75 ± 0.56 vs. 12.27 ± 1.07 (%CVC(max), CFS vs. control)], there were no differences between groups to local heat. We then remeasured this with apocynin to inhibit NADPH oxidase, allopurinol to inhibit xanthine oxidase, tempol to inhibit superoxide, and ebselen to reduce H(2)O(2). Apocynin significantly increased baseline blood flow (before heat, 14.91 ± 2.21 vs. 8.75 ± 1.66) and the first heat peak (69.33 ± 3.36 vs. 59.75 ± 2.75). Allopurinol and ebselen only enhanced the first heat peaks (71.55 ± 2.48 vs. 61.72 ± 2.01 and 76.55 ± 5.21 vs. 58.56 ± 3.66, respectively). Tempol had no effect on local heating. None of these agents changed the response to local heat in control subjects. Thus the response to heat may be altered by local levels of ROS, particularly H(2)O(2) in CFS subjects, and may be related to their hyperesthesia/hyperalgesia.
Meeus M, Goubert D, De Backer F, Struyf F, Hermans L, Coppieters I, De Wandele I, Da Silva H, Calders P.	Department of Rehabilitation Sciences and Physiotherapy, Ghent University and Artevelde University College, Ghent Campus Heymans (UZ) 3 B3, De Pintelaan 185, Ghent, Belgium; "Pain in Motion" Research Group, Department of Rehabilitation Sciences and Physiotherapy, Faculty of Medicine and Health Sciences, University of Antwerp, Belgium. Electronic address: mira.meeus@artesis.be.	Heart rate variability in patients with fibromyalgia and patients with chronic fatigue syndrome: a systematic review.	Semin Arthritis Rheum. 2013 Oct; 43(2):279-87. doi: 10.1016/j.semarthrit.2013.03.004. Epub 2013 Jul 6.	OBJECTIVE: The goal of this systematic literature review is to determine whether there are differences and similarities in heart rate variability (HRV) between adult patients with fibromyalgia (FM), chronic fatigue syndrome (CFS), and healthy pain-free control subjects. METHODS: To obtain relevant articles, PubMed and Web of Knowledge were searched for case-control studies. Selection of the literature was based on selection criteria ascertaining studies with adult human patient groups comparing HRV. Risk of bias and levels of evidence were determined. RESULTS: Sixteen case-control studies were included, 10 comparing FM patients to controls and 6 comparing CFS patients to controls. Methodological quality was moderate to good. Both time domain and frequency domain measurements were used. The majority of the researchers observed lower HRV in FM patients compared to healthy control persons, as well as increased sympathetic activity and a blunted autonomic response to stressors. Resistance training improved HRV in FM patients. In CFS patients HRV was only reduced during sleep. CONCLUSION: FM patients show more HRV aberrances and indices of increased sympathetic activity. Increased sympathetic activity is only present in CFS patients at night. Since direct comparisons are lacking and some confounders have to be taken into account, further research is warranted. The role of pain and causality can be subject of further research, as well as therapy studies directed to reduced HRV.

Meeus M, Ickmans K, Struyf F, Hermans L, Van Noesel K, Oderkerk J, Declerck LS, Moorkens G, Hans G, Grosemans S, Nijs J.	Department of Human Physiology and Rehabilitation Sciences, Vrije Universiteit Brussels, Belgium. Mira.Meeus@artesis.be	Does acetaminophen activate endogenous pain inhibition in chronic fatigue syndrome/fibromyalgia and rheumatoid arthritis? A double-blind randomized controlled cross-over trial.	Pain Physician. 2013 Mar-Apr; 16(2):E61-70.	BACKGROUND: Although enhanced temporal summation (TS) and conditioned pain modulation (CPM), as characteristic for central sensitization, has been proved to be impaired in different chronic pain populations, the exact nature is still unknown. OBJECTIVES: We examined differences in TS and CPM in 2 chronic pain populations, patients with both chronic fatigue syndrome (CFS) and comorbid fibromyalgia (FM) and patients with rheumatoid arthritis (RA), and in sedentary, healthy controls, and evaluated whether activation of serotonergic descending pathways by acetaminophen improves central pain processing. STUDY DESIGN: Double-blind randomized controlled trial with cross-over design. METHODS: Fifty-three women (19 CFS/FM patients, 16 RA patients, and 18 healthy women) were randomly allocated to the experimental group (1 g acetaminophen) or the placebo group (1 g dextrose). Participants underwent an assessment of endogenous pain inhibition, consisting of an evaluation of temporal summation with and without conditioned pain modulation (CPM). Seven days later groups were crossed-over. Patients and assessors were blinded for the allocation. RESULTS: After intake of acetaminophen, pain thresholds increased slightly in CFS/FM patients, and decreased in the RA and the control group. Temporal summation was reduced in the 3 groups and CPM at the shoulder was better overall, however only statistically significant for the RA group. Healthy controls showed improved CPM for both finger and shoulder after acetaminophen, although not significant. LIMITATIONS: The influence of acetaminophen on pain processing is inconsistent, especially in the patient groups examined. CONCLUSION: This is the first study comparing the influence of acetaminophen on central pain processing in healthy controls and patients with CFS/FM and RA. It seems that CFS/FM patients present more central pain processing abnormalities than RA patients, and that acetaminophen may have a limited positive effect on central pain inhibition, but other contributors have to be identified and evaluated.
Meeus M, Nijs J, Hermans L, Goubert D, Calders P.	University of Antwerp, Faculty of Medicine and Health Sciences, Department of Rehabilitation Sciences and Physiotherapy, Pain in Motion Research Group, Antwerp, Belgium. mira.meeus@ugent.be	The role of mitochondrial dysfunctions due to oxidative and nitrosative stress in the chronic pain or chronic fatigue syndromes and fibromyalgia patients: peripheral and central mechanisms as therapeutic targets?	Expert Opin Ther Targets. 2013 Sep; 17(9):1081-9. doi: 10.1517/14728222.2013.818657. Epub 2013 Jul 9.	INTRODUCTION: Chronic fatigue syndrome (CFS) and fibromyalgia (FM) are characterized by persistent pain and fatigue. It is hypothesized that reactive oxygen species (ROS), caused by oxidative and nitrosative stress, by inhibiting mitochondrial function can be involved in muscle pain and central sensitization as typically seen in these patients. AREAS COVERED: The current evidence regarding oxidative and nitrosative stress and mitochondrial dysfunction in CFS and FM is presented in relation to chronic widespread pain. Mitochondrial dysfunction has been shown in leukocytes of CFS patients and in muscle cells of FM patients, which could explain the muscle pain. Additionally, if mitochondrial dysfunction is also present in central neural cells, this could result in lowered ATP pools in neural cells, leading to generalized hypersensitivity and chronic widespread pain. EXPERT OPINION: Increased ROS in CFS and FM, resulting in impaired mitochondrial function and reduced ATP in muscle and neural cells, might lead to chronic widespread pain in these patients. Therefore,

				targeting increased ROS by antioxidants and targeting the mitochondrial biogenesis could offer a solution for the chronic pain in these patients. The role of exercise therapy in restoring mitochondrial dysfunction remains to be explored, and provides important avenues for future research in this area.
Melikoglu M, Melikoglu MA.	Department of Dermatology, Ministry of Health Erzurum Regional Training and Research Hospital, Erzurum, Turkey. mmelikoglu@gmail.com	The prevalence of fibromyalgia in patients with Behçet's disease and its relation with disease activity.	Rheumatol Int. 2013 May; 33(5):1219-22. doi: 10.1007/s00296-012-2530-1. Epub 2012 Sep 28.	Behçet's disease (BD) is a chronic disorder characterized by mucocutaneous and multisystem manifestations. Fibromyalgia (FM) is characterized by widespread musculoskeletal pain and may be present concomitantly with several rheumatic diseases. Our aims were to investigate the prevalence of FM in patients with BD and to evaluate the possible relation of FM presence with BD disease activity. A total of 104 Behcet patients were included in this study. Age, sex, disease durations and the BD Current Activity Form (BDCAF) scores as disease activity evaluation were recorded. Presence of FM and the Fibromyalgia Impact Questionnaire (FIQ) scores was investigated. Also, ESR and CRP concentrations were determined in all patients. Mann-Whitney U test and Pearson's correlation tests were used for the statistical analysis. There were 60 female and 40 male patients with an age range of 19-51 years. Eighteen of 100 BD patients were diagnosed as FM. Although ages, disease duration and laboratory parameters did not differ between BD patients with and without FM, BD patients with FM were more frequently female ($p < 0.000$). The presence of FM did not differ significantly between patients with and without systemic manifestations. Also, oral-genital ulcers, erythema nodosum, thrombophlebitis, pustular lesions and doctor's impression of disease activity scores were not found to be different in BD patients with or without FM. However, there were significant differences in fatigue, headache, arthralgia and patient impression of disease activity (today and last 28 days) between these groups ($p < 0.000$; $p < 0.01$; $p < 0.01$; $p = 0.021$ and $p = 0.027$, respectively). Also, there were significant correlations between BDCAF and FIQ items that refer pain and fatigue ($p < 0.01$). FM is a common and important clinical problem that may represent an additional factor that worsens pain and physical limitations in patients with BD. The higher prevalence of FM in patients with BD seems to be affected by BD itself, rather than its severity.

	Education, St George's, University of London, London, UK.	sleep and activity levels in disease-free breast cancer patients with or without cancer-related fatigue syndrome.	2012 May 31.	objective cognitive function, activity levels and sleep in disease-free women who do and do not meet criteria for cancer-related fatigue syndrome (CRFS). METHODS: Women between 3 months and 2 years after completion of any primary therapy were recruited from a cancer centre follow-up clinic. On the basis of a diagnostic semi-structured interview they were classified as being CRFS cases or non-fatigued controls. Participants underwent objective cognitive testing using a computerised battery, wore an activity monitor for 1 week and completed quality of life and fatigue questionnaires. RESULTS: 114 women were recruited (69 controls and 45 CRFS cases). There were significant differences between groups on fatigue, mood, sleep and quality of life scores, and in objective cognitive testing (tests of sustained attention, reaction time and verbal memory all $p<0.03$). There was an overall difference in daytime activity ($p=0.03$) from actigraphy recordings. There were no differences on objective measures of sleep or in routine laboratory measures. CONCLUSIONS: Our preliminary results suggest that disease-free women with CRFS after successful breast cancer treatment have significantly lower subjective quality of life and mood. Additionally, objective cognitive impairment in certain domains may play an important role in the subjective manifestation of these symptoms. There is also objective evidence on actigraphy of differing levels of activity. The subjective sleep disturbance and higher prevalence of insomnia do not correlate with objective measures.
Mizuno K, Watanabe Y.	Pathophysiological and Health Science Team, RIKEN Center for Life Science Technologies Kobe City, Hyogo, Japan ; Department of Physiology, Osaka City University Graduate School of Medicine Osaka, Japan ; Department of Medical Science on Fatigue, Osaka City University Graduate School of Medicine Osaka, Japan.	Neurocognitive impairment in childhood chronic fatigue syndrome.	Front Physiol. 2013 Apr 19; 4:87. doi: 10.3389/fphys.2013.00087. eCollection 2013.	Neurocognitive impairment is a feature of childhood chronic fatigue syndrome (CCFS). Several studies have demonstrated reduced attention control in CCFS patients in switching and divided attention tasks. In students, the extent of deterioration in task performance depends on the level of fatigue. Poor performance in switching and divided attention is common in both fatigued students and CCFS patients. Additionally, attentional functions show dramatic development from childhood to adolescence, suggesting that abnormal development of switching and divided attention may be induced by chronic fatigue. The brain structures associated with attentional control are situated in the frontal and parietal cortices, which are the last to mature, suggesting that severe fatigue in CCFS patients and students may inhibit normal structural and functional development in these regions. A combination of treatment with cognitive behavioral therapy and antidepressant medication is effective to improve attentional control processing in CCFS patients. Studies identifying the features of neurocognitive impairment in CCFS have improved our current understanding of the neurophysiological mechanisms of CCFS.
Moerman RV, Bootsma H, Kroese FG, Vissink A.	Servei de Malalties Autoimmunes, Hospital Clínic, Barcelona, Spain.	Primary Sjögren syndrome: an update on current pharmacotherapy	Expert Opin Pharmacother. 2013 Feb; 14(3):279-89. doi: 10.1517/14656566.2013.767333. Epub 2013 Jan 25.	INTRODUCTION: Primary Sjögren syndrome (SS) is a chronic systemic autoimmune disease characterized by sicca features and systemic manifestations, and requires a multidisciplinary therapeutic approach. AREAS COVERED: Treatment of sicca manifestations is symptomatic and is based on the administration of topical therapies

		options and future directions.		(saliva substitutes and preservative-free artificial tears). In severe cases of keratoconjunctivitis sicca, topical cyclosporine A may be used. For patients with residual salivary gland function, stimulation of salivary flow with a sialogogue (pilocarpine or cevimeline) is the treatment of choice. The management of extraglandular features must be tailored to the specific organ(s) involved. Hydroxychloroquine may be appropriate for patients with fatigue, arthralgia and myalgia, while glucocorticoids and immunosuppressive agents should be reserved for severe systemic involvement (although no controlled trials in primary SS guide their use). RCTs have demonstrated the lack of efficacy of antitumor necrosis factor agents and promising results for B-cell depleting agents. EXPERT OPINION: The overall low level of evidence in therapeutic studies in primary SS suggests that much larger trials of the most promising therapies are necessary. The use of drugs targeting molecules and receptors involved in the etiopathogenesis of primary SS may open up a new era in the therapeutic management of the disease, but the potential risks and benefits of these agents must be weighed carefully.
Moerman RV, Bootsma H, Kroese FG, Vissink A.	Department of Rheumatology and Clinical Immunology, University of Groningen, University Medical Center Groningen, Groningen, The Netherlands.	Sjögren's syndrome in older patients: aetiology, diagnosis and management.	Drugs Aging. 2013 Mar; 30(3):137-53. doi: 10.1007/s40266-013-0050-7.	Sjögren's syndrome (SS) is a systemic autoimmune disease, characterized by chronic inflammation of exocrine glands that results in development of xerostomia and keratoconjunctivitis sicca. The disease activity of SS is not restricted to exocrine glands, and many other organs and organ systems can be involved. Diagnosis of SS in the elderly population can be challenging because xerostomia, dry eyes, symptoms of fatigue, weight loss and muscle pain are also common features of old age. Delay between clinical onset and diagnosis of SS in the elderly may be due to the shared features of SS and old age. The 2002 revised American-European Consensus Group (AECG) classification criteria for SS are the preferred tool used to confirm diagnosis of SS, but recently alternative criteria have been put forward by the American College of Rheumatology (ACR). The AECG criteria set combines subjective symptoms of dry eyes and dry mouth with objective signs of keratoconjunctivitis sicca, salivary gland dysfunction and histopathological (salivary gland biopsy) and serological (autoantibodies against SSA/Ro and SSB/La antigens) features. Treatment of SS in the elderly does not differ from that in younger patients. The aims of the treatment of SS are to control glandular and extraglandular manifestations, to prevent damage to organ systems and loss of function, and to decrease morbidity and mortality. Treatment of the elderly can be complicated by co-morbidities, an increased rate of adverse events related to therapeutic agents, and polypharmacy. Therefore, careful follow-up of the treatment is required.
Montoya JG, Kogelnik AM, Bhangoo M, Lunn MR, Flamand L, Merrihew LE, Watt	Department of Medicine, Stanford University School of Medicine, Stanford, California; Division of	Randomized clinical trial to evaluate the efficacy and safety of valganciclovir in a subset of patients	J Med Virol. 2013 Dec; 85(12):2101-9. doi: 10.1002/jmv.23713. Epub 2013 Aug 19	There is no known treatment for chronic fatigue syndrome (CFS). Little is known about its pathogenesis. Human herpesvirus 6 (HHV-6) and Epstein-Barr virus (EBV) have been proposed as infectious triggers. Thirty CFS patients with elevated IgG antibody titers against HHV-6 and EBV were randomized 2:1 to receive valganciclovir (VGCV) or placebo for 6 months in a double-blind, placebo-controlled trial. Clinical

T, Kubo JT, Paik J, Desai M.	Infectious Diseases and Geographic Medicine, Stanford University School of Medicine, Stanford, California.	with chronic fatigue syndrome.		endpoints aimed at measuring physical and mental fatigue included the Multidimensional Fatigue Inventory (MFI-20) and Fatigue Severity Scale (FSS) scores, self-reported cognitive function, and physician-determined responder status. Biological endpoints included monocyte and neutrophil counts and cytokine levels. VGCV patients experienced a greater improvement by MFI-20 at 9 months from baseline compared to placebo patients but this difference was not statistically significant. However, statistically significant differences in trajectories between groups were observed in MFI-20 mental fatigue subscore (P=0.039), FSS score (P=0.006), and cognitive function (P=0.025). VGCV patients experienced these improvements within the first 3 months and maintained that benefit over the remaining 9 months. Patients in the VGCV arm were 7.4 times more likely to be classified as responders (P=0.029). In the VGCV arm, monocyte counts decreased (P<0.001), neutrophil counts increased (P=0.037) and cytokines were more likely to evolve towards a Th1-profile (P<0.001). Viral IgG antibody titers did not differ between arms. VGCV may have clinical benefit in a subset of CFS patients independent of placebo effect, possibly mediated by immunomodulation and/or antiviral effect. Further investigation with longer treatment duration and a larger sample size is warranted.
Mørch K, Hanevik K, Rivenes AC, Bødtker JE, Næss H, Stubhaug B, Wensaas KA, Rortveit G, Eide GE, Hausken T, Langeland N.	National Centre for Tropical Infectious Diseases, Department of Medicine, Haukeland University Hospital, Bergen, Norway. kristine.morch@helse-bergen.no	Chronic fatigue syndrome 5 years after giardiasis: differential diagnoses, characteristics and natural course.	BMC Gastroenterol. 2013 Feb 12;13:28. doi: 10.1186/1471-230X-13-28.	BACKGROUND: A high prevalence of chronic fatigue has previously been reported following giardiasis after a large waterborne outbreak in Bergen, Norway in 2004. The aim of this study was to describe and evaluate differential diagnoses and natural course of fatigue five years after giardiasis among patients who reported chronic fatigue three years after the infection. METHODS: Patients who three years after Giardia infection met Chalder's criteria for chronic fatigue (n=347) in a questionnaire study among all patients who had laboratory confirmed giardiasis during the Bergen outbreak (n=1252) were invited to participate in this study five years after the infection (n=253). Structured interviews and clinical examination were performed by specialists in psychiatry, neurology and internal medicine/infectious diseases. Fukuda et al's 1994 criteria were used to diagnose chronic fatigue syndrome (CFS) and idiopathic chronic fatigue (ICF). Self-reported fatigue recorded with Chalder Fatigue Questionnaire three and five years after infection were compared. RESULTS: 53 patients were included. CFS was diagnosed in 41.5% (22/53) and ICF in 13.2% (7/53). Chronic fatigue caused by other aetiology was diagnosed in 24.5% (13/53); five of these patients had sleep apnoea/hypopnoea syndrome, six had depression and five anxiety disorder, and among these two had more than one diagnosis. Fatigue had resolved in 20.8% (11/53). Self-reported fatigue score in the cohort was significantly reduced at five years compared to three years (p<0.001). CONCLUSION: The study shows that Giardia duodenalis may induce CFS persisting as long as five years after the infection. Obstructive sleep apnoea/hypopnoea syndrome, depression and anxiety were important differential diagnoses, or possibly comorbidities, to post-

				infectious fatigue in this study. Improvement of chronic fatigue in the period from three to five years after giardiasis was found.
Morris G, Anderson G, Berk M, Maes M.	Tir Na Nog, Bryn Road Seaside 87, Llanelli, SA152LW, Wales, UK.	Coenzyme Q10 depletion in medical and neuropsychiatric disorders: potential repercussions and therapeutic implications	Mol Neurobiol. 2013 Dec; 48(3):883-903. doi: 10.1007/s12035-013-8477-8. Epub 2013 Jun 13.	Coenzyme Q10 (CoQ10) is an antioxidant, a membrane stabilizer, and a vital cofactor in the mitochondrial electron transport chain, enabling the generation of adenosine triphosphate. It additionally regulates gene expression and apoptosis; is an essential cofactor of uncoupling proteins; and has anti-inflammatory, redox modulatory, and neuroprotective effects. This paper reviews the known physiological role of CoQ10 in cellular metabolism, cell death, differentiation and gene regulation, and examines the potential repercussions of CoQ10 depletion including its role in illnesses such as Parkinson's disease, depression, myalgic encephalomyelitis/chronic fatigue syndrome, and fibromyalgia. CoQ10 depletion may play a role in the pathophysiology of these disorders by modulating cellular processes including hydrogen peroxide formation, gene regulation, cytoprotection, bioenegetic performance, and regulation of cellular metabolism. CoQ10 treatment improves quality of life in patients with Parkinson's disease and may play a role in delaying the progression of that disorder. Administration of CoQ10 has antidepressive effects. CoQ10 treatment significantly reduces fatigue and improves ergonomic performance during exercise and thus may have potential in alleviating the exercise intolerance and exhaustion displayed by people with myalgic encepholamyletis/chronic fatigue syndrome. Administration of CoQ10 improves hyperalgesia and quality of life in patients with fibromyalgia. The evidence base for the effectiveness of treatment with CoQ10 may be explained via its ability to ameliorate oxidative stress and protect mitochondria.
Morris G, Anderson G, Galecki P, Berk M, Maes M.	Tir Na Nog, Bryn Road Seaside 87, Llanelli SA152LW, UK.	A narrative review on the similarities and dissimilarities between myalgic encephalomyelitis/chronic fatigue syndrome (ME/CFS) and sickness behavior.	BMC Med. 2013 Mar 8; 11:64. doi: 10.1186/1741-7015-11-64.	It is of importance whether myalgic encephalomyelitis/chronic fatigue syndrome (ME/CFS) is a variant of sickness behavior. The latter is induced by acute infections/injury being principally mediated through proinflammatory cytokines. Sickness is a beneficial behavioral response that serves to enhance recovery, conserves energy and plays a role in the resolution of inflammation. There are behavioral/symptomatic similarities (for example, fatigue, malaise, hyperalgesia) and dissimilarities (gastrointestinal symptoms, anorexia and weight loss) between sickness and ME/CFS. While sickness is an adaptive response induced by proinflammatory cytokines, ME/CFS is a chronic, disabling disorder, where the pathophysiology is related to activation of immunoinflammatory and oxidative pathways and autoimmune responses. While sickness behavior is a state of energy conservation, which plays a role in combating pathogens, ME/CFS is a chronic disease underpinned by a state of energy depletion. While sickness is an acute response to infection/injury, the trigger factors in ME/CFS are less well defined and encompass acute and chronic infections, as well as inflammatory or autoimmune diseases. It is concluded that sickness behavior and ME/CFS are two different conditions.
Morris G, Berk M,	Mumbles Head,	The Emerging Role of	Mol Neurobiol. 2013 Sep 26.	The World Health Organization classifies myalgic encephalomyelitis/chronic fatigue

Galecki P, Maes M.	Pembrey, Llanelli, UK.	Autoimmunity in Myalgic Encephalomyelitis/Chronic Fatigue Syndrome (ME/cfs).	[Epub ahead of print]	syndrome (ME/cfs) as a nervous system disease. Together with other diseases under the G93 heading, ME/cfs shares a triad of abnormalities involving elevated oxidative and nitrosative stress (O&NS), activation of immuno-inflammatory pathways, and mitochondrial dysfunctions with depleted levels of adenosine triphosphate (ATP) synthesis. There is also abundant evidence that many patients with ME/cfs (up to around 60 %) may suffer from autoimmune responses. A wide range of reported abnormalities in ME/cfs are highly pertinent to the generation of autoimmunity. Here we review the potential sources of autoimmunity which are observed in people with ME/cfs. The increased levels of pro-inflammatory cytokines, e.g., interleukin-1 and tumor necrosis factor-α, and increased levels of nuclear factor-κB predispose to an autoimmune environment. Many cytokine abnormalities conspire to produce a predominance of effector B cells and autoreactive T cells. The common observation of reduced natural killer cell function in ME/cfs is a source of disrupted homeostasis and prolonged effector T cell survival. B cells may be pathogenic by playing a role in autoimmunity independent of their ability to produce antibodies. The chronic or recurrent viral infections seen in many patients with ME/cfs can induce autoimmunity by mechanisms involving molecular mimicry and bystander activation. Increased bacterial translocation, as observed in ME/cfs, is known to induce chronic inflammation and autoimmunity. Low ATP production and mitochondrial dysfunction is a source of autoimmunity by inhibiting apoptosis and stimulating necrotic cell death. Self-epitopes may be damaged by exposure to prolonged O&NS, altering their immunogenic profile and become a target for the host's immune system. Nitric oxide may induce many faces of autoimmunity stemming from elevated mitochondrial membrane hyperpolarization and blockade of the methionine cycle with subsequent hypomethylation of DNA. Here we also outline options for treatment involving rituximab and endotherapia.
Morris G, Maes M.	Tir Na Nog, Pembrey, Llanelli, UK. activatedmicroglia@gmail.com.	Myalgic encephalomyelitis/ chronic fatigue syndrome and encephalomyelitis disseminata/multiple sclerosis show remarkable levels of similarity in phenomenology and neuroimmune characteristics.	BMC Med. 2013 Sep 17;11:205. doi: 10.1186/1741-7015-11-205.	BACKGROUND: 'Encephalomyelitis disseminata' (multiple sclerosis) and myalgic encephalomyelitis/chronic fatigue syndrome (ME/CFS) are both classified as diseases of the central nervous system by the World Health Organization. This review aims to compare the phenomenological and neuroimmune characteristics of MS with those of ME/CFS. DISCUSSION: There are remarkable phenomenological and neuroimmune overlaps between both disorders. Patients with ME/CFS and MS both experience severe levels of disabling fatigue and a worsening of symptoms following exercise and resort to energy conservation strategies in an attempt to meet the energy demands of day-to-day living. Debilitating autonomic symptoms, diminished cardiac responses to exercise, orthostatic intolerance and postural hypotension are experienced by patients with both illnesses. Both disorders show a relapsing-remitting or progressive course, while infections and psychosocial stress play a large part in worsening of fatigue symptoms. Activated immunoinflammatory, oxidative and nitrosative (O+NS) pathways and autoimmunity occur in both illnesses. The consequences of O+NS

				damage to self-epitopes is evidenced by the almost bewildering and almost identical array of autoantibodies formed against damaged epitopes seen in both illnesses. Mitochondrial dysfunctions, including lowered levels of ATP, decreased phosphocreatine synthesis and impaired oxidative phosphorylation, are heavily involved in the pathophysiology of both MS and ME/CFS. The findings produced by neuroimaging techniques are quite similar in both illnesses and show decreased cerebral blood flow, atrophy, gray matter reduction, white matter hyperintensities, increased cerebral lactate and choline signaling and lowered acetyl-aspartate levels. SUMMARY: This review shows that there are neuroimmune similarities between MS and ME/CFS. This further substantiates the view that ME/CFS is a neuroimmune illness and that patients with MS are immunologically primed to develop symptoms of ME/CFS
Morris G, Maes M.	Mumbles Head, Pembrey llanelli, UK.	Case definitions and diagnostic criteria for Myalgic Encephalomyelitis and Chronic fatigue Syndrome: from clinical-consensus to evidence-based case definitions.	Neuro Endocrinol Lett. 2013; 34(3):185-99.	The symptom spectrum of Myalgic Encephalomyelitis (ME) was first detailed in 1959 and later operationalised into a diagnostic protocol (Melvin Ramsey). In 1988 the Holmes case definition coined the term chronic fatigue syndrome (CFS). Fukuda's Centers for Disease Control and Prevention criteria are very heterogeneous and comprise patients with milder symptoms than the Holmes case definition. The CDC Empirical Criteria for CFS lack sensitivity and/or specificity. Other CFS definitions, e.g. the Oxford criteria, delineate people with idiopathic fatigue. Some authors make the clinical CFS diagnosis when slightly increased self-rated fatigue scores are present. In 2011, Carruthers' International Consensus Criteria attempted to restore the focus on selecting people who suffer from ME. Cognitive bias in criteria construction, patient selection, data collection and interpretation has led to the current state of epistemological chaos with ME, CFS, CFS/ME and ME/CFS, and CF being used interchangeably. Moreover, none of the above mentioned classifications meet statistically based criteria for validation. Diagnostic criteria should be based on statistical methods rather than consensus declarations. Ongoing discussions about which case definition to employ miss the point that the criteria did not pass appropriate external validation. In 2012, Maes et al. performed pattern recognition methods and concluded that CFS patients (according to Fukuda's criteria) should be divided into those with CFS or ME, on the basis that people with ME display a worsening of their illness following increases in physical or cognitive activity. Both ME and CFS are complex disorders that share neuro-immune disturbances, which are more severe in ME than in CFS. This paper expands on that strategy and details a range of objective tests, which confirm that a person with ME or CFS has a neuro-immune disease. By means of pattern recognition methods future research should refine the Maes' case definitions for ME and CFS by including well-scaled symptoms, staging characteristics and neuro-immune biomarkers, including immune-inflammatory assays, bioenergetic markers and brain imaging.
Morris G, Maes M.	Tir Na Nog, Pembrey,	A neuro-immune	Metab Brain Dis. 2013 Dec;	This paper proposes a neuro-immune model for Myalgic Encephalomyelitis/Chronic

	Llanelli, UK.	model of Myalgic Encephalomyelitis/Chronic fatigue syndrome.	28(4):523-40. doi: 10.1007/s11011-012-9324-8. Epub 2012 Jun 21.	fatigue syndrome (ME/CFS). A wide range of immunological and neurological abnormalities have been reported in people suffering from ME/CFS. They include abnormalities in proinflammatory cytokines, raised production of nuclear factor-κB, mitochondrial dysfunctions, autoimmune responses, autonomic disturbances and brain pathology. Raised levels of oxidative and nitrosative stress (O&NS), together with reduced levels of antioxidants are indicative of an immuno-inflammatory pathology. A number of different pathogens have been reported either as triggering or maintaining factors. Our model proposes that initial infection and immune activation caused by a number of possible pathogens leads to a state of chronic peripheral immune activation driven by activated O&NS pathways that lead to progressive damage of self epitopes even when the initial infection has been cleared. Subsequent activation of autoreactive T cells conspiring with O&NS pathways cause further damage and provoke chronic activation of immuno-inflammatory pathways. The subsequent upregulation of proinflammatory compounds may activate microglia via the vagus nerve. Elevated proinflammatory cytokines together with raised O&NS conspire to produce mitochondrial damage. The subsequent ATP deficit together with inflammation and O&NS are responsible for the landmark symptoms of ME/CFS, including post-exertional malaise. Raised levels of O&NS subsequently cause progressive elevation of autoimmune activity facilitated by molecular mimicry, bystander activation or epitope spreading. These processes provoke central nervous system (CNS) activation in an attempt to restore immune homeostatsis. This model proposes that the antagonistic activities of the CNS response to peripheral inflammation, O&NS and chronic immune activation are responsible for the remitting-relapsing nature of ME/CFS. Leads for future research are suggested based on this neuro-immune model.
Morriss R.	[No address quoted]	Chronic fatigue syndrome/myalgic encephalomyelitis: more heat, some light--directions for research and clinical practice.	J Neurol Neurosurg Psychiatry. 2013 Feb 13. [Epub ahead of print]	[No abstract given]
Moss-Morris R, Deary V, Castell B.	Psychology Department, King's College London, London, UK. rona.moss-morris@kcl.ac.uk	Chronic fatigue syndrome.	Handb Clin Neurol. 2013; 110:303-14. doi: 10.1016/B978-0-444-52901-5.00025-3.	Chronic fatigue syndrome (CFS) is an illness characterized by disabling fatigue of at least 6 months. The aetiology of the condition has been hotly debated. In this chapter the evidence for CFS as a post viral condition and/or a neurological condition is reviewed. Although there is evidence that CFS is triggered by certain viruses in some patients and that neurobiological changes such as hypocortisolism are associated with the syndrome, neither mechanism is sufficient to explain the extent of the symptoms or disability experienced by patients. It is unlikely that CFS can be understood through one aetiological mechanism. Rather it is a complex illness which is best explained in

				terms of a multifactorial cognitive behavioural model. This model proposes that CFS is precipitated by life events and/or viral illness in vulnerable individuals, such as those who are genetically predisposed, prone to distress, high achievement, and over or under activity. A self perpetuating cycle where physiological changes, illness beliefs, reduced and inconsistent activity, sleep disturbance, medical uncertainty and lack of guidance interact to maintain symptoms. Treatments based on this model including cognitive behavioural therapy and graded exercise therapy are effective at significantly reducing fatigue and disability in CFS. This chapter provides a description of these approaches and details of the trials conducted in the area.
Mostafalou S, Abdollahi M.	Department of Toxicology and Pharmacology, Faculty of Pharmacy and Pharmaceutical Sciences Research Center, Tehran University of Medical Sciences, Tehran, Iran.	Pesticides and human chronic diseases: evidences, mechanisms, and perspectives.	Toxicol Appl Pharmacol. 2013 Apr 15; 268(2):157-77. doi: 10.1016/j.taap.2013.01.025. Epub 2013 Feb 9.	Along with the wide use of pesticides in the world, the concerns over their health impacts are rapidly growing. There is a huge body of evidence on the relation between exposure to pesticides and elevated rate of chronic diseases such as different types of cancers, diabetes, neurodegenerative disorders like Parkinson, Alzheimer, and amyotrophic lateral sclerosis (ALS), birth defects, and reproductive disorders. There is also circumstantial evidence on the association of exposure to pesticides with some other chronic diseases like respiratory problems, particularly asthma and chronic obstructive pulmonary disease (COPD), cardiovascular disease such as atherosclerosis and coronary artery disease, chronic nephropathies, autoimmune diseases like systemic lupus erythematous and rheumatoid arthritis, chronic fatigue syndrome, and aging. The common feature of chronic disorders is a disturbance in cellular homeostasis, which can be induced via pesticides' primary action like perturbation of ion channels, enzymes, receptors, etc., or can as well be mediated via pathways other than the main mechanism. In this review, we present the highlighted evidence on the association of pesticide's exposure with the incidence of chronic diseases and introduce genetic damages, epigenetic modifications, endocrine disruption, mitochondrial dysfunction, oxidative stress, endoplasmic reticulum stress and unfolded protein response (UPR), impairment of ubiquitin proteasome system, and defective autophagy as the effective mechanisms of action.
Murgai M, Thomas J, Cherepanova O, Delviks-Frankenberry K, Deeble P, Pathak VK, Rekosh D, Owens G.	Robert M, Berne Cardiovascular Research Center, University of Virginia, School of Medicine Charlottesville, Charlottesville, VA 22908, USA.	Xenotropic MLV envelope proteins induce tumor cells to secrete factors that promote the formation of immature blood vessels.	Retrovirology. 2013 Mar 27; 10:34. doi: 10.1186/1742-4690-10-34.	BACKGROUND: Xenotropic Murine leukemia virus-Related Virus (XMRV) is a γ-retrovirus initially reported to be present within familial human prostate tumors and the blood of patients with chronic fatigue syndrome. Subsequent studies however were unable to replicate these findings, and there is now compelling evidence that the virus evolved through rare retroviral recombination events in human tumor cell lines established through murine xenograft experiments. There is also no direct evidence that XMRV infection has any functional effects that contribute to tumor pathogenesis. RESULTS: Herein we describe an additional xenotropic MLV, "B4rv", found in a cell line derived from xenograft experiments with the human prostate cancer LNCaP cell line. When injected subcutaneously in nude mice, LNCaP cells infected with XMRV or B4rv formed larger tumors that were highly hemorrhagic and displayed poor pericyte/smooth muscle cell (SMC) investment, markers of increased

				metastatic potential. Conditioned media derived from XMRV- or B4rv-infected LNCaPs, but not an amphotropic MLV control virus infected LNCaPs, profoundly decreased expression of marker genes in cultured SMC, consistent with inhibition of SMC differentiation/maturation. Similar effects were seen with a chimeric virus of the amphotropic MLV control virus containing the XMRV env gene, but not with an XMRV chimeric virus containing the amphotropic MLV env gene. UV-inactivated XMRV and pseudovirions that were pseudotyped with XMRV envelope protein also produce conditioned media that down-regulated SMC marker gene expression in vitro. CONCLUSIONS: Together these results indicate that xenotropic MLV envelope proteins are sufficient to induce the production of factors by tumor cells that suppress vascular SMC differentiation, providing evidence for a novel mechanism by which xenotropic MLVs might alter tumor pathogenesis by disrupting tumor vascular maturation. Although it is highly unlikely that either XMRV or B4Rv themselves infect humans and are pathogenic, the results suggest that xenograft approaches commonly used in the study of human cancer promote the evolution of novel retroviruses with pathogenic properties.
Murray B, Yashar BM, Uhlmann WR, Clauw DJ, Petty EM.	Division of Cardiology, Johns Hopkins Hospital, Baltimore, Maryland.	Ehlers-Danlos syndrome, hypermobility type: A characterization of the patients' lived experience.	Am J Med Genet A. 2013 Dec; 161(12):2981-8. doi: 10.1002/ajmg.a.36293. Epub 2013 Nov 6.	Hypermobility type Ehlers-Danlos syndrome (EDS-HT) is an inherited connective tissue disorder clinically diagnosed by the presence of significant joint hypermobility and associated skin manifestations. This article presents a large-scale study that reports the lived experience of EDS-HT patients, the broad range of symptoms that individuals with EDS-HT experience, and the impact these symptoms have on daily functioning. A 237-item online survey, including validated questions regarding pain and depression, was developed. Four hundred sixty-six (466) adults (90% female, 52% college or higher degree) with a self-reported diagnosis of EDS-HT made in a clinic or hospital were included. The most frequently reported symptoms were joint pain (99%), hypermobility (99%), and limb pain (91%). They also reported a high frequency of other conditions including chronic fatigue (82%), anxiety (73%), depression (69%), and fibromyalgia (42%). Forty-six percent of respondents reported constant pain often described as aching and tiring/exhausting. Despite multiple interventions and therapies, many individuals (53%) indicated that their diagnosis negatively affected their ability to work or attend school. Our results show that individuals with EDS-HT can experience a wide array of symptoms and co-morbid conditions. The degree of constant pain and disability experienced by the majority of EDS-HT respondents is striking and illustrates the impact this disorder has on quality of life as well as the clinical challenges inherent in managing this complex connective tissue disorder.
Myhill S, Booth NE, McLaren-Howard J.	Sarah Myhill Ltd Llangunllo, Powys UK.	Targeting mitochondrial dysfunction in the treatment of Myalgic Encephalomyelitis/C	Int J Clin Exp Med. 2013; 6(1):1-15. Epub 2012 Nov 20.	We report on an audit of 138 ME/CFS patients who attended a private practice and took the ATP Profile biomedical test. The results revealed that all of these patients had measureable mitochondrial dysfunction. A basic treatment regime, based on 1) eating the evolutionary correct stone-age diet, 2) ensuring optimum hours of good quality sleep, 3) taking a standard package of nutritional supplements, and 4) getting

		hronic Fatigue Syndrome (ME/CFS) - a clinical audit.		the right balance between work and rest, was recommended for all patients. Additions to the basic regime were tailored for each patient according to the results of the ATP Profile and additional nutritional tests and clues from the clinical history. Mitochondrial function is typically impaired in two ways: substrate or co-factor deficiency, and inhibition by chemicals, exogenous or endogenous. For the former, additional nutrients are recommended where there is a deficiency, and for the latter, improvement of anti-oxidant status and selective chelation therapy or far-infrared saunas are appropriate. We show case histories of nine patients who have taken the ATP Profile on three or four occasions, and a before-and-after treatment summary of the 34 patients who have had at least two ATP Profile tests separated by some months. Finally, we summarize the results for the 30 patients who followed all aspects of the treatment regime and compare them with the 4 patients who were lax on two or more aspects of the treatment regime. All patients who followed the treatment regime improved in mitochondrial function by on average a factor of 4.
Nakamura T, Schwander S, Donnelly R, Cook DB, Ortega F, Togo F, Yamamoto Y, Cherniack NS, Klapholz M, Rapoport D, Natelson BH.	Pain & Fatigue Study Center.	Exercise and sleep deprivation do not change cytokine expression levels in patients with chronic fatigue syndrome.	Clin Vaccine Immunol. 2013 Nov; 20 (11):1736-42. doi: 10.1128/CVI.00527-13. Epub 2013 Sep 11.	A major hypothesis regarding the cause of chronic fatigue syndrome (CFS) is immune dysregulation, thought to be reflected in upregulated proinflammatory cytokines leading to the symptoms that are characteristic of this illness. Because the symptoms worsen with physical exertion or sleep loss, we hypothesized that we could use these stressors to magnify the underlying potential pathogenic abnormalities in the cytokine systems of people with CFS. We conducted repeat blood sampling for cytokine levels from healthy subjects and CFS patients during both postexercise and total sleep deprivation nights and assayed for protein levels in the blood samples, mRNA activity in peripheral blood lymphocytes (PBLs), and function in resting and stimulated PBLs. We found that these environmental manipulations did not produce clinically significant upregulation of proinflammatory cytokines. These data do not support an important role of immune dysregulation in the genesis of stress-induced worsening of CFS.
Nam KJ, Kim YJ, Lee SY, Lee JG, Cho YH, Lee YH, Choi EJ, Tak YJ, Yi DW, Park SW, Jeong DW.	Department of Family Medicine, Pusan National University Yangsan Hospital, Yangsan, Korea.	A case of incidentally discovered subclinical Cushing syndrome in a patient with chronic fatigue and anxiety.	Korean J Fam Med. 2013 Jul;34(4):289-92. doi: 10.4082/kjfm.2013.34.4.289. Epub 2013 Jul 24.	Subclinical Cushing syndrome (SCS) is a hypothalamic-pituitary-adrenal axis abnormality characterized by autonomous cortisol secretion in patients with no typical signs or symptoms of Cushing syndrome. SCS patients may have adverse metabolic and cardiovascular effects due to slight, but continuous glucocorticoid secretion. Glucocorticoids also affect behavior, mood, neural activity, and a number of specific biochemical processes in the central nervous system. Here, we report a case of SCS due to an adrenal incidentaloma in a hypertensive diabetic patient who presented with chronic fatigue and anxiety that disappeared after the removal of the adrenal adenoma.
Natelson BH.	Director, Pain and Fatigue Study Center, Department of Pain Medicine and Palliative	Brain dysfunction as one cause of CFS symptoms including difficulty with	Front Physiol. 2013 May 20; 4:109. doi: 10.3389/fphys.2013.00109. eCollection 2013.	We have been able to reduce substantially patient pool heterogeneity by identifying phenotypic markers that allow the researcher to stratify chronic fatigue syndrome (CFS) patients into subgroups. To date, we have shown that stratifying based on the presence or absence of comorbid psychiatric diagnosis leads to a group with evidence

	Care, Beth Israel Medical Center, Manhattan New York, NY, USA; Professor of Neurology, Albert Einstein College of Medicine, Bronx New York, NY, USA.	attention and concentration.		of neurological dysfunction across a number of spheres. We have also found that stratifying based on the presence or absence of comorbid fibromyalgia leads to information that would not have been found on analyzing the entire, unstratified patient group. Objective evidence of orthostatic intolerance (OI) may be another important variable for stratification and may define a group with episodic cerebral hypoxia leading to symptoms. We hope that this review will encourage other researchers to collect data on discrete phenotypes in CFS to allow this work to continue more broadly. Finding subgroups of CFS suggests different underlying pathophysiological processes responsible for the symptoms seen. Understanding those processes is the first step toward developing discrete treatments for each.
Neblett R, Cohen H, Choi Y, Hartzell MM, Williams M, Mayer TG, Gatchel RJ.	PRIDE Research Foundation, Dallas, Texas, USA.	The Central Sensitization Inventory (CSI): establishing clinically significant values for identifying central sensitivity syndromes in an outpatient chronic pain sample.	J Pain. 2013 May; 14(5):438-45. doi: 10.1016/j.jpain.2012.11.012. Epub 2013 Mar 13.	Central sensitization (CS) is a proposed physiological phenomenon in which central nervous system neurons become hyperexcitable, resulting in hypersensitivity to both noxious and non-noxious stimuli. The term central sensitivity syndrome (CSS) describes a group of medically indistinct (or nonspecific) disorders, such as fibromyalgia, chronic fatigue syndrome, and irritable bowel syndrome, for which CS may be a common etiology. In a previous study, the Central Sensitization Inventory (CSI) was introduced as a screening instrument for clinicians to help identify patients with a CSS. It was found to have high reliability and validity (test-retest reliability = .82; Cronbach's alpha = .88). The present study investigated a cohort of 121 patients who were referred to a multidisciplinary pain center, which specializes in the assessment and treatment of complex pain and psychophysiological disorders, including CSSs. A large percentage of patients (n = 89, 74%) met clinical criteria for one or more CSSs, and CSI scores were positively correlated with the number of diagnosed CSSs. A receiver operating characteristic analysis determined that a CSI score of 40 out of 100 best distinguished between the CSS patient group and a nonpatient comparison sample (N = 129) (area under the curve = .86, sensitivity = 81%, specificity = 75%).PERSPECTIVE: The CSI is a new self-report screening instrument to help identify patients with CSSs, including fibromyalgia. The present study investigated CSI scores in a heterogeneous pain population with a large percentage of CSSs, and a normative nonclinical sample to determine a clinically relevant cutoff value.
Nes LS, Ehlers SL, Whipple MO, Vincent A.	Department of Psychiatry and Psychology, Mayo Clinic, Rochester, MN, USA ; Center for Shared Decision Making and Collaborative Care Research, Oslo University Hospital,	Self-regulatory fatigue in chronic multisymptom illnesses: scale development, fatigue, and self-control.	J Pain Res. 2013; 6:181-8. doi: 10.2147/JPR.S40014. Epub 2013 Mar 6.	BACKGROUND: Self-regulatory capacity involves ability to regulate thoughts, emotions, and behavior. Chronic multisymptom illnesses such as fibromyalgia and chronic fatigue syndrome are accompanied by numerous challenges, and have recently been associated with self-regulatory fatigue (SRF). Chronic multisymptom illnesses are also frequently associated with physical fatigue, and through development of a scale measuring SRF, the current study aimed to examine how SRF can be distinguished from physical fatigue. The study also sought to distinguish SRF from self-control. METHODS: Two self-regulation researchers developed 30 items related to self-regulatory capacity. These items were distributed to patients (n = 296)

	Oslo, Norway.			diagnosed with chronic multisymptom illness together with validated measures of physical fatigue and self-control. A principal factor analysis was employed to examine factor structures, identify inter-item relationships, and aid in scale development. RESULTS: The final proposed scale consisted of 18 items measuring self-regulatory capacity (SRF-18) with cognitive, emotional, and behavioral SRF components. Internal consistency and reliability was acceptable (Cronbach's á = 0.81). The final scale was moderately correlated with self-control (r = -0.48) and highly correlated with physical fatigue (r = 0.75), although more so with emotional (r = 0.72) and mental (r = 0.65) than physical (r = 0.46) fatigue components. CONCLUSION: The current study suggests a new scale for measurement of SRF in chronic multisymptom illness. Although cross-validation studies are necessary, such a scale may contribute to a better understanding of the concept of self-regulation and the role of SRF in chronic illness. Although related to physical fatigue and self-control, the results point to SRF as a distinct construct.
Ng SM, Yiu YM.	Department of Social Work and Social Administration, University of Hong Kong, Hong Kong, China. ngsiuman@hku.hk	Acupuncture for chronic fatigue syndrome: a randomized, sham-controlled trial with single-blinded design.	Altern Ther Health Med. 2013 Jul-Aug;19 (4):21-6.	CONTEXT: Given that the etiology of chronic fatigue syndrome (CFS) is believed to be multidimensional, interventions generally have been nonspecific and typically produce only mild to moderate effects. In medical practice, treatment for CFS remains largely symptomatic. Preliminary evidence of the efficacy of acupuncture for CFS is available, but the field has lacked high-quality trials. OBJECTIVE: The research team conducted the study to determine the efficacy of acupuncture for CFS. DESIGN: A two-arm, randomized, controlled, singleblinded design was adopted. SETTING: The study took place in a teaching laboratory at the School of Chinese Medicine at the University of Hong Kong, Hong Kong, China. PARTICIPANTS: Recruited through press publicity in Hong Kong, 127 individuals--40 men and 87 women--participated in the study. Intervention Through careful implementation of sham acupuncture in the control group (CG), the study blinded all participants with regard to their experimental or control status. The treatment regime was 2 sessions/wk for 4 consecutive wk. OUTCOME MEASURES: Measures of fatigue (Chalder's Fatigue Scale), health-related quality of life (SF-12), and general mental health (GH Q-12) were taken at baseline and upon completion of treatment. RESULTS: Ninety-nine participants completed the interventions, with 50 and 49 participants in the experimental group (EG) and CG respectively. Repeated measures ANOVA revealed a significant decrease in physical (F (1,93) = 4.327; P = .040) and mental fatigue (F(1,96) = 10.451; P = .002) and improvement in the physical component score of SF-12 (F(1,93) = 4.774; P = .031). Considerable effects with Cohen's d were observed in the sham-control group: 0.92, 0.78, and 0.38 for the three scores, respectively. These positive effects could have included some therapeutic effects due to pressure on the acupuncture points from the sham needles in addition to normal placebo effects. The EG showed moderate net effect sizes with Cohen's d: 0.52, 0.63, and 0.54 for the three outcome measures, respectively. CONCLUSION: Despite considerable positive effects for the

				CG, the EG demonstrated significant net-effect sizes at a moderate magnitude in physical and mental fatigue and in the physical component of health-related quality of life. The impacts on general mental health outcomes appeared to be smaller.
Nguyen RH, Veasley C, Smolenski D.	Division of Epidemiology and Community Health, School of Public Health, University of Minnesota, Minneapolis, MN.	Latent class analysis of comorbidity patterns among women with generalized and localized vulvodynia: preliminary findings.	J Pain Res. 2013 Apr 18; 6:303-9. doi: 10.2147/JPR.S42940. Print 2013.	BACKGROUND: The pattern and extent of clustering of comorbid pain conditions with vulvodynia is largely unknown. However, elucidating such patterns may improve our understanding of the underlying mechanisms involved in these common causes of chronic pain. We sought to describe the pattern of comorbid pain clustering in a population-based sample of women with diagnosed vulvodynia. METHODS: A total of 1457 women with diagnosed vulvodynia self-reported their type of vulvar pain as localized, generalized, or both. Respondents were also surveyed about the presence of comorbid pain conditions, including temporomandibular joint and muscle disorders, interstitial cystitis, fibromyalgia, chronic fatigue syndrome, irritable bowel syndrome, endometriosis, and chronic headache. Age-adjusted latent class analysis modeled extant patterns of comorbidity by vulvar pain type, and a multigroup model was used to test for the equality of comorbidity patterns using a comparison of prevalence. A two-class model (no/single comorbidity versus multiple comorbidities) had the best fit in individual and multigroup models. RESULTS: For the no/single comorbidity class, the posterior probability prevalence of item endorsement ranged from 0.9% to 24.4%, indicating a low probability of presence. Conversely, the multiple comorbidity class showed that at least two comorbid conditions were likely to be endorsed by at least 50% of women in that class, and irritable bowel syndrome and fibromyalgia were the most common comorbidities regardless of type of vulvar pain. Prevalence of the multiple comorbidity class differed by type of vulvar pain: both (37.6% prevalence, referent), generalized (21.6% prevalence, adjusted odds ratio 0.41, 95% confidence interval 0.27-0.61), or localized (12.5% prevalence, adjusted odds ratio 0.31, 95% confidence interval 0.21-0.47). CONCLUSION: This novel work provides insight into potential shared mechanisms of vulvodynia by describing that a prominent comorbidity pattern involves having both irritable bowel syndrome and fibromyalgia. In addition, the prevalence of a multiple comorbidity class pattern increases with increasing severity of vulvar pain.

Functional improvement is accompanied by reduced pain in adolescent chronic fatigue syndrome.	Pain Med. 2013 Sep; 14(9):1435-8. doi: 10.1111/pme.12181. Epub 2013 Jun 26.	[No abstract given]
Nijhof SL, Priesterbach LP, Uiterwaal CS,	Department of Pediatrics, University Medical Center	Internet-based therapy for adolescents with	Pediatrics. 2013 Jun; 131(6):e1788-95. doi: 10.1542/peds.2012-2007.	OBJECTIVE: Cognitive behavioral therapy (CBT) is known to be an effective treatment of adolescents with chronic fatigue syndrome (CFS), but its availability is limited. Fatigue in Teenagers on the Internet (FITNET), an Internet-based CBT program for

Bleijenberg G, Kimpen JL, van de Putte EM.	Utrecht, Utrecht, Netherlands. s.l.nijhof@umcutrecht.nl	chronic fatigue syndrome: long-term follow-up.	Epub 2013 May 13.	adolescents with CFS, has been developed as an alternative to face-to-face CBT. Recently, its short-term effectiveness has been proven in a randomized clinical trial. Here we aimed to assess the long-term outcome of CFS in adolescents after FITNET treatment and after usual care. In addition, factors related to recovery at long-term follow-up (LTFU) for adolescents treated with the FITNET program were investigated. METHODS: The study was an LTFU of participants of the FITNET trial. Data were completed for 112 (88.2%) of 127 approached FITNET study participants. Primary outcomes were fatigue severity (Checklist Individual Strength-20), physical functioning (87-item Child Health Questionnaire), and school/work attendance. RESULTS: After a mean follow-up of 2.7 years, 66 (58.9%) adolescents had recovered from CFS. Most adolescents who recovered directly after treatment with FITNET were still recovered at LTFU. At LTFU there was no difference between the recovery rates for the different treatment strategies (original randomization: FITNET [64%] versus any form of usual care [52.8%]). Per additional month of "pretreatment disease duration," the odds for recovery were 4% lower (odds ratio: 0.96; 95% confidence interval: 0.93-0.99; P = .016), and per added point on "focus on bodily symptoms" (Body Consciousness Scale) of the mother (0-20 points) the odds for recovery were 11% lower (odds ratio: 0.89; 95% confidence interval: 0.80-0.99; P = .029). CONCLUSIONS: The short-term effectiveness of Internet-based CBT on adolescent CFS is maintained at LTFU. At LTFU, usual care led to similar recovery rates, although these rates were achieved at a slower pace.

Pain in Motion research group, Department of Human Physiology and Rehabilitation Sciences, Faculty of Physical Education and Physiotherapy, Vrije Universiteit Brussel, Building L-Mfys, Pleinlaan 2, 1050 Brussels, Belgium. Jo.Nijs@vub.ac.be	Fear of movement and avoidance behaviour toward physical activity in chronic-fatigue syndrome and fibromyalgia: state of the art and implications for clinical practice.	Clin Rheumatol. 2013 Aug; 32(8):1121-9. doi: 10.1007/s10067-013-2277-4. Epub 2013 May 3.	Severe exacerbation of symptoms following physical activity is characteristic for chronic-fatigue syndrome (CFS) and fibromyalgia (FM). These exacerbations make it understandable for people with CFS and FM to develop fear of performing body movement or physical activity and consequently avoidance behaviour toward physical activity. The aims of this article were to review what measures are available for measuring fear of movement and avoidance behaviour, the prevalence fear of movement and avoidance behaviour toward physical activity and the therapeutic options with fear of movement and avoidance behaviour toward physical activity in patients with CFS and FM. The review revealed that fear of movement and avoidance behaviour toward physical activity is highly prevalent in both the CFS and FM population, and it is related to various clinical characteristics of CFS and FM, including symptom severity and self-reported quality of life and disability. It appears to be crucial for treatment (success) to identify CFS and FM patients displaying fear of movement and avoidance behaviour toward physical activity. Individually tailored cognitive behavioural therapy plus exercise training, depending on the patient's classification as avoiding or persisting, appears to be the most promising strategy for treating fear of movement and avoidance behaviour toward physical activity in patients with CFS and FM.
Nirenberg MJ.	Department of Neurology, NYU School of Medicine, New York, NY, USA. melissa.nirenberg@nyumc.org	Dopamine agonist withdrawal syndrome: implications for patient care.	Drugs Aging. 2013 Aug; 30(8):587-92. doi: 10.1007/s40266-013-0090-z.	Dopamine agonists are effective treatments for a variety of indications, including Parkinson's disease and restless legs syndrome, but may have serious side effects, such as orthostatic hypotension, hallucinations, and impulse control disorders (including pathological gambling, compulsive eating, compulsive shopping/buying, and hypersexuality). The most effective way to alleviate these side effects is to taper or discontinue dopamine agonist therapy. A subset of patients who taper a dopamine agonist, however, develop dopamine agonist withdrawal syndrome (DAWS), which has been defined as a severe, stereotyped cluster of physical and psychological

				symptoms that correlate with dopamine agonist withdrawal in a dose-dependent manner, cause clinically significant distress or social/occupational dysfunction, are refractory to levodopa and other dopaminergic medications, and cannot be accounted for by other clinical factors. The symptoms of DAWS include anxiety, panic attacks, dysphoria, depression, agitation, irritability, suicidal ideation, fatigue, orthostatic hypotension, nausea, vomiting, diaphoresis, generalized pain, and drug cravings. The severity and prognosis of DAWS is highly variable. While some patients have transient symptoms and make a full recovery, others have a protracted withdrawal syndrome lasting for months to years, and therefore may be unwilling or unable to discontinue DA therapy. Impulse control disorders appear to be a major risk factor for DAWS, and are present in virtually all affected patients. Thus, patients who are unable to discontinue dopamine agonist therapy may experience chronic impulse control disorders. At the current time, there are no known effective treatments for DAWS. For this reason, providers are urged to use dopamine agonists judiciously, warn patients about the risks of DAWS prior to the initiation of dopamine agonist therapy, and follow patients closely for withdrawal symptoms during dopamine agonist taper.
Norheim KB, Le Hellard S, Nordmark G, Harboe E, Gøransson L, Brun JG, Wahren-Herlenius M, Jonsson R, Omdal R.	Clinical Immunology Unit, Department of Internal Medicine, Stavanger University Hospital, Pb. 8100 Forus, 4068, Stavanger, Norway, katnorheim@gmail.com.	A possible genetic association with chronic fatigue in primary Sjögren's syndrome: a candidate gene study.	Rheumatol Int. 2013 Sep 3. [Epub ahead of print]	Fatigue is prevalent and disabling in primary Sjögren's syndrome (pSS). Results from studies in chronic fatigue syndrome (CFS) indicate that genetic variation may influence fatigue. The aim of this study was to investigate single nucleotide polymorphism (SNP) variations in pSS patients with high and low fatigue. A panel of 85 SNPs in 12 genes was selected based on previous studies in CFS. A total of 207 pSS patients and 376 healthy controls were genotyped. One-hundred and ninety-three patients and 70 SNPs in 11 genes were available for analysis after quality control. Patients were dichotomized based on fatigue visual analogue scale (VAS) scores, with VAS <50 denominated "low fatigue" (n = 53) and VAS ≥50 denominated "high fatigue" (n = 140). We detected signals of association with pSS for one SNP in SLC25A40 (unadjusted p = 0.007) and two SNPs in PKN1 (both p = 0.03) in our pSS case versus control analysis. The association with SLC25A40 was stronger when only pSS high fatigue patients were analysed versus controls (p = 0.002). One SNP in PKN1 displayed an association in the case-only analysis of pSS high fatigue versus pSS low fatigue (p = 0.005). This candidate gene study in pSS did reveal a trend for associations between genetic variation in candidate genes and fatigue. The results will need to be replicated. More research on genetic associations with fatigue is warranted, and future trials should include larger cohorts and multicentre collaborations with sharing of genetic material to increase the statistical power.
Oakes B, Hoagland-Henefield M, Komaroff AL,	Graduate Program in Pharmacology and Experimental Therapeutics, Sackler	Human endogenous retrovirus-K18 superantigen expression and	Clin Infect Dis. 2013 May; 56(10):1394-400. doi: 10.1093/cid/cit086. Epub 2013 Feb 13.	BACKGROUND: Chronic fatigue syndrome (CFS) is a complex, heterogeneous disease characterized by debilitating fatigue that is not improved with bed rest and worsens after physical activity or mental exertion. Despite extensive research into a cause of CFS, no definitive etiology has been determined; however, a large percentage of CFS

Erickson JL, Huber BT.	School of Graduate Biomedical Sciences, Tufts University, Boston, MA, USA.	human herpesvirus-6 and human herpesvirus-7 viral loads in chronic fatigue patients.		patients note an acute infectious event that triggers their fatigue. METHODS: Blood and saliva were collected from 39 CFS cases and 9 healthy control subjects. Peripheral blood mononuclear cells (PBMCs) were tested for human endogenous retrovirus-K18 (HERV-K18) env transcripts using a TaqMan quantitative polymerase chain reaction (qPCR). In addition, viral copy number of human herpesvirus-6 (HHV-6) and human herpesvirus-7 (HHV-7) were measured in both saliva and PBMCs using TaqMan qPCRs. Transcript levels and viral copy number were compared to patient CFS symptom severity. RESULTS: HERV-K18 env transcripts were not significantly different between healthy control subjects and CFS patients. Also, HERV-K18 env transcripts did not correlate with HHV-6 viral copy number or HHV-7 viral copy number in either PBMCs or saliva. HHV-6 viral copy number and HHV-7 viral copy number in both PBMCs and saliva were not significantly different between healthy control subjects and CFS patients. HERV-K18 env transcripts, HHV-6 viral copy number, and HHV-7 viral copy number did not correlate with CFS symptom severity. CONCLUSIONS: We fail to demonstrate a difference in HERV-K18 env transcripts, HHV-6 viral copy number, and HHV-7 viral copy number between CFS patients and healthy controls. Our data do not support the hypothesis of reactivation of HHV-6 or HHV-7 in CFS.
Ocon AJ.	Departments of Physiology/Medicine, Center for Hypotension, New York Medical College Valhalla, NY, USA.	Caught in the thickness of brain fog: exploring the cognitive symptoms of Chronic Fatigue Syndrome.	Front Physiol. 2013 Apr 5; 4:63. doi: 10.3389/fphys.2013.00063. eCollection 2013.	Chronic Fatigue Syndrome (CFS) is defined as greater than 6 months of persistent fatigue that is experienced physically and cognitively. The cognitive symptoms are generally thought to be a mild cognitive impairment, but individuals with CFS subjectively describe them as "brain fog." The impairment is not fully understood and often is described as slow thinking, difficulty focusing, confusion, lack of concentration, forgetfulness, or haziness in thought processes. Causes of "brain fog" and mild cognitive impairment have been investigated. Possible physiological correlates may be due to the effects of chronic orthostatic intolerance (OI) in the form of the Postural Tachycardia Syndrome (POTS) and decreases in cerebral blood flow (CBF). In addition, fMRI studies suggest that individuals with CFS may require increased cortical and subcortical brain activation to complete difficult mental tasks. Furthermore, neurocognitive testing in CFS has demonstrated deficits in speed and efficiency of information processing, attention, concentration, and working memory. The cognitive impairments are then perceived as an exaggerated mental fatigue. As a whole, this is experienced by those with CFS as "brain fog" and may be viewed as the interaction of physiological, cognitive, and perceptual factors. Thus, the cognitive symptoms of CFS may be due to altered CBF activation and regulation that are exacerbated by a stressor, such as orthostasis or a difficult mental task, resulting in the decreased ability to readily process information, which is then perceived as fatiguing and experienced as "brain fog." Future research looks to further explore these interactions, how they produce cognitive impairments, and explain the perception of "brain fog" from a mechanistic standpoint.
Oka T, Kanemitsu	Department of	Psychological stress	Biopsychosoc Med. 2013 Mar	BACKGROUND: Low-grade fever is a common symptom in patients with chronic

Y, Sudo N, Hayashi H, Oka K.	Psychosomatic Medicine, Graduate School of Medical Sciences, Kyushu University, Fukuoka 812-8582, Japan. oka-t@cephal.med.kyushu-u.ac.jp.	contributed to the development of low-grade fever in a patient with chronic fatigue syndrome: a case report.	8; 7(1):7. doi: 10.1186/1751-0759-7-7.	fatigue syndrome (CFS), but the mechanisms responsible for its development are poorly understood. We submit this case report that suggests that psychological stress contributes to low-grade fever in CFS. CASE PRESENTATION: A 26-year-old female nurse with CFS was admitted to our hospital. She had been recording her axillary temperature regularly and found that it was especially high when she felt stress at work. To assess how psychological stress affects temperature and to investigate the possible mechanisms for this hyperthermia, we conducted a 60-minute stress interview and observed the changes in the following parameters: axillary temperature, fingertip temperature, systolic blood pressure, diastolic blood pressure, heart rate, plasma catecholamine levels, and serum levels of interleukin (IL)-1β and IL-6 (pyretic cytokines), tumor necrosis factor-α and IL-10 (antipyretic cytokines). The stress interview consisted of recalling and talking about stressful events. Her axillary temperature at baseline was 37.2°C, increasing to 38.2°C by the end of the interview. In contrast, her fingertip temperature decreased during the interview. Her heart rate, systolic and diastolic blood pressures, and plasma levels of noradrenaline and adrenaline increased during the interview; there were no significant changes in either pyretic or antipyretic cytokines during or after the interview. CONCLUSIONS: A stress interview induced a 1.0°C increase in axillary temperature in a CFS patient. Negative emotion-associated sympathetic activation, rather than pyretic cytokine production, contributed to the increase in temperature induced by the stress interview. This suggests that psychological stress may contribute to the development or the exacerbation of low-grade fever in some CFS patients.
Oltra E, García-Escudero M, Mena-Durán AV, Monsalve V, Cerdá-Olmedo G.	Facultad de Medicina, C/Quevedo, 2, 46001 Valencia, Spain. elisa.oltra@ucv.es.	Lack of evidence for retroviral infections formerly related to chronic fatigue in Spanish Fibromyalgia patients.	Virol J. 2013 Nov 11; 10 (1):332. doi: 10.1186/1743-422X-10-332.	BACKGROUND: The etiology of fibromyalgia and chronic fatigue syndrome (FM/CFS) is currently unknown. A recurrent viral infection is an attractive hypothesis repeatedly found in the literature since it would explain the persistent pain and tiredness these patients suffer from. The initial striking link of two distinct orphan retroviruses: the gamma retroviruses murine leukemia virus (MLV)-related virus and the delta retrovirus T-lymphotropic virus type 2 (HTLV-2) to chronic fatigue have not been confirmed to date. RESULTS: Genomic DNA (gDNA) from 75 fibromyalgia patients suffering from chronic fatigue and 79 age-matched local healthy controls were screened for the presence of MLV-related and HTLV-2 related proviral sequences. The XMRV env gene was amplified in 20% of samples tested (24% patients/15% healthy controls). Unexpectedly, no PCR amplifications from independent gDNA preparations of the same individuals were obtained. None of the positive samples showed presence of contaminating murine sequences previously reported by other investigators, neither contained additional regions of the virus making us conclude that the initial env amplification came from spurious air-driven amplicon contaminants. No specific HTLV-2 sequences were obtained at any time from any of the 154 quality-controlled gDNA preparations screened. CONCLUSIONS: Previous associations between MLV-related or HTLV-2 retrovirus infection with chronic fatigue

				must be discarded. Thus, studies showing positive amplification of HTLV-2 sequences from chronic fatigue participants should be revised for possible undetected technical problems.To avoid false positives of viral infection, not only extreme precautions should be taken when nested-PCR reactions are prepared and exhaustive foreign DNA contamination controls performed, but also consistent amplification of diverse regions of the virus in independent preparations from the same individual must be demanded.The fact that our cohort of patients did not present evidence of any of the two types of retroviral infection formerly associated to chronic fatigue does not rule out the possibility that other viruses are involved in inciting or maintaining fibromyalgia and/or chronic fatigue conditions.
Oral A, Ilieva EM, Küçükdeveci AA, Varela E, Valero R, Berteanu M, Christodoulou N.	Member, Board Committee, UEMS Board of PRM, Department of Physical Medicine and RehabilitationIstanbul Faculty of Medicine, Istanbul University, Istanbul, Turkey - aydanoral@yahoo.com .	Generalised and regional soft tissue pain syndromes. The role of physical and rehabilitation medicine physicians. The European perspective based on the best evidence. A paper by the UEMS-PRM Section Professional Practice Committee.	Eur J Phys Rehabil Med. 2013 Aug; 49 (4):535-49.	One of the objectives of the Professional Practice Committee (PPC) of the Physical and Rehabilitation Medicine (PRM) Section of the Union of European Medical Specialists (UEMS) is the development of the field of competence of PRM physicians in Europe. To achieve this objective, UEMS PRM Section PPC has adopted a systematic action plan of preparing a series of papers describing the role of PRM physicians in a number of disabling health conditions, based on the evidence of effectiveness of PRM interventions. Generalised and regional soft tissue pain syndromes constitute a major problem leading to loss of function and disability, resulting in enormous societal burden. The aim of this paper is to describe the unique role of PRM physicians in the management of these disabling conditions that require not only pharmacological interventions but also a holistic approach including the consideration of body functions, activities and participation as well as contextual factors as described in the ICF. Evidence-based effective PRM interventions include exercise and multicomponent treatment including a psychotherapeutic intervention such as cognitive behavioural therapy (CBT) in addition to exercise, the latter based on strong evidence for reducing pain and improving quality of life in fibromyalgia syndrome (FMS). Balneotherapy, meditative movement therapies, and acupuncture have also been shown as efficacious in improving symptoms in FMS. Emerging evidence suggests the use of transcranial magnetic or direct current stimulation (rTMS or tDCS) in FMS patients with intractable pain not alleviated by other interventions. Graded exercise therapy and CBT are evidence-based options for chronic fatigue syndrome. The use of some physical modalities and manipulation for myofascial pain syndrome is also supported by evidence. As for complex regional pain syndrome (CRPS), strong evidence exists for rTMS and graded motor imagery as well as moderate evidence for mirror therapy. Interventional techniques such as blocks and spinal cord stimulation may also be considered for CRPS based on varying levels of evidence. PRM physicians' functioning oriented approaches on the assessment and management, adopting the ICF as a reference, may well meet the needs of patients with soft tissue pain syndromes, the common problems for whom are loss of function and impaired quality of life. Available evidence for the effectiveness of PRM interventions serves as the

				basis for the explicit role of PRM specialists in the management of these health conditions
Osnes LT, Nakken B, Bodolay E, Szodoray P.	Institute of Immunology, Rikshospitalet, Oslo University Hospital, Norway.	Assessment of intracellular cytokines and regulatory cells in patients with autoimmune diseases and primary immunodeficiencies - novel tool for diagnostics and patient follow-up.	Autoimmun Rev. 2013 Aug; 12(10):967-71. doi: 10.1016/j.autrev.2013.02.003. Epub 2013 Mar 26.	Serum and intracytoplasmic cytokines are mandatory in host defense against microbes, but also play a pivotal role in the pathogenesis of autoimmune diseases by initiating and perpetuating various cellular and humoral autoimmune processes. The intricate interplay and fine balance of pro- and anti-inflammatory processes drive, whether inflammation and eventually organ damage will occur, or the inflammatory cascade quenches. In the early and late, as well as inactive and active stages of autoimmune diseases, different cellular and molecular patterns can dominate in these patients. However, the simultaneous assessment of pro- and anti-inflammatory biomarkers aids to define the immunological state of a patient. A group of the most useful inflammatory biomarkers are cytokines, and with increasing knowledge during the last decade their role have been well-defined in patients with autoimmune diseases and immunodeficiencies. Multiple pathological processes drive the development of autoimmunity and immunodeficiencies, most of which involve quantitative and qualitative disturbances in regulatory cells, cytokine synthesis and signaling pathways. The assessment of these biomarkers does not aid only in the mechanistic description of autoimmune diseases and immunodeficiencies, but further helps to subcategorize diseases and to evaluate therapy responses. Here, we provide an overview, how monitoring of cytokines and regulatory cells aid in the diagnosis and follow-up of patients with autoimmune diseases and immunodeficiencies furthermore, we pinpoint novel cellular and molecular diagnostic possibilities in these diseases.
Ozsahin M, Gonen I, Ermis F, Oktay M, Besir FH, Kutlucan A, Sahin A, Ataoglu S.	Department of Physical Medicine and Rehabilitation, Medical School of Duzce University Duzce, Turkey.	The prevalence of fibromyalgia among patients with hepatitis B virus infection.	Int J Clin Exp Med. 2013 Sep 25;6(9):804-8.	Fibromyalgia (FM) is a syndrome characterized by widespread and chronic musculoskeletal pain, fatigue, morning stiffness, and sleep disturbance. However, the etiopathogenesis of FM remains unclear. Various etiological factors have been suggested to trigger FM. These include systemic rheumatismal disease, physical trauma, psychological disorders, and chronic infections. We determined the prevalence of FM in patients with chronic active hepatitis B virus (HBV) and inactive hepatitis B carriers, compared with matched healthy controls. Seventy-seven HBV patients (39 HBV carriers and 38 with chronic active hepatitis), were evaluated for FM syndrome. Seventy-seven HBsAg-negative healthy subjects were enrolled as a control group. We found that FM was very prevalent in patients with HBV infections (22% of the total). We found no difference in FM prevalence when patients with chronic active hepatitis B infections (21% FM prevalence) and those who were inactive hepatitis B carriers (23% FM prevalence) were compared. FM was not associated with the levels of HBV-DNA, ALT, or AST. Recognition and management of FM in HBsAg-positive patients will aid in improvement of quality-of-life. We fully accept that our preliminary results require confirmation in studies including larger numbers of patients. More work is needed to allow us to understand the role played by, and the

				relevance of, infections (including HBV) in FM syndrome pathogenesis.
Pantry SN, Medveczky MM, Arbuckle JH, Luka J, Montoya JG, Hu J, Renne R, Peterson D, Pritchett JC, Ablashi DV, Medveczky PG.	Department of Molecular Medicine, University of South Florida, Morsani College of Medicine, Tampa, Florida 33612, USA.	Persistent human herpesvirus-6 infection in patients with an inherited form of the virus.	J Med Virol. 2013 Nov; 85(11):1940-6. doi: 10.1002/jmv.23685. Epub 2013 Jul 25.	Human herpesvirus-6 (HHV-6) A and 6B are ubiquitous betaherpesviruses viruses with lymphotropic and neurotropic potential. As reported earlier, these viruses establish latency by integration into the telomeres of host chromosomes. Chromosomally integrated HHV-6 (CIHHV-6) can be transmitted vertically from parent to child. Some CIHHV-6 patients are suffering from neurological symptoms, while others remain asymptomatic. Four patients with CIHHV-6 and CNS dysfunction were treated with valganciclovir or foscarnet. HHV-6 replication was detected by reverse transcriptase polymerase chain reaction amplification of a late envelope glycoprotein. In this study we also compared the inherited and persistent HHV-6 viruses by DNA sequencing. The prevalence of CIHHV-6 in this cohort of adult patients from the USA suffering from a wide range of neurological symptoms including long-term fatigue were found significantly greater than the reported 0.8% in the general population. Long-term antiviral therapy inhibited HHV-6 replication as documented by loss of viral mRNA production. Sequence comparison of the mRNA and the inherited viral genome revealed that the transcript is produced by an exogenous virus. In conclusion, the data presented here document that some individuals with CIHHV-6 are infected persistently with exogenous HHV-6 strains that lead to a wide range of neurological symptoms; the proposed name for this condition is inherited herpesvirus 6 syndrome or IHS.
Parkman HP, Yates K, Hasler WL, Nguyen L, Pasricha PJ, Snape WJ, Farrugia G, Koch KL, Calles J, Abell TL, Sarosiek I, McCallum RW, Lee L, Unalp-Arida A, Tonascia J, Hamilton F.	Gastroenterology Section, Parkinson Pavilion, School of Medicine, Temple University, 8th Floor 3401 North Broad Street, Philadelphia, PA 19140, USA. henry.parkman@temple.edu	Cholecystectomy and clinical presentations of gastroparesis.	Dig Dis Sci. 2013 Apr; 58(4):1062-73. doi: 10.1007/s10620-013-2596-y. Epub 2013 Mar 2.	BACKGROUND: Many patients with gastroparesis have had their gallbladders removed. AIM: To determine if clinical presentations of patients with gastroparesis differ in those with prior cholecystectomy compared to patients who have not had their gallbladder removed. METHODS: Gastroparetic patients were prospectively enrolled in the NIDDK Gastroparesis Registry. Detailed history and physical examinations were performed; patients filled out questionnaires including patient assessment of GI symptoms. RESULTS: Of 391 subjects with diabetic or idiopathic gastroparesis (IG), 142 (36 %) had a prior cholecystectomy at the time of enrollment. Patients with prior cholecystectomy were more often female, older, married, and overweight or obese. Cholecystectomy had been performed in 27/59 (46 %) of T2DM compared to 19/78 (24 %) T1DM and 96/254 IG (38 %) ($p = 0.03$). Patients with cholecystectomy had more comorbidities, particularly chronic fatigue syndrome, fibromyalgia, depression, and anxiety. Postcholecystectomy gastroparesis patients had increased health care utilization, and had a worse quality of life. Independent characteristics associated with prior cholecystectomy included insidious onset (OR = 2.06; $p = 0.01$), more comorbidities (OR = 1.26; $p < 0.001$), less severe gastric retention (OR(severe) = 0.68; overall $p = 0.03$) and more severe symptoms of retching (OR = 1.19; $p = 0.02$) and upper abdominal pain (OR = 1.21; $p = 0.02$), less severe constipation symptoms (OR = 0.84; $p = 0.02$), and not classified as having irritable bowel syndrome (OR = 0.51; $p = 0.02$). Etiology was not independently associated

				with a prior cholecystectomy. CONCLUSIONS: Symptom profiles in patients with and without cholecystectomy differ: postcholecystectomy gastroparesis patients had more severe upper abdominal pain and retching and less severe constipation. These data suggest that prior cholecystectomy is associated with selected manifestations of gastroparesis.
Payne BA, Hateley CL, Ong EL, Premchand N, Schmid ML, Schwab U, Newton JL, Price DA.	Department of Infection and Tropical Medicine, Royal Victoria Infirmary, Newcastle-upon-Tyne, UK. brendan.payne@ncl.ac.uk	HIV-associated fatigue in the era of highly active antiretroviral therapy: novel biological mechanisms?	HIV Med. 2013 Apr; 14(4):247-51. doi: 10.1111/j.1468-1293.2012.01050.x. Epub 2012 Sep 23.	OBJECTIVE: The aim of the study was to determine the prevalence and risk factors for HIV-associated fatigue in the era of highly active antiretroviral therapy (HAART). METHODS: A cross-sectional survey of 100 stable HIV-infected out-patients was carried out. Severity of fatigue was measured using the Fatigue Impact Scale (FIS). Symptoms of orthostatic intolerance (dysautonomia) were evaluated using the Orthostatic Grading Scale (OGS). Data for HIV-infected patients were compared with those for 166 uninfected controls and 74 patients with chronic fatigue syndrome (CFS)/myalgic encephalomyelitis (encephalopathy) (ME). RESULTS: Ninety-one per cent of HIV-infected patients were on HAART and 78% had suppressed plasma HIV viral load (≤40 HIV-1 RNA copies/mL). Fifty-one per cent of HIV-infected patients reported excessive symptomatic fatigue (FIS≥40), and 28% reported severe fatigue symptoms (FIS≥80). The mean FIS score among HIV-infected patients was 50.8 [standard deviation (SD) 41.9] compared with 13.0 (SD 17.6) in uninfected control subjects, and 92.9 (SD 29.0) in CFS patients ($P < 0.001$ for comparison of HIV-infected patients and uninfected controls). Among HIV-infected patients, fatigue severity was not significantly associated with current or nadir CD4 lymphocyte count, HIV plasma viral load, or whether on HAART. Prior dideoxynucleoside analogue (d-drug) exposure ($P = 0.016$) and the presence of clinical lipodystrophy syndrome ($P = 0.011$) were associated with fatigue. Additionally, fatigue severity correlated strongly with symptomatic orthostatic intolerance ($r = 0.65$; $P < 0.001$). CONCLUSIONS: Fatigue is very common and often severe in HIV-infected out-patients, despite viral suppression and good immune function. In a subgroup of patients, prior d-drug exposure may contribute to fatigue, suggesting a metabolic basis. Dysautonomia may also drive fatigue associated with HIV infection, as in other chronic diseases, and CFS/ME, and should be further evaluated with the potential for a shared therapeutic approach.
Pemberton S, Cox DL.	Yorkshire Fatigue Clinic, Forsyth Business Centre , York, North Yorkshire , UK	Experiences of daily activity in chronic fatigue syndrome/myalgic encephalomyelitis (CFS/ME) and their implications for rehabilitation programmes.	Disabil Rehabil. 2013 Dec 27. [Epub ahead of print]	Abstract Purpose: Chronic Fatigue Syndrome, also known as Myalgic Encephalomyelitis (CFS/ME), has a significant impact upon daily functioning. Most recommended treatments aim to alter activity patterns based upon assumptions of activity avoidance. However, as there is limited research on the experience of activity and occupational beliefs in people with CFS/ME, this study took a qualitative approach to understand the meaning of activity in people with this disabling condition. Method: This study applied a social constructivist grounded theory methodology. Semi-structured interviews took place with 14 participants attending a Specialist CFS/ME Service in England. Findings: The emergent themes described a premorbid state of constant action with difficulty stopping an activity once it had

				commenced. When this pattern was interrupted by illness, participants attempted to maintain their previous level of occupational engagement. Negative associations and emotions were described in response to the concept of doing nothing or limited activity. A recurring cycle was reported of increasing activity levels when symptoms improved, followed by post-exertional symptoms. Conclusions: Consequently, participants' beliefs about concepts of both activity and inactivity need to be considered within the application of rehabilitation programmes for CFS/ME that aim to modify activity related behaviours. Implications for Rehabilitation Chronic fatigue syndrome/myalgic encephalomyelitis (CFS/ME) is commonly treated in the UK using activity modification. In this small qualitative study, patients expressed negative feelings and beliefs towards the concept of doing nothing and therefore sought to push their activity levels when this was available, leading to recurring cycles of symptoms and activity. Rehabilitation programmes need to consider how people with CFS/ME engaged with activity and inactivity before the condition and how this may impact upon engagement with activity-based rehabilitation programmes.
Pinquart M.	Department of Psychology, Philipps University, Marburg, Germany. pinquart@staff.uni-marburg.de	Self-esteem of children and adolescents with chronic illness: a meta-analysis.	Child Care Health Dev. 2013 Mar; 39(2):153-61. doi: 10.1111/j.1365-2214.2012.01397.x. Epub 2012 Jun 19.	Chronic illness may be a risk factor for low self-esteem; however, previous meta-analyses are inconclusive whether children with a chronic illness have lower self-esteem than their healthy peers. The goal of the present study was to summarize available research in order to compare the self-esteem of children and adolescents with a chronic illness with that of healthy children. Random-effects meta-analysis was used to integrate the results of 621 empirical studies that compare levels of self-esteem of children with a chronic physical illness with healthy peers or general test norms. Studies were identified via the electronic databases Adolesc, Embase, Google Scholar, MEDLINE, PSNYDEX, PSYCINFO, and cross-referencing. Children with chronic illnesses have lower self-esteem than healthy peers or test norms (g = -0.18 standard deviation units). The lowest levels of self-esteem were observed in children with chronic fatigue syndrome and chronic headaches. Lower levels of self-esteem in children with a chronic illness were found in girls than in boys, in adolescents than in children, in children from developing or threshold countries, when results were collected from observer ratings rather than child reports, in studies published in the 1990s, and when children with chronic illnesses were directly compared with healthy children instead of test norms. Paediatricians, parents, and teachers should promote experiences of success and positive peer-relations, which are important sources of self-esteem. In addition, psychosocial interventions for children with chronic illnesses should be offered for children with reduced self-esteem.

Poeschla B, Strachan E, Dansie E, Buchwald DS, Afari N.	Department of Psychiatry and Behavioral Sciences, School of Medicine, University of Washington, Seattle, WA 98104-2499, USA. bpoeschl@u.washington.edu	Chronic fatigue and personality: a twin study of causal pathways and shared liabilities.	Ann Behav Med. 2013 Jun; 45(3):289-98. doi: 10.1007/s12160-012-9463-5. Comment in Ann Behav Med. 2013 Jun; 45(3):271-2.	BACKGROUND: The etiology of chronic fatigue syndrome (CFS) remains unknown. Personality traits influence well-being and may play a role in CFS and unexplained chronic fatigue. PURPOSE: This study aimed to examine the association of emotional instability and extraversion with chronic fatigue and CFS in a genetically informative sample. METHODS: We evaluated 245 twin pairs for two definitions of chronic fatigue. They completed the Neuroticism and Extraversion subscales of the NEO Five Factor Inventory. Using a co-twin control design, we examined the association between personality and chronic fatigue. RESULTS: Higher emotional instability was associated with both definitions of chronic fatigue and was confounded by shared genetics. Lower extraversion was also associated with both definitions of fatigue, but was not confounded by familial factors. CONCLUSIONS: Both emotional instability and extraversion are related to chronic fatigue and CFS. Whereas emotional instability and chronic fatigue are linked by shared genetic mechanisms, the relationship with extraversion may be causal and bidirectional.
Pontari M, Giusto L.	Temple University Hospital, Department of Urology, Philadelphia, Pennsylvania, USA.	New developments in the diagnosis and treatment of chronic prostatitis/chronic pelvic pain syndrome.	Curr Opin Urol. 2013 Nov; 23 (6):565-9. doi: 10.1097/MOU.0b013e3283656a55.	PURPOSE OF REVIEW: To describe new developments in the diagnosis and treatment of chronic prostatitis/chronic pelvic pain syndrome (CPPS). RECENT FINDINGS: Symptoms in men with chronic prostatitis/CPPS appear to cluster into a group with primarily pelvic or localized disease, and a group with more systemic symptoms. Several other chronic pain conditions can be associated with chronic prostatitis/CPPS, including irritable bowel syndrome, fibromyalgia, and chronic fatigue syndrome. Markers of neurologic inflammation and autoimmune disease parallel changes in symptoms after treatment. Treatment options include new alpha-blockers, psychological intervention, and prostate-directed therapy. The areas of acupuncture and pelvic floor physical therapy/myofascial release have received increased recent attention and appear to be good options in these patients. Future therapy may include antibodies to mediators of neurogenic inflammation and even treatment of bacteria in the bowel. SUMMARY: The diagnosis of chronic prostatitis/CPPS must include conditions traditionally outside the scope of urologic practice but important for the care of men with chronic pelvic pain. The treatment is best done using multiple simultaneous therapies aimed at the different aspects of the condition.
Poppe C, Petrovic M, Vogelaers D, Crombez G.	Department of General Internal Medicine, Ghent University Hospital, Belgium.	Cognitive behavior therapy in patients with chronic fatigue syndrome: the role	J Psychosom Res. 2013 May; 74(5):367-72. doi: 10.1016/j.jpsychores.2013.02.011. Epub 2013 Mar 25.	OBJECTIVE: Increasing the quality of life (QoL) of patients with chronic fatigue is challenging because recovery is seldom achieved. Therefore, it is important to identify processes that improve QoL. This study examined the extent of improvement related to cognitive behavior group therapy (CBT), and whether improvement is affected by

	Carine.Poppe@ugent.be	of illness acceptance and neuroticism.		initial levels of acceptance and neuroticism. METHODS: Eighty CFS patients followed CBT, and self-reported (pre-post design) on mental and physical QoL (MQoL and PQoL), fatigue, acceptance, and neuroticism. The extent of improvement was analyzed using t-tests, effect sizes, and clinically significant change criteria. Whether acceptance and neuroticism at baseline predicted changes were analyzed by means of correlation and regression analyses. RESULTS: Significant improvement was found for all variables. The effect size for MQoL and PQoL was small; for acceptance and fatigue, effect size was moderate. About 20% (MQoL) to 40% (fatigue) of the participants clinically improved. Pre-treatment level of acceptance was negatively correlated with changes in MQoL, not with PQoL changes. Neuroticism pre-treatment was positively related with MQoL changes. Regression analysis showed an effect of acceptance on changes in MQoL beyond the effect of neuroticism. CONCLUSIONS: Although CBT is an evidence-based treatment, the sizes of the effects are often small regarding QoL. Our study also revealed small effect sizes. Our study showed that patient characteristics at baseline were significantly associated with MQoL outcome; indicating that CFS patients with high neuroticism or with a low acceptance show more improvement in MQoL. We propose to specifically target acceptance and neuroticism before treatment in order to maximize clinical relevance.
Post RM, Altshuler LL, Leverich GS, Frye MA, Suppes T, McElroy SL, Keck PE Jr, Nolen WA, Kupka RW, Grunze H, Rowe M.	Bipolar Collaborative Network, 5415 West Cedar Lane Suite 201B, Bethesda, MD 20814, USA. robert.post@speakeasy.net	Role of childhood adversity in the development of medical co-morbidities associated with bipolar disorder.	J Affect Disord. 2013 May; 147(1-3):288-94. doi: 10.1016/j.jad.2012.11.020. Epub 2013 Jan 18.	OBJECTIVE: A role for childhood adversity in the development of numerous medical conditions in adults has been described in the general population, but has not been examined in patients with bipolar disorder who have multiple medical comorbidities which contribute to their premature mortality. METHODS: More than 900 outpatients (average age 41) with bipolar disorder completed questionnaires that included information about the occurrence of verbal, physical, or sexual abuse in childhood and whether their parents had a mood or substance abuse disorder, or a history of suicidality. These factors were combined to form a total childhood adversity score, which was then related to one or more of 30 medical conditions patients rated as present or absent. RESULTS: The child adversity score was significantly related to the total number of medical comorbidities a patient had ($p<.001$), as well as to 11 specific medical conditions that could be modeled in a logistic regression ($p<.03$). These included: asthma, arthritis, allergies, chronic fatigue syndrome, chronic menstrual irregularities, fibromyalgia, head injury (without loss of consciousness), hypertension, hypotension, irritable bowel syndrome, and migraine headaches. LIMITATIONS: The contribution of parental diagnosis to childhood adversity is highly inferential. CONCLUSIONS: These data link childhood adversity to the later occurrence of multiple medical conditions in adult outpatients with bipolar disorder. Recognition of these relationships and early treatment intervention may help avert a more severe course of not only bipolar disorder but also of its prominent medical comorbidities and their combined adverse effects on patients'health, wellbeing, and longevity.
Powell DJ, Liossi C,	Faculty of Social and	Unstimulated cortisol	Psychoneuroendocrinology.	The hypothalamic-pituitary-adrenal (HPA) axis is a psychoneuroendocrine regulator of

Moss-Morris R, Schlotz W.	Human Sciences, University of Southampton, Southampton, UK. Electronic address: daniel.powell@soton.ac.uk.	secretory activity in everyday life and its relationship with fatigue and chronic fatigue syndrome: a systematic review and subset meta-analysis.	2013 Nov;38(11):2405-22. doi: 10.1016/j.psyneuen.2013.07.004. Epub 2013 Aug 2.	the stress response and immune system, and dysfunctions have been associated with outcomes in several physical health conditions. Its end product, cortisol, is relevant to fatigue due to its role in energy metabolism. The systematic review examined the relationship between different markers of unstimulated salivary cortisol activity in everyday life in chronic fatigue syndrome (CFS) and fatigue assessed in other clinical and general populations. Search terms for the review related to salivary cortisol assessments, everyday life contexts, and fatigue. All eligible studies (n=19) were reviewed narratively in terms of associations between fatigue and assessed cortisol markers, including the cortisol awakening response (CAR), circadian profile (CP) output, and diurnal cortisol slope (DCS). Subset meta-analyses were conducted of case-control CFS studies examining group differences in three cortisol outcomes: CAR output; CAR increase; and CP output. Meta-analyses revealed an attenuation of the CAR increase within CFS compared to controls (d=-.34) but no statistically significant differences between groups for other markers. In the narrative review, total cortisol output (CAR or CP) was rarely associated with fatigue in any population; CAR increase and DCS were most relevant. Outcomes reflecting within-day change in cortisol levels (CAR increase; DCS) may be the most relevant to fatigue experience, and future research in this area should report at least one such marker. Results should be considered with caution due to heterogeneity in one meta-analysis and the small number of studies.
Prados G, Miró E, Martínez MP, Sánchez AI, López S, Sáez G.	Department of Personality, Assessment and Psychological Treatment, School of Psychology, University of Granada, Granada, Spain/ Internal Medicine Service, Virgen de las Nieves University Hospital, Granada, Spain. germanprados@ugr.es.	Fibromyalgia: gender differences and sleep-disordered breathing.	Clin Exp Rheumatol. 2013 Nov-Dec; 31 (6 Suppl 79):102-10. Epub 2013 Dec 2.	OBJECTIVES: The prevalence of fibromyalgia (FM) is much lower in men than in women. Therefore, current knowledge about this chronic pain syndrome emerged mainly from research on women. The aim of the present study was to compare clinical symptoms and sleep parameters between male and female FM patients. METHODS: Forty FM patients (18 men and 22 women) aged 48.00±8.45 years were evaluated with questionnaires on pain, sleep, fatigue, depression, anxiety and functional impact, and polysomnography (PSG). RESULTS: 61% of male FM patients had an apnea-hypopnea index (AHI) greater than 15, compared to 31.8% of women, and a desaturation index (DI) above five, which was twice more prevalent in men than in women. In addition, males had poorer sleep quality (16.05±2.92% vs. 13.08±3.88%; p=0.01) and slow wave sleep (SWS) (stage 3 duration: 9.02±7.84% vs. 14.44±7.32%; p=0.03) than women. No differences were found between the two groups in the level of pain, emotional distress, or daily functioning. However, pain in men, fatigue in women, and functional impact in both sexes seemed to be related to worse sleep quality. Also in women, alterations in total sleep time (TST) and rapid eye movement (REM) sleep features appeared to be related to emotional status. CONCLUSIONS: Alterations in sleep respiratory patterns were more highly prevalent in male than in female FM patients. More so in male FM patients, the alterations in sleep patterns, non-refreshing sleep, and other FM-related symptoms observed in this population might be part of a primary sleep-disordered breathing.

Prinsen H, Heerschap A, Bleijenberg G, Zwarts MJ, Leer JW, van Asten JJ, van der Graaf M, Rijpkema M, van Laarhoven HW.	Department of Medical Oncology, Radboud University Nijmegen Medical Centre, Nijmegen, Gelderland, The Netherlands.	PLoS One. 2013 Sep 11;8 (9):e74638. doi: 10.1371/journal.pone.0074638.	Magnetic resonance spectroscopic imaging and volumetric measurements of the brain in patients with postcancer fatigue: a randomized controlled trial.	BACKGROUND: Postcancer fatigue is a frequently occurring problem, impairing quality of life. Until now, little is known about (neuro) physiological factors determining postcancer fatigue. For non-cancer patients with chronic fatigue syndrome, certain characteristics of brain morphology and metabolism have been identified in previous studies. We investigated whether these volumetric and metabolic traits are a reflection of fatigue in general and thus also of importance for postcancer fatigue. METHODS: Fatigued patients were randomly assigned to either the intervention condition (cognitive behavior therapy) or the waiting list condition. Twenty-five patients in the intervention condition and fourteen patients in the waiting list condition were assessed twice, at baseline and six months later. Baseline measurements of 20 fatigued patients were compared with 20 matched non-fatigued controls. All participants had completed treatment of a malignant, solid tumor minimal one year earlier. Global brain volumes, subcortical brain volumes, metabolite tissue concentrations, and metabolite ratios were primary outcome measures. RESULTS: Volumetric and metabolic parameters were not significantly different between fatigued and non-fatigued patients. Change scores of volumetric and metabolic parameters from baseline to follow-up were not significantly different between patients in the therapy and the waiting list group. Patients in the therapy group reported a significant larger decrease in fatigue scores than patients in the waiting list group. CONCLUSIONS: No relation was found between postcancer fatigue and the studied volumetric and metabolic markers. This may suggest that, although postcancer fatigue and chronic fatigue syndrome show strong resemblances as a clinical syndrome, the underlying physiology is different. TRIAL REGISTRATION: ClinicalTrials.gov NCT01096641.
Prior KN, Bond MJ.	General Practice, School of Medicine, Flinders University, Adelaide, Australia.	Construct validity and temporal stability of the abridged 31-item Illness Behaviour Questionnaire.	Psychol Health. 2013 Dec 16. [Epub ahead of print]	Objective: Key psychometric information was sought for three newly derived dimensions from an abridged Illness Behaviour Questionnaire (IBQ-31): Affirmation of Illness (AI), Concern for Health (CH) and General Affective State (GAS). The construct validity of these scales was examined along with their test-retest reliability and long-term stability. Design: A longitudinal, observational study was conducted with 675 participants (general community members and those with eitherasthma, diabetes and chronic pain or chronic fatigue syndrome) providing self-report questionnaire data at baseline, with additional information sought at three (n = 483; 71.6%) and 12 months (n = 517, 76.6%). Main outcome measures: Construct validity of the IBQ-31 was explored using well-validated psychological measures of Symptom Attributions and Symptom Experience, Cognitive Distortion of Somatic Information and Illness Likelihood. Results: In general, AI, CH and GAS shared predictable empirical overlap with related psychological indices across the five samples. Adequate three-month test-retest reliability was evident, with greater score variability over 12 months. Conclusion: The IBQ-31 comprises three theoretically relevant dimensions which demonstrate relative short- and long-term stability for individuals with diverse illness

				experiences. Future investigations should explore the predictive validity of AI, CH and GAS, along with the potential value of 'cut-off' scores for clinical use.
Proal AD, Albert PJ, Marshall TG, Blaney GP, Lindseth IA.	Autoimmunity Research Foundation, 3423 Hill Canyon Ave, Thousand Oaks, CA 91360, USA.	Immunostimulation in the treatment for chronic fatigue syndrome/myalgic encephalomyelitis.	Immunol Res. 2013 Jul; 56(2-3):398-412. doi: 10.1007/s12026-013-8413-z.	Chronic fatigue syndrome (CFS)/myalgic encephalomyelitis (ME) has long been associated with the presence of infectious agents, but no single pathogen has been reliably identified in all patients with the disease. Recent studies using metagenomic techniques have demonstrated the presence of thousands of microbes in the human body that were previously undetected and unknown to science. More importantly, such species interact together by sharing genes and genetic function within communities. It follows that searching for a singular pathogen may greatly underestimate the microbial complexity potentially driving a complex disease like CFS/ME. Intracellular microbes alter the expression of human genes in order to facilitate their survival. We have put forth a model describing how multiple species-bacterial, viral, and fungal-can cumulatively dysregulate expression by the VDR nuclear receptor in order to survive and thus drive a disease process. Based on this model, we have developed an immunostimulatory therapy that is showing promise inducing both subjective and objective improvement in patients suffering from CFS/ME.

Rayhan RU, Raksit MP, Timbol CR, Adewuyi O, Vanmeter JW, Baraniuk JN.	Division of Rheumatology, Immunology and Allergy; Department of Medicine, Georgetown University Medical Center Room 3004F 3rd Floor PHC Building, 3800 Reservoir Road, NW, Washington, DC 20007, USA.	Prefrontal lactate predicts exercise-induced cognitive dysfunction in Gulf War Illness.	Am J Transl Res. 2013; 5(2):212-23. Epub 2013 Mar 28.	BACKGROUND: 25% to 30% of Veterans deployed to the 1990 to 1991 Persian Gulf War exhibit an idiopathic syndrome of chronic fatigue, exertional exhaustion, pain, hyperalgesia, cognitive and affective dysfunction known as Gulf War Illness (GWI). METHODS: Gulf War veterans (n=15) and sedentary veteran and civilian controls (n=11) completed a 2-back working memory test in an fMRI before and after two bicycle exercise stress test. We performed single voxel (1)H MRS to evaluate brain metabolic differences in the left anterior cingulate cortex and the changes associated with exercise. RESULTS: Eight GWI subjects increased their 2-back scores after exercise (labelled increasers) and seven GWI subjects decreased their 2-back scores after exercise (labelled decreasers). These phenotypic responses were absent for controls. Decreasers had significantly elevated prefrontal lactate levels compared to Increasers prior to completion of the exercise stress tests. Evaluation of prefrontal lactate levels prior to exercise demonstrated predictability (ROC analysis) of the two diametrically opposed subgroups. CONCLUSION: Prefrontal lactate levels may be a potential biomarker for exercise-induced subgroups in GWI. The alterations in brain energetics may be in part responsible for a subgroup of GWI and underlie some of the symptoms present in the patient population.
Rayhan RU, Ravindran MK, Baraniuk JN.	Division of Rheumatology, Immunology and Allergy, Department of Medicine, Georgetown University Washington, DC, USA.	Migraine in gulf war illness and chronic fatigue syndrome: prevalence, potential mechanisms, and evaluation.	Front Physiol. 2013 Jul 24; 4:181. doi: 10.3389/fphys.2013.00181. eCollection 2013.	Objective: To assess the prevalence of headache subtypes in Gulf War Illness (GWI) and Chronic Fatigue Syndrome (CFS) compared to controls. Background: Approximately, 25% of the military personnel who served in the 1990-1991 Persian Gulf War have developed GWI. Symptoms of GWI and CFS have considerable overlap, including headache complaints. Migraines are reported in CFS. The type and prevalence of headaches in GWI have not been adequately assessed. Methods: 50 GWI, 39 CFS and 45 controls had structured headache evaluations based on the 2004 International Headache Society criteria. All subjects had history and physical examinations, fatigue and symptom related questionnaires, measurements of systemic hyperalgesia (dolorimetry), and assessments for exclusionary conditions. Results: Migraines were detected in 64% of GWI (odds ratio = 11.6 [4.1-32.5]) (mean [±95% CI]) and 82% of CFS subjects (odds ratio = 22.5 [7.8-64.8]) compared to only 13% of controls. There was a predominance of females in the CFS compared to GWI and controls. However, migraine status was independent of gender in GWI and CFS groups (x (2) = 2.7; P = 0.101). Measures of fatigue, pain, and other ancillary criteria were comparable between GWI and CFS subjects with and without headache. Conclusion: The high prevalence of migraine in CFS was confirmed and extended to

				GWI subjects. GWI and CFS may share dysfunctional central pathophysiological pathways that contribute to migraine and subjective symptoms. The high migraine prevalence warrants the inclusion of a structured headache evaluation in GWI and CFS subjects, and treatment when present.
Rayhan RU, Stevens BW, Timbol CR, Adewuyi O, Walitt B, VanMeter JW, Baraniuk JN.	Georgetown University Medical Center, Department of Medicine, Division of Rheumatology, Immunology and Allergy, Washington, DC, United States of America. rur@georgetown.edu	Increased brain white matter axial diffusivity associated with fatigue, pain and hyperalgesia in Gulf War illness.	PLoS One. 2013; 8(3):e58493. doi: 10.1371/journal.pone.0058493Epub 2013 Mar 20.	BACKGROUND: Gulf War exposures in 1990 and 1991 have caused 25% to 30% of deployed personnel to develop a syndrome of chronic fatigue, pain, hyperalgesia, cognitive and affective dysfunction. METHODS: Gulf War veterans (n=31) and sedentary veteran and civilian controls (n=20) completed fMRI scans for diffusion tensor imaging. A combination of dolorimetry, subjective reports of pain and fatigue were correlated to white matter diffusivity properties to identify tracts associated with symptom constructs. RESULTS: Gulf War Illness subjects had significantly correlated fatigue, pain, hyperalgesia, and increased axial diffusivity in the right inferior fronto-occipital fasciculus. ROC generated thresholds and subsequent binary regression analysis predicted CMI classification based upon axial diffusivity in the right inferior fronto-occipital fasciculus. These correlates were absent for controls in dichotomous regression analysis. CONCLUSION: The right inferior fronto-occipital fasciculus may be a potential biomarker for Gulf War Illness. This tract links cortical regions involved in fatigue, pain, emotional and reward processing, and the right ventral attention network in cognition. The axonal neuropathological mechanism(s) explaining increased axial diffusivity may account for the most prominent symptoms of Gulf War Illness.
Reeves WC, Lin JM, Nater UM.	Public Health Surveillance and Informatics Program Office, Mail Stop E-33, Centers for Disease Control and Prevention, 1600 Clifton Road NE, Atlanta, GA 30333, USA.	Mental illness in metropolitan, urban and rural Georgia populations.	BMC Public Health. 2013 Apr 30; 13:414. doi: 10.1186/1471-2458-13-414.	BACKGROUND: Mental illness represents an important public health problem. Local-level data concerning mental illness in different populations (e.g., socio-demographics and residence--metropolitan/urban/rural) provides the evidence-base for public health authorities to plan, implement and evaluate control programs. This paper describes prevalence and covariates of psychiatric conditions in Georgia populations in three defined geographic areas. METHODS: Data came from the Georgia population-based random-digit-dialing study investigating unwellness and chronic fatigue syndrome (CFS) in Georgia populations of three defined geographic areas (metropolitan, urban, and rural). Respondents were screened for symptoms of fatigue, sleep, cognition, and pain at household screening interviews, and a randomly selected sample completed detailed individual phone interviews. Based on the detailed phone interviews, we conducted one-day clinical evaluations of 292 detailed interview participants classified as unwell with a probable CFS (i.e. CFS-like; a functional somatic syndrome), 268 classified as other unwell, and 223 well (matched to CFS-like). Clinical evaluation included psychiatric classification by means of the Structured Clinical Interview for DSM (SCID). To derive prevalence estimates we used sample weighting to account for the complexity of the multistage sampling design. We used 2- and 3-way table analyses to examine socio-demographic and urbanicity specific associations and multiple logistic regression to calculate adjusted odds ratios.

				RESULTS: Anxiety and mood disorders were the most common psychiatric conditions. Nineteen percent of participants suffered a current anxiety disorder, 18% a mood disorder and 10% had two or more conditions. There was a significant linear trend in occurrence of anxiety or mood disorders from well to CFS-like. The most common anxiety disorders were post-traumatic stress disorder (PTSD) (6.6%) and generalized anxiety disorder (GAD) (5.8%). Logistic regression showed that lower education and female sex contributed significantly to risk for both PTSD and GAD. In addition, rural/urban residence and Hispanic ethnicity were associated with PTSD. We defined moderate to severe depression as Major Depressive Disorder or a Zung score>60 and logistic regression found lower education to be significantly associated but sex, age and urbanicity were not. CONCLUSIONS: Overall occurrence of anxiety and mood disorders in Georgia mirrored national findings. However, PTSD and GAD occurred at twice the published national rates (3.6 and 2.7%, respectively). State and local prevalence and associations with education, sex and urbanicity comprise important considerations for developing control programs. The increased prevalence of anxiety and mood disorders in people with a functional somatic syndrome (or CFS-like illness) is important for primary care providers, who should consider additional psychiatric screening or referral of individuals presenting with somatoform symptoms.
Reme SE, Archer N, Chalder T.	Harvard School of Public Health, Harvard University, Boston, Massachusetts, USA. sreme@hsph.harvard.edu	Experiences of young people who have undergone the Lightning Process to treat chronic fatigue syndrome/myalgic encephalomyelitis--a qualitative study.	Br J Health Psychol. 2013 Sep; 18(3):508-25. doi: 10.1111/j.2044-8287.2012.02093.x. Epub 2012 Sep 19.	OBJECTIVES: Chronic fatigue syndrome/myalgic encephalomyelitis (CFS/ME) is a serious condition characterized by debilitating but unexplained fatigue. Treatment alternatives are few, and especially so for young people. The aetiology of CFS/ME is still unclear and controversial, but rehabilitative interventions seem so far most promising. The Lightning Process is a 3-day training programme that has recently become available, but no outcome studies have yet been published. It is a non-medical training programme that combines concepts from Neuro-Linguistic Programming, Life Coaching and Osteopathy. The aim of this study was to explore the experiences of young people with CFS/ME after they had undergone the Lightning Process. DESIGN: Qualitative research study. METHODS: Semi-structured interviews were conducted with an opportunistic sample recruited through open advertisements of nine young people, aged 14-26, who had undergone the treatment, and three of their parents. Inductive thematic analysis was used to evaluate the content of the interviews. RESULTS: Mostly positive experiences were reported of the Lightning Process. Two reported dissatisfaction and no improvement, while seven were satisfied and were much improved. Particular helpful aspects were the theoretical rationale, practical exercises, and the technique they learned. Less helpful aspects were the intensity and short duration of the treatment with little follow-up, the secrecy surrounding it, and feelings of being blamed if the treatment did not work. CONCLUSIONS: As this is the first report of young people's experiences with the Lightning Process, it will be important to consider the helpful and unhelpful treatment components for future refinement of interventions for CFS/ME.

Reynolds GK, Lewis DP, Richardson AM, Lidbury BA.	Department of Genome Biology, The John Curtin School of Medical Research, The Australian National University, Canberra, Australian Capital Territory, Australia.	Comorbidity of postural orthostatic tachycardia syndrome and chronic fatigue syndrome in an Australian cohort.	J Intern Med. 2013 Nov 9. doi: 10.1111/joim.12161. [Epub ahead of print]	OBJECTIVE: Patients with chronic fatigue syndrome (CFS) are frequently diagnosed with comorbid postural orthostatic tachycardia syndrome (POTS), suggesting a shared pathogenesis. The aim of this study was to examine the relationship between demographic characteristics, autonomic functioning and fatigue levels amongst CFS patients with and without comorbid POTS. DESIGN AND SETTING: All patients presenting to the CFS Discovery Clinic between 2009 and 2012 completed a 20-min standing task as part of their initial assessment. Heart rate and pulse pressure were recorded at baseline, at 2-min intervals poststanding, at the end of the task and following a recovery period. Average heart rate and pulse pressure variability were calculated from this data. Age, gender, length of illness and self-reported fatigue scores were also recorded. POTS patients were diagnosed by an orthostatic increase in heart rate >30 beats per min, concomitant symptoms of orthostatic intolerance and no orthostatic hypotension. Differences in autonomic functioning between POTS and CFS patients were compared using independent samples t-tests, whilst logistic and linear regressions were performed to examine the contribution of autonomic functioning to task completion and perceived fatigue, respectively. RESULTS: Comorbidity of CFS and POTS (CFS-POTS) was observed in 11% (33/306) of patients. CFS-POTS patients were significantly younger ($P < 0.001$), had a shorter length of illness ($P = 0.034$), experienced greater task difficulty ($P = 0.002$) and were able to stand for significantly shorter periods compared to the CFS-only patients ($P < 0.001$). CFS-POTS patients experienced significantly lower baseline diastolic blood pressure ($P = 0.002$), significantly higher heart rate and lower pulse pressures at each standing measurement. Early heart rate changes ($P = 0.002$) and overall heart rate change ($P < 0.001$) were significant predictors of completion status, whereas heart rate variability ($P < 0.001$) and female gender ($P < 0.001$) were significant predictors of increased perceived task difficulty. CONCLUSIONS: Haemodynamic and demographic differences between CFS-POTS and CFS-only patients suggest that the former group reflects a distinct subgroup of the CFS population. The findings highlight the utility of screening younger patients with fatigue for POTS, and identified heart rate variability as an important marker of fatigue for CFS patients in general.
Rezaei SD, Hearps AC, Mills J, Pedersen J, Tachedjian G.	Retroviral Biology and Antivirals Laboratory, Centre for Virology, Burnet Institute, 85 Commercial Road, Melbourne, Victoria 3004, Australia.	No association between XMRV or related gammaretroviruses in Australian prostate cancer patients.	Virol J. 2013 Jan 10; 10:20. doi: 10.1186/1743-422X-10-20.	BACKGROUND: Xenotropic murine leukemia virus-related virus (XMRV) is a gammaretrovirus reported to be associated with prostate cancer (PC) and chronic fatigue syndrome (CFS). While the association of XMRV with CFS and PC has recently been discredited, no studies have been performed in Australian patients to investigate the association between PC and XMRV or related murine leukemia virus (MLV) in matched PC and normal tissue. METHODS: Genomic DNA (gDNA) was purified from matched normal and cancer formalin-fixed paraffin-embedded (FFPE) prostate tissue from 35 Australian PC patients with Gleason scores ranging from 7 - 10. The presence of the ribonuclease L (RNase L) polymorphism R462Q was determined by allele specific PCR. Samples were screened for XMRV and related

				murine leukemia virus (MLV) variants by qPCR. Contaminating mouse DNA was detected using qPCR targeting mouse intracisternal A particle long terminal repeat DNA. RESULTS: gDNA was successfully purified from 94% (66/70) of normal and cancer FFPE prostate tissues. RNase L typing revealed 8% were homozygous (QQ), 60% were heterozygous (RQ) and 32% were wild-type (RR) for the RNase L mutation. None of the 66 samples tested were positive for XMRV or related MLV sequences using broad MLV or XMRV specific primers with detection sensitivities of 1 viral copy of MLV/XMRV and XMRV DNA, respectively. CONCLUSIONS: Using highly sensitive qPCR we found no evidence of XMRV or related gammaretroviruses in prostate tissues from 35 Australian PC patients. Our findings are consistent with other studies demonstrating that XMRV is a laboratory contaminant that has no role in the aetiology of PC.
Richardson G, Epstein D, Chew-Graham C, Dowrick C, Bentall RP, Morriss RK, Peters S, Riste L, Lovell K, Dunn G, Wearden AJ; FINE Trial Writing group on behalf of the FINE Trial group. **Collaborators Bennett C, Bentall R, Booth L, Brocki J, Cahill G, Chapman A, Chew-Graham C, Connell S, Dowrick C, Dunn G, Fleetwood D, Ibbotson L, Jerman D, Lovell K, Mann J, Morriss R, Peters S, Powell P, Quarmby D, Richardson G, Riste L, Wearden A, Williams J.**	Centre for Health Economics, University of York, Hull/York Medical School, York YO10 5DD, United Kingdom.	Cost-effectiveness of supported self-management for CFS/ME patients in primary care.	BMC Fam Pract. 2013 Jan 18; 14:12. doi: 10.1186/1471-2296-14-12.	BACKGROUND: Nurse led self-help treatments for people with chronic fatigue syndrome/myalgic encephalitis (CFS/ME) have been shown to be effective in reducing fatigue but their cost-effectiveness is unknown. METHODS: Cost-effectiveness analysis conducted alongside a single blind randomised controlled trial comparing pragmatic rehabilitation (PR) and supportive listening (SL) delivered by primary care nurses, and treatment as usual (TAU) delivered by the general practitioner (GP) in North West England. A within trial analysis was conducted comparing the costs and quality adjusted life years (QALYs) measured within the time frame of the trial. 296 patients aged 18 and over with CFS/ME diagnosed using the Oxford criteria were included in the cost-effectiveness analysis. RESULTS: Treatment as usual is less expensive and leads to better patient outcomes compared with Supportive Listening. Treatment as usual is also less expensive than Pragmatic Rehabilitation. PR was effective at reducing fatigue in the short term, but the impact of the intervention on QALYs was uncertain. However, based on the results of this trial, PR is unlikely to be cost-effective in this patient population. CONCLUSIONS: This analysis does not support the introduction of SL. Any benefits generated by PR are unlikely to be of sufficient magnitude to warrant recommending PR for this patient group on cost-effectiveness grounds alone. However, dissatisfaction with current treatment options means simply continuing with 'treatment as usual' in primary care is unlikely to be acceptable to patients and practitioners. TRIAL REGISTRATION: The trial registration number is IRCTN74156610.

Rimes KA, Wingrove J.	University of Bath, Department of Psychology, Claverton Down, Bath, UK. K.A.Rimes@bath.ac.uk	Mindfulness-based cognitive therapy for people with chronic fatigue syndrome still experiencing excessive fatigue after cognitive behaviour therapy: a pilot randomized study.	Clin Psychol Psychother. 2013 Mar-Apr;20(2):107-17. doi: 10.1002/cpp.793. Epub 2011 Oct 9.	Cognitive behaviour therapy (CBT) is an effective treatment for chronic fatigue syndrome (CFS; sometimes known as myalgic encephalomyelitis). However, only a minority of patients fully recover after CBT; thus, methods for improving treatment outcomes are required. This pilot study concerned a mindfulness-based cognitive therapy (MBCT) intervention adapted for people with CFS who were still experiencing excessive fatigue after CBT. The study aimed to investigate the acceptability of this new intervention and the feasibility of conducting a larger-scale randomized trial in the future. Preliminary efficacy analyses were also undertaken. Participants were randomly allocated to MBCT or waiting list. Sixteen MBCT participants and 19 waiting-list participants completed the study, with the intervention being delivered in two separate groups. Acceptability, engagement and participant-rated helpfulness of the intervention were high. Analysis of covariance controlling for pre-treatment scores indicated that, at post-treatment, MBCT participants reported lower levels of fatigue (the primary clinical outcome) than the waiting-list group. Similarly, there were significant group differences in fatigue at 2-month follow-up, and when the MBCT group was followed up to 6 months post-treatment, these improvements were maintained. The MBCT group also had superior outcomes on measures of impairment, depressed mood, catastrophic thinking about fatigue, all-or-nothing behavioural responses, unhelpful beliefs about emotions, mindfulness and self-compassion. In conclusion, MBCT is a promising and acceptable additional intervention for people still experiencing excessive fatigue after CBT for CFS, which should be investigated in a larger randomized controlled trial.KEY PRACTITIONER MESSAGE: Only about 30% of people with chronic fatigue syndrome (CFS) recover after cognitive behaviour therapy (CBT); thus, methods for improving treatment outcomes are needed. This is the first pilot randomized study to demonstrate that a mindfulness-based intervention was associated with reduced fatigue and other benefits for people with CFS who were still experiencing excessive fatigue after a course of CBT. Levels of acceptability, engagement in the intervention and rated helpfulness were high. A larger-scale randomized controlled trial is required.
Roca M, Verduri A, Corbetta L, Clini E, Fabbri LM, Beghé B.	Section of Respiratory Diseases, Department of Oncology, Haematology and Respiratory Diseases, University of Modena and Reggio Emilia, Modena, Italy.	Mechanisms of acute exacerbation of respiratory symptoms in chronic obstructive pulmonary disease.	Eur J Clin Invest. 2013 May; 43(5):510-21. doi: 10.1111/eci.12064. Epub 2013 Mar 12.	Exacerbations of chronic obstructive respiratory disease (ECOPD) are acute events characterized by worsening of the patient's respiratory symptoms, particularly dyspnoea, leading to change in medical treatment and/or hospitalisation. AECOP are considered respiratory diseases, with reference to the respiratory nature of symptoms and to the involvement of airways and lung. Indeed respiratory infections and/or air pollution are the main causes of ECOPD. They cause an acute inflammation of the airways and the lung on top of the chronic inflammation that is associated with COPD. This acute inflammation is responsible of the development of acute respiratory symptoms (in these cases the term ECOPD is appropriate). However, the acute

				inflammation caused by infections/pollutants is almost associated with systemic inflammation, that may cause acute respiratory symptoms through decompensation of concomitant chronic diseases (eg acute heart failure, thromboembolism, etc) almost invariably associated with COPD. Most concomitant chronic diseases share with COPD not only the underlying chronic inflammation of the target organs (i.e. lungs, myocardium, vessels, adipose tissue), but also clinical manifestations like fatigue and dyspnoea. For this reason, in patients with multi-morbidity (eg COPD with chronic heart failure and hypertension, etc), the exacerbation of respiratory symptoms may be particularly difficult to investigate, as it may be caused by exacerbation of COPD and/or ≥ comorbidity, (e.g. decompensated heart failure, arrhythmias, thromboembolisms) without necessarily involving the airways and lung. In these cases the term ECOPD is inappropriate and misleading.
Rodgers CC, Hooke MC, Hockenberry MJ.	Baylor College of Medicine/Texas Children's Hospital, Houston, Texas 77030, USA.	Symptom clusters in children.	Curr Opin Support Palliat Care. 2013 Mar; 7(1):67-72. doi: 10.1097/SPC.0b013e32835ad551.	PURPOSE OF REVIEW: Researchers have focused on identifying and describing symptom experiences among children with various diseases but symptoms can have a synergistic and/or an antecedent effect that must be evaluated. This review reports the current knowledge of symptoms among various pediatric diseases and highlights symptom cluster research. RECENT FINDINGS: Symptoms of depression and anxiety are the most prevalent variables studied across pediatric disease studies followed by pain, fatigue, and quality of life. Although previous pediatric symptom research provides a foundation for understanding the complexities of these symptoms, there is limited evidence on symptom cluster research in pediatrics. Pain and fatigue are the most common symptoms analyzed for correlations, and relationships among symptoms that have been evaluated in children with juvenile idiopathic arthritis, HIV, cancer, cardiac disease requiring an implantable cardioverter defibrillator, and at end of life. Pain and fatigue have been associated with sleep disturbances, anxiety, depression, anorexia, and nausea/vomiting. SUMMARY: Pediatric oncology researchers are leading the way with symptom cluster studies; however, this work remains in the early stages. There is great potential to advance the state of the science with cluster analysis. Future research work should focus on evaluating symptoms and their interactions.
Roest HI, Bossers A, van Zijderveld FG, Rebel JM.	Department of Bacteriology and TSEs, Central Veterinary Institute, Wageningen University and Research Centre, Lelystad, The Netherlands.	Clinical microbiology of Coxiella burnetii and relevant aspects for the diagnosis and control of the zoonotic disease Q fever.	Vet Q. 2013 Sep; 33(3):148-60. doi: 10.1080/01652176.2013.843809. Epub 2013 Oct 28.	Coxiella burnetii is the causative agent of the zoonotic disease Q fever. Since its first recognition as a disease in the 1930s, the knowledge about the agent and the disease itself has increased. This review summarizes the current knowledge on C. burnetii and Q fever, its pathogenesis, diagnosis and control. C. burnetii is a bacterium which naturally replicates inside human or animal host cells. The clinical presentation of Q fever varies per host species. C. burnetii infection in animals is mainly asymptomatic except for pregnant ruminants in which abortions and stillbirth can occur. In humans, the disease is also mainly asymptomatic, but clinical presentations include acute and chronic Q fever and the post-Q fever fatigue syndrome. Knowledge of the pathogenesis of Q fever in animals and excretion of C. burnetii in infected animals is

				crucial in understanding the transmission routes and risks of human infection. Our studies indicated that infected pregnant animals only excrete C. burnetii during and after parturition, independent of abortion, and that C. burnetii phase specific serology can be a useful tool in the early detection of infection. Domestic ruminants are the main reservoir for human Q fever, which has a major public health impact when outbreaks occur. In outbreaks, epidemiological source identification can only be refined by genotypic analysis of the strains involved. To control outbreaks and Q fever in domestic ruminants, vaccination with a phase 1 vaccine is effective. Future challenges are to identify factors for virulence, host susceptibility and protection.

Rowe PC, Fontaine KR, Violand RL.	Division of General Pediatrics and Adolescent Medicine, Department of Pediatrics, Johns Hopkins University School of Medicine Baltimore, MD, USA.	Neuromuscular strain as a contributor to cognitive and other symptoms in chronic fatigue syndrome: hypothesis and conceptual model.	Front Physiol. 2013 May 16; 4:115. doi: 10.3389/fphys.2013.00115. eCollection 2013.	Individuals with chronic fatigue syndrome (CFS) have heightened sensitivity and increased symptoms following various physiologic challenges, such as orthostatic stress, physical exercise, and cognitive challenges. Similar heightened sensitivity to the same stressors in fibromyalgia (FM) has led investigators to propose that these findings reflect a state of central sensitivity. A large body of evidence supports the concept of central sensitivity in FM. A more modest literature provides partial support for this model in CFS, particularly with regard to pain. Nonetheless, fatigue and cognitive dysfunction have not been explained by the central sensitivity data thus far. Peripheral factors have attracted attention recently as contributors to central sensitivity. Work by Brieg, Sunderland, and others has emphasized the ability of the nervous system to undergo accommodative changes in length in response to the range of limb and trunk movements carried out during daily activity. If that ability to elongate is impaired-due to movement restrictions in tissues adjacent to nerves, or due to swelling or adhesions within the nerve itself-the result is an increase in mechanical tension within the nerve. This adverse neural tension, also termed neurodynamic dysfunction, is thought to contribute to pain and other symptoms through a variety of mechanisms. These include mechanical sensitization and altered nociceptive signaling, altered proprioception, adverse patterns of muscle recruitment and force of muscle contraction, reduced intra-neural blood flow, and release of inflammatory neuropeptides. Because it is not possible to differentiate completely between adverse neural tension and strain in muscles, fascia, and other soft tissues, we use the more general term "neuromuscular strain." In our clinical work, we have found that neuromuscular restrictions are common in CFS, and that many symptoms of CFS can be reproduced by selectively adding neuromuscular strain during the examination. In this paper we submit that neuromuscular strain is a previously

				unappreciated peripheral source of sensitizing input to the nervous system, and that it contributes to the pathogenesis of CFS symptoms, including cognitive dysfunction.
Sarkisiants NK, Grigorian ÉG.	[No address quoted]	Predicting side effects of the treatment of chronic hepatitis with peginterferon alpha-2A with ribaverin. [Article in Russian]	Klin Med (Mosk). 2013; 91(5):46-9.	The aim of the study was to monitor the commonest side effects of the treatment of chronic hepatitis with peginterferon alpha-2A (PEG-IFN) and ribaverin (RBV) and the influence of various factors on their development. The work was done in the Department of Infectious Disease, Erevan State Medical University. Monitoring 16 adverse reactions was carried out with the use of special tables within 1, 2, 4 and 6 months after the onset of therapy in patients with genotypes 2 and 3 and in addition after 8, 10 and 12 months in patients with genotype 1. The influence of independent prognostic factors was estimated by logistic regression analysis. The commonest side effects of PEG-IFN plus RBV therapy were leukopenia, thrombocytopenia, weight loss, depression, fatigue, and insomnia that occurred at one time or another in more than half of the patients. Weight loss during therapy amounted to 8.36 kg (95% CI 6.7-10) (maximum 21 kg). Myalgia, anorexia, arthralgia, headache, alopecia, and vomiting were documented in 20-50% of the cases. Anemia, pruritis, eruption, erythema, and hair shedding at injection sites occurred in 1/4 of the patients. It is concluded that logistic regression analysis with matching selected prognostic factors permits to estimate the probability of such side effects as weight loss, flu-like syndrome, and myalgia.
Schouwers S, Bonnet M, Verschueren P, Westhovens R, Blockmans D, Mariën G, Bossuyt X.	[No address quoted]	Value-added reporting of antinuclear antibody testing by automated indirect immunofluorescence analysis.	Clin Chem Lab Med. 2013 Nov 13:1-5. doi: 10.1515/cclm-2013-0610. [Epub ahead of print]	Abstract Background: Automated systems for antinuclear antibody analysis are being introduced. The aim was to evaluate whether automated quantitative reading of fluorescence intensity is clinically relevant and allows for value-added reporting of test results. Methods: Consecutive samples (n=260) were used to correlate fluorescence intensity with end-point titer. Moreover, 434 samples from controls (150 healthy blood donors, 150 chronic fatigue syndrome, and 134 diseased controls) and 252 samples (obtained at diagnosis) from patients with systemic rheumatic diseases were screened for antinuclear antibodies (1:80) on HEp-2 cells using NOVA View®, and likelihood ratios were calculated for fluorescence intensity result intervals. Results: There was a significant correlation between end-point titer and fluorescence intensity. Likelihood ratios for a systemic rheumatic disease increased with increasing fluorescence intensity. The likelihood ratio for a systemic rheumatic disease was 0.06, 0.18, 0.51, 5.3, and 37.5 for a fluorescence intensity of ≤66, 67-150, 151-300, 301-1000, >1000, respectively. A range of 31%-37% of the patients with Sjögren's syndrome, systemic sclerosis or systemic lupus erythematosus had fluorescence intensities >1000. Conclusions: Estimation of fluorescence intensity by automated antinuclear antibody analysis offers clinically useful information. Likelihood ratios based on fluorescence intensity test result intervals aid with the interpretation of automated antinuclear antibody analysis and allow value-added reporting.
Schüttrumpf J, Hourfar MK, Alesci	Institut für Transfusionsmedizin	No detection of the retrovirus xenotropic	Transfus Med Hemother. 2013 Feb; 40(1):32-5. doi:	BACKGROUND: Xenotropic murine leukemia virus-related virus (XMRV) is a retrovirus that has recently been related to prostate cancers and chronic fatigue syndrome.

S, Miesbach W, Seifried E, Schmidt M.	und Immunhämatologie, Klinikum der Johann Wolfgang Goethe Universität, DRK-Blutspendedienst Baden-Württemberg - Hessen, Frankfurt/M., Germany ; Chemotherapeutisches Forschungsinstitut Georg-Speyer-Haus, Frankfurt/M., Germany.	murine leukemia virus-related virus in individuals with hemophilia.	10.1159/000345661. Epub 2013 Jan 3.	Since other human-pathogenic retroviruses, such as HIV, human T-lymphotropic virus type I (HTLV-I) and -II, are known blood-transmitted pathogens, XMRV might present another hazard associated with products derived from in vitro cultures of human or animal origin, or blood component-based therapeutics. Here, we investigated whether XMRV was transmitted to individuals with hemophilia and frequent exposure to plasma-derived or recombinant clotting factors. METHODS: We used highly sensitive real-time PCR to test plasma samples from 127 consecutive individuals with hemophilia who consulted our hemophilia center either for treatment or for a standard check-up. RESULTS: From the 127 hemophiliacs, 80 had prior contact to persons with either hepatitis B (n = 30), hepatitis C (n = 74) and/or HIV (n = 21), and 30 were currently being treated with plasma-derived and 97 with recombinant factor concentrates. None of the individuals tested positive for XMRV. CONCLUSIONS: Independent of the ongoing discussion on whether the positive XMRV testing in initial reports was a result of reagent, sample, or tissue contamination, and whether XMRV is a real threat or a testing artifact, our data suggest that XMRV might not play an important role for hemophiliacs.
Senel K, Baygutalp F, Baykal T, Erdal A, Ugur M.	Department of Physical Medicine and Rehabilitation, Atatürk University Medical Faculty, Erzurum, Turkey. kazimsenel@gmail.com	Melatonin levels in premenopausal women with fibromyalgia syndrome.	Rheumatol Int. 2013 Jun; 33(6):1609-10. doi: 10.1007/s00296-011-2315-y. Epub 2011 Dec 23.	The fibromyalgia syndrome (FMS) is a chronic, widespread pain disorder of unknown etiology. It has been suggest that familial component, environmental factors, endocrine and neurotransmitter alterations, and psychological factors may contribute to the development of FMS. The role of melatonin in FMS is unclear. Some studies describe a lower nocturnal peak and a decreased secretion of melatonin in women with FMS when compared with healthy matched controls. The aim of the present study was to determine the possible role of melatonin in FMS patients. We examined the characteristics and levels of melatonin in 25 consecutive premenopausal women with FMS. Serum blood samples were collected from 25 patients and 20 the age and gender matched healthy controls. Melatonin levels were measured by enzyme-linked immunosorbent assay. Then, the results were compared with those from healthy subjects. Serum melatonin levels of FMS patients were not statistically different from those of controls ($P > 0.05$). No association was observed between melatonin levels of patients with FMS and disease duration, sleep disturbances, fatigue, and pain scores. Our results demonstrate that melatonin levels were similar in patients with FMS and healthy controls. Further studies are needed to determine the possible role of melatonin.
Shanks L, Jason LA, Evans M, Brown A.	Center for Community Research, DePaul University Chicago, IL, USA.	Cognitive impairments associated with CFS and POTS.	Front Physiol. 2013 May 16; 4:113. doi: 10.3389/fphys.2013.00113. eCollection 2013.	Chronic fatigue syndrome (CFS) is characterized by fatigue, sleep dysfunction, and cognitive deficits (Fukuda et al., 1994). Research surrounding cognitive functioning among patients with CFS has found difficulty with memory, attention, and information processing. A similar disorder, postural tachycardia syndrome (POTS), is characterized by increased heart rate, fatigue, and mental cloudiness (Raj et al., 2009). Potential implications of cognitive deficits for patients with CFS and/or POTS are discussed, including difficulties with school and/or employment. A few biological

				theories (i.e., kindling, impairments in the central nervous system, and difficulty with blood flow) have emerged as potential explanations for the cognitive deficits reported in both CFS and POTS Future research should continue to examine possible explanations for cognitive impairments in CFS and POTS, and ultimately use this information to try and reduce cognitive impairments for these patients.

Shreevathsa M, Ravishankar B, Dwivedi R.	Professor and Head, Department of Post Graduate Studies in Ayurveda Siddhanta, Government Ayurveda Medical College, Mysore, India.	Anti depressant activity of Mamsyadi Kwatha: An Ayurvedic compound formulation.	Ayu. 2013 Jan; 34(1):113-7. doi: 10.4103/0974-8520.115448.	Depression is a psychiatric condition in which there is loss of interest in all pleasurable outlets, viz. food, sex, work, friends, hobbies and entertainment. The prevalence rate of the disease is 6-8% in women and 3-5% in men. Ayurveda, the science of life, provides systematic management principles for depression. Mamsyadi Kwatha is one such formulation stated by Yadavji Trikamji Acharya in Siddha Yoga Sangraha and Bheshaja Samhita, which is said to be effective in psychiatric conditions. The ingredients are Jatamansi (Nardostachys jatamansi), Ashwagandh (Withania somnifera) and Parasika Yavani (Hyocymus niger) in an 8:4:1 ratio, respectively. The test drug was subjected for antidepressant activity in experimental models. The models selected for anti depressant activity were behavioral despair test, anti-reserpine test and Chronic Fatigue Syndrome (CFS) test in albino mice. The test formulation showed significant inhibition of behavioural despair ($P < 0.05$), weak to moderate anti-reserpine activity - ptosis ($P < 0.001$), catatonia ($P < 0.01$), sedation ($P < 0.01$) and moderate effect in CFS test ($P < 0.050$). These effects clearly show that Mamsyadi Kwatha has an anti-depressant activity.
Shultz E, Malone DA Jr.	Department of Psychiatry and Psychology, Cleveland Clinic; Clinical Instructor, Cleveland Clinic Lerner College of Medicine of Case Western Reserve University, Cleveland, OH.	A practical approach to prescribing antidepressants.	Cleve Clin J Med. 2013 Oct; 80 (10):625-31. doi: 10.3949/ccjm.80a.12133.	Although antidepressant drugs do not differ much in their efficacy rates, the particular characteristics of one drug may make it a better choice in a given patient. This article provides insight into the art of prescribing antidepressants in primary care, with recommendations for prescribing for patients with chronic pain, sexual dysfunction, anxiety, chronic fatigue syndrome, fibromyalgia, severe insomnia, old age, diabetes, and heart problems.
Skalova S, Neuman D, Lnenicka P,	Department of Pediatrics, Faculty of	Gitelman syndrome as a cause of	Arab J Nephrol Transplant. 2013 Jan; 6(1):37-9.	INTRODUCTION: Gitelman syndrome (GS) is a very rare autosomal recessive tubulopathy due to loss-of-function or mutation in solute carrier family12, member 3

Stekrova J.	Medicine in Hradec Kralove, Charles University, Prague, Czech Republic. skalovasylva@seznam.cz	psychomotor retardation in a toddler.		gene (SLC12A3 gene) encoding thiazide-sensitive NaCl co-transporter in the distal convoluted tubule, leading to hypokalemia, metabolic alkalosis, hypomagnesemia, hypocalciuria and low-to-normal blood pressure. Clinical signs are mostly secondary to chronic hypokalemia and include dizziness, fatigue, constipation and weakness. Patients can also present with muscle cramps, tetany, fatigue and convulsions due to severe metabolic alkalosis or hypomagnesemia. Manifestations of GS are rarely apparent before the age of five, and the syndrome is usually diagnosed during adolescence or adulthood. Here we describe a case of GS presenting in infancy with hypokalemia and psychomotor retardation. CASE REPORT: We present an 18-month-old boy who presented with psychomotor retardation and failure to thrive. Investigations revealed hypokalemia at 2.7 mmol/L, metabolic alkalosis, hypocalciuria and normal serum magnesium level. The diagnoses of Barter syndrome (BS) and Gitelman syndrome (GS) were considered. Genetic studies confirmed the diagnosis of GS and three different mutations of in SLC12A3 gene were detected. Two mutations (c.2576T>C and c.2929C>Ty) were considered as causal ones, with the patient´s parents being the heterozygous carriers. Oral potassium supplementation resulted in normalisation of the hypokalemia and psychomotor improvement. CONCLUSION: We report a rare case of psychomotor retardation occurring at an early age in genetically confirmed GS. In spite of being a rare disorder, GS has to be considered in children with developmental delay and muscle weakness. With adequate treatment, GS patients have an excellent prognosis.
Smith SN, Crawley E.	School of Medicine, Swansea University, Swansea, UK. 630443@swansea.ac.uk	Is there effective behavioural treatment for children with chronic fatigue syndrome/myalgic encephalomyelitis?	Arch Dis Child. 2013 Jul; 98(7):561-3. doi: 10.1136/archdischild-2013-304307.	[No abstract given]
Smorgick N, Marsh CA, As-Sanie S, Smith YR, Quint EH.	Department of Obstetrics and Gynecology, University of Michigan Health System, Ann Arbor, Michigan 48109, USA. noam_yossi@yahoo.com	Prevalence of pain syndromes, mood conditions, and asthma in adolescents and young women with endometriosis.	J Pediatr Adolesc Gynecol. 2013 Jun; 26(3):171-5. doi: 10.1016/j.jpag.2012.12.006. Epub 2013 Mar 16.	STUDY OBJECTIVE: Adult women with endometriosis are often diagnosed with comorbid pain, mood, and autoimmune conditions. This study aims to describe the occurrence of pain syndromes, mood conditions, and asthma in adolescents and young women with endometriosis evaluated at our medical center. DESIGN: Retrospective review of medical records. SETTING: Department of Obstetrics and Gynecology at a tertiary referral center. PARTICIPANTS: 138 adolescents/young women who were less than age 24 years at the time of their initial visit at our medical center, and whose surgical diagnosis of endometriosis was made at our institution or by outside institutions by the age of 21. INTERVENTIONS: None. MAIN OUTCOME MEASURES: Prevalence of comorbid pain syndromes (defined as interstitial cystitis, irritable bowel syndrome, chronic headaches, chronic low back pain, vulvodynia, fibromyalgia, temporomandibular joint disease, and chronic fatigue syndrome), mood

				conditions (defined as depression and anxiety), and asthma. RESULTS: Comorbid pain syndromes were found in 77 (56%) women, mood conditions in 66 (48%) women, and asthma in 31 (26%) women. Comparing endometriosis patients with and without comorbid pain syndromes, no differences were found in age at time of diagnosis, endometriosis symptoms, and endometriosis stage. Patients with comorbid pain syndromes were more likely to report mood conditions (62% vs 30% respectively, P < .001) and smoking (31% vs 10% respectively, P = .003), underwent more surgeries for endometriosis (median of 2 [range, 1-7] vs 1 [range, 1-5], P < .005), and were more likely to undergo appendectomy or cholecystectomy (30% vs 13%, P = .02). CONCLUSIONS: Comorbid pain syndromes, mood conditions and asthma are common in adolescents and young women with endometriosis.
Smylie AL, Broderick G, Fernandes H, Razdan S, Barnes Z, Collado F, Sol C, Fletcher MA, Klimas N.	Department of Medicine, University of Alberta, Edmonton, AB, Canada.	A comparison of sex-specific immune signatures in Gulf War illness and chronic fatigue syndrome.	BMC Immunol. 2013 Jun 25; 14:29. doi: 10.1186/1471-2172-14-29.	BACKGROUND: Though potentially linked to the basic physiology of stress response we still have no clear understanding of Gulf War Illness (GWI), a debilitating condition presenting complex immune, endocrine and neurological symptoms. Here we compared male (n = 20) and female (n = 10) veterans with GWI separately against their healthy counterparts (n = 21 male, n = 9 female) as well as subjects with chronic fatigue syndrome/ myalgic encephalomyelitis (CFS/ME) (n = 12 male, n = 10 female). METHODS: Subjects were assessed using a Graded eXercise Test (GXT) with blood drawn prior to exercise, at peak effort (VO2 max) and 4-hours post exercise. Using chemiluminescent imaging we measured the concentrations of IL-1a, 1b, 2, 4, 5, 6, 8, 10, 12 (p70), 13, 15, 17 and 23, IFNγ, TNFα and TNFβ in plasma samples from each phase of exercise. Linear classification models were constructed using stepwise variable selection to identify cytokine co-expression patterns characteristic of each subject group. RESULTS: Classification accuracies in excess of 80% were obtained using between 2 and 5 cytokine markers. Common to both GWI and CFS, IL-10 and IL-23 expression contributed in an illness and time-dependent manner, accompanied in male subjects by NK and Th1 markers IL-12, IL-15, IL-2 and IFNγ. In female GWI and CFS subjects IL-10 was again identified as a delineator but this time in the context of IL-17 and Th2 markers IL-4 and IL-5. Exercise response also differed between sexes: male GWI subjects presented characteristic cytokine signatures at rest but not at peak effort whereas the opposite was true for female subjects. CONCLUSIONS: Though individual markers varied, results collectively supported involvement of the IL-23/Th17/IL-17 axis in the delineation of GWI and CFS in a sex-specific way.
Snell CR, Stevens SR, Davenport TE, Van Ness JM.	C.R. Snell, PhD, Department of Sport Sciences, University of the Pacific, Stockton, California, and Workwell Foundation, Ripon, California.	Discriminative validity of metabolic and workload measurements for identifying people with chronic fatigue syndrome.	Phys Ther. 2013 Nov; 93(11):1484-92. doi: 10.2522/ptj.20110368. Epub 2013 Jun 27.	BACKGROUND: Reduced functional capacity and postexertion fatigue after physical activity are hallmark symptoms of chronic fatigue syndrome (CFS) and may even qualify for biomarker status. That these symptoms are often delayed may explain the equivocal results for clinical cardiopulmonary exercise testing in people with CFS. Test reproducibility in people who are healthy is well documented. Test reproducibility may not be achievable in people with CFS because of delayed symptoms. OBJECTIVE: The objective of this study was to determine the discriminative validity of objective

				measurements obtained during cardiopulmonary exercise testing to distinguish participants with CFS from participants who did not have a disability but were sedentary. DESIGN: A prospective cohort study was conducted. METHODS: Gas exchange data, workloads, and related physiological parameters were compared in 51 participants with CFS and 10 control participants, all women, for 2 maximal exercise tests separated by 24 hours. RESULTS: Multivariate analysis showed no significant differences between control participants and participants with CFS for test 1. However, for test 2, participants with CFS achieved significantly lower values for oxygen consumption and workload at peak exercise and at the ventilatory or anaerobic threshold. Follow-up classification analysis differentiated between groups with an overall accuracy of 95.1%. LIMITATIONS: Only individuals with CFS who were able to undergo exercise testing were included in this study. Individuals who were unable to meet the criteria for maximal effort during both tests, were unable to complete the 2-day protocol, or displayed overt cardiovascular abnormalities were excluded from the analysis. CONCLUSIONS: The lack of any significant differences between groups for the first exercise test would appear to support a deconditioning hypothesis for CFS symptoms. However, the results from the second test indicated the presence of CFS-related postexertion fatigue. It might be concluded that a single exercise test is insufficient to reliably demonstrate functional impairment in people with CFS. A second test might be necessary to document the atypical recovery response and protracted fatigue possibly unique to CFS, which can severely limit productivity in the home and workplace.
Stahl D, Rimes KA, Chalder T.	Department of Biostatistics, Institute of Psychiatry, King's College London, UK.	Mechanisms of change underlying the efficacy of cognitive behaviour therapy for chronic fatigue syndrome in a specialist clinic: a mediation analysis.	Psychol Med. 2013 Aug 12:1-14. [Epub ahead of print]	BACKGROUND: Several randomized controlled trials (RCTs) have shown that cognitive behavioural psychotherapy (CBT) is an efficacious treatment for chronic fatigue syndrome (CFS). However, little is known about the mechanisms by which the treatment has its effect. The aim of this study was to investigate potential mechanisms of change underlying the efficacy of CBT for CFS. We applied path analysis and introduce novel model comparison approaches to assess a theoretical CBT model that suggests that fearful cognitions will mediate the relationship between avoidance behaviour and illness outcomes (fatigue and social adjustment). Method Data from 389 patients with CFS who received CBT in a specialist service in the UK were collected at baseline, at discharge from treatment, and at 3-, 6- and 12-month follow-ups. Path analyses were used to assess possible mediating effects. Model selection using information criteria was used to compare support for competing mediational models. RESULTS: Path analyses were consistent with the hypothesized model in which fear avoidance beliefs at the 3-month follow-up partially mediate the relationship between avoidance behaviour at discharge and fatigue and social adjustment respectively at 6 months. CONCLUSIONS: The results strengthen the validity of a theoretical model of CBT by confirming the role of cognitive and behavioural factors in CFS.

Stenhoff AL, Sadreddini S, Peters S, Wearden A.	University of Manchester, UK.	Understanding medical students' views of Chronic Fatigue Syndrome: A qualitative study.	J Health Psychol. 2013 Sep 20. [Epub ahead of print]	Chronic fatigue syndrome receives little attention in the medical curriculum. This study explores UK medical students' knowledge of and attitudes towards chronic fatigue syndrome. Semi-structured interviews (average length 22 minutes) were conducted with 21 participants (7 females and 14 males) in years 3 (n = 4), 4 (n = 11) and 5 (n = 6) of their studies. Inductive thematic analysis taking a realist perspective produced three themes: limited knowledge, influences on attitudes and training needs. Students acquired their knowledge and attitudes largely from informal sources and expressed difficulty understanding chronic fatigue syndrome within a traditional biomedical framework. Incorporating teaching about chronic fatigue syndrome into the medical curriculum within the context of a biopsychosocial understanding of illness could encourage more positive attitudes towards chronic fatigue syndrome.
Strahler J, Fischer S, Nater UM, Ehlert U, Gaab J.	Clinical Biopsychology, Department of Psychology, University of Marburg, Gutenbergstrasse 18, 35032 Marburg, Germany. jana.strahler@gmail.com	Norepinephrine and epinephrine responses to physiological and pharmacological stimulation in chronic fatigue syndrome.	Biol Psychol. 2013 Sep;94(1):160-6. doi: 10.1016/j.biopsycho.2013.06.002. Epub 2013 Jun 13.	Chronic fatigue syndrome (CFS) is characterized by fatigue lasting 6 months or longer. CFS has been associated with a disturbed (re-)activity of the autonomic nervous system. However, the sympathetic adrenomedulla (SAM) remains under-examined in CFS. To investigate SAM reactivity, we implemented a submaximal cycle ergometry (ERGO) and a pharmacological test (Insulin Tolerance Test, ITT) in 21 CFS patients and 20 age-, sex-, and BMI-matched controls. Plasma norepinephrine and epinephrine were collected once before and twice after the tests (+10/+20, and +30 min). Lower baseline levels and attenuated responses of epinephrine to the ERGO were found in CFS patients compared to controls, while the groups did not differ in their responses to the ITT. To conclude, we found evidence of altered sympathetic-neural and SAM reactivity in CFS. Exercise stress revealed a subtle catecholaminergic hyporeactivity in CFS patients. It is conceivable that inadequate catecholaminergic responses to physical exertion might contribute to CFS symptoms.
Stringer EA, Baker KS, Carroll IR, Montoya JG, Chu L, Maecker HT, Younger JW.	Department of Anesthesiology, Stanford University School of Medicine, Stanford, CA 94304, USA.	Daily cytokine fluctuations, driven by leptin, are associated with fatigue severity in chronic fatigue syndrome: evidence of inflammatory pathology.	J Transl Med. 2013 Apr 9; 11:93. doi: 10.1186/1479-5876-11-93.	BACKGROUND: Chronic fatigue syndrome (CFS) is a debilitating disorder characterized by persistent fatigue that is not alleviated by rest. The lack of a clearly identified underlying mechanism has hindered the development of effective treatments. Studies have demonstrated elevated levels of inflammatory factors in patients with CFS, but findings are contradictory across studies and no biomarkers have been consistently supported. Single time-point approaches potentially overlook important features of CFS, such as fluctuations in fatigue severity. We have observed that individuals with CFS demonstrate significant day-to-day variability in their fatigue severity. METHODS: Therefore, to complement previous studies, we implemented a novel longitudinal study design to investigate the role of cytokines in CFS pathophysiology. Ten women meeting the Fukuda diagnostic criteria for CFS and ten healthy age- and body mass index (BMI)-matched women underwent 25 consecutive days of blood draws and self-reporting of symptom severity. A 51-plex cytokine panel via Luminex was performed for each of the 500 serum samples collected. Our primary hypothesis was that daily fatigue severity would be significantly correlated with the inflammatory adipokine

				leptin, in the women with CFS and not in the healthy control women. As a post-hoc analysis, a machine learning algorithm using all 51 cytokines was implemented to determine whether immune factors could distinguish high from low fatigue days. RESULTS: Self-reported fatigue severity was significantly correlated with leptin levels in six of the participants with CFS and one healthy control, supporting our primary hypothesis. The machine learning algorithm distinguished high from low fatigue days in the CFS group with 78.3% accuracy. CONCLUSIONS: Our results support the role of cytokines in the pathophysiology of CFS.
Stürzel CM, Palesch D, Khalid M, Wissing S, Fischer N, Münch J.	Institute of Molecular Virology, Ulm University Medical Centre, Ulm, Germany.	Utilization of replication-competent XMRV reporter-viruses reveals severe viral restriction in primary human cells.	PLoS One. 2013 Sep 13; 8(9):e74427. doi: 10.1371/journal.pone.0074427.	The gammaretrovirus termed xenotropic murine leukemia virus-related virus (XMRV) was described to be isolated from prostate cancer tissue biopsies and from blood of patients suffering from chronic fatigue syndrome. However, many studies failed to detect XMRV and to verify these disease associations. Data suggesting the contamination of specimens in particular by PCR-based methods and recent reports demonstrating XMRV generation via recombination of two murine leukemia virus precursors raised serious doubts about XMRV being a genuine human pathogen. To elucidate cell tropism of XMRV, we generated replication competent XMRV reporter viruses encoding a green fluorescent protein or a secretable luciferase as tools to analyze virus infection of human cell lines or primary human cells. Transfection of proviral DNAs into LNCaP prostate cancer cells resulted in readily detectably reporter gene expression and production of progeny virus. Inoculation of known XMRV susceptible target cells revealed that these virions were infectious and expressed the reporter gene, allowing for a fast and highly sensitive quantification of XMRV infection. Both reporter viruses were capable of establishing a spreading infection in LNCaP and Raji B cells and could be easily passaged. However, after inoculation of primary human blood cells such as CD4 T cells, macrophages or dendritic cells, infection rates were very low, and a spreading infection was never established. In line with these results we found that supernatants derived from these XMRV infected primary cell types did not contain infectious virus. Thus, although XMRV efficiently replicated in some human cell lines, all tested primary cells were largely refractory to XMRV infection and did not support viral spread. Our results provide further evidence that XMRV is not a human pathogen.
Suskind AM, Berry SH, Suttorp MJ, Elliott MN, Hays RD, Ewing BA, Clemens JQ.	Department of Urology, University of Michigan Health System, University of Michigan, 1500 E. Medical Center Drive, Ann Arbor, MI 48109, USA.	Health-related quality of life in patients with interstitial cystitis/bladder pain syndrome and frequently associated comorbidities.	Qual Life Res. 2013 Sep; 22(7):1537-41. doi: 10.1007/s11136-012-0285-5. Epub 2012 Oct 7.	PURPOSE: To estimate the association of chronic non-urologic conditions [i.e., fibromyalgia (FM), chronic fatigue syndrome (CFS), and irritable bowel syndrome (IBS)] with health-related quality of life (HRQOL) in patients with interstitial cystitis/bladder pain syndrome (IC/BPS). METHODS: A total of 276 women with established diagnoses of IC/BPS completed a telephone interview which included demographics, self-reported medical conditions, the SF-36 health survey, and the interstitial cystitis symptom index (ICSI). Multivariate linear regression analysis was used to identify correlates of SF-36 physical and mental component summary scores. RESULTS: Mean patient age was 45.1 (SD 15.9) years, and 83% of the subjects were

				white. Mean values for the SF-36 Physical Component Score (PCS) and Mental Component Score (MCS) means were 39 (SD 14) and 45 (SD 12), respectively, indicating significant HRQOL reductions. Mean ICSI score was 11.27 (SD = 4.86). FM and IBS were significantly associated with worse SF-36 scores: -8 points on the PCS ($p < 0.001$) and -6 points on the MCS ($p < 0.001$). CFS and the presence of other pelvic conditions (overactive bladder, vulvodynia, endometriosis) were not significantly associated with SF-36 PCS and MCS scores. CONCLUSIONS: In patients with IC/BPS, the presence of FM, CFS, and IBS has a significant association with HRQOL, equivalent in impact to the bladder symptoms themselves. These results emphasize the importance of a multidisciplinary approach to treating patients with IC/BPS and other conditions.

Teixeira F, Moreira I, Silva AM, Vasconcelos C, Farinha F, Santos E.	[No address quoted]	Neurological involvement in Primary Sjögren Syndrome.	Acta Reumatol Port. 2013 Jan-Mar;38(1):29-36.	OBJECTIVES: To perform an observational retrospective cross-sectional case-control study to evaluate prevalence, clinical patterns and outcomes of neurological involvement in a cohort of Primary Sjögren Syndrome (pSS) patients followed up in a single center. MATERIAL AND METHODS: From a total of 93 pSS patients, diagnosed according to the 2002 criteria proposed by the American-European Consensus Group, we reviewed the clinical data of those with neurological complaints that were referred to observation by Neuroimmunology doctors. Demographic, clinical, seroimmunological data were compared between patients with and without neurological involvement. RESULTS: Neurological involvement was detected in 26 (28%) of the 93 patients. Neurological symptoms preceded the diagnosis of pSS in 12 (46%) patients. They were all females. The mean age at disease onset and neurological onset were 41,2 and 47,9 years, respectively. Twelve patients (46%) had peripheral system involvement (PNS), 13 (50%) patients had central nervous involvement (CNS) disorders and one (4%) patient had both PNS and CNS involvement. In patients with PNS, pure sensory neuropathy (small fiber neuropathy confirmed by quantitative sensory testing and sural neuropathy) occurred most frequently (n =5), followed by cranial nerve involvement affecting trigeminal, facial, or trochlear nerves (n = 4). Multiple mononeuropathy (n = 1), sensorimotor polyneuropathy (n=1), autonomic neuropathy (n=1) and myasthenia gravis (n = 1), were also observed. In patients with CNS disorders, headache (n=3) occurred most frequently, in two patients with MRI abnormalities compatible with inflammatory

				disease. Spinal cord involvement (n=2), seizures (n = 2), motor and sensory deficit (n=2), movement disorders (n=2), neuromyelitis optica (n=2), aseptic meningitis (n=1) were others manifestations observed. Cognitive dysfunction was observed in 3 of these patients. The frequency of constitutional symptoms (such as fever and fatigue) and lung involvement was significantly higher (p< 0,05) and the articular symptoms were significantly less frequent (p< 0,05) in pSS with neurological involvement. The neurologic outcome was good in 77% of the patients. CONCLUSION: The current study underlines the diversity of neurologic complications of pSS. The frequency of neurologic manifestations as first manifestation of pSS, especially in the event of CNS involvement, could explain why SS is frequently under diagnosed or late diagnosed. Screening for SS should be systematically performed in cases of acute or chronic myelopathy, axonal sensorimotor neuropathy, or cranial nerve involvement.
Tirelli U, Lleshi A, Berretta M, Spina M, Talamini R, Giacalone A.	Department of Medical Oncology, Division of Medical Oncology A, National Cancer Institute of Aviano, Pordenone, Italy. oma@cro.it	Treatment of 741 Italian patients with chronic fatigue syndrome.	Eur Rev Med Pharmacol Sci. 2013 Nov; 17(21):2847-52.	BACKGROUND: Chronic Fatigue Syndrome (CFS) is a distinctive syndrome characterized by specific symptoms cluster. CFS mostly affects women and often results in severe functional limitation. Its prevalence varies from 0.4 to 2.5% in the general population. In our prior studies on the clinical features of 205 CFS patients we founded immunological and brain abnormalities. In this paper we illustrate our caseload on CFS treatment. PATIENTS AND METHODS: From January 2000 to December 2005, we evaluated all the patients admitted at the CFS Unit of the Aviano National Cancer Institute, for staging procedures and treatments. Patients not meeting the Fukuda diagnostic criteria were excluded. RESULTS: 250 male and 491 female (median age 35.5 and 39.3 years, respectively) were enrolled and treated for CFS. As expected, CFS resulted from previous infectious disease in all patients. Female patients showed to be more affected by symptoms than male patients. The treatment schedules followed by the patients included nutritional supplements alone, corticosteroids, antidepressant/sedative drugs, and antiviral/immunoglobulin drugs. Antiviral/ immunoglobulin drugs achieved the best response (15.3% positive responses vs. 8.3% negative responses; OR 0.44, CI 0.26-0.74, p = 0.002). The carrying out of 4 or more treatments showed a protective effect (OR 0.46, CI 0.28-0.77, p = 0.003). This finding was confirmed in the multivariate analysis, adjusted by type of drugs (OR 0.49, CI 0.28-0.84, p = 0.009) and number of treatments carried out (OR 0.51, CI 0.30-0.86, p = 0.01); these two variables were independent. CONCLUSIONS: These findings show that the antiviral/immunoglobulin approach has a longer positive disease free survival in comparison with other approaches. However, CSF still remains a difficult disease to be effectively treated.
Tjensvoll AB, Harboe E, Gøransson LG, Beyer MK, Greve OJ, Kvaløy JT,	Department of Neurology, Stavanger University Hospital, Stavanger, Norway.	Headache in primary Sjøgren's syndrome: a population-based retrospective cohort study.	Eur J Neurol. 2013 Mar;20(3):558-63. doi: 10.1111/ene.12033. Epub 2012 Nov 28.	BACKGROUND: We investigated whether the prevalence of primary headaches was higher in patients with primary Sjøgren's syndrome (PSS) than in healthy individuals. METHODS: This retrospective cohort study included 71 patients with PSS (patients) based on the American European Consensus Classification criteria, and 71 age- and gender-matched healthy subjects (controls). Headaches were classified according to

Omdal R.				the International Classification of Headache Disorders. We measured depression with the Beck Depression Inventory, and fatigue with the Fatigue Severity Scale. RESULTS: Fifty-one patients and 42 controls had headaches in the previous 12 months (71.8% vs. 59.2%, P = 0.10). Thirty-eight patients and 28 controls had tension type headaches (TTHs) (53.5% vs. 39.4%, P = 0.12). Eight patients (11.3%) and one control had chronic TTHs (P = 0.05). Migraines and migraines with aura were equally prevalent in patients (26.8% and 11.3%, respectively) and controls (28.2% and 15.5%, respectively; P = 0.61). CONCLUSIONS: In general, patients did not have more migraines or headaches than controls. However, patients had more chronic TTHs than controls. Chronic TTHs were not associated with PSS-related autoantibodies, fatigue, depression, abnormalities on magnetic resonance imaging or abnormalities in the cerebrospinal fluid. Patients with PSS did, however, have higher depression and fatigue scores than controls.
Togo F, Lange G, Natelson BH, Quigley KS.	Educational Physiology Laboratory, Graduate School of Education, University of Tokyo, Japan.	Attention network test: Assessment of cognitive function in chronic fatigue syndrome.	J Neuropsychol. 2013 Sep 24. doi: 10.1111/jnp.12030. [Epub ahead of print]	Information processing difficulties are common in patients with chronic fatigue syndrome (CFS). It has been shown that the time it takes to process a complex cognitive task, rather than error rate, may be the critical variable underlying CFS patients' cognitive complaints. The Attention Network Task (ANT) developed by Fan and colleagues may be of clinical utility to assess cognitive function in CFS, because it allows for simultaneous assessment of mental response speed, also called information processing speed, and error rate under three conditions challenging the attention system. Comparison of data from two groups of CFS patients (those with and without comorbid major depressive disorder; n = 19 and 22, respectively) to controls (n = 29) consistently showed that error rates did not differ among groups across conditions, but speed of information processing did. Processing time was prolonged in both CFS groups and most significantly affected in response to the most complex task conditions. For simpler tasks, processing time was only prolonged in CFS participants with depression. The data suggest that the ANT may be a task that could be used clinically to assess information processing deficits in individuals with CFS.
Togo F, Natelson BH.	Educational Physiology Laboratory, Graduate School of Education, The University of Tokyo, Tokyo, Japan. tougou@p.u-tokyo.ac.jp	Heart rate variability during sleep and subsequent sleepiness in patients with chronic fatigue syndrome.	Auton Neurosci. 2013 Jun;176(1-2):85-90. doi: 10.1016/j.autneu.2013.02.015 . Epub 2013 Mar 15.	We determined whether alterations in heart rate dynamics during sleep in patients with chronic fatigue syndrome (CFS) differed from controls and/or correlated with changes of sleepiness before and after a night in the sleep laboratory. We compared beat-to-beat RR intervals (RRI) during nocturnal sleep, sleep structure, and subjective scores on visual analog scale for sleepiness in 18 CFS patients with 19 healthy controls aged 25-55 after excluding subjects with sleep disorders. A short-term fractal scaling exponent (α1) of RRI dynamics, analyzed by the detrended fluctuation analysis (DFA) method, was assessed after stratifying patients into those who reported more or less sleepiness after the night's sleep (a.m. sleepier or a.m. less sleepy, respectively). Patients in the a.m. sleepier group showed significantly ($p<0.05$) higher fractal scaling index α1 during non-rapid eye movement (non-REM) sleep (Stages 1, 2, and 3 sleep) than healthy controls, although standard polysomnographic measures did not differ

				between the groups. The fractal scaling index α1 during non-REM sleep was significantly ($p<0.05$) higher than that during awake periods after sleep onset for healthy controls and patients in the a.m. less sleepy group, but did not differ between sleep stages for patients in the a.m. sleepier group. For patients, changes in self-reported sleepiness before and after the night correlated positively with the fractal scaling index α1 during non-REM sleep ($p<0.05$). These results suggest that RRI dynamics or autonomic nervous system activity during non-REM sleep might be associated with disrupted sleep in patients with CFS.
Tokizane K, Konishi H, Yasui M, Ogawa T, Sasaki K, Minamino N, Kiyama H.	Department of Functional Anatomy and Neuroscience, Nagoya University, Graduate School of Medicine, Nagoya, Aichi 466-8550, Japan.	Continuous stress promotes expression of VGF in melanotroph via suppression of dopamine.	Mol Cell Endocrinol. 2013 Jun 15; 372(1-2):49-56. doi: 10.1016/j.mce.2013.03.012. Epub 2013 Mar 26.	Prolonged exposure to stress elicits profound effects on homeostasis that may lead to cryptogenic disorders such as chronic fatigue syndrome. To investigate the pathophysiology associated with the syndrome, we used a rat continuous stress (CS) model where the pituitary represents one of the most affected organs. Here we found that mRNA for VGF (non-acronymic), a member of the granin family, was induced specifically in the intermediate lobe (IL). This was matched by a concomitant increase at the peptide/protein level assessed by C-terminal antibody. Furthermore, the up-regulation of VGF was confirmed by immunohistochemistry in a subset of melanotrophs. VGF expression was altered in the IL of rats receiving the dopamine D2 receptor agonist bromocriptine or the antagonist sulpiride. In vitro, dopamine dose-dependently decreased the mRNA levels in cultured melanotrophs. These findings suggest that VGF expression under CS is negatively regulated by dopaminergic neurons projecting from the hypothalamus.
Tschudi-Madsen H, Kjeldsberg M, Natvig B, Ihlebaek C, Straand J, Bruusgaard D.	Department of General Practice, Institute of Health and Society, Faculty of Medicine, University of Oslo, PO Box 1130, Blindern, N-0318 Oslo	Medically unexplained conditions considered by patients in general practice.	Fam Pract. 2013 Dec 24. [Epub ahead of print]	BACKGROUND: Patients frequently present with multiple and 'unexplained' symptoms, often resulting in complex consultations. To better understand these patients is a challenge to health care professionals, in general, and GPs, in particular. OBJECTIVES: In our research on symptom reporting, we wanted to explore whether patients consider that they may suffer from conditions commonly regarded as unexplained, and we explored associations between these concerns and symptom load, life stressors and socio-demographic factors. METHODS: Consecutive, unselected patients in general practice completed questionnaires addressing eight conditions commonly regarded as unexplained (amalgam poisoning, Candida syndrome, fibromyalgia, food intolerance, electromagnetic hypersensitivity, burnout syndrome, chronic fatigue syndrome and irritable bowel syndrome). With logistic regression, we analysed associations with symptom load, burden of life stressors with negative impact on present health and socio-demographic variables. RESULTS: Out of the 909 respondents (response rate = 88.8%), 863 had complete data. In total, 39.6% of patients had considered that they may suffer from one or more unexplained conditions (UCs). These concerns were strongly and positively associated with recent symptom load and number of life stressors. If we excluded burnout and food intolerance, corresponding associations were found. CONCLUSION: Patients frequently considered that they may suffer from UCs. The likelihood of such concerns

				strongly increased with an increasing symptom load and with the number of life stressors with negative impact on present health. Hence, the number of symptoms may be a strong indicator of whether patients consider their symptoms part of such often controversial multi-symptom conditions.
Tummers M, Knoop H, van Dam A, Bleijenberg G.	Expert Centre for Chronic Fatigue, Radboud University Nijmegen Medical Centre, Nijmegen, The Netherlands. m.tummers@nkcv.umcn.nl	Moderators of the treatment response to guided self-instruction for chronic fatigue syndrome.	J Psychosom Res. 2013 May; 74(5):373-7. doi: 10.1016/j.jpsychores.2013.01.007. Epub 2013 Mar 5.	OBJECTIVE: The efficiency and efficacy of guided self-instruction for chronic fatigue syndrome (CFS) can be enhanced if it is known which patients will benefit from the intervention. This study aimed to identify moderators of treatment response. METHODS: This study is a secondary analysis of two randomized controlled trials evaluating the efficacy of guided self-instruction for CFS. A sample of 261 patients fulfilling US Center for Disease Control and Prevention criteria for CFS was randomly allocated to guided self-instruction or a wait list. The following potential treatment moderators were selected from the literature: age, fatigue severity, level of physical functioning, pain, level of depressive symptoms, self-efficacy with respect to fatigue, somatic attributions, avoidance of activity, and focus on bodily symptoms. Logistic and linear regression analyses were used with interaction term between treatment response and the potential moderator. RESULTS: Age, level of depression, and avoidance of activity moderated the response to guided self-instruction. Patients who were young, had low levels of depressive symptoms, and who had a low tendency to avoid activity benefited more from the intervention than older patients and patients with high levels of depressive symptoms and a strong tendency to avoid activity. CONCLUSION: Guided self-instruction is exclusively aimed at cognitions and behaviours that perpetuate fatigue. Patients with severe depressive symptom may need more specific interventions aimed at the reduction of depressive symptoms to profit from the intervention. Therefore we suggest that patients with substantial depressive symptoms be directly referred to regular cognitive behaviour therapy.

Tzanis G, Dimopoulos S, Agapitou V, Nanas S.	1st Critical Care Medicine Department, Cardiopulmonary Exercise Testing and	Exercise Intolerance in Chronic Heart Failure: The Role of Cortisol and the	Curr Heart Fail Rep. 2013 Nov 30. [Epub ahead of print]	Chronic heart failure (CHF) is a complex clinical syndrome leading to exercise intolerance due to muscular fatigue and dyspnea. Hemodynamics fail to explain the reduced exercise capacity, while a significant skeletal muscular pathology seems to constitute the main underlying mechanism for exercise intolerance in CHF patients.

	Rehabilitation Laboratory, "Evgenidio Hospital", National & Kapodestrian University of Athens, Papadiamantopoulou str., 20, Athens, 11528, Greece.	Catabolic State.		There have been proposed several metabolic, neurohormonal and immune system abnormalities leading to an anabolic/catabolic imbalance that plays a central role in the pathogenesis of the wasting process of skeletal muscle myopathy. The impairment of the anabolic axes is associated with the severity of symptoms and the poor outcome in CHF, whereas increased cortisol levels are predictive of exercise intolerance, ventilatory inefficiency and chronotropic incompetence, suggesting a significant contributing mechanism to the limited functional status. Exercise training and device therapy could have beneficial effects in preventing and treating muscle wasting in CHF. However, specific anabolic treatment needs more investigation to prove possible beneficial effects.
Valero S, Sáez-Francàs N, Calvo N, Alegre J, Casas M.	Department of Psychiatry, Hospital Universitari Vall d'Hebron, CIBERSAM, Universitat Autònoma de Barcelona, Passeig de la Vall d'Hebron 119-129, 08035 Barcelona, Catalonia, Spain. Electronic address: svalero@vhebron.net.	The role of neuroticism, perfectionism and depression in chronic fatigue syndrome. A structural equation modeling approach.	Compr Psychiatry. 2013 Oct; 54(7):1061-7. doi: 10.1016/j.comppsych.2013.04.015. Epub 2013 Jun 5.	OBJECTIVE: Previous studies have reported consistent associations between Neuroticism, maladaptive perfectionism and depression with severity of fatigue in Chronic Fatigue Syndrome (CFS). Depression has been considered a mediator factor between maladaptive perfectionism and fatigue severity, but no studies have explored the role of neuroticism in a comparable theoretical framework. This study aims to examine for the first time, the role of neuroticism, maladaptive perfectionism and depression on the severity of CFS, analyzing several explanation models. METHODS: A sample of 229 CFS patients were studied comparing four structural equation models, testing the role of mediation effect of depression severity in the association of Neuroticism and/or Maladaptive perfectionism on fatigue severity. RESULTS: The model considering depression severity as mediator factor between Neuroticism and fatigue severity is the only one of the explored models where all the structural modeling indexes have fitted satisfactorily (Chi square=27.01, p=0.079; RMSE=0.047, CFI=0.994; SRMR=0.033). Neuroticism is associated with CFS by the mediation effect of depression severity. This personality variable constitutes a more consistent factor than maladaptive perfectionism in the conceptualization of CFS severity.
Valle LA, Gorodeski Baskin RL, Porter K, Sipos JA, Khawaja R, Ringel MD, Kloos RT.	Department of Internal Medicine, The Ohio State University, Columbus, Ohio, USA.	In thyroidectomized patients with thyroid cancer, a serum thyrotropin of 30μU/mL after thyroxine withdrawal is not always adequate for detecting an elevated stimulated serum thyroglobulin.	Thyroid. 2013 Feb; 23(2):185-93. doi: 10.1089/thy.2012.0327.	BACKGROUND: The thyrotropin (TSH) level or duration of thyroid hormone withdrawal (THW) required to detect stimulated thyroglobulin (Tg) in differentiated thyroid cancer (DTC) monitoring is unknown. The objective of this study was to evaluate the TSH cutoff of >30μU/mL as a means to detect stimulated Tg ≥2ng/mL after THW (THW-Tg≥2), and sensitivity of the Functional Assessment of Chronic Illness Therapy-Fatigue (FACIT-F) questionnaire for detecting hypothyroid symptoms. METHODS: This was a prospective longitudinal cohort study done at a tertiary academic medical center. Forty-seven patients with DTC undergoing their first Tg stimulation or after previously abnormal Tg stimulation had weekly measurements of TSH and Tg during the 4 weeks THW, and repeated questionnaire assessments. RESULTS: TSH did not reach a plateau in any patient, and in those whose Tg did not remain undetectable, Tg continued to rise. Seventy-five percent of patients had an undetectable Tg <0.2ng/mL at baseline (95% were <0.5mg/mL) with 16% remaining

				undetectable throughout THW. The majority of patients (72.7% and 97.8%) achieved TSH >30 µU/mL by 3 and 4 weeks THW, respectively. Of the 15 patients with maximum stimulated THW-Tg≥2, 38% were detected before the minimal TSH >30µU/mL cutoff. At 2 weeks THW, 3 had a TSH>30µU/mL, and none of them had Tg ≥2ng/mL. At 3 weeks THW, 11 had a TSH >30µU/mL, and 64% of them had Tg ≥2ng/mL. Only 60% were detected at 3-week THW regardless of their TSH level. Eighty-six percent were detected by TSH 60-<80µU/mL. Conversely, all patients whose serum Tg was <0.2ng/mL when their serum TSH was >20µU/mL did not achieve a THW-Tg≥2. CONCLUSION: The minimal TSH cutoff of >30µU/mL was inadequate to detect many patients with final stimulated THW-Tg≥2 during complete THW. TSH >80-100µU/mL was a better cutoff, achieved in only 53% after 4-week THW. Conversely, we propose a preliminary THW-stopping rule for ending THW early in selected patients. In patients with a Tg <0.2ng/mL when TSH >20µU/mL, all had a final stimulated Tg ≤2ng/mL, potentially saving qualifying patients 40% of THW duration compared to 4-week THW. FACIT-F correlated with TSH, but was not sensitive to detect mild hypothyroidism.

van Doorn PA.	Department of Neurology, Erasmus MC, Rotterdam, The Netherlands. p.a.vandoorn@erasmusmc.nl	Diagnosis, treatment and prognosis of Guillain-Barré syndrome (GBS).	Presse Med. 2013 Jun; 42(6 Pt 2):e193-201. doi: 10.1016/j.lpm.2013.02.328. Epub 2013 Apr 28.	Guillain-Barré syndrome (GBS) is an acute polyneuropathy with a variable degree of weakness that reaches its maximal severity within 4 weeks. The disease is mostly preceded by an infection and generally runs a monophasic course. Both intravenous immunoglobulin (IVIg) and plasma exchange (PE) are effective in GBS. Rather surprisingly, steroids alone are ineffective. Mainly for practical reasons, IVIg usually is the preferred treatment. GBS can be subdivided in the acute inflammatory demyelinating polyneuropathy (AIDP), the most frequent form in the western world; acute motor axonal neuropathy (AMAN), most frequent in Asia and Japan; and in Miller-Fisher syndrome (MFS). Additionally, overlap syndromes exist (GBS-MFS

				overlap). About 10% of GBS patients have a secondary deterioration within the first 8 weeks after start of IVIg. Such a treatment-related fluctuation (TRF) requires repeated IVIg treatment. About 5% of patients initially diagnosed with GBS turn out to have chronic inflammatory demyelinating polyradiculoneuropathy (CIDP) with acute onset (A-CIDP). It is yet unknown whether GBS patients who remain able to walk ('mildly affected GBS patients'), or patients with MFS, also benefit from IVIg. Despite current treatment, GBS remains a severe disease, as about 25% of patients require artificial ventilation during a period of days to months, about 20% of patients are still unable to walk after 6 months and 3-10% of patients die. Additionally, many patients have pain, fatigue or other residual complaints that may persist for months or years. Pain can also be very confusing in making the diagnosis, especially when it precedes the onset of weakness. Advances in prognostic modelling resulted in the development of a simple prognostic scale that predicts the chance for artificial ventilation, already at admission; and in an outcome scale that can be used to determine the chance to be able to walk unaided after 1, 3 or 6 months. GBS patients with a poor prognosis potentially might benefit from a more intensified treatment. A larger increase in serum IgG levels after standard IVIg treatment (0.4 g/kg/day for 5 consecutive days) seems to be related with an improved outcome after GBS. This was one of the reasons to start the second course IVIg trial (SID-GBS trial) in GBS patients with a poor prognosis. This study is currently going on. The international GBS outcome study (IGOS) is a new worldwide prognostic study that aims to get further insight in the (immune) pathophysiology and outcome of GBS, both in children and adults. Hopefully these and other studies will further help to improve the understanding and especially the outcome in patients with GBS.

VanElzakker MB.	Tufts University Psychology, Massachusetts General Hospital Psychiatric Neuroscience, 490 Boston Avenue, Medford, MA 02155, USA.	Chronic fatigue syndrome from vagus nerve infection: a psychoneuroimmunological hypothesis.	Med Hypotheses. 2013 Sep; 81(3):414-23. doi: 10.1016/j.mehy.2013.05.034. Epub 2013 Jun 19.	Chronic fatigue syndrome (CFS) is an often-debilitating condition of unknown origin. There is a general consensus among CFS researchers that the symptoms seem to reflect an ongoing immune response, perhaps due to viral infection. Thus, most CFS research has focused upon trying to uncover that putative immune system dysfunction or specific pathogenic agent. However, no single causative agent has been found. In this speculative article, I describe a new hypothesis for the etiology of CFS: infection of the vagus nerve. When immune cells of otherwise healthy individuals detect any peripheral infection, they release proinflammatory cytokines.

	michael.vanelzakker@gmail.com			Chemoreceptors of the sensory vagus nerve detect these localized proinflammatory cytokines, and send a signal to the brain to initiate sickness behavior. Sickness behavior is an involuntary response that includes fatigue, fever, myalgia, depression, and other symptoms that overlap with CFS. The vagus nerve infection hypothesis of CFS contends that CFS symptoms are a pathologically exaggerated version of normal sickness behavior that can occur when sensory vagal ganglia or paraganglia are themselves infected with any virus or bacteria. Drawing upon relevant findings from the neuropathic pain literature, I explain how pathogen-activated glial cells can bombard the sensory vagus nerve with proinflammatory cytokines and other neuroexcitatory substances, initiating an exaggerated and intractable sickness behavior signal. According to this hypothesis, any pathogenic infection of the vagus nerve can cause CFS, which resolves the ongoing controversy about finding a single pathogen. The vagus nerve infection hypothesis offers testable hypotheses for researchers, animal models, and specific treatment strategies.
Vieira da Motta M, Vieira da Motta E.	University of Sao Paulo, Medical School, Pinheiros, Sao Paulo Brazil.	Levonorgestrel-releasing intrauterine system and iron overload syndrome.	Clin Med Insights Case Rep. 2013 Jun 3;6: 93-7. doi: 10.4137/CCRep.S11888. Print 2013.	Severe fatigue is a common complaint among patients. This report presents a clinical case of a woman complaining of fatigue associated with diarrhea and myalgia that were first attributed to emotional stress and depression. Initially, the patient was diagnosed with chronic fatigue and irritable bowel syndrome. The patient followed nutritional and physical exercise programs without any improvement. Other clinical conditions, such as nutritional deficiencies, endocrine dysfunctions, autoimmune diseases and neoplasias, were then assessed. During clinical investigation, serum ferritin and iron levels were abnormally elevated despite normal hemoglobin levels, which pointed to an iron overload syndrome later diagnosed as hemochromatosis. It is possible that the symptoms were triggered by the amenorrhea caused by the levonorgestrel-releasing intrauterine system used for contraception.
Vishnu VY, Modi M, Prabhakar S, Bhansali A, Goyal MK.	Department of Neurology, Post Graduate Institute of Medical Education and Research, Chandigarh 160012, India. Electronic address: vishnuvy16@yahoo.com.	"A" motor neuron disease.	Department of Neurology, Post Graduate Institute of Medical Education and Research, Chandigarh 160012, India. Electronic address: vishnuvy16@yahoo.com.	Importance: Allgrove syndrome is a rare autosomal recessive disorder characterised by achalasia, alacrima, adrenal insufficiency, autonomic dysfunction and amyotrophy. The syndrome has been described in childhood and adult presentation, as in our case, is very rare. There is a considerable delay in diagnosis due to lack of awareness about the syndrome. Observations: We report a single case of a 36year old man who was initially diagnosed and treated for achalasia cardia in our institute 14years before. After 8years he presented again with weakness and wasting predominantly distally. He had tongue fasciculations, brisk reflexes and extensor plantar. After supportive electrophysiological studies he was diagnosed as Amyotrophic lateral sclerosis. After 5years he presented with generalised fatigue without any significant worsening of his neurological status. On reevaluation he had alacrimia, autonomic dysfunction and mild ACTH resistance. Conclusions and relevance: Allgrove syndrome may be an underdiagnosed cause of multisystem neurological disease due to the heterogeneous clinical presentation as well as for ignorance of clinician about the syndrome. Based on our case, we also believe that there does exist a subgroup of patients who follow a

				less severe and chronic course. Recognition of syndrome allows for treatment of autonomic dysfunction, adrenal insufficiency and dysphagia.
Vos-Vromans DC, Huijnen IP, Köke AJ, Seelen HA, Knottnerus JA, Smeets RJ.	Revant Rehabilitation Centre Breda, Brabantlaan 1, 4817 JW Breda, The Netherlands. d.vos@revant.nl	Differences in physical functioning between relatively active and passive patients with Chronic Fatigue Syndrome.	J Psychosom Res. 2013 Sep;75(3):249-54. doi: 10.1016/j.jpsychores.2013.05.001. Epub 2013 Jun 2.	OBJECTIVE: According to the Cognitive behavioral therapy (CBT) protocol for patients with Chronic Fatigue Syndrome (CFS), therapists are advised to categorize patients in relatively active and passive patients. However, evidence to support the differences in physical functioning between these subgroups is limited. Using the baseline data from a multicentre randomized controlled trial (FatiGo), the differences in actual and perceived physical functioning between active and passive patients with CFS were evaluated. METHODS: Sixty patients, who received CBT during the FatiGo trial were included. Based on the expert opinion and using the definitions of subgroups defined in the CBT protocols, the therapist categorized the patient. Data from an activity monitor was used to calculate actual physical functioning, physical activity, daily uptime, activity fluctuations and duration of rest during daily life. Perceived physical functioning was assessed by measuring physical activity, physical functioning and functional impairment with the Checklist Individual Strength, Short Form-36 and Sickness-Impact Profile 8. RESULTS: Relatively active patients have a significantly higher daily uptime and show significantly less fluctuations in activities between days. Passive patients experience a significantly lower level of physical functioning and feel more functionally impaired in their mobility. However, no significant differences were found in the other actual or perceived physical functioning indices. CONCLUSIONS: A clear difference in actual and perceived physical functioning between relatively active and passive patients with CFS as judged by their therapists could not be found. Future research is needed to form a consensus on how to categorize subgroups of patients with CFS.
Walwyn R, Potts L, McCrone P, Johnson AL, Decesare JC, Baber H, Goldsmith K, Sharpe M, Chalder T, White PD.	MH&N Clinical Trials Unit, Institute of Psychiatry, King's College London, DeCrespigny Park, London, SE5 8AF, UK. R.E.A.Walwyn@leeds.ac.uk.	A randomised trial of adaptive pacing therapy, cognitive behaviour therapy, graded exercise, and specialist medical care for chronic fatigue syndrome (PACE): statistical analysis plan.	Trials. 2013 Nov 13;14:386. doi: 10.1186/1745-6215-14-386.	BACKGROUND: The publication of protocols by medical journals is increasingly becoming an accepted means for promoting good quality research and maximising transparency. Recently, Finfer and Bellomo have suggested the publication of statistical analysis plans (SAPs).The aim of this paper is to make public and to report in detail the planned analyses that were approved by the Trial Steering Committee in May 2010 for the principal papers of the PACE (Pacing, graded Activity, and Cognitive behaviour therapy: a randomised Evaluation) trial, a treatment trial for chronic fatigue syndrome. It illustrates planned analyses of a complex intervention trial that allows for the impact of clustering by care providers, where multiple care-providers are present for each patient in some but not all arms of the trial. RESULTS: The trial design, objectives and data collection are reported. Considerations relating to blinding, samples, adherence to the protocol, stratification, centre and other clustering effects, missing data, multiplicity and compliance are described. Descriptive, interim and final analyses of the primary and secondary outcomes are then outlined. CONCLUSIONS: This SAP maximises transparency, providing a record of all planned analyses, and it may be a resource for those who are developing SAPs,

				acting as an illustrative example for teaching and methodological research. It is not the sum of the statistical analysis sections of the principal papers, being completed well before individual papers were drafted. TRIAL REGISTRATION: ISRCTN54285094 assigned 22 May 2003; First participant was randomised on 18 March 2005.

The effective mechanism of the polysaccharides from Panax ginseng on chronic fatigue syndrome.	Arch Pharm Res. 2013 Aug 21. [Epub ahead of print]	Ginseng acidic polysaccharide WGPA isolated from the root of Panax ginseng C. A. Meyer was fractionated into WGPA-A and WGPA-N by anion-exchange chromatography. The antifatigue activity of ginseng acidic polysaccharide WGPA has been reported in our previous research. This present study was designed to identify its active component and elucidate the mechanism for preventing chronic fatigue syndrome (CFS). WGPA, WGPA-A and WGPA-N were orally administered to mice once daily for 15 days. The effects of these compounds on physiological biomarkers of oxidative stress and on the morphology of the mitochondria in striated skeletal muscle were assessed. The results of forced swimming test-induced indicated that WGPA and WGPA-A could lengthen the swimming time, while WGPA-N could not. In addition, malondialdehyde and lactate dehydrogenase levels in serum were enhanced; while those of superoxide dismutase and glutathione peroxidase were lowered. Interestingly, the structural degeneration of mitochondria were all ameliorated. These findings suggested that WGPA-A is the active component of WGPA, it might have potential therapeutic effects for CFS and the oxidative stress might be involved in the pathogenesis. Our results also provided essential data for a better understanding of the antifatigue effects of P. ginseng extracts.
Wang WJ, Lu G, Ding N, Huang HP, Ding WX, Zhang XL.	Department of Respiratory Medicine, Nanjing Hospital Affiliated to Nanjing Medical University, Nanjing, Jiangsu 210001, China.	Adiponectin alleviates contractile dysfunction of genioglossus in rats exposed to chronic intermittent hypoxia.	Chin Med J (Engl). 2013; 126 (17):3259-63.	BACKGROUND: Genioglossal dysfuntion takes an important role in pathogenesis of obstructive sleep apnea hypopnea syndrome (OSAHS) in which chronic intermittent hypoxia (CIH) is the major pathological origin. Recent studies have suggested genioglossal injury induced by CIH might be improved by adiponectin. The aim of this study was to investigate the effects of adiponectin on genioglossus contractile properties in rats exposed to CIH. METHODS: Thirty-nine healthy male Wistar rats were randomly divided into three groups: normal control (NC), CIH and adiponectin supplement (CIH+Ad) with 13 rats in each. Rats in NC were kept breathing normal air, while rats in CIH and CIH+Ad experienced the same CIH environment eight hours per day for 35 successive days. Rats in CIH+Ad were given intravenous adiponectin of 10 μg twice a week for 30 successive days. Rats in the NC and CIH were injected with normal saline as a control. After 35 days' CIH exposure, the levels of serum adiponectin and genioglossus contractile properties were compared. RESULTS: Serum adiponectin level was significantly lower in CIH than in NC (1210 ng/ml vs. 2236 ng/ml). Serum adiponectin level in CIH+Ad (1844 ng/ml) was significantly higher than CIH but lower than NC. Twitch tension, time to peak tension, half relaxation time and tetanic tension were significantly lower in CIH than NC and improved in CIH+Ad. All mean tetanic fatigue indices decreased more rapidly in the first 20 seconds than during the subsequent 100 seconds. Tetanic fatigue indices in NC and CIH+Ad were

				significantly higher compared to CIH. CONCLUSIONS: CIH could lead to hypoadiponectinaemia, impaired genioglossus contractile properties and decreased fatigue resistance in rats. Such changes could be partially offset by supplementation of adiponectin.
Warren JW, Clauw DJ, Langenberg P.	Department of Medicine, University of Maryland School of Medicine, Baltimore, MD 21201, USA. jwarren@medicine.umaryland.edu	Prognostic factors for recent-onset interstitial cystitis/painful bladder syndrome.	Comment in J Urol. 2013 Aug; 190(2):551.	Study Type - Prognosis (case series) Level of Evidence 4 What's known on the subject? and What does the study add? Interstitial cystitis/painful bladder syndrome (IC/PBS) comprises pain perceived to be from the bladder, urinary urgency and frequency, and nocturia. As diagnosed at present, it is primarily identified in adult women. It is a chronic disease yet its natural history has not been well studied. In a prospective study of 304 incident female IC/PBS cases followed for a median of 33 months after onset, women with baseline chronic fatigue syndrome had a worse prognosis for IC/PBS. Mild IC/PBS at baseline was the only variable that was directly associated with a good prognosis.OBJECTIVE: To identify baseline variables that predict the prognosis of interstitial cystitis/painful bladder syndrome (IC/PBS) in women seeking medical care for recent onset of this syndrome. SUBJECTS AND METHODS: In a prospective study of women with incident IC/PBS (≤12 months of symptoms), we contacted patients at intervals and asked standardized questions about IC/PBS symptoms in the previous week. Logistic regression analyses assessed baseline variables as predictors of mild vs more severe IC/PBS at the last follow-up. RESULTS: Median length of follow-up was 33 months after onset of IC/PBS; 304 (97%) patients had at least one follow-up assessment. Mild IC/PBS at baseline was the only variable that was directly associated with a mild IC/PBS endpoint. Conversely, a history of chronic fatigue syndrome (CFS) was inversely associated with a mild endpoint of IC/PBS (i.e. individuals with CFS had a worse prognosis for their IC/PBS symptoms). CONCLUSIONS: At a median of nearly 3 years after onset, baseline mild IC/PBS was directly associated with a milder disease severity. Baseline co-morbid CFS was associated with more severe disease. Whether CFS was uniquely associated or represented several co-morbid non-bladder syndromes (NBSs) could not be determined.
Warren JW, Langenberg P, Clauw DJ.	Department of Medicine, University of Maryland School of Medicine, Baltimore, MD 21201, USA. jwarren@medicine.umaryland.edu	The number of existing functional somatic syndromes (FSSs) is an important risk factor for new, different FSSs.	J Psychosom Res. 2013 Jan; 74(1):12-7. doi: 10.1016/j.jpsychores.2012.09.002. Epub 2012 Sep 26. J Psychosom Res. 2013 Aug; (2):190. J Psychosom Res. 2013 Aug; 5(2):191.	OBJECTIVE: The objective of this study is to test the hypothesis that the number of functional somatic syndromes (FSSs) predicts new, additional FSSs. METHODS: In a recent case-control study of interstitial cystitis/painful bladder syndrome (IC/PBS), we used symptom-based consensus definitions to identify these FSSs: fibromyalgia (FM), chronic fatigue syndrome (CFS), irritable bowel syndrome (IBS), chronic pelvic pain, migraine, sicca syndrome and panic disorder. Those present before the incidence year were called antecedent FSSs; those with onset during the incidence year were called incident FSSs. In each of two groups, 312 IC/PBS cases and 313 controls, rates of incident FSSs were compared among those with 0, 1, 2, or ≥3 antecedent FSSs. Confounding was assessed using logistic regression analyses that included the individual antecedent FSSs, published correlates of these FSSs, and demographic variables. RESULTS: The incidence of a new FSS increased with the number of

				antecedent FSSs, as did that of incident FM, CFS and IBS studied separately. These findings were not confounded by other variables. The presence of multiple antecedent FSSs generally had the highest odds ratio for new, different, incident FSSs. CONCLUSIONS: This study revealed that the number of antecedent FSSs was among the strongest risk factors for other FSSs, especially incident FM, CFS and IBS. This suggests that the FSSs are linked through a polysyndromic phenotype. If each FSS is heterogeneous, to seek a pathogenesis common to all FSSs, individuals with multiple FSSs should be sought; to seek a pathogenesis unique to a specific FSS, mature persons who have only that FSS should be studied.
Wearden AJ, Emsley R.	School of Psychological Sciences, University of Manchester.	Mediators of the effects on fatigue of pragmatic rehabilitation for chronic fatigue syndrome.	J Consult Clin Psychol. 2013 Oct; 81(5):831-8. doi: 10.1037/a0033561. Epub 2013 Jun 24.	OBJECTIVE: To examine potential mediators of the effect of pragmatic rehabilitation on improvements in fatigue following a randomized controlled trial for patients with chronic fatigue syndrome (CFS/ME) in primary care (IRCTN 74156610). METHOD: Patients fulfilled the Oxford criteria for CFS. Ninety-five patients were randomized to pragmatic rehabilitation and 100 to general practitioner (GP) treatment as usual. The outcome was the Chalder fatigue scale score (0123 scoring) at end of treatment (20 weeks) and 1-year follow up (70 weeks). First, the effect of treatment on potential mediators was assessed. Then fatigue was regressed on significant mediators, treatment allocation, and baseline measures of fatigue and significant mediators. RESULTS: Reduction in limiting activities at 20 weeks mediated the positive effect of pragmatic rehabilitation on fatigue at 70 weeks (mediated effect size = -2.64, SE = 0.81, p = .001, proportion of effect mediated = 82.0%). Reduction in catastrophizing at 20 weeks mediated the positive effect of pragmatic rehabilitation on fatigue at 70 weeks (mediated effect size = -1.39, SE = 0.61, p = .023, proportion of effect mediated = 43.2%). Reductions in 70-week measures of fear avoidance, embarrassment avoidance, limiting activities, and all-or-nothing behavior all mediated improvement in fatigue at 70 weeks, although the causal direction of these cross-sectional effects cannot be determined. There were no between-group differences on measures of exercise capacity (a timed step test). CONCLUSIONS: Improvements in fatigue following pragmatic rehabilitation are related to changes in behavioral responses to and beliefs about fatigue.
Werker CL, Nijhof SL, van de Putte EM.	Department of Pediatrics, Wilhelmina Children's Hospital, University Medical Centre Utrecht, Utrecht, The Netherlands, c.l.werker@students.uu.nl.	Clinical Practice: Chronic fatigue syndrome.	Eur J Pediatr. 2013 Oct; 172(10):1293-8. doi: 10.1007/s00431-013-2058-8. Epub 2013 Jun 12.	The diagnosis chronic fatigue syndrome (CFS) was conceptualized in the mid-1980s. It is a clinically defined condition characterized by severe and disabling new onset fatigue with at least four additional symptoms: impaired memory or concentration, sore throat, tender cervical or axillary lymph nodes, muscle pain, multi-joint pain, new headaches, unrefreshing sleep or post-exertion malaise. Chronic fatigue syndrome in adolescents is a rare condition compared to symptomatic fatigue. The estimated prevalence of adolescent CFS ranges between 0.11 and 1.29 % in Dutch, British, and US populations. Diagnosis of the chronic fatigue syndrome is established through exclusion of other medical and psychiatric causes of chronic fatiguing illness. Taking a full clinical history and a full physical examination are therefore vital. In adolescence,

				CFS is associated with considerable school absence with long-term detrimental effects on academic and social development. One of the most successful potential treatments for adolescents with CFS is cognitive behavioural therapy, which has been shown to be effective after 6 months in two thirds of the adolescents with CFS. This treatment effect sustains at 2-3-year follow-up. In conclusion, the diagnosis CFS should be considered in any adolescent patient with severe disabling long-lasting fatigue. Cognitive behavioural therapy is effective in 60-70 % of the patients. Prompt diagnosis favours the prognosis.

White PD, Goldsmith K, Johnson AL, Chalder T, Sharpe M.	Wolfson Institute of Preventive Medicine, Barts and the London School of Medicine and Dentistry, Queen Mary University of London, UK. p.d.white@qmul.ac.uk	Recovery from chronic fatigue syndrome after treatments given in the PACE trial.	Psychol Med. 2013 Oct; 43(10):2227-35. doi: 10.1017/S0033291713000020.	BACKGROUND: A multi-centre, four-arm trial (the PACE trial) found that rehabilitative cognitive behaviour therapy (CBT) and graded exercise therapy (GET) were more effective treatments for chronic fatigue syndrome (CFS) than specialist medical care (SMC) alone, when each was added to SMC, and more effective than adaptive pacing therapy (APT) when added to SMC. In this study we compared how many participants recovered after each treatment. METHOD: We defined recovery operationally using multiple criteria, and compared the proportions of participants meeting each individual criterion along with two composite criteria, defined as (a) recovery in the context of the trial and (b) clinical recovery from the current episode of the illness, however defined, 52 weeks after randomization. We used logistic regression modelling to compare treatments. RESULTS: The percentages (number/total) meeting trial criteria for recovery were 22% (32/143) after CBT, 22% (32/143) after GET, 8% (12/149) after APT and 7% (11/150) after SMC. Similar proportions met criteria for clinical recovery. The odds ratio (OR) for trial recovery after CBT was 3.36 [95% confidence interval (CI) 1.64–6.88] and for GET 3.38 (95% CI 1.65–6.93), when compared to APT, and after CBT 3.69 (95% CI 1.77–7.69) and GET 3.71 (95% CI 1.78–

				7.74), when compared to SMC (p values < or =0.001 for all comparisons). There was no significant difference between APT and SMC. Similar proportions recovered in trial subgroups meeting different definitions of the illness. CONCLUSIONS: This study confirms that recovery from CFS is possible, and that CBT and GET are the therapies most likely to lead to recovery.
Winger A, Ekstedt M, Wyller VB, Helseth S.	Faculty of Nursing, Oslo and Akershus University College of Applied Sciences, Oslo, Norway; Medical Faculty, Institute of Clinical Medicine, University of Oslo, Oslo, Norway.	'Sometimes it feels as if the world goes on without me': adolescents' experiences of living with chronic fatigue syndrome.	J Clin Nurs. 2013 Dec 20. Doi : 10.1111/jocn.12522. [Epub ahead of print]	AIMS AND OBJECTIVES: To explore the experience of being an adolescent with chronic fatigue syndrome. BACKGROUND: Despite ample research, chronic fatigue syndrome is still poorly understood, and there are still controversies related to the illness. Adolescents with chronic fatigue syndrome are often unable to attend school and lose social relations with friends. The challenges they face will affect their quality of life. DESIGN: A qualitative, phenomenological hermeneutical design. METHOD: Six boys and twelve girls, aged 12-18, were interviewed, emphasising their own experiences living with chronic fatigue syndrome. Analyses were performed using a phenomenological hermeneutical method. RESULTS: The core theme, 'Sometimes it feels as if the world goes on without me', encompasses the feelings an adolescent living with chronic fatigue syndrome might have about life. The core theme was supported by four subthemes: 'On the side of life - locked in and shut out'; 'the body, the illness and me'; 'if the illness is not visible to others, does it exist? '; and 'handling life while hoping for a better future'. The subthemes reflect the experience of social isolation, their own and others' understanding of the illness and hope for the future. CONCLUSIONS: Not being able to be with friends, or attend school, made the adolescents feel different and forgotten. They felt alienated in their own bodies and were struggling to be visible to themselves and to their surroundings. Spending less time with friends and more time with their parents constituted a threat to independence and development. Yet they managed to envision a better future despite all the difficulties. RELEVANCE FOR CLINICAL PRACTICE: To provide effective support and constructive relations to adolescents with chronic fatigue syndrome, all health professions involved need insight from the persons who are themselves ill. Health centres could function as resource centres for patients and healthcare professionals.
Witsch J, Galldiks N, Bender A, Kollmar R, Bösel J, Hobohm C, Günther A, Schirotzek I, Fuchs K, Jüttler E.	Center for Stroke Research Berlin (CSB), Charité University Medicine Berlin, Charitéplatz 1, 10117 Berlin, Germany. Jens.Witsch@charite.de	Long-term outcome in patients with Guillain-Barré syndrome requiring mechanical ventilation.	J Neurol. 2013 May; 260(5):1367-74. doi: 10.1007/s00415-012-6806-x. Epub 2013 Jan 9.	We aimed to determine long-term disability and quality of life in patients with Guillain-Barré syndrome (GBS) who required mechanical ventilation (MV) in the acute phase. Our retrospective cohort study included 110 GBS patients admitted to an intensive care unit and requiring MV (01/1999-08/2010) in nine German tertiary academic medical centers. Outcome was determined 1 year or longer after hospital admission using the GBS disability scale, Barthel index (BI), EuroQuol-5D (EQ-5D) and Fatigue Severity Scale. Linear/multivariate regression analysis was used to analyze predicting factors for outcome. Mean time to follow up was 52.6 months. Hospital mortality was 5.5 % and long-term mortality 13.6 %. Overall 53.8 % had a favorable outcome (GBS disability score 0-1) and 73.7 % of survivors had no or mild disability (BI

				90-100). In the five dimensions of the EQ-5D "mobility", "self-care", "usual activities", "pain" and "anxiety/depression" no impairments were stated by 50.6, 58.4, 36.4, 36.4 and 50.6 % of patients, respectively. A severe fatigue syndrome was present in 30.4 % of patients. Outcome was statistically significantly correlated with age, type of therapy and number of immunoglobulin courses. In GBS-patients requiring MV in the acute phase in-hospital, and long-term mortality are lower than that in previous studies, while long-term quality of life is compromised in a large fraction of patients, foremost by immobility and chronic pain. Efforts towards improved treatment approaches should address autonomic dysfunction to further reduce hospital mortality while improved rehabilitation concepts might ameliorate long-term disability.
Wyller VB, Helland IB.	Department of Paediatrics, Oslo University Hospital and University of Oslo, Oslo, Norway. brwylle@online.no.	Relationship between autonomic cardiovascular control, case definition, clinical symptoms, and functional disability in adolescent chronic fatigue syndrome: an exploratory study.	Biopsychosoc Med. 2013 Feb 7; 7(1):5. doi: 10.1186/1751-0759-7-5.	Chronic Fatigue Syndrome (CFS) is characterized by severe impairment and multiple symptoms. Autonomic dysregulation has been demonstrated in several studies. We aimed at exploring the relationship between indices of autonomic cardiovascular control, the case definition from Centers for Disease Control and Prevention (CDC criteria), important clinical symptoms, and disability in adolescent chronic fatigue syndrome. 38 CFS patients aged 12-18 years were recruited according to a wide case definition (ie. not requiring accompanying symptoms) and subjected to head-up tilt test (HUT) and a questionnaire. The relationships between variables were explored with multiple linear regression analyses. In the final models, disability was positively associated with symptoms of cognitive impairments ($p<0.001$), hypersensitivity ($p<0.001$), fatigue ($p=0.003$) and age ($p=0.007$). Symptoms of cognitive impairments were associated with age ($p=0.002$), heart-rate (HR) at baseline ($p=0.01$), and HR response during HUT ($p=0.02$). Hypersensitivity was associated with HR response during HUT ($p=0.001$), high-frequency variability of heart rate (HF-RRI) at baseline ($p=0.05$), and adherence to the CDC criteria ($p=0.005$). Fatigue was associated with gender ($p=0.007$) and adherence to the CDC criteria ($p=0.04$). In conclusion, a) The disability of CFS patients is not only related to fatigue but to other symptoms as well; b) Altered cardiovascular autonomic control is associated with certain symptoms; c) The CDC criteria are poorly associated with disability, symptoms, and indices of altered autonomic nervous activity.
Young JL.	Wayne State University School of Medicine, Detroit, MI 48307, USA. jyoung@rcbm.net	Chronic fatigue syndrome: 3 cases and a discussion of the natural history of attention-deficit/hyperactivity disorder.	Postgrad Med. 2013 Jan; 125(1):162-8. doi: 10.3810/pgm.2013.01.2631.	Fatigue is commonly reported in the primary care setting; however, its cause is often unclear. This article presents 3 cases involving patients with chronic fatigue syndrome who responded poorly to treatment. After clinical evaluation, all patients were found to meet criteria for attention-deficit/hyperactivity disorder (ADHD) and underwent a standard regimen of a psychostimulant medication. After treatment with psychostimulants, the 3 patients reported improved symptoms of fatigue and pain, and cognitive and core ADHD symptoms. These cases suggest that ADHD and chronic fatigue syndrome (and possibly fibromyalgia) share a common underlying mechanism. This article presents a model suggesting that over time, ADHD (predominantly

				inattentive type) develops into a syndrome of chronic fatigue and pain. These cases indicate that fatigue may be an important presenting symptom of adult ADHD. These cases also suggest the need for additional research to determine the prevalence of ADHD in patients who present with fatigue, and, in those meeting criteria for ADHD, the responsiveness of fatigue to psychostimulant treatment.
Young JL.	Wayne State University School of Medicine, Detroit, MI, USA. jyoung@rcbm.net	Use of lisdexamfetamine dimesylate in treatment of executive functioning deficits and chronic fatigue syndrome: a double blind, placebo-controlled study.	Psychiatry Res. 2013 May 15; 207(1-2):127-33. doi: 10.1016/j.psychres.2012.09.007. Epub 2012 Oct 9.	The purpose of this study was to assess the efficacy of lisdexamfetamine dimesylate (LDX) for the treatment of executive functioning deficits in adults (ages 18-60) with chronic fatigue syndrome (CFS). The study's primary outcome measure was the Behavior Rating Inventory of Executive Function-Adult (BRIEF-A). Secondary outcome measures were standardized assessments of fatigue, pain and global functioning. Twenty-six adults who met criteria for CFS and had clinically significant executive functioning deficits were randomly assigned to a flexible morning dose (30, 50, 70 mg/day) of either placebo or LDX for a 6-week trial. The data were analyzed with standard analysis of variance (ANOVA) procedures. Participants in the LDX group showed significantly more positive change in BRIEF-A scores (Mchange=21.38, SD=15.85) than those in the placebo group (Mchange=3.36, SD=7.26). Participants in the active group also reported significantly less fatigue and generalized pain relative to the placebo group. Although future studies with LDX should examine whether these benefits generalize to larger, more diverse samples of patients, these results suggest that LDX could be a safe and efficacious treatment for the executive functioning deficits often associated with CFS. The possibility that dopaminergic medications could play an important role addressing the symptoms of CFS is also discussed.
Zhang L, Xu MM, Zeng L, Liu S, Liu X, Wang X, Li D, Huang RZ, Zhao LB, Zhan QL, Zhu D, Zhang YY, Xu P, Xie P.	Department of Neurology, The First Affiliated Hospital of Chongqing Medical University, No. 1 Youyi Road, Yuzhong District, 400016, Chongqing, People's Republic of China.	Evidence for Borna disease virus infection in neuropsychiatric patients in three western China provinces.	Eur J Clin Microbiol Infect Dis. 2013 Oct 30. [Epub ahead of print]	Borna disease virus (BDV) is a non-cytolytic, neurotropic RNA virus that can infect a wide variety of vertebrate species from birds and primates to humans. Several studies have been carried out to investigate whether BDV is associated with neuropsychiatric diseases. However, this association is still inconclusive. Two panels of subjects consisting of 1,679 various neuropsychiatric patients and healthy people from three western China provinces were enrolled in this study. BDV p24 or p40 RNA in peripheral blood mononuclear cells (PBMCs) were detected in the first panel of 1,481 subjects using reverse transcription quantitative polymerase chain reaction (RT-qPCR) and cerebrospinal fluid (CSF) samples from the BDV RNA-positive individuals were subjected to BDV p24 antibodies testing by enzyme-linked immunosorbent assay (ELISA). BDV p24 or p40 RNA in PBMCs and p24 antibodies in plasma were detected in the second panel of 198 subjects by RT-qPCR and Western blot. A higher prevalence for BDV RNA was demonstrated in patients with viral encephalitis (6.70 %), Guillain-Barré syndrome (6.70 %), schizophrenia (9.90 %) and chronic fatigue syndrome (CFS) (12.70 %) compared to healthy controls

				in the first panel. CSF p24 antibodies were demonstrated in three viral encephalitis patients, two schizophrenia patients and two major depressive disorder (MDD) patients. The prevalences of p24 antibodies in plasma from patients with viral encephalitis (13.24 %), multiple sclerosis (25.00 %) and Parkinson's disease (22.73 %) were significantly higher than healthy controls. This study demonstrates that BDV infection also exists in humans from three western China provinces, and suggests the involvement of the contribution of BDV in the aetiology of Chinese patients with some neuropsychiatric disorders, including viral encephalitis, schizophrenia, CFS, multiple sclerosis and Parkinson's disease.

Abbi B, Natelson BH.	MD, Pain and Fatigue Study Center, Department of Pain Medicine and Palliative Care, Beth Israel Medical Center, 120 East 16th Street, 12th Floor, New York, NY 10003, USA. bnatelson@chpnet.org.	Is chronic fatigue syndrome the same illness as fibromyalgia: evaluating the 'single syndrome' hypothesis.	QJM. 2013 Jan;106(1):3-9. doi: 10.1093/qjmed/hcs156. Epub 2012	Chronic fatigue syndrome (CFS) and fibromyalgia (FM) are medically unexplained syndromes that can and often do co-occur. For this reason, some have posited that the two are part of the same somatic syndrome-examples of symptom amplification. This hypothesis would suggest that few differences exist between the two syndromes. To evaluate this interpretation, we have searched the literature for articles comparing CFS to FM, reviewing only those articles which report differences between the two. This review presents data showing differences across a number of parameters-implying that the underlying pathophysiology in CFS may differ from that of FM. We hope that our review encourages other groups to look for additional differences between CFS and FM. By continuing to preserve the unique illness definitions of the two syndromes, clinicians will be able to better identify, understand and provide treatment for these individuals.
Ablin JN, Buskila D, Van Houdenhove B, Luyten P, Atzeni F, Sarzi-Puttini P.	Institute of Rheumatology and Internal Medicine F, Tel Aviv Sourasky Medical Center, Israel.	Is fibromyalgia a discrete entity?	Autoimmun Rev. 2012 Jun;11(8):585-8. doi: 10.1016/j.autrev.2011.10.018.	Fibromyalgia (FM) is defined as chronic widespread pain (CWP) with allodynia or hyperalgesia to pressure pain, and is classified as one of the largest group of soft tissue pain syndromes. Its pathogenesis is not entirely understood, although it is currently believed to be the result of a central nervous system (CNS) malfunction that increases pain transmission and perception. There are no instrumental tests to confirm the diagnosis, but many of the differential diagnoses can be excluded by means of an extensive clinical examination and patient history. Although fibromyalgia is a recognisable clinical entity, it would seem appropriate to consider the entire range of tenderness and distress in clinic patients in order to tailor treatment on an individual basis.
Agliari E, Barra A, Vidal KG, Guerra F.	Dipartimento di Fisica, Università degli Studi di Parma, viale G.P. Usberti 7/A, 43100, Parma, Italy. elena.agliari@fis.unipr.it	Can persistent Epstein-Barr virus infection induce chronic fatigue syndrome as a Pavlov reflex of the immune response?	J Biol Dyn. 2012;6(2):740-62. doi: 10.1080/17513758.2012.704083.	Chronic fatigue syndrome is a protracted illness condition (lasting even years) appearing with strong flu symptoms and systemic defiances by the immune system. Here, by means of statistical mechanics techniques, we study the most widely accepted picture for its genesis, namely a persistent acute mononucleosis infection, and we show how such infection may drive the immune system towards an out-of-equilibrium metastable state displaying chronic activation of both humoral and cellular responses (a state of full inflammation without a direct 'causes-effect' reason). By exploiting a bridge with a neural scenario, we mirror killer lymphocytes T(K) and B cells to neurons and helper lymphocytes [Formula: see text] and [Formula: see text] to synapses, hence showing that the immune system may experience the Pavlov conditional reflex phenomenon: if the exposition to a stimulus (Epstein-Barr virus antigens) lasts for too long, strong internal correlations among B,T(K) and T(H)

				may develop ultimately resulting in a persistent activation even though the stimulus itself is removed. These outcomes are corroborated by several experimental findings.

Allen J, Murray A, Di Maria C, Newton JL.	Microvascular Diagnostics, Regional Medical Physics Department, Freeman Hospital, Newcastle upon Tyne NE7 7DN, UK.	Chronic fatigue syndrome and impaired peripheral pulse characteristics on orthostasis--a new potential diagnostic biomarker.	Physiol Meas. 2012 Feb;33(2):231-41. doi: 10.1088/0967-3334/33/2/231.	Autonomic nervous system dysfunction is frequently reported in chronic fatigue syndrome (CFS) with orthostatic intolerance, a common symptom that can be objectively assessed. The frequent finding of autonomic dysfunction and symptoms on standing has the potential to provide a diagnostic biomarker in chronic fatigue. In this study we explored the clinical value of non-invasive optical multi-site photoplethysmography (PPG) technology to assess cardiovascular responses to standing. Multi-site PPG pulses were collected from tissue pads of the ears, fingers and toes of 14 patients with CFS and 14 age-matched sedentary subjects using a measurement protocol of a 10 min baseline (subject supine) followed by 3 min of tilting on a tilt table (head-up to 70°). Percentage change in pulse timing (pulse transit time, PTTf) and pulse amplitude (AMP) at each site were calculated using beat-to-beat pulse wave analysis. A significant reduction in the overall pulse timing response to controlled standing was found for the CFS group (using summed absolute percentage change in PTTf for ear, finger and toe sites, median change of 26% for CFS and 37% for control with $p = 0.002$). There were no significant differences between subject groups for the AMP measure at any site. Changes in AMP with tilt were, however, weakly significantly and negatively correlated with fatigue severity ($p < 0.05$). Receiver operating characteristic (ROC) analysis of timing measures produced an area under the curve of 0.81. Experimental linear discriminant classification analysis comparing both timing and amplitude measures produced an overall diagnostic accuracy of 82%. Pulse wave abnormalities have been observed in CFS and represent a potential objective measure to help differentiate between CFS patients and healthy controls.
Alter HJ, Mikovits JA, Switzer WM, Ruscetti FW, Lo SC, Klimas N, Komaroff AL, Montoya JG, Bateman L, Levine S, Peterson D, Levin B, Hanson	Department of Transfusion Medicine, Warren G. Magnuson Clinical Center, National Institutes of Health, Bethesda, Maryland, USA.	A multicenter blinded analysis indicates no association between chronic fatigue syndrome/myalgic encephalomyelitis and either xenotropic murine	MBio. 2012 Sep 18;3(5). pii: e00266-12. doi: 10.1128/mBio.00266-12. Print 2012.	The disabling disorder known as chronic fatigue syndrome or myalgic encephalomyelitis (CFS/ME) has been linked in two independent studies to infection with xenotropic murine leukemia virus-related virus (XMRV) and polytropic murine leukemia virus (pMLV). Although the associations were not confirmed in subsequent studies by other investigators, patients continue to question the consensus of the scientific community in rejecting the validity of the association. Here we report blinded analysis of peripheral blood from a rigorously characterized, geographically diverse population of 147 patients with CFS/ME and 146 healthy subjects by the investigators describing the original association. This analysis reveals no evidence of

MR, Genfi A, Bhat M, Zheng H, Wang R, Li B, Hung GC, Lee LL, Sameroff S, Heneine W, Coffin J, Hornig M, Lipkin WI.		leukemia virus-related virus or polytropic murine leukemia virus.		either XMRV or pMLV infection. IMPORTANCE Chronic fatigue syndrome/myalgic encephalomyelitis has an estimated prevalence of 42/10,000 in the United States, with annual direct medical costs of $7 billion. Here, the original investigators who found XMRV and pMLV (polytropic murine leukemia virus) in blood of subjects with this disorder report that this association is not confirmed in a blinded analysis of samples from rigorously characterized subjects. The increasing frequency with which molecular methods are used for pathogen discovery poses new challenges to public health and support of science. It is imperative that strategies be developed to rapidly and coherently address discoveries so that they can be carried forward for translation to clinical medicine or abandoned to focus resource investment more productively. Our study provides a paradigm for pathogen dediscovery that may be helpful to others working in this field.
Alves ED, Ackel-D'Elia C, Luz GP, Cunha TC, Carneiro G, Tufik S, Bittencourt LR, de Mello MT.	Disciplina de Medicina e Biologia do Sono, Departamento de Psicobiologia, Universidade Federal de São Paulo-UNIFESP, São Paulo, CEP: 04020-050, Brazil.	Does physical exercise reduce excessive daytime sleepiness by improving inflammatory profiles in obstructive sleep apnea patients?	Sleep Breath. 2012 Jun 20.	INTRODUCTION: Obstructive sleep apnea syndrome (OSAS) is associated with a variety of long-term consequences such as high rates of morbidity and mortality, due to excessive diurnal somnolence as well as cardiovascular and metabolic diseases. Obesity, recurrent episodes of upper airway obstruction, progressive hypoxemia, and sleep fragmentation during sleep cause neural, cardiovascular, and metabolic changes. These changes include activation of peripheral sympathetic nervous system and the hypothalamic-pituitary-adrenal axis, insulin sensitivity, and inflammatory cytokines alterations, which predispose an individual to vascular damage. DISCUSSION: Previous studies proposed that OSAS modulated the expression and secretion of inflammatory cytokines from fat and other tissues. Independent of obesity, patients with OSAS exhibited elevated levels of C-reactive protein, tumor necrosis factor-α and interleukin-6, which are associated with sleepiness, fatigue, and the development of a variety of metabolic and cardiovascular diseases. OSAS and obesity are strongly associated with each other and share many common pathways that induce chronic inflammation. Previous studies suggested that the protective effect of exercise may be partially attributed to the anti-inflammatory effect of regular exercise, and this effect was observed in obese patients. Although some studies assessed the effects of physical exercise on objective and subjective sleep parameters, the quality of life, and mood in patients with OSAS, no study has evaluated the effects of this treatment on inflammatory profiles. In this review, we cited some studies that directed our opinion to believe that since OSAS causes increased inflammation and has excessive daytime sleepiness as a symptom and being that physical exercise improves inflammatory profiles and possibly OSAS symptoms, it must be that physical exercise improves excessive daytime sleepiness due to its improvement in inflammatory profiles.
Anderson G, Maes M, Berk M.	CRC, Rm 30, 57 Laurel St., Glasgow, G11 7QT Scotland, United	Biological underpinnings of the commonalities in	Med Hypotheses. 2012 Jun;78(6):752-6. doi: 10.1016/j.mehy.2012.02.023.	BACKGROUND: Somatization is a multisomatoform disorder characterized by medically unexplained, functional or psychosomatic symptoms. Similar somatic symptoms are key components of depression and Myalgic Encephalomyelitis/Chronic

	Kingdom. anderson.george@rocketmail.com	depression, somatization, and Chronic Fatigue Syndrome.		Fatigue Syndrome (ME/CFS). METHODS: This paper reviews the evidence that such symptoms are organically based. We use the term "physio-somatic" to describe these symptoms. RESULTS: Inflammation, cell-mediated immune (CMI) activation and alterations in the tryptophan catabolite (TRYCAT) pathway are associated with the physio-somatic symptoms of depression, ME/CFS and/or somatization. Proinflammatory cytokines, decreased tryptophan and aberrations in TRYCATs may cause physio-somatic symptoms, such as fatigue, autonomic symptoms, hyperalgesia and somatic presentations. CONCLUSIONS: The data suggest co-ordinated and interacting biological pathways driving the occurrence of physio-somatic symptoms across these three disorders, giving a biologically validated "pathway phenotype". These data have far-reaching implications for DSM-IV diagnostic conceptualizations of somatization (and ME/CFS) suggesting the presence of an emerging organic explanation. Future research should focus on the role of immune regulation, and co-ordination, of neuronal activity and, through larger data sets, ultimately creating new, biologically validated classification rules. These data have implications for the development of novel therapies utilizing these insights, buttressing the role of psychotherapy in psychosomatic presentations.
Anderson VR, Jason LA, Hlavaty LE, Porter N, Cudia J.	Department of Psychology, Michigan State University, East Lansing, MI 48824, USA. ande1538@msu.edu	A review and meta-synthesis of qualitative studies on myalgic encephalomyelitis/chronic fatigue syndrome.	Patient Educ Couns. 2012 Feb;86(2):147-55. doi: 10.1016/j.pec.2011.04.016.	OBJECTIVE: To review and synthesize findings across qualitative studies on Myalgic Encephalomyelitis/chronic fatigue syndrome (ME/CFS). METHODS: Articles were systematically reviewed and analyzed within a meta-analytic framework. Analyses included a multi-perspective examination of ME/CFS, as well as a comparative analysis of ME/CFS versus other chronic conditions. RESULTS: Thirty-four qualitative studies on ME/CFS were included. Findings include three substantive thematic areas that focus on: (1) experiences of people with ME/CFS, (2) experiences of physicians, and (3) themes that intersect both of these groups. For patients, illness development influenced identity, reductions in functioning, and coping. Physician-specific themes described lack of awareness about ME/CFS and recommended improvement in educational resources. Intersecting themes expressed issues with diagnosis creating tensions and fueling the stigmatization of ME/CFS. CONCLUSIONS: Findings indicate multilayered, context-specific experiences and ways in which both people with ME/CFS, as well as those involved in their lives (e.g., family or the medical community), interpret this illness. Future qualitative studies should recognize the various facets of the ME/CFS experience, the network members of people with ME/CFS, and the sociocultural environment through which the illness is understood. PRACTICE IMPLICATIONS: Health care professionals can gain unique insight from patient experiences, allowing for more accurate diagnoses and treatment recommendations.

Angeletti C, Guetti C, Piroli A, Angeletti PM, Paladini A, Ciccozzi A, Marinangeli F, Varrassi G.	Anesthesiology and Pain Medicine, Department of Health Sciences, University of L'Aquila, Italy.	Duloxetine and Pregabalin for Pain Management in Multiple Rheumatic Diseases Associated with Fibromyalgia.	Pain Pract. 2012 Nov 5. doi: 10.1111/papr.12009.	The fibromyalgia syndrome (FMS) is characterized by chronic and widespread musculoskeletal pain and soreness accompanied by sleep disorders, chronic fatigue and affective disorders. FMS is often associated with other forms of immuno-rheumatic diseases. Although FMS pathophysiology is still not fully understood, a number of neuroendocrine, neurotransmission and neurosensitive disorders might generate a mechanism for the elicitation of pain by "central sensitization," which is common to many other painful conditions. The present case describes the success of a therapeutic scheme, which associates two different pharmacological classes, anticonvulsants and new-generation antidepressants, when FMS complicates a rare pathology called Cogan's syndrome. The association of two drugs might noticeably affect the molecular mechanisms of difficult pain, thus solving painful conditions of multifactorial origin.
Aparicio VA, Carbonell-Baeza A, Ortega FB, Estevez F, Ruiz JR, Delgado-Fernández M.	Department of Physical Education and Sport, School of Sports Sciences, University of Granada, Spain. virginiaparicio@ugr.es	Usefulness of tenderness to characterise fibromyalgia severity in women.	Clin Exp Rheumatol. 2011 Nov-Dec;29(6 Suppl 69):S28-33.	OBJECTIVES: To investigate the usefulness of tenderness (tender points count (TPC) and algometer score) to characterise fibromyalgia (FM) severity and symptomatology in women. METHODS: The study sample comprised 174 women aged 51±7 years. We ossesse tenderness using pressure algometry; quality of life by means of the Short-Form 36 Health Survey (SF-36) and the Hospital Anxiety and Depression Scale (HADS). We used the FM impact questionnaire (FIQ) to assess FM severity and symptomatology. Patients were categorised according to three FIQ-derived categories: FIQ<70 vs. ≥70; FIQ<59 vs. ≥59; and FM-type I and II. RESULTS: TPC was significantly higher in the group of patients with FIQ≥59 (16.9±2 vs. 15.6±4, p=0.02), whereas no differences between groups were observed according to FIQ≥70 (17.0±2 vs. 16.2±3, p=0.12) or FM type (16.8±3 for type II vs. 15.9±4 for type I, p=0.13). We observed a significant association between TPC and FIQ-job difficulty, pain, morning tiredness and stiffness dimensions (all p<0.05), yet it was not correlated with total score of FIQ, FIQ-anxiety, fatigue and depression dimensions (all p>0.05). Algometer score was lower in the FIQ≥70 (45.7±12 vs. 51.1±14, p=0.05) and FIQ≥59 (46.7±13 vs. 52.7±14, p=0.05) groups, and there were no difference between FM types (48.7±13 vs. 49.5±14 for type II and I respectively, p=0.81). Algometer score was not associated with total score of FIQ or FIQ dimensions (all p≥0.1). CONCLUSIONS: Widespread pain and pain hypersensitivity, as measured by TPC and algometer score, do not seem to be useful to characterise FM severity and symptomatology (measured by FIQ) in women.
Armstrong CW, McGregor NR,	Department of Biochemistry and	NMR metabolic profiling of serum	Clin Chim Acta. 2012 Oct 9;413(19-20):1525-31. doi:	Chronic fatigue syndrome (CFS) is a debilitating multisystem disorder characterised by long-term fatigue with a variety of other symptoms including cognitive dysfunction,

Sheedy JR, Buttfield I, Butt HL, Gooley PR.	Molecular Biology, University of Melbourne, Parkville, Victoria 3010, Australia.	identifies amino acid disturbances in chronic fatigue syndrome.	10.1016/j.cca.2012.06.022.	unrefreshing sleep, muscle pain, and post-exertional malaise. It is a poorly understood condition that occurs in ~5 in every 1000 individuals. We present here a preliminary study on the analysis of blood samples from 11 CFS and 10 control subjects through NMR metabolic profiling. Identified metabolites that were found to be significantly altered between the groups were subjected to correlation analysis to potentially elucidate disturbed metabolic pathways. Our results showed a significant reduction of glutamine ($P=0.002$) and ornithine ($P<0.05$) in the blood of the CFS samples. Correlation analysis of glutamine and ornithine with other metabolites in the CFS sera showed relationships with glucogenic amino acids and metabolites that participate in the urea cycle. This indicates a possible disturbance to amino acid and nitrogen metabolism. It would be beneficial to identify any potential biomarkers of CFS for accurate diagnosis of the disorder.
Arnett SV, Clark IA.	Research School of Biology, Australian National University, Australia. simon.arnett@anu.edu.au	Inflammatory fatigue and sickness behaviour - lessons for the diagnosis and management of chronic fatigue syndrome.	J Affect Disord. 2012 Dec 10;141(2-3):130-42. doi: 10.1016/j.jad.2012.04.004.	Persistent and severe fatigue is a common part of the presentation of a diverse range of disease processes. There is a growing body of evidence indicating a common inflammatory pathophysiology underlying many conditions where fatigue is a primary patient concern, including chronic fatigue syndrome. This review explores current models of how inflammatory mediators act on the central nervous system to produce fatigue and sickness behaviour, and the commonality of these processes in conditions as diverse as surgical trauma, infection, various cancers, inflammatory bowel disease, connective tissue diseases and autoimmune diseases. We also discuss evidence indicating chronic fatigue syndrome may have important pathophysiological similarities with cytokine mediated sickness behaviour, and what lessons can be applied from sickness behaviour to chronic fatigue syndrome with regards to the diagnosis and management.
Arredondo M, de Bethencourt F, Treviño A, Collado A, Torres P, Barbolla L, Soriano V, de Mendoza C.	Infectious Diseases Department, Hospital Carlos III, Madrid, Spain.	Short communication: RNASEL alleles and susceptibility to infection by human retroviruses and hepatitis viruses.	AIDS Res Hum Retroviruses. 2012 Oct;28(10):1259-61.	RNASEL seems to function as an intracellular restriction factor blocking the establishment of infections caused by viral agents. Herein, we investigated whether allelic variants at the RNASEL gene might influence the susceptibility to viral infections or conditions potentially linked to viral agents. The allelic distribution at codon 462 was 139 (33.9%), 204 (49.8%), and 67 (16.3%) for RR, RQ, and QQ, respectively, in 410 individuals in Spain. There were no significant differences comparing 105 blood donors and 71 patients with HIV-1 infection, 27 with chronic hepatitis C, 67 with prostate cancer, and 107 with chronic fatigue syndrome. In contrast, two-thirds of 18 patients with HTLV-1 infection and 15 with chronic hepatitis B harbored RR. Thus, polymorphisms at the RNASEL gene do not seem to influence the susceptibility to common viral infections or conditions potentially of viral etiology. The role in influencing the susceptibility to HTLV-1 or HBV chronic infection warrants further examination in larger patient populations.
Arredondo M, Hackett J Jr, de Bethencourt FR,	Infectious Diseases Department, Hospital Carlos III, Madrid,	Prevalence of xenotropic murine leukemia virus-	AIDS Res Hum Retroviruses. 2012 Sep;28(9):1089-94. doi: 10.1089/AID.2011.0149.	Human infection with the xenotropic murine leukemia virus-related virus (XMRV) has been associated controversially with prostate cancer and chronic fatigue syndrome. Information is lacking about the mechanisms of transmission and potential risk groups

Treviño A, Escudero D, Collado A, Qiu X, Swanson P, Soriano V, de Mendoza C.	Spain.	related virus infection in different risk populations in Spain.		for XMRV infection. Plasma and peripheral blood mononuclear cells (PBMCs) from individuals with retroviral infections, chronic viral hepatitis, autoimmune diseases, prostate cancer, chronic fatigue syndrome, and blood donors were tested for XMRV markers. Antibodies to XMRV proteins p15E and gp70 were examined using research assays. DNA extracted from PBMCs was tested for the presence of XMRV gag and env sequences. A total of 1103 specimens belonging to individuals with chronic fatigue syndrome and/or fibromyalgia (437), prostate cancer (69), HIV-1 (149), HTLV-1/2 (31), chronic hepatitis B (81), chronic hepatitis C (72), autoimmune diseases (18), and blood donors (246) were examined. Overall, three samples (0.3%) were p15E seroreactive (two HTLV-1 and one HCV patient). Another 15 (1.4%) were gp70 seroreactive (six chronic fatigue syndrome-fibromyalgia, four blood donors, two HIV-1, one prostate cancer, one HBV, and one HCV). Four specimens were initially positive for XMRV gag sequences, but none could be confirmed by repeated testing. In summary, no evidence of XMRV infection was found in populations with retroviral and viral hepatitis infections in Spain. Likewise, XMRV was not recognized in patients with autoimmune diseases, chronic fatigue syndrome-fibromyalgia, prostate cancer, or healthy blood donors.
Arroll MA, Howard A	The Optimum Health Clinic , London , UK.	'The letting go, the building up, (and) the gradual process of rebuilding': Identity change and post-traumatic growth in myalgic encephalomyelitis/chronic fatigue syndrome.	Psychol Health. 2012 Sep 11	The aim of this study was to explore the phenomenon of identity change and subsequent post-traumatic growth (PTG) in individuals with myalgic encephalomyelitis/chronic fatigue syndrome (ME/CFS). Ten participants (average illness duration 7.4 years) were interviewed (average length, 79 minutes) via a semi-structured interview schedule and verbatim transcriptions were analysed with interpretative phenomenological analysis. The four superordinate themes revealed were 'comparisons of past to present self: "you have to be someone else, and you have to live with that"', 'the effect of social isolation on identity and subsequent insights into others' behaviours', 'contemplation of future and identity: ''where do I go from here?"', and 'PTG: "the letting go, the building up, [and] the gradual process of rebuilding"'. These themes outlined the experiences of those with ME/CFS as they underwent changes in identity due to the limitations the condition imposed on activities and roles, understanding others' behaviours after a period of isolation, the comparison of the past self with the present self and finally, the positive growth that was noted by two of the interviewees with regards to a new 'true' self. Despite the distressing and unpredictable nature of ME/CFS, it appears that individuals with this disorder can experience personal growth.
Arroll MA, Howard A.	Department of Research, The Optimum Health Clinic, London, UK.	A preliminary prospective study of nutritional, psychological and combined therapies for myalgic	BMJ Open. 2012 Nov 19;2(6). pii: e001079. doi: 10.1136/bmjopen-2012-001079. Print 2012.	BACKGROUND: Myalgic encephalomyelitis/chronic fatigue syndrome (ME/CFS) is a condition characterised by severe and persistent fatigue, neurological disturbances, autonomic and endocrine dysfunctions and sleep difficulties that have a pronounced and significant impact on individuals' lives. Current National Institute for Health and Clinical Excellence guidelines within the UK suggest that this condition should be treated with cognitive behavioural therapy and/or graded exercise therapy, where

		encephalomyelitis/chronic fatigue syndrome (ME/CFS) in a private care setting.		appropriate. There is currently a lack of an evidence base concerning alternative techniques that may be beneficial to those with ME/CFS. OBJECTIVES: This study aimed to investigate whether three modalities of psychology, nutrition and combined treatment influenced symptom report measures in those with ME/CFS over a 3-month time period and whether there were significant differences in these changes between groups. DESIGN AND SETTING: This is a preliminary prospective study with one follow-up point conducted at a private secondary healthcare facility in London, UK. PARTICIPANTS: 138 individuals (110 females, 79.7%; 42 participants in psychology, 44 in nutrition and 52 in combined) participated at baseline and 72 participants completed the battery of measures at follow-up (52.17% response rate; 14, 27 and 31 participants in each group, respectively). OUTCOME MEASURES: Self-reported measures of ME/CFS symptoms, functional ability, multidimensional fatigue and perceived control. RESULTS: Baseline comparisons showed those in the combined group had higher levels of fatigue. At follow-up, all groups saw improvements in fatigue, functional ability and symptomatology; those within the psychology group also experienced a shift in perceived control over time. CONCLUSIONS: This study provides early evidence that psychological, nutritional and combined techniques for the treatment of ME/CFS may influence symptomatology, fatigue, function and perceived control. However, these results must be viewed with caution as the allocation to groups was not randomised, there was no control group and the study suffered from high drop-out rates.
Aschbacher K, Adam EK, Crofford LJ, Kemeny ME, Demitrack MA, Ben-Zvi A.	Department of Psychiatry, University of California, San Francisco, CA, United States. kirstin.aschbacher@ucsf.edu	Linking disease symptoms and subtypes with personalized systems-based phenotypes: a proof of concept study.	Brain Behav Immun. 2012 Oct;26(7):1047-56. doi: 10.1016/j.bbi.2012.06.002. Comment in Brain Behav Immun. 2012 Oct;26(7):1045-6.	A dynamic systems model was used to generate parameters describing a phenotype of Hypothalamic-Pituitary-Adrenal (HPA) behavior in a sample of 36 patients with chronic fatigue syndrome (CFS) and/or fibromyalgia (FM) and 36 case-matched healthy controls. Altered neuroendocrine function, particularly in relation to somatic symptoms and poor sleep quality, may contribute to the pathophysiology of these disorders. Blood plasma was assayed for cortisol and ACTH every 10 min for 24h. The dynamic model was specified with an ordinary differential equation using three parameters: (1) ACTH-adrenal signaling, (2) inhibitory feedback, and (3) non-ACTH influences. The model was "personalized" by estimating an individualized set of parameters from each participant's data. Day and nighttime parameters were assessed separately. Two nocturnal parameters (ACTH-adrenal signaling and inhibitory feedback) significantly differentiated the two patient subgroups ("fatigue-predominant" patients with CFS only versus "pain-predominant" patients with FM and comorbid chronic fatigue) from controls (all p's<.05), whereas daytime parameters and diurnal/nocturnal slopes did not. The same nocturnal parameters were significantly associated with somatic symptoms among patients (p's<.05). There was a significantly different pattern of association between nocturnal non-ACTH influences and sleep quality among patients versus controls (p<.05). Although speculative, the finding that patient somatic symptoms decreased when more cortisol

				was produced per unit ACTH, is consistent with cortisol's anti-inflammatory and sleep-modulatory effects. Patients' HPA systems may compensate by promoting more rapid or sustained cortisol production. Mapping "behavioral phenotypes" of stress-arousal systems onto symptom clusters may help disentangle the pathophysiology of complex disorders with frequent comorbidity.
Aslakson E, Szekely S, Vernon SD, Bateman L, Baumbach J, Setty Y.	Department of Computer Science and Applied Mathematics, Weizmann Institute of Science, Rehovot, 76100, Israel. yaki.setty@gmail.com.	Live sequence charts to model medical information.	Theor Biol Med Model. 2012 Jun 15;9:22. doi: 10.1186/1742-4682-9-22.	ABSTRACT:BACKGROUND: Medical records accumulate data concerning patient health and the natural history of disease progression. However, methods to mine information systematically in a form other than an electronic health record are not yet available. The purpose of this study was to develop an object modeling technique as a first step towards a formal database of medical records. METHOD: Live Sequence Charts (LSC) were used to formalize the narrative text obtained during a patient interview. LSCs utilize a visual scenario-based programming language to build object models. LSC extends the classical language of UML message sequence charts (MSC), predominantly through addition of modalities and providing executable semantics. Inter-object scenarios were defined to specify natural history event interactions and different scenarios in the narrative text. RESULT: A simulated medical record was specified into LSC formalism by translating the text into an object model that comprised a set of entities and events. The entities described the participating components (i.e., doctor, patient and record) and the events described the interactions between elements. A conceptual model is presented to illustrate the approach. An object model was generated from data extracted from an actual new patient interview, where the individual was eventually diagnosed as suffering from Chronic Fatigue Syndrome (CFS). This yielded a preliminary formal designated vocabulary for CFS development that provided a basis for future formalism of these records. CONCLUSIONS: Translation of medical records into object models created the basis for a formal database of the patient narrative that temporally depicts the events preceding disease, the diagnosis and treatment approach. The LSCs object model of the medical narrative provided an intuitive, visual representation of the natural history of the patient's disease.
Atzeni F, Sallì S, Benucci M, Di Franco M, Alciati A, Sarzi-Puttini P.	sarzi@tiscalinet.it	Fibromyalgia and arthritides.	Reumatismo. 2012 Sep 28;64(4):286-92. doi: 10.4081/reumatismo.2012.286.	Fibromyalgia (FM) is a chronic pain syndrome that affects at least 2% of the adult population. It is characterised by widespread pain, fatigue, sleep alterations and distress, and emerging evidence suggests a central nervous system (CNS) malfunction that increases pain transmission and perception. FM is often associated with other diseases that act as confounding and aggravating factors, such as rheumatoid arthritis (RA), spondyloarthritides (SpA), osteoarthritis (OA) and thyroid disease. Mechanism-based FM management should consider both peripheral and central pain, including effects due to cerebral input and that come from the descending inhibitory pathways. Rheumatologists should be able to distinguish primary and secondary FM, and need new guidelines and instruments to avoid making mistakes, bearing in mind that the diffuse pain of arthritides compromises the patients' quality of life.

Bäckström T, Bixo M, Nyberg S, Savic I.	Umeå Neurosteroid Research Centre, Department of Clinical Science, Umeå University, SE-901 85 Umeå, Sweden. Electronic address: torbjorn.backstrom@ogbyn.umu.se.	Increased neurosteroid sensitivity - An explanation to symptoms associated with chronic work related stress in women?	Psychoneuroendocrinology. 2012 Nov 21. pii: S0306-4530(12)00349-6. doi: 10.1016/j.psyneuen.2012.10.014.	Work related psychosocial stress can be accompanied by so called burnout syndrome with symptoms of mental exhaustion, physical fatigue, and cognitive dysfunction. Underlying mechanisms for acquiring burnout syndrome are not clear. Animal studies show that chronic stress is associated with altered release of GABA-A receptor modulating steroids (GAMS), altered composition of the GABA-A receptor and altered sensitivity to GAMS. In the present study we investigated if such changes occur in women with burnout syndrome. We further asked whether flumazenil (a benzodiazepine antagonist, but with positive modulating effects on GABA-A receptors with altered subunit composition) can block the effect of the GAMS allopregnanolone. Ten women with occupational psychosocial stress and burnout syndrome were compared with twelve healthy controls in an experimental setting. Saccadic eye velocity (SEV) was measured after an injection of allopregnanolone, followed by an injection of flumazenil and a second injection of allopregnanolone. The sensitivity to allopregnanolone was significantly higher in the patients compared to controls after the first injection (p=0.04) and the difference increased when the response per allopregnanolone concentration unit was compared (p=0.006). Following the flumazenil injection the burnout patients (p=0.016), but not controls, showed a decrease in SEV and flumazenil acted like a positive modulator that is agonistic. There was no significant difference between the groups after second allopregnanolone injection. In conclusion, patients with work related psychosocial stress and burnout syndrome show a different response to GABA-A receptor modulators than controls suggesting a changed GABA-A receptor function in these patients. More precisely we hypothesize that the α4 and delta subunits are up-regulated elevating the responsiveness to allopregnanolone and change the effect of flumazenil, which provides a potential explanation to the burnout syndrome. Flumazenil does not block the effect of allopregnanolone.
Bansal AS, Bradley AS, Bishop KN, Kiani-Alikhan S, Ford B.	Dept. of Immunology, Epsom and St. Helier University Hospitals NHS Trust, Carshalton, Surrey, SM5 1AA and Chronic Illness Research Team, Stratford Campus, University of East London, London E15 4LZ, UK. Amolak.Bansal@ESTH.nhs.uk	Chronic fatigue syndrome, the immune system and viral infection.	Brain Behav Immun. 2012 Jan;26(1):24-31. doi: 10.1016/j.bbi.2011.06.016.	The chronic fatigue syndrome (CFS), as defined by recent criteria, is a heterogeneous disorder with a common set of symptoms that often either follows a viral infection or a period of stress. Despite many years of intense investigation there is little consensus on the presence, nature and degree of immune dysfunction in this condition. However, slightly increased parameters of inflammation and pro-inflammatory cytokines such as interleukin (IL) 1, IL6 and tumour necrosis factor (TNF) α are likely present. Additionally, impaired natural killer cell function appears evident. Alterations in T cell numbers have been described by some and not others. While the prevalence of positive serology for the common herpes viruses appears no different from healthy controls, there is some evidence of viral persistence and inadequate containment of viral replication. The ability of certain herpes viruses to impair the development of T cell memory may explain this viral persistence and the continuation of symptoms. New therapies based on this understanding are more likely to produce benefit than current methods.

Barnden LR, Crouch B, Kwiatek R, Burnet R, Mernone A, Chryssidis S, Scroop G, Del Fante P.	Department of Nuclear Medicine, The Queen Elizabeth Hospital, Adelaide, South Australia. Leighton.Barnden@health.sa.gov.au	A brain MRI study of chronic fatigue syndrome: evidence of brainstem dysfunction and altered homeostasis.	NMR Biomed. 2011 Dec;24(10):1302-12. doi: 10.1002/nbm.1692.	To explore brain involvement in chronic fatigue syndrome (CFS), the statistical parametric mapping of brain MR images has been extended to voxel-based regressions against clinical scores. Using SPM5 we performed voxel-based morphometry (VBM) and analysed T(1) - and T(2) -weighted spin-echo MR signal levels in 25 CFS subjects and 25 normal controls (NC). Clinical scores included CFS fatigue duration, a score based on the 10 most common CFS symptoms, the Bell score, the hospital anxiety and depression scale (HADS) anxiety and depression, and hemodynamic parameters from 24-h blood pressure monitoring. We also performed group × hemodynamic score interaction regressions to detect locations where MR regressions were opposite for CFS and NC, thereby indicating abnormality in the CFS group. In the midbrain, white matter volume was observed to decrease with increasing fatigue duration. For T(1) -weighted MR and white matter volume, group × hemodynamic score interactions were detected in the brainstem [strongest in midbrain grey matter (GM)], deep prefrontal white matter (WM), the caudal basal pons and hypothalamus. A strong correlation in CFS between brainstem GM volume and pulse pressure suggested impaired cerebrovascular autoregulation. It can be argued that at least some of these changes could arise from astrocyte dysfunction. These results are consistent with an insult to the midbrain at fatigue onset that affects multiple feedback control loops to suppress cerebral motor and cognitive activity and disrupt local CNS homeostasis, including resetting of some elements of the autonomic nervous system (ANS).
Barrioluengo V, Wang Y, Le Grice SF, Menéndez-Arias L.	Centro de Biología Molecular Severo Ochoa (Consejo Superior de Investigaciones Científicas and Universidad Autónoma de Madrid), Madrid, Spain.	Intrinsic DNA synthesis fidelity of xenotropic murine leukemia virus-related virus reverse transcriptase.	FEBS J. 2012 Apr;279(8):1433-44. doi: 10.1111/j.1742-4658.2012.08532.x.	Although recent reports have provided strong evidence to suggest that xenotropic murine leukemia virus-related virus (XMRV) is unlikely to be the causative agent of prostate cancer and chronic fatigue syndrome, this recombinant retrovirus can nonetheless infect human cells in vitro and induce a chronic infection in macaques. In the present study, we determined the accuracy of DNA synthesis of the reverse transcriptases (RTs) of XMRV and Moloney murine leukemia virus (MoMLV) using a combination of pre-steady-state kinetics of nucleotide incorporation and an M13mp2-based forward mutation assay. The results obtained were compared with those previously reported for the HIV type 1 BH10 strain (HIV-1(BH10)) RT. MoMLV and XMRV RTs were 13.9 and 110 times less efficient [as determined by the catalytic rate constant of the nucleotide incorporation reaction ((pol))/equilibrium constant (K(d))] than the HIV-1(BH10) RT in incorporating correct nucleotides. Misinsertion and mispair extension kinetic studies demonstrated that MoMLV RT was more accurate than the HIV-1(BH10) RT. In comparison with the MoMLV RT, the XMRV RT showed decreased mispair extension fidelity and was less faithful when misincorporating C or A opposite A. However, the XMRV RT showed stronger selectivity against G in misinsertion fidelity assays. Forward mutation assays revealed that XMRV and MoMLV RTs had similar accuracy of DNA-dependent DNA synthesis, but were > 13 times more faithful than the HIV-1(BH10) enzyme. The mutational spectra of XMRV

				and MoMLV RTs were similar in having a relatively higher proportion of frameshifts and transversions compared with the HIV-1(BH10) RT. However, the XMRV polymerase was less prone to introduce large deletions and one-nucleotide insertions.
Bazzichi L, Sernissi F, Consensi A, Giacomelli C, Sarzi-Puttini P.	Division of Rheumatology, Department of Internal Medicine, University of Pisa, Piza, Italy. l.bazzichi@gmail.com	Fibromyalgia: a critical digest of the recent literature.	Clin Exp Rheumatol. 2011 Nov-Dec;29(6 Suppl 69):S1-11.	Fibromyalgia is a common syndrome characterised by widespread pain and a constellation of other symptoms and overlapping conditions that contribute to complicate the diagnosis, the assessment and the treatment. Furthermore, the etiological causes for the moment only consist of assumptions, and the underlying pathogenetic mechanisms still remain to be clarified. For the above-mentioned reasons, with the present review we sought to provide an overview of the literature on fibromyalgia from both the pre-clinical and clinical studies indexed in PubMed during the last year, classifying original articles and reviews into etiopathogenesis, assessment and therapy.
Beaumont A, Burton AR, Lemon J, Bennett BK, Lloyd A, Vollmer-Conna U.	School of Psychiatry, University of New South Wales, Sydney, New South Wales, Australia.	Reduced cardiac vagal modulation impacts on cognitive performance in chronic fatigue syndrome.	PLoS One. 2012;7(11):e49518. doi: 10.1371/journal.pone.0049518.	BACKGROUND: Cognitive difficulties and autonomic dysfunction have been reported separately in patients with chronic fatigue syndrome (CFS). A role for heart rate variability (HRV) in cognitive flexibility has been demonstrated in healthy individuals, but this relationship has not as yet been examined in CFS. The objective of this study was to examine the relationship between HRV and cognitive performance in patients with CFS. METHODS: Participants were 30 patients with CFS and 40 healthy controls; the groups were matched for age, sex, education, body mass index, and hours of moderate exercise/week. Questionnaires were used to obtain relevant medical and demographic information, and assess current symptoms and functional impairment. Electrocardiograms, perceived fatigue/effort and performance data were recorded during cognitive tasks. Between-group differences in autonomic reactivity and associations with cognitive performance were analysed. RESULTS: Patients with CFS showed no deficits in performance accuracy, but were significantly slower than healthy controls. CFS was further characterized by low and unresponsive HRV; greater heart rate (HR) reactivity and prolonged HR-recovery after cognitive challenge. Fatigue levels, perceived effort and distress did not affect cognitive performance. HRV was consistently associated with performance indices and significantly predicted variance in cognitive outcomes. CONCLUSIONS: These findings reveal for the first time an association between reduced cardiac vagal tone and cognitive impairment in CFS and confirm previous reports of diminished vagal activity.
Benarroch EE.	Department of Neurology, Mayo Clinic, Rochester, MN. Electronic address: benarroch.eduardo@mayo.edu.	Postural tachycardia syndrome: a heterogeneous and multifactorial disorder.	Mayo Clin Proc. 2012 Dec;87(12):1214-25. doi: 10.1016/j.mayocp.2012.08.013.	Postural tachycardia syndrome (POTS) is defined by a heart rate increment of 30 beats/min or more within 10 minutes of standing or head-up tilt in the absence of orthostatic hypotension; the standing heart rate is often 120 beats/min or higher. POTS manifests with symptoms of cerebral hypoperfusion and excessive sympathoexcitation. The pathophysiology of POTS is heterogeneous and includes impaired sympathetically mediated vasoconstriction, excessive sympathetic drive, volume dysregulation, and deconditioning. POTS is frequently included in the

				differential diagnosis of chronic unexplained symptoms, such as inappropriate sinus tachycardia, chronic fatigue, chronic dizziness, or unexplained spells in otherwise healthy young individuals. Many patients with POTS also report symptoms not attributable to orthostatic intolerance, including those of functional gastrointestinal or bladder disorders, chronic headache, fibromyalgia, and sleep disturbances. In many of these cases, cognitive and behavioral factors, somatic hypervigilance associated with anxiety, depression, and behavioral amplification contribute to symptom chronicity. The aims of evaluation in patients with POTS are to exclude cardiac causes of inappropriate tachycardia; elucidate, if possible, the most likely pathophysiologic basis of postural intolerance; assess for the presence of treatable autonomic neuropathies; exclude endocrine causes of a hyperadrenergic state; evaluate for cardiovascular deconditioning; and determine the contribution of emotional and behavioral factors to the patient's symptoms. Management of POTS includes avoidance of precipitating factors, volume expansion, physical countermaneuvers, exercise training, pharmacotherapy (fludrocortisone, midodrine, β-blockers, and/or pyridostigmine), and behavioral-cognitive therapy. A literature search of PubMed for articles published from January 1, 1990, to June 15, 2012, was performed using the following terms (or combination of terms): POTS; postural tachycardia syndrome, orthostatic; orthostatic; syncope; sympathetic; baroreceptors; vestibulosympathetic; hypovolemia; visceral pain; chronic fatigue; deconditioning; headache; Chiari malformation; Ehlers-Danlos; emotion; amygdala; insula; anterior cingulate; periaqueductal gray; fludrocortisone; midodrine; propranolol; β-adrenergic; and pyridostigmine. Studies were limited to those published in English. Other articles were identified from bibliographies of the retrieved articles.
Bercea R, Bercea B, Mihăescu T.	Universitatea de Medicină şi Farmacie "Grigore T. Popa" Iaşi, România. ralbercea@yahoo.com	Association between the serum level of testosterone and other comorbidities in obstructive sleep apnea]. [Article in Romanian]	Pneumologia. 2012 Apr-Jun;61(2):98-101.	Testosterone seems to play a role in the pathophysiology of OSAS but the mechanisms are not yet well defined. Research of this relationship has focused on two main assumptions: first case support the emergence of OSAS or augmentation of OSAS severity in men treated with testosterone for symptomatic hypogonadism; the second hypothesis suggest that serum testosterone deficiency is due to hypoxia and microarousals generated by OSAS with direct impact on hypothalamic-pituitary-gonadal axis. The correlation between sleep apnea and androgenic disorders should be considered in the light of the intervention of many other factors which can act as confounding factors: age, obesity and other associated pathologies (chronic lung disease, smoking status). Many studies conducted so far on this interrelation (sleep apnea, endocrine system) have ignored these factors. In most cases CPAP (continuous positive airway pressure) therapy revert low serum testosterone levels to normal levels. Depressive status and fatigue, as OSAS consequences associated with hypogonadism have been reported in the literature and may have clinically significant aspects due to summary effect, with notable improvement after CPAP therapy avoiding adverse effects of hormonal or antidepressant treatment. The clinical

				implications and major consequences of association between androgen dysfunction and sleep apnea syndrome require a correct management in the recognition and treatment of obstructive sleep apnea syndrome associated with comorbidities.
Bernstein CN.	John Buhler Research Centre, University of Manitoba, 804F-175 McDermot Avenue, Winnipeg, MB, Canada. cbernst@cc.umanitoba.ca	Summing up: quality of life in chronic immune-mediated inflammatory diseases.	J Rheumatol Suppl. 2011 Nov;88:62-5. doi: 10.3899/jrheum.110908.	A series of reports is summarized in which measurement of quality of life (QOL) in various immune-mediated inflammatory diseases (IMID), the parameters that contribute to QOL, and the interrelationship between inflammatory diseases in specific organ systems and psychosocial domains are explored. Current treatment trials in IMID include QOL measures, particularly clinical trials of biologic therapy. There is increasing evidence that several available therapies benefit QOL. Among the factors that contribute to QOL, fatigue, depression, and stress are common and deserve attention from clinicians managing these patients.
Berstad A, Undseth R, Lind R, Valeur J.	Department of Medicine, Unger-Vetlesen's Institute, Lovisenberg Diakonale Hospital, Oslo, 0440, Norway. Arnold.Berstad@med.uib.no	Functional bowel symptoms, fibromyalgia and fatigue: a food-induced triad?	Scand J Gastroenterol. 2012 Sep;8-9(47):914-9. doi: 10.3109/00365521.2012.690045.	OBJECTIVE: Patients with perceived food hypersensitivity typically present with multiple health complaints. We aimed to assess the severity of their intestinal and extra-intestinal symptoms. MATERIALS AND METHODS: In a prospective study, 84 patients referred to our outpatient clinic for investigation of perceived food hypersensitivity were enrolled consecutively. Irritable bowel syndrome (IBS) was diagnosed according to the Rome III criteria. Severity and impact of bowel symptoms, fatigue and musculoskeletal pain were evaluated by using the following questionnaires: The IBS Severity Scoring System (IBS-SSS), the Fatigue Impact Scale (FIS), the FibroFatigue Scale (FFS), and visual analogue scales (VAS) for scoring of musculoskeletal pain. RESULTS: All but one patient were diagnosed with IBS, 58% with severe symptoms. Extra-intestinal symptoms suggestive of chronic fatigue and fibromyalgia were demonstrated in 85% and 71%, respectively. Neither IgE-mediated food allergy nor organic pathology could explain the patients' symptoms. Nevertheless, malabsorption of fat was demonstrated in 10 of 38 subjects. CONCLUSIONS: Perceived food hypersensitivity may be associated with severe, debilitating illness. The comorbid triad of IBS, chronic fatigue, and musculoskeletal pain is striking and may point to a common underlying cause.

Blankfield A.	Kew, Australia.	A Brief Historic Overview of Clinical Disorders Associated with Tryptophan: The Relevance to Chronic Fatigue Syndrome	Int J Tryptophan Res. 2012;5:27-32. doi: 10.4137/IJTR.S10085	Last century there was a short burst of interest in the tryptophan related disorders of pellagra and related abnormalities that are usually presented in infancy.1,2 Nutritional physiologists recognized that a severe human dietary deficiency of either tryptophan or the B group vitamins could result in central nervous system (CNS) sequelae such as ataxia, cognitive dysfunction and dysphoria, accompanied by skin hyperpigmentation.3,4 The current paper will focus on the emerging role of

		(CFS) and Fibromyalgia (FM).		tryptophan in chronic fatigue syndrome (CFS) and fibromyalgia (FM).
Blazquez A, Guillamó E, Alegre J, Ruiz E, Javierre C.	Faculty of Medicine, Department of Physiological Sciences II, Medical School, University of Barcelona, IDIBELL. L'Hospitalet, Barcelona, Spain.ablazquez@ub.edu	Psycho-physiological impact on women with chronic fatigue syndrome in the context of their couple relationship.	Psychol Health Med. 2012;17(2):150-63. doi: 10.1080/13548506.2011.582124.	The quality of dyadic adjustment is likely to play an important role in patients' relational problems and may also be associated with the clinical presentation of chronic fatigue syndrome (CFS) symptoms. The objective of this study was (1) to determine whether CFS patients and their partners have similar perceptions of their dyadic adjustment and (2) to evaluate whether the influence of dyadic satisfaction in women with CFS, as well as common psychological parameters such as anxiety, may correlate with physiological responses at rest and/or when performing very low intensity exercise. Forty females with CFS and their partners completed the Dyadic Adjustment Scale, the State-Trait Anxiety Inventory, and the Hospital Anxiety and Depression scale. The cardiovascular adaptation of patients was evaluated during resting conditions and on a precalibrated cycle ergometer while performing very low intensity exercise. Patients and partners had similar perceptions of their marital relationship. Both at rest and during very low workload, various physiological parameters in the patient group showed statistical correlations with certain psychological parameters. Several psychological variables, such as anxiety and dyadic adjustment, were associated with the cardioventilatory response monitored at rest and during very low intensity exercise. Further studies are needed to determine the nature of this association.
Blomberg J, Blomberg F, Sjösten A, Sheikholvaezin A, Bölin-Wiener A, Elfaitouri A, Hessel S, Gottfries CG, Zachrisson O, Ohrmalm C, Jobs M, Pipkorn R.	Section of Clinical Microbiology, Department of Medical Sciences, Uppsala University, Uppsala, Sweden. Jonas.Blomberg@medsci.uu.se	No evidence for xenotropic murine leukemia-related virus infection in Sweden using internally controlled multiepitope suspension array serology.	Clin Vaccine Immunol. 2012 Sep;19(9):1399-410. doi: 10.1128/CVI.00391-12	Many syndromes have a large number of differential diagnoses, a situation which calls for multiplex diagnostic systems. Myalgic encephalomyelitis (ME), also named chronic fatigue syndrome (CFS), is a common disease of unknown etiology. A mouse retrovirus, xenotropic murine leukemia-related virus (XMRV), was found in ME/CFS patients and blood donors, but this was not corroborated. However, the paucity of serological investigations on XMRV in humans prompted us to develop a serological assay which cover many aspects of XMRV antigenicity. It is a novel suspension array method, using a multiplex IgG assay with nine recombinant proteins from the env and gag genes of XMRV and 38 peptides based on known epitopes of vertebrate gammaretroviruses. IgG antibodies were sought in 520 blood donors and 85 ME/CFS patients and in positive- and negative-control sera from animals. We found no differences in seroreactivity between blood donors and ME/CFS patients for any of the antigens. This did not support an association between ME/CFS and XMRV infection. The multiplex serological system had several advantages: (i) biotinylated protein G allowed us to run both human and animal sera, which is essential because of a lack of XMRV-positive humans; (ii) a novel quality control was a pan-peptide positive-control rabbit serum; and (iii) synthetic XMRV Gag peptides with degenerate positions covering most of the variation of murine leukemia-like viruses did not give higher background than nondegenerate analogs. The principle may be used for creation of variant tolerant peptide serologies. Thus, our system allows rational large-

				scale serological assays with built-in quality control.
Bloom S, Ablin JN, Lebel D, Rath E, Faran Y, Daphna-Tekoah S, Buskila D.	Orthopedic Surgery Department, Soroka Medical Center, Beersheba, Israel	Awareness of diagnostic and clinical features of fibromyalgia among orthopedic surgeons.	Rheumatol Int. 2012 Jul 22.	Fibromyalgia Syndrome (FMS) is a chronic pain syndrome characterized by widespread musculoskeletal pain and fatigue. The current study was designed to evaluate the awareness and skills of orthopedic surgeons (OS) regarding FMS diagnosis and treatment. For the examination of awareness and familiarity of OS in Israel to Fibromyalgia, a questionnaire-based survey was conducted. Two hundred and nineteen OS, residents and specialists, were asked anonymously about awareness, knowledge, and treatment of FM. Multivariable statistical analysis was performed. 91 % (199) of responders reported that they recognized the disease. Notwithstanding, the mean knowledge score was 7.6 out of 17. In addition, OS who were trained in the south of Israel were found to have a better degree of knowledge about FM (9.7 vs. 7.4; $p < 0.03$). The awareness and knowledge among OS regarding FM needs to be improved. OS who were trained in the south of Israel were found to have better degree of knowledge regarding FM.
Bodei L, Cremonesi M, Grana CM, Chinol M, Baio SM, Severi S, Paganelli G.	Division of Nuclear Medicine, European Institute of Oncology, Via Ripamonti 435, 20141 Milan, Italy.	Yttrium-labelled peptides for therapy of NET.	Eur J Nucl Med Mol Imaging. 2012 Feb;39 Suppl 1:S93-102. doi: 10.1007/s00259-011-2002-y.	Peptide receptor radionuclide therapy (PRRT) consists in the systemic administration of a synthetic peptide, labelled with a suitable beta-emitting radionuclide, able to irradiate tumours and their metastases via the internalization through a specific receptor, overexpressed on the cell membrane. After 15 years of experience, we can state that PRRT with (90)Y-labelled peptides is generally well tolerated. Acute side effects are usually mild, some of which are related to the co-administration of amino acids, such as nausea. Others are related to the radiopeptide, such as fatigue or the exacerbation of an endocrine syndrome, which rarely occurs in functioning tumours. Chronic and permanent effects on target organs, particularly the kidneys and the bone marrow, are generally mild if the necessary precautions are taken. Currently, the potential risk to kidney and red marrow limits the amount of radioactivity that may be administered. However, when tumour masses are irradiated with adequate doses, volume reduction may be observed. (90)Y-octreotide has been the most widely used radiopeptide in the first 8-10 years of experience. Unfortunately, all of the published results derive from different and inhomogeneous phase I/II studies. Hence, a direct comparison is virtually impossible to date. Nevertheless, even with these limitations, objective responses are registered in 10-34% of patients. The optimal timing of (90)Y-DOTATOC in the management of somatostatin receptor (SSTR)-positive tumours and the way in which it should be integrated with other treatments have yet to be defined, and prospective phase II/III trials comparing the efficacy and toxicity of different schemes of (90)Y-DOTATOC administration are still warranted.
Booth NE, Myhill S, McLaren-Howard J.	[No address quoted]	Mitochondrial dysfunction and the pathophysiology of Myalgic Encephalomyelitis/C	Int J Clin Exp Med. 2012;5(3):208-20.	The objectives of this study are to test the hypothesis that the fatigue and accompanying symptoms of Chronic Myalgic Encephalomyelitis/Fatigue Syndrome are in part due to defects in energy provision at the cellular level, and to understand the pathophysiology of the defects so that effective medical intervention can be implemented. We performed an audit of 138 patients (ages 18-65) diagnosed with

		hronic Fatigue Syndrome (ME/CFS).		ME/CFS and attending a private practice. The patients and 53 normal, healthy controls had the ATP Profile test carried out on neutrophils from a 3-ml venous blood sample. This test yields 6 numerical factors that describe the availability of ATP and the efficiency of oxidative phosphorylation in mitochondria. Other biomedical measurements, including the concentration of cell-free DNA in plasma, were made. The results of the audit are compared with the controls and a previous cohort of 61 patients. We find that all patients tested have measureable mitochondrial dysfunction which correlates with the severity of the illness. The patients divide into two main groups differentiated by how cellular metabolism attempts to compensate for the dysfunction. Comparisons with exercise studies suggest that the dysfunction in neutrophils also occurs in other cells. This is confirmed by the cell-free DNA measurements which indicate levels of tissue damage up to 3.5 times the normal reference range. The major immediate causes of the dysfunction are lack of essential substrates and partial blocking of the translocator protein sites in mitochondria. The ATP Profile is a valuable diagnostic tool for the clinical management of ME/CFS.
Bossuyt X, Cooreman S, De Baere H, Verschueren P, Westhovens R, Blockmans D, Mariën G.	Experimental Laboratory Immunology, Catholic University Leuven, Leuven, Belgium; Department of Laboratory Medicine, Immunology, University Hospitals Leuven, Leuven, Belgium. Electronic address: xavier.bossuyt@uz.kuleuven.ac.be.	Detection of antinuclear antibodies by automated indirect immunofluorescence analysis.	Clin Chim Acta. 2013 Jan 16;415:101-6. doi: 10.1016/j.cca.2012.09.021.	BACKGROUND: Testing for antinuclear antibodies is useful for the diagnosis of systemic rheumatic diseases. Automated systems for image acquisition and interpretation of indirect immunofluorescence-based tests are increasingly used. The diagnostic performance of such automated approach in untreated patients has not been reported. METHODS: Antinuclear antibodies were measured by automated indirect immunofluorescence using Zenit G. Sight on HEp2 and HEp2000 substrate in 268 consecutive samples submitted to the laboratory for antinuclear antibody testing, and in 231 patients with a systemic rheumatic disease at the time of diagnosis, 143 blood donors, 134 patients with chronic fatigue syndrome, and 133 diseased controls. RESULTS: Image acquisition by G-Sight was of high quality. The accuracy of pattern assignment was limited. There was a significant correlation between automated estimation of fluorescence intensity (probability index of positivity) and end-point titer. Probability index interval specific likelihood ratios for systemic rheumatic disease increased with increasing level of positivity probability. With the HEp-2 substrate, the likelihood ratio for systemic lupus erythematosus was 0.06, 0.4, 6.8, 12.1, and 43.9 for a probability measure of positivity of ≤10, 11-≤30, 31-≤50, 51-≤85, and >85, respectively. CONCLUSION: Quantitative data generated by automated image acquisition facilitates standardized interpretation.
Bower JE.	UCLA Department of Psychology, 1285 Franz Hall, Los Angeles, CA 90095-1563, USA. jbower@ucla.edu	Fatigue, brain, behavior, and immunity: summary of the 2012 Named Series on fatigue.	Brain Behav Immun. 2012 Nov;26(8):1220-3. doi: 10.1016/j.bbi.2012.08.009.	The focus on fatigue for the 2012 Named Series in brain, behavior, and immunity reflects the growing wave of research examining immune underpinnings of fatigue in healthy and clinical populations. Fatigue is prevalent in the general population and in patients with a variety of medical conditions. However, the etiology of fatigue remains elusive. Psychoneuroimmunological approaches to fatigue have yielded important advances in our understanding of this complex symptom and are represented in the twelve articles included in the Named Series. These articles

				include animal and human models of fatigue and cross a variety of different medical conditions, including cancer, chronic fatigue syndrome, and diabetes. This review briefly summarizes the articles included in the series and highlights the themes that have emerged from this body of work.
Brenu EW, Ashton KJ, van Driel M, Staines DR, Peterson D, Atkinson GM, Marshall-Gradisnik SM.	Faculty of Health Science and Medicine, Population Health and Neuroimmunology Unit, Bond University, Robina, Queensland, Australia. ekbrenu@bond.edu.au	Cytotoxic lymphocyte microRNAs as prospective biomarkers for Chronic Fatigue Syndrome/Myalgic Encephalomyelitis.	J Affect Disord. 2012 Dec 10;141(2-3):261-9. doi: 10.1016/j.jad.2012.03.037.	BACKGROUND: Immune dysfunction associated with a disease often has a molecular basis. A novel group of molecules known as microRNAs (miRNAs) have been associated with suppression of translational processes involved in cellular development and proliferation, protein secretion, apoptosis, immune function and inflammatory processes. MicroRNAs may be implicated in Chronic Fatigue Syndrome/Myalgic Encephalomyelitis (CFS/ME), where immune function is impaired. The objective of this study was to determine the association between miRNAs in cytotoxic cells and CFS/ME. METHODS: Natural Killer (NK) and CD8(+)T cells were preferentially isolated from peripheral blood mononuclear cells from all participants (CFS/ME, n=28; mean age=41.8±9.6 years and controls, n=28; mean age=45.3±11.7 years), via negative cell enrichment. Following total RNA extraction and subsequent synthesis of cDNA, reverse transcriptase-quantitative polymerase chain reaction (RT-qPCR) was used to determine the expression levels of nineteen miRNAs. RESULTS: There was a significant reduction in the expression levels of miR-21, in both the NK and CD8(+)T cells in the CFS/ME sufferers. Additionally, the expression of miR-17-5p, miR-10a, miR-103, miR-152, miR-146a, miR-106, miR-223 and miR-191 was significantly decreased in NK cells of CFS/ME patients in comparison to the non-fatigued controls. LIMITATIONS: The results from these investigations are not yet transferable into the clinical setting, further validatory studies are now required. CONCLUSIONS: Collectively these miRNAs have been associated with apoptosis, cell cycle, development and immune function. Changes in miRNAs in cytotoxic cells may reduce the functional capacity of these cells and disrupt effective cytotoxic activity along with other immune functions in CFS/ME patients.
Brenu EW, van Driel ML, Staines DR, Ashton KJ, Hardcastle SL, Keane J, Tajouri L, Peterson D, Ramos SB, Marshall-Gradisnik SM.	Population Health and Neuroimmunology Unit, Bond University, Robina, QLD, Australia. ekbrenu@bond.edu.au	Longitudinal investigation of natural killer cells and cytokines in chronic fatigue syndrome/myalgic encephalomyelitis.	J Transl Med. 2012 May 9;10:88. doi: 10.1186/1479-5876-10-88.	BACKGROUND: Chronic Fatigue Syndrome/Myalgic Encephalomyelitis (CFS/ME) is an etiologically unexplained disorder characterised by irregularities in various aspects of the immunological function. Presently, it is unknown whether these immunological changes remain consistent over time. This study investigates Natural Killer (NK) cell cytotoxic activity, NK cell subsets (CD56brightCD16- and CD56dimCD16+) and cytokines, over the course of a12 month period in patients with CFS/ME. METHODS: The participants in the study comprised 65 (47.2 ± 11.5 years) CFS/ME participants and 21 (45.2 ± 9.3 years) non-fatigued controls. Flow cytometry protocols were used to assess NK subsets and NK cytotoxic activity at various time points that included baseline (T1), 6 (T2) and 12 months (T3). Cytokine secretions were measured following mitogenic stimulation of peripheral blood mononuclear cells. RESULTS: NK cytotoxic activity was significantly decreased in the CFS/ME patients at T1, T2 and T3 compared to the non-fatigued group. Additionally, in comparison to the non-fatigued

				controls, the CFS/ME group had significantly lower numbers of CD56brightCD16- NK cells at both T1 and T2. Interestingly, following mitogenic stimulation, cytokine secretion revealed significant increases in IL-10, IFN-γ and TNF-α at T1 in the CFS/ME group. A significant decrease was observed at T2 in the CFS/ME group for IL-10 and IL-17A while at T3, IL-2 was increased in the CFS/ME group in comparison to the non-fatigued controls. Overall cytotoxic activity was significantly decreased at T3 compared to T1 and T2. CD56brightCD16- NK cells were much lower at T2 compared to T1 and T3. IL-10 and IL-17A secretion was elevated at T2 in comparison to T1 and T3. CONCLUSION: These results confirm decreases in immune function in CFS/ME patients, suggesting an increased susceptibility to viral and other infections. Furthermore, NK cytotoxic activity may be a suitable biomarker for diagnosing CFS/ME as it was consistently decreased during the course of the 12 months study.
Broderick G, Ben Hamo R, Vashishtha S, Efroni S, Nathanson L, Barnes Z, Fletcher MA, Klimas N.	Department of Medicine, University of Alberta, Edmonton, Canada. Electronic address: gordon.broderick@ualberta.ca.	Altered immune pathway activity under exercise challenge in Gulf War Illness: An exploratory analysis.	Brain Behav Immun. 2012 Nov 29. pii: S0889-1591(12)00493-X. doi: 10.1016/j.bbi.2012.11.007.	Though potentially linked to the basic physiology of stress response we still have no clear understanding of Gulf War Illness (GWI), a debilitating illness presenting with a complex constellation of immune, endocrine and neurological symptoms. Here we compared male GWI (n=20) with healthy veterans (n=22) and subjects with chronic fatigue syndrome/myalgic encephalomyelitis (CFS/ME) (n=7). Blood was drawn during a Graded eXercise Test (GXT) prior to exercise, at peak effort (VO2 max) and 4-h post exercise. Affymetrix HG U133 plus 2.0 microarray gene expression profiling in peripheral blood mononuclear cells (PBMCs) was used to estimate activation of over 500 documented pathways. This was cast against ELISA-based measurement of 16 cytokines in plasma and flow cytometric assessment of lymphocyte populations and cytotoxicity. A 2-way ANOVA corrected for multiple comparisons (q statistic <0.05) indicated significant increases in neuroendocrine-immune signaling and inflammatory activity in GWI, with decreased apoptotic signaling. Conversely, cell cycle progression and immune signaling were broadly subdued in CFS. Partial correlation networks linking pathways with symptom severity via changes in immune cell abundance, function and signaling were constructed. Central to these were changes in IL-10 and CD2+ cell abundance and their link to two pathway clusters. The first consisted of pathways supporting neuronal development and migration whereas the second was related to androgen-mediated activation of NF-κB. These exploratory results suggest an over-expression of known exercise response mechanisms as well as illness-specific changes that may involve an overlapping stress-potentiated neuro-inflammatory response.
Broderick G, Fletcher MA, Gallagher M, Barnes Z, Vernon SD, Klimas NG.	Department of Medicine, Division of Pulmonary Medicine, University of Alberta, Edmonton, AB, Canada. gordon.broderick@ual	Exploring the diagnostic potential of immune biomarker coexpression in Gulf War Illness.	Methods Mol Biol. 2012;934:145-64. doi: 10.1007/978-1-62703-071-7_8.	Complex disorders like Gulf War Illness (GWI) often defy diagnosis on the basis of a single biomarker and may only be distinguishable by considering the coexpression of multiple markers measured in response to a challenge. We demonstrate the practical application of such an approach using an example where blood was collected from 26 GWI, 13 healthy control subjects, and 9 unhealthy controls with Chronic Fatigue at three points during a graded exercise challenge. A 3-way multivariate projection

	berta.ca			model based on 12 markers of endocrine and immune function was constructed using a training set of n = 10 GWI and n = 11 healthy controls. These groups were separated almost completely on the basis of two coexpression patterns. In a separate test set these same features allowed for discrimination of new GWI subjects (n = 16) from unhealthy (n = 9) and healthy control subjects with a sensitivity of 70% and a specificity of 90%.
Broderick G, Katz BZ, Fernandes H, Fletcher MA, Klimas N, Smith FA, O'Gorman MR, Vernon SD, Taylor R.	Division of Pulmonary Medicine, Department of Medicine, University of Alberta, WMC 2E4.41 WC Mackenzie Health Sciences Centre, 8440 112 Street, Edmonton, AB T6G 2R7, Canada. gordon.broderick@ualberta.ca	Cytokine expression profiles of immune imbalance in post-mononucleosis chronic fatigue.	J Transl Med. 2012 Sep 13;10:191. doi: 10.1186/1479-5876-10-191.	BACKGROUND: As Chronic Fatigue Syndrome (CFS) has been known to follow Epstein-Bar virus (EBV) and other systemic infections; our objective was to describe differences in immune activation in post-infective CFS (PI-CFS) patients and recovered controls. We studied 301 adolescents prospectively over 24 months following the diagnosis of monospot-positive infectious mononucleosis (IM). We found an incidence of CFS at 6, 12 and 24 months of 13%, 7% and 4% respectively. METHODS: Using chemiluminescent imaging we measured the concentrations of IL-1a, 1b, 2, 4, 5, 6, 8, 10, 12 (p70), 13, 15, 17 and 23, IFN-γ, TNF-α and TNF-β in duplicate plasma samples available in bio-bank from 9 PI-CFS subjects and 12 recovered controls at 24 months post-infection. RESULTS: Standard comparative analysis indicated significant differences in IL-8 and 23 across subject groups. In constructing a linear classification model IL-6, 8 and 23 were selected by two different statistical approaches as discriminating features, with IL-1a, IL-2 and IFN-γ also selected in one model or the other. This supported an assignment accuracy of better than 80% at a confidence level of 0.95 into PI-CFS versus recovered controls. CONCLUSION: These results suggest that co-expression patterns in as few as 5 cytokines associated with Th17 function may hold promise as a tool for the diagnosis of post-infectious CFS.

Brooks J, Daglish J, Wearden A.	University of Huddersfield, UK.	Attributions, distress and behavioural responses in the significant others of people with Chronic Fatigue Syndrome.	J Health Psychol. 2012 Nov 23.	To test an attribution-emotion model of reactions to chronic fatigue syndrome/myalgic encephalomyelitis, 30 significant others of 30 adult patients with chronic fatigue syndrome/myalgic encephalomyelitis were administered a semi-structured interview about their beliefs regarding the patient's illness and completed questionnaire measures of distress and behavioural responses to the patient. Spontaneous causal explanations (attributions) for illness events, symptom exacerbation and negative patient mood were extracted and coded. Significant others' distress and negative behavioural responses towards the chronic fatigue syndrome/myalgic encephalomyelitis patient were associated with attributing illness events to causes personal and internal to the patient. Our findings may inform the future family-based interventions for chronic fatigue syndrome/myalgic encephalomyelitis.

Brooks J, Lycett-Lambert K, Caminiti K, Merks H, McMillan R, Sandstrom P.	National HIV & Retrovirology Laboratories, National Microbiology Laboratory, Public Health Agency of Canada, Ottawa, Canada. james.brooks@phac-aspc.gc.ca	No evidence of cross-species transmission of mouse retroviruses to animal workers exposed to mice.	Transfusion. 2012 Feb;52(2):317-25. doi: 10.1111/j.1537-2995.2011.03463.x	BACKGROUND: Although recent data have brought into question the association between xenotropic murine leukemia virus-related virus (XMRV) and chronic fatigue syndrome, one group has reported evidence of human infection with distinct polytropic murine leukemia viruses (MLVs). Occult retroviral infection among humans poses a significant public health risk should it be introduced into the blood supply. To explore the possibility of cross-species transmission of MLVs to humans, we sought molecular and serologic evidence of XRMV/MLV infection among a cohort of animal workers highly exposed to mice. STUDY DESIGN AND METHODS: Before the commencement of the study, the laboratory and equipment were demonstrated to be free of XMRV/MLV DNA sequences. DNA extracted from 43 animal workers was tested using nested polymerase chain reaction (PCR) with published primer sets, targeting regions of XMRV and MLV gag. Negative controls were assayed in a 1:1 ratio with specimens. Serum specimens were tested using a validated immunoblot assay containing cross-reactive XMRV antigens. RESULTS: Initial molecular assays demonstrated that the physical space and laboratory equipment were free of MLV and XMRV DNA sequences. Nested PCR assays using multiple primer sets successfully amplified XMRV and MLV sequences from positive controls with high sensitivity. A single, nonreproducible, false-positive result from one specimen was shown to be the result of subsequent contamination. Immunoblotting of all subjects' sera failed to demonstrate any evidence of seroreactivity to XMRV proteins. CONCLUSIONS: There was no evidence of human infection with XMRV/MLV among a cohort of individuals highly exposed to mice. These data suggest that the likelihood of cross-species transmission events of MLV from mice to humans is low.
Brooks SK, Rimes KA, Chalder T.	Department of Psychological Medicine, King's College London, UK.	The role of acceptance in chronic fatigue syndrome.	J Psychosom Res. 2011 Dec;71(6):411-5. doi: 10.1016/j.jpsychores.2011.08.001.	OBJECTIVE: In this paper we consider the role that acceptance plays in fatigue and physical and social functioning. We predicted that lack of acceptance would be positively correlated with fatigue and impairment in functioning; that there would be a significant relationship between perfectionism and acceptance; and cognitive behavioural therapy (CBT) would increase acceptance. METHODS: Two hundred and fifty nine patients with chronic fatigue syndrome (CFS) completed questionnaires measuring fatigue, physical functioning, work and social adjustment, lack of acceptance, perfectionism and depression. Ninety consecutive attenders received a course of CBT and completed further questionnaires at discharge and 3months post-treatment. Correlations and multiple hierarchical regressions were used to determine relationships between acceptance, perfectionism and clinical outcome variables. RESULTS: At baseline, lack of acceptance was the key factor associated with impaired physical functioning and work and social adjustment. Lack of acceptance and doubts about actions were associated with fatigue in a multiple regression analysis. At discharge and follow-up patients showed significantly increased acceptance, as well as reduced Concern over Mistakes, less fatigue and impairment of physical functioning, and improved work and social adjustment. CONCLUSION: This is the first

				study to our knowledge which shows a change in acceptance after CBT and a relationship between acceptance and perfectionism. Acceptance may be an important factor to consider within treatments for CFS.
Brown M, Kaplan C, Jason L.	DePaul University, Chicago 60618, USA. mbrown59@depaul.edu	Factor analysis of the Beck Depression Inventory-II with patients with chronic fatigue syndrome. Brown M, Kaplan C, Jason L.	J Health Psychol. 2012 Sep;17(6):799-808. doi: 10.1177/1359105311424470.	This study examined the properties of the Beck Depression Inventory-II (BDI-II) in a sample of 111 patients with chronic fatigue syndrome (CFS). Exploratory factor analysis identified two factors. The mean score for the Somatic-Affective factor was significantly higher than the Cognitive factor. Convergent and discriminant validity were assessed for BDI-II total score, the two factor scores, and the BDI for Primary Care (BDI-PC). The BDI-PC and Cognitive factor demonstrated superior validity. Results suggest patients endorse BDI-II somatic items that overlap with CFS symptoms at a high rate. Factor scores should be evaluated separately, or the BDI-PC should be utilized with this population.
Brown MM, Bell DS, Jason LA, Christos C, Bell DE.	DePaul University, Chicago, IL 60614, USA. mbrown59@depaul.edu	Understanding long-term outcomes of chronic fatigue syndrome.	J Clin Psychol. 2012 Sep;68(9):1028-35. doi: 10.1002/jclp.21880.	OBJECTIVE: This study sought to examine long-term health, symptom, and disability outcomes among patients with chronic fatigue syndrome (CFS) by comparing those diagnosed with CFS 25 years ago with healthy controls. METHOD: Of the 25 participants diagnosed with CFS 25 years ago, 5 self-reported that they maintained a diagnosis of CFS, while 20 reported no longer having a diagnosis. These two groups were compared with healthy controls on outcomes related to functioning and symptom severity. RESULTS: Those who remitted from CFS showed significantly more impairment on 21 out of 23 outcomes compared with controls. On 17 outcomes, those who remitted had nonsignificant differences in impairment compared to those who maintained a CFS diagnosis. CONCLUSIONS: Findings from this study suggest that over time many individuals will not maintain a CFS diagnosis but will not return to their premorbid level of functioning.
Brubakk O.	[No address quoted]	Two sub editorials. [Article in Norwegian]	Tidsskr Nor Laegeforen. 2012 Apr 30;132(8):927. doi: 10.4045/tidsskr.12.0202.	Comment on Tidsskr Nor Laegeforen. 2012 Jan 24;132(2):125. Tidsskr Nor Laegeforen. 2012 Feb 7;132(3):261-2.
Burbelo PD, Bayat A, Wagner J, Nutman TB, Baraniuk JN, Iadarola MJ.	Neurobiology and Pain Therapeutics Section, Laboratory of Sensory Biology, National Institute of Dental and Craniofacial Research, National Institutes of Health Bethesda, MD.	No serological evidence for a role of HHV-6 infection in chronic fatigue syndrome	Am J Transl Res. 2012;4(4):443-51.	Human herpesvirus 6A (HHV-6A) and human herpesvirus 6B (HHV-6B) are associated with a variety of conditions including rash, fever, and encephalitis and may play a role in several neurological diseases. Here luciferase immunoprecipitation systems (LIPS) was used to develop HHV-6 serologic diagnostic tests using antigens encoded by the U11 gene from HHV-6A (p100) and HHV-6B (p101). Analysis of the antibody responses against Renilla luciferase fusions with different HHV-6B p101 fragments identified an antigenic fragment (amino acids 389 to 858) that demonstrated ~86% seropositivity in serum samples from healthy US blood donors. Additional experiments detected a HHV-6A antigenic fragment (amino acids 751-870) that showed ~48% antibody seropositivity in samples from Mali, Africa, a known HHV-6A endemic region. In contrast to the high levels of HHV-6A immunoreactivity seen in the African samples, testing of US blood donors with the HHV-6A p100 antigenic fragment revealed little immunoreactivity. To potentially explore the role of HHV-6 infection in human

				disease, a blinded cohort of controls (n=59) and chronic fatigue syndrome (CFS) patients (n=72) from the US was examined for serum antibodies. While only a few of the controls and CFS patients showed high level immunoreactivity with HHV-6A, a majority of both the controls and CFS patients showed significant immunoreactivity with HHV-6B. However, no statistically significant differences in antibody levels or frequency of HHV-6A or HHV-6B infection were detected between the controls and CFS patients. These findings highlight the utility of LIPS for exploring the seroepidemiology of HHV-6A and HHV-6B infection, but suggest that these viruses are unlikely to play a role in the pathogenesis of CFS.
Burgess M, Andiappan M, Chalder T.	South London & Maudsley Trust, London, UK. mary.burgess@slam.nhs.uk	Cognitive behaviour therapy for chronic fatigue syndrome in adults: face to face versus telephone treatment: a randomized controlled trial.	Behav Cogn Psychother. 2012 Mar;40(2):175-91. doi: 10.1017/S1352465811000543.	BACKGROUND: Previous research has shown that face to face cognitive behaviour therapy (CBT) is an effective treatment for chronic fatigue syndrome (CFS)/Myalgic Encephalomyelitis (ME). However, some patients are unable to travel to the hospital for a number of reasons. AIMS: The aim of this study was to assess whether face to face CBT was more effective than telephone CBT (with face to face assessment and discharge appointment) for patients with CFS. METHOD: Patients aged 18-65 were recruited from consecutive referrals to the Chronic Fatigue Syndrome (CFS) Research and Treatment Unit at The South London and Maudsley NHS Trust in London. Participants were randomly allocated to either face to face CBT or telephone CBT by a departmental administrator. Blinding of participants and care givers was inappropriate for this trial. A parallel-groups randomised controlled trial was used to compare the two treatments. The primary outcomes were physical functioning and fatigue. RESULTS: Significant improvements in the primary outcomes of physical functioning and fatigue occurred and were maintained to one year follow-up after discharge from treatment. Improvements in social adjustment and global outcome were noted and patient satisfaction was similar in both groups. CONCLUSIONS: Results from this study indicate that telephone CBT with two face to face appointments is a mild to moderately effective treatment for CFS and may be offered to patients where face to face treatment is not a viable option. Despite these encouraging conclusions, dropout was relatively high and therapists should be aware of this potential problem.
Burns D.	School of Nursing, Midwifery and Social Work, University of Manchester. dianne.burns@manchester.ac.uk	Chronic fatigue syndrome or myalgic encephalomyelitis.	Nurs Stand. 2012 Feb 22-28;26(25):48-56; quiz 58.	Chronic fatigue syndrome or myalgic encephalomyelitis (CFS/ME) is a debilitating illness that affects many systems of the body, particularly the nervous and immune systems. The condition affects all age, racial, ethnic and socioeconomic groups. This article focuses on the knowledge, understanding and skills necessary to recognise, assess, manage and support patients with CFS/ME. The principles of management and rehabilitation can be applied by nurses and other healthcare professionals irrespective of the clinical setting and context.
Calandre EP, Rico-Villademoros F.	Institute of Neuroscience and Center for Biomedical	The role of antipsychotics in the management of	CNS Drugs. 2012 Feb 1;26(2):135-53. doi: 10.2165/11597130-	Fibromyalgia is a syndrome characterized by chronic generalized pain associated with different somatic symptoms, such as sleep disturbances, fatigue, stiffness, balance problems, hypersensitivity to physical and psychological environmental stimuli,

	Investigations, University of Granada, Granada, Spain. calandre@gmail.com	fibromyalgia.	000000000-00000.	depression and anxiety. It has been estimated to affect roughly the 2-4% of the general population in most countries studied, and it has been shown to be much more prevalent in women than in men. Although its pathophysiology is not yet fully understood, it is known that both genetic and environmental factors are involved in its development. Fibromyalgia shares a high degree of co-morbidity with other conditions, including chronic headache, temporomandibular disorder, irritable bowel syndrome, major depression, anxiety disorders and chronic fatigue syndrome. Therefore, this is a syndrome difficult to treat for which multimodal treatments including physical exercise, psychological therapies and pharmacological treatment are recommended. Although different kinds of drugs have been studied for the treatment of fibromyalgia, the most widely used drugs that have the higher degree of evidence for efficacy include the α(2)δ ligands pregabalin and gabapentin, and the tricyclic antidepressants (TCAs) and serotonin noradrenaline (norepinephrine) reuptake inhibitors (SNRIs). However, there is a need to look for newer additional therapeutic pharmacological options for the treatment of this complex and disabling disease. First- and second-generation antipsychotics have shown analgesic properties both in an experimental setting and in humans, although most of the available evidence for the treatment of human pain concerns older antipsychotics and involves clinical trials performed several decades ago. In addition, several second-generation antipsychotics, risperidone, olanzapine and quetiapine, have shown efficacy in the treatment of some anxiety disorders. Some second-generation antipsychotics, mainly quetiapine, aripiprazole and amisulpride, have demonstrated antidepressant activity, with quetiapine approved for the treatment of bipolar depression and refractory major depression, and aripiprazole approved as an adjunctive treatment for major depressive disorder. Finally, several old and new antipsychotics, including promethazine, levopromazine, olanzapine, quetiapine and ziprasidone, have been shown to improve sleep parameters in healthy subjects. Each of these properties suggests that antipsychotics could represent a new potential alternative for the treatment of fibromyalgia syndrome. To date, most of the published studies on the use of antipsychotics in the treatment of fibromyalgia syndrome have been uncontrolled, either case reports or case series, dealing with olanzapine, quetiapine, ziprasidone, levopromazine and amisulpride. The studies on olanzapine and quetiapine have suggested therapeutic efficacy although, in the case of olanzapine, hampered by tolerability problems. A double-blind controlled trial, published in 1980, showed that chlorpromazine increased slow-wave sleep and improved pain and mood disturbances. More recently, four double-blind controlled studies have explored the efficacy of quetiapine, either alone or as an add-on treatment, in fibromyalgia management. None of these trials has yet been published, although two of them have been presented as congress communications, both of them suggesting that quetiapine could be a potential alternative treatment for fibromyalgia. In summary,

				the current available evidence suggests that at least some antipsychotics, specifically quetiapine, could be useful for the treatment of fibromyalgia and that further studies on the efficacy of these compounds are worth pursuing.
Callaway E.	[No address quoted]	Embattled scientist in theft probe.	Nature. 2011 Nov 29;480(7375):13-4. doi: 10.1038/480013a.	[No abstract given]
Cao Y, Hu Y, Liu P, Zhao HX, Zhou XJ, Wei YM.	Department of Clinical Pharmacology, Chinese PLA General Hospital, Beijing 100853, China.	Effects of a Chinese traditional formula Kai Xin San (KXS) on chronic fatigue syndrome mice induced by forced wheel running.	J Ethnopharmacol. 2012 Jan 6;139(1):19-25. doi: 10.1016/j.jep.2011.08.030.	ETHNOPHARMACOLOGICAL RELEVANCE: In traditional medicine, Kai Xin San (KXS), composed of ginseng (Panax ginseng), hoelen (Wolfiporia cocos), polygala (Polygala tenuifolia) and Acorus gramineus, is famous for the treatment of emotion-thought disease, such as settling fright, quieting the spirit and nourishing the heart. AIM OF THE STUDY: The present study investigated the effect of KXS on chronic fatigue syndrome (CFS) mice induced by forced wheel running. MATERIALS AND METHODS: Seventy two healthy adult male Kunming mice were randomly divided into six groups: home cage control group, CFS group, CFS group with Modafinil treatment at 13 mg/kg/d doge, KXS treatment at 175 mg/kg/d, 350 mg/kg/d and 700 mg/kg/d doge. CFS mice were induced by forced wheel running with higher speed for 4 weeks and then taken an exhausted exercise. The biochemical parameters including serum lactate dehydrogenase (LDH), serum urea nitrogen (SUN), serum testosterone (T), liver glycogen (LG), muscle glycogen (MG) and muscle lactic acid (MLA) were determined by using commercially available kits. The splenocytes proliferation from mice was examined by MTT method. The levels of interleukin-2 (IL-2) and interleukin-4 (IL-4) secreted by splenocytes were determined by ELISA. RESULTS: CFS mice with KXS administration exhibited less electric shock time when compared with CFS group without drug treatment. The effect of KXS has after demonstrated reduction in SUN, LDH and MLA levels and an increase in T, LG and MG levels. CFS mice with KXS could improve the proliferation of splenocytes compared with CFS group without drug treatment. The cultured splenocytes from CFS mice without KXS supplementation produced more interleukin-2 (IL-2) but less interleukin-4 (IL-4) when compared with home cage control mice. The cultured splenocytes of CFS mice with KXS supplementation produced more interleukin-2 (IL-2) but less interleukin-4 (IL-4) when compared with CFS group without drug treatment. CONCLUSIONS: The results of this preliminary study provide evidence that KXS could ameliorate CFS by affecting the physiological markers for fatigue. This study also supported the use of KXS against CFS by improving the proliferation of splenocytes from CFS mice and modulating the disturbance of cytokines induced by CFS.
Carbonell-Baeza A, Aparicio VA, Chillón P, Femia P, Delgado-Fernandez M, Ruiz	Department of Physical Education and Sport, University of Granada, Granada, Spain. anellba@ugr.es	Effectiveness of multidisciplinary therapy on symptomatology and quality of life in	Clin Exp Rheumatol. 2011 Nov-Dec;29(6 Suppl 69):S97-103.	OBJECTIVES: To study the effects of a 3-month multidisciplinary intervention based on exercise and psychological therapy on symptomatology and quality of life in women with fibromyalgia. METHODS: Seventy-five women with fibromyalgia volunteered to participate and were allocated to a 3-month (3-times/week) multidisciplinary (pool, land-based and psychological session based on the Acceptance and Commitment

JR.		women with fibromyalgia.		Therapy) intervention (n=41), or to a usual care group (n=34). Sixty-five women with fibromyalgia completed the study protocol (n=33 multidisciplinary intervention, aged 51.4±7.4 years and n=32 usual care group, aged 50.0±7.3 years). The outcomes variables were Fibromyalgia Impact Questionnaire (FIQ), Short Form Health Survey 36 (SF-36), Hospital Anxiety and Depression Scale, Vanderbilt Pain Management Inventory and Rosenberg Self-Esteem Scale. RESULTS: We observed a significant interaction effect (group*time) for the FIQ total score, the subscales fatigue, stiffness, anxiety and depression, and the subscales of SF-36 physical role, bodily pain, vitality and social functioning. Post-hoc analysis revealed significant improvements in total score of FIQ ($p<0.001$), fatigue ($p=0.001$), stiffness ($p<0.001$), anxiety ($p=0.011$), depression ($p=0.008$), physical role ($p=0.002$), bodily pain ($p<0.001$), vitality ($p<0.001$) and social functioning ($p<0.001$) in the intervention group, whereas in the control group, there was a significant worsening in the subscale depression ($p=0.006$) and social functioning ($p=0.019$). CONCLUSIONS: A 3-month low-moderate intensity multidisciplinary intervention improved fibromyalgia symptomatology and quality of life in women with fibromyalgia.
Castori M, Morlino S, Celletti C, Celli M, Morrone A, Colombi M, Camerota F, Grammatico P.	Division of Medical Genetics, Department of Molecular Medicine, Sapienza University, San Camillo-Forlanini Hospital, Rome, Italy. mcastori@scamilloforlanini.rm.it	Management of pain and fatigue in the joint hypermobility syndrome (a.k.a. Ehlers-Danlos syndrome, hypermobility type): principles and proposal for a multidisciplinary approach.	Am J Med Genet A. 2012 Aug;158A(8):2055-70. doi: 10.1002/ajmg.a.35483.	Joint hypermobility syndrome (JHS), or Ehlers-Danlos syndrome (EDS) hypermobility type (EDS-HT), is a underdiagnosed heritable connective tissue disorder characterized by generalized joint hypermobility and a wide range of visceral, pelvic, neurologic, and cognitive dysfunctions. Deterioration of quality of life is mainly associated with pain and fatigue. Except for the recognized effectiveness of physiotherapy for some musculoskeletal features, there are no standardized guidelines for the assessment and treatment of pain and fatigue. In this work, a practical classification of pain presentations and factors contributing in generating painful sensations in JHS/EDS-HT is proposed. Pain can be topographically classified in articular limb (acute/subacute and chronic), muscular limb (myofascial and fibromyalgia), neuropathic limb, back/neck, abdominal and pelvic pain, and headache. For selected forms of pain, specific predisposing characteristics are outlined. Fatigue appears as the result of multiple factors, including muscle weakness, respiratory insufficiency, unrefreshing sleep, dysautonomia, intestinal malabsorption, reactive depression/anxiety, and excessive use of analgesics. A set of lifestyle recommendations to instruct patients as well as specific investigations aimed at characterizing pain and fatigue are identified. Available treatment options are discussed in the set of a structured multidisciplinary approach based on reliable outcome tools.
Castori M, Ritelli M, Zoppi N, Molisso L, Chiarelli N, Zaccagna F, Grammatico P, Colombi M.	Medical Genetics, Department of Molecular Medicine, Sapienza University, San Camillo-Forlanini Hospital, Rome, Italy.	Adult presentation of arterial tortuosity syndrome in a 51-year-old woman with a novel homozygous c.1411+1G>A	Am J Med Genet A. 2012 May;158A(5):1164-9. doi: 10.1002/ajmg.a.35266.	Arterial tortuosity syndrome (ATS) is an autosomal recessive connective tissue disorder, mainly characterized by tortuosity and elongation of the large- and medium-sized arteries with predisposition to stenoses and aneurysms. ATS is caused by mutations in the SLC2A10 gene, encoding for the facilitative glucose transporter 10 (GLUT10) and is described typically in pediatric patients. We report on a 51-year-old woman, originally ascertained because of unexplained widespread chronic pain and

	mcastori@scamilloforlanini.rm.it	mutation in the SLC2A10 gene.		positive family history of aortic malformation. The main findings included aged appearance, congenital joint hypermobility, joint instability complications, chronic fatigue syndrome, progressive painful joint stiffness, abdominal hernias, pelvic prolapses, multiple cardiac valve prolapses, varicose veins, easy bruising, and gingival recession. Vascular imaging revealed kinking and anomalous origin of the aortic arch branches, marked tortuosity of the aorta, pulmonary and most middle arteries, and a small aneurysm of the splenic artery. SLC2A10 analysis disclosed homozygosity for the novel c.1411+1G>A splice mutation, leading to a 41 amino acids GLUT10 internal deletion. Expression study by immunofluorescence using healthy control cells showed lack of membrane internalization of GLUT10 in patient's skin fibroblasts. This report describes the first splice-site SLC2A10 mutation and increases to 19 the repertoire of known mutations in this gene. Comparison with the few previously published adult patients with ATS contributes to the natural history of this condition, which is probably under diagnosed within the expanding family of inherited connective tissue disorders.
Castori M, Sperduti I, Celletti C, Camerota F, Grammatico P.	Department of Molecular Medicine, Sapienza University, San Camillo-Forlanini Hospital, Rome, Italy. mcastori@scamilloforlanini.rm.it	Symptom and joint mobility progression in the joint hypermobility syndrome (Ehlers-Danlos syndrome, hypermobility type).	Clin Exp Rheumatol. 2011 Nov-Dec;29(6):998-1005.	OBJECTIVES: To evaluate progression of symptoms and joint mobility in the joint hypermobility syndrome (JHS) in order to identify specific disease pictures by age at presentation. METHODS: Fifty JHS patients (44 females, 6 males) were evaluated by Beighton score (BS) calculation, and presence/absence and age at onset of 20 key symptoms. Incidence and prevalence rates by age at onset and sex were calculated and compared by chi-square, Fisher's exact test and Mann-Whitney U-test. Relationship between BS and age at examination was evaluated by the Spearman rho correlation. The existence of an age cut-off separating patients with or without a positive BS was analysed by the receiver operating characteristic analysis. Influence of age on the single components of the BS was also investigated. RESULTS: Except for isolated features, the overall clinical presentation was the same between sexes. In the whole sample, statistically significant differences by age at presentation were registered for fatigue, myalgias, muscle cramps, strains/sprains, dislocations, tendon ruptures, tendonitis, gastroesophageal reflux, chronic gastritis, constipation/diarrhoea and abdominal hernias. A clear inverse correlation between age at examination and BS was demonstrated with an age cut-off fixed at 33 years. Among the components of the BS, spine and elbow joints were not significantly influenced by age. CONCLUSIONS: This study confirmed the existence of a protean clinical history of JHS which may be exemplified in different phases with distinguishable presentations. The knowledge of the peculiarities of each of them will help the practitioner in recognising and, hopefully, treating this condition.

Cavalcante AG, de Bruin PF, de Bruin VM, Pereira ED, Cavalcante MM, Nunes DM, Viana CS.	Faculdade de Medicina, Universidade Federal do Ceará, Brazil.	Restless legs syndrome, sleep impairment, and fatigue in chronic obstructive pulmonary disease.	Sleep Med. 2012 Aug;13(7):842-7. doi: 10.1016/j.sleep.2012.03.017.	OBJECTIVE: To investigate the frequency of factors associated with restless legs syndrome (RLS) in patients with chronic obstructive pulmonary disease (COPD). METHODS: RLS diagnosis was investigated (International RLS Study Group, IRLSSG) and severity was assessed (IRLS rating scale) in 104 consecutive COPD patients (age 69.1±8). Other measures were dyspnea severity (Modified Medical Research Council, MMRC), sleep quality (Pittsburgh Sleep Quality Index, PSQI), daytime somnolence (Epworth Sleepiness Scale, ESS), depressive symptoms (Beck Depression Inventory, BDI-II), and fatigue (Fatigue Severity Scale, FSS). Laboratory values included hemoglobin, ferritin, creatinine, and fibrinogen. RESULTS: Thirty-two patients (30.8%) were diagnosed with RLS (65.6% women), which was moderate/severe (IRLS >11) in 26 (81.3%). RLS symptoms started after age 40 in most patients (93.3%). RLS patients had poorer sleep quality (PSQI >5=59.6%; p=0.002), worse fatigue (FSS >27=51%; p=0.005), and more depressive symptoms (BDI-II >10=14.4%; p=0.005). Patients with RLS also presented more severe dyspnea (p=0.009) and lower creatinine levels (p=0.005). Overall, fatigue severity was correlated with older age (p=0.001); level of dyspnea was positively correlated with PSQI and FSS (p<0.005) and negatively correlated with ferritin (p=0.03) and creatinine (p=0.005), and PSQI scores correlated positively with FSS (p<0.005) and negatively with ferritin (p=0.005) and creatinine (p=0.02). Quality of sleep was independently predicted by dyspnea severity and creatinine and fatigue by age and depression. CONCLUSION: RLS is common in COPD. Patients with RLS have low creatinine, poorer quality of sleep, and more fatigue and depressive symptoms. RLS symptom severity is correlated to lower ferritin and severity of dyspnea.

Cella M, White PD, Sharpe M, Chalder T.	Institute of Psychiatry, King's College London, UK.	Cognitions, behaviours and co-morbid psychiatric diagnoses in patients with chronic fatigue syndrome.	Psychol Med. 2013 Feb;43(2):375-80. doi: 10.1017/S0033291712000979.	BACKGROUND: Specific cognitions and behaviours are hypothesized to be important in maintaining chronic fatigue syndrome (CFS). Previous research has shown that a substantial proportion of CFS patients have co-morbid anxiety and/or depression. This study aims to measure the prevalence of specific cognitions and behaviours in patients with CFS and to determine their association with co-morbid anxiety or depression disorders. Method A total of 640 patients meeting Oxford criteria for CFS were recruited into a treatment trial (i.e. the PACE trial). Measures analysed were: the Cognitive Behavioural Response Questionnaire, the Chalder Fatigue Scale and the Work and Social Adjustment Scale. Anxiety and depression diagnoses were from the Structured Clinical Interview for DSM-IV. Multivariate analysis of variance was used to explore the associations between cognitive-behavioural factors in patients with and without co-morbid anxiety and/or depression. RESULTS: Of the total sample, 54% had a diagnosis of CFS and no depression or anxiety disorder, 14% had CFS and one anxiety disorder, 14% had CFS and depressive disorder and 18% had CFS and both depression and anxiety disorders. Cognitive and behavioural factors were associated with co-morbid diagnoses; however, some of the mean differences between groups were small. Beliefs about damage and symptom focussing were more frequent in patients with anxiety disorders while embarrassment and behavioural avoidance were more common in patients with depressive disorder. CONCLUSIONS: Cognitions and behaviours hypothesized to perpetuate CFS differed in patients with concomitant depression and anxiety. Cognitive behavioural treatments should be tailored appropriately.

Chandran V, Pal PK, Reddy JY, Thennarasu K, Yadav R, Shivashankar N.	Department of Neurology, National Institute of Mental Health & Neurosciences, Bangalore, India.	Non-motor features in essential tremor.	Acta Neurol Scand. 2012 May;125(5):332-7. doi: 10.1111/j.1600-0404.2011.01573.x.	INTRODUCTION: Essential tremor (ET) is increasingly recognized to have several non-motor manifestations. The aim of this study was to determine the prevalence of non-motor manifestations in ET and its impact on the quality of life (QOL). METHODS: This was a cross-sectional case-control questionnaire-based study. The subjects were 50 patients with ET and 50 matched healthy controls. All subjects were assessed by Pittsburgh Sleep Quality Index, Epworth Sleepiness Scale, Parkinson Fatigue Scale, Brief Pain Inventory, Hamilton Anxiety Rating Scale, and Hamilton Depression Rating Scale. In addition, QOL in Essential Tremor questionnaire was administered to patients with ET. RESULTS: Patients with ET, when compared with controls, had significantly higher prevalence and higher mean scores of sleep disturbances (46% vs 8%, $P < 0.001$; 5.9 ± 4.6 vs 2.6 ± 2.3, $P < 0.001$), fatigue (30% vs 8%, $P = 0.009$; 5.8 ± 0.8 vs 2.5 ± 0.4, $P < 0.001$), anxiety (66% vs 18%, $P = 0.009$; 7.4 ± 9.0 vs 0.7 ± 2.6, $P < 0.001$), depression (44% vs 8%, $P = 0.009$; 7.8 ± 7.9 vs 1.7 ± 3.3, $P < 0.001$) as well as higher mean score of pain severity (1.9 ± 2.3 vs 0.6 ± 1.2, $P = 0.001$) and interference

				owing to pain (2.0 ± 2.9 vs 0.5 ± 1.2, P = 0.001). Following hierarchical regression analysis, depression was the only non-motor feature that affected the QOL. CONCLUSION: There was a significantly higher prevalence and greater severity of sleep disturbances, fatigue, pain, anxiety, and depression in patients with ET and depression significantly affected the QOL.
Chang CM, Warren JL, Engels EA.	Division of Cancer Epidemiology and Genetics, National Cancer Institute, Rockville, Maryland.	Chronic fatigue syndrome and subsequent risk of cancer among elderly US adults	Cancer. 2012 Dec 1;118(23):5929-36. doi: 10.1002/cncr.27612.	BACKGROUND: The cause of chronic fatigue syndrome (CFS) is unknown but is thought to be associated with immune abnormalities or infection. Because cancer can arise from similar conditions, associations between CFS and cancer were examined in a population-based case-control study among the US elderly. METHODS: Using linked Surveillance, Epidemiology, and End Results (SEER)-Medicare registry data, approximately 1.2 million cancer cases and 100,000 controls (age range, 66-99 years; 1992-2005) were evaluated. CFS was identified in the period more than 1 year prior to selection, using linked Medicare claims. Unconditional logistic regression was used to estimate the odds ratios (ORs) comparing the CFS prevalence in cases and controls, adjusting for age, sex, and selection year. All statistical tests were 2-sided. RESULTS: CFS was present in 0.5% of cancer cases overall and 0.5% of controls. CFS was associated with an increased risk of non-Hodgkin lymphoma (NHL) (OR = 1.29, 95% confidence interval [CI] = 1.16-1.43, P = 1.7 × 10(-6)). Among NHL subtypes, CFS was associated with diffuse large B cell lymphoma (OR = 1.34, 95% CI = 1.12-1.61), marginal zone lymphoma (OR = 1.88, 95% CI = 1.38-2.57), and B cell NHL not otherwise specified (OR = 1.51, 95% CI = 1.03-2.23). CFS associations with NHL overall and NHL subtypes remained elevated after excluding patients with medical conditions related to CFS or NHL, such as autoimmune conditions. CFS was also associated, although not after multiple comparison adjustment, with cancers of the pancreas (OR = 1.25, 95% CI = 1.07-1.47), kidney (OR = 1.27, 95% CI = 1.07-1.49), breast (OR = 0.85, 95% CI = 0.74-0.98), and oral cavity and pharynx (OR = 0.70, 95% CI = 0.49-1.00). CONCLUSIONS: Chronic immune activation or an infection associated with CFS may play a role in explaining the increased risk of NHL.
Chapenko S, Krumina A, Logina I, Rasa S, Chistjakovs M, Sultanova A, Viksna L, Murovska M.	August Kirchenstein Institute of Microbiology and Virology, Riga Stradins University, Ratsupites Street 5, LV-1067 Riga, Latvia.	Association of active human herpesvirus-6, -7 and parvovirus b19 infection with clinical outcomes in patients with myalgic encephalomyelitis/chronic fatigue syndrome.	Adv Virol. 2012;2012:205085. doi: 10.1155/2012/205085.	Frequency of active human herpesvirus-6, -7 (HHV-6, HHV-7) and parvovirus B19 (B19) infection/coinfection and its association with clinical course of ME/CFS was evaluated. 108 ME/CFS patients and 90 practically healthy persons were enrolled in the study. Viral genomic sequences were detected by PCR, virus-specific antibodies and cytokine levels-by ELISA, HHV-6 variants-by restriction analysis. Active viral infection including concurrent infection was found in 64.8% (70/108) of patients and in 13.3% (12/90) of practically healthy persons. Increase in peripheral blood leukocyte DNA HHV-6 load as well as in proinflammatory cytokines' levels was detected in patients during active viral infection. Definite relationship was observed between active betaherpesvirus infection and subfebrility, lymphadenopathy and malaise after exertion, and between active B19 infection and multijoint pain. Neuropsychological disturbances were detected in all patients. The manifestation of symptoms was of

				more frequent occurrence in patients with concurrent infection. The high rate of active HHV-6, HHV-7 and B19 infection/coinfection with the simultaneous increase in plasma proinflammatory cytokines' level as well as the association between active viral infection and distinctive types of clinical symptoms shows necessity of simultaneous study of these viral infections for identification of possible subsets of ME/CFS.
Chelimsky G, Heller E, Buffington CA, Rackley R, Zhang D, Chelimsky T.	Department of Pediatric Gastroenterology, Medical College of Wisconsin Milwaukee, WI, USA.	Co-morbidities of interstitial cystitis.	Front Neurosci. 2012;6:114. doi: 10.3389/fnins.2012.00114.	Introduction: This study aimed to estimate the proportion of patients with interstitial cystitis/painful bladder syndrome (IC/BPS) with systemic dysfunction associated co-morbidities such as irritable bowel syndrome (IBS) and fibromyalgia (FM). Materials and Methods: Two groups of subjects with IC/BPS were included: (1) physician diagnosed patients with IC/BPS and (2) subjects meeting NIDDK IC/PBS criteria based on a questionnaire (ODYSA). These groups were compared to healthy controls matched for age and socio-economic status. NIDDK criteria required: pain with bladder filling that improves with emptying, urinary urgency due to discomfort or pain, polyuria >11 times/24 h, and nocturia >2 times/night. The ODYSA instrument evaluates symptoms pertaining to a range of disorders including chronic fatigue, orthostatic intolerance, syncope, IBS, dyspepsia, cyclic vomiting syndrome, headaches and migraines, sleep, Raynaud's syndrome, and chronic aches and pains. Results: IC/BPS was diagnosed in 26 subjects (mean age 47 ± 16 years, 92% females), 58 had symptoms of IC/BPS by NIDDK criteria (mean age 40 ± 17 years, 79% females) and 48 were healthy controls (mean age 31 ± 14 years, mean age 77%). Co-morbid complaints in the IC/BPS groups included gastrointestinal symptoms suggestive of IBS and dyspepsia, sleep abnormalities with delayed onset of sleep, feeling poorly refreshed in the morning, waking up before needed, snoring, severe chronic fatigue and chronic generalized pain, migraines, and syncope. Discussion: Patients with IC/BPS had co-morbid central and autonomic nervous system disorders. Our findings mirror those of others in regard to IBS, symptoms suggestive of FM, chronic pain, and migraine. High rates of syncope and functional dyspepsia found in the IC/BPS groups merit further study to determine if IC/BPS is part of a diffuse disorder of central, autonomic, and sensory processing affecting multiple organs outside the bladder.
Chen M, Cheung FW, Chan MH, Hui PK, Ip SP, Ling YH, Che CT, Liu WK.	School of Chinese Medicine, The Chinese University of Hong Kong, Shatin, Hong Kong.	Protective roles of Cordyceps on lung fibrosis in cellular and rat models.	J Ethnopharmacol. 2012 Sep 28;143(2):448-54. doi: 10.1016/j.jep.2012.06.033	ETHNOPHARMACOLOGICAL RELEVANCE: Cordyceps sinensis is a fungus used in traditional Chinese medicine as a tonic to soothe the lung for the treatment of fatigue and respiratory diseases. Idiopathic pulmonary fibrosis is a chronic, irreversible and debilitating lung disease showing fibroblast/myofibroblast expansion and excessive deposition of extracellular matrix in the interstitium leading to breathing difficulty. Our previous observation revealed a partial relief of lung fibrosis in patients suffering from severe acute respiratory syndrome (SARS). We hypothesize that Cordyceps has beneficial effects on lung fibrosis and the objective of this study is to explore the target(s) of Cordyceps in the relief of lung fibrosis in animal and cell models and to gain insight into its underlying mechanisms. MATERIAL AND METHODS: A rat model of

				bleomycin (BLM)-induced lung fibrosis and a fibrotic cell model with transforming growth factor beta-1 induction were employed in the studies. RESULTS: Reduction of infiltration of inflammatory cells, deposition of fibroblastic loci and collagen, formation of reactive oxygen species, and production of cytokines, as well as recovery from imbalance of MMP-9/TIMP-1, were observed in fibrotic rats after treatment with Cordyceps in preventive (from the day of BLM administration) and therapeutic (from 14 days after BLM) regimens. In a fibrotic cell model with transforming growth factor beta-1 induction, the human lung epithelial A549 acquired a mesenchymal phenotype and an increase of vimentin expression with a concomitant decrease of E-cadherin. This epithelial-mesenchymal transition could be partially reverted by cordycepin, a major component of Cordyceps. CONCLUSION: The findings provide an insight into the preventive and therapeutic potentials of Cordyceps for the treatment of lung fibrosis.
Christley Y, Duffy T, Martin CR.	School of Health, Nursing and Midwifery, University of the West of Scotland, Ayr Campus, UK.	A review of the definitional criteria for chronic fatigue syndrome.	J Eval Clin Pract. 2012 Feb;18(1):25-31. doi: 10.1111/j.1365-2753.2010.01512.x.	RATIONALE, AIMS AND OBJECTIVES: The research community has for more than three decades tried to unravel the diagnostic mystery that is Chronic Fatigue Syndrome (CFS). This has resulted in considerable amounts of time and money being invested in attempts aimed at establishing the aetiology and pathogenesis of CFS. All of this investment has produced evidence of an interesting variety of endocrine, immune, infectious, muscular and neurological abnormalities in CFS; however, the cause remains elusive. The absence of a known causative agent or diagnostic test for CFS has resulted in the development of a number of CFS case definitions. As such, the main objectives of this paper are to provide a critical review of the similarities and differences between the varying approaches to CFS case definition. The conflicts and controversies that have emerged as a result of the differing definitional criterion for CFS are highlighted and the potential impact on future research is identified. METHODS, RESULTS AND CONCLUSIONS: This paper presents a critical review of the most frequently used case definitions in CFS. There are currently five case definitions of CFS; however, the most prominent and widely used of these definitions is the 1994 Centre for Disease Control and Prevention Case Definitions. However, the pre-eminence of this definition over the others has never been substantiated and it has been widely criticized for its lack of specificity. Furthermore, none of the above case definitions have produced evidence to demonstrate their accuracy or precision at defining cases of CFS. A summary description of the symptom profile included in each of the case definitions is provided. The inconsistencies that have emerged in CFS research as a consequence of differing approaches to case definition are also highlighted and discussed.

Cingöz O, Paprotka T, Delviks-Frankenberry KA, Wildt S, Hu WS, Pathak VK, Coffin JM.	Department of Molecular Biology and Microbiology, Genetics Program, Sackler School of Graduate Biomedical Sciences, Tufts University, Boston, Massachusetts, USA.	Characterization, mapping, and distribution of the two XMRV parental proviruses.	J Virol. 2012 Jan;86(1):328-38. doi: 10.1128/JVI.06022-11.	Xenotropic murine leukemia virus-related virus (XMRV) was previously reported to be associated with human prostate cancer and chronic fatigue syndrome. Our groups recently showed that XMRV was created through recombination between two endogenous murine retroviruses, PreXMRV-1 and PreXMRV-2, during the passaging of a prostate tumor xenograft in nude mice. Here, multiple approaches that led to the identification of PreXMRV-2, as well as the distribution of both parental proviruses among different mouse species, are described. The chromosomal loci of both proviruses were determined in the mouse genome, and integration site information was used to analyze the distribution of both proviruses in 48 laboratory mouse strains and 46 wild-derived strains. The strain distributions of PreXMRV-1 and PreXMRV-2 are quite different, the former being found predominantly in Asian mice and the latter in European mice, making it unlikely that the two XMRV ancestors could have recombined independently in the wild to generate an infectious virus. XMRV was not present in any of the mouse strains tested, and among the wild-derived mouse strains analyzed, not a single mouse carried both parental proviruses. Interestingly, PreXMRV-1 and PreXMRV-2 were found together in three laboratory strains, Hsd nude, NU/NU, and C57BR/cd, consistent with previous data that the recombination event that led to the generation of XMRV could have occurred only in the laboratory. The three laboratory strains carried the Xpr1(n) receptor variant nonpermissive to XMRV and xenotropic murine leukemia virus (X-MLV) infection, suggesting that the xenografted human tumor cells were required for the resulting XMRV recombinant to infect and propagate.
Clemens JQ, Elliott MN, Suttorp M, Berry SH.	Department of Urology, University of Michigan Medical Center, Ann Arbor, Michigan. Electronic address: qclemens@umich.edu.	Temporal Ordering of Interstitial Cystitis/Bladder Pain Syndrome and Non-bladder Conditions.	Urology. 2012 Dec;80(6):1227-32. doi: 10.1016/j.urology.2012.06.059.	OBJECTIVE: To examine the prevalence and timing of nonbladder conditions in a community cohort of women with symptoms of interstitial cystitis/bladder pain syndrome (IC/BPS). METHODS: As part of the Rand Interstitial Cystitis Epidemiology (RICE) study, we identified 3397 community women who met a validated case definition for IC/BPS symptoms. Each completed a survey asking if they had a physician diagnose them as having irritable bowel syndrome, fibromyalgia, chronic fatigue syndrome, migraines, panic attacks, or depression. If a positive response was received, subjects were asked to provide the age of symptom onset. All subjects were

				also asked to provide the date of IC/BPS symptom onset. RESULTS: A total of 2185 women reported a diagnosis of at least one of the nonbladder conditions. Onset of bladder symptoms was not consistently earlier or later than the onset of nonbladder symptoms. Depression tended to occur earlier (P < .05), whereas fibromyalgia generally occurred later (P < .05). Mean age of onset was lowest for migraine symptoms, depression symptoms, and panic attacks symptoms, and greatest for fibromyalgia and chronic fatigue syndrome symptoms. Mean age of irritable bowel syndrome and IC/BPS symptom onset was between these other conditions. CONCLUSION: These findings confirm the common co-occurrence of IC/BPS with chronic nonbladder conditions. In women with IC/BPS symptoms and coexistent nonbladder conditions, bladder symptoms do not uniformly predate the nonbladder symptoms. These observations suggest that phenotypic progression from isolated bladder symptoms to regional/systemic symptoms is not a predominant pattern in IC/BPS, although such a pattern may occur in a subset of individuals.
Cockshell SJ, Mathias JL.	School of Psychology, The University of Adelaide, Adelaide, SA, Australia.	Test effort in persons with Chronic Fatigue Syndrome when assessed using the Validity Indicator Profile.	J Clin Exp Neuropsychol. 2012;34(7):679-87. doi: 10.1080/13803395.2012.668176.	The current study examined the potential contribution of suboptimal effort to the cognitive deficits that are associated with Chronic Fatigue Syndrome (CFS) using the Validity Indicator Profile (VIP). Unlike most tests of effort, the VIP distinguishes between intentional and unintentional poor performance and does not assess cognitive functions that are affected by CFS, thereby reducing the risk of mistakenly attributing genuinely poor performance to reduced effort. The VIP was administered to 54 persons with CFS and 54 matched healthy community controls, and performance categorized into 1 of 4 response styles (valid: compliant; invalid: suppressed, irrelevant, inconsistent), based on the level of effort expended (high or low) and the intention to perform well or not. VIP performance was classified as valid for the majority of participants (CFS and controls), indicating high levels of effort and an intention to perform well. Three participants in the CFS group and four in the control group showed low levels of effort but an intention to do well (invalid: inconsistent). No participant performed in a manner indicative of an intent to perform poorly (invalid: suppressed, inconsistent). These findings suggest that poor effort is unlikely to contribute to cognitive test performance of persons with CFS.

Collin SM, Sterne JA, Hollingworth W, May MT, Crawley E.	School of Social and Community Medicine, University of Bristol, Bristol, UK.	Equity of access to specialist chronic fatigue syndrome (CFS/ME) services in England (2008-2010): a national survey and	BMJ Open. 2012 Aug 16;2(4). pii: e001417. doi: 10.1136/bmjopen-2012-001417. Print 2012.	OBJECTIVES: Provision of National Health Service (NHS) specialist chronic fatigue syndrome or myalgic encephalomyelitis (CFS/ME) services in England has been deemed patchy and inconsistent. Our objective was to explore variation in the provision of NHS specialist CFS/ME services and to investigate whether access is related to measures of deprivation and inequality. DESIGN: Survey of all CFS/ME clinical teams in England, plus cross-sectional data from a subset of teams. SETTING:

		cross-sectional study.		Secondary care. OUTCOME MEASURES: We used clinic activity data from CFS/ME clinical teams in England to describe provision of specialist CFS/ME services (referral, assessment and diagnosis rates per 1000 adults per year) during 2008-2011 according to Primary Care Trust (PCT) population estimates, and to investigate whether use of services was related to PCT-level measures of deprivation and inequality. We used postcode data from seven services to investigate variation in provision by deprivation. RESULTS: Clinic activity data were obtained from 93.9% (46/49) of clinical teams in England which between them received referrals from 84.9% (129/152) of PCTs. 12 PCTs, covering a population of 2.08 million adults, provided no specialist CFS/ME service. There was a six-fold variation in referral and assessment rates between services which could not be explained by PCT-level measures of deprivation and inequality. The median assessment rate in 2010 was 0.25 (IQR 0.17, 0.35) per 1000 adults per year. 91.9% (IQR 76.5%, 100.0%) of adults assessed were diagnosed with CFS/ME. Postcode data from seven clinical teams showed that assessment rates were equal across deprivation quartiles for four teams but were 40-50% lower in the most deprived compared with the most affluent areas for three teams. CONCLUSIONS: Two million adults in England do not have access to a specialist CFS/ME service. In some areas which do have a specialist service, access is inequitable. This inequity may worsen with the impending fragmentation of NHS commissioning across England.
Cook DB, Stegner AJ, Nagelkirk PR, Meyer JD, Togo F, Natelson BH.	Department of Kinesiology, University of Wisconsin - Madison, Madison, WI 53706, USA. dcook@education.wisc.edu	Responses to exercise differ for chronic fatigue syndrome patients with fibromyalgia.	Med Sci Sports Exerc. 2012 Jun;44(6):1186-93. doi: 10.1249/MSS.0b013e3182417b9a.	Chronic fatigue syndrome (CFS) and fibromyalgia (FM) are chronic multisymptom illnesses with substantial clinical and diagnostic overlap. We have previously shown that, when controlling for aerobic fitness and accounting for comorbid FM, CFS patients do not exhibit abnormal cardiorespiratory responses during maximal aerobic exercise compared with healthy controls, despite differences in pain and exertion.PURPOSE: The purpose of the present study was to examine cardiac and perceptual responses to steady-state submaximal exercise in CFS patients and healthy controls. METHODS: Twenty-one CFS patients (13 CFS with comorbid FM (CFS + FM)) and 14 controls completed 20 min of submaximal cycling exercise. Impedance cardiography was used to determine cardiac responses during exercise. Systolic blood pressure (SBP), RPE, and leg muscle pain were also measured. Data were analyzed using a doubly multivariate, repeated-measures MANOVA to model the exercise response. RESULTS: There was a significant multivariate time-by-group interaction ($P < 0.05$). The CFS + FM group exhibited an exercise response characterized by higher stroke index, ventilatory equivalents for oxygen and carbon dioxide and RPE, lower SBP, and similar HR responses compared to controls. CONCLUSIONS: The present results extend on our previous work with maximal exercise and show that CFS and CFS + FM differ in their responses to steady-state exercise. These results highlight the importance of accounting for comorbid conditions when conducting CFS research, particularly when examining psychophysiological responses to exercise.
Cool M, Bouchard	Laboratory of	No detectable XMRV	Virology. 2011 Nov	We investigated the presence of XMRV in a cohort of Quebec patients with chronic

N, Massé G, Laganière B, Dumont A, Hanna Z, Phaneuf D, Morisset R, Jolicoeur P.	Molecular Biology, Clinical Research Institute of Montreal, Montreal, Quebec, Canada H2W 1R7.	in subjects with chronic fatigue syndrome from Quebec.	10;420(1):66-72. doi: 10.1016/j.virol.2011.08.018.	fatigue syndrome (CFS). DNA was purified from activated peripheral blood mononuclear cells (PBMCs) and PCR was used to detect XMRV gag and env in 72 patients. Anti-XMRV antibodies were searched in sera of 62 patients by Western blot analysis. Attempts to detect XMRV antigens was made, using immunofluorescence with Gag anti-p30 antiserum on activated PBMC from 50 patients. Plasma viremia was measured by RT-PCR on 9 subjects. Finally, detection of infectious virus in 113 CFS subjects was made by co-culture of PHA+IL-2 activated PBMC with human LNCaP carcinoma cells, and by infecting the same susceptible cells with plasma, using a reverse transcriptase (RT) assay as a readout in both experiments. No detection of XMRV footprints nor infectious virus was detected with any of the approaches, in any of the tested individuals.
Cordero MD, Cano-García FJ, Alcocer-Gómez E, De Miguel M, Sánchez-Alcázar JA.	Centro Andaluz de Biología del Desarrollo, Universidad Pablo de Olavide-CSIC-Junta de Andalucía and Centro de Investigación Biomédica en Red de Enfermedades Raras, ISCIII, Sevilla, Spain. mdcormor@upo.es	Oxidative stress correlates with headache symptoms in fibromyalgia: coenzyme Q_{10} effect on clinical improvement.	PLoS One. 2012;7(4):e35677. doi: 10.1371/journal.pone.0035677.	BACKGROUND: Fibromyalgia (FM) is a chronic pain syndrome with unknown etiology and a wide spectrum of symptoms such as allodynia, debilitating fatigue, joint stiffness and migraine. Recent studies have shown some evidences demonstrating that oxidative stress is associated to clinical symptoms in FM of fibromyalgia. We examined oxidative stress and bioenergetic status in blood mononuclear cells (BMCs) and its association to headache symptoms in FM patients. The effects of oral coenzyme Q(10) (CoQ(10)) supplementation on biochemical markers and clinical improvement were also evaluated. METHODS: We studied 20 FM patients and 15 healthy controls. Clinical parameters were evaluated using the Fibromyalgia Impact Questionnaire (FIQ), visual analogues scales (VAS), and the Headache Impact Test (HIT-6). Oxidative stress was determined by measuring CoQ(10), catalase and lipid peroxidation (LPO) levels in BMCs. Bioenergetic status was assessed by measuring ATP levels in BMCs. RESULTS: We found decreased CoQ(10), catalase and ATP levels in BMCs from FM patients as compared to normal control ($P < 0.05$ and $P < 0.001$, respectively) We also found increased level of LPO in BMCs from FM patients as compared to normal control ($P < 0.001$). Significant negative correlations between CoQ(10) or catalase levels in BMCs and headache parameters were observed ($r = -0.59$, $P < 0.05$; $r = -0.68$, $P < 0.05$, respectively). Furthermore, LPO levels showed a significant positive correlation with HIT-6 ($r = 0.33$, $P<0.05$). Oral CoQ(10) supplementation restored biochemical parameters and induced a significant improvement in clinical and headache symptoms ($P < 0.001$). DISCUSSION: The results of this study suggest a role for mitochondrial dysfunction and oxidative stress in the headache symptoms associated with FM. CoQ10 supplementation should be examined in a larger placebo controlled trial as a possible treatment in FM.
Côté M, Zheng YM, Liu SL.	Department of Microbiology and Immunology, McGill University, Montreal, Quebec, Canada.	Membrane fusion and cell entry of XMRV are pH-independent and modulated by the	PLoS One. 2012;7(3):e33734. doi: 10.1371/journal.pone.0033734.	Xenotropic murine leukemia virus-related virus (XMRV) is a gammaretrovirus that was originally identified from human prostate cancer patients and subsequently linked to chronic fatigue syndrome. Recent studies showed that XMRV is a recombinant mouse retrovirus; hence, its association with human diseases has become questionable. Here, we demonstrated that XMRV envelope (Env)-mediated pseudoviral infection is

		envelope glycoprotein's cytoplasmic tail.		not blocked by lysosomotropic agents and cellular protease inhibitors, suggesting that XMRV entry is not pH-dependent. The full length XMRV Env was unable to induce syncytia formation and cell-cell fusion, even in cells overexpressing the viral receptor, XPR1. However, truncation of the C-terminal 21 or 33 amino acid residues in the cytoplasmic tail (CT) of XMRV Env induced substantial membrane fusion, not only in the permissive 293 cells but also in the nonpermissive CHO cells that lack a functional XPR1 receptor. The increased fusion activities of these truncations correlated with their enhanced SU shedding into culture media, suggesting conformational changes in the ectodomain of XMRV Env. Noticeably, further truncation of the CT of XMRV Env proximal to the membrane-spanning domain severely impaired the Env fusogenicity, as well as dramatically decreased the Env incorporations into MoMLV oncoretroviral and HIV-1 lentiviral vectors resulting in greatly reduced viral transductions. Collectively, our studies reveal that XMRV entry does not require a low pH or low pH-dependent host proteases, and that the cytoplasmic tail of XMRV Env critically modulates membrane fusion and cell entry. Our data also imply that additional cellular factors besides XPR1 are likely to be involved in XMRV entry.
Cottle LE, Mekonnen E, Beadsworth MB, Miller AR, Beeching NJ.	Tropical and Infectious Disease Unit, Royal Liverpool University Hospital, Prescot Street, Liverpool L7 8XP, UK.	Lyme disease in a British referral clinic.	QJM. 2012 Jun;105(6):537-43. doi: 10.1093/qjmed/hcs003.	BACKGROUND: Concerns about over-diagnosis and inappropriate management of Lyme disease (LD) are well documented in North America and supported by clinical data. There are few parallel data on the situation in the UK. AIM: To describe the patterns of referral, investigation, diagnosis and treatment of patients with suspected LD referred to an infectious disease unit in Liverpool, UK. Previous management by National Health Service (NHS) and non-NHS practitioners was reviewed. DESIGN: Descriptive study conducted by retrospective casenotes review. METHODS: Retrospective casenotes review of adults referred with possible LD to an infectious disease unit in Liverpool, UK, over 5 years (2006-2010). RESULTS: Of 115 patients, 27 (23%) were diagnosed with LD, 38 (33%) with chronic fatigue syndrome (CFS) and 13 (11%) with other medical conditions. No specific diagnosis could be made in 38 (33%). At least 53 unnecessary antibiotic courses had been given by non-NHS practitioners; 21 unnecessary courses had been prescribed by NHS practitioners. Among 38 patients, 17 (45%) with CFS had been misdiagnosed as having LD by non-NHS practitioners. CONCLUSION: A minority of referred patients had LD, while a third had CFS. LD is over-diagnosed by non-specialists, reflecting the complexities of clinical and/or laboratory diagnosis. Patients with CFS were susceptible to misdiagnosis in non-NHS settings, reinforcing concerns about missed opportunities for appropriate treatment for this group and about the use of inappropriate diagnostic modalities and anti-microbials in non-NHS settings.
Crawford BK, Piault EC, Lai C, Bennett RM.	Mapi Values, Tokyo, Japan. bruce.crawford@mapivalues.com	Assessing fibromyalgia-related fatigue: content validity and	Clin Exp Rheumatol. 2011 Nov-Dec;29(6 Suppl 69):S34-43.	OBJECTIVES: To document 1) the content validity and 2) measure improvements in fatigue, using the Fatigue Visual Analogue Scale (VAS) assessment tool in patients with fibromyalgia. METHODS: The relevance and comprehensiveness of the Fatigue VAS were tested through a qualitative analysis of 20 subjects' verbatim transcripts from

		psychometric performance of the Fatigue Visual Analog Scale in adult patients with fibromyalgia.		semi-structured qualitative interviews. Data from two randomised, controller trials in fibromyalgia (n=1121) were used to conduct correlation analyses with the Fatigue and Tiredness items from the Fibromyalgia Impact Questionnaire (FIQ) and the Short Form-36 Vitality scale. Known-groups and cross classification analyses were conducted to demonstrate the ability to measure improvement in fatigue using the Fatigue VAS. RESULTS: All subjects spontaneously reported that fatigue was an important symptom to capture in fibromyalgia. The Fatigue VAS was well understood by most subjects (n=18/20). High correlations (Pearson r>0.75) and good agreement (k>0.66) were found between the Fatigue VAS and the FIQ tiredness items no. 16 and 17 and SF-36™ Vitality scale. In both clinical trials there was a substantial separation of approximately 20 points on the mean change in the Fatigue VAS score between responders (>30% improvement in pain VAS) and non-responders. CONCLUSIONS: Previous studies have confirmed that fatigue is a major component of the fibromyalgia experience. This current study reports that fibromyalgia patients spontaneously rated fatigue as a highly significant feature of their illness, and supports the use of the Fatigue VAS as a valid questionnaire in fibromyalgia clinical trials.
Crawford J.	[No address quoted]	Internet-based CBT for adolescents with chronic fatigue syndrome.	Lancet. 2012 Aug 11;380(9841):561-2; author reply 562. doi: 10.1016/S0140-6736(12)61325-7.	Comment on Lancet. 2012 Apr 14;379(9824):1412-8.
Crawley EM, Emond AM, Sterne JA.	Centre for Child and Adolescent Health, School of Social and Community Medicine, Bristol, UK.	Unidentified Chronic Fatigue Syndrome/myalgic encephalomyelitis (CFS/ME) is a major cause of school absence: surveillance outcomes from school-based clinics.	BMJ Open. 2011 Dec 12;1(2):e000252. doi: 10.1136/bmjopen-2011-000252. Print 2011.	Objective To investigate the feasibility of conducting clinics for chronic fatigue syndrome/myalgic encephalomyelitis (CFS/ME) in schools. Design School-based clinical project. Participants Children aged 11-16 years were enrolled in three state secondary schools in England. Main outcome measures Number of children newly diagnosed as having CFS/ME. Methods Attendance officers identified children missing ≥20% of school in a 6-week term without a known cause, excluding those with a single episode off school, a known medical illness explaining the absence or known to be truanting. Children with fatigue were referred to a specialist CFS/ME service for further assessment. The authors compared children with CFS/ME identified through school-based clinics with those referred via health services. Outcomes of CFS/ME were evaluated at 6 weeks and 6 months. Results 461 of the 2855 enrolled children had missed ≥20% school over a 6-week period. In 315, of whom three had CFS/ME, the reason for absence was known. 112 of the 146 children with unexplained absence attended clinical review at school; two had been previously diagnosed as having CFS/ME and 42 were referred on to a specialist clinic, where 23 were newly diagnosed as having CFS/ME. Therefore, 28 of the 2855 (1.0%) children had CFS/ME. Children with CFS/ME identified through surveillance had been ill for an amount of time comparable to those referred via health services but had less fatigue (mean difference

				4.4, 95% CI 2.2 to 6.6), less disability (mean difference -5.7, 95% CI -7.9 to -3.5) and fewer symptoms (mean difference 1.86, 95% CI 0.8 to 2.93). Of 19 children followed up, six had fully recovered at 6 weeks and a further six at 6 months. Conclusions Chronic fatigue is an important cause of unexplained absence from school. Children diagnosed through school-based clinics are less severely affected than those referred to specialist services and appear to make rapid progress when they access treatment.

Creed FH, Tomenson B, Chew-Graham C, Macfarlane GJ, Davies I, Jackson J, Littlewood A, McBeth J.	School of Community Based Medicine, University of Manchester, Jean Macfarlane Building (3rd floor), Oxford Road, Manchester, M13 9PL, UK, francis.creed@manchester.ac.uk.	Multiple Somatic Symptoms Predict Impaired Health Status in Functional Somatic Syndromes.	Int J Behav Med. 2012 Aug 30.	BACKGROUND: The relationship between functional somatic syndromes and multiple somatic symptoms is unclear. PURPOSE: We assessed whether the number of somatic symptoms is a predictor of health status in three functional somatic syndromes (FSS). METHODS: In a population-based study of 990 UK adults we assessed chronic widespread pain (CWP), chronic fatigue (CF) and irritable bowel syndrome (IBS) by questionnaire and medical record data. We assessed health status (Short Form 12 and EQ-5D), number of somatic symptoms (Somatic Symptom Inventory) and anxiety/depression (Hospital Anxiety and Depression Scale) both at baseline and at follow-up 1 year later. RESULTS: The proportion of people with an FSS who also have multiple somatic symptoms (52-55 %) was similar in the three functional syndromes. The presence of multiple somatic symptoms was associated with more impaired health status both at baseline and at follow-up. This finding was not explained by severity of FSS. In the absence of multiple somatic symptoms, the health status of the FSS was fair or good. In multiple regression analysis, the number of somatic symptoms, the presence of a functional syndrome (CWP or CF) and anxiety/depression were predictors of EQ-5D thermometer at follow-up after adjustment for confounders. CONCLUSIONS: Multiple somatic symptoms in people with an FSS are associated with impaired health status and this cannot be explained by more severe functional syndrome or the presence of anxiety and depression.
Dansie EJ, Furberg H, Afari N, Buchwald D, Edwards K, Goldberg J, Schur E, Sullivan PF.	Center for Clinical and Epidemiological Research, University of Washington, Seattle, WA 98101, USA. Edansie@uw.edu	Conditions comorbid with chronic fatigue in a population-based sample.	Psychosomatics. 2012 Jan-Feb;53(1):44-50. doi: 10.1016/j.psym.2011.04.001.	BACKGROUND: Chronic fatigue syndrome (CFS) has been found to be comorbid with various medical conditions in clinical samples, but little research has investigated CFS comorbidity in population-based samples. OBJECTIVE: This study investigated conditions concurrent with a CFS-like illness among twins in the population-based Mid-Atlantic Twin Registry (MATR), including chronic widespread pain (CWP), irritable bowel syndrome (IBS), and major depressive disorder (MDD). METHOD: A survey was

				mailed to participants in the MATR in 1999. Generalized estimating equations were used to estimate odds ratios to assess associations between CFS-like illness and each comorbid condition. RESULTS: A total of 4590 completed surveys were collected. Most participants were female (86.3%); mean age was 44.7 years. Among participants with a CFS-like illness, lifetime prevalences of CWP, IBS, and MDD were 41%, 16%, and 57% respectively. Participants reporting at least one of the three comorbid conditions were about 14 times more likely to have CFS-like illness than those without CWP, IBS, or MDD (95% confidence interval 8.1%-21.3%). Only MDD showed a temporal pattern of presentation during the same year as diagnosis of CFS-like illness. Age, gender, body mass index, age at illness onset, exercise level, self-reported health status, fatigue symptoms, and personality measures did not differ between those reporting CFS-like illness with and without comorbidity. CONCLUSION: These results support findings in clinically based samples that CFS-like illness is frequently cormorbid with CWP, IBS, and/or MDD. We found no evidence that CFS-like illnesses with comorbidities are clinically distinct from those without comorbidities.
Dansie EJ, Heppner P, Furberg H, Goldberg J, Buchwald D, Afari N.	Department of Psychiatry and Behavioral Sciences, University of Washington, Seattle, WA, USA.	The comorbidity of self-reported chronic fatigue syndrome, post-traumatic stress disorder, and traumatic symptoms.	Psychosomatics. 2012 May;53(3):250-7. doi: 10.1016/j.psym.2011.08.007.	BACKGROUND: Data from primary care and community samples suggest higher rates of post-traumatic stress disorder (PTSD) among individuals with chronic fatigue syndrome (CFS). OBJECTIVE: This study investigated the co-occurrence of CFS, PTSD, and trauma symptoms and assessed the contribution of familial factors to the association of CFS with lifetime PTSD and current traumatic symptoms. METHOD: Data on lifetime CFS and PTSD, as measured by self-report of a doctor's diagnosis of the disorder, and standardized questionnaire data on traumatic symptoms, using the Impact of Events Scale (IES), were obtained from 8544 female and male twins from the community-based University of Washington Twin Registry. RESULTS: Lifetime prevalence of CFS was 2% and lifetime prevalence of PTSD was 4%. Participants who reported a history of PTSD were over eight times more likely to report a history of CFS. Participants with scores ≥ 26 on the IES were over four times more likely to report CFS than those who had scores ≤ 25. These associations were attenuated but remained significant after adjusting for familial factors through within-twin pair analyses. CONCLUSION: These results support similar findings that a lifetime diagnosis of CFS is strongly associated with both lifetime PTSD and current traumatic symptoms, although familial factors, such as shared genetic and environmental contributions, played a limited role in the relationship between CFS, PTSD, and traumatic symptoms. These findings suggest that future research should investigate both the familial and the unique environmental factors that may give rise to both CFS and PTSD.
de Carvalho Leite JC, de L Drachler M, Killett A, Kale S, Nacul L, McArthur M, Hong CS,	School of Allied Health Professions, University of East Anglia, Norwich, England, United Kingdom, NR4	Social support needs for equity in health and social care: a thematic analysis of experiences of	Int J Equity Health. 2011 Nov 2;10(1):46. doi: 10.1186/1475-9276-10-46.	BACKGROUND: Needs-based resource allocation is fundamental to equitable care provision, which can meet the often-complex, fluctuating needs of people with Chronic Fatigue Syndrome/Myalgic Encephalomyelitis (CFS/ME). This has posed challenges both for those providing and those seeking support providers, in building shared understanding of the condition and of actions to address it. This qualitative

O'Driscoll L, Pheby D, Campion P, Lacerda E, Poland F.	7TJ, UK. f.poland@uea.ac.uk.	people with chronic fatigue syndrome/myalgic encephalomyelitis.		study reports on needs for equity in health and social care expressed by adults living with CFS/ME. METHODS: The participants were 35 adults with CFS/ME in England, purposively selected to provide variation in clinical presentations, social backgrounds and illness experiences. Accounts of experienced needs and needs-related encounters with health and social services were obtained through a focus group (n = 6) and semi-structured interviews (n = 35). These were transcribed and needs related topics identified through data-led thematic analysis. FINDINGS: Participants emphasised needs for personalised, timely and sustained support to alleviate CFS/ME impacts and regain life control, in three thematic areas: (1) Illness symptoms, functional limitations and illness management; (2) practical support and social care; (3) financial support. Access of people with CFS/ME to support from health and social services was seen to be constrained by barriers stemming from social, cultural, organisational and professional norms and practices, further heightened for disadvantaged groups including some ethnic minorities. These reduced opportunities for their illness to be explained or associated functional limitations and social disadvantages to be addressed through social support. Participants sought more understanding of bio-psycho-social aspects of CFS/ME, of felt needs of people with CFS/ME and of human rights and disability rights, for providing person-centred, equitable care. CONCLUSIONS: Changes in attitudes of health practitioners, policy makers and general public and more flexibly organised health and social care provision are needed to address equity issues in support needs expressed by people with CFS/ME, to be underpinned by research-based knowledge and communication, for public and professional education. Policy development should include shared decision-making and coordinated action across organizations working for people with CFS/ME, human rights and disadvantaged groups. Experiences of people with CFS/ME can usefully inform an understanding of equity in their health and social care.
de Souza PA, Matheus SM, Castan EP, Campos DH, Cicogna AC, Carvalho RF, Dal-Pai-Silva M.	Department of Morphology, Institute of Biosciences, UNESP, Botucatu, São Paulo, Brazil. pats_souza@yahoo.com.br	Morphological aspects of neuromuscular junctions and gene expression of nicotinic acetylcholine receptors (nAChRs) in skeletal muscle of rats with heart failure.	J Mol Histol. 2011 Dec;42(6):557-65. doi: 10.1007/s10735-011-9354-2.	HF is syndrome initiated by a reduction in cardiac function and it is characterized by the activation of compensatory mechanisms. Muscular fatigue and dyspnoea are the more common symptoms in HF; these may be due in part to specific skeletal muscle myopathy characterized by reduced oxidative capacity, a shift from slow fatigue resistant type I to fast less fatigue resistant type II fibers and downregulation of myogenic regulatory factors (MRFs) gene expression that can regulate gene expression of nicotinic acetylcholine receptors (nAChRs). In chronic heart failure, skeletal muscle phenotypic changes could influence the maintenance of the neuromuscular junction morphology and nAChRs gene expression during this syndrome. Two groups of rats were studied: control (CT) and Heart Failure (HF), induced by a single intraperitoneal injection of monocrotaline (MCT). At the end of the experiment, HF was evaluated by clinical signs and animals were sacrificed. Soleus (SOL) muscles were removed and processed for morphological, morphometric and molecular NMJ analyses. Our major finding was an up-regulation in the gene

				expression of the alpha1 and epsilon subunits of nAChR and a spot pattern of nAChR in SOL skeletal muscle in this acute monocrotaline induced HF. Our results suggest a remodeling of nAChR alpha1 and epsilon subunit during heart failure and may provide valuable information for understanding the skeletal muscle myopathy that occurs during this syndrome.
de Tommaso M, Federici A, Serpino C, Vecchio E, Franco G, Sardaro M, Delussi M, Livrea P.	Neurophysiopathology of Pain Unit, Neurological and Psychiatric Sciences Department, Medical Faculty, Policlinico General Hospital, Aldo Moro University, Neurological Building, Piazza Giulio Cesare 11, 70124, Bari, Italy. m.detommaso@neurol.uniba.it	Clinical features of headache patients with fibromyalgia comorbidity.	J Headache Pain. 2011 Dec;12(6):629-38. doi: 10.1007/s10194-011-0377-6.	Our previous study assessed the prevalence of fibromyalgia (FM) syndrome in migraine and tension-type headache. We aimed to update our previous results, considering a larger cohort of primary headache patients who came for the first time at our tertiary headache ambulatory. A consecutive sample of 1,123 patients was screened. Frequency of FM in the main groups and types of primary headaches; discriminating factor for FM comorbidity derived from headache frequency and duration, age, anxiety, depression, headache disability, allodynia, pericranial tenderness, fatigue, quality of life and sleep, and probability of FM membership in groups; and types of primary headaches were assessed. FM was present in 174 among a total of 889 included patients. It prevailed in the tension-type headache main group (35%, $p < 0.0001$) and chronic tension-type headache subtype (44.3%, $p < 0.0001$). Headache frequency, anxiety, pericranial tenderness, poor sleep quality, and physical disability were the best discriminating variables for FM comorbidity, with 81.2% sensitivity. Patients presenting with chronic migraine and chronic tension-type headache had a higher probability of sharing the FM profile (Bonferroni test, $p < 0.01$). A phenotypic profile where headache frequency concurs with anxiety, sleep disturbance, and pericranial tenderness should be individuated to detect the development of diffuse pain in headache patients.
Deák M, Szvetnik A, Balog A, Sohár N, Varga R, Pokorny G, Tóth G, Kiss M, Kovács L.	Department of Rheumatology, Faculty of Medicine, Albert Szent-Györgyi Health Centre, University of Szeged, Szeged, Hungary.	Neuroimmune Interactions in Sjögren's Syndrome: Relationship of Exocrine Gland Dysfunction with Autoantibodies to Muscarinic Acetylcholine Receptor-3 and Mental Health Status Parameters.	Neuroimmunomodulation. 2012 Dec 12;20(2):79-86.	Objectives: Antimuscarinic acetylcholine receptor-3 (m3AChR) autoantibodies have been described in primary Sjögren's syndrome (pSS). The aim of this study was to compare various methods for their detection and to assess the contributions of anti-m3AChR and other immunological and psychosocial factors to the pathomechanism of secondary SS (sSS). Methods: Sixty-five rheumatoid arthritis (RA) patients, 103 systemic lupus erythematosus (SLE) patients, 76 pSS patients and 50 controls were compared. Three immunodominant epitopes of m3AChR were synthesized and used in ELISA. Two extracellular epitopes were also prepared in fusion with glutathione-S-transferase and one in conjugation with bovine serum albumin. Mental health status was assessed with the 36-item Short-Form Health Survey and Functional Assessment of Chronic Illness Therapy fatigue scale. Correlations were evaluated between glandular function and anti-m3AChR positivities and specificities, features of SLE and RA, and mental health parameters. Results: Fourteen RA and 27 SLE patients had sSS. The autoantibody levels to all epitopes of m3AChR were significantly higher in pSS and SLE patients than in the controls. The fusion protein forms discriminated RA from pSS and SLE; furthermore, the YNIP fusion protein also distinguished pSS from SLE. The prevalence and the mean levels of all autoantibodies did not differ statistically

				between sicca and non-sicca SLE or RA patients. Glandular dysfunction correlated with higher age in SLE and RA and an impaired health-related quality of life in SLE. Conclusions: The second and third extracellular loops of m3AChR are antigenic in pSS. Immunoassays with antigens as fusion peptides demonstrate the best performance. Sicca SLE patients have worse mental health status. Anti-m3AChR antibodies represent a peculiar example of neuroimmune interactions.
Dean ME, Karsandas R, Bland JM, Gooch D, Macpherson H.	Dept, of Health Sciences, University of York, York YO10 5DD, UK. hugh.macpherson@york.ac.uk.	Homeopathy for mental fatigue: lessons from a randomized, triple blind, placebo-controlled cross-over clinical trial.	BMC Complement Altern Med. 2012 Oct 1;12(1):167. doi: 10.1186/1472-6882-12-167.	ABSTRACT:BACKGROUND: Difficulty in controlling attention can lead to mental fatigue in the healthy population. We identified one trial reporting a benefit in patients' attention using a homeopathic formula preparation. One component of the preparation was potassium phosphate, widely available off the shelf as Kali phos 6x for cognitive problems. The aim of this exploratory trial was to assess the effectiveness of Kali phos 6x for attention problems associated with mental fatigue. METHODS: We recruited student and staff volunteers (University of York) with self-reported mental fatigue, excluding any using homeopathy or prescribed stimulants, or with a diagnosis of chronic fatigue syndrome. In a triple blind, cross-over, placebo-controlled clinical trial, 86 volunteers were randomized to receive Kali phos 6x or identical placebo 10 minutes before taking a psychological test of attention (Stroop Colour-Word Test). One week later they were crossed over and took the other preparation before repeating the test. RESULTS: We found no evidence of a treatment effect in a comparison of Kali phos 6x with placebo (Kali phos minus placebo = -1.1 (95% CI -3.0 to 0.9, P = 0.3) Stroop score units, Cohen effect size = -0.17) even when allowing for a weak period effect with accuracy scores in the second period being higher than those in the first (P = 0.05). We observed a ceiling effect in the Stroop test which undermined our ability to interpret this result. CONCLUSIONS: Kali phos 6x was not found to be effective in reducing mental fatigue. A ceiling effect in our primary outcome measure meant that we could not rule out a type II error. Thorough piloting of an adequate outcome measure could have led to an unequivocal result. CURRENT CONTROLLED TRIALS: ISRCTN16521161.
Del Prete GQ, Kearney MF, Spindler J, Wiegand A, Chertova E, Roser JD, Estes JD, Hao XP, Trubey CM, Lara A, Lee K, Chaipan C, Bess JW Jr, Nagashima K, Keele BF, Macallister R,	AIDS and Cancer Virus Program, National Cancer Institute, Frederick, Maryland, USA.	Restricted replication of xenotropic murine leukemia virus-related virus in pigtailed macaques.	J Virol. 2012 Mar;86(6):3152-66. doi: 10.1128/JVI.06886-11.	Although xenotropic murine leukemia virus-related virus (XMRV) has been previously linked to prostate cancer and myalgic encephalomyelitis/chronic fatigue syndrome, recent data indicate that results interpreted as evidence of human XMRV infection reflect laboratory contamination rather than authentic in vivo infection. Nevertheless, XMRV is a retrovirus of undefined pathogenic potential that is able to replicate in human cells. Here we describe a comprehensive analysis of two male pigtailed macaques (Macaca nemestrina) experimentally infected with XMRV. Following intravenous inoculation with >10(10) RNA copy equivalents of XMRV, viral replication was limited and transient, peaking at ≤2,200 viral RNA (vRNA) copies/ml plasma and becoming undetectable by 4 weeks postinfection, though viral DNA (vDNA) in peripheral blood mononuclear cells remained detectable through 119 days of follow-up. Similarly, vRNA was not detectable in lymph nodes by in situ hybridization despite

Smedley J, Pathak VK, Kewalramani VN, Coffin JM, Lifson JD.				detectable vDNA. Sequencing of cell-associated vDNA revealed extensive G-to-A hypermutation, suggestive of APOBEC-mediated viral restriction. Consistent with limited viral replication, we found transient upregulation of type I interferon responses that returned to baseline by 2 weeks postinfection, no detectable cellular immune responses, and limited or no spread to prostate tissue. Antibody responses, including neutralizing antibodies, however, were detectable by 2 weeks postinfection and maintained throughout the study. Both animals were healthy for the duration of follow-up. These findings indicate that XMRV replication and spread were limited in pigtailed macaques, predominantly by APOBEC-mediated hypermutation. Given that human APOBEC proteins restrict XMRV infection in vitro, human XMRV infection, if it occurred, would be expected to be characterized by similarly limited viral replication and spread.
Dell'Osso L, Carmassi C, Consoli G, Conversano C, Ramacciotti CE, Musetti L, Massimetti E, Pergentini I, Corsi M, Ciapparelli A, Bazzichi L.	Department of Psychiatry, Neurobiology, Pharmacology and Biotecnology, University of Pisa, Pisa, Italy.	Lifetime post-traumatic stress symptoms are related to the health-related quality of life and severity of pain/fatigue in patients with fibromyalgia.	Clin Exp Rheumatol. 2011 Nov-Dec;29(6 Suppl 69):S73-8.	OBJECTIVES: The aim of the present study was to investigate the impact of lifetime potentially traumatic events, including losses, and of post-traumatic stress symptoms on the severity of illness and health-related quality of life in patients with fibromyalgia (FM). METHODS: Seventy patients with FM, diagnosed according to the American College of Rheumatology criteria, were consecutively enrolled at the Unit of Rheumatology of the University of Pisa, Italy. Assessments included: SCID-I/P; the Fibromyalgia Impact Questionnaire (FIQ) and the Medical Outcomes Study Short Form-36 Health Survey (MOS SF-36), for the severity of pain; the Health-Related Quality of Life (HRQoL); the Trauma and Loss Spectrum Self-Report (TALS-SR) life-time version. RESULTS: The FIQ total score was related to the number of loss events (Domain I) and to symptoms of grief reactions (Domain II) and re-experiencing (Domain V) of the TALS-SR. The 'VAS fatigue' scores (FIQ) were significantly related to the TALS-SR symptoms of grief reactions (Domain II) and re-experiencing (Domain V). The Mental Component Summary and Bodily Pain scores of the MOS SF-36 were significantly related to all TALS-SR domains, the latter with the exception of the VIII (Arousal). CONCLUSIONS: Our results corroborate the presence of a relationship between the lifetime exposure to potentially traumatic events, in particular loss events, and lifetime post-traumatic stress symptoms and the severity of illness and HRQoL in patients with FM.
Delviks-Frankenberry K, Cingöz O, Coffin JM, Pathak VK.	Viral Mutation Section, NCI, HIV DRP, Frederick National Laboratory for Cancer Research, Frederick, MD, United States.	Recombinant origin, contamination, and de-discovery of XMRV.	Curr Opin Virol. 2012 Aug;2(4):499-507. doi: 10.1016/j.coviro.2012.06.009	The discovery and de-discovery of the xenotropic murine leukemia virus-related virus (XMRV) has been a tumultuous roller-coaster ride for scientists and patients. The initial associations of XMRV with chronic fatigue syndrome and prostate cancer, while providing much hope and optimism, have now been discredited and/or retracted following overwhelming evidence that (1) numerous patient cohorts from around the world are XMRV-negative, (2) the initial reports of XMRV-positive patients were due to contamination with mouse DNA, XMRV plasmid DNA, or virus from the 22Rv1 cell line and (3) XMRV is a laboratory-derived virus generated in the mid 1990s through recombination during passage of a prostate tumor xenograft in immuno-

				compromised mice. While these developments are disappointing to scientists and patients, they provide a valuable road map of potential pitfalls to the would-be microbe hunters.
Devasahayam A, Lawn T, Murphy M, White PD.	NHS Greater Glasgow and Clyde, Yorkhill Hospital , Glasgow , UK.	Alternative diagnoses to chronic fatigue syndrome in referrals to a specialist service: service evaluation survey.	JRSM Short Rep. 2012 Jan;3(1):4. doi: 10.1258/shorts.2011.011127.	OBJECTIVE: To assess the accuracy of diagnoses made by referrers to a chronic fatigue syndrome (CFS) service. DESIGN: Retrospective service evaluation surveys of both rejected referral letters and medical case-notes after full clinical assessment. SETTING: A specialist CFS clinic in London, UK. PARTICIPANTS: In the first survey, we assessed rejected referral letters between March 2007 and September 2008. In the second survey, we ascertained the primary diagnosis made in case-notes of 250 consecutive new patients assessed between April 2007 and November 2008. MAIN OUTCOME MEASURES: Reasons for rejection of referrals and primary diagnosis in those assessed. RESULTS: In the first survey, 154 out of 418 referrals (37%) were rejected. Of these, 77 out of the available 127 referrals (61%) had a likely alternative diagnosis. In the second survey of clinically assessed patients, 107 (43%) had alternative medical/psychiatric diagnoses, while 137 out of 250 (54%) patients received a diagnosis of CFS. The commonest alternative medical diagnoses of those assessed were sleep disorders and the commonest alternative psychiatric diagnosis was depressive illness. Altogether 184 of 377 (49%) patients had alternative diagnoses to CFS. CONCLUSIONS: Half of all the referred patients to a specialist CFS clinic had alternative medical and psychiatric diagnoses. Specialist medical assessment for patients with unexplained, disabling, chronic fatigue needs to incorporate both medical and psychiatric assessments.
Dodd RY, Hackett J Jr, Linnen JM, Dorsey K, Wu Y, Zou S, Qiu X, Swanson P, Schochetman G, Gao K, Carrick JM, Krysztof DE, Stramer SL.	American Red Cross Holland Laboratory, Rockville, Maryland 20855, USA. dodd@usa.redcross.org	Xenotropic murine leukemia virus-related virus does not pose a risk to blood recipient safety.	Transfusion. 2012 Feb;52(2):298-306. doi: 10.1111/j.1537-2995.2011.03450.x.	BACKGROUND: When xenotropic murine leukemia virus-related virus (XMRV) was first reported in association with chronic fatigue syndrome, it was suggested that it might offer a risk to blood safety. Thus, the prevalence of the virus among blood donors and, if present, its transmissibility by transfusion need to be defined. STUDY DESIGN AND METHODS: Two populations of routine blood donor samples (1435 and 13,399) were obtained for prevalence evaluations; samples from a linked donor-recipient repository were also evaluated. Samples were tested for the presence of antibodies to XMRV-related recombinant antigens and/or for XMRV RNA, using validated, high-throughput systems. RESULTS: The presence of antibodies to XMRV could not be confirmed among a total of 17,249 blood donors or recipients (0%; 95% confidence interval [CI], 0%-0.017%); 1763 tested samples were nonreactive for XMRV RNA (0%; 95% CI, 0%-0.17%). Evidence of infection was absent from 109 recipients and 830 evaluable blood samples tested after transfusion of a total of 3741 blood components. CONCLUSIONS: XMRV and related murine leukemia virus (MLV) markers are not present among a large population of blood donors and evidence of transfusion transmission could not be detected. Thus, these viruses do not currently pose a threat to blood recipient safety and further actions relating to XMRV and MLV are not justified.

Dörr J, Ohlraun S, Skarabis H, Paul F.	NeuroCure Clinical Research Center, Charité - Universitätsmedizin Berlin, Berlin, Germany. jan-markus.doerr@charite.de	Efficacy of vitamin D supplementation in multiple sclerosis (EVIDIMS Trial): study protocol for a randomized controlled trial.	Trials. 2012 Feb 8;13:15. doi: 10.1186/1745-6215-13-15.	BACKGROUND: Multiple sclerosis is the most common chronic inflammatory disease of the central nervous system in young adults. Despite the fact that numerous lines of evidence link both the risk of disease development and the disease course to the serum level of 25-hydroxyvitamin D it still remains elusive whether multiple sclerosis patients benefit from boosting the serum level of 25-hydroxyvitamin D, mainly because interventional clinical trials that directly address the therapeutic effects of vitamin D in multiple sclerosis are sparse. We here present the protocol of an interventional clinical phase II study to test the hypothesis, that high-dose vitamin D supplementation of multiple sclerosis patients is safe and superior to low-dose supplementation with respect to beneficial therapeutic effects. METHODS/DESIGN: The EVIDIMS trial is a German multi-center, stratified, randomized, controlled and double-blind clinical phase II pilot study. Eighty patients with the diagnosis of definite multiple sclerosis or clinically isolated syndrome who are on a stable immunomodulatory treatment with interferon-β1b will be randomized to additionally receive either high-dose (average daily dose 10.200 IU) or low-dose (average daily dose 200 IU) cholecalciferol for a total period of 18 months. The primary outcome measure is the number of new lesions detected on T2-weighted cranial MRI at 3 tesla. Secondary endpoints include additional magnetic resonance imaging and optical coherence tomography parameters for neuroinflammation and -degeneration, clinical parameters for disease activity, as well as cognition, fatigue, depression, and quality of life. Safety and tolerability of high-dose vitamin D supplementation are further outcome parameters. DISCUSSION: In light of the discrepancy between existing epidemiological and preclinical data on the one hand and available clinical data on the other the EVIDIMS trial will substantially contribute to the evaluation of the efficacy of high-dose vitamin D supplementation in MS patients. The study design presented here fulfills the criteria of a high-quality clinical phase II trial in MS. TRIAL REGISTRATION: ClinicalTrials.gov Identifier: NCT01440062.

Erdur FM, Soyoral YU, Emre H, Begenik H, Canbaz ET, Erkoc R.	Yuzuncu Yil University, Medical Faculty, Department of Internal Medicine, Van, Turkey. drfme@yahoo.com	Fenofibrate-induced rhabdomyolysis in a patient with chronic renal failure due to nephrotic syndrome: a rare case report.	Clin Biochem. 2012 Jan;45(1-2):162-4. doi: 10.1016/j.clinbiochem.2011.09.025.	OBJECTIVES: Fenofibrate is a fibric acid derivative that is used alone or combination with statins in the treatment of hyperlipidemia. These drugs have potential risks, including rhabdomyolysis and acute renal failure. Despite reports of rhabdomyolysis with the use of fenofibrate alone or with statin-fibrate combinations, there have been no cases of rhabdomyolysis described when fenofibrate was used alone to treat patients with chronic renal failure owing to nephrotic syndrome. DESIGN AND METHODS: We report on a 26-year-old male who presented with fenofibrate-induced rhabdomyolysis with chronic renal failure due to nephrotic syndrome. RESULTS: After the discontinuation of fenofibrate, the patient was treated with intravenous fluid replacement and urine alkalization. Subsequently, his clinical and biochemical findings improved. CONCLUSIONS: Before starting fenofibrate therapy, the causes of secondary hyperlipidemia, especially nephrotic syndrome, should be investigated. In the presence of chronic renal failure and hypoalbuminemia, the fenofibrate dose should be adjusted. Physicians should be aware of the potential toxicities of fenofibrate, and patients should be informed about its potential side effects.
Erueti C, Glasziou P, Mar CD, van Driel ML.	Faculty of Health Sciences and Medicine, Bond University, Gold Coast, Queensland, Australia. cerueti@bond.edu.au	Do you think it's a disease? a survey of medical students.	BMC Med Educ. 2012 Apr 3;12:19. doi: 10.1186/1472-6920-12-19.	BACKGROUND: The management of medical conditions is influenced by whether clinicians regard them as "disease" or "not a disease". The aim of the survey was to determine how medical students classify a range of conditions they might encounter in their professional lives and whether a different name for a condition would influence their decision in the categorisation of the condition as a 'disease' or 'not a disease'. METHODS: We surveyed 3 concurrent years of medical students to classify 36 candidate conditions into "disease" and "non-disease". The conditions were given a 'medical' label and a (lay) label and positioned where possible in alternate columns of the survey. RESULTS: The response rate was 96% (183 of 190 students attending a lecture): 80% of students concurred on 16 conditions as "disease" (eg diabetes, tuberculosis), and 4 as "non-disease" (eg baldness, menopause, fractured skull and heat stroke). The remaining 16 conditions (with 21-79% agreement) were more contentious (especially obesity, infertility, hay fever, alcoholism, and restless leg syndrome). Three pairs of conditions had both a more, and a less, medical label: the more medical labels (myalgic encephalomyelitis, hypertension, and erectile dysfunction) were more frequently classified as 'disease' than the less medical (chronic fatigue syndrome, high blood pressure, and impotence), respectively, significantly different for the first two pairs. CONCLUSIONS: Some conditions excluded from the classification of "disease" were unexpected (eg fractured skull and heat stroke). Students were mostly concordant on what conditions should be classified as "disease". They were more likely to classify synonyms as 'disease' if the label was medical. The findings indicate there is still a problem 30 years on in the concept of 'what is a disease'. Our findings suggest that we should be addressing such concepts to medical students.

Fagermoen E, Sulheim D, Winger A, Andersen AM, Vethe NT, Saul JP, Thaulow E, Wyller VB.	Department of Pediatrics, Oslo University Hospital and University of Oslo, Oslo, Norway.	Clonidine in the treatment of adolescent chronic fatigue syndrome: a pilot study for the NorCAPITAL trial.	BMC Res Notes. 2012 Aug 7;5:418. doi: 10.1186/1756-0500-5-418.	BACKGROUND: This pilot study (ClinicalTrials.gov ID: NCT01507701) assessed the feasibility and safety of clonidine in adolescent chronic fatigue syndrome (CFS). Specifically, we assessed clonidine dosage in relation to a) plasma concentration levels, b) orthostatic cardiovascular responses, and c) possible adverse effects. FINDINGS: Five adolescent CFS patients (14-19 years old) received 50 µg clonidine twice per day during 14 days in an open, uncontrolled design. Plasma concentration of clonidine was assayed by standard laboratory methods. Changes in orthostatic cardiovascular responses were assessed by a 20o head-up tilt-test (HUT). Adverse effects were mapped by a questionnaire.After 14 days, C0 median (range) of clonidine was 0.21 (0.18-0.36) µg/L, and Cmax median (range) of clonidine was 0.41 (0.38-0.56) µg/L. Also, supine blood pressures and heart rate were lower during clonidine treatment, and the HUT response was closer to the normal response. No serious adverse effects were registered. CONCLUSION: Clonidine 50 µg BID seems to be safe enough to proceed from a pilot study to a controlled trial in a select group of adolescents with CFS (ClinicalTrials.gov ID: NCT01040429).
Felger JC, Cole SW, Pace TW, Hu F, Woolwine BJ, Doho GH, Raison CL, Miller AH.	Department of Psychiatry and Behavioral Sciences, Emory University, Atlanta, GA 30322, USA. jfelger@gmail.com	Molecular signatures of peripheral blood mononuclear cells during chronic interferon-α treatment: relationship with depression and fatigue.	Psychol Med. 2012 Aug;42(8):1591-603. doi: 10.1017/S0033291711002868.	BACKGROUND: Interferon-alpha (IFN-α) treatment for infectious disease and cancer causes high rates of depression and fatigue, and has been used to investigate the impact of inflammatory cytokines on brain and behavior. However, little is known about the transcriptional impact of chronic IFN-α on immune cells in vivo and its relationship to IFN-α-induced behavioral changes. METHOD: Genome-wide transcriptional profiling was performed on peripheral blood mononuclear cells (PBMCs) from 21 patients with chronic hepatitis C virus (HCV) either awaiting IFN-α therapy (n=10) or at 12 weeks of IFN-α treatment (n=11). RESULTS: Significance analysis of microarray data identified 252 up-regulated and 116 down-regulated gene transcripts. Of the up-regulated genes, 2'-5'-oligoadenylate synthetase 2 (OAS2), a gene linked to chronic fatigue syndrome (CFS), was the only gene that was differentially expressed in patients with IFN-α-induced depression/fatigue, and correlated with depression and fatigue scores at 12 weeks (r=0.80, p=0.003 and r=0.70, p=0.017 respectively). Promoter-based bioinformatic analyses linked IFN-α-related transcriptional alterations to transcription factors involved in myeloid differentiation, IFN-α signaling, activator protein-1 (AP1) and cAMP responsive element binding protein/activation transcription factor (CREB/ATF) pathways, which were derived primarily from monocytes and plasmacytoid dendritic cells. IFN-α-treated patients with high depression/fatigue scores demonstrated up-regulation of genes bearing promoter motifs for transcription factors involved in myeloid differentiation, IFN-α and AP1 signaling, and reduced prevalence of motifs for CREB/ATF, which has been implicated in major depression. CONCLUSIONS: Depression

				and fatigue during chronic IFN-α administration were associated with alterations in the expression (OAS2) and transcriptional control (CREB/ATF) of genes linked to behavioral disorders including CFS and major depression, further supporting an immune contribution to these diseases.
Fisher H, Crawley E.	Paediatric CFS/ME Service, Royal National Hospital for Rheumatic Diseases, UK.	Why do young people with CFS/ME feel anxious? A qualitative study.	Clin Child Psychol Psychiatry. 2012 Oct 23	Young people with chronic fatigue syndrome or myalagic encephalopathy (CFS/ME) (CFS/ME) experience higher levels of psychological distress than healthy controls and young people with other chronic illnesses, and it was recently demonstrated that 38% of this population scored above the clinical cut-off on the Spence Child Anxiety Scale. Subscales of social and separation anxiety were consistently high across gender and age groups. In this study, we used qualitative methods to help us understand more about these two types of anxiety in young people with CFS/ME. Eleven young people (age 12-18) were interviewed. Interviews were self-directed by the participants and were wide ranging. The transcripts were analysed using interpretative phenomenological analysis. Five superordinate themes were identified: social loss and adjustment; introduction of uncertainty and unpredictability; the vulnerable self; individual differences; and contributions towards recovery. Many themes were identical to those described in young people coping with other chronic illnesses in adolescence. In addition, young people with CFS/ME describe experiences associated with the perceived illegitimacy of this condition, namely: feeling unable to explain their illness; bullying from peers; disbelief; and distrust from adults around them. This becomes an additional challenge for these young people. Clinicians need to be aware of these problems, and offer appropriate support.
Fjorback LO, Arendt M, Ornbøl E, Walach H, Rehfeld E, Schröder A, Fink P	The Research Clinic for Functional Disorders and Psychosomatics, Aarhus University Hospital, Denmark. Electronic address: lonefjor@rm.dk	Mindfulness therapy for somatization disorder and functional somatic syndromes - Randomized trial with one-year follow-up	J Psychosom Res. 2013 Jan;74(1):31-40. doi: 10.1016/j.jpsychores.2012.09.006. Epub 2012 Oct 1	OBJECTIVE: To conduct a feasibility and efficacy trial of mindfulness therapy in somatization disorder and functional somatic syndromes such as fibromyalgia, irritable bowel syndrome, and chronic fatigue syndrome, defined as bodily distress syndrome (BDS). METHODS: We randomized 119 patients to either mindfulness therapy (mindfulness-based stress reduction and some cognitive behavioral therapy elements for BDS) or to enhanced treatment as usual (2-hour specialist medical care and brief cognitive behavioral therapy for BDS). The primary outcome measure was change in physical health (SF-36 Physical Component Summary) from baseline to 15-month follow-up. RESULTS: The study is negative as we could not demonstrate a different development over time for the two groups ($F(3,2674)=1.51$, $P=.21$). However, in the mindfulness therapy group, improvement was obtained toward the end of treatment and it remained present at the 15-month follow-up, whereas the enhanced treatment as usual group achieved no significant change until 15-month follow-up. The change scores averaged half a standard deviation which amounts to a clinically significant change, 29% changed more than 1 standard deviation. Significant between-group differences were observed at treatment cessation. CONCLUSION: Mindfulness therapy is a feasible and acceptable treatment. The study showed that mindfulness therapy was comparable to enhanced treatment as usual in improving

				quality of life and symptoms. Nevertheless, considering the more rapid improvement following mindfulness, mindfulness therapy may be a potentially
Fjorback LO, Carstensen T, Arendt M, Ornbøl E, Walach H, Rehfeld E, Fink P.	The Research Clinic for Functional Disorders and Psychosomatics, Aarhus University Hospital, Nørrebrogade 4, Aarhus, Denmark. Electronic address: lonefjor@rm.dk.	Mindfulness therapy for somatization disorder and functional somatic syndromes: Analysis of economic consequences alongside a randomized trial.	J Psychosom Res. 2013 Jan;74(1):41-8. doi: 10.1016/j.jpsychores.2012.09.010.	OBJECTIVE: The objective of the present study is to estimate the economic consequences of somatization disorder and functional somatic syndromes such as fibromyalgia and chronic fatigue syndrome, defined as bodily distress syndrome (BDS), when mindfulness therapy is compared with enhanced treatment as usual. METHODS: A total of 119 BDS patients were randomized to mindfulness therapy or enhanced treatment as usual and compared with 5950 matched controls. Register data were analyzed from 10years before their inclusion to 15-month follow-up. The main outcome measures were disability pension at the 15-month follow-up and a reduction in total health care costs. Unemployment and sickness benefit prior to inclusion were tested as possible risk factors. RESULTS: At 15-month follow-up, 25% from the mindfulness therapy group received disability pension compared with 45% from the specialized treatment group (p=.025). The total health care utilization was reduced over time in both groups from the year before inclusion (mean $5325, median $2971) to the year after inclusion (mean $3644, median $1593) (p=.0001). This overall decline was seen in spite of elevated costs due to assessment and mindfulness therapy or enhanced treatment as usual. The BDS patients accumulated significantly more weeks of unemployment and sickness benefit 5 and 10years before inclusion (p<.0001) than the population controls. CONCLUSIONS: Mindfulness therapy may prevent disability pension and it may have a potential to significantly reduce societal costs and increase the effectiveness of care. Accumulated weeks of unemployment and sickness benefit are possible risk factors for BDS.
Fjorback LO.	The Research Clinic for Functional Disorders and Psychosomatics, Aarhus University Hospital, Nørrebrogade 44, 8000 Aarhus C, Denmark. lonefjor@rm.dk.	Mindfulness and bodily distress.	Dan Med J. 2012 Nov;59(11):B4547.	We have created a mindfulness approach to treat patients who experience multiple, persistent, and disabling physical symptoms that cannot be explained by a well-defined medical or surgical condition. Randomized controlled trials in this area are few, and research is hampered by the lack of clear definitions. Bodily distress syndrome (BDS) or bodily stress is an empirically defined definition unifying various conditions such as fibromyalgia, chronic fatigue syndrome, and somatization disorder. In the present PhD, we explored whether patients suffering from BDS may be committed to mental training in the form of mindfulness therapy, which is a mindfulness program specifically targeted patients suffering from BDS. The theoretical model for including mindfulness training in the treatment of BDS is based on identified neurobiological impairments in these patients and the neurobiological improvements that mindfulness training may offer. BDS is a major public health issue possibly associated with the pathology of the immuno-endocrine and autonomic nervous system. BDS patients are often stigmatized, and effective treatment is rarely delivered, which leaves these patients isolated, left by themselves, vulnerable to potentially harming medical and/or alternative treatments. Accordingly, there is a need for non-harming practical tools that patients can learn to master so that they

				can improve the ability to take responsibility for their own health and wellbeing. Mindfulness-Based Stress Reduction (MBSR) is a group program that employs mindfulness practice to alleviate suffering associated with physical, psychosomatic, and psychiatric disorders. Mindfulness-Based Cognitive Therapy (MBCT) is designed to prevent depressive relapse. Paper I and II present systematic literature reviews only of randomized controlled trials on MBSR and MBCT. The effect of MBSR has been explored on fibromyalgia in three studies, none of them showed convincing results, but gave some indications as to improvement. The reviews recommended MBSR as a useful method for improving mental health; however, lack of long-term follow-up and active control groups are limitations in most studies. MBCT was recommended as a tool for preventing depressive relapse in recovered, recurrently depressed patients, but the implication of MBSR and MBCT is problematic, especially due to the lack of well educated mindfulness teachers. We combined MBSR with cognitive behavioral therapy, CBT, specifically targeted BDS. Paper III provides original data from 119 patients enrolled in a randomized clinical trial, mindfulness therapy for BDS. The randomized controlled trial indicates that BDS patients are capable of and willing to engage in mindfulness therapy. This thesis showed that mindfulness therapy can safely and successfully engage BDS patients in mindfulness practice. Since individual CBT and psychiatric consultation have previously been found to have positive outcomes for BDS patients, we compared mindfulness therapy to an active control group entitled specialized treatment in which an individual treatment was planned in collaboration between the patient and an MD specialized in BDS, CBT, and psychiatry. Mindfulness therapy was comparable to specialized treatment in improving the quality of life and the symptoms of the patients with BDS at 15-month follow-up. For primary outcome physical health (PCS) at 15-month follow-up, different developments over time for the two treatment groups could not be established ($F(3,2674) = 1.51$, $p = 0.21$). However, in the mindfulness therapy group, PCS significant changed at the end of treatment and this change remained at 15-month follow-up, whereas no significantly change was seen in the specialized treatment group until at the 15-month follow-up. In the mindfulness therapy group, 26%; CI: 14-38 reported a marked improvement (> 1 SD) at the end of treatment compared with 10%; CI: 2-18 in the specialized treatment group. This amounts to a statistically significant difference between the groups (OR = 3.21; CI 1.05-9.78, $p = 0.04$). The results are indicating that mindfulness therapy produced greater and more rapid improvements than specialized treatment. Mindfulness therapy appears to produce improvements within the range of those reported in the STreSS-1 trial, where CBT was compared with enhanced usual care, and no improvements on the SF-36 scale were observed in the enhanced usual care group. This indicates that the changes accomplished with the two treatments mindfulness therapy and specialized treatment reflect real changes attributable to the interventions. The economic effects

				of mindfulness therapy are evaluated in paper IV by the use of original register data from the 119 enrolled patients and a matched control group of 5,950 individuals. Mindfulness therapy had substantial socioeconomic benefits over specialized treatment. The costs incurred to cover permanent health-related benefits, especially disability pension, were significantly lower in the mindfulness therapy group than in the specialized treatment group over a 15-month follow-up period; 25% from the mindfulness therapy group received disability pension compared with 45% from the specialized treatment group (p = 0.025). The total health care utilization was reduced over time in both groups from the year before inclusion (mean $ 5,325, median $ 2,971) to the year after inclusion (mean $ 3,644, median $ 1,593) (p = 0.0001). There was no difference between the two groups. Five and ten years before their inclusion, the BDS patients were less self-supporting than an age-, gender- and ethnicity-matched population control group; the BDS patients accumulated more weeks of sickness benefit and unemployment. Thus, the included BDS patients may have been ill and in high risk for a social decline five and ten years before they received a proper diagnosis and treatment. In conclusion, the social and economic consequences of BDS are significant and mindfulness therapy may have a potential to significantly improve function, quality of life and symptoms, prevent a social decline, and reduce societal costs.
Friedlander JI, Shorter B, Moldwin RM.	The Arthur Smith Institute for Urology, Department of Nutrition, New Hyde Park, NY, USA. justinfriedlander@gmail.com	Diet and its role in interstitial cystitis/bladder pain syndrome (IC/BPS) and comorbid conditions.	BJU Int. 2012 Jun;109(11):1584-91. doi: 10.1111/j.1464-410X.2011.10860.x. Epub 2012 Jan 11.	What's known on the subject? and What does the study add? Nearly 90% of patients with interstitial cystitis/bladder pain syndrome (IC/BPS) report sensitivities to a wide variety of dietary comestibles. Current questionnaire-based literature suggests that citrus fruits, tomatoes, vitamin C, artificial sweeteners, coffee, tea, carbonated and alcoholic beverages, and spicy foods tend to exacerbate symptoms, while calcium glycerophosphate and sodium bicarbonate tend to improve symptoms. At present we recommend employing a controlled method to determine dietary sensitivities, such as an elimination diet, in order to identify sensitivities while at the same time maintain optimal nutritional intake. We review current literature with regard to diet's effect upon IC/BPS and common comorbidities (irritable bowel syndrome, fibromyalgia, chronic fatigue syndrome, neuropathic pain, vulvodynia, and headache) with a focus upon questionnaire-based investigations. We discuss the pathologic mechanisms that may link diet and IC/BPS related-pain, concentrating upon specific comestibles such as acidic foods, foods high in potassium, caffeine, and alcohol. Up to 90% of patients with interstitial cystitis/bladder pain syndrome (IC/BPS) report sensitivities to a wide variety of comestibles. Pathological mechanisms suggested to be responsible for the relationship between dietary intake and symptom exacerbation include peripheral and/or central neural upregulation, bladder epithelial dysfunction, and organ 'cross-talk', amongst others. Current questionnaire-based data suggests that citrus fruits, tomatoes, vitamin C, artificial sweeteners, coffee, tea, carbonated and alcoholic beverages, and spicy foods tend to exacerbate symptoms, while calcium

				glycerophosphate and sodium bicarbonate tend to improve symptoms. Specific comestible sensitivities varied between patients and may have been influenced by comorbid conditions. This suggests that a controlled method to determine dietary sensitivities, such as an elimination diet, may play an important role in patient management.
Frith J, Zalewski P, Klawe JJ, Pairman J, Bitner A, Tafil-Klawe M, Newton JL.	UK NIHR Biomedical Research Centre in Ageing, Newcastle, UK.	Impaired blood pressure variability in chronic fatigue syndrome--a potential biomarker.	QJM. 2012 Sep;105(9):831-8. doi: 10.1093/qjmed/hcs085.	INTRODUCTION: Autonomic dysfunction is common in chronic fatigue syndrome (CFS). This study set out to derive an autonomic biomarker using a comprehensive assessment of heart rate and blood pressure variability. METHODS: Heart rate and non-invasive continuous blood pressure measurements (task force monitor) at rest and on standing were performed in CFS (Fukuda n = 68) and matched controls (n = 68) to derive high frequency (HF; parasympathetic) and low frequency (LF; sympathetic) heart rate variability (HRV), systolic (SBPV) and diastolic (DBPV) blood pressure variability. Variables of significance were combined using receiver operator curves to explore the diagnostic utility of parameters particularly at rest. RESULTS: At rest, LF-HRV (sympathetic) was significantly increased in CFS compared to controls, while parasympathetic markers were significantly reduced (P = 0.006). Total DBP spectral power was increased (P = 0.0003) across all domains, with a shift towards sympathetic and away from parasympathetic SBPV (P = 0.05). On standing, overall SBPV response was significantly reduced with reductions in both sympathetic and parasympathetic components of SBPV (all P < 0.0001). Change in LF-DBP and relative balance of LF/HF DBP on standing differed between CFS and controls (P < 0.0001). Using the 85% sensitivity levels, we determined a threshold for three chosen resting BPV parameters of LF DBP >3.185, rest HF DBP >0.86, rest total DBP >7.05. Achieving all of these differentiated between CFS and controls with 77% sensitivity and 53% specificity. CONCLUSION: This study has shown that there are objectively measured abnormalities of blood pressure variability in CFS and that these abnormalities have the potential to be a bedside diagnostic tool.
Fuchs CE, van Geelen SM, van Geel R, Sinnema G, van de Putte EM, Hermans HJ, Kuis W.	Division of Paediatric Psychology, University Medical Centre Utrecht, The Netherlands.	Health and identity: Self-positioning in adolescent chronic fatigue syndrome and juvenile idiopathic arthritis.	Clin Child Psychol Psychiatry. 2012 Oct 11.	The aim of this study is to gain more insight into basic aspects of identity, in relation to adolescent chronic fatigue syndrome (CFS) and juvenile idiopathic arthritis (JIA). In dialogical self theory, identity is regarded as incorporating multiple self-positions, such as 'I as tired', 'I as pessimistic', or 'I as decisive'. Physical and psychosocial impairment might alter the organization of these self-positions. The Personal Position Repertoire procedure, a quantitative method to analyse the prominence of self-positions, the Child Health Questionnaire, assessing health-related functioning, and the Checklist Individual Strength, measuring fatigue, were completed by 42 adolescents with CFS, 37 adolescents with JIA and 23 healthy teenagers. Adolescents with JIA report impaired physical functioning and general health. However, they position themselves very similar to healthy teenagers - i.e. as strong and healthy. While this self-positioning approach might be adequate and sustainable in adolescence, it could prove too strenuous to maintain throughout adult life.

				Adolescents with CFS, besides indicating severe physical difficulties, also report more psychosocial problems. They position themselves as significantly less strong and more unwell. With this emphasis on positions relating to their illness, there seems to be little room left for stronger positions. It is regarded of clinical importance to address these issues in this crucial developmental period.
Fukuda S, Horiguchi M, Yamaguti K, Nakatomi Y, Kuratsune H, Ichinose H, Watanabe Y.	Department of Medical Science on Fatigue, Osaka City University, Graduate School of Medicine, Osaka, Japan; Center for Molecular Imaging Science, RIKEN, Kobe, Hyogo, Japan.	Association of monoamine-synthesizing genes with the depression tendency in chronic fatigue syndrome patients.	Life Sci. 2012 Dec 13. pii: S0024-3205(12)00711-4. doi: 10.1016/j.lfs.2012.11.016.	AIMS: Tyrosine hydroxylase (TH) and GTP cyclohydrolase I (GCH) are the rate-limiting enzymes for the biosynthesis of catecholamines and tetrahydrobiopterin (BH4), respectively. Since catecholamines and BH4 are thought to be involved in the pathophysiology of CFS, we explored the genetic factors that influence CFS development and examined the possible association between the SNPs of the TH and GCH genes and the various characteristics of CFS patients. MAIN METHODS: After drawing venous blood from CFS patients and controls, genomic DNA was then extracted from whole blood in accordance with standard procedures. Digestion patterns of the PCR products were used for genotyping the SNPs of GCH (rs841; C+243T) and TH (rs10770141; C-824T). We also performed questionnaires consisting of fatigue-scale and temperament and character inventory scale (TCI) to CFS patients. KEY FINDINGS: Our results demonstrated that the allele differences for the GCH and TH SNPs were not associated with CFS patients. We did find that the GCH gene with the C+243T polymorphism affected harm avoidance, while the TH gene with the C-824T polymorphism affected persistence in the CFS patients. SIGNIFICANCE: Our results suggest that the biosynthetic pathways of the monoamine neurotransmitters that are mediated by TH and GCH might be associated with the CFS clinical findings, because persistence is one of the typical personality traits observed in CFS and patients with major depressive disorder exhibit a higher harm avoidance score.
Galbraith S, Cameron B, Li H, Lau D, Vollmer-Conna U, Lloyd AR.	School of Mathematics and Statistics, Faculty of Science, University of New South Wales, Sydney, Australia.	Peripheral blood gene expression in postinfective fatigue syndrome following from three different triggering infections.	J Infect Dis. 2011 Nov 15;204(10):1632-40. doi: 10.1093/infdis/jir612.	BACKGROUND: Several infections trigger postinfective fatigue syndromes, which share key illness characteristics with each other and with chronic fatigue syndrome (CFS). Previous cross-sectional case-control studies of CFS have suggested that unique gene expression signatures are evident in peripheral blood samples. METHODS: Peripheral blood transcriptomes in samples collected longitudinally, in 18 subjects with a fatigue syndrome lasting ≥ 6 months after acute infection due to Epstein-Barr virus, Ross River virus, or Coxiella burnetii (Q fever), and 18 matched control subjects who had recovered promptly, were studied by microarray (n = 127) and confirmatory quantitative polymerase chain reaction (PCR). Gene expression patterns associated with CFS were sought by univariate statistics and regression modeling. RESULTS: There were 23 genes with modest differential expression (0.6-2.3-fold change) in within-subject comparisons of early, symptomatic time points with late, recovered time points. There were modest differences found in 63 genes, either in cross-sectional comparison of cases and controls at 6 months after infection onset or in the regression model. There were 223 genes significantly correlated with individual symptom domains. Quantitative PCR confirmed 33 (73%) of 45 genes-none were

				consistent across cohorts. CONCLUSIONS: Although the illness characteristics of patients with postinfective fatigue syndromes have more similarities than differences, no reliable peripheral blood gene expression correlate is evident.
Gherardi RK, Authier FJ.	AP-HP, Hôpital H. Mondor, France.	Macrophagic myofasciitis: characterization and pathophysiology.	Lupus. 2012 Feb;21(2):184-9. doi: 10.1177/0961203311429557.	Aluminium oxyhydroxide (alum), a nanocrystalline compound forming agglomerates, has been used in vaccines for its immunological adjuvant effect since 1927. Alum is the most commonly used adjuvant in human and veterinary vaccines, but the mechanisms by which it stimulates immune responses remain incompletely understood. Although generally well tolerated, alum may occasionally cause disabling health problems in presumably susceptible individuals. A small proportion of vaccinated people present with delayed onset of diffuse myalgia, chronic fatigue and cognitive dysfunction, and exhibit very long-term persistence of alum-loaded macrophages at the site of previous intramuscular (i.m.) immunization, forming a granulomatous lesion called macrophagic myofasciitis (MMF). Clinical symptoms associated with MMF are paradigmatic of the recently delineated 'autoimmune/inflammatory syndrome induced by adjuvants' (ASIA). The stereotyped cognitive dysfunction is reminiscent of cognitive deficits described in foundry workers exposed to inhaled Al particles. Alum safety concerns will largely depend on whether the compound remains localized at the site of injection or diffuses and accumulates in distant organs. Animal experiments indicate that biopersistent nanomaterials taken up by monocyte-lineage cells in tissues, such as fluorescent alum surrogates, can first translocate to draining lymph nodes, and thereafter circulate in blood within phagocytes and reach the spleen, and, eventually, slowly accumulate in the brain.
Gibson PR, Morrison G.	Eastern Health Clinical School, Monash University, Melbourne, Victoria, Australia. peter.gibson@monash.edu	Effects of methylnaltrexone in patients with narcotic bowel syndrome: a pilot observational study.	Intern Med J. 2012 Aug;42(8):907-12. doi: 10.1111/j.1445-5994.2012.02726.x.	BACKGROUND: Narcotic bowel syndrome (NBS) describes disabling chronic severe abdominal pain that worsens despite continuing or escalating doses of opiates. Therapy is very limited. AIM: To examine effects of blocking peripheral μ-opioid receptors on the symptomatology of patients with NBS and its safety. METHODS: An open-label observational study was performed in four women with NBS. After a 2-week run-in period, patients were treated for 12 weeks with 8-12 mg methylnaltrexone bromide subcutaneously every other day, increasing to daily if there was poor response. Patient and physician assessment was documented, and patients completed an eight-symptom visual analogue scale weekly and the Functional Assessment of Chronic Illnesses Therapy-Fatigue questionnaire for fatigue. Patients were observed for 4 weeks following withdrawal of the drug. RESULTS: One patient was unable to tolerate the study medication because of worsening pain after injection, and withdrew. Two showed clear benefit with reduction of symptoms overall, pain, bloating, distension, nausea and tiredness, with improved satisfaction and consistency of bowel actions and fatigue scores. Both reduced analgesic usage. The third had improved ileostomy output and had no episodes of severe bloating, but pain scores remained high. All three worsened after drug withdrawal and requested retreatment. Three experienced abdominal pains of moderate severity for 30-60 min

				consistently within 5 min of each injection. No other adverse events were experienced. CONCLUSIONS: Methylnaltrexone has a positive impact on symptoms in women with NBS, although treatment does induce transient pain following its administration. Larger studies are required to examine its efficacy and longer term safety in this patient group.
Gingaras C, Danielson BP, Vigil KJ, Vey E, Arduino RC, Kimata JT.	Section of Retrovirology, Department of Pediatrics, Baylor College of Medicine, Houston, Texas, USA.	Absence of XMRV in peripheral blood mononuclear cells of ARV-treatment naïve HIV-1 infected and HIV-1/HCV coinfected individuals and blood donors.	PLoS One. 2012;7(2):e31398. doi: 10.1371/journal.pone.0031398.	BACKGROUND: Xenotropic murine leukemia virus-related virus (XMRV) has been found in the prostatic tissue of prostate cancer patients and in the blood of chronic fatigue syndrome patients. However, numerous studies have found little to no trace of XMRV in different human cohorts. Based on evidence suggesting common transmission routes between XMRV and HIV-1, HIV-1 infected individuals may represent a high-risk group for XMRV infection and spread. METHODOLOGY/PRINCIPAL FINDINGS: DNA was isolated from the peripheral blood mononuclear cells (PBMCs) of 179 HIV-1 infected treatment naïve patients, 86 of which were coinfected with HCV, and 54 healthy blood donors. DNA was screened for XMRV provirus with two sensitive, published PCR assays targeting XMRV gag and env and one sensitive, published nested PCR assay targeting env. Detection of XMRV was confirmed by DNA sequencing. One of the 179 HIV-1 infected patients tested positive for gag by non-nested PCR whereas the two other assays did not detect XMRV in any specimen. All healthy blood donors were negative for XMRV proviral sequences. Sera from 23 HIV-1 infected patients (15 HCV(+)) and 12 healthy donors were screened for the presence of XMRV-reactive antibodies by Western blot. Thirteen sera (57%) from HIV-1(+) patients and 6 sera (50%) from healthy donors showed reactivity to XMRV-infected cell lysate. CONCLUSIONS/SIGNIFICANCE: The virtual absence of XMRV in PBMCs suggests that XMRV is not associated with HIV-1 infected or HIV-1/HCV coinfected patients, or blood donors. Although we noted isolated incidents of serum reactivity to XMRV, we are unable to verify the antibodies as XMRV specific.
Gonzalez M, Fisher M.	Division of Adolescent Medicine, Steven and Alexandra Cohen Children's Medical Center of New York, North Shore-Long Island Jewish Health System, Hofstra-North Shore LIJ School of Medicine, Hempstead, New York, USA. Mgonzalez52@NSHS.edu	An adolescent evaluated for chronic fatigue: does she have a sleep disorder?	Adolesc Med State Art Rev. 2012 Aug;23(2):277-84.	A 13-year-old girl presented to our Division of Adolescent Medicine for evaluation of ongoing fatigue. She and her mother reported that 15 months earlier, when the patient was in the 7th grade, she started to be tired and "sleep all the time." They do not remember her being ill at that time; a test for mononucleosis was reportedly positive, but Epstein-Barr virus titers showed "old disease." She remained fatigued throughout 7th grade but attended school without falling asleep; however, she was too tired to do her work and had to attend summer school. The patient received home instruction in 8th grade and reported that on weekdays she slept from 1 AM to 11 AM with a nap from 4 to 8 PM and on weekends she slept from 3 AM to 1 PM without a nap.
Goudsmit EM, Nijs	School of Psychology,	Pacing as a strategy	Disabil Rehabil.	PURPOSE: Myalgic encephalomyelitis/chronic fatigue syndrome (ME/CFS) is a

J, Jason LA, Wallman KE.	University of East London, Stratford, London, E15 4LZ, UK. ellengoudsmit@hotmail.com	to improve energy management in myalgic encephalomyelitis/chronic fatigue syndrome: a consensus document.	2012;34(13):1140-7. doi: 10.3109/09638288.2011.635746.	debilitating condition characterized by a number of symptoms which typically worsen following minimal exertion. Various strategies to manage the limited energy levels have been proposed. Of these, pacing has been consistently rated as one of the most helpful in surveys conducted by patient groups. This review is a response to the paucity of the information on pacing in the scientific literature. METHOD: We describe the principle of pacing and how this can be adapted to meet individual abilities and preferences. A critical evaluation of the research was conducted to ascertain the benefits and limitations of this strategy. RESULTS: Based on various studies, it is proposed that pacing can help to stabilize the condition and avoid post-exertional malaise. CONCLUSION: Pacing offers practitioners an additional therapeutic option which is acceptable to the majority of patients and can reduce the severity of the exertion-related symptoms of ME/CFS.
Graff LA, Walker JR, Russell AS, Bissonnette R, Bernstein CN.	Department of Clinical Health Psychology, University of Manitoba, 771 Bannatyne Avenue, Winnipeg, Manitoba, Canada. lgraff@hsc.mb.ca	Fatigue and quality of sleep in patients with immune-mediated inflammatory disease.	Int J Equity Health. 2011 Nov 2;10(1):46. doi: 10.1186/1475-9276-10-46.	Fatigue, a systemic feeling of exhaustion, is a common symptom of many chronic illnesses, including immune-mediated inflammatory diseases (IMID). IMID-related fatigue is associated with disease activity and pain and has detrimental effects on patient quality of life and overall well-being. Thus, routine assessment and management of fatigue in clinical practice is important. This article provides an overview of the prevalence, correlates, and predictors of fatigue in IMID. There is also discussion of the effects of different treatments on fatigue outcomes, as well as management recommendations.
Groom HC, Bishop KN.	Division of Virology, MRC National Institute for Medical Research, London NW7 1AA, UK.	The tale of xenotropic murine leukemia virus-related virus.	J Gen Virol. 2012 May;93(Pt 5):915-24. doi: 10.1099/vir.0.041038-0.	In 2006, a new retrovirus was isolated from prostate cancer patient tissue. Named xenotropic murine leukemia virus-related virus (XMRV), this was potentially the third class of retrovirus to be pathogenic in humans. XMRV made a more dramatic impact on the wider scientific community, and indeed the media, in 2009 when it was reported to be present in a remarkably high proportion of patients with chronic fatigue syndrome as well as a significant, albeit smaller, proportion of healthy controls. The apparent strong link to disease and the fear of a previously unknown retrovirus circulating in the general population lead to a surge in XMRV research. Subsequent studies failed to find an association of XMRV with disease and, in most cases, failed to find the virus in human samples. In 2011, the case against XMRV and human disease strengthened, ending with several decisive publications revealing the origin of the virus and demonstrating contamination of samples. In this review, we outline the passage of research on XMRV and its potential association with disease from its isolation to the present day, where we find ourselves at the end of a turbulent story.
Guidelli GM, Tenti S, De Nobili E, Fioravanti A.	Rheumatology Unit, Department of Clinical Medicine and Immunological Sciences, University of	Fibromyalgia syndrome and spa therapy: myth or reality?	Clin Med Insights Arthritis Musculoskelet Disord. 2012;5:19-26. doi: 10.4137/CMAMD.S8797.	Fibromyalgia syndrome (FS) is a common musculoskeletal disorder characterized by otherwise unexplained chronic widespread pain, a lowered pain threshold, high tender point counts, sleep disturbances, fatigue, headache, irritable bowel syndrome, morning stiffness, paraesthesias in the extremities, often psychological distress and depressed mood. Consequently, FS has a negative impact on working capacity, family

	Siena, Italy.			life, social functioning and quality of life. Because of unknown etiology and not clearly understood pathogenesis, there is no standard therapy regime for FS. A variety of medical treatments, including antidepressants, opioids, analgesic or non-steroidal anti-inflammatory drugs, sedatives, muscle relaxants and antiepileptics, have been used to treat FS. Currently, no pharmacological treatment for FS is consistently successful. According to recent guidelines, the optimal treatment of FS requires a multidisciplinary approach with a combination of non-pharmacological and pharmacological treatment modalities. Spa therapy is a popular treatment for FS in many European countries, as well as in Japan and Israel. However, despite their long history and popularity spa treatments are still the subject of debate and their role in modern medicine is still not clear. The objective of this review is to summarize the currently available information on clinical effects and mechanism of action of spa therapy in FS. We also provide some suggestions for further development in this area.
Guillard O, Fauconneau B, Pineau A, Marrauld A, Bellocq JP, Chenard MP.	CHU Poitiers, Department of Biochemistry, Poitiers, France. olivier.guillard@univ-poitiers.fr	Aluminium overload after 5 years in skin biopsy following post-vaccination with subcutaneous pseudolymphoma.	J Trace Elem Med Biol. 2012 Oct;26(4):291-3. doi: 10.1016/j.jtemb.2012.02.005.	Aluminium hydroxide is used as an effective adjuvant in a wide range of vaccines for enhancing immune response to the antigen. The pathogenic role of aluminium hydroxide is now recognized by the presence of chronic fatigue syndrome, macrophagic myofasciitis and subcutaneous pseudolymphoma, linked to intramuscular injection of aluminium hydroxide-containing vaccines. The aim of this study is to verify if the subcutaneous pseudolymphoma observed in this patient in the site of vaccine injection is linked to an aluminium overload. Many years after vaccination, a subcutaneous nodule was discovered in a 45-year-old woman with subcutaneous pseudolymphoma. In skin biopsy at the injection site for vaccines, aluminium (Al) deposits are assessed by Morin stain and quantification of Al is performed by Zeeman Electrothermal Atomic Absorption Spectrophotometry. Morin stain shows Al deposits in the macrophages, and Al assays (in µg/g, dry weight) were 768.10±18 for the patient compared with the two control patients, 5.61±0.59 and 9.13±0.057. Given the pathology of this patient and the high Al concentration in skin biopsy, the authors wish to draw attention when using the Al salts known to be particularly effective as adjuvants in single or repeated vaccinations. The possible release of Al may induce other pathologies ascribed to the well-known toxicity of this metal.
Güthlin C, Anton A, Kruse J, Walach H.	Johann Wolfgang Goethe University, Frankfurt/Main, Germany. guethlin@allgemeinmedizin.uni-frankfurt.de	Subjective concepts of chronically ill patients using distant healing.	Qual Health Res. 2012 Mar;22(3):320-31. doi: 10.1177/1049732311421914.	Distant healing procedures consist of benevolent intentions, often taking the form of prayers for a patient. Despite inconclusive evidence regarding distant healing, prayers are a widespread health-related technique. We studied subjective concepts of distant healing in 17 patients suffering from chronic fatigue syndrome and multiple chemical sensitivity who were given distant healing during a randomized controlled trial. We applied reconstructive interview analysis when analyzing the results. The overall theme was the tension between mainstream medicine and the immaterial healing procedure. Several components highlighted this tension: (a) patterns of legitimizing the use of distant healing, (b) distant healing and the social setting, (c) integrating

				distant healing into their belief system, and (d) reconstruction of effects by means of hindsight. The interviews showed that patients felt the need to legitimize having tried distant healing. They had to bear the full ambiguity of biomedicine being in competition with distant healing, though also experiencing distant healing as giving support.
Haba-Rubio J, de Seigneux S, Heinzer R.	Centre d'investigation et de recherche sur le sommeil, CHU Vaudois (CHUV), BH 06-204, 1011 Lausanne, Suisse.	Sleep disorders in chronic renal failure. [Article in French]	Nephrol Ther. 2012 Apr;8(2):74-80. doi: 10.1016/j.nephro.2011.07.408.	Sleep disorders are common in patients with chronic renal failure (CRF), especially in those receiving hemodialysis. Sleep-related complaints in this patient population may include insomnia, daytime sleepiness or fatigue and depression. In addition to causing impairment of daytime function and quality of life, sleep apnea may also increase the cardiovascular morbidity and mortality, especially in dialysis patients. In CRF patients, an increased prevalence of sleep apnea, restless legs syndrome and periodic limb movement during sleep has been reported. Epidemiology, pathophysiology and treatment of sleep disorders in CRF and dialysis patients are still unclear and require further research.
Hanevik K, Kristoffersen EK, Sørnes S, Mørch K, Næss H, Rivenes AC, Bødtker JE, Hausken T, Langeland N.	[No address quoted]	Immunophenotyping in post-giardiasis functional gastrointestinal disease and chronic fatigue syndrome.	BMC Infect Dis. 2012 Oct 14;12(1):258.	ABSTRACT: BACKGROUND: A Giardia outbreak was associated with development of post-infectious functional gastrointestinal disorders (PI-FGID) and chronic fatigue syndrome (PI-CFS). Markers of immune dysfunction have given conflicting results in CFS and FGID patient populations. The aim of this study was to evaluate a wide selection of markers of immune dysfunction in these two co-occurring post-infectious syndromes. METHODS: 48 patients, reporting chronic fatigue in a questionnaire study, were clinically evaluated five years after the outbreak and grouped according to Fukuda criteria for CFS (n=19) and idiopathic chronic fatigue (n=5) and Rome II criteria for FGIDs (n=54). 22 Giardia exposed non-fatigued individuals and 10 healthy unexposed individuals were recruited as controls. Peripheral blood lymphocyte subsets were analyzed by flow cytometry. RESULTS: In peripheral blood we found significantly higher CD8 T-cell levels in PI-FGID, and significantly lower NK-cell levels in PI-CFS patients. Severity of abdominal and fatigue symptoms correlated negatively with NK-cell levels. A tendency towards lower T-cell CD26 expression in FGID was seen. CONCLUSION: Patients with PI-CFS and/or PI-FGID 5 years after Giardia lamblia infection showed alterations in NK-cell and CD8-cell populations suggesting a possible immunological abnormality in these conditions. We found no significant changes in other markers examined in this well-defined group of PI-CFS and PI-FGID elicited by a gastrointestinal infection. Controlling for co-morbid conditions is important in evaluation of CFS-biomarkers.
Hannon KL, Peters S, Fisher L, Riste L, Wearden A, Lovell K, Turner P, Leech Y, Chew-Graham C.	[No address quoted]	Developing resources to support the diagnosis and management of Chronic Fatigue Syndrome/Myalgic	BMC Fam Pract. 2012 Sep 21;13(1):93	ABSTRACT: BACKGROUND: NICE guidelines emphasise the need for a confident, early diagnosis of Chronic Fatigue Syndrome/ Myalgic Encephalitis (CFS/ME) in Primary Care with management tailored to the needs of the patient. Research suggests that GPs are reluctant to make the diagnosis and resources for management are currently inadequate. This study aimed to develop resources for practitioners and patients to support the diagnosis and management of CFS/ME in primary care. METHODS: Semi

		Encephalitis (CFS/ME) in primary care. A qualitative study.		structured interviews were conducted with patients, carers, GPs, practice nurses and CFS/ME specialists in North West England. All interviews were audio recorded, transcribed and analysed qualitatively using open explorative thematic coding. Two patient involvement groups were consulted at each stage of the development of resources to ensure that the resources reflect everyday issues faced by people living with CFS/ME. RESULTS: Patients and carers stressed the importance of recognising CFS/ME as a legitimate condition, and the need to be believed by health care professionals. GPs and practice nurses stated that they do not always have the knowledge or skills to diagnose and manage the condition. They expressed a preference for an online training package. For patients, information on getting the most out of a consultation and the role of carers was thought to be important. Patients did not want to be overloaded with information at diagnosis, and suggested information should be given in steps. A DVD was suggested, to enable information sharing with carers and family, and also for those whose symptoms act as a barrier to reading. CONCLUSION: Rather than use a top-down approach to the development of training for health care practitioners and information for patients and carers, we have used data from key stakeholders to develop a patient DVD, patient leaflets to guide symptom management and a modular e-learning resource which should equip GPs to diagnose and manage CFS/ME effectively, meet NICE guidelines and give patients acceptable, evidence-based information.

Hawkes N.	[No address quoted]	Researcher who linked chronic fatigue syndrome to mouse virus is arrested.	BMJ. 2011 Nov 22;343:d7573. doi: 10.1136/bmj.d7573.	[No abstract given]
Haywood KL, Staniszewska S, Chapman S.	Royal College of Nursing Research Institute, School of Health and Social Studies, University of Warwick, Coventry CV4 7AL, UK. k.l.haywood@warwick.ac.uk	Quality and acceptability of patient-reported outcome measures used in chronic fatigue syndrome/myalgic encephalomyelitis (CFS/ME): a systematic review.	Qual Life Res. 2012 Feb;21(1):35-52. doi: 10.1007/s11136-011-9921-8.	PURPOSE: To review the quality and acceptability of condition-specific, domain-specific and generic multi-item patient-reported outcome measures (PROMs) used in the assessment of adults with chronic fatigue syndrome/myalgic encephalomyelitis (CFS/ME). METHODS: Systematic literature searches were made to identify PROMs. Quality and acceptability was assessed against an appraisal framework, which captured evidence of both the thoroughness and results of evaluations: evidence of measurement (reliability, validity, responsiveness, interpretability, data quality/precision) and practical properties (feasibility, patient acceptability), and the extent of active patient involvement was sought. RESULTS: A total of 11 CFS/ME-specific, 55 domain-specific and 11 generic measures were reviewed. With the exception of the generic SF-36, all measures had mostly limited evidence of measurement and/or practical properties. Patient involvement was poorly reported and often cursory. CONCLUSIONS: The quality and acceptability of reviewed PROMs is

				limited, and recommendations for patient-reported assessment are difficult. Significant methodological and quality issues in PROM development/evaluation were identified by the appraisal framework, which must be addressed in future research. Clear discrepancies exist between what is measured in research and how patients define their experience of CFS/ME. Future PROM development/evaluation must seek to involve patients more collaboratively to measure outcomes of importance using relevant and credible methods of assessment.
He X, Walker TD, Maranga IO, Oliver AW, Hampson L, Hampson IN.	Viral Oncology Laboratories, University of Manchester School of Cancer & Enabling Sciences, St Mary's Hospital, Manchester, United Kingdom.	No biological evidence of XMRV infection in cervical smears from HIV/ HPV positive and negative Kenyan women.	PLoS One. 2012;7(10):e47208. doi: 10.1371/journal.pone.0047208.	BACKGROUND: XMRV (xenotropic murine leukaemia virus-related virus) is a gammaretrovirus first discovered in human prostate carcinomas and later linked to chronic fatigue syndrome (CFS). Emerging conflicting data and lack of reproducibility of results within the scientific community has now led to the association of XMRV with CFS being discounted. Indeed the case for an involvement with any human disease has been questioned with the suggestion that XMRV is a laboratory generated recombinant virus. The fact that not all published positive findings can be easily explained as contamination artefacts coupled with the observation that XMRV may have a sexually transmitted mode of infectivity and can be infectious for primates, where it preferential resides in cells of the reproductive tract, prompted us to look for evidence of XMRV in the cervical cells of a cohort of Kenyan women both with and without pre-existing HIV/HPV infections. RESULTS: Using a highly sensitive and selective triplex PCR approach we analysed DNA from the liquid based cytology (LBC) cervical smears of 224 Kenyan women. There was no evidence of XMRV expression in any of the sample population irrespective of HPV and/or HIV status. CONCLUSIONS: The data presented show no indication of XMRV infection in any of the cervical samples screened in this study. Approximately 50% of the women were HIV positive but this did not influence the findings signifying that XMRV does not act as an opportunistic infection in this cohort nor is it related to HPV status. Our results therefore support the findings that XMRV is confined to the laboratory and does not currently represent an infectious agent for humans, with a cautionary adage that such potential zoonotic viruses should be carefully monitored in the future.
Heins M, Knoop H, Nijs J, Feskens R, Meeus M, Moorkens G, Bleijenberg G.	Expert Centre for Chronic Fatigue, Radboud University Nijmegen Medical Centre, 4628, PO Box 9101, 6500, HB, Nijmegen, The Netherlands, m.heins@nkcv.umcn.nl.	Influence of Symptom Expectancies on Stair-Climbing Performance in Chronic Fatigue Syndrome: Effect of Study Context	Int J Behav Med. 2012 Aug 4.	BACKGROUND: In patients with chronic fatigue syndrome (CFS), performance of physical activities may be affected by an anticipated increase in symptoms after these activities. Nijs et al. previously studied the influence of symptom expectancies and related psychological processes on the performance of an isolated physical activity [Nijs J, Meeus M, Heins M, Knoop H, Moorkens G, Bleijenberg G. Kinesiophobia, catastrophizing and anticipated symptoms before stair climbing in chronic fatigue syndrome: an experimental study. Disabil Rehabil 2012. doi: 10.3109/09638288.2011.641661 .]. PURPOSE: We aimed to validate the previous findings in a larger group of patients in a different setting. We also extended the possible underlying psychological processes studied. METHOD: In 49 CFS patients, we measured performance (duration and increase in heart rate) during self-paced

				climbing and descending of two floors of stairs. Before this task, patients rated experienced fatigue and anticipated fatigue after stair climbing. In addition, kinesiophobia, catastrophising and focusing on bodily symptoms were measured. Using correlational and regression analyses, we tested whether performance during stair climbing could be explained by experienced and anticipated fatigue and psychological factors. RESULTS: Longer duration of stair climbing correlated with higher anticipated fatigue, independently of sex, age, body mass index and fatigue before stair climbing. Focusing on bodily symptoms and fatigue-related catastrophising were related to anticipated fatigue. CONCLUSION: Symptom expectations affect the performance of physical activity in CFS patients, possibly through focusing on bodily symptoms and catastrophising. These findings partially contradict the findings of the previous study, which stresses the importance of study context in conducting this type of experiments (i.e., patient characteristics, instructions).
Heins MJ, Knoop H, Lobbestael J, Bleijenberg G.	Expert Centre for Chronic Fatigue, Radboud University Nijmegen Medical Centre, The Netherlands. m.heins@nkcv.umcn.nl	Childhood maltreatment and the response to cognitive behavior therapy for chronic fatigue syndrome.	J Psychosom Res. 2011 Dec;71(6):404-10. doi: 10.1016/j.jpsychores.2011.05.005.	OBJECTIVE: To examine the relationship between a history of childhood maltreatment and the treatment response to cognitive behavior therapy for chronic fatigue syndrome (CFS). METHODS: A cohort study in a tertiary care clinic with a referred sample of 216 adult patients meeting the Centers for Disease Control and Prevention criteria for CFS, and starting cognitive behavior therapy. Main outcome measures changes between pre- and post therapy in fatigue (Checklist Individual Strength fatigue subscale), disabilities (Sickness Impact Profile total score), physical functioning (short form 36 health survey subscale) and psychological distress (Symptom checklist 90 total score). RESULTS: At baseline, patients with a history of childhood maltreatment had significantly more limitations and a higher level of psychological distress, but were not more severely fatigued. Change scores on the outcome measures after cognitive behavior therapy did not differ significantly between patients with or without a history of childhood maltreatment, or between the different types of childhood maltreatment. However, patients with a history of childhood maltreatment still experienced more limitations and a higher level of psychological distress after CBT. CONCLUSIONS: A history of childhood maltreatment was not related to the treatment response of cognitive behavior therapy for CFS. In patients with a history of childhood maltreatment CFS symptoms can be treated with CBT just as well as those without.
Helfenstein M Jr, Goldenfum MA, Siena CA.	Universidade Federal de São Paulo, São Paulo, SP, Brazil. m.helfen@terra.com.br	Fibromyalgia: clinical and occupational aspects. [Article in English & Portuguese]	Rev Assoc Med Bras. 2012 Jun;58(3):358-65.	Fibromyalgia (FM) is a clinical syndrome commonly observed in daily medical practice and its etiopathogenesis is still unclear. As it is characterized by chronic musculoskeletal pain associated with several symptoms, FM may be confused with several other rheumatic and nonrheumatic diseases when they course with pictures of diffuse pain and chronic fatigue. FM treatment should be multidisciplinary, individualized, count on active participation of the patient, and based on combined pharmacological and nonpharmacological modalities. It is found both in work and

				non-work settings, and there is no scientific evidence in the literature showing that FM might be caused by occupation. FM seldom leads to incapacity to work. In cases where pain or fatigue do not respond to appropriate treatment, reaching significant levels, a short period away from work can be considered. As FM is a relevant subject, this review article was based on exploratory, qualitative, and bibliographic investigation, aiming to study the main clinical and occupational aspects of FM, emphasizing the theoretical-conceptual background and the experience of specialists.
Henningsen P, Martin A.	Klinik für Psychosomatische Medizin und Psychotherapie, Klinikum rechts der Isar der TU München	Chronic fatigue syndrome [Article in German]	Dtsch Med Wochenschr. 2013 Jan;138(1-2):33-8. doi: 10.1055/s-0032-1327358.	Enduring and disabling fatigue that cannot be explained by a known disease is the main characteristic of chronic fatigue syndrome. Several definitions do exist, and classification approaches vary regarding supplementary symptoms, time course, and by implicit concepts of aetiology. CFS can be considered as a functional somatic syndrome, e.g. supported by the high rates of comorbid bodily complaints and syndromes that lack clear medical explanation. Accordingly the diagnostic process should not be limited to the thorough physical examination, but also address additional somatic complaints, psychosocial factors (specifically subjective illness beliefs), and impairments. Recently German medical and psychological societies provided treatment guidelines for functional somatic syndromes. Cognitive behavioural therapy and graded activity are evidence based treatment methods for CFS.
Ho RT, Chan JS, Wang CW, Lau BW, So KF, Yuen LP, Sham JS, Chan CL.	Centre on Behavioral Health, The University of Hong Kong, China. tinho@hku.hk	A randomized controlled trial of qigong exercise on fatigue symptoms, functioning, and telomerase activity in persons with chronic fatigue or chronic fatigue syndrome.	Ann Behav Med. 2012 Oct;44(2):160-70. doi: 10.1007/s12160-012-9381-6. Comment in Ann Behav Med. 2012 Oct;44(2):145-6.	BACKGROUND: Chronic fatigue is common in the general population. Complementary therapies are often used by patients with chronic fatigue or chronic fatigue syndrome to manage their symptoms. PURPOSE: This study aimed to assess the effect of a 4-month qigong intervention program among patients with chronic fatigue or chronic fatigue syndrome. METHODS: Sixty-four participants were randomly assigned to either an intervention group or a wait list control group. Outcome measures included fatigue symptoms, physical functioning, mental functioning, and telomerase activity. RESULTS: Fatigue symptoms and mental functioning were significantly improved in the qigong group compared to controls. Telomerase activity increased in the qigong group from 0.102 to 0.178 arbitrary units ($p < 0.05$). The change was statistically significant when compared to the control group ($p < 0.05$). CONCLUSION: Qigong exercise may be used as an alternative and complementary therapy or rehabilitative program for chronic fatigue and chronic fatigue syndrome.
Hollingsworth KG, Hodgson T, Macgowan GA, Blamire AM, Newton JL.	Newcastle Magnetic Resonance Centre, Institute of Cellular Medicine, Newcastle University, NE4 5PL, Newcastle upon Tyne, UK. k.g.hollingsworth@ncl.	Impaired cardiac function in chronic fatigue syndrome measured using magnetic resonance cardiac tagging.	J Intern Med. 2012 Mar;271(3):264-70. doi: 10.1111/j.1365-2796.2011.02429.x.	OBJECTIVES: Impaired cardiac function has been confirmed in patients with chronic fatigue syndrome (CFS). Magnetic resonance cardiac tagging is a novel technique that assesses myocardial wall function in vivo. We hypothesized that patients with CFS may have impaired development and release of myocardial torsion and strain. METHODS: Cardiac morphology and function were assessed using magnetic resonance imaging and cardiac tagging methodology in 12 CFS patients (Fukuda) and 10 matched controls. RESULTS: Compared to controls, the CFS group had substantially reduced left ventricular mass (reduced by 23%), end-diastolic volume (30%), stroke

	ac.uk			volume (29%) and cardiac output (25%). Residual torsion at 150% of the end-systolic time was found to be significantly higher in the patients with CFS (5.3 ± 1.6°) compared to the control group (1.7 ± 0.7°, P = 0.0001). End-diastolic volume index correlated negatively with both torsion-to-endocardial-strain ratio (TSR) (r = -0.65, P = 0.02) and the residual torsion at 150% end-systolic time (r = -0.76, P = 0.004), so decreased end-diastolic volume is associated with raised TSR and torsion persisting longer into diastole. Reduced end-diastolic volume index also correlated significantly with increased radial thickening (r = -0.65, P = 0.03) and impaired diastolic function represented by the ratio of early to late ventricular filling velocity (E/A ratio, r = 0.71, P = 0.009) and early filling percentage (r = 0.73, P = 0.008). CONCLUSION: Patients with CFS have markedly reduced cardiac mass and blood pool volumes, particularly end-diastolic volume: this results in significant impairments in stroke volume and cardiac output compared to controls. The CFS group appeared to have a delay in the release of torsion.
Hong P, Li J.	National Center for Clinical Laboratories, Beijing Hospital of the Ministry of Health, Beijing, People's Republic of China. Pinghong98@yahoo.com	Lack of evidence for a role of xenotropic murine leukemia virus-related virus in the pathogenesis of prostate cancer and/or chronic fatigue syndrome.	Virus Res. 2012 Jul;167(1):1-7. doi: 10.1016/j.virusres.2012.04.004.	Since the discovery of xenotropic murine leukemia virus-related virus (XMRV) in 2006, one of the most controversial topics is whether it contributes to the pathogenesis of prostate cancer (PCa) and/or chronic fatigue syndrome (CFS). The debate began with the failure to detect XMRV in clinical PCa samples. Concerns about the potential health risk of XMRV exposure were reinforced by a study demonstrating the presence of XMRV in patients with CFS. However, serious concerns on whether XMRV plays a role in the development of PCa and/or CFS have been raised. However, inconsistent reports linking XMRV with PCa and/or CFS have led to conflicting views about the potential of XMRV as a human pathogen. Several recent studies suggest that contamination could account for the positive correlations between XMRV and PCa and/or CFS to date. At present, evidence does not indicate that XMRV plays any role in the pathogenesis of PCa or CFS.
Hooper PL, Hightower LE, Hooper PL.	Division of Endocrinology, Metabolism, and Diabetes, School of Medicine, University of Colorado, Anschutz Medical Campus, Aurora, CO 80045, USA. phoopermd@gmail.com	Loss of stress response as a consequence of viral infection: implications for disease and therapy.	Cell Stress Chaperones. 2012 Nov;17(6):647-55. doi: 10.1007/s12192-012-0352-4.	Herein, we propose that viral infection can induce a deficient cell stress response and thereby impairs stress tolerance and makes tissues vulnerable to damage. Having a valid paradigm to address the pathological impacts of viral infections could lead to effective new therapies for diseases that have previously been unresponsive to intervention. Host response to viral infections can also lead to autoimmune diseases like type 1 diabetes. In the case of Newcastle disease virus, the effects of viral infection on heat shock proteins may be leveraged as a therapy for cancer. Finally, the search for a specific virus being responsible for a condition like chronic fatigue syndrome may not be worthwhile if the disease is simply a nonspecific response to viral infection.
Hornig M, Briese T, Licinio J, Khabbaz RF, Altshuler LL,	Center for Infection and Immunity, Columbia University	Absence of evidence for bornavirus infection in	Mol Psychiatry. 2012 May;17(5):486-93. doi: 10.1038/mp.2011.179.	In 1983, reports of antibodies in subjects with major depressive disorder (MDD) to an as-yet uncharacterized infectious agent associated with meningoencephalitis in horses and sheep led to molecular cloning of the genome of a novel, negative-

Potkin SG, Schwemmle M, Siemetzki U, Mintz J, Honkavuori K, Kraemer HC, Egan MF, Whybrow PC, Bunney WE, Lipkin WI.	Mailman School of Public Health, New York, NY 10032, USA. mady.hornig@columbia.edu	schizophrenia, bipolar disorder and major depressive disorder.	Comment in Mol Psychiatry. 2012 May;17(5):472-3.	stranded neurotropic virus, Borna disease virus (BDV). This advance has enabled the development of new diagnostic assays, including in situ hybridization, PCR and serology based on recombinant proteins. Since these assays were first implemented in 1990, more than 80 studies have reported an association between BDV and a wide range of human illnesses that include MDD, bipolar disorder (BD), schizophrenia (SZ), anxiety disorder, chronic fatigue syndrome, multiple sclerosis, amyotrophic lateral sclerosis, dementia and glioblastoma multiforme. However, to date there has been no blinded case-control study of the epidemiology of BDV infection. Here, in a United States-based, multi-center, yoked case-control study with standardized methods for clinical assessment and blinded serological and molecular analysis, we report the absence of association of psychiatric illness with antibodies to BDV or with BDV nucleic acids in serially collected serum and white blood cell samples from 396 subjects, a study population comprised of 198 matched pairs of patients and healthy controls (52 SZ/control pairs, 66 BD/control pairs and 80 MDD/control pairs). Our results argue strongly against a role for BDV in the pathogenesis of these psychiatric disorders.
Hsu ES.	Department of Anesthesiology, David Geffen School of Medicine at UCLA, Los Angeles, CA, USA. ehsu@mednet.ucla.edu	Acute and chronic pain management in fibromyalgia: updates on pharmacotherapy.	Am J Ther. 2011 Nov;18(6):487-509. doi: 10.1097/MJT.0b013e3181d6b6d4.	Fibromyalgia (FM) is a mysterious pain syndrome with progressive and widespread pain, explicit areas of tender points, stiffness, sleep disturbance, fatigue, and psychological distress without any obvious disease. FM is commonly perceived as a condition of central pain and sensory augmentation. There are documented functional abnormalities in pain and sensory processing in FM. Central sensitization and lack of descending analgesic activity are the 2 leading mechanisms that have been demonstrated by advance in both basic and clinical research. The pathogenesis of FM may also be attributed to the genetic polymorphisms involving serotoninergic, dopaminergic, and catecholaminergic systems. Any psychiatric disorders and psychosocial influences in FM may also affect the severity of pain. The various external stimuli or trigger such as infection, trauma, and stress may all contribute to proceed to presentation of FM. The recent launches of 3 US Food and Drug Administration-approved pharmacotherapy for FM namely pregabalin, duloxetine, and milnacipran have certainly raised the profile of optimal chronic pain management. However, appropriate evaluation and efficacious management of acute pain has not been as well publicized as chronic pain in FM. Acute pain or flare up caused by any trauma or surgery certainly may present a real challenge for patients with FM and their health care providers. Pre-emptive analgesia and pro-active treatment may offer the momentum for acute pain control based on model of central sensitization and pain in FM. This review article on FM appraises the modern practice of multimodal therapy focus on both acute and chronic pain management. Meanwhile, the evolving nonpharmacological approach is summarized and stressed as an essential component of integrated care in FM.
Hunskar GS,	Department of Public	The impact of atopic	Scand J Gastroenterol. 2012	OBJECTIVE: To investigate whether atopic disease influences the prevalence of

Langeland N, Wensaas KA, Hanevik K, Eide GE, Mørch K, Rortveit G.	Health and Primary Health Care, University of Bergen, Norway. gunnhild.hunskar@student.uib.no	disease on the risk of post-infectious fatigue and irritable bowel syndrome 3 years after Giardia infection. A historic cohort study.	Sep;8-9(47):956-61. doi: 10.3109/00365521.2012.696681.	irritable bowel syndrome (IBS) and chronic fatigue (CF) after giardiasis. METHODS: A questionnaire was sent to all confirmed cases of giardiasis after a Norwegian outbreak, with response rate of 65.3% (817/1252). Controls were randomly selected matched on age and sex, with response rate of 31.4% (1128/3598). Associations were evaluated by use of logistic regression analyses. RESULTS: In the Giardia exposed group, 47.8% of those with asthma had IBS compared with 45.3% in those without asthma (p = 0.662). For controls, corresponding percentages were 23.9% and 12.2% (p < 0.001). Among those with asthma, the adjusted relative risk (RR) for IBS was 2.03 (95% confidence interval (CI): 1.45, 2.62) for the exposed group compared with controls. In those without asthma, the corresponding RR was 3.80 (95% CI: 3.30, 4.32). In the exposed group, 51.5% of those with asthma had CF compared with 44.9% in those without asthma (p = 0.218). For controls, corresponding percentages were 19.3% and 10.7% (p = 0.004). Among those with asthma, the adjusted RR for CF was 2.73 (95% CI: 1.98, 3.45) for the exposed compared with controls. In those without asthma, the corresponding RR for CF was 4.25 (95% CI: 3.66, 4.85). CONCLUSION: For the exposed, having asthma or allergy did not increase the outcome of IBS or CF. For the control group, having an atopic disease made a substantial risk difference, with significantly more IBS and CF.
Iannuccelli C, Sarzi-Puttini P, Atzeni F, Cazzola M, di Franco M, Guzzo MP, Bazzichi L, Cassisi GA, Marsico A, Stisi S, Salaffi F.	La Sapienza University, Rome, Italy.	Psychometric properties of the Fibromyalgia Assessment Status (FAS) index: a national web-based study of fibromyalgia.	Clin Exp Rheumatol. 2011 Nov-Dec;29(6 Suppl 69):S49-54.	Fibromyalgia (FM) is a generalized chronic pain condition that is often accompanied by symptoms such as fatigue, sleep disturbances, psychological and cognitive alterations, headache, migraine, variable bowel habits, diffuse abdominal pain, and urinary frequency. Its key assessment domains include pain, fatigue, disturbed sleep, physical and emotional functioning, and patient global satisfaction and health-related quality of life (HRQL). A number of evaluation measures have been adapted from the fields of rheumatoid arthritis, psoriatic arthritis and ankylosing spondylitis, and others such as the Fibromyalgia Assessment Status (FAS) index and the Fibromyalgia Impact Questionnaire (FIQ) have been specifically developed. The aim of this study was to assess the impact of FM on HRQL by comparing the performance of the FAS index, the FIQ and the Health Assessment Questionnaire [HAQ] in 541 female and 31 male FM patients (mean age 50 years; mean disease duration 7.7 years) entered in the database of a web-based survey registry developed by the Italian Fibromyalgia Network (IFINET). Tests of convergent validity showed that the FAS index and FIQ significantly correlated with each other (rho=0.608, p<0.0001), but there were also significant correlations between the FAS index and other clinical measures of disability, including the HAQ (rho=0.423, p<0.0001), anxiety (rho=0.138, p=0.0009), depression (rho=0.174, p<0.0001) and, especially, the number of comorbidities (rho=0.147, p=0.0004). The FAS index revealed a statistically significant difference between males and females (p=0.048), analysed using the Mann-Whitney U-test for all pair wise comparisons. The FAS index is a valid three-item instrument (pain, fatigue and sleep disturbances) that performs at least as well as the FIQ in FM patients, and

				is simpler to administer and score. Both questionnaires may be useful when screening FM patients, with the choice of the most appropriate instrument depending on the setting.
Israeli E.	The Zabludowicz Center for Autoimmune Diseases, Chaim Sheba Medical Center, Tel-Hashomer, Israel. eitanister@gmail.com	Gulf War syndrome as a part of the autoimmune (autoinflammatory) syndrome induced by adjuvant (ASIA).	Lupus. 2012 Feb;21(2):190-4. doi: 10.1177/0961203311429552.	Gulf War syndrome (GWS) is a multi-symptom condition comprising a variety of signs and symptoms described in the literature, which not been fully resolved. The various symptoms of the condition include muscle fatigue and tiredness, malaise, myalgia, impaired cognition, ataxia, diarrhoea, bladder dysfunction, sweating disturbances, headaches, fever, arthralgia, skin rashes, and gastrointestinal and sleep disturbances. In addition, excessive chemical sensitivity and odour intolerance is reported. The aetiology of the condition is unclear, but many reviews and epidemiological analyses suggest association with pyridostigmine bromide (PB), certain vaccination regimes, a variety of possible chemical exposures, including smoke from oil-well fires or depleted uranium from shells, as well as physical and psychological stress. Recently, Shoenfeld et al. suggested that four conditions--siliconosis, macrophagic myofaciitis (MMF), GWS and post-vaccination phenomena--that share clinical and pathogenic resemblances, may be incorporated into common syndrome called 'Autoimmune (Autoinflammatory) Syndrome induced by Adjuvants' (ASIA). Symptoms and signs of the four conditions described by Shoenfeld et al. show that at least eight out of ten main symptoms are in correlation in all four conditions. Namely, myalgia, arthralgias, chronic fatigue, neurological cognitive impairment, gastrointestinal symptoms, respiratory symptoms, skin manifestations and appearance of autoantibodies. Regardless of the aetiology of GWS, be it exposure to environmental factors or chemical drugs, vaccinations or the adjuvants in them, GWS fits well with the definition of ASIA and is included as part of 'Shoenfeld's syndrome'.
Itoh Y, Shigemori T, Igarashi T, Fukunaga Y.	Department of Pediatrics, Nippon Medical School, Sendagi, Bukyo City, Tokyo, Japan. yasuhiko@nms.ac.jp	Fibromyalgia and chronic fatigue syndrome in children.	Pediatr Int. 2012 Apr;54(2):266-71. doi: 10.1111/j.1442-200X.2011.03514.x	BACKGROUND: Fibromyalgia (FM) is characterized by widespread persistent pain and the presence of multiple discrete tender points. Chronic fatigue syndrome (CFS) is a syndrome characterized by debilitating fatigue associated with a variable number of non-specific complaints. Because neither condition had necessarily been recognized in children until recently, those patients have been treated as having school refusal without being diagnosed as having either syndrome. There is a considerable overlap of clinical symptoms between these two syndromes. It is therefore controversial as to whether these syndromes have the same pathogenesis or not. The aim of the present study was to clarify the relationship between these syndromes in children. METHODS: Fifteen patients with FM and 21 patients with CFS were investigated both clinically and immunologically. Immunological assessments included thorough analysis of autoantibodies using several techniques. RESULTS: Anti-nuclear antibody titers were higher and the prevalence of anti-Sa antibody was far more frequent in CFS patients than in FM patients. CONCLUSION: CFS and FM are different from each other at least in childhood, from an immunological aspect, although some patients could have both conditions.

Jackson ML, Bruck D.	School of Social Sciences and Psychology, Victoria University, Victoria, Australia.	Sleep abnormalities in chronic fatigue syndrome/myalgic encephalomyelitis: a review.	J Clin Sleep Med. 2012 Dec 15;8(6):719-28. doi: 10.5664/jcsm.2276.	Chronic fatigue syndrome/myalgic encephalomyelitis (CFS/ME) is a chronic, disabling illness that affects approximately 0.2% of the population. Non-restorative sleep despite sufficient or extended total sleep time is one of the major clinical diagnostic criteria; however, the underlying cause of this symptom is unknown. This review aims to provide a comprehensive overview of the literature examining sleep in CFS/ME and the issues surrounding the current research findings. Polysomnographic and other objective measures of sleep have observed few differences in sleep parameters between CFS/ME patients and healthy controls, although some discrepancies do exist. This lack of significant objective differences contrasts with the common subjective complaints of disturbed and unrefreshed sleep by CFS/ME patients. The emergence of new, more sensitive techniques that examine the microstructure of sleep are showing promise for detecting differences in sleep between patients and healthy individuals. There is preliminary evidence that alterations in sleep stage transitions and sleep instability, and other physiological mechanisms, such as heart rate variability and altered cortisol profiles, may be evident.Future research investigating the etiology of non-restorative sleep in CFS/ME may also help us to undercover the causes of non-restorative sleep and fatigue in other medical conditions
Jahan F, Nanji K, Qidwai W, Qasim R.	[No address quoted]	Fibromyalgia syndrome: an overview of pathophysiology, diagnosis and management.	Oman Med J. 2012 May;27(3):192-5. doi: 10.5001/omj.2012.44.	Fibromyalgia Syndrome (FMS) is a chronic condition causing pain, stiffness, and tenderness of the muscles, tendons, and joints. It is also characterized by restless sleep, tiredness, fatigue, anxiety, depression, and disturbances in bowel functions. The etiology of fibromyalgia remains unknown, but recent advances and discoveries have helped to unravel some of the mysteries of this disease. Research highlights some of the biochemical, metabolic, and immunoregulatory abnormalities associated with fibromyalgia. Management of FMS at the present time is very difficult as it has multiple etiological factors and psychological predispositions; however, a patient centered approach is essential to handle this problem.
Jammes Y, Steinberg JG, Delliaux S.	UMR MD2 P2COE, Faculty of Medicine, Aix-Marseille University and Clinical Respiratory Physiology and Exercise Testing Laboratory, Thorax Pole, National Assistance - Hospitals in Marseille, Marseille, France. yves.jammes@univmed.fr	Chronic fatigue syndrome: acute infection and history of physical activity affect resting levels and response to exercise of plasma oxidant/antioxidant status and heat shock proteins.	J Intern Med. 2012 Jul;272(1):74-84. doi: 10.1111/j.1365-2796.2011.02488.x	OBJECTIVES: A history of high-level physical activity and/or acute infection might constitute stress factors affecting the plasma oxidant-antioxidant status and levels of heat shock proteins (HSPs) in patients with chronic fatigue syndrome (CFS). DESIGN: This case-control study compared data from 43 CFS patients to results from a matched control group of 23 healthy sedentary subjects. SETTING AND SUBJECTS: Five patients had no relevant previous history (group I). Eighteen had practised high-level sport (group II), and severe acute infection had been diagnosed in nine patients (group III). A combination of sport practice and infection was noted in 11 patients (group IV). INTERVENTIONS: After examination at rest, all subjects performed a maximal cycling exercise test. Plasma levels of two markers of oxidative stress [thiobarbituric acid reactive substances (TBARS) and reduced ascorbic acid (RAA)] and both HSP27 and HSP70 were measured. RESULTS: At rest, compared with the control group, the TBARS level was higher in groups II, III and IV patients, and the RAA level

				was lower in groups III and IV. In addition, HSP70 levels were significantly lower in all CFS groups, compared with controls, but negative correlations were found between resting HSP27 and HSP70 levels and the history of physical activity. After exercise, the peak level of TBARS significantly increased in groups II, III and IV, and the variations in HSP27 and HSP70 were attenuated or suppressed, with the greatest effects in groups III and IV. CONCLUSION: The presence of stress factors in the history of CFS patients is associated with severe oxidative stress and the suppression of protective HSP27 and HSP70 responses to exercise.
Jason L, Sorenson M, Sebally K, Alkazemi D, Lerch A, Porter N, Kubow S.	Department of Psychology, DePaul University, Chicago, IL 60614, United States.	Increased HDAC in association with decreased plasma cortisol in older adults with chronic fatigue syndrome.	Brain Behav Immun. 2011 Nov;25(8):1544-7. doi: 10.1016/j.bbi.2011.04.007.	Hypocortisolism is a frequent finding in individuals with chronic fatigue syndrome (CFS) with other research findings implying potential dysregulation of glucocorticoid signaling. Glucocorticoid signaling is under the influence of several pathways, several of which are of interest in the study of CFS. Oxidative stress and decreased antioxidant capacity are known to disrupt the hypothalamic-pituitary-adrenal (HPA) axis (Epel et al., 2004) and the presence of histone deacetylases (HDAC) could also impact glucocorticoid signaling. The intent of this pilot study was to investigate the relationship among oxidative stress elements, select HDAC's (2/3) and glucocorticoid receptor signaling in an elderly sample with CFS. Findings suggest increased histone deacetylase activity, lower total antioxidant power, in the context of decreased plasma cortisol and increased plasma dehydroepiandrosterone concomitant with decreased expression of the encoding gene for the glucocorticoid receptor. These findings support the presence of HPA axis dysregulation in elderly individuals with CFS.
Jason LA, Brown A, Clyne E, Bartgis L, Evans M, Brown M.	DePaul University, Chicago, IL 60614, USA.	Contrasting case definitions for chronic fatigue syndrome, Myalgic Encephalomyelitis/chronic fatigue syndrome and myalgic encephalomyelitis.	Eval Health Prof. 2012 Sep;35(3):280-304. doi: 10.1177/0163278711424281.	This article uses data from patients recruited using the 1994 case definition of chronic fatigue syndrome (CFS) to contrast those meeting criteria for the Myalgic Encephalomyelitis/chronic fatigue syndrome (ME/CFS) Canadian case definition with those that did not meet these criteria. The study also contrasts those meeting criteria for Myalgic Encephalomyelitis (ME) based on criteria from Ramsay and other theorists with those that did not meet the ME criteria. The ME/CFS case definition criteria identified a subset of patients with more functional impairments and physical, mental, and cognitive problems than the subset not meeting these criteria. The ME subset had more functional impairments, and more severe physical and cognitive symptoms than the subset not meeting ME criteria. When applied to a population meeting the 1994 CFS case definition, both ME/CFS and ME criteria appear to select a more severe subset of patients.
Jason LA, Brown MM.	Center for Community Research , DePaul University , Chicago, IL , USA.	Sub-typing daily fatigue progression in chronic fatigue syndrome.	J Ment Health. 2012 May 1.	Background Activity logs involve patients writing down their activities and symptoms over 1 or more days. Aims This study sought to classify daily fatigue patterns among patients with chronic fatigue syndrome (CFS) using activity logs. Method Fatigue intensity was self-reported every 30 min in a sample of 90 patients with CFS over 1 day. A cluster analysis using fatigue intensity, variability and slope was conducted. Results Three clusters emerged involving patients with different trajectories. One

				group evidenced high fatigue intensity, low variability, and fatigue intensity stayed the same over time. A second group had moderate fatigue intensity, high variability, and fatigue intensity decreased over time. A third group had moderate fatigue intensity, high variability, but fatigue intensity increased over time. The three clusters of patients differed on measures of actigraphy, pain and immune functioning. Conclusions Activity logs can provide investigators and clinicians with valuable sources of data for understanding patterns of fatigue and activity among patients with CFS.
Jason LA, Skendrovic B, Furst J, Brown A, Weng A, Bronikowski C.	DePaul University, USA. Ljason@depaul.edu	Data mining: comparing the empiric CFS to the Canadian ME/CFS case definition.	J Clin Psychol. 2012 Jan;68(1):41-9. doi: 10.1002/jclp.20827.	This article contrasts two case definitions for myalgic encephalomyelitis/chronic fatigue syndrome (ME/CFS). We compared the empiric CFS case definition (Reeves et al., 2005) and the Canadian ME/CFS clinical case definition (Carruthers et al., 2003) with a sample of individuals with CFS versus those without. Data mining with decision trees was used to identify the best items to identify patients with CFS. Data mining is a statistical technique that was used to help determine which of the survey questions were most effective for accurately classifying cases. The empiric criteria identified about 79% of patients with CFS and the Canadian criteria identified 87% of patients. Items identified by the Canadian criteria had more construct validity. The implications of these findings are discussed.
Jason LA, Unger ER, Dimitrakoff JD, Fagin AP, Houghton M, Cook DB, Marshall GD Jr, Klimas N, Snell C.	DePaul University, United States. LJason@DePaul.edu	Minimum data elements for research reports on CFS.	Brain Behav Immun. 2012 Mar;26(3):401-6. doi: 10.1016/j.bbi.2012.01.014.	Chronic fatigue syndrome (CFS) is a debilitating condition that has received increasing attention from researchers in the past decade. However, it has become difficult to compare data collected in different laboratories due to the variability in basic information regarding descriptions of sampling methods, patient characteristics, and clinical assessments. The issue of variability in CFS research was recently highlighted at the NIH's 2011 State of the Knowledge of CFS meeting prompting researchers to consider the critical information that should be included in CFS research reports. To address this problem, we present our consensus on the minimum data elements that should be included in all CFS research reports, along with additional elements that are currently being evaluated in specific research studies that show promise as important patient descriptors for subgrouping of CFS. These recommendations are intended to improve the consistency of reported methods and the interpretability of reported results. Adherence to minimum standards and increased reporting consistency will allow for better comparisons among published CFS articles, provide guidance for future research and foster the generation of knowledge that can directly benefit the patient.
Jason LA.	DePaul University, Chicago, IL, USA. ljason@depaul.edu	Small wins matter in advocacy movements: giving voice to patients.	Am J Community Psychol. 2012 Jun;49(3-4):307-16. doi: 10.1007/s10464-011-9457-7.	In this article, the various players are delineated in a story of a contested illness and patient advocacy, played out within the corridors of federal power. It is suggested that the mistreatment and negative attitudes that health care providers and others have towards those with chronic fatigue syndrome (CFS) is possibly due to the social construction of this illness as being a "Yuppie flu" disease. Institutional factors are identified that created these norms and attributions, as well as the multiple stakeholders and constituent groups invested in exerting pressure on policy makers to

				effect systemic change. This article also provides examples of how the field of Community Psychology, which is fundamentally committed to/based on listening to and giving voice to patients, is broadly relevant to patient activism communities. This approach focused, over time, on epidemiological studies, the name, the case definition, and ultimately the change in CFS leadership at the Centers for Disease Control and Prevention. Keys to this "small wins" approach were coalition building, use of "oppositional experts" (professionals in the scientific community who support patient advocacy goals) to challenge federal research, and taking advantage of developing events/shifts in power. Ultimately, this approach can result in significant scientific and policy gains, and changes in medical and public perception of an illness.
Jelsness-Jørgensen LP, Bernklev T, Henriksen M, Torp R, Moum B.	Department of Gastroenterology, Oslo University Hospital Aker and Østfold Hospital Trust, 1603 Fredrikstad, Norway. l.p.jelsness-jorgensen@medisin.uio.no	Chronic fatigue is associated with increased disease-related worries and concerns in inflammatory bowel disease.	World J Gastroenterol. 2012 Feb 7;18(5):445-52. doi: 10.3748/wjg.v18.i5.445.	AIM: To investigate the impact of chronic fatigue on disease-related worries in inflammatory bowel disease (IBD) and the potential multicolinearity between subjective questionnaires. METHODS: Patients in remission or with mild-to-moderate disease activity completed the fatigue questionnaire (FQ), the rating form of IBD patient concerns (RFIPC), the Short-Form 36 (SF-36), and IBD questionnaire (N-IBDQ). In addition, clinical and epidemiological data were obtained. RESULTS: In total, 140 patients were included; of which 92 were diagnosed with ulcerative colitis and 48 with Crohn's disease. The mean age of patients with chronic fatigue was 44.2 years (SD = 15.8) and for non-fatigued patients was 44.7 years (SD = 16.0). Chronic fatigued patients had clinically significantly increased levels of disease-related worries, as measured by Cohen's d effect size. Worries about having an ostomy bag, loss of bowel control, and energy levels were most prominent in both chronic fatigued and non-chronic fatigued IBD patients. Variance inflation factor (VIF) and tolerance indicated that there were no problematic multicolinearity among the FQ, RFIPC, SF-36 and N-IBDQ responses (VIF < 5 and tolerance > 2). CONCLUSION: Chronic fatigue is associated with increased levels of disease-related worries and concerns in IBD. Increased levels of worries were also associated with impaired health-related quality of life.
Jones DE, Hollingsworth KG, Jakovljevic DG, Fattakhova G, Pairman J, Blamire AM, Trenell MI, Newton JL.	Institute of Cellular Medicine Newcastle, Newcastle University, Newcastle, UK.	Loss of capacity to recover from acidosis on repeat exercise in chronic fatigue syndrome: a case-control study.	Eur J Clin Invest. 2012 Feb;42(2):186-94. doi: 10.1111/j.1365-2362.2011.02567.x.	BACKGROUND: Chronic fatigue syndrome (CFS) patients frequently describe difficulties with repeat exercise. Here, we explore muscle bioenergetic function in response to three bouts of exercise. METHODS: A total of 18 CFS (CDC 1994) patients and 12 sedentary controls underwent assessment of maximal voluntary contraction (MVC), repeat exercise with magnetic resonance spectroscopy and cardio-respiratory fitness test to determine anaerobic threshold. RESULT: Chronic fatigue syndrome patients undertaking MVC fell into two distinct groups: 8 (45%) showed normal PCr depletion in response to exercise at 35% of MVC (PCr depletion >33%; lower 95% CI for controls); 10 CFS patients had low PCr depletion (generating abnormally low MVC values). The CFS whole group exhibited significantly reduced anaerobic threshold, heart rate, VO(2) , VO(2) peak and peak work compared to controls. Resting muscle pH was similar in controls and both CFS patient groups. However, the CFS group

				achieving normal PCr depletion values showed increased intramuscular acidosis compared to controls after similar work after each of the three exercise periods with no apparent reduction in acidosis with repeat exercise of the type reported in normal subjects. This CFS group also exhibited significant prolongation (almost 4-fold) of the time taken for pH to recover to baseline. CONCLUSION: When exercising to comparable levels to normal controls, CFS patients exhibit profound abnormality in bioenergetic function and response to it. Although exercise intervention is the logical treatment for patients showing acidosis, any trial must exclude subjects who do not initiate exercise as they will not benefit. This potentially explains previous mixed results in CFS exercise trials.
Julkunen H.	HYKS, medisiininen tulosyksikkö, Peijaksen sairaala.	Systemic lupus erythematosus]. [Article in Finnish]	Duodecim. 2012;128(1):51-61.	Systemic lupus erythematosus (SLE) is a chronic syndrome with unknown etiology and polymorphic clinical picture occurring mainly in women. The patients have immunological abnormalities such as autoantibodies against nuclear structures. The prognosis has improved due to active early diagnostics and more efficient treatment of the disease. Mild forms of the disease are associated with fatigue, articular and muscular symptoms, skin rashes, pleuritis or pericarditis and minor changes in the blood. Severe SLE involves glomerulonephritis, complications in the central nervous system, cardiac and pulmonary complications and major changes in the blood.
Kahraman H, Ozkan F, Altınoluk B, Koksal N.	Department of Chest Diseases, Kahramanmaras Sutcuimam University, Turkey.	Scimitar syndrome with renal agenesis.	N Am J Med Sci. 2012 Apr;4(4):193-5. doi: 10.4103/1947-2714.94948.	Partial pulmonary venous connection anomaly is relatively uncommon form of congenital heart diseases. The quite rare combination of this anomaly with hypoplasia of the right lung and dextroposition of the heart is designated as scimitar syndrome. Most cases are presented in infantile period and adult presentation is exceedingly rare. Our patient, a 38-year-old man, was admitted to a doctor with flu-like complaint and because of abnormalities on chest X-ray he was sent to our clinic. He did not have any chronic complaints such as shortness of breath and fatigue. After investigation, scimitar syndrome was diagnosed. Left renal agenesis was determined with abdominal examination. Best of our knowledge in literature we did not detect any case both with Scimitar syndrome and renal agenesis, and we wanted to report the asymptomatic adult Scimitar syndrome case with left renal agenesis.

Kapfhammer HP.	Klinik für Psychiatrie, Medizinische Universität Graz, Auenbruggerplatz 31, 8036 Graz, Österreich. Hans-peter.kapfhammer@kli	Psychopharmacological treatment in patients with somatoform disorders and functional body syndromes. [Article	Nervenarzt. 2012 Sep;83(9):1128-41. doi: 10.1007/s00115-011-3446-9.	Somatoform disorders and functional body syndromes define a major, diagnostically heterogeneous group of patients with medically unexplained physical symptoms. Psychopharmacological approaches can be derived from the conceptualization of somatoform symptoms and syndromes within a biopsychosocial model. The survey presented focuses on randomized, double-blind and placebo-controlled studies. Antidepressants show a statistically and clinically relevant impact on many somatoform symptoms. In special reference to pain symptoms serotonergic and

	nikum-graz.at	in German]		noradrenergic antidepressants seem to mediate a more favorable effect than selective serotonin reuptake inhibitors. For some functional body syndromes, e.g. irritable bowel syndrome and fibromyalgia, a major analgesic effect of antidepressants can be underlined as well. The empirical data for fibromyalgia, however, seem to be more convincing than for irritable bowel syndrome. Pregabalin holds an empirically well established position in the treatment of fibromyalgia. As yet there is no convincing psychopharmacological strategy for chronic fatigue syndrome. Probably due to the inherent relationships to anxiety, obsessive-compulsive and depressive disorders, both hypochondria and body dysmorphic disorder can be positively treated by serotonergic antidepressants as well.

Karakus N, Yigit S, Inanir A, Inanir S, Toprak H, Okan S.	Ondokuz Mayis University, Faculty of Medicine, Department of Medical Biology, Samsun, Turkey; Gaziosmanpasa University, Faculty of Medicine, Department of Medical Biology, Tokat, Turkey.	Association between sequence variations of the Mediterranean fever gene and fibromyalgia syndrome in a cohort of Turkish patients.	Clin Chim Acta. 2012 Dec 24;414:36-40. doi: 10.1016/j.cca.2012.07.019.	OBJECTIVE: Fibromyalgia syndrome (FMS) is a common chronic widespread pain syndrome mainly affecting women. Genetic risk factors are known to contribute to the etiology of the syndrome. Clinical features show that FMS and familial Mediterranean fever (FMF) have some overlapping symptoms. Mediterranean fever (MEFV) gene has already been identified as being responsible for FMF. The aim of this study was to explore the frequency and clinical significance of missense mutations and a common polymorphism of MEFV gene in a cohort of Turkish patients with FMS. METHODS: The study included 187 patients with FMS and 190 healthy controls. Genomic DNA was isolated and genotyped using polymerase chain reaction (PCR) and restriction fragment length polymorphism (RFLP) analyses for the five MEFV gene mutations (M694V, M680I, V726A, E148Q and P369S) and one polymorphism (R202Q). RESULTS: There were statistically significant differences of the MEFV gene mutation carrier rates and allele frequencies between FMS patients and healthy controls (p=0.002, OR: 2.3, 95% CI: 1.35-4.16 and p=0.003, OR: 2.2, 95% CI: 1.28-3.75, respectively). There was also a significant difference between MEFV mutation carriers and non-carriers with respect to the clinical characteristic of morning fatigue (p=0.045). The genotype and allele frequencies of R202Q polymorphism of MEFV gene showed statistically significant differences between FMS patients and healthy controls (p<0.0001 and p<0.0001, respectively) and especially the homozygous AA genotype was significantly higher in FMS patients than in healthy controls (p=0.0003; OR: 7.43, 95% CI: 2.14-39.75). While 13 of the 44 FMS patients with MEFV mutation

				had R202Q polymorphism, none of the 22 controls with MEFV mutation had R202Q polymorphism. Stratification analysis according to clinical features for this disease reveals that morning fatigue and irritable bowel syndrome had associations with R202Q polymorphism (p=0.022 and p=0.031 respectively). CONCLUSION: The results of this study suggest that MEFV gene mutations and polymorphism are positively associated with predisposition to develop FMS. Further studies with larger populations will be required to confirm these findings.

Karthikeyan P, Ramalingam KP.	Department of Physiotherapy, Divine Word University, Madang, Papua New Guinea. pkarthi@dwu.ac.pg	Meningitis: is a major cause of disability amongst Papua New Guinea children?	Disabil Rehabil. 2012;34(18):1585-8. doi: 10.3109/09638288.2011.651190.	PURPOSE: This article is intended to focus on the need for the use of rehabilitation services, for children with meningitis in Papua New Guinea, which is one of largest developing country in The Pacific with diverse culture and landscape. Meningitis is the fifth leading disease that results in disability in the country. The first line of treatment is usually antibiotics, administration of vaccination is also recommended. Currently community based rehabilitation workers and Physiotherapist offer the rehabilitation services. There is a need for the other rehabilitation professionals and appropriate education to the CBR workers, caregivers for providing effective Rehabilitation. METHOD: Articles related to meningitis were recruited through various electronic database such as Ovid SP, MEDLINE, CINHAL, Google Scholar and HINARI and EBSCOhost for full text. The search includes journal articles, editorials, research reports, systematic reviews and books. RESULTS: The neurological sequelae resulting from meningitis are increasing. There is a need for Hib vaccination to reduce the rate of mortality. Physiotherapists are new professionals that emerged since 2006 and are assisting in reducing the motor and neurological disability. CONCLUSIONS: A multidisciplinary approach is required to manage the child with meningitis. Adequate knowledge, resources and assistance about the condition among the health professionals, carers and teachers would enable the children to achieve the quality of life.
Katz BZ, Jason LA	Division of Infectious	Chronic fatigue	Curr Opin Pediatr. 2012 Dec	PURPOSE OF REVIEW: To review the recent epidemiology, pathophysiology, and

	Diseases, Ann and Robert H. Lurie Children's Hospital of Chicago, Northwestern University Feinberg School of Medicine & Center for Community Research, DePaul University, Chicago, Illinois, USA.	syndrome following infections in adolescents	19	treatment of postinfectious chronic fatigue syndrome (CFS) in adolescents. RECENT FINDINGS: Thirteen percent of adolescents (mainly women) met the criteria for CFS 6 months following infectious mononucleosis; the figure was 7% at 12 months and 4% at 24 months. Peak work capacity, activity level, orthostatic intolerance, salivary cortisol, and natural killer cell number and function were similar between adolescents with CFS following infectious mononucleosis and recovered controls. Autonomic system, oxygen consumption, peak oxygen pulse, psychological and cytokine network differences were documented between those who recovered and those who did not. SUMMARY: The prognosis of CFS is better in adolescents than in adults. Activity level, exercise tolerance, and orthostatic testing could not distinguish patients with CFS from adolescents who have recovered from infectious mononucleosis (controls), while certain cytokine network analyses, life stress factors, and autonomic symptoms could.
Katz BZ, Stewart JM, Shiraishi Y, Mears CJ, Taylor R.	Northwestern University, Chicago, IL 60611, USA. bkatz@northwestern.edu	Orthostatic tolerance testing in a prospective cohort of adolescents with chronic fatigue syndrome and recovered controls following infectious mononucleosis.	Clin Pediatr (Phila). 2012 Sep;51(9):835-9. doi: 10.1177/0009922812455094	Chronic fatigue syndrome (CFS) is a complex condition responsible for marked functional impairment. The authors recently reported that 6 months following acute infectious mononucleosis (IM), 13%, of adolescents met criteria for CFS. The authors' objective was to assess standing orthostatic tolerance (SOT) in adolescents with CFS and in controls 6 months following IM. In all, 36 of 39 adolescents diagnosed with CFS 6 months following IM and 43 of 50 recovered controls had SOT testing (SOTT) performed. χ(2) Analysis was performed to study the relationships between SOTT and the diagnosis of CFS. Adolescents diagnosed with CFS and recovered controls did not differ significantly in age, weight, or body mass index. The authors found that 9 of 36 adolescents with CFS (25%) versus 9 of 43 recovered controls (21%) had an abnormal SOTT, which was not a statistically significant difference. Adolescents who meet criteria for CFS 6 months following IM do not have, as a group, more standing orthostatic intolerance than recovered controls.
Kawatani J, Mizuno K, Shiraishi S, Takao M, Joudoi T, Fukuda S, Watanabe Y, Tomoda A.	Department of Child Development, Faculty of Life Sciences, Kumamoto University, Kumamoto, Japan.	Cognitive dysfunction and mental fatigue in childhood chronic fatigue syndrome--a 6-month follow-up study.	Brain Dev. 2011 Nov;33(10):832-41. doi: 10.1016/j.braindev.2010.12.009.	OBJECTIVES: Cognitive function was investigated in patients with childhood type chronic fatigue syndrome (CCFS) using the modified advanced trail making test (mATMT). METHODS: mATMT was performed on 19 patients with CCFS and 25 healthy controls of comparable age and sex. The effectiveness of combined treatment with cognitive behavioral therapy (CBT) and pharmacotherapy and its relationship to cognitive function was investigated by evaluation of Chalder's fatigue scale and behavior state before and after treatment for 6 consecutive months. RESULTS: All three tasks (motor skill, selective and alternative attention, and spatial working memory) of the mATMT, especially the difference in reaction time of the alternative attention task, could discriminate CCFS patients from control subjects with 70.5% accuracy (P=0.007). CCFS patients showed significantly lower alternative attention and Chalder's fatigue score before treatment (P=0.037 and 0.002, respectively). A significant improvement in performance status scores was found during the 6 months follow-up period with combined treatment with CBT and

				medication (P<0.001). Improvement of their cognitive symptoms was significantly correlated with improvement of alternative attention (r=0.653, P=0.002). CONCLUSIONS: Higher-order level cognitive dysfunction affects CCFS pathogenesis. Alternative attention performance evaluated by the mATMT may be used to monitor improvement in patients with CCFS. Combined treatment with CBT and medication may be effective to improve poor attention characteristics associated with CCFS.
Kearney MF, Lee K, Bagni RK, Wiegand A, Spindler J, Maldarelli F, Pinto PA, Linehan WM, Vocke CD, Delviks-Frankenberry KA, Devere White RW, Del Prete GQ, Mellors JW, Lifson JD, Kewalramani VN, Pathak VK, Coffin JM, Le Grice SF.	HIV Drug Resistance Program, National Cancer Institute at Frederick, Frederick, MD 21702-1201, USA.	Nucleic Acid, Antibody, and Virus Culture Methods to Detect Xenotropic MLV-Related Virus in Human Blood Samples.	Adv Virol. 2011;2011:272193. doi: 10.1155/2011/272193.	The MLV-related retrovirus, XMRV, was recently identified and reported to be associated with both prostate cancer and chronic fatigue syndrome. At the National Cancer Institute-Frederick, MD (NCI-Frederick), we developed highly sensitive methods to detect XMRV nucleic acids, antibodies, and replication competent virus. Analysis of XMRV-spiked samples and/or specimens from two pigtail macaques experimentally inoculated with 22Rv1 cell-derived XMRV confirmed the ability of the assays used to detect XMRV RNA and DNA, and culture isolatable virus when present, along with XMRV reactive antibody responses. Using these assays, we did not detect evidence of XMRV in blood samples (N = 134) or prostate specimens (N = 19) from two independent cohorts of patients with prostate cancer. Previous studies detected XMRV in prostate tissues. In the present study, we primarily investigated the levels of XMRV in blood plasma samples collected from patients with prostate cancer. These results demonstrate that while XMRV-related assays developed at the NCI-Frederick can readily measure XMRV nucleic acids, antibodies, and replication competent virus, no evidence of XMRV was found in the blood of patients with prostate cancer.
Kearney MF, Spindler J, Wiegand A, Shao W, Anderson EM, Maldarelli F, Ruscetti FW, Mellors JW, Hughes SH, Le Grice SF, Coffin JM.	HIV Drug Resistance Program, National Cancer Institute, Frederick, Maryland, United States of America. kearneym@mail.nih.gov	Multiple sources of contamination in samples from patients reported to have XMRV infection.	PLoS One. 2012;7(2):e30889. doi: 10.1371/journal.pone.0030889.	Xenotropic murine leukemia virus (MLV)-related retrovirus (XMRV) was reported to be associated with prostate cancer by Urisman, et al. in 2006 and chronic fatigue syndrome (CFS) by Lombardi, et al. in 2009. To investigate this association, we independently evaluated plasma samples from 4 patients with CFS reported by Lombardi, et al. to have XMRV infection and from 5 healthy controls reported to be XMRV uninfected. We also analyzed viral sequences obtained from supernatants of cell cultures found to contain XMRV after coculture with 9 clinical samples from 8 patients. A qPCR assay capable of distinguishing XMRV from endogenous MLVs showed that the viral sequences detected in the CFS patient plasma behaved like endogenous MLVs and not XMRV. Single-genome sequences (N = 89) from CFS patient plasma were indistinguishable from endogenous MLVs found in the mouse genome that are distinct from XMRV. By contrast, XMRV sequences were detected by qPCR in 2 of the 5 plasma samples from healthy controls (sequencing of the qPCR product confirmed XMRV not MLV). Single-genome sequences (N = 234) from the 9 culture supernatants reportedly positive for XMRV were indistinguishable from XMRV sequences obtained from 22Rv1 and XMRV-contaminated 293T cell-lines. These results indicate that MLV DNA detected in the plasma samples from CFS patients evaluated in this study was from contaminating mouse genomic DNA and that XMRV detected in plasma samples from healthy controls and in cultures of patient samples

				was due to cross-contamination with XMRV (virus or nucleic acid).
Keller J, Chen YK, Lin HC.	School of Public Health, Taipei Medical University, Taipei, Taiwan.	Association of bladder pain syndrome/interstitial cystitis with urinary calculus: a nationwide population-based study.	Int Urogynecol J. 2012 Aug 16.	INTRODUCTION AND HYPOTHESIS: Although one prior study reported an association between bladder pain syndrome/interstitial cystitis (BPS/IC) and urinary calculi (UC), no population-based study to date has been conducted to explore this relationship. Therefore, using a population-based data set in Taiwan, this study set out to investigate the association between BPS/IC and a prior diagnosis of UC. METHODS: This study included 9,269 cases who had received their first-time diagnosis of BPS/IC between 2006 and 2007 and 46,345 randomly selected controls. We used conditional logistic regression analysis to compute the odds ratio (OR) and its corresponding 95 % confidence interval (CI) for having been previously diagnosed with UC between cases and controls. RESULTS: There was a significant difference in the prevalence of prior UC between cases and controls (8.1 vs 4.3 %, $p < 0.001$). Conditional logistic regression analysis revealed that cases were more likely to have been previously diagnosed with UC than controls (OR = 1.70; 95 % CI = 1.56-1.84) after adjusting for chronic pelvic pain, irritable bowel syndrome, fibromyalgia, chronic fatigue syndrome, depression, panic disorder, migraine, sicca syndrome, allergy, endometriosis, and asthma. BPS/IC was found to be significantly associated with prior UC regardless of stone location; the adjusted ORs of kidney calculus, ureter calculus, bladder calculus, and unspecified calculus when compared to controls were 1.58 (95 % CI = 1.38-1.81), 1.73 (95 % CI = 1.45-2.05), 3.80 (95 % CI = 2.18-6.62), and 1.83 (95 % CI = 1.59-2.11), respectively. CONCLUSIONS: This work generates the hypothesis that UC may be associated with BPS/IC.
Keller JJ, Liu SP, Lin HC.	School of Public Health, Taipei Medical University, Taipei, Taiwan.	A case-control study on the association between rheumatoid arthritis and bladder pain syndrome/interstitial cystitis.	Neurourol Urodyn. 2012 Nov 5. doi: 10.1002/nau.22348.	AIM: While bladder pain syndrome/interstitial cystitis (BPS/IC) has been suggested by a number of studies to have autoimmune character, no population-based study to date has been conducted investigating its association with rheumatoid arthritis (RA). This study aimed to examine the association between IC/BPS and having previously been diagnosed with RA. METHODS: We conducted this study by using administrative claims data sourced from the Taiwan National Health Insurance Database. Our study included 9,269 cases with BPS/IC and 46,345 randomly selected controls. Conditional logistic regression was performed to calculate the odds ratio (OR) for the association between previously diagnosed RA and IC/BPS. RESULTS: RA was found among 202 (2.2%) cases and 504 (1.12%) controls. Conditional logistic regression analysis suggested that when compared with controls, the OR for prior RA among cases was 1.66 (95% CI = 1.47-1.87, $P < 0.001$) after adjusting for diabetes, hypertension, coronary heart disease, obesity, hyperlipidemia, chronic pelvic pain, irritable bowel syndrome, fibromyalgia, chronic fatigue syndrome, depression, panic disorder, migraine, sicca syndrome, allergy, endometriosis, asthma, overactive bladder, tobacco use disorder, and alcohol abuse. Additionally, BPS/IC was consistently and significantly associated with a previous diagnosis of RA regardless of prescription drug use; the OR for prior RA among groups prescribed ≤1 type of disease-modifying antirheumatic

				drug (DMARD), two types of DMARDs, and ≥3 types of DMARDs or TNF-alpha inhibitor when compared to controls were 1.49 (95% CI = 1.28-1.72), 1.91 (95% CI = 1.38-2.68), and 2.36 (95% CI = 1.77-3.17), respectively. CONCLUSIONS: There is an association between RA and BPS/IC after adjusting for socio-demographic characteristics and medical co-morbidities.
Kempke S, Luyten P, Claes S, Goossens L, Bekaert P, Van Wambeke P, Van Houdenhove B.	Department of Psychology, University of Leuven, Belgium.	Self-critical perfectionism and its relationship to fatigue and pain in the daily flow of life in patients with chronic fatigue syndrome.	Psychol Med. 2012 Aug 30:1-8	BACKGROUND: Research suggests that the personality factor of self-critical or maladaptive perfectionism may be implicated in chronic fatigue syndrome (CFS). However, it is not clear whether self-critical perfectionism (SCP) also predicts daily symptoms in CFS. Method In the present study we investigated whether SCP predicted fatigue and pain over a 14-day period in a sample of 90 CFS patients using a diary method approach. After completing the Depressive Experiences Questionnaire (DEQ) as a measure of SCP, patients were asked each day for 14 days to complete Visual Analogue Scales (VAS) of fatigue, pain and severity of depression. Data were analysed using multilevel analysis. RESULTS: The results from unconditional models revealed considerable fluctuations in fatigue over the 14 days, suggesting strong temporal variability in fatigue. By contrast, pain was relatively stable over time but showed significant inter-individual differences. Congruent with expectations, fixed-effect models showed that SCP was prospectively associated with higher daily fatigue and pain levels over the 14-day period, even after controlling for levels of depression. CONCLUSIONS: This is the first study to show that SCP predicts both fatigue and pain symptoms in CFS in the daily course of life. Hence, therapeutic interventions aimed at targeting SCP should be considered in the treatment of CFS patients with such features.
Kempke S, Luyten P, Van Houdenhove B, Goossens L, Bekaert P, Van Wambeke P.	Department of Psychology, University of Leuven, Tiensestraat 102, 3000 Leuven, Belgium. stefan.kempke@psy.kuleuven.be	Self-esteem mediates the relationship between maladaptive perfectionism and depression in chronic fatigue syndrome.	Clin Rheumatol. 2011 Dec;30(12):1543-8. doi: 10.1007/s10067-011-1772-8.	Patients with chronic fatigue syndrome (CFS) often experience depression which may negatively affect prognosis and treatment outcome. Research has shown that depression in CFS is associated with maladaptive or self-critical perfectionism. However, currently, little is known about factors that may explain this relationship, but studies in nonclinical samples suggest that low self-esteem may be an important mediator of this relationship. The present study therefore examined whether self-esteem mediated the cross-sectional association between maladaptive perfectionism and severity of depression in 192 patients meeting Centres for Disease Control and Prevention criteria for CFS. Patients completed self-report measures of maladaptive perfectionism, self-esteem, depression, and fatigue. Regression analyses and more direct tests of indirect effects (i.e., the Sobel test and bootstrapping) were used to test for mediation. Congruent with expectations, we found that self-esteem fully mediated the relationship between maladaptive perfectionism and depression in CFS. Findings from this study suggest that self-esteem may explain the link between maladaptive perfectionism and depression in CFS, which may have important implications for the treatment and prevention of depression in these patients.
Kempke S, Van	Department of	Prevalence of DSM-	Int J Behav Med. 2012 Oct 13.	BACKGROUND: It is not yet clear whether chronic fatigue syndrome (CFS) is associated

Den Eede F, Schotte C, Claes S, Van Wambeke P, Van Houdenhove B, Luyten P.	Psychology, University of Leuven, Tiensestraat 102, 3000, Leuven, Belgium, Stefan.Kempke@ppw.kuleuven.be.	IV Personality Disorders in Patients with Chronic Fatigue Syndrome: A Controlled Study.		with elevated levels of personality disorders. PURPOSE: This study aims to determine the prevalence of DSM-IV axis II personality disorders among patients with CFS. METHODS: We examined the prevalence of personality disorders in a sample of 92 female CFS patients and in two well-matched control groups, i.e., normal community individuals (N = 92) and psychiatric patients (N = 92). Participants completed the assessment of DSM-IV personality disorders questionnaire (ADP-IV), which yields a categorical and dimensional evaluation of personality disorder features. RESULTS: The prevalence of personality disorders in CFS patients (16.3 %) was significantly lower than in psychiatric patients (58.7 %) and was similar to that in the community sample (16.3 %). Similar results were found for dimensional and pseudodimensional scores, except for the Depressive (DE) and Obsessive-Compulsive Personality Disorder (O-C) subscales. Patients with CFS had significantly higher levels of DE features compared to normal controls and similar dimensional scores on the O-C scale compared to psychiatric controls. CONCLUSIONS: Although the CFS sample was characterized by depressive and obsessive-compulsive personality features, this study provides no evidence for the assumption that these patients generally show a higher prevalence of axis II pathology. Given the conflicting findings in this area, future studies using multiple measures to assess personality disorders in CFS are needed to substantiate these findings.
Kim SE, Chang L.	Oppenheimer Family Center of Neurobiology of Stress, Los Angeles, CA, USA.	Overlap between functional GI disorders and other functional syndromes: what are the underlying mechanisms?	Neurogastroenterol Motil. 2012 Oct;24(10):895-913. doi: 10.1111/j.1365-2982.2012.01993.x.	BACKGROUND: Irritable bowel syndrome and other gastrointestinal (GI) and non-GI disorders such as functional dyspepsia, fibromyalgia, temporomandibular joint disorder, interstitial cystitis/painful bladder syndrome, and chronic fatigue syndrome are known as functional pain syndromes. They commonly coexist within the same individual. The pathophysiologic mechanisms of these disorders are not well understood, but it has been hypothesized that they share a common pathogenesis. PURPOSE: The objective of this review is to discuss the proposed pathophysiologic mechanisms, which have been similarly studied in these conditions. These mechanisms include enhanced pain perception, altered regional brain activation, infectious etiologies, dysregulations in immune and neuroendocrine function, and genetic susceptibility. Studies suggest that these functional disorders are multifactorial, but factors which increase the vulnerability of developing these conditions are shared.

King M, Kingery J, Casey B.	Department of Family and Community Medicine, University of Kentucky College of Medicine, Lexington, KY 40536, USA. mrking02@uky.edu	Diagnosis and evaluation of heart failure.	Am Fam Physician. 2012 Jun 15;85(12):1161-8.	Heart failure is a common clinical syndrome characterized by dyspnea, fatigue, and signs of volume overload, which may include peripheral edema and pulmonary rales. Heart failure has high morbidity and mortality rates, especially in older persons. Many conditions, such as coronary artery disease, hypertension, valvular heart disease, and diabetes mellitus, can cause or lead to decompensation of chronic heart failure. Up to 40 to 50 percent of patients with heart failure have diastolic heart failure with preserved left ventricular function, and the overall mortality is similar to that of systolic heart failure. The initial evaluation includes a history and physical examination, chest radiography, electrocardiography, and laboratory assessment to identify causes or precipitating factors. A displaced cardiac apex, a third heart sound, and chest radiography findings of venous congestion or interstitial edema are useful in identifying heart failure. Systolic heart failure is unlikely when the Framingham criteria are not met or when B-type natriuretic peptide level is normal. Echocardiography is the diagnostic standard to confirm systolic or diastolic heart failure through assessment of left ventricular ejection fraction. Evaluation for ischemic heart disease is warranted in patients with heart failure, especially if angina is present, given that coronary artery disease is the most common cause of heart failure.
Kingma EM, Moddejonge R, Rosmalen J.	Rijksuniversiteit Groningen, Universitair Medisch Centrum Groningen, Interdisciplinair Centrum Psychopathologie en Emotieregulatie (ICPE), Groningen, the Netherlands. e.m.kingma@umcg.nl	How do patients interpret terms for medically unexplained symptoms? [Article in Dutch]	Ned Tijdschr Geneeskd. 2012;156(37):A4541.	OBJECTIVE: To investigate how primary care patients interpret the existing terminology used to describe medically unexplained symptoms; to contribute to the current academic discussion on unequivocal terminology. DESIGN: Descriptive cohort study. METHODS: We approached patients in the waiting rooms of two general medical practices in the city of Groningen and in the province of Drenthe. Based on a fictitious case, the patients were asked to assign connotations to a number of possible diagnoses for medically unexplained tiredness. The patients could choose from seven predetermined connotations. Among the diagnoses for medically unexplained tiredness were 'functional fatigue', 'chronic fatigue syndrome', 'psychosomatic tiredness', and 'medically unexplained tiredness'. From the seven connotations, we labeled three connotations as being negative. When patients gave at least one negative connotation to a possible diagnosis, the diagnosis was labeled as 'offensive'. RESULTS: A total of 184 patients participated in the study. From the alternative diagnoses for medically unexplained tiredness, 'psychosomatic tiredness' had the most negative connotations: at least one negative connotation for 65 (35%) patients. 'Chronic fatigue syndrome' and 'functional fatigue' had the fewest negative connotations: at least one negative connotation for respectively 17 (9%) and 24 (13%)

				patients. CONCLUSION: The terms 'chronic fatigue syndrome' and 'functional fatigue' were less offensive. Our results could imply that terms for medically unexplained tiredness that refer less to a psychological basis are most acceptable for the patient.
Kishi A, Natelson BH, Togo F, Struzik ZR, Rapoport DM, Yamamoto Y.	Educational Physiology Laboratory, Graduate School of Education, University of Tokyo, Tokyo, Japan.	Sleep-stage dynamics in patients with chronic fatigue syndrome with or without fibromyalgia.	Sleep. 2011 Nov 1;34(11):1551-60. doi: 10.5665/sleep.1396.	STUDY OBJECTIVES: Chronic fatigue syndrome (CFS) and fibromyalgia (FM) are medically unexplained conditions that often have overlapping symptoms, including sleep-related complaints. However, differences between the 2 conditions have been reported, and we hypothesized that dynamic aspects of sleep would be different in the 2 groups of patients. PARTICIPANTS: Subjects were 26 healthy control subjects, 14 patients with CFS but without FM (CFS alone), and 12 patients with CFS and FM (CFS+FM)-all women. MEASUREMENTS AND RESULTS: We studied transition probabilities and rates between sleep stages (waking, rapid eye movement [REM] sleep, stage 1 [S1], stage 2 [S2], and slow-wave sleep [SWS]) and duration distributions of each sleep stage. We found that the probability of transition from REM sleep to waking was significantly greater in subjects with CFS alone than in control subjects, which may be the specific sleep problem for people with CFS alone. Probabilities of (a) transitions from waking, REM sleep, and S1 to S2 and (b) those from SWS to waking and S1 were significantly greater in subjects with CFS+FM than in control subjects; in addition, rates of these transitions were also significantly increased in subjects with CFS+FM. Result (a) might indicate increased sleep pressure in subjects with CFS+FM whereas result (b) may be the specific sleep problem of subjects with CFS+FM. We also found that shorter durations of S2 sleep are specific to patients with CFS+FM, not to CFS alone. CONCLUSIONS: These results suggest that CFS and FM may be different illnesses associated with different problems of sleep regulation.
Klimas NG, Broderick G, Fletcher MA.	Miami Veterans Affairs Medical Center, Miami, FL, USA. Nancy.Klimas@va.gov	Biomarkers for chronic fatigue.	Brain Behav Immun. 2012 Nov;26(8):1202-10. doi: 10.1016/j.bbi.2012.06.006.	Fatigue that persists for 6 months or more is termed chronic fatigue. Chronic fatigue (CF) in combination with a minimum of 4 of 8 symptoms and the absence of diseases that could explain these symptoms, constitute the case definition for chronic fatigue syndrome/myalgic encephalomyelitis (CFS/ME). Inflammation, immune system activation, autonomic dysfunction, impaired functioning in the hypothalamic-pituitary-adrenal axis, and neuroendocrine dysregulation have all been suggested as root causes of fatigue. The identification of objective markers consistently associated with CFS/ME is an important goal in relation to diagnosis and treatment, as the current case definitions are based entirely on physical signs and symptoms. This review is focused on the recent literature related to biomarkers for fatigue associated with CFS/ME and, for comparison, those associated with other diseases. These markers are distributed across several of the body's core regulatory systems. A complex construct of symptoms emerges from alterations and/or dysfunctions in the nervous, endocrine and immune systems. We propose that new insight will depend on our ability to develop and deploy an integrative profiling of CFS/ME pathogenesis at the molecular level. Until such a molecular signature is obtained efforts to develop

				effective treatments will continue to be severely limited.
Kmietowicz Z.	[No address quoted]	Researchers get 1.6m pound to look at scientific basis of chronic fatigue syndrome.	BMJ. 2011 Dec 21;343:d8281. doi: 10.1136/bmj.d8281.	[No abstract given]
Knudsen A, Lervik L, Harvey S, Løvvik C, Omenås A, Mykletun A.	Department of Health Promotion and Development, Faculty of Psychology, University of Bergen , Bergen , Norway.	Comparison of chronic fatigue syndrome/myalgic encephalopathy with other disorders: an observational study.	JRSM Short Rep. 2012 May;3(5):32. doi: 10.1258/shorts.2011.011167.	OBJECTIVES: To examine the level of activity in online discussion forums for chronic fatigue syndrome/myalgic encephalopathy (CFS/ME) compared to other disorders. We hypothesized the level of activity to be higher in CFS/ME online discussion forums. DESIGN: Observational study SETTING: Norway, which has more than 80% household coverage in internet access, September 2009 PARTICIPANTS: Twelve Norwegian disorder-related online discussion forums MAIN OUTCOME MEASURES: Number of registered users and number of posted messages on each discussion forum RESULTS: Two forums were targeted towards individuals with CFS/ME. These forums had the highest number of registered users per estimated 1,000 cases in the population (50.5 per 1,000 and 29.7 per 1,000), followed by a site for drug dependency (5.4 per 1,000). Counting the number of posted messages per 1,000 cases gave similar indications of high online activity in the CFS/ME discussion forums. CONCLUSIONS: CFS/ME online forums had more than ten times the relative activity of any other disorder or condition related forum. This high level of activity may have multiple explanations. Individuals suffering from a stigmatized condition of unknown aetiology may use the internet to look for explanations of symptoms or to seek out alternative treatments. Internet forum activity may also be reinforced by the creation of in-group identity and pre-morbid personality traits. More knowledge on the type and quality of information provided in online forums is urgently needed.
Knudsen AK, Henderson M, Harvey SB, Chalder T.	Research Section of Mental Health Epidemiology, Department of Health Promotion and Development, Faculty of Psychology, University of Bergen, Christiesgt. 13, N-5020 Bergen, Norway. Ann.Knudsen@psych.uib.no	Long-term sickness absence among patients with chronic fatigue syndrome	Br J Psychiatry. 2011 Nov;199(5):430-1. doi: 10.1192/bjp.bp.110.082974.	Chronic fatigue syndrome is associated with high levels of occupational disability. Consecutive out-patients at a chronic fatigue syndrome treatment service were studied for associations between occupational status, symptom severity and cognitive and behavioural responses to symptoms. All patients had high symptom levels; however, those on long-term sickness absence had significantly more physical fatigue ($\beta = 0.098$, $P<0.05$) and worse sleep ($\beta = 0.075$, $P<0.05$). Patients with long-term sickness absence also demonstrated more embarrassment avoidance cognitions ($\beta = 0.086$, $P<0.05$) and avoidance resting behavioural responses ($\beta = 0.078$, $P<0.05$). Identifying and addressing avoidance behaviours and cognitions regarding embarrassment in interventions may enhance the chances of individuals returning to work.
Korenromp IH, Meeus M, Bleijenberg G.	St. Antonius Ziekenhuis, centrum Interstitiële	Dutch language area definition of chronic fatigue. [Article in	Ned Tijdschr Geneeskd. 2012;156(16):A4403.	Chronic fatigue is a frequent but unspecific characteristic of many diseases. However, a clear definition of 'chronic fatigue' is still lacking. The Flemish-Dutch Research Group - Chronic Fatigue (VNO-CHROVER) has taken the opportunity to formulate such a

	Longziekten, Nieuwegein, the Netherlands. i.korenromp@antoniusziekenhuis.nl	Dutch]		definition that can be widely applied. This definition is not only beneficial to researchers conducting, reporting and comparing scientific studies on chronic fatigue in diverse patient populations, but also to clinicians of various disciplines in order to improve patient care. VNO-CHROVER proposes to define chronic fatigue as 'a self-reported reduction of physical and/or mental well-being that persists longer than 6 months and is manifested as exhaustion by which one fails to function at the desired level.'
Korn K, Reil H, Ensser A, Knöll A.	Institute of Clinical and Molecular Virology, Friedrich-Alexander-University Erlangen-Nuremberg, Erlangen, Germany.	No evidence of XMRV infection in immunocompromised patients and HIV-positive individuals from Germany.	Infection. 2012 Apr;40(2):181-4. doi: 10.1007/s15010-012-0249-2.	BACKGROUND: Xenotropic murine leukaemia virus-related virus (XMRV) has been detected in patients with prostate cancer and chronic fatigue syndrome (CFS). The detection of XMRV in healthy individuals has raised concern about a possible virus transmission by blood products. However, recent studies challenge the association between XMRV and human disease. This study investigated whether or not XMRV is present in patients with altered immune function and individuals at increased risk of blood-borne viral infections in Germany. METHODS: We investigated 503 peripheral blood mononuclear cell (PBMC) samples from 240 patients with iatrogenic immune suppression (71 haematopoietic stem cell recipients, 132 solid organ transplant recipients, 37 others) and 311 PBMC samples from 302 patients with HIV-1 infection for the presence of proviral XMRV by real-time polymerase chain reaction (PCR). RESULTS: All 814 PBMC samples from 542 patients tested negative for XMRV DNA and positive for an internal herpesvirus saimiri (HVS) control. Human genomic DNA was detected in all samples, and 90% of the samples contained >10,000 cell equivalents per XMRV PCR reaction. CONCLUSIONS: Our failure to detect proviral XMRV provides evidence against the presence of XMRV in patients at increased risk of viral infections in Ge
Koshimichi M, Sugimoto K, Yanagida H, Fujita S, Miyazawa T, Sakata N, Okada M, Takemura T.	Department of Pediatrics, Kinki University School of Medicine, Osaka, Japan.	Newly-identified symptoms of left renal vein entrapment syndrome mimicking orthostatic disturbance.	World J Pediatr. 2012 May;8(2):116-22. doi: 10.1007/s12519-012-0349-1.	BACKGROUND: In addition to the urinary abnormalities, symptoms of left renal vein entrapment between the aorta and superior mesenteric artery (left renal vein entrapment syndrome, LRVES) may include abdominal and flank pain as well as chronic fatigue. We investigated various LRVES symptoms in this study. METHODS: In 53 pediatric LRVES patients treated at our department, 22 had a score of 5 points or higher on orthostasis. Initial evaluation of LRVES by abdominal ultrasonography showed a stenotic-to-prestenotic vein diameter ratio of 0.2 or less. Definitive diagnosis was made by computed tomography and magnetic resonance angiography. Cortisol, catecholamine (CA), and brain natriuretic peptide (BNP) were also measured. RESULTS: The frequency of LRVES was 2.5 times higher in girls than in boys. Low or very low body mass indexes were seen in both sexes. The most common initial finding was urine abnormalities, followed by dizziness and malaise. In 6 patients, orthostasis precluded school attendance. Ten patients had orthostasis scores above 12. Patients unable to attend school had either low levels of plasma or urinary cortisol. Midodrine significantly decreased orthostasis scores. Some patients required treatment with fludrocortisone. Plasma CA, renin, and BNP levels were all normal. CONCLUSIONS:

				Locally excessive venous pressure may cause reversible adrenal dysfunction with transitory Addisonian symptoms. Children with cryptogenic malaise or severe orthostasis should be evaluated for LRVES.
Krause K, Grattan CE, Bindslev-Jensen C, Gattorno M, Kallinich T, de Koning HD, Lachmann HJ, Lipsker D, Navarini AA, Simon A, Traidl-Hoffmann C, Maurer M.	Autoinflammation Reference Center Charité, Charité-Universitätsmedizin Berlin, Berlin, Germany.	How not to miss autoinflammatory diseases masquerading as urticaria.	Allergy. 2012 Dec;67(12):1465-74. doi: 10.1111/all.12030.	Urticarial skin reactions are one of the most frequent problems seen by allergists and clinical immunologists in daily practice. The most common reason for recurrent wheals is spontaneous urticaria. There are, however, several less common diseases that present with urticarial rash, such as urticarial vasculitis and autoinflammatory disorders. The latter include cryopyrin-associated periodic syndrome and Schnitzler's syndrome, both rare and disabling conditions mediated by increased interleukin-1 secretion. Apart from the urticarial rash, patients are suffering from a variety of systemic symptoms including recurrent fever attacks, arthralgia or arthritis and fatigue. Autoinflammatory diseases are often associated with a diagnostic delay of many years and do not respond to antihistamines and other treatments of urticaria. Also, the chronic inflammation may lead to long-term complications such as amyloidosis. It is therefore important not to miss these diseases when diagnosing and treating patients with chronic recurrent urticarial rash. Here, we present clinical clues and tips that can help to identify autoinflammatory disorders in patients presenting with chronic urticarial rash and discuss their clinical picture and management.
Kreijkamp-Kaspers S, Brenu EW, Marshall S, Staines D, Van Driel ML.	Academic General Practice, Faculty of Health Sciences & Medicine, Bond University, Gold Coast, Queensland. skreijka@bond.edu.au	Treating chronic fatigue syndrome - a study into the scientific evidence for pharmacological treatments.	Aust Fam Physician. 2011 Nov;40(11):907-12.	BACKGROUND: Chronic fatigue syndrome, or myalgic encephalomyelitis (CFS), is a severe disabling condition. Patients with CFS usually trial many different medicines, both conventional and complementary. An overview of the pharmacological treatments used by CFS patients and the available evidence underpinning the use of these treatments would be of great value to both patients and their healthcare providers. METHODS: Ninety-four CFS patients recruited into an Australian study investigating immunological biomarkers filled out a questionnaire assessing the medicines they were taking. Evidence from randomised clinical trials was sought in biomedical databases. RESULTS: The 94 CFS patients used 474 different medicines and supplements. The most commonly used medicines were antidepressants, analgesics, sedatives, and B vitamins. We identified 20 randomised controlled trials studying these medicines in CFS patients. DISCUSSION: While conventional and complementary medicines are widely used by CFS patients, the evidence for effectiveness in CFS is very limited.
Kümmerle-Deschner JB	Klinik für Kinder- und Jugendmedizin, Abteilung für pädiatrische Rheumatologie, Autoinflammation Reference Center Tübingen,	Cryopyrin-associated periodic syndrome. [Article in German]	Z Rheumatol. 2012 Apr;71(3):199-208. doi: 10.1007/s00393-011-0856-9.	The cryopyrin-associated periodic syndrome is a very rare disease. It is estimated that there are 1-2 cases out of 1 million inhabitants in the USA and 1/360,000 in France. However, many patients are diagnosed very late or not at all. Therefore the real prevalence is likely to be higher. CAPS encompasses the three entities familial cold autoinflammatory syndrome (FCAS), the Muckle-Wells syndrome and the neonatal-onset multisystem inflammatory disease (NOMID)/chronic infantile neurologic cutaneous and articular (CINCA) syndrome. They have in common a causative mutation in the NLRP3-gene. The altered gene product cryopyrin leads to activation of

	Universitätsklinikum Tübingen, Hoppe-Seyler-Str. 1, 72076, Tübingen, Deutschland. kuemmerle.deschner@uni-tuebingen.de			the inflammasome which in turn is responsible for excessive production of IL-1β. IL-1β causes the inflammatory manifestations in CAPS. These appear as systemic inflammation including fever, headache or fatigue, rash, eye disease, progressive sensorineural hearing loss, musculoskeletal manifestations and CNS symptoms (NOMID/CINCA only). With the advent of the IL-1 inhibitors anakinra, rilonacept and canakinumab for the first time safe and effective therapeutic options are available for this devastating disease. To prevent severe and possible life-threatening disease sequelae, early and correct diagnosis and immediate initiation of therapy are mandatory.
Kunos L, Varga J, Horváth G.	Semmelweis Egyetem, Általános Orvostudományi Kar Pulmonológiai Klinika, Budapest.	Simultaneous occurrence of chronic obstructive pulmonary disease and obstructive sleep apnea: the overlap syndrome. [Article in Hungarian]	Orv Hetil. 2012 Jun 10;153(23):892-7. doi: 10.1556/OH.2012.29394.	Obstructive sleep apnea syndrome is a common disorder in adults associated with several cardiovascular diseases and impaired quality of life. Chronic obstructive pulmonary disease is also a common clinical condition in middle-aged adults. The combination of these two conditions can eventuate a severe combined sleep-related breathing disorder. It is important to recognize coexisting sleep apnea in patients with chronic obstructive pulmonary disease in time and to treat it appropriately.
Lalremruta V, Prasanna GS.	Department of Pharmacology, KLE University's College of Pharmacy, Rajajinagar, Bangalore, India.	Evaluation of protective effect of Aegle marmelos Corr. in an animal model of chronic fatigue syndrome.	Indian J Pharmacol. 2012 May;44(3):351-6. doi: 10.4103/0253-7613.96316.	OBJECTIVE: To evaluate ethanolic extract of leaves of Aegle marmelos in an experimental animal model of chronic fatigue syndrome for potential therapeutic benefit. MATERIALS AND METHODS: Age/weight-matched female Wistar albino rats were grouped into five groups. (Group I- V) (n = 8). Group I served as naïve control and II served as stress control. Except for group I animals, other group animals were subjected to forced swimming every day for 15 minutes to induce a state of chronic fatigue and simultaneously treated with ethanolic extract of Aegle marmelos (EEAM) 150 and 250 mg/kg b.w. and Imipramine (20 mg.kg b.w.), respectively. Duration of immobility, anxiety level and locomotor activity were assessed on day 1, 7, 14 and 21 followed by biochemical estimation of oxidative biomarkers at the end of the study. RESULTS: Treatment with EEAM (150 and 250 mg/kg b.w.) resulted in a statistically significant and dose dependent reduction ($P < 0.001$) in the duration of immobility, reduction in anxiety and increase in locomotor activity. Dose dependent and significant reduction in LPO level and increase in CAT and SOD was observed in extract treated animals. CONCLUSION: The results are suggestive of potential protective effect of A. marmelos against experimentally induced CFS.
Lattie EG, Antoni MH, Fletcher MA, Penedo F, Czaja S, Lopez C, Perdomo D, Sala A, Nair S, Fu SH, Klimas N.	Department of Psychology, University of Miami, Coral Gables, FL 33124, USA.	Stress management skills, neuroimmune processes and fatigue levels in persons with chronic fatigue syndrome.	Brain Behav Immun. 2012 Aug;26(6):849-58. doi: 10.1016/j.bbi.2012.02.008.	OBJECTIVES: Stressors and emotional distress responses impact chronic fatigue syndrome (CFS) symptoms, including fatigue. Having better stress management skills might mitigate fatigue by decreasing emotional distress. Because CFS patients comprise a heterogeneous population, we hypothesized that the role of stress management skills in decreasing fatigue may be most pronounced in the subgroup manifesting the greatest neuroimmune dysfunction. METHODS: In total, 117 individuals with CFS provided blood and saliva samples, and self-report measures of

				emotional distress, perceived stress management skills (PSMS), and fatigue. Plasma interleukin-1-beta (IL-1β, IL-2, IL-6, IL-10, and tumor necrosis factor-alpha (TNF-α), and diurnal salivary cortisol were analyzed. We examined relations among PSMS, emotional distress, and fatigue in CFS patients who did and did not evidence neuroimmune abnormalities. RESULTS: Having greater PSMS related to less fatigue (p=.019) and emotional distress (p<.001), greater diurnal cortisol slope (p=.023) and lower IL-2 levels (p=.043). PSMS and emotional distress related to fatigue levels most strongly in CFS patients in the top tercile of IL-6, and emotional distress mediated the relationship between PSMS and fatigue most strongly in patients with the greatest circulating levels of IL-6 and a greater inflammatory (IL-6):anti-inflammatory (IL-10) cytokine ratio. DISCUSSION: CFS patients having greater PSMS show less emotional distress and fatigue, and the influence of stress management skills on distress and fatigue appear greatest among patients who have elevated IL-6 levels. These findings support the need for research examining the impact of stress management interventions in subgroups of CFS patients showing neuroimmune dysfunction.
Law ST, Ma KM, Li KK.	Department of Medicine and Geriatrics, Tuen Mun Hospital, Tuen Mun, Hong Kong.	Protein-losing enteropathy associated with or without systemic autoimmune disease: what are the differences?	Eur J Gastroenterol Hepatol. 2012 Mar;24(3):294-302. doi: 10.1097/MEG.0b013e32834f3ea0.	OBJECTIVE: The aim of our study was to compare protein-losing enteropathy (PLE) associated with or without systemic autoimmune (SA) diseases. METHODS: Patients diagnosed with PLE were selected, and their clinical characteristics, laboratory, endoscopic and imaging characteristics, treatment, and outcome were analyzed. RESULTS: From 2001 to 2010, 74 patients (60 patients with SA disease) with a female predominance were diagnosed with PLE. The SA group tended to be younger, presented early (4.3 vs. 7 weeks, P=0.08), and had significantly more mucocutaneous-articular involvement (16.7 vs. 0%, P<0.05; 50 vs. 0%, P<0.02; 43.3 vs. 0%, P<0.01), compared with the other group, which showed more weight loss (64.3 vs. 25%, P<0.01), malaise and fatigue (57.1 vs. 28.3%, P<0.02), and tended to have more gastrointestinal (GI) symptoms. The SA group was associated with lymphopenia (0.8 vs. 2.7 × 10^9/l, P<0.01), hyperglobulinemia (43 vs. 31.2 IU/l, P<0.04), lactate dehydrogenase (511.1 vs. 393.5 IU/l, P<0.05), hematuria (48.3 vs. 7.1%, P<0.01), and pyuria (23.3 vs. 0%, P<0.03), whereas the non-SA group had a higher platelet count (402 vs. 262.5 × 10^9/l, P<0.01) and alkaline phosphatase (111 vs. 78.2 IU/l, P<0.03) on admission. A subgroup analysis of patients with SA disease showed that more lupus patients had pericardial effusion (14.6 vs. 0%, P=0.08), polyarthritis (50 vs. 16.7%, P=0.02), lower C3 level (0.5 vs. 0.85 mg/l, P<0.01), antinuclear factors (89.6 vs. 58.3%, P<0.01), and antiextractable nuclear antigen antibody (73.3 vs. 37.5%, P<0.03), whereas nonlupus patients had higher C-reactive protein (87.9 vs. 40 mg/l, P<0.01) and more antineutrophil cytoplasmic antibody (ANCA) (60 vs. 3%, P=0.00). Thirty-seven (71%) patients with SA disease had diffuse nonerosive erythematous GI mucosa with chronic inflammatory cells in the lamina propria layer, and 12 (85.7%) patients without SA disease had focal lesions. The treatment response was comparable between the two groups. However, the time required to normalize the serum albumin

				level (6.3 vs. 12.3 months, P=0.02) of patients with SA disease was much shorter than that of the non-SA group and those of inflammatory markers, specifically, C-reactive protein and complement C3, of its own group (6.3 vs. 11.6 vs. 12.1 months, P<0.04). More patients without SA disease had infective episodes during the management period (14.3 vs. 1.7%, P<0.01). CONCLUSION: Patients with PLE associated with SA disease tend to have a distinct clinical syndrome with regard to the extent of clinical manifestations and laboratory, endoscopic, and histological features compared with those without. Patients without SA disease are more prone to develop complications and mortality. However, both can be effectively treated with comparable treatment response.
Le Bon O, Neu D, Berquin Y, Lanquart JP, Hoffmann R, Mairesse O, Armitage R.	Brugmann University Hospital, Sleep Laboratory and Unit for Chronobiology U78, Université Libre de Bruxelles (U.L.B.), Brussels, Belgium; Hôpital Erasme, Sleep Research Unit, Université Libre de Bruxelles (U.L.B.), Brussels, Belgium. Electronic address: olebon@chu-tivoli.be.	Ultra-Slow delta power in chronic fatigue syndrome.	Psychiatry Res. 2012 Dec 30;200(2-3):742-7. doi: 10.1016/j.psychres.2012.06.027.	The role of sleep in patients diagnosed with chronic fatigue syndrome is not fully understood. Studies of polysomnographic and quantitative sleep electroencephalographic (EEG) measures have provided contradictory results, with few consistent findings in patients with Chronic Fatigue Syndrome (CFS). For the most part, it appears that delta EEG activity may provide the best discrimination between patients and healthy controls. A closer examination of delta activity in the very slow end of the frequency band is still to be considered in assessing sleep in CFS. The present preliminary study compared absolute and relative spectral power in conventional EEG bands and ultra-slow delta (0.5-0.8Hz) between 10 young female patients with the CFS and healthy controls without psychopathology. In absolute measures, the ultra-slow delta power was lower in CFS, about one-fifth that of the control group. Other frequency bands did not differ between groups. Relative ultra-slow delta power was lower in patients than in controls. CFS is associated with lower ultra-slow (0.5-0.8Hz) delta power, underscoring the importance of looking beyond conventional EEG frequency bands. From a neurophysiological standpoint, lower ultra-slow wave power may indicate abnormalities in the oscillations in membrane potential or a failure in neural recruitment in those with CFS.
Lee D, Das Gupta J, Gaughan C, Steffen I, Tang N, Luk KC, Qiu X, Urisman A, Fischer N, Molinaro R, Broz M, Schochetman G, Klein EA, Ganem D, Derisi JL, Simmons G, Hackett J Jr, Silverman RH, Chiu CY.	Department of Laboratory Medicine, University of San Francisco, San Francisco, California, United States of America.	In-depth investigation of archival and prospectively collected samples reveals no evidence for XMRV infection in prostate cancer.	PLoS One. 2012;7(9):e44954. doi: 10.1371/journal.pone.0044954.	XMRV, or xenotropic murine leukemia virus (MLV)-related virus, is a novel gammaretrovirus originally identified in studies that analyzed tissue from prostate cancer patients in 2006 and blood from patients with chronic fatigue syndrome (CFS) in 2009. However, a large number of subsequent studies failed to confirm a link between XMRV infection and CFS or prostate cancer. On the contrary, recent evidence indicates that XMRV is a contaminant originating from the recombination of two mouse endogenous retroviruses during passaging of a prostate tumor xenograft (CWR22) in mice, generating laboratory-derived cell lines that are XMRV-infected. To confirm or refute an association between XMRV and prostate cancer, we analyzed prostate cancer tissues and plasma from a prospectively collected cohort of 39 patients as well as archival RNA and prostate tissue from the original 2006 study. Despite comprehensive microarray, PCR, FISH, and serological testing, XMRV was not detected in any of the newly collected samples or in archival tissue, although archival

				RNA remained XMRV-positive. Notably, archival VP62 prostate tissue, from which the prototype XMRV strain was derived, tested negative for XMRV on re-analysis. Analysis of viral genomic and human mitochondrial sequences revealed that all previously characterized XMRV strains are identical and that the archival RNA had been contaminated by an XMRV-infected laboratory cell line. These findings reveal no association between XMRV and prostate cancer, and underscore the conclusion that XMRV is not a naturally acquired human infection.
Lerner AM, Ariza ME, Williams M, Jason L, Beqaj S, Fitzgerald JT, Lemeshow S, Glaser R.	Department of Medicine, Oakland University William Beaumont School of Medicine, Rochester, Michigan, United States of America.	Antibody to epstein-barr virus deoxyuridine triphosphate nucleotidohydrolase and deoxyribonucleotide polymerase in a chronic fatigue syndrome subset.	PLoS One. 2012;7(11):e47891. doi:10.1371/journal.pone.0047891.	BACKGROUND: A defined diagnostic panel differentiated patients who had been diagnosed with chronic fatigue syndrome (CFS), based upon Fukuda/Carruthers criteria. This diagnostic panel identified an Epstein-Barr virus (EBV) subset of patients (6), excluding for the first time other similar "clinical" conditions such as cytomegalovirus (CMV), human herpesvirus 6 (HHV6), babesiosis, ehrlichiosis, borreliosis, Mycoplasma pneumoniae, Chlamydia pneumoniae, and adult rheumatic fever, which may be mistakenly called CFS. CFS patients were treated with valacyclovir (14.3 mg/kg q6h) for ≥12 months. Each patient improved, based upon the Functional Activity Appraisal: Energy Index Score Healthcare Worker Assessment (EIPS), which is a validated (FSS-9), item scale with high degree of internal consistency measured by Cronbach's alpha. METHODS: Antibody to EBV viral capsid antigen (VCA) IgM, EBV Diffuse Early Antigen EA(D), and neutralizing antibodies against EBV-encoded DNA polymerase and EBV-encoded dUTPase were assayed serially approximately every three months for 13-16 months from sera obtained from patients with CFS (6) and from sera obtained from twenty patients who had no history of CFS. RESULTS: Antibodies to EBV EA(D) and neutralizing antibodies against the encoded-proteins EBV DNA polymerase and deoxyuridine triphosphate nucleotidohydrolase (dUTPase) were present in the EBV subset CFS patients. Of the sera samples obtained from patients with CFS 93.9% were positive for EA(D), while 31.6% of the control patients were positive for EBV EA(D). Serum samples were positive for neutralizing antibodies against the EBV-encoded dUTPase (23/52; 44.2%) and DNA polymerase (41/52; 78.8%) in EBV subset CFS patients, but negative in sera of controls. CONCLUSIONS: There is prolonged elevated antibody level against the encoded proteins EBV dUTPase and EBV DNA polymerase in a subset of CFS patients, suggesting that this antibody panel could be used to identify these patients, if these preliminary findings are corroborated by studies with a larger number of EBV subset CFS patients.
Lewis I, Pairman J, Spickett G, Newton JL.	Institute for Ageing & Health, Newcastle University, Newcastle, UK.	Clinical characteristics of a novel subgroup of chronic fatigue syndrome patients with postural	J Intern Med. 2012 Dec 4. doi: 10.1111/joim.12022.	OBJECTIVES: A significant proportion of patients with chronic fatigue syndrome (CFS) also have postural orthostatic tachycardia syndrome (POTS). We aimed to characterise these patients and differentiate them from CFS patients without POTS in terms of clinical and autonomic features. METHODS: A total of 179 patients with CFS (1994 Centers for Disease Control and Prevention criteria) attending one of the largest Department of Health-funded CFS clinical services were included in the study.

		orthostatic tachycardia syndrome.		Outcome measures were: (i) symptom assessment tools including the fatigue impact scale, Chalder fatigue scale, Epworth sleepiness scale (ESS), orthostatic grading scale (OGS) and hospital anxiety and depression scale (HADS-A and -D, respectively), (ii) autonomic function analysis including heart rate variability and (iii) haemodynamic responses including left ventricular ejection time and systolic blood pressure drop upon standing. RESULTS: CFS patients with POTS (13%, n=24) were younger (29±12 vs. 42±13 years, P<0.0001), less fatigued (Chalder fatigue scale, 8±4 vs. 10±2, P=0.002), less depressed (HADS-D, 6±4 vs. 9±4, P=0.01) and had reduced daytime hypersomnolence (ESS, 7±6 vs. 10±5, P=0.02), compared with patients without POTS. In addition, they exhibited greater orthostatic intolerance (OGS, 11±5; P<0.0001) and autonomic dysfunction. A combined clinical assessment tool of ESS ≤9 and OGS ≥9 identifies accurately CFS patients with POTS with 100% positive and negative predictive values. CONCLUSIONS: The presence of POTS marks a distinct clinical group of CFS patents, with phenotypic features differentiating them from those without POTS. A combination of validated clinical assessment tools can determine which CFS patients have POTS with a high degree of accuracy, and thus potentially identify those who require further investigation and consideration for therapy to control heart rate.
Lewis JD, Wassermann EM, Chao W, Ramage AE, Robin DA, Clauw DJ.	National Institute of Neurological Disorders and Stroke, Behavioral Neurology Unit, Bethesda, MD, USA Uniformed Services University of the Health Sciences, Bethesda, MD, USA.	Central sensitization as a component of post-deployment syndrome	NeuroRehabilitation. 2012 Jan 1;31(4):367-72. doi: 10.3233/NRE-2012-00805.	Many service members and veterans report chronic unexplained symptoms such as pain, fatigue and memory complaints, which have most recently been characterized as post-deployment syndrome (PDS). Chronic widespread pain is a component of this syndrome, producing significant disability and considerable health care costs. The similarity between the nature of these complaints and other medically unexplained illnesses such as fibromyalgia, irritable bowel syndrome, and chronic fatigue syndrome suggest that they may share a common mechanism. Here, we provide support for PDS as a consequence of pain and sensory amplification secondary to neuroplastic changes within the central nervous system, a phenomenon often termed central sensitization. We also discuss how factors such as stress and genetics may promote chronic widespread pain in veterans and service members who develop PDS.
Light AR, Bateman L, Jo D, Hughen RW, Vanhaitsma TA, White AT, Light KC.	Department of Anesthesiology The Brain Institute Department of Neurobiology and Anatomy Department of Exercise and Sport Science, University of Utah, Salt Lake City, UT 84132, USA. alan.light@hsc.utah.ed	Gene expression alterations at baseline and following moderate exercise in patients with Chronic Fatigue Syndrome and Fibromyalgia Syndrome.	J Intern Med. 2012 Jan;271(1):64-81. doi: 10.1111/j.1365-2796.2011.02405.x.	OBJECTIVES: To determine mRNA expression differences in genes involved in signalling and modulating sensory fatigue, and muscle pain in patients with chronic fatigue syndrome (CFS) and fibromyalgia syndrome (FM) at baseline, and following moderate exercise. DESIGN: Forty-eight patients with CFS only, or CFS with comorbid FM, 18 patients with FM that did not meet criteria for CFS, and 49 healthy controls underwent moderate exercise (25 min at 70% maximum age-predicted heart rate). Visual-analogue measures of fatigue and pain were taken before, during and after exercise. Blood samples were taken before and 0.5, 8, 24 and 48 h after exercise. Leucocytes were immediately isolated from blood, number coded for blind processing and analyses and flash frozen. Using real-time, quantitative PCR, the amount of mRNA for 13 genes (relative to control genes) involved in sensory, adrenergic and

	u			immune functions was compared between groups at baseline and following exercise. Changes in amounts of mRNA were correlated with behavioural measures and functional clinical assessments. RESULTS: No gene expression changes occurred following exercise in controls. In 71% of patients with CFS, moderate exercise increased most sensory and adrenergic receptor's and one cytokine gene's transcription for 48 h. These postexercise increases correlated with behavioural measures of fatigue and pain. In contrast, for the other 29% of patients with CFS, adrenergic α-2A receptor's transcription was decreased at all time-points after exercise; other genes were not altered. History of orthostatic intolerance was significantly more common in the α-2A decrease subgroup. FM-only patients showed no postexercise alterations in gene expression, but their pre-exercise baseline mRNA for two sensory ion channels and one cytokine were significantly higher than controls. CONCLUSIONS: At least two subgroups of patients with CFS can be identified by gene expression changes following exercise. The larger subgroup showed increases in mRNA for sensory and adrenergic receptors and a cytokine. The smaller subgroup contained most of the patients with CFS with orthostatic intolerance, showed no postexercise increases in any gene and was defined by decreases in mRNA for α-2A. FM-only patients can be identified by baseline increases in three genes. Postexercise increases for four genes meet published criteria as an objective biomarker for CFS and could be useful in guiding treatment selection for different subgroups.
Light KC, White AT, Tadler S, Iacob E, Light AR.	Departments of Anesthesiology, Neurobiology and Anatomy, and Exercise and Sport Science, The University of Utah, Salt Lake City, UT 84132, USA.	Genetics and Gene Expression Involving Stress and Distress Pathways in Fibromyalgia with and without Comorbid Chronic Fatigue Syndrome.	Pain Res Treat. 2012;2012:427869. doi: 10.1155/2012/427869.	In complex multisymptom disorders like fibromyalgia syndrome (FMS) and chronic fatigue syndrome (CFS) that are defined primarily by subjective symptoms, genetic and gene expression profiles can provide very useful objective information. This paper summarizes research on genes that may be linked to increased susceptibility in developing and maintaining these disorders, and research on resting and stressor-evoked changes in leukocyte gene expression, highlighting physiological pathways linked to stress and distress. These include the adrenergic nervous system, the hypothalamic-pituitary-adrenal axis and serotonergic pathways, and exercise responsive metabolite-detecting ion channels. The findings to date provide some support for both inherited susceptibility and/or physiological dysregulation in all three systems, particularly for catechol-O-methyl transferase (COMT) genes, the glucocorticoid and the related mineralocorticoid receptors (NR3C1, NR3C2), and the purinergic 2X4 (P2X4) ion channel involved as a sensory receptor for muscle pain and fatigue and also in upregulation of spinal microglia in chronic pain models. Methodological concerns for future research, including potential influences of comorbid clinical depression and antidepressants and other medications, on gene expression are also addressed.
Liu CZ, Lei B.	School of Aesthetic Medicine, Yichun College, Yichun	Effect of acupuncture on serum malonaldehyde	Zhen Ci Yan Jiu. 2012 Feb;37(1):38-40, 58.	OBJECTIVE: To study the effect of acupuncture on blood oxygen free radical metabolism in rats with chronic fatigue syndrome (CFS). METHODS: Thirty male SD rats were randomly divided into control group (n = 10), model group (n = 10) and

	336000, China. liuchangzheng1980@yahoo.com.cn	content, superoxide dismutase and glutathione peroxidase activity in chronic fatigue syndrome rats. [Article in Chinese]		acupuncture group (n = 10). CFS model was established by repeated suspension (1.0-2.5 h) and forced cold water swimming (7 min), once daily continuously for 12 days. For rats in the acupuncture group, bilateral "Zusanli" (ST 36) and "Sanyinjiao" (SP 6) were stimulated by manipulating the acupuncture needles intermittently for 20 min, once daily, and with 7 days being a treatment course. The treatment was conducted for three courses with an interval of 3 days between two courses. Serum malonaldehyde (MDA) content, superoxide dismutase (SOD) activity, and glutathione peroxidase (GSH-PX) activity were detected by thiobarbituric acid chromatometry (TBA), xanthine oxidase (XOD) and dithio-bis-nitrobenzoic acid (DTNB), respectively. RESULTS: In comparison with the control group, serum MDA content was up-regulated significantly, while serum SOD activity and GSH-PX activity were decreased considerably in the model group (P < 0.01). Compared with the model group, serum MDA level was down-regulated apparently, and serum SOD activity and GSH-PX activity were up-regulated remarkably in the acupuncture group (P < 0.01). CONCLUSION: Acupuncture can adjust metabolism of serum oxygen free radicals in CFS rats, which probably contributes to its effect in relieving CFS in clinic.
Liu KP, Fang M, Jiang SY.	Department of Tuina, Yueyang Hospital of Integrated Chinese and Western Medicine, Shanghai University of Traditional Chinese Medicine, Shanghai 200437.	Effects of tuina on the mechanical properties of skeletal muscles of four limbs in patients with chronic fatigue syndrome. [Article in Chinese]	Zhongguo Zhong Xi Yi Jie He Za Zhi. 2012 May;32(5):599-602.	OBJECTIVE: To study the effects of tuina on the mechanical properties of skeletal muscles of four limbs in patients with chronic fatigue syndrome (CFS). METHODS: Thirty CFS patients were recruited as the test group, while another 30 healthy volunteers were recruited as the healthy control group. Patients in the test group received tuina therapy, 30 min each time, once every other day, for totally 10 times. Isokinetic testing technology was used to compare peak torque (PT), total watt (TW), average power (AP), and flexor/extensor (F/E) ratio in the elbow and knee muscles of CFS patients before and after treatment. The Functional Assessment of Chronic Illness Therapy (FACIT) fatigue scale was used to evaluate the fatigue degree before and after treatment, and compared with the healthy control group. RESULTS: After treatment the FACIT fatigue scale score decreased significantly in the test group when compared with before treatment (27.5 +/- 9.1 vs 42.5 +/- 11.2), showing statistical difference (P < 0.05). The pre-treatment PT, TW, AP, and F/E ratio in the skeletal muscle were all lower in the test group than in the healthy control group. Compared with before treatment in the test group, patients' elbow 60 degrees/s angular velocity values during exercise extensor PT and TW, knee 60 degrees/s and 180 degrees/s angular velocity values during exercise flexor PT and TW increased significantly; elbow extensor and knee extensor, flexor AP was significantly elevated; knee in 180 degrees/s angular velocity of movement F/E ratio significantly increased, and all the differences were statistically significant (P < 0.05). The improvement of the fatigue degree in CFS patients and elbow in 60 degrees/s angular velocity values under the flexor and extensor TW, and flexor AP value of the degree of improvement were negatively correlated (r = -0.282, -0.482, -0.285, P < 0.05, P < 0.01). Meanwhile, the muscles with the knee in 180 degrees/s angular velocity was negatively correlated

				with the F/E ratio of the degree of improvement (r = -0. 330, P < 0.05). CONCLUSIONS: CFS patients have lowered mechanical properties of four limbs. Tuina therapy can improve the biomechanical properties of limb skeletal muscle and reduce the overall degree of fatigue in patients. The changes of limb skeletal muscle and mechanical properties can provide objective reference for the clinical diagnosis and assessment of CFS.
Liu Y, Zhang HG, Li XH.	Institute of Materia Medica and Department of Pharmaceutics, College of Pharmacy, Third Military Medical University, Chongqing, 400038, PR China.	A Chinese herbal decoction, Danggui Buxue Tang, improves chronic fatigue syndrome induced by food restriction and forced swimming in rats.	Phytother Res. 2011 Dec;25(12):1825-32. doi: 10.1002/ptr.3499.	Danggui Buxue Tang (DBT), a Chinese medicinal decoction that contains Radix Angelicae sinensis (Danggui) and Radix Astragali (Huangqi) at a ratio of 1:5, is used commonly for treating women's ailments. The present study explored the effects of this preparation on chronic fatigue syndrome (CFS). Rats were subjected to a combination of food restriction and forced swimming to induce CFS, and rats were gavaged once daily with either 12 or 24 g/kg DBT for 28 days. Body weights, T-cell subset counts, (3) H-TdR incorporation measurements and mRNA levels of IL-1β, TNF-α, NF-κB, p38MAPK and JNK were determined on days 14 and 28. The swimming endurance capacity was measured on day 28. Rats that received DBT exhibited increased body weight and endurance capacity, corrected T cell subsets counts, increased (3) H-TdR incorporation and decreased mRNA levels of IL-1β, TNF-α, NF-κB, p38MAPK and JNK compared with rats that did not receive DBT. The results indicate that DBT can ameliorate CFS through immune modulation and may act to normalize cytokines and their related signaling pathways.
Ljøstad U, Mygland Å.	Department of Neurology, Sørlandet Hospital, Kristiansand, Norway. unn.ljostad@sshf.no	The phenomenon of 'chronic Lyme'; an observational study.	Eur J Neurol. 2012 Aug;19(8):1128-35. doi: 10.1111/j.1468-1331.2012.03691.x.	PURPOSES: To chart clinical, laboratory, and psychometric profiles in patients who attribute their complaints to chronic Lyme disease. METHODS: We assessed the patients by clinical examination, laboratory tests, and questionnaires measuring fatigue, depression, anxiety, health-related quality of life, hypochondriasis, and illness perceptions. RESULTS: We found no evidence of ongoing Borrelia burgdorferi (Bb) infection in any of the 29 included patients using current diagnostic guidelines and an extended array of tests. Eight (28%) had other well-defined illnesses. Twenty-one (72%) had symptoms of unknown cause, of those six met the suggested criteria for post-Lyme disease syndrome. Fourteen (48%) had presence of anti-Bb antibodies. The patients had more fatigue and poorer health-related quality of life as compared to normative data, but were not more depressed, anxious, or hypochondriacal. Their beliefs about the illness were characterized by negative expectations. CONCLUSION: Our patients, who all attributed their symptoms to chronic Lyme disease, were heterogeneous. None had evidences of persistent Bb infection, but whether current diagnostic criteria are functional in patients with longstanding complaints is controversial. Other well-defined illnesses or sequelae from earlier Lyme disease were probable as main explanatory factor in some cases. The patients were not more depressed, anxious, or hypochondriacal than the normal population, but they had poorer health-related quality of life, more fatigue, and negative expectations about their illness.

Lloyd S, Chalder T, Rimes KA.	Department of Psychological Medicine, Institute of Psychiatry, King's College London, Weston Education Centre, Cutcombe Road, London SE5 9RJ, UK. Samantha.lloyd@kcl.ac.uk	Family-focused cognitive behaviour therapy versus psycho-education for adolescents with chronic fatigue syndrome: long-term follow-up of an RCT.	Behav Res Ther. 2012 Nov;50(11):719-25. doi: 10.1016/j.brat.2012.08.005.	The aim of this study was to investigate the long term efficacy of family-focused cognitive behaviour therapy (CBT) compared with psycho-education in improving school attendance and other secondary outcomes in adolescents with chronic fatigue syndrome (CFS). A 24 month follow-up of a randomised controlled trial was carried out. Participants received either 13 one-hour sessions of family-focused CBT or four one-hour sessions of psycho-education. Forty-four participants took part in the follow-up study. The proportion of participants reporting at least 70% school attendance (the primary outcome) at 24 months was 90% in CBT group and 84% in psycho-education group; the difference between the groups was not statistically significant (OR = 1.29, p = 0.80). The proportion of adolescents who had recovered in the family-focused CBT group was 79% compared with 64% in the psycho-education, according to a definition including fatigue and school attendance. This difference was not statistically significant (Fisher's exact test, p = 0.34). Family-focused CBT was associated with significantly better emotional and behavioural adjustment at 24 month follow-up compared to psycho-education, as reported by both adolescents (F = 6.49, p = 0.02) and parents (F = 4.52, P = 0.04). Impairment significantly decreased in both groups between six and 24 month follow-ups, with no significant group difference in improvement over this period. Gains previously observed for other secondary outcomes at six month follow-up were maintained at 24 month follow-up with no further significant improvement or group differences in improvement. In conclusion, gains achieved by adolescents with CFS who had undertaken family-focused CBT and psycho-education generally continued or were maintained at two-year follow-up. The exception was that family-focused CBT was associated with maintained improvements in emotional and behavioural difficulties whereas psycho-education was associated with deterioration in these outcomes between six and 24-month follow-up.
Lloyd S, Chalder T, Sallis HM, Rimes KA.	Department of Psychological Medicine, Institute of Psychiatry, King's College London, Weston Education Centre, Cutcombe Road, London, UK. Samantha.lloyd@kcl.ac.uk	Telephone-based guided self-help for adolescents with chronic fatigue syndrome: A non-randomised cohort study	Behav Res Ther. 2012 May;50(5):304-12. doi: 10.1016/j.brat.2012.02.014.	The aim of this study was to gain preliminary evidence about the efficacy of a new telephone-based guided self-help intervention, based on cognitive-behavioural principles, which aimed to reduce fatigue and improve school attendance in adolescents with chronic fatigue syndrome (CFS). A non-randomised cohort design was used, with a two-month baseline period. Sixty-three 11-18 year-old participants recruited from a specialist CFS unit received the intervention. Participants received six half-hour fortnightly telephone sessions and two follow-up sessions. Fatigue and school attendance were the main outcomes and the main time point for assessing outcome was 6 months post-treatment. Using multi-level modelling, a significant decrease in fatigue was found between pre-treatment and 6 month follow-up, treatment effect estimate = - 5.68 (-7.63, -3.72), a large effect size (Cohen's d = 0.79). The decrease in fatigue between pre and post-treatment was significantly larger than between baseline and pre-treatment. A significant increase in school attendance was found between pre-treatment and 6 month follow-up, effect estimate = 1.38 (0.76,

				2.00), a medium effect size (d = -0.48). Univariate logistic regression found baseline perfectionism to be associated with poorer school attendance at six-month follow-up. In conclusion, telephone-based guided self-help is an acceptable minimal intervention which is efficacious in reducing fatigue in adolescents with CFS.

Loew SJ, Watson K.	Centre for Bioactive Discovery in Health and Ageing, School of Science & Technology, University of New England, Armidale, Australia.	A prospective genetic marker of the visual-perception disorder Meares-Irlen syndrome.	Percept Mot Skills. 2012 Jun;114(3):870-82.	Prior investigations of scotopic sensitivity or Meares-Irlen syndrome have identified several features also found in attention deficit/hyperactivity disorder, chronic fatigue syndrome, and a subtype of dyslexia in which visual recognition is the primary deficit. In particular, anomalies in lipid metabolism, including low essential fatty acid status and decreased serum cholesterol, have been identified in all three disorders. Genetic expression of the transportermolecule apolipoprotein B-100 (APOB) has been correlated with abnormal lipid metabolism, particularly in relation to levels of cholesterol. Cholesterol esters are important carriers of essential fatty acids entering the retina. The APOB gene coding for apolipoprotein B-100 is located on the short arm of Chromosome 2, and closely neighbours a gene (DYX3) known to confer susceptibility to dyslexia. The APOB locus is also recognised as being one of the most highly polymorphic regions of the human genome, and thus provides a promising tool for genetic researchers. In this pilot study, certain allelic variants of the APOB gene were more common in participants diagnosed with Meares-Irlen syndrome than in individuals without the condition. This study appears to be a first in which a condition known to cause reading difficulties has been associated with the APOB gene.
Lucini D, Pagani M.	Centro di Ricerca Terapia Neurovegetativa e Medicina dell'Esercizio, Dipartimento Scienze Cliniche, Università degli Studi di Milano, Italy. daniela.lucini@unimi.it	From stress to functional syndromes: an internist's point of view.	Eur J Intern Med. 2012 Jun;23(4):295-301. doi: 10.1016/j.ejim.2011.11.016.	In this brief review we address schematically the relationship between two emerging issues in clinical medicine: stress and functional syndromes. It is becoming increasingly clear that they demand a multidimensional approach, considering simultaneously elements of behavioral therapy with traditional pharmacological treatment, guided by a better physiopathological understanding including autonomic assessment. New techniques, based on innovative analysis of continuous segments of electrocardiogram and non invasive arterial pressure recordings capable to extract hidden oscillations, provide quantitative indices of sympathetic and vagal modulation of the cardiovascular system. This more complete diagnostic process facilitates explanation of symptoms and reassurance of patients, based on functional evidence. The described clinical approach implies in addition an active collaboration of patients

				requiring the implementation of a creative alliance. Physical exercise, eating habits and muscular-mental relaxation are combined with pharmacological tools as needed.
Luczkowiak J, Martínez-Prats L, Sierra O, Fiorante S, Rubio R, Pulido F, Otero JR, Delgado R.	Laboratory of Molecular Microbiology, Instituto de Investigación i+12, Hospital Universitario 12 de Octubre, Madrid, Spain.	Lack of the detection of XMRV or polytropic MLV-related sequences in blood cells from HIV-1-infected patients in Spain.	J Acquir Immune Defic Syndr. 2012 Feb 1;59(2):101-4. doi: 10.1097/QAI.0b013e318238b596.	BACKGROUND: Xenotropic murine leukemia virus-related virus (XMRV) and polytropic murine leukemia virus (MLV)-related virus are recently described human gammaretroviruses that have been associated with prostate cancer and chronic fatigue syndrome. These studies have been controversial because a number of laboratories have been unable to find evidence of XMRV in similar groups of patients or controls. Because the existence of XMRV raises many questions, we decided to study its presence in a group of patients infected with HIV-1 with a high proportion of intravenous drug use and coinfection by hepatitis C virus. METHODS: Forty HIV-1-infected patients under follow-up in our institution were screened for XMRV/MLV by nested polymerase chain reaction using primers targeting the gag and env region. Specific primers for mouse mitochondrial DNA were used to rule out contamination. RESULTS: No evidence of XMRV or polytropic MLV-related sequences was found in any sample from patients or controls. Four samples yielded polymerase chain reaction bands whose sequence corresponded to murine endogenous retroviral sequences, however, contamination with mouse cell DNA was subsequently confirmed. CONCLUSIONS: XMRV/MLV viruses do not seem to be associated with HIV-1 infection or intravenous drug use. Contamination of samples or reagents by genomic murine DNA or XMRV vectors could account for the sporadic detection of positive samples for XMRV and related agents.
Ma X, Zhou S, Wei M, Chen Y, Li J, Xiong W, Jiang S, Pan C.	The Institute of Human Virology and Department of Biochemistry, Key Laboratory of Tropical Disease Control of Ministry of Education, Zhongshan School of Medicine, Sun Yat-Sen University, Guangzhou 510080, China.	Phylogenetic and biological analysis of a laboratory-generated gammaretrovirus xenotropic murine leukemia virus-related virus (XMRV).	Virus Genes. 2012 Oct;45(2):218-24.	A xenotropic murine leukemia virus-related virus (XMRV) has been reported to be an emerging pathogen associated with prostate cancer (PC) and chronic fatigue syndrome (CFS). However, recent studies have demonstrated that XMRV is a laboratory-derived virus resulting from genetic recombination between two mouse viral genomes during serial xenograft tissue transplantation. This study describes a phylogenetic analysis that compared XMRV with the ecotropic murine leukemia viruses (E-MLV), xenotropic MLV (X-MLV), and other retroviruses, including HTLV-1 and HIV-1. We found that sequences corresponding to three XMRV structural proteins (Env, Gag, and Pol) exhibited high degrees of homology with X-MLV (>91 %) and E-MLV (67-96 %), but not HTLV-1 (13-16 %) or HIV-1 (10-15 %), indicating that XMRV was derived from X-MLV and/or E-MLV. We then compared the infectivity of XMRV and E-MLV for human and murine lymphocytes, respectively. Results showed that human PBMCs were not susceptible to XMRV infection, suggesting that XMRV exhibits host cell tropism similar to E-MLV that only infects murine PBMCs. These data suggest that it is unlikely that this laboratory-generated retrovirus could cause disease in humans.
Macciò A, Madeddu C, Mantovani G.	Sirai Hospital, Department of Obstetrics and	Current pharmacotherapy options for cancer	Expert Opin Pharmacother. 2012 Dec;13(17):2453-72. doi: 10.1517/14656566.2012.7342	INTRODUCTION: Anorexia and cachexia syndrome represents a complex clinical picture that occurs in the late stage of several chronic inflammatory diseases, including cancer. Unless counteracted cancer-related anorexia and cachexia

	Gynecology, Carbonia, Italy. a.maccio@tin.it	anorexia and cachexia.	97.	syndrome affects quality of life (QL) and survival. However, to date a standard effective treatment is lacking. AREAS COVERED: The aim of this review is to describe the current pharmacological approaches for anorexia and cachexia syndrome, focusing on cancer-related syndrome. The several pharmacological agents tested so far are discussed, distinguishing them in unproven drugs, effective drugs, and drugs under investigation. Moreover, a section is devoted to the promising use of nutritional supplements and nutraceuticals. The emerging role of a multitargeted combined treatment approach is exhaustively reviewed. EXPERT OPINION: Considering the complex clinical picture and the multifactorial pathogenesis of anorexia and cachexia syndrome, we believe that its clinical management requires a multidisciplinary and multipharmacological approach. In our opinion the anorexia and cachexia syndrome treatment should include drugs that target the following conditions: inflammatory status, oxidative stress, nutritional disorders, muscle catabolism, anemia, immunosuppression, and fatigue. The multidimensional therapies for anorexia and cachexia syndrome should ideally be introduced within a context of the "best supportive care," which includes optimal symptom management and careful psychosocial counseling.
Maddali Bongi S, Di Felice C, Del Rosso A, Landi G, Maresca M, Giambalvo Dal Ben G, Matucci-Cerinic M.	Department of BioMedicine, Division of Rheumatology, University of Florence, and AMuRR, Rehabilitative Medicine and Assistive Devices Centre, Careggi Hospital, Florence, Italy.	Efficacy of the "body movement and perception" method in the treatment of fibromyalgia syndrome: an open pilot study.	Clin Exp Rheumatol. 2011 Nov-Dec;29(6 Suppl 69):S12-8.	OBJECTIVES: Group exercises may be useful in fibromyalgia syndrome (FMS). The 'Body movement and perception' (BMP) method is based on low impact exercises, awareness of body perception and relaxation, aimed at treating small groups of patients following the Resseguier method (RM) and integrating RM with exercises derived from soft gymnastics. We assessed the effects of BMP method on FMS. METHODS: 40 women with FMS (age and disease duration: 51.7±7.2 and 4.9±3.8 years) participated in an open pilot study. BMP sessions were performer twice a week (50 minutes each) for 8 weeks. Patients were assessed at enrolment (T0) and at the end of the study (T1) by a self-administered questionnaire (temporal characteristics of pain, pain interference in working and recreational activities and in night-time rest, awareness of pain, fatigue, irritability, well-being, quality of movement, ability to focus on perception and to perceive whole body, postural selfcontrol, ability to relax) and a clinical evaluation (tender points, assumption of analgesics/NSAIDs, distribution of pain, pain in sitting and standing position, pain during postural passages and gait, postural body alignment, muscular contractures). RESULTS: At T1, FMS patients significantly improved with respect to T0 in pain, fatigue, irritability, well-being, quality of movement, postural self-control, ability to relax mind and body, movement perception, tender point scores, assumption of analgesic/NSAIDs, body alignment and muscle contractures ($p<0.05$ for all the comparisons T1 versus T0). CONCLUSIONS: In FMS patients, rehabilitation with BMP improves pain and well being, reduces the number of tender points and muscle contractures, thus it is useful in FMS management.
Maes M, Kubera	Maes Clinics, Tria,	Increased IgA and	J Affect Disord. 2012 Dec	BACKGROUND: Recently, we discovered that depression is accompanied by increased

M, Leunis JC, Berk M.	Bangkok, Thailand. dr.michaelmaes@hotmail.com	IgM responses against gut commensals in chronic depression: further evidence for increased bacterial translocation or leaky gut.	1;141(1):55-62. doi: 10.1016/j.jad.2012.02.023.	IgM and IgA responses directed against gram negative gut commensals. The aim of this study was to replicate these findings in a larger study group of depressed patients and to examine the associations between the IgA and IgM responses to gut commensals and staging of depression as well as the fatigue and somatic (F&S) symptoms of depression. METHODS: We measured serum concentrations of IgM and IgA against the LPS of gram-negative enterobacteria, i.e. Hafnia alvei, Pseudomonas aeruginosa, Morganella morganii, Pseudomonas putida, Citrobacter koseri, and Klebsiella pneumoniae in 112 depressed patients and 28 normal controls. The severity of F&S symptoms was measured using the Fibromyalgia and Chronic Fatigue Syndrome Rating Scale. RESULTS: The prevalences and median values of serum IgM and IgA against LPS of these commensals were significantly higher in depressed patients than in controls. The IgM levels directed against the LPS of these commensal bacteria were significantly higher in patients with chronic depression than in those without. The immune responses directed against LPS were not associated with melancholia or recurrent depression. There was a significant correlation between the IgA response directed against LPS and gastro-intestinal symptoms. DISCUSSION: The results indicate that increased bacterial translocation with immune responses to the LPS of commensal bacteria may play a role in the pathophysiology of depression, particularly chronic depression. Bacterial translocation may a) occur secondary to systemic inflammation in depression and intensify and perpetuate the primary inflammatory response once the commensals are translocated; or b) be a primary trigger factor associated with the onset of depression in some vulnerable individuals. The findings suggest that "translocated" gut commensal bacteria activate immune cells to elicit IgA and IgM responses and that this phenomenon may play a role in the pathophysiology of (chronic) depression by causing progressive amplifications of immune pathways.
Maes M, Mihaylova I, Kubera M, Leunis JC, Geffard M.	Maes Clinics, TRIA, Bangkok, Thailand. dr.michaelmaes@hotmail.com	IgM-mediated autoimmune responses directed against multiple neoepitopes in depression: new pathways that underpin the inflammatory and neuroprogressive pathophysiology.	J Affect Disord. 2011 Dec;135(1-3):414-8. doi: 10.1016/j.jad.2011.08.023.	BACKGROUND: There is evidence that depression is accompanied by oxidative and nitrosative stress (O&NS), as indicated by increased free radical levels, lipid peroxidation, and lowered antioxidant levels. The aims of the present study are to examine whether depression is accompanied by autoimmune responses directed against a) neoepitopes that are formed following O&NS damage; and b) the major anchorage molecules, i.e. palmitic and myristic acids and S-farnesyl-L-cysteine. METHODS: We examined serum IgM antibodies to the conjugated fatty acids, palmitic and myristic acids; acetylcholine; S-farnesyl-L-cysteine; and NO-modified adducts in 26 depressed patients and 17 normal controls. Severity of depression was measured with the Hamilton Depression Rating Scale and severity of fatigue and somatic (F&S) symptoms with the Fibromyalgia and Chronic Fatigue Syndrome (FF) Rating Scale. RESULTS: The prevalences and mean values for the serum IgM levels directed against conjugated palmitic and myristic acids, acetylcholine, S-farnesyl-L-cysteine; and the conjugated NO adducts, NO-tyrosine, NO-phenylalanine, NO-aspartate, NO-histidine,

				and NO-creatine were significantly higher in depressed patients than in normal controls. The autoimmune responses were significantly related to FF symptoms, such as fatigue and a flu-like malaise, whereas the indicants of nitrosative stress were related to gastro-intestinal and autonomic symptoms. DISCUSSION: Depression is characterized by IgM-related autoimmune responses directed against a) neoepitopes that are normally not detected by the immune system but that due to damage by O&NS have become immunogenic; and b) anchorage epitopes, i.e. palmitic and myristic acids, and S-farnesyl-L-cysteine. These autoimmune responses play a role in the inflammatory and O&NS pathophysiology of depression and may mediate the cellular dysfunctions that contribute to neuroprogression, e.g. aberrations in signal transduction, cellular differentiation and apoptosis.
Maes M, Mihaylova I, Kubera M, Leunis JC, Twisk FN, Geffard M.	Maes Clinics, TRIA, Piyavate Hospital, 998 Rimklongsamsen Road, Bangkok, 10310, Thailand. dr.michaelmaes@hotmail.com	IgM-mediated autoimmune responses directed against anchorage epitopes are greater in Myalgic Encephalomyelitis/Chronic Fatigue Syndrome (ME/CFS) than in major depression.	Metab Brain Dis. 2012 Dec;27(4):415-23. doi: 10.1007/s11011-012-9316-8.	Myalgic Encephalomyelitis/Chronic Fatigue Syndrome (ME/CFS) and depression are considered to be neuro-immune disorders (Maes and Twisk, BMC Medicine 8:35, 2010). There is also evidence that depression and ME/CFS are accompanied by oxidative and nitrosative stress (O&NS) and by increased autoantibodies to a number of self-epitopes some of which have become immunogenic due to damage by O&NS. The aim of this study is to examine IgM-mediated autoimmune responses to different self-epitopes in ME/CFS versus depression. We examined serum IgM antibodies to three anchorage molecules (palmitic and myristic acid and S-farnesyl-L-cysteine); acetylcholine; and conjugated NO-modified adducts in 26 patients with major depression; 16 patients with ME/CFS, 15 with chronic fatigue; and 17 normal controls. Severity of fatigue and physio-somatic (F&S) symptoms was measured with the Fibromyalgia and Chronic Fatigue Syndrome Rating Scale. Serum IgM antibodies to the three anchorage molecules and NO-phenylalanine were significantly higher in ME/CFS than in depression. The autoimmune responses to oxidatively, but not nitrosatively, modified self-epitopes were significantly higher in ME/CFS than in depression and were associated with F&S symptoms. The autoimmune activity directed against conjugated acetylcholine did not differ significantly between ME/CFS and depression, but was greater in the patients than controls. Partially overlapping pathways, i.e. increased IgM antibodies to a multitude of neo-epitopes, underpin both ME/CFS and depression, while greater autoimmune responses directed against anchorage molecules and oxidatively modified neo-epitopes discriminate patients with ME/CFS from those with depression. These autoimmune responses directed against neoantigenic determinants may play a role in the dysregulation of key cellular functions in both disorders, e.g. intracellular signal transduction, cellular differentiation and apoptosis, but their impact may be more important in ME/CFS than in depression.
Maes M, Mihaylova I, Kubera M, Ringel	Maes Clinics, TRIA, Bangkok, Thailand. dr.michaelmaes@hotm	Activation of cell-mediated immunity in depression:	Prog Neuropsychopharmacol Biol Psychiatry. 2012 Jan 10;36(1):169-75. doi:	BACKGROUND: Depression is characterized by activation of cell-mediated immunity (CMI), including increased neopterin levels, and increased pro-inflammatory cytokines (PICs), such as interleukin-1 (IL-1) and tumor necrosis factor-α (TNFα). These PICs may

K.	ail.com	association with inflammation, melancholia, clinical staging and the fatigue and somatic symptom cluster of depression.	10.1016/j.pnpbp.2011.09.006.	induce depressive, melancholic and chronic fatigue (CF) symptoms. METHODS: We examined serum neopterin and plasma PIC levels in depressive subgroups in relation to the depressive subtypes and the melancholic and CF symptoms of depression. Participants were 85 patients with depression and in 26 normal controls. Severity of depression was assessed with the Hamilton Depression Rating Scale (HDRS) and severity of CF with the Fibromyalgia and Chronic Fatigue Syndrome (FF) Rating Scale. RESULTS: Serum neopterin was significantly higher in depressed patients and in particular in those with melancholia. There were positive correlations between serum neopterin, the plasma PICs and the number of previous depressive episodes. Neopterin and TNFα were associated with melancholia, while both PICs were associated with CF. Melancholia-group membership was predicted by the HDRS and neopterin, and CF group membership by age, the FF score and serum TNFα. DISCUSSION: Depression and melancholia are accompanied by CMI activation, suggesting that neopterin plays a role in their pathophysiology, e.g. through activation of oxidative and nitrosative stress and apoptosis pathways. The intertwined CMI and inflammatory responses are potentially associated with the onset of depression and with the melancholic and CF symptoms of depression. Exposure to previous depressive episodes may magnify the size of CMI and PIC responses, possibly increasing the likelihood of new depressive episodes. CMI activation and inflammation may contribute to the staging or recurrence of depression.
Maes M, Ringel K, Kubera M, Berk M, Rybakowski J.	Maes Clinics, TRIA, Piyavate Hospital, Bangkok, Thailand. dr.michaelmaes@hotmail.com	Increased autoimmune activity against 5-HT: a key component of depression that is associated with inflammation and activation of cell-mediated immunity, and with severity and staging of depression.	J Affect Disord. 2012 Feb;136(3):386-92. doi: 10.1016/j.jad.2011.11.016.	BACKGROUND: Depression is characterized by inflammation and cell-mediated immune (CMI) activation and autoimmune reactions directed against a multitude of self-epitopes. There is evidence that the inflammatory response in depression causes dysfunctions in the metabolism of 5-HT, e.g. lowering the 5-HT precursor tryptophan, and upregulating 5-HT receptor mRNA. This study has been undertaken to examine autoimmune activity directed against 5-HT in relation to CMI activation and inflammation. METHODS: 5-HT antibodies were examined in major depressed patients (n=109) versus normal controls (n=35) in relation to serum neopterin and lysozyme, and plasma pro-inflammatory cytokines (PIC), i.e. interleukin-1 (IL-1) and tumor necrosis factor-α (TNFα). Severity of depression was assessed with the Hamilton Depression Rating Scale (HDRS) and severity of fatigue and somatic symptoms with the Fibromyalgia and Chronic Fatigue Syndrome (FF) Rating Scale. RESULTS: The incidence of anti-5-HT antibody activity was significantly higher in depressed patients (54.1%), and in particular in those with melancholia (82.9%), than in controls (5.7%). Patients with positive 5-HT antibodies showed increased serum neopterin and lysozyme, and plasma TNFα and IL-1; higher scores on the HDRS and FF scales, and more somatic symptoms, including malaise and neurocognitive dysfunctions. There was a significant association between autoimmune activity to 5-HT and the number of previous depressive episodes. DISCUSSION: The autoimmune reactions directed against 5-HT might play a role in the pathophysiology of depression

				and the onset of severe depression. The strong association between autoimmune activity against 5-HT and inflammation/CMI activation is explained by multiple, reciprocal pathways between these factors. Exposure to previous depressive episodes increases the incidence of autoimmune activity directed against 5-HT, which in turn may increase the likelihood to develop new depressive episodes. These findings suggest that sensitization (kindling) and staging of depression are in part based on progressive autoimmune responses.
Maes M, Twisk FN, Johnson C.	Maes Clinics, TRIA, Piyavate Hospital, 998 Rimklongsamsen Road, Bangkok 10310, Thailand. Electronic address: http://www.michaelmaes.com.	Myalgic Encephalomyelitis (ME), Chronic Fatigue Syndrome (CFS), and Chronic Fatigue (CF) are distinguished accurately: Results of supervised learning techniques applied on clinical and inflammatory data.	Psychiatry Res. 2012 Dec 30;200(2-3):754-60. doi: 10.1016/j.psychres.2012.03.031.	There is much debate on the diagnostic classification of Myalgic Encephalomyelitis (ME), Chronic Fatigue Syndrome (CFS) and chronic fatigue (CF). Post-exertional malaise (PEM) is stressed as a key feature. This study examines whether CF and CFS, with and without PEM, are distinct diagnostic categories. Fukuda's criteria were used to diagnose 144 patients with chronic fatigue and identify patients with CFS and CF, i.e. those not fulfilling the Fukuda's criteria. PEM was rated by means of a scale with defined scale steps between 0 and 6. CFS patients were divided into those with PEM lasting more than 24h (labeled: ME) and without PEM (labeled: CFS). The 12-item Fibromyalgia and Chronic Fatigue Syndrome (FF) Rating Scale was used to measure severity of illness. Plasma interleukin-1 (IL-1), tumor necrosis factor (TNF)α, and lysozyme, and serum neopterin were employed as external validating criteria. Using fatigue, a subjective feeling of infection and PEM we found that ME, CFS, and CF were distinct categories. Patients with ME had significantly higher scores on concentration difficulties and a subjective experience of infection, and higher levels of IL-1, TNFα, and neopterin than patients with CFS. These biomarkers were significantly higher in ME and CFS than in CF patients. PEM loaded highly on the first two factors subtracted from the data set, i.e. "malaise-sickness" and "malaise-hyperalgesia". Fukuda's criteria are adequate to make a distinction between ME/CFS and CF, but ME/CFS patients should be subdivided into ME (with PEM) and CFS (without PEM).
Maes M, Twisk FN, Kubera M, Ringel K, Leunis JC, Geffard M.	Maes Clinics, TRIA, Bangkok, Thailand. dr.michaelmaes@hotmail.com	Increased IgA responses to the LPS of commensal bacteria is associated with inflammation and activation of cell-mediated immunity in chronic fatigue syndrome.	J Affect Disord. 2012 Feb;136(3):909-17. doi: 10.1016/j.jad.2011.09.010.	BACKGROUND: Myalgic Encephalomyelitis/Chronic Fatigue Syndrome (ME/CFS) is accompanied by a) systemic IgA/IgM responses against the lipopolysaccharides (LPS) of commensal bacteria; b) inflammation, e.g. increased plasma interleukin-(IL)1 and tumor necrosis factor (TNF)α; and c) activation of cell-mediated immunity (CMI), as demonstrated by increased neopterin. METHODS: To study the relationships between the IgA/IgM responses to the LPS of microbiota, inflammation, CMI and the symptoms of ME/CFS we measured the IgA/IgM responses to the LPS of 6 different enterobacteria, serum IL-1, TNFα, neopterin, and elastase in 128 patients with ME/CFS and chronic fatigue (CF). Severity of symptoms was assessed by the Fibromyalgia and Chronic Fatigue Syndrome (FF) Rating Scale. RESULTS: Serum IL-1, TNFα, neopterin and elastase are significantly higher in patients with ME/CFS than in CF patients. There are significant and positive associations between the IgA responses to LPS and serum IL-1, TNFα, neopterin and elastase. Patients with an abnormally high IgA response show increased serum IL-1, TNFα and neopterin levels, and higher

				ratings on irritable bowel syndrome (IBS) than subjects with a normal IgA response. Serum IL-1, TNFα and neopterin are significantly related to fatigue, a flu-like malaise, autonomic symptoms, neurocognitive disorders, sadness and irritability. CONCLUSIONS: The findings show that increased IgA responses to commensal bacteria in ME/CFS are associated with inflammation and CMI activation, which are associated with symptom severity. It is concluded that increased translocation of commensal bacteria may be responsible for the disease activity in some ME/CFS patients.
Maes M, Twisk FN, Kubera M, Ringel K.	Maes Clinics, TRIA, Bangkok, Thailand. dr.michaelmaes@hotmail.com	Evidence for inflammation and activation of cell-mediated immunity in Myalgic Encephalomyelitis/Chronic Fatigue Syndrome (ME/CFS): increased interleukin-1, tumor necrosis factor-α, PMN-elastase, lysozyme and neopterin.	J Affect Disord. 2012 Feb;136(3):933-9. doi: 10.1016/j.jad.2011.09.004.	BACKGROUND: There is evidence that inflammatory pathways and cell-mediated immunity (CMI) play an important role in the pathophysiology of Myalgic Encephalomyelitis/Chronic Fatigue Syndrome (ME/CFS). Activation of inflammatory and CMI pathways, including increased levels of cytokines, is known to induce fatigue and somatic symptoms. Given the broad spectrum inflammatory state in ME/CFS, the aim of this study was to examine whether inflammatory and CMI biomarkers are increased in individuals with ME/CFS. METHODS: In this study we therefore measured plasma interleukin-(IL)1, tumor necrosis factor (TNF)α, and PMN-elastase, and serum neopterin and lysozyme in 107 patients with ME/CFS, 37 patients with chronic fatigue (CF), and 20 normal controls. The severity of ME/CFS was measured with the Fibromyalgia and Chronic Fatigue Syndrome (FF) Rating Scale. RESULTS: Serum IL-1, TNFα, neopterin and lysozyme are significantly higher in patients with ME/CFS than in controls and CF patients. Plasma PMN-elastase is significantly higher in patients with ME/CFS than in controls and CF patients and higher in the latter than in controls. Increased IL-1 and TNFα are significantly correlated with fatigue, sadness, autonomic symptoms, and a flu-like malaise; neopterin is correlated with fatigue, autonomic symptoms, and a flu-like malaise; and increased PMN-elastase is correlated with concentration difficulties, failing memory and a subjective experience of infection. CONCLUSIONS: The findings show that ME/CFS is characterized by low-grade inflammation and activation of CMI. The results suggest that characteristic symptoms of ME/CFS, such as fatigue, autonomic symptoms and a flu-like malaise, may be caused by inflammatory mediators, e.g. IL-1 and TNFα.
Maes M, Twisk FN, Ringel K.	Maes Clinics, TRIA, Bangkok, Thailand. dr.michaelmaes @ hotmail.com	Inflammatory and cell-mediated immune biomarkers in myalgic encephalomyelitis/chronic fatigue syndrome and depression: inflammatory markers are higher in	Psychother Psychosom. 2012;81(5):286-95. doi: 10.1159/000336803.	BACKGROUND: Depression is an inflammatory disorder while many authors declare myalgic encephalomyelitis/chronic fatigue syndrome (ME/CFS) to be a functional disorder. The aim of the present study is to compare inflammatory and cell-mediated immune (CMI) responses between depression and ME/CFS. METHODS: We measured two proinflammatory cytokines (PICs) in plasma, interleukin-1 (IL-1) and tumor necrosis factor-α (TNF-α), with enzyme-linked immunosorbent assays, and serum neopterin with a radioimmunoassay in controls, ME/CFS and depressive patients. RESULTS: Plasma PICs were significantly higher in ME/CFS than in depression and higher in both patient groups than in controls. Increased PIC levels in depression were attributable to the presence of fatigue and physio-somatic symptoms. Serum

		myalgic encephalomyelitis/chronic fatigue syndrome than in depression.		neopterin did not differ significantly between depression and ME/CFS but was higher in both patient groups than in controls. The significant positive correlations between neopterin and either IL-1 or TNF-α were significantly greater in depression than in ME/CFS. CONCLUSIONS: Since PICs cause depression-like behaviors and fatigue/malaise, we suggest that inflammation may play a role in the pathophysiology of ME/CFS and depression. Increased neopterin also seems to contribute to the pathophysiology of both disorders. This study has detected a shared 'pathway phenotype', i.e. disorders in inflammatory and CMI pathways, which underpins both ME/CFS and depression and, therefore, may explain the co-occurrence of both disorders. ME/CFS and depression are discriminated from each other by increased PICs in ME/CFS and differences in the immune cell communication networks.
Maggi F, Bazzichi L, Sernissi F, Mazzetti P, Lanini L, Scarpellini P, Consensi A, Giacomelli C, Macera L, Vatteroni ML, Bombardieri S, Pistello M.	[No address quoted]	Absence of xenotropic murine leukemia virus-related virus in Italian patients affected by chronic fatigue syndrome, fibromyalgia, or rheumatoid arthritis.	Int J Immunopathol Pharmacol. 2012 Apr-Jun;25(2):523-9.	The xenotropic murine leukemia virus-related virus (XMRV) has been recently linked to chronic fatigue syndrome in a US cohort in whom the virus was demonstrated in 67% patients vs 3.7% healthy controls. Albeit this finding was not substantiated by subsequent reports and eventually considered a laboratory contamination, the matter is still the object of intense debate and scrutiny in various cohorts of patients. In this work we examined well-clinically characterized Italian patients affected by chronic fatigue syndrome, and also fibromyalgia and rheumatoid arthritis, two chronic illnesses of basically unknown etiology which show quite a few symptoms in common with chronic fatigue syndrome. Although we used recently updated procedures and controls, the XMRV was not found in 65 patients with chronic fatigue syndrome diagnosis, 55 with fibromyalgia, 25 with rheumatoid arthritis, nor in 25 healthy controls. These results add to the ever-growing number of surveys reporting the absence of XMRV in chronic fatigue syndrome patients and suggest that the virus is also absent in fibromyalgia and rheumatoid arthritis.
Maggi F, Focosi D, Lanini L, Sbranti S, Mazzetti P, Macera L, Davini S, De Donno M, Mariotti ML, Antonelli G, Scatena F, Pistello M.	Virology Unit, Pisa University Hospital, Pisa, Italy. fabrizio.maggi63@gmail.com	Xenotropic murine leukaemia virus-related virus is not found in peripheral blood cells from treatment-naive human immunodeficiency virus-positive patients.	Clin Microbiol Infect. 2012 Feb;18(2):184-8. doi: 10.1111/j.1469-0691.2011.03580.x.	The human pathogen xenotropic murine leukaemia virus-related virus (XMRV) has been tentatively associated with prostate cancer and chronic fatigue syndrome. Unfortunately, subsequent studies failed to identify the virus in various clinical settings. To determine whether XMRV circulates in humans and the relationship with its host, we searched for the virus in 124 human immunodeficiency virus-infected patients who might have been exposed to XMRV, might be prone to infection as a result of progressive immunodeficiency, and had not yet been treated with antiretroviral drugs. Using nested PCR and single-step TaqMan real-time PCR, both designed on the XMRV gag gene, we could not find any positive samples. These findings add to the growing amount of scepticism regarding XMRV.
Maher-Edwards L, Fernie BA, Murphy G, Nikcevic AV, Spada MM.	Fatigue Service, Royal Free Hospital, London, UK.	Metacognitive factors in chronic fatigue syndrome.	Clin Psychol Psychother. 2012 Nov;19(6):552-7. doi: 10.1002/cpp.757.	Chronic fatigue syndrome (CFS), which is characterized by fatigue and flu-like symptoms that are not alleviated by rest, is a poorly understood condition and an often controversial diagnosis. Earlier research has indicated that general metacognitions are associated with the severity of symptoms in patients with CFS. In the current study, we aimed to determine whether specific metacognitive factors are

				implicated in CFS. Using the metacognitive profiling interview template we investigated the following: (1) whether patients held positive or negative metacognitions about conceptual processes; (2) what their goals with respect to engaging in these processes were; and (3) what indicated that it was appropriate to stop. We also examined attention focus when experiencing CFS symptoms, and its advantages and disadvantages. Results showed that patients endorsed positive and negative metacognitions pertaining to conceptual processes. The goals of engaging in these processes were to identify the cause of, and devise strategies to cope with, symptoms. Patients were either unable to identify a stop signal for conceptual processing or identified an improvement in fatigue-related symptoms as representing the stop signal. Finally, patients reported that their attention focus when experiencing symptoms included distraction and monitoring of symptoms. Advantages to these strategies included symptom management, whereas disadvantages included an escalation of negative affect. The present findings provide preliminary evidence that specific metacognitive factors may be involved in CFS. profiling that may aid assessment and conceptualisation of psychological distress in CFS.
Malaguarnera M.	Research Centre The Great Senescence, University of Catania, Catania, Italy. malaguar@unict.it	Carnitine derivatives: clinical usefulness.	Curr Opin Gastroenterol. 2012 Mar;28(2):166-76. doi: 10.1097/MOG.0b013e3283505a3b.	PURPOSE OF REVIEW: Carnitine and its derivatives are natural substances involved in both carbohydrate and lipid metabolism. This review summarizes the recent progress in the field in relation to the molecular mechanisms. RECENT FINDINGS: The pool of different carnitine derivatives is formed by acetyl-L-carnitine (ALC), propionyl-L-carnitine (PLC), and isovaleryl-carnitine. ALC may have a preferential effect on the brain tissue. ALC represents a compound of great interest for its wide clinical application in various neurological disorders: it may be of benefit in treating Alzheimer's dementia, depression in the elderly, HIV infection, chronic fatigue syndrome, peripheral neuropathies, ischemia and reperfusion of the brain, and cognitive impairment associated with various conditions. PLC has been demonstrated to replenish the intermediates of the tricarboxylic acid cycle by the propionyl-CoA moiety, a greater affinity for the sarcolemmal carrier, peripheral vasodilator activity, a greater positive inotropism, and more rapid entry into myocytes. Most studies of the therapeutic use of PLC are focused on the prevention and treatment of ischemic heart disease, congestive heart failure, hypertrophic heart disease, and peripheral arterial disease. ALC and PLC are considered well tolerated without significant side-effects. SUMMARY: A number of therapeutic effects possibly come from the interaction of carnitine and its derivatives with the elements of cellular membranes.
Mariman A, Vogelaers D, Hanoulle I, Delesie L, Pevernagie D.	Subjective sleep quality and daytime sleepiness in a large sample of patients with chronic fatigue syndrome (CFS).	Department of General Internal Medicine, Infectious Diseases and Psychosomatic Medicine, University	Acta Clin Belg. 2012 Jan-Feb;67(1):19-24.	Chronic fatigue syndrome (CFS) is characterised by incapacitating fatigue in combination with a number of minor criteria, including unrefreshing sleep without further specifications, in the absence of psychiatric and internal disease. As little data exist on subjective sleep quality and daytime sleepiness, these parameters were assessed in a large sample of CFS patients. Consecutive patients with a diagnosis of CFS in a tertiary referral centre filled out the Fatigue Questionnaire (FQ), Medical

		Hospital Ghent, Belgium. an.mariman@ugent.be		Outcomes Study 36-Item Short Form Health Survey (MOS SF-36), Epworth Sleepiness Scale (ESS) and Pittsburgh Sleep Quality Index (PSQI). Inclusion comprised 415 individuals (mean age 40.5 yr, SD 7.9, range 18-64; 86% female). Mean FQ (26.90; SD 4.04), mean Global Physical Health from the MOS SF-36 (29.30; SD 12.25) and Global Mental Health from the MOS SF-36 (49.62; SD 18.31) scores corresponded with literature data for similar CFS samples. High mean ESS (10.51; SD 5.52) and global PSQI (10.17; SD 4.02) were observed. No significant relationship was found between ESS and global PSQI. In contrast, regression analysis demonstrated a significant cubic relation between ESS and 'PSQI without daytime dysfunction'. A subgroup (n=69) with an insomnia-like phenotype low ESS (<5), high PSQI (mean 11.51; SD 3.86) was observed. The assessment of subjective sleep quality and daytime sleepiness in a large sample of CFS patients indicated high mean PSQI and ESS values. ESS and 'PSQI without daytime dysfunction' were inversely related at the spectral ends of ESS. A distinct subgroup with clinical features of insomnia was identified.
Mariman A, Vogelaers D, Hanoulle I, Delesie L, Tobback E, Pevernagie D.	Department of General Internal Medicine, Infectious Diseases and Psychosomatic Medicine, University Hospital Ghent, Belgium. an.mariman@ugent.be	Validation of the three-factor model of the PSQI in a large sample of chronic fatigue syndrome (CFS) patients.	J Psychosom Res. 2012 Feb;72(2):111-3. doi: 10.1016/j.jpsychores.2011.11.004.	OBJECTIVE: To evaluate whether a 3-factor model of the Pittsburgh Sleep Quality Index (PSQI) scale would fit the constellation of sleep disturbances in patients with a diagnosis of chronic fatigue syndrome (CFS). METHODS: Consecutive CFS patients filled out the PSQI. Scores from this self-report questionnaire were examined with exploratory and confirmatory factor analysis (CFA). RESULTS: 413 CFS patients were included for analysis in this study. CFA showed that the 7 PSQI component scores clustered into the 3 factors reported by Cole et al. (2006), i.e. Sleep Efficiency, Perceived Sleep Quality and Daily Disturbances. In contrast with the single-factor and all 2-factor models, all factor loadings were significant, and all goodness-of-fit values were acceptable. CONCLUSION: In CFS, the PSQI operates as a 3-factor scoring model as initially seen in healthy and depressed older adults. The separation into 3 discrete factors suggests the limited usefulness of the global PSQI as a single factor for the assessment of subjective sleep quality, as also evidenced by a low Cronbach's alpha (0.64) in this patient sample.
Mariman AN, Vogelaers DP, Tobback E, Delesie LM, Hanoulle IP, Pevernagie DA.	Ghent University Hospital, Department of Internal Diseases, Infectious Diseases and Psychosomatic Medicine, 185 De Pintelaan, 9000 Ghent, Belgium. Electronic address: An.mariman@ugent.be.	Sleep in the chronic fatigue syndrome.	Sleep Med Rev. 2012 Oct 6. pii: S1087-0792(12)00073-1. doi: 10.1016/j.smrv.2012.06.003.	Chronic fatigue syndrome (CFS) is a disabling condition characterized by severe fatigue lasting for more than six months and the presence of at least four out of eight minor criteria. Sleep disturbance presenting as unrefreshing or nonrestorative sleep is one of these criteria and is very common in CFS patients. Biologically disturbed sleep is a known cause of fatigue and could play a role in the pathogenesis of CFS. However, the nature of presumed sleep impairment in CFS remains unclear. Whilst complaints of NRS persist over time, there is no demonstrable neurophysiological correlate to substantiate a basic deficit in sleep function in CFS. Polysomnographic findings have not shown to be significantly different between subjects with CFS and normal controls. Discrepancies between subjectively poor and objectively normal sleep suggest a role for psychosocial factors negatively affecting perception of sleep quality. Primary sleep disorders are often detected in patients who otherwise qualify for a

				CFS diagnosis. These disorders could contribute to the presence of daytime dysfunctioning. There is currently insufficient evidence to indicate that treatment of primary sleep disorders sufficiently improves the fatigue associated with CFS. Therefore, primary sleep disorders may be a comorbid rather than an exclusionary condition with respect to CFS.
Marques M, De Gucht V, Leal I, Maes S.	Health Psychology, Leiden University, Wassenaarseweg 52, P.O. BOX 955, 2300 RB, Leiden, The Netherlands, mmarques@ispa.pt.	A Cross-Cultural Perspective on Psychological Determinants of Chronic Fatigue Syndrome: a Comparison Between a Portuguese and a Dutch Patient Sample.	Int J Behav Med. 2012 Sep 13.	BACKGROUND: Few studies focus on cross-cultural differences in Chronic fatigue syndrome (CFS). PURPOSE: This study aimed to (1) compare fatigue severity and impairment, somatic complaints, psychological distress, and quality of life (QoL) in a population of Portuguese and Dutch patients; (2) explore the differential contribution of behavioral and cognitive determinants of fatigue severity; and (3) investigate the relation between fatigue severity and somatic complaints on one hand and QoL on the other in both populations. METHOD: Eighty-five female patients from Portugal (Mean age = 47.54) and 167 female CFS patients from The Netherlands (Mean age = 44.93) participated in the study. All participants were surveyed for demographic and clinical characteristics, fatigue severity, somatic symptoms, psychological distress, (physical and psychological) QoL, physical activity, behavior regulation patterns, and illness representations. RESULTS: Cross-cultural differences were found in relation to working status, duration of fatigue symptoms, psychological distress, somatic complaints, and psychological QoL. Although behavioral characteristics and illness representations were significantly associated with fatigue severity in both Portuguese and Dutch patients, there were important differences in the determinants of CFS. Moreover, higher levels of fatigue and severity of other somatic complaints were related to poor QoL. CONCLUSIONS: These findings show cross-cultural similarities and differences in clinical characteristics and psychological determinants of CFS that are important in view of diagnosis and treatment.
Marques M, De Gucht V, Maes S, Leal I.	Health Psychology Department, Leiden university, Wassenaarseweg 52, P,O, BOX 955, 2300 RB Leiden, The Netherlands. mmarques@ispa.pt	Protocol for the "four steps to control your fatigue (4-STEPS)" randomised controlled trial: a self-regulation based physical activity intervention for patients with unexplained chronic fatigue.	BMC Public Health. 2012 Mar 19;12:202. doi: 10.1186/1471-2458-12-202.	BACKGROUND: Unexplained Chronic Fatigue is a medical condition characterized by the presence of persistent, severe and debilitating medically unexplained fatigue, leading to impaired functioning and lower quality of life. Research suggests that physical activity can contribute to the reduction of fatigue and other somatic symptoms and can thus significantly improve physical functioning and quality of life in these patients. Based on the self-regulation (SR) theory of behaviour change, we developed a brief physical activity program for patients suffering from unexplained chronic fatigue which focuses on the training of self-regulation skills, the "4-STEPS to control your fatigue" program. METHODS/DESIGN: This is a multi-centre, randomised controlled trial (RCT) that will be carried out in local primary care centres and at the Portuguese Fibromyalgia and Chronic Fatigue Syndrome Patients Association. Patients aged between 18 and 65 and fulfilling operationalized criteria for Idiopathic Chronic Fatigue (ICF) and Chronic Fatigue Syndrome (CFS) will be recruited and randomly allocated to standard care (SC) or standard care plus a self-regulation based physical activity program (4-STEPS). Patients will be assessed at baseline, after the

				intervention (3 months) and at 12 months follow-up. The primary outcome is fatigue severity. DISCUSSION: The results of the RCT will provide information about the effectiveness of a brief self-regulation intervention for promoting physical activity in patients with unexplained chronic fatigue. If the program proves to be effective, it may be considered as an adjunctive treatment for these patients. TRIAL REGISTRATION: ISRCTN: ISRCTN70763996.
Martorell L, Tondo M, Garcia-Fructuoso F, Naudo M, Alegre C, Gamez J, Genovés J, Poo P.	Molecular Genetics Section, Hospital Sant Joan de Deu, Edifici docent C/ Santa Rosa 39, 08950 Barcelona, Spain. lmartorell@hsjdbcn.org	Screening for the presence of FMR1 premutation alleles in a Spanish population with fibromyalgia.	Clin Rheumatol. 2012 Nov;31(11):1611-5. doi: 10.1007/s10067-012-2052-y.	Fragile X mental retardation 1 (FMR1) premutation carriers, who are at risk of having children with fragile X Syndrome, were initially considered as clinically unaffected. However, recent clinical and molecular studies have shifted this point of view. The incidence of premutation in the general population is substantial. Apart from the well-documented fragile X-associated tremor-ataxia and fragile X premature ovarian insufficiency, there is a broad constellation of symptoms including depression, anxiety, muscle pain, autoimmune and thyroid disease, chronic fatigue, and fibromyalgia that has been described, particularly in females with the premutation (55-200 repeats). Fibromyalgia (FM) is the most common cause of widespread pain and comprises a heterogeneous group of patients, affecting 2-3 % of the general population. We analyzed the FMR1 gene in a cohort of females diagnosed with fibromyalgia in order to assess the incidence of premutated alleles. CGG repeat size was determined in 353 females suffering from FM and results were compared with a control group. Four premutated carriers in the FM group were detected. The observed incidence is higher than that described for a normal female population (1/88 vs 1/250). The early detection of premutation carriers for the FMR1 gene among individuals diagnosed with fibromyalgia is important and would be helpful in correct genetic counseling of patients and their families, who may be at risk of having children with fragile X syndrome, the most common known cause of inherited intellectual disability and autism. Our data should be cautiously interpreted based on just this study; nevertheless, screening for the FMR1 gene in FM patients at least with presentations suggestive of FMR1 gene-related disease seems recommendable.
Mastaglia FL.	Australian Neuro-Muscular Research Institute and Centre for Neuromuscular and Neurological Disorders, University of Western Australia, Queen Elizabeth II Medical Centre, Perth, WA, Australia. Electronic address: francis.mastaglia@anri.	The relationship between muscle pain and fatigue	Neuromuscul Disord. 2012 Dec;22 Suppl 3:S178-80. doi: 10.1016/j.nmd.2012.10.003.	Pain and fatigue may occur together during sustained exhausting muscle contractions, particularly as the limit of endurance is approached, and both can restrict muscle performance. Patients with neuromuscular disorders may have chronic myofascial pain (e.g. fibromyalgia) or contraction-induced pain (e.g. in metabolic myopathies). In some patients these two types of pain may coexist and both may inhibit central motor drive during exercise. Little is known about the central motor adaptations that occur in patients with neuromuscular disorders and how the effects of pain are mediated. Transcranial magnetic brain stimulation has made it possible to investigate the changes in excitability of the central motor pathway during fatiguing muscle activity and have thrown light on the mechanisms of fatigue in normal subjects and individuals with chronic fatigue syndrome and multiple sclerosis, but there have been few studies in patients with neuromuscular disorders. Repetitive magnetic brain

	uwa.edu.au.			stimulation protocols can now be used to modulate the excitability of the motor system during exercise to delay the onset of peripheral fatigue, and to reduce chronic pain. The possible application of these techniques in patients with neuromuscular disorders warrants further investigation.
Matsui T, Ii K, Hojo S, Sano K.	Japan Neurological Institute and Matsui Hospital, Kannonji, Kagawa, Japan. t.matsui@matsui-hp.com	Cervical neuro-muscular syndrome: discovery of a new disease group caused by abnormalities in the cervical muscles.	Neurol Med Chir (Tokyo). 2012;52(2):75-80.	Our previous study of whiplash injury found that abnormalities in the cervical muscles cause autonomic dystonia. Further research has found that abnormalities in the cervical muscles cause headache, chronic fatigue syndrome, vertigo, and dizziness. We named this group of diseases cervical neuro-muscular syndrome. Patients treated within a 2-year period from April 1, 2002 to March 31, 2004 reported good outcomes in 83.8% for headache, 88.4% for vertigo and dizziness, 84.5% for chronic fatigue syndrome, 88.0% for autonomic dystonia, and 83.7% for whiplash-associated disorder. A large number of outpatients present with general malaise, including many general physical complaints without identifiable cause. We propose that treatment of the cervical muscle is effective for general malaise.
McCall B.	[No address quoted]	Psychiatrist and journalist win prize for defending science.	Lancet. 2012 Nov 17;380(9855):1725	[No abstract given]
McCarberg BH.	Family Medicine, Kaiser Permanente, Escondido, California 92025, USA. bill.h.mccarberg@kp.org	Clinical overview of fibromyalgia.	Am J Ther. 2012 Sep;19(5):357-68. doi: 10.1097/MJT.0b013e3181ff7bee.	Fibromyalgia (FM) is a complex disorder that affects up to 5% of the general population worldwide, more frequently in women than in men. In addition to chronic widespread pain, patients with FM usually experience other characteristic symptoms, including fatigue, disturbed sleep, stiffness, reduced functioning, dyscognition, and depressed mood. Many patients also have comorbid conditions such as depression, irritable bowel syndrome, temporomandibular disorder, or migraine. Although the etiology of FM remains unclear, evidence suggests that biologic, genetic, and environmental factors are involved. The variability of symptoms and the frequency of comorbidities among patients with FM make this a difficult disorder to diagnose. Diagnosis may be further complicated by the stigmatization of this disorder among treatment providers, the health insurance industry, and the general population. Treating chronic pain disorders such as FM can be time consuming and costly, and other issues such as polypharmacy, treatment adherence, and access to treatment often need to be addressed. The aim of this article is to provide physicians with a general overview of FM, including a brief review of the pathophysiology that explains the biologic and genetic bases of this disorder. Also included is a synopsis of new diagnostic criteria and other useful diagnostic tools and a discussion of various treatment challenges and strategies.
McClellan L. Bodei L, Cremonesi M, Grana CM, Chinol M, Baio SM,	lauriemcclellan@hotmail.com Division of Nuclear Medicine, European Institute of	Chronic Lyme disease: it's time to solve the medical mystery inside an	Health Aff (Millwood). 2012 Mar;31(3):647-9. doi: 10.1377/hlthaff.2011.0792. Eur J Nucl Med Mol Imaging.	Comment in Health Aff (Millwood). 2012 Jun;31(6):1368. Peptide receptor radionuclide therapy (PRRT) consists in the systemic administration of a synthetic peptide, labelled with a suitable beta-emitting radionuclide, able to irradiate tumours and their metastases via the internalization through a specific receptor,

Severi S, Paganelli G.	Oncology, Via Ripamonti 435, 20141 Milan, Italy.	enigma. Yttrium-labelled peptides for therapy of NET.	2012 Feb;39 Suppl 1:S93-102. doi: 10.1007/s00259-011-2002-y.	overexpressed on the cell membrane. After 15 years of experience, we can state that PRRT with (90)Y-labelled peptides is generally well tolerated. Acute side effects are usually mild, some of which are related to the co-administration of amino acids, such as nausea. Others are related to the radiopeptide, such as fatigue or the exacerbation of an endocrine syndrome, which rarely occurs in functioning tumours. Chronic and permanent effects on target organs, particularly the kidneys and the bone marrow, are generally mild if the necessary precautions are taken. Currently, the potential risk to kidney and red marrow limits the amount of radioactivity that may be administered. However, when tumour masses are irradiated with adequate doses, volume reduction may be observed. (90)Y-octreotide has been the most widely used radiopeptide in the first 8-10 years of experience. Unfortunately, all of the published results derive from different and inhomogeneous phase I/II studies. Hence, a direct comparison is virtually impossible to date. Nevertheless, even with these limitations, objective responses are registered in 10-34% of patients. The optimal timing of (90)Y-DOTATOC in the management of somatostatin receptor (SSTR)-positive tumours and the way in which it should be integrated with other treatments have yet to be defined, and prospective phase II/III trials comparing the efficacy and toxicity of different schemes of (90)Y-DOTATOC administration are still warranted.
McCrone P, Sharpe M, Chalder T, Knapp M, Johnson AL, Goldsmith KA, White PD.	Centre for the Economics of Mental and Physical Health, Health Service and Population Research Department, Institute of Psychiatry, King's College London, London, United Kingdom. paul.mccrone@kcl.ac.uk	Adaptive pacing, cognitive behaviour therapy, graded exercise, and specialist medical care for chronic fatigue syndrome: a cost-effectiveness analysis.	PLoS One. 2012;7(8):e40808. doi: 10.1371/journal.pone.0040808.	BACKGROUND: The PACE trial compared the effectiveness of adding adaptive pacing therapy (APT), cognitive behaviour therapy (CBT), or graded exercise therapy (GET), to specialist medical care (SMC) for patients with chronic fatigue syndrome. This paper reports the relative cost-effectiveness of these treatments in terms of quality adjusted life years (QALYs) and improvements in fatigue and physical function. METHODS: Resource use was measured and costs calculated. Healthcare and societal costs (healthcare plus lost production and unpaid informal care) were combined with QALYs gained, and changes in fatigue and disability; incremental cost-effectiveness ratios (ICERs) were computed. RESULTS: SMC patients had significantly lower healthcare costs than those receiving APT, CBT and GET. If society is willing to value a QALY at £30,000 there is a 62.7% likelihood that CBT is the most cost-effective therapy, a 26.8% likelihood that GET is most cost effective, 2.6% that APT is most cost-effective and 7.9% that SMC alone is most cost-effective. Compared to SMC alone, the incremental healthcare cost per QALY was £18,374 for CBT, £23,615 for GET and £55,235 for APT. From a societal perspective CBT has a 59.5% likelihood of being the most cost-effective, GET 34.8%, APT 0.2% and SMC alone 5.5%. CBT and GET dominated SMC, while APT had a cost per QALY of £127,047. ICERs using reductions in fatigue and disability as outcomes largely mirrored these findings. CONCLUSIONS: Comparing the four treatments using a health care perspective, CBT had the greatest probability of being the most cost-effective followed by GET. APT had a lower probability of being the most cost-effective option than SMC alone. The relative cost-effectiveness was even greater from a societal perspective as additional

				cost savings due to reduced need for informal care were likely.
McMahon L, Murray C, Sanderson J, Daiches A.	Tees, Esk & Wear Valleys NHS Foundation Trust, Middlesbrough, UK.	"Governed by the pain": narratives of fibromyalgia.	Disabil Rehabil. 2012;34(16):1358-66. doi: 10.3109/09638288.2011.645114.	PURPOSE: Fibromyalgia (FM) is a chronic syndrome characterized by pain and fatigue. The aim of this study was to explore how individuals with FM make sense of the illness experience and integrate it into their personal biographies. METHOD: Ten women from a pain management service in the north west of England were interviewed for the study. A chronological summary of each life story was produced and narrative features such as plot, tone, imagery and metaphors were identified and compared. RESULTS: Findings are presented in the form of a meta-narrative incorporating all 10 narratives over five phases: (1) making sense of FM: when I was younger, I didn't have any problems at all; (2) onset and diagnosis: you just feel like you're constantly complaining; (3) invasion of FM: you're just trapped; trapped in this body; (4) coping with FM: you try to do things in a pattern it will obey and (5) ongoing struggle: I refuse to give in to it. CONCLUSIONS: The narrative is characterized by a lack of movement and resolution, with participants engaged in an enduring struggle against the challenges of FM. Psychological approaches that facilitate this ongoing adjustment process may prove beneficial in FM treatment and rehabilitation.
McMahon L, Murray C, Simpson J.	Tees Time to Talk IAPT Service, Middlesbrough, UK.	The potential benefits of applying a narrative analytic approach for understanding the experience of fibromyalgia: a review.	Disabil Rehabil. 2012;34(13):1121-30. doi: 10.3109/09638288.2011.628742.	PURPOSE: People with fibromyalgia (FM), a medically unexplained illness, habitually experience widespread pain and fatigue. While some qualitative research has aimed to understand the experiences of people with FM, studies from a specific narrative perspective are particularly lacking. This review argues that future research could be significantly enhanced by studies which analyse the narratives of people with FM. METHOD: This argument is made through reference to an examination of the extant qualitative literature on the experience of FM and theories and narrative studies on chronic illnesses and identity. RESULTS: The empirical literature is reviewed from a narrative perspective; this assumes that the stories people tell reveal much about their identities and social worlds. As such, it is proposed that narrative analysis is particularly well suited for exploring issues of self and culture and for appreciating how meanings evolve over time. Further, it is also argued that consideration of these issues is particularly relevant for understanding the experience of FM given the enigmatic nature of the syndrome and its chronic course. CONCLUSIONS: The review concludes by emphasizing that narrative analysis is a valuable method which offers the potential for uncovering novel insights about the illness experience for these individuals.
Medow MS, Aggarwal A, Baugham I, Messer Z, Stewart JM.	Department of Pediatrics, New York Medical College and The Center for Pediatric Hypotension, Hawthorne, New York.	Modulation of the axon-reflex response to local heat by reactive oxygen species in subjects with chronic fatigue syndrome.	J Appl Physiol. 2013 Jan;114(1):45-51. doi: 10.1152/japplphysiol.00821.2012.	Local cutaneous heating causes vasodilation as an initial first peak, a nadir, and increase to plateau. Reactive oxygen species (ROS) modulate the heat plateau in healthy controls. The initial peak, due to C-fiber nociceptor-mediated axon reflexes, is blunted with local anesthetics and may serve as a surrogate for the cutaneous response to peripheral heat. Chronic fatigue syndrome (CFS) subjects report increased perception of pain. To determine the role of ROS in this neurally mediated response, we evaluated changes in cutaneous blood flow from local heat in nine CFS subjects

				(16-22 yr) compared with eight healthy controls (18-26 yr). We heated skin to 42°C and measured local blood flow as a percentage of maximum cutaneous vascular conductance (%CVC(max)). Although CFS subjects had significantly lower baseline flow [8.75 ± 0.56 vs. 12.27 ± 1.07 (%CVC(max), CFS vs. control)], there were no differences between groups to local heat. We then remeasured this with apocynin to inhibit NADPH oxidase, allopurinol to inhibit xanthine oxidase, tempol to inhibit superoxide, and ebselen to reduce H(2)O(2). Apocynin significantly increased baseline blood flow (before heat, 14.91 ± 2.21 vs. 8.75 ± 1.66) and the first heat peak (69.33 ± 3.36 vs. 59.75 ± 2.75). Allopurinol and ebselen only enhanced the first heat peaks (71.55 ± 2.48 vs. 61.72 ± 2.01 and 76.55 ± 5.21 vs. 58.56 ± 3.66, respectively). Tempol had no effect on local heating. None of these agents changed the response to local heat in control subjects. Thus the response to heat may be altered by local levels of ROS, particularly H(2)O(2) in CFS subjects, and may be related to their hyperesthesia/hyperalgesia.
Meeus M, Ickmans K, De Clerck LS, Moorkens G, Hans G, Grosemans S, Nijs J.	Department of Human Physiology, Faculty of Physical Education and Physiotherapy, Vrije Universiteit Brussel, Building L-Mfys, Pleinlaan 2, 1050 Brussels, Belgium. Mira.Meeus@vub.ac.be	Serotonergic descending inhibition in chronic pain: design, preliminary results and early cessation of a randomized controlled trial.	In Vivo. 2011 Nov-Dec;25(6):1019-25.	AIM: We examined whether activation of serotonergic descending pathways improves pain inhibition during exercise in patients with chronic fatigue syndrome (CFS) and comorbid fibromyalgia (FM) in comparison with rheumatoid arthritis (RA) and sedentary, healthy controls in a double-blind randomized controlled trial with cross-over design. PATIENTS AND METHODS: Three female CFS/FM patients, one female RA patient and two healthy women were randomly allocated to the experimental group (2 ml of citalopram intravenously) or the placebo group (2 ml of 0.9% NaCl intravenously). Participants performed a submaximal exercise protocol, preceded and followed by an assessment of endogenous pain inhibition. Seven days later, groups were crossed over. RESULTS: Significant side-effects were observed in all, but one participant immediately after intravenous administration of citalopram. One CFS/FM patient withdrew because of severe post-exertional malaise. CONCLUSION: It was decided that proceeding with the study would be unethical. No conclusion could be made regarding pain inhibition during exercise in CFS/FM compared to RA and controls.
Meeus M, Nijs J, Van Mol E, Truijen S, De Meirleir K.	Division of Musculoskeletal Physiotherapy, Department of Health Sciences, Artesis University College Antwerp, Van Aertselaerstraat 31, Merksem, Antwerp, Belgium.	Role of psychological aspects in both chronic pain and in daily functioning in chronic fatigue syndrome: a prospective longitudinal study.	Clin Rheumatol. 2012 Jun;31(6):921-9. doi: 10.1007/s10067-012-1946-z. Epub 2012 Feb 16.	In addition to fatigue, many patients with chronic fatigue syndrome (CFS) experience chronic musculoskeletal pain. We aimed at examining the role of catastrophizing, coping, kinesiophobia, and depression in the chronic pain complaints and in the daily functioning of CFS patients. A consecutive sample of 103 CFS patients experiencing chronic widespread musculoskeletal pain completed a battery of questionnaires evaluating pain, daily functioning, and psychological characteristics (depression, kinesiophobia, pain coping, and catastrophizing). Thirty-nine patients participated in the 6-12-month follow-up, consisting of questionnaires evaluating pain and pressure pain algometry. Correlation and linear regression analyses were performed to identify predictors. The strongest correlations with pain intensity were found for catastrophizing ($r = -.462$, $p < .001$) and depression ($r = -.439$, $p < .001$). The stepwise

				multiple regression analysis revealed that catastrophizing was both the immediate main predictor for pain (20.2%) and the main predictor on the longer term (20.1%). The degree of depression was responsible for 10% in the observed variance of the VAS pain after 6-12 months. No significant correlation with pain thresholds could be revealed. The strongest correlations with daily functioning at baseline were found for catastrophizing ($r = .435$, $p < .001$) and depression ($r = .481$, $p < .001$). Depression was the main predictor for restrictions in daily functioning (23.1%) at baseline. Pain catastrophizing and depression were immediate and long-term main predictors for pain in patients with CFS having chronic widespread musculoskeletal pain. They were also correlated to daily functioning, with depression as the main predictor for restrictions in daily functioning at baseline.
Meeus M, van Eupen I, van Baarle E, De Boeck V, Luyckx A, Kos D, Nijs J.	Division of Musculoskeletal Physiotherapy, Department of Health Sciences, Artesis University College Antwerp, Belgium.	Symptom fluctuations and daily physical activity in patients with chronic fatigue syndrome: a case-control study.	Arch Phys Med Rehabil. 2011 Nov;92(11):1820-6. doi: 10.1016/j.apmr.2011.06.023.	OBJECTIVES: To compare the activity pattern of patients with chronic fatigue syndrome (CFS) with healthy sedentary subjects and examine the relationship between the different parameters of performed activity (registered by an accelerometer device) and symptom severity and fluctuation (registered by questionnaires) in patients with CFS. DESIGN: Case-control study. Participants were asked to wear an accelerometer device on the nondominant hand for 6 consecutive days. Every morning, afternoon, and evening patients scored the intensity of their pain, fatigue, and concentration difficulties on a visual analog scale. SETTING: Patients were recruited from a specialized chronic fatigue clinic in the university hospital, where all subjects were invited for 2 appointments (for questionnaire and accelerometer adjustments). In between, activity data were collected in the subject's normal home environment. PARTICIPANTS: Female patients (n=67) with CFS and female age-matched healthy sedentary controls. INTERVENTIONS: Not applicable. MAIN OUTCOME MEASURES: Accelerometry (average activity counts, peak activity counts, ratio peak/average, minutes spent per activity category) and symptom severity (intensity of pain, fatigue, and concentration difficulties). RESULTS: Patients with CFS were less active, spent more time sedentary, and less time lightly active ($P<.05$). The course of the activity level during the registration period (P interaction$>.05$), peak activity, and the staggering of activities (ratio peak/average) on 1 day were not different between groups ($P>.05$). Negative correlations (-.242 varying to -.307) were observed for sedentary activity and the ratio with symptom severity and variation on the same and the next day. Light, moderate, and vigorous, as well as the average activity and the peak activity, were positively correlated (.242 varying to .421) with symptom severity and variation. CONCLUSIONS: The more patients with CFS are sedentary and the better activity is dispersed, the fewer symptoms and variations they experience on the same and next day. Inversely, more symptoms and variability is experienced when patients were more active that day or the previous day. The direction of these relations cannot be determined in a cross-sectional study and requires further study.

Méndez-Vidal MJ, Martínez Ortega E, Montesa Pino A, Pérez Valderrama B, Viciana R.	Hospital Provincial de Córdoba, Córdoba, Spain. mariajose.mendezvidal@gmail.com	Management of adverse events of targeted therapies in normal and special patients with metastatic renal cell carcinoma.	Cancer Metastasis Rev. 2012 Sep;31 Suppl 1:S19-27. doi: 10.1007/s10555-012-9355-y.	Treatment options for metastatic renal cell carcinoma (mRCC) have evolved very rapidly, as reflected by the approval of the many drugs that have shown efficacy in phase III studies. Approved drugs include tyrosine kinase inhibitors (TKI) such as sunitinib, sorafenib and pazopanib, vascular endothelial growth factor inhibitors such as bevacizumab, and mammalian target of rapamycin (mTOR) inhibitors such as temsirolimus and everolimus. These biological agents have toxicity profiles that differ from those accompanying current chemotherapeutic agents, but their novelty leads to a lack of exhaustive clinical data regarding related adverse events (AEs), whose symptoms may overlap with those of the chronic illnesses of patients with mRCC such as hypertension, hyperglycemia, and pneumonitis. Hypertension, hypothyroidism, hand-foot syndrome, and fatigue are AEs frequently associated with TKIs; whereas immunosuppression, stomatitis, metabolic alterations, and non-infectious pneumonitis are AEs of mTOR inhibitors. Recommendations for treating these adverse events in patients with mRCC are usually the same as those for the general population. Mild to moderate toxicities may be managed with supportive and pharmacologic interventions, but higher-grade toxicities usually require external specialist consultation, dose reductions, and treatment interruption or discontinuation. Some groups of patients with mRCC, such as frail, elderly patients, and patients with renal or liver dysfunction, require special management of AEs.
Mendoza R, Silverman RH, Klein EA, Miller AD.	Human Biology Division, Fred Hutchinson Cancer Research Center, Seattle, Washington, United States of America.	No biological evidence of XMRV in blood or prostatic fluid from prostate cancer patients.	PLoS One. 2012;7(5):e36073. doi: 10.1371/journal.pone.0036073.	BACKGROUND: XMRV (xenotropic murine leukemia virus-related virus) was initially discovered in association with prostate cancer and later with chronic fatigue syndrome (CFS). Its association with CFS is now largely discredited, and current results support a laboratory origin for XMRV with no reproducible evidence for infection of humans. However, some results indicating the presence of XMRV in prostate cancer are difficult to attribute to sample contamination. Here we have sought biological evidence that might confirm the presence of XMRV in prostate cancer samples previously having tested positive. METHODS AND RESULTS: We have tested for infectious XMRV and neutralizing antibodies against XMRV in blood plasma from 29 subjects with prostate cancer, and for infectious XMRV in prostate secretions from another five prostate cancer subjects. Nine of these subjects had previously tested positive for XMRV by PCR or by virus assay. We did not detect XMRV or related retroviruses in any sample, and the neutralizing activities of the plasma samples were all very low, a result inconsistent with XMRV infection of the plasma donors. CONCLUSIONS: We find no evidence for XMRV infection of any human subject tested, either by assay for infectious virus or for neutralizing antibodies. Our results are consistent with the majority of published studies on XMRV, which find that XMRV is not present in humans. The observed low to undetectable XMRV neutralization by human plasma indicates a lack of innate restriction of XMRV replication by soluble factors in human blood.
Menzies V, Jallo N.	Virginia	Guided imagery as a	J Holist Nurs. 2011	PURPOSE: Fatigue is one of the most common complaints experienced among the

	Commonwealth University, Richmond, USA. vsmenzies@vcu.edu	treatment option for fatigue: a literature review	Dec;29(4):279-86. doi: 10.1177/0898010111412187.	general population. Because fatigue is recognized as a biobehavioral occurrence, a biobehavioral intervention such as guided imagery may be effective in reducing self-reported fatigue. Therefore, the purpose of this study was to explore the research literature related to the use of guided imagery as a nonpharmacological mind-body intervention for the symptom of fatigue. METHOD: The electronic databases MEDLINE, CINAHL, PsychInfo, Psychology and Behavioral Sciences Collection and the Cochrane Library were searched from January 1980 to June 2010. Findings: Of 24 articles retrieved, eight met the inclusion criteria and were included in this systematic literature review. Findings were inconsistent regarding the effectiveness of guided imagery on fatigue. Studies varied in study length, duration of the applied guided imagery intervention, dosage, and whether the images were targeted to the purpose of the intervention. IMPLICATIONS: Guided imagery is a simple, economic intervention with the potential to effectively treat fatigue, thus further research is warranted using systematic, well-designed methodologies Standardizing guided imagery interventions according to total duration of exposure and targeted imagery in a variety of different populations adequately powered to detect changes will contribute to and strengthen nursing's symptom-management armamentarium.
Merkies IS, Faber CG.	Department of Neurology, Spaarne Hospital, Hoofddorp, The Netherlands; Department of Neurology, Maastricht University Medical Centre, Maastricht, The Netherlands. Electronic address: isjmerkies@planet.nl.	Fatigue in immune-mediated neuropathies	Neuromuscul Disord. 2012 Dec;22 Suppl 3:S203-7. doi: 10.1016/j.nmd.2012.10.014.	Fatigue, a highly debilitating symptom, is reported in most patients with immune-mediated neuropathies, particularly in Guillain-Barré syndrome, chronic immune-mediated demyelinating polyradiculoneuropathy, monoclonal gammopathy of undetermined significance related polyneuropathy, and multifocal motor neuropathy. Aspects like the degree of known fatigue in these disorders, its impact on daily functioning and quality of life, the suggested underlying mechanisms, and possible therapeutic interventions for fatigue will be addressed in this review.
Mi Z, Lu Y, Zhang S, An X, Wang X, Chen B, Wang Q, Tong Y.	Beijing Institute of Microbiology and Epidemiology and Affiliated Hospital, Academy of Military Medical Sciences, Beijing, China. zhiqiangmi@yahoo.com.cn	Absence of xenotropic murine leukemia virus-related virus in blood donors in China.	Transfusion. 2012 Feb;52(2):326-31. doi: 10.1111/j.1537-2995.2011.03267.x.	BACKGROUND: Xenotropic murine leukemia virus-related virus (XMRV) is a novel human gammaretrovirus that was first identified in patients with prostate cancer in 2006. Subsequent studies have shown that XMRV is also detected in patients with chronic fatigue syndrome (CFS) and even in some healthy controls and blood donors. However, some conflicting findings have been reported by different laboratories or in different regions. The association of XMRV with human diseases and the prevalence of XMRV in different populations needs to be further determined. STUDY DESIGN AND METHODS: XMRV was screened in 391 blood samples from healthy blood donors in China. Nested reverse transcription-polymerase chain reaction (PCR) was used to amplify gag and env genes of XMRV from total RNA of peripheral blood mononuclear cells (PBMNCs) and plasma, respectively. Quantitative PCR was performed to detect XMRV env gene in genomic DNA of PBMNCs. To enhance the detection sensitivity,

				plasma was added into LNCaP cells to amplify XMRV in the plasma samples. RESULTS: No XMRV was found in the 391 blood donors in China or in the LNCaP cells inoculated with plasma from the blood donors. CONCLUSION: Both PCR and virus isolation in highly permissive LNCaP cells failed to detect XMRV in 391 Chinese blood donors, indicating that XMRV infection might not be present in blood donors in China.
Mikirova N, Casciari J, Hunninghake R.	Riordan Clinic, Wichita, Kansas, USA. nmikirova@riordanclinic.org	The assessment of the energy metabolism in patients with chronic fatigue syndrome by serum fluorescence emission.	Altern Ther Health Med. 2012 Jan-Feb;18(1):36-40.	CONTEXT: Chronic fatigue syndrome (CFS) is a debilitating fatigue illness that has unknown etiology and lacks an objective diagnostic marker. OBJECTIVE: To examine the metabolic component of CFS to determine if practitioners can use serum NAD(P)H concentration measurements to monitor metabolism and fatigue status in patients with CFS. DESIGN: The research team conducted a case-control study, comparing a group of patients who were diagnosed with CFS with a control group of healthy subjects. The team obtained venous blood samples from fasting patients to examine the serum NAD(P)H concentrations. SETTING: The study occurred at the Riordan Clinic in Witchita, Kansas. PARTICIPANTS: The study included 44 CFS patients at the Riordan Clinic and 30 healthy control participants. The CFS patients presented a spectrum of symptoms that had existed for at least 6 months: new, unexplained, persistent, or relapsing chronic fatigue that bed rest did not resolve and that was severe enough to reduce daily activity significantly by 50% in conjunction with headache, muscle pain, pain in multiple joints, and unrefreshing sleep. In the control group, the research team enrolled subjects without diagnosis of disease or injury. OUTCOME MEASURES: The research team determined levels of serum reduced nicotinamide adenine dinucleotides (NADH and NAD[P]H) by measuring serum fluorescence emission at 450 nm. The team then conducted sensitivity and specificity analyses. Results NAD(P)H concentrations in serum of CFS participants averaged 8.0 ± 1.4 (standard deviation [SD]) nmol/mL, while those in the healthy controls averaged 10.8 ± 0.8 (SD) nmol/mL, a statistically significant difference. Using a cut-off concentration of 9.5 nmol/mL, the research team attained a sensitivity of 0.73 and a specificity of 1.0. An analysis of receiver-operator characteristics yielded an area under the curve of 0.9. The research team compared serum NAD(P)H to several endocrine and metabolic lab parameters. Serum NAD(P)H was directly correlated with serum CoQ10 levels and inversely correlated with urine hydroxyhemopyrrolin-2-one levels. CONCLUSIONS: Based on these findings, the research team proposed using serum NAD(P)H, measured as an intrinsic serum-fluorescence emission, to monitor metabolism and fatigue status in patients with CFS. Following patients NAD(P)H levels over time may aid in selecting therapeutic strategies and monitoring treatment outcomes.
Miletić V, Relja M.	University of Zagreb, School of Medicine and Zagreb University Hospital Centre, Department of	Restless legs syndrome.	Coll Antropol. 2011 Dec;35(4):1339-47.	Being of the most frequent causes of insomnia, which in the end leads to chronic fatigue, inadequate performance of daily activities, and serious disruption of quality of living, restless legs syndrome (RLS) is nowadays not only a serious medical problem but a socio-economical one as well. Prevalence of the disorder in general population is estimated at 5 to 15%. Family history is positive in over 50% of idiopathic RLS

	Neurology, Zagreb, Croatia.			patients which points to genetic basis of the disorder. The characteristics of the secondary or acquired form of RLS are symptoms that start later in life as well as a rapid progression of the disease. On the other hand, idiopathic RLS more often starts at a younger age and the prognoses are better. Over twenty disorders and conditions are brought in connection with secondary RLS. Although the cause of primary RLS is still unknown, there is a strong connection between central metabolism of iron as well as dopamine levels and RLS manifestation. A differential diagnosis of RLS includes a wide specter of motor and sensory disorders. Diagnosis is based on clinical features and the history of disease. To correctly diagnose idiopathic RLS one must first eliminate secondary causes of RLS and then also exclude any disorders with clinical features that mimic those of RLS. It has been estimated that some 20 to 25% of patients need pharmacological therapy. Best initial therapy is the application of nonergot dopamine agonists. Anticonvulsants, benzodiazepines and opioides can be given to patients who are refractory to dopaminergic therapy, those suffering from RLS with emphasized painful sensory component and those with RLS connected with insomnia.
Miller P, Iyer M, Gold AR.	[No address quoted]	Treatment resistant adolescent depression with upper airway resistance syndrome treated with rapid palatal expansion: a case report.	J Med Case Rep. 2012 Dec 4;6(1):415	ABSTRACT: INTRODUCTION: To the best of our knowledge this is the first report of a case of treatment-resistant depression in which the patient was evaluated for sleep disordered breathing as the cause and in which rapid palatal expansion to permanently treat the sleep disordered breathing produced a prolonged symptom-free period off medication. CASE PRESENTATION: An 18-year-old Caucasian man presented to our sleep disorders center with chronic severe depression that was no longer responsive to medication but that had recently responded to electroconvulsive therapy. Ancillary, persistent symptoms included mild insomnia, moderate to severe fatigue, mild sleepiness and severe anxiety treated with medication. Our patient had no history of snoring or witnessed apnea, but polysomnography was consistent with upper airway resistance syndrome. Although our patient did not have an orthodontic indication for rapid palatal expansion, rapid palatal expansion was performed as a treatment of his upper airway resistance syndrome. Following rapid palatal expansion, our patient experienced a marked improvement of his sleep quality, anxiety, fatigue and sleepiness. His improvement has been maintained off all psychotropic medication and his depression has remained in remission for approximately two years following his electroconvulsive therapy. CONCLUSIONS: This case report introduces the possibility that unrecognized sleep disordered breathing may play a role in adolescent treatment-resistant depression. The symptoms of upper airway resistance syndrome are non-specific enough that every adolescent with depression, even those responding to medication, may have underlying sleep disordered breathing. In such patients, rapid palatal expansion, by widening the upper airway and improving airflow during sleep, may produce a prolonged improvement of symptoms and a tapering of medication. Psychiatrists treating

				adolescents may benefit from having another treatment option for treatment-resistant depression.
Minelli A, Vaona A.	alessandra.minelli@med.unibs.it.	[Article in Italian]	Reumatismo. 2012 Jul 19;64(3):151-7. doi: 10.4081/reumatismo.2012.151.	Fibromyalgia (FM) is a chronic disorder caused by a dysfunction of central nervous system sensitization. This syndrome is characterized by widespread pain and diffuse tenderness, but often also presents fatigue, sleep disturbances, and a whole range of symptoms such as morning stiffness, decreased physical function and dyscognition. FM is usually treated with pharmacological and non-pharmacological treatments. The non-pharmacological interventions include cognitive behavioral therapy (CBT), physiotherapy, acupuncture and patient education programs. In order to evaluate the efficacy of CBT and compare it with other non-pharmacological treatments, we performed a review of the meta-analytic literature. We evaluated the methodological quality of publications found by following the recommendations of the PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) statement. Data showed that CBT does not provide better results than other non-pharmacological treatments on outcomes of pain, fatigue, sleep disturbance and quality of life, at either a short or long-term evaluation. On the contrary, CBT seems to be more effective on symptoms of depression for a short period, whereas it considerably improves the pain self-management and reduces the number of visits to the doctor. The data currently available indicate that cost-effectiveness studies could help us to understand whether the reduction in the number of visits to the doctor could balance the cost of CBT to the health public system.
Missen A, Hollingworth W, Eaton N, Crawley E.	School of Social and Community Medicine, University of Bristol, Bristol, UK.	The financial and psychological impacts on mothers of children with chronic fatigue syndrome (CFS/ME).	Child Care Health Dev. 2012 Jul;38(4):505-12. doi: 10.1111/j.1365-2214.2011.01298.x.	BACKGROUND: Paediatric chronic fatigue syndrome or myalgic encephalopathy (CFS/ME) is relatively common and children can be severely affected attending little or no school for extended periods. There are no studies quantifying the financial impact of having a child with CFS/ME and there is little information of the impact on parental mood. METHODS: Forty mothers of children with CFS/ME from a regional specialist CFS/ME service completed inventories to assess their psychological well-being (Hospital Anxiety and Depression Scale, General Health Questionnaire-12) loss of earnings and increased expenditure. In addition, eight mothers took part in a semi-structured qualitative interview. RESULTS: Most parents of children with CFS/ME experience loss of monthly income (mean = £247) and increase in monthly expenditure (mean = £206). Twenty-eight (72%) mothers were above the cut-off for the General Health Questionnaire-12 compared with 20% in the healthy population (95% CI 55, 85, P < 0.001) suggesting they probably have a mental health problem. This may be explained by the qualitative interviews where mothers described five areas contributing to poor parental health: lack of understanding from others; marital tension; concern about their child's distress; concern about the impact on siblings and emotional distress causing physical symptoms. CONCLUSIONS: The majority of families of children with CFS/ME experience decreased income and increased expenditure with a marked impact on maternal psychological health. Clinicians need

				to be aware of this to provide appropriate support to families who care for children with CFS/ME.
Miwa K, Fujita M.	Department of Internal Medicine, Miwa Naika Clinic, Toyama, Japan. info@miwa-naika.com	Small heart with low cardiac output for orthostatic intolerance in patients with chronic fatigue syndrome.	Clin Cardiol. 2011 Dec;34(12):782-6. doi: 10.1002/clc.20962.	BACKGROUND: The etiology of chronic fatigue syndrome (CFS) is unknown. Orthostatic intolerance (OI) is common in CFS patients. Recently, small heart with low cardiac output has been postulated to be related to the genesis of both CFS and OI. HYPOTHESIS: Small heart is associated with OI in patients with CFS. METHODS: Study CFS patients were divided into groups of 26 (57%) CFSOI(+) and 20 (43%) CFSOI(-) according to the presence or absence of OI. In addition, 11 OI patients and 27 age- and sex-matched control subjects were studied. Left ventricular (LV) dimensions and function were determined echocardiographically. RESULTS: The mean values of cardiothoracic ratio, systemic systolic and diastolic pressures, LV end-diastolic dimension, LV end-systolic dimension, stroke volume index, cardiac index, and LV mass index were all significantly smaller in CFSOI(+) patients than in CFSOI(-) patients and healthy controls, and also in OI patients than in controls. A smaller LV end-diastolic dimension (<40 mm) was significantly (P<0.05) more prevalently noted in CFSOI(+) (54%) and OI (45%) than in CFSOI(-) (5%) and controls (4%). A lower cardiac index (<2 L/min/mm(2)) was more prevalent in CFSOI(+) (65%) than in CFSOI(-) (5%, P<0.01), OI (27%), and controls (11%, P<0.01). CONCLUSIONS: A small size of LV with low cardiac output was noted in OI, and its degree was more pronounced in CFSOI(+). A small heart appears to be related to the genesis of OI and CFS via both cerebral and systemic hypoperfusion. CFSOI(+) seems to constitute a well-defined and predominant subgroup of CFS.
Mohammad A, Carey JJ, Storan E, Scarry M, Coughlan RJ, Lee JM.	Department of Rheumatology, Merlin Park University Hospital, Galway, Ireland. ausafmohammad@gmail.com	Prevalence of fibromyalgia among patients with chronic hepatitis C infection: relationship to viral characteristics and quality of life.	J Clin Gastroenterol. 2012 May-Jun;46(5):407-12. doi: 10.1097/MCG.0b013e3182485528.	OBJECTIVES: We determined the prevalence of fibromyalgia syndrome (FMS) in a cohort of subjects with chronic hepatitis C virus (HCV), and the relationship to subject demographics, viral characteristics, and quality of life. METHODS: In a cross-sectional study of a cohort of HCV-infected individuals, all subjects underwent a standard assessment including history, clinical examination, and functional assessments for pain and disability. RESULTS: A total of 185 subjects met the inclusion criteria. Median age was 48.7 years, and 110 (59%) were women. A total of 106 (57%) of the subjects met criteria for the presence of FMS. Widespread pain and ≥11 tender points were present in all of the subjects with FMS, fatigue in 98 (92%), and depression in 60 (57%). Among those with FMS, mean pain score was 70±11.78 and 36% reported some functional impairment on (HAQ-DI>0), with 17% reporting moderate-to-severe functional impairment (HAQ-DI≥1.5). CONCLUSIONS: This study reveals a high prevalence of FMS (57%) among subjects with chronic HCV infection, one third of whom reported some degree of functional impairment. Recognition and management of this condition in such patients will help improve their quality of life.
Mohan KV, Devadas K, Sainath Rao S, Hewlett I,	Section of Cell Biology, Laboratory of Cellular Hematology, Center for	Identification of XMRV infection-associated	PLoS One. 2012;7(3):e32853. doi: 10.1371/journal.pone.003285	INTRODUCTION: XMRV is a gammaretrovirus that was thought to be associated with prostate cancer (PC) and chronic fatigue syndrome (CFS) in humans until recently. The virus is culturable in various cells of human origin like the lymphocytes, NK cells,

Atreya C.	Biologics Evaluation and Research, Food and Drug Administration, Bethesda, Maryland, United States of America.	microRNAs in four cell types in culture.	3	neuronal cells, and prostate cell lines. MicroRNAs (miRNA), which regulate gene expression, were so far not identified in cells infected with XMRV in culture. METHODS: Two prostate cell lines (LNCaP and DU145) and two primary cells, Peripheral Blood Lymphocytes [PBL] and Monocyte-derived Macrophages [MDM] were infected with XMRV. Total mRNA was extracted from mock- and virus-infected cells at 6, 24 and 48 hours post infection and evaluated for microRNA profile in a microarray. RESULTS: MicroRNA expression profiles of XMRV-infected continuous prostate cancer cell lines differ from that of virus-infected primary cells (PBL and MDMs). miR-193a-3p and miRPlus-E1245 observed to be specific to XMRV infection in all 4 cell types. While miR-193a-3p levels were down regulated miRPlus-E1245 on the other hand exhibited varied expression profile between the 4 cell types. DISCUSSION: The present study clearly demonstrates that cellular microRNAs are expressed during XMRV infection of human cells and this is the first report demonstrating the regulation of miR193a-3p and miRPlus-E1245 during XMRV infection in four different human cell types.
Morelli V.	Department of Family and Community Medicine, Meharry Medical College, 1005 Dr. D.B. Todd Jr. Boulevard, Nashville, TN 37208, USA. vmorelli@mmc.edu	Fatigue and chronic fatigue in the elderly: definitions, diagnoses, and treatments.	Clin Geriatr Med. 2011 Nov;27(4):673-86. doi: 10.1016/j.cger.2011.07.011.	Because fatigue is so prevalent in the elderly population, it is important that physicians be well versed in the evaluation and management of this complaint. This article discusses the clinical manifestations and predisposing factors for the three major categories of fatigue: recent, prolonged, and chronic. The CDC classification of chronic fatigue syndrome is included. Patient dissatisfaction with the care for their fatigue is a common problem. Several pharmaceutical treatment methods are presented. Non-pharmacologic options, such as use of vitamins, exercise, behavior modification,and diet are also discussed.
Morris G, Maes M.	Tir Na Nog, Pembrey, Llanelli, UK.	Increased nuclear factor-κB and loss of p53 are key mechanisms in Myalgic Encephalomyelitis/chronic fatigue syndrome (ME/CFS).	Med Hypotheses. 2012 Nov;79(5):607-13. doi: 10.1016/j.mehy.2012.07.034.	Fukuda's criteria are adequate to make a distinction between Myalgic Encephalomyelitis/chronic fatigue syndrome (ME/CFS) and chronic fatigue (CF), but ME/CFS patients should be subdivided into those with (termed ME) and without (termed CFS) post exertional malaise [Maes et al. 2012]. ME/CFS is considered to be a neuro-immune disease. ME/CFS is characterized by activated immuno-inflammatory pathways, including increased levels of pro-inflammatory cytokines, nuclear factor κB (NF-κB) and aberrations in mitochondrial functions, including lowered ATP. These processes may explain typical symptoms of ME/CFS, e.g. fatigue, malaise, hyperalgesia, and neurologic and autonomic symptoms. Here we hypothesize that increased NF-κB together with a loss of p53 are key phenomena in ME/CFS that further explain ME/CFS symptoms, such as fatigue and neurocognitive dysfunction, and explain ME symptoms, such as post-exertional malaise following mental and physical activities. Inactivation of p53 impairs aerobic mitochondrial functions and causes greater dependence on anaerobic glycolysis, elevates lactate levels, reduces mitochondrial density in skeletal muscle and reduces endurance during physical exercise. Lowered p53 and increased NF-κB are associated with elevated reactive oxygen species. Increased NF-κB induces the production of pro-inflammatory

				cytokines, which increase glycolysis and further compromise mitochondrial functions. All these factors together may contribute to mitochondrial exhaustion and indicate that the demand for extra ATP upon the commencement of increased activity cannot be met. In conditions of chronic inflammation and oxidative stress, high NF-κB and low p53 may conspire to promote neuron and glial cell survival at a price of severely compromised metabolic brain function. Future research should examine p53 signaling in ME/CFS.
Morris G, Maes M.	Tir Na Nog, Pembrey, Llanelli, UK.	A neuro-immune model of Myalgic Encephalomyelitis/Chronic fatigue syndrome.	Metab Brain Dis. 2012 Jun 21	This paper proposes a neuro-immune model for Myalgic Encephalomyelitis/Chronic fatigue syndrome (ME/CFS). A wide range of immunological and neurological abnormalities have been reported in people suffering from ME/CFS. They include abnormalities in proinflammatory cytokines, raised production of nuclear factor-κB, mitochondrial dysfunctions, autoimmune responses, autonomic disturbances and brain pathology. Raised levels of oxidative and nitrosative stress (O&NS), together with reduced levels of antioxidants are indicative of an immuno-inflammatory pathology. A number of different pathogens have been reported either as triggering or maintaining factors. Our model proposes that initial infection and immune activation caused by a number of possible pathogens leads to a state of chronic peripheral immune activation driven by activated O&NS pathways that lead to progressive damage of self epitopes even when the initial infection has been cleared. Subsequent activation of autoreactive T cells conspiring with O&NS pathways cause further damage and provoke chronic activation of immuno-inflammatory pathways. The subsequent upregulation of proinflammatory compounds may activate microglia via the vagus nerve. Elevated proinflammatory cytokines together with raised O&NS conspire to produce mitochondrial damage. The subsequent ATP deficit together with inflammation and O&NS are responsible for the landmark symptoms of ME/CFS, including post-exertional malaise. Raised levels of O&NS subsequently cause progressive elevation of autoimmune activity facilitated by molecular mimicry, bystander activation or epitope spreading. These processes provoke central nervous system (CNS) activation in an attempt to restore immune homeostatsis. This model proposes that the antagonistic activities of the CNS response to peripheral inflammation, O&NS and chronic immune activation are responsible for the remitting-relapsing nature of ME/CFS. Leads for future research are suggested based on this neuro-immune model.
Moss JI.	[No address quoted]	Gulf War illnesses are autoimmune illnesses caused by reactive oxygen species which were caused by nerve agent prophylaxis.	Med Hypotheses. 2012 Aug;79(2):283-4. doi: 10.1016/j.mehy.2012.04.043.	Gulf War illnesses (GWI share many of the features of chronic fatigue syndrome (CFS) and both CFS and GWI may be the result of chronic immune system processes. The main suspected cause for GWI, the drug pyridostigmine bromide (PB), has been shown to cause neuronal damage from reactive oxygen species (ROS). ROS have been associated with IgM mediated autoimmune responses against ROS induced neoepitopes in depressed patients and this may also apply to CFS. It therefore follows that the drug used in the Gulf War caused ROS, the ROS modified native molecules,

				and that this trigged the autoimmune condition we refer to as Gulf War illnesses. Similar mechanisms may apply to other autoimmune illnesses.
Mount DL, Johnson DM, Rego MI, Schofield K, Amponsah A, Graham LF.	Wake Forest University School of Medicine, Winston-Salem, NC 27157, USA. Dmount@wfubmc.edu	Preliminary findings exploring the social determinants of Black males' lay health perspectives.	Am J Mens Health. 2012 Jan;6(1):71-9. doi: 10.1177/1557988311420993.	The unequal discussion of Black males' health is a pressing social problem. This study addressed Black males' lay perspectives regarding their health, illness, and mortality, with attention to the determinants of men's health, prevention, lifestyle, and opportunities for health promotion using an exploratory/qualitative research methodology. Participants were 68 Black males aged 15 to 68 years, with an average age of 44 years (SD = 14.5). The narratives represented a complex interplay of biopsychosocial factors, ranging from intrapersonal attitudes, interpersonal experiences to discussions about community and public policy injustices. Five prominent themes emerged: (a) lack of chronic disease awareness, (b) fatalism, (c) fear and anxiety of academic-medical settings, (d) hyperactive masculinity fatigue, and (e) the gay-straight divide. The term Tired Black Male Health syndrome was coined in the forum. Implications of these findings are discussed in the context of culturally relevant strategies for improving Black male community health engagement.
Myhill S, Booth NE, McLaren-Howard J.	Sarah Myhill Ltd Llangunllo, Powys UK.	Targeting mitochondrial dysfunction in the treatment of Myalgic Encephalomyelitis/Chronic Fatigue Syndrome (ME/CFS) - a clinical audit.	Int J Clin Exp Med. 2013;6(1):1-15.	Report on an audit of 138 ME/CFS patients who attended a private practice and took the ATP Profile biomedical test. The results revealed that all of these patients had measureable mitochondrial dysfunction. A basic treatment regime, based on 1) eating the evolutionary correct stone-age diet, 2) ensuring optimum hours of good quality sleep, 3) taking a standard package of nutritional supplements, and 4) getting the right balance between work and rest, was recommended for all patients. Additions to the basic regime were tailored for each patient according to the results of the ATP Profile and additional nutritional tests and clues from the clinical history. Mitochondrial function is typically impaired in two ways: substrate or co-factor deficiency, and inhibition by chemicals, exogenous or endogenous. For the former, additional nutrients are recommended where there is a deficiency, and for the latter, improvement of anti-oxidant status and selective chelation therapy or far-infrared saunas are appropriate. We show case histories of nine patients who have taken the ATP Profile on three or four occasions, and a before-and-after treatment summary of the 34 patients who have had at least two ATP Profile tests separated by some months. Finally, we summarize the results for the 30 patients who followed all aspects of the treatment regime and compare them with the 4 patients who were lax on two or more aspects of the treatment regime. All patients who followed the treatment regime improved in mitochondrial function by on average a factor of 4.

Naess H, Nyland	Institute of Clinical	Chronic fatigue	BMC Gastroenterol. 2012 Feb	BACKGROUND: A waterborne outbreak of Giardia lamblia gastroenteritis led to a high

M, Hausken T, Follestad I, Nyland HI.	Medicine, Department of Neurology, and Unit for Gastroenterology, Department for Medicine, Haukeland University Hospital, Bergen, Norway. halvor.naess@haukeland.no	syndrome after Giardia enteritis: clinical characteristics, disability and long-term sickness absence.	8;12:13. doi: 10.1186/1471-230X-12-13.	prevalance of long-lasting fatigue and abdominal symptoms. The aim was to describe the clinical characteristics, disability and employmentloss in a case series of patients with Chronic Fatigue Syndrome (CFS) after the infection. METHODS: Patients who reported persistent fatigue, lowered functional capacity and sickness leave or delayed education after a large community outbreak of giardiasis enteritis in the city of Bergen, Norway were evaluated with the established Centers for Disease Control and Prevention criteria for CFS. Fatigue was self-rated by the Fatigue Severity Scale (FSS). Physical and mental health status and functional impairment was measured by the Medical Outcome Severity Scale-short Form-36 (SF-36). The Hospital Anxiety and Depression Scale (HADS) was used to measure co-morbid anxiety and depression. Inability to work or study because of fatigue was determined by sickness absence certified by a doctor. RESULTS: A total of 58 (60%) out of 96 patients with long-lasting post-infectious fatigue after laboratory confirmed giardiasis were diagnosed with CFS. In all, 1262 patients had laboratory confirmed giardiasis. At the time of referral (mean illness duration 2.7 years) 16% reported improvement, 28% reported no change, and 57% reported progressive course with gradual worsening. Mean FSS score was 6.6. A distinctive pattern of impairment was documented with the SF-36. The physical functioning, vitality (energy/fatigue) and social functioning were especially reduced. Long-term sickness absence from studies and work was noted in all patients. CONCLUSION: After giardiasis enteritis at least 5% developed clinical characteristics and functional impairment comparable to previously described post-infectious fatigue syndrome.

Nguyen RH,	Division of	Co-morbid pain	Psychol Health Med.	Many women with vulvodynia also suffer from other chronic co-morbid pain

Ecklund AM, Maclehose RF, Veasley C, Harlow BL.	Epidemiology & Community Health, University of Minnesota, Minneapolis, MA, USA. nguyen@umn.edu	conditions and feelings of invalidation and isolation among women with vulvodynia.	2012;17(5):589-98. doi: 10.1080/13548506.2011.647703.	conditions. Alone, these pain conditions are associated with feeling invalidated by others and feeling socially isolated. It is unclear, however, how the presence of additional pain co-morbidities are associated with the psychosocial wellbeing of women with vulvodynia. We used data from a survey administered by the National Vulvodynia Association. Women reported clinician-diagnosed vulvodynia, presence of co-morbid pain, and how often they felt that they felt no one believed their pain existed (invalidated) and isolated. Analyses determined prevalence of feeling invalidated or isolated, and the difference in prevalence when co-morbidities existed. Forty-five percent of these 1847 women with vulvodynia reported having at least one of the following five chronic pain conditions, chronic fatigue syndrome, endometriosis, fibromyalgia, interstitial cystitis, or irritable bowel syndrome. Adjusted baseline prevalence among all women of feeling invalidated was 9% and of feeling isolated was 14%. Having a co-morbid condition with vulvodynia, as well as having an increasing number of co-morbid conditions with vulvodynia, was significantly associated with the presence of feeling both invalidated and isolated. Chronic fatigue syndrome was the co-morbidity most strongly associated with feelings invalidation and isolation. One or more co-morbid pain conditions in addition to vulvodynia were significantly associated with psychosocial wellbeing. However, the temporality of the association could not be elucidated and therefore we cannot conclude that these pain conditions cause poor psychosocial wellbeing. Despite this, future studies should explore the utility of promoting validation of women's pain conditions and reducing social isolation for women with chronic pain.
Nijhof SL, Bleijenberg G, Uiterwaal CS, Kimpen JL, van de Putte EM.	Department of Paediatrics, Wilhelmina Children's Hospital, University Medical Centre Utrecht, Netherlands. s.l.nijhof@umcutrecht.nl	Effectiveness of internet-based cognitive behavioural treatment for adolescents with chronic fatigue syndrome (FITNET): a randomised controlled trial.	Lancet. 2012 Apr 14;379(9824):1412-8. doi: 10.1016/S0140-6736(12)60025-7. Comment in Lancet. 2012 Apr 14;379(9824):1372-3. Lancet. 2012 Aug 11;380(9841):561; author reply 562. Lancet. 2012 Aug 11;380(9841):561-2; author reply 562. Evid Based Ment Health. 2012 Aug;15(3):81.	BACKGROUND: Chronic fatigue syndrome is characterised by persistent fatigue and severe disability. Cognitive behavioural therapy seems to be a promising treatment, but its availability is restricted. We developed Fatigue In Teenagers on the interNET (FITNET), the first dedicated internet-based therapeutic program for adolescents with this disorder, and compared its effectiveness with that of usual care. METHODS: Adolescents aged 12-18 years with chronic fatigue syndrome were assigned to FITNET or usual care in a 1:1 ratio at one tertiary treatment centre in the Netherlands by use of a computer-generated blocked randomisation allocation schedule. The study was open label. Primary outcomes were school attendance, fatigue severity, and physical functioning, and were assessed at 6 months with computerised questionnaires. Analysis was by intention to treat. Thereafter, all patients were offered FITNET if needed. This trial is registered, number ISRCTN59878666. FINDINGS: 68 of 135 adolescents were assigned to FITNET and 67 to usual care, and 67 and 64, respectively, were analysed. FITNET was significantly more effective than was usual care for all dichotomised primary outcomes at 6 months-full school attendance (50 [75%] vs 10 [16%], relative risk 4·8, 95% CI 2·7-8·9; p<0·0001), absence of severe fatigue (57 [85%] vs 17 [27%], 3·2, 2·1-4·9; p<0·0001), and normal physical functioning (52 [78%] vs 13 [20%], 3·8, 2·3-6·3; p<0·0001). No serious adverse events were

				reported. INTERPRETATION: FITNET offers a readily accessible and highly effective treatment for adolescents with chronic fatigue syndrome. The results of this study justify implementation on a broader scale. FUNDING: Netherlands Organisation for Health Research and Development.
Nijs J, Crombez G, Meeus M, Knoop H, Damme SV, Cauwenbergh V, Bleijenberg G.	Chronic Pain and Chronic Fatigue Research Group, Department of Human Physiology, Faculty of Physical Education & Physiotherapy, Vrije Universiteit Brussels, Belgium. drlm@thepainmd.com	Pain in patients with chronic fatigue syndrome: time for specific pain treatment?	Pain Physician. 2012 Sep-Oct;15(5):E677-86.	BACKGROUND: Besides chronic fatigue, patients with chronic fatigue syndrome (CFS) have debilitating widespread pain. Yet pain from CFS is often ignored by clinicians and researchers. OBJECTIVES: To examine whether pain is a unique feature of CFS, or does it share the same underlying mechanisms as other CFS symptoms? Second, it is examined whether effective treatments for pain from CFS are currently available. STUDY DESIGN: Narrative review covering the scientific literature up through December 2011. SETTING: Several universities. RESULTS: From the available literature, it is concluded that musculoskeletal factors are unlikely to account for pain from CFS. Pain seems to be one out of many symptoms related to central sensitization from CFS. This idea is supported by the findings of generalized hyperalgesia (including widespread increased responsiveness to painful stimuli) and dysfunctional endogenous analgesia in response to noxious thermal stimuli. Pain catastrophizing and depression partly account for pain from CFS. Pain increases during exercise is probably due to the lack of endogenous analgesia and activation of several genes in response to exercise in CFS. There is currently no evidence in support for the efficacy of complementary medicine in the treatment of pain from CFS. Intensive education about the biology of pain from CFS (within the framework of central sensitization) has positive short-term effects for patients with CFS, and fatigue-targeting cognitive behavioral therapy appears to be effective for pain from CFS as well. LIMITATIONS: The role of the deficient hypothalamus-pituitary-adrenal axis in relation to pain from CFS, as well as the interactions with immune (dys)functioning require further study. CONCLUSION: Recent research has increased our understanding of pain from CFS, including its treatment. It is advocated to optimize current CFS treatment protocols by targeting the underlying mechanism for those patients having severe pain.
Nijs J, Meeus M, Heins M, Knoop H, Moorkens G, Bleijenberg G.	Department of Human Physiology, Faculty of Physical Education & Physiotherapy, Vrije Universiteit Brussel, Belgium. Jo.Nijs@vub.ac.be	Kinesiophobia, catastrophizing and anticipated symptoms before stair climbing in chronic fatigue syndrome: an experimental study.	Disabil Rehabil. 2012;34(15):1299-305. doi: 10.3109/09638288.2011.641661.	PURPOSE: Kinesiophobia and catastrophizing are frequent among people with chronic fatigue syndrome (CFS). This study was aimed at examining (1) whether kinesiophobia, anticipated symptoms and fatigue catastrophizing are related to stair climbing performance in people with CFS; and (2) whether kinesiophobia and fatigue catastrophizing are related to daily physical activity in CFS. METHOD: Patients with CFS filled in a set of questionnaires, performed a physical demanding task (two floors stair of climbing and descending) with pre-test and post-test heart rate monitoring and immediate post-stair climbing symptom assessment. Real-time activity monitoring was used between the baseline and second assessment day (7 days later). RESULTS: Kinesiophobia and fatigue catastrophizing were strongly related ($\rho = 0.62$ and 0.67, respectively) to poorer stair climbing performance (i.e. more time required to complete the threatening activity). Kinesiophobia and fatigue catastrophizing were

				unrelated to the amount of physical activity on the first day following stair climbing or during the seven subsequent days. CONCLUSION: These findings underscore the importance of kinesiophobia and fatigue catastrophizing for performing physical demanding tasks in everyday life of people with CFS, but refute a cardinal role for kinesiophobia and fatigue catastrophizing in determining daily physical activity level in these patients.
Nijs J, Meeus M, Van Oosterwijck J, Ickmans K, Moorkens G, Hans G, De Clerck LS.	Department of Human Physiology, Vrije Universiteit Brussel (VUB), Brussels, Belgium. Jo.Nijs@vub.ac.be	In the mind or in the brain? Scientific evidence for central sensitisation in chronic fatigue syndrome.	Eur J Clin Invest. 2012 Feb;42(2):203-12. doi: 10.1111/j.1365-2362.2011.02575.x.	BACKGROUND: Central sensitisation entails several top-down and bottom-up mechanisms, all contributing to the hyperresponsiveness of the central nervous system to a variety of inputs. In the late nineties, it was first hypothesised that chronic fatigue syndrome (CFS) is characterised by hypersensitivity of the central nervous system (i.e. central sensitisation). Since then, several studies have examined central sensitisation in patients with CFS. This study provides an overview of such studies. MATERIALS AND METHODS: Narrative review. RESULTS: Various studies showed generalised hyperalgesia in CFS for a variety of sensory stimuli, including electrical stimulation, mechanical pressure, heat and histamine. Various tissues are affected by generalised hyperalgesia: the skin, muscle tissue and the lungs. Generalised hyperalgesia in CFS is augmented, rather than decreased, following various types of stressors like exercise and noxious heat pain. Endogenous inhibition is not activated in response to exercise and activation of diffuse noxious inhibitory controls following noxious heat application to the skin is delayed. CONCLUSIONS: The observation of central sensitisation in CFS is in line with our current understanding of CFS. The presence of central sensitisation in CFS corroborates with the presence of several psychological influences on the illness, the presence of infectious agents and immune dysfunctions and the dysfunctional hypothalamus-pituitary-adrenal axis as seen in these severely debilitated patients.

Nugraha B, Karst M, Engeli S, Gutenbrunner C.	Department of Rehabilitation Medicine, Hannover Medical School, Carl-Neuberg-Str. 1, Hannover, Germany. Nugraha.Boya@mh-hannover.de	Brain-derived neurotrophic factor and exercise in fibromyalgia syndrome patients: a mini review.	Rheumatol Int. 2012 Sep;32(9):2593-9. doi: 10.1007/s00296-011-2348-2.	Fibromyalgia syndrome (FMS) is a common chronic pain condition characterized by chronic widespread pain and decreased pain threshold, with hyperalgesia and allodynia. Associated signs include fatigue, morning stiffness, non-restorative sleep, mood disturbance, depression, irritable bowel syndrome, and headache. In addition to the administration of drugs, psychological therapies treatment of FMS mainly consists of physical therapies. Although the precise pathogenesis of FMS remains elucidated, modern understanding conceptualizes FMS as central sensitization as a consequence of altered endogenous pain- and stress-response system and continuous nociceptive input. Altered brain-derived neurotrophic factor (BDNF) levels in FMS suggest that BDNF--well known for its effects on neuronal plasticity--is involved in this sensitization process. Exercise leads to changes in serum BDNF levels, too. This association highlights the importance of exercise in FMS and other chronic pain conditions.
Ocon AJ, Messer ZR, Medow MS, Stewart JM.	Department of Physiology, New York Medical College, Valhalla, NY, USA. anthony_ocon@nymc.edu	Increasing orthostatic stress impairs neurocognitive functioning in chronic fatigue syndrome with postural tachycardia syndrome.	Clin Sci (Lond). 2012 Mar;122(5):227-38. doi: 10.1042/CS20110241.	CFS (chronic fatigue syndrome) is commonly co-morbid with POTS (postural tachycardia syndrome). Individuals with CFS/POTS experience unrelenting fatigue, tachycardia during orthostatic stress and ill-defined neurocognitive impairment, often described as 'mental fog'. We hypothesized that orthostatic stress causes neurocognitive impairment in CFS/POTS related to decreased CBFV (cerebral blood flow velocity). A total of 16 CFS/POTS and 20 control subjects underwent graded tilt table testing (at 0, 15, 30, 45, 60 and 75°) with continuous cardiovascular, cerebrovascular, and respiratory monitoring and neurocognitive testing using an n-back task at each angle. The n-back task tests working memory, concentration, attention and information processing. The n-back task imposes increasing cognitive challenge with escalating (0-, 1-, 2-, 3- and 4-back) difficulty levels. Subject dropout due to orthostatic presyncope at each angle was similar between groups. There were no n-back accuracy or RT (reaction time) differences between groups while supine. CFS/POTS subjects responded less correctly during the n-back task test and had greater nRT (normalized RT) at 45, 60 and 75°. Furthermore, at 75° CFS/POTS subjects responded less correctly and had greater nRT than controls during the 2-, 3- and 4-

				back tests. Changes in CBFV were not different between the groups and were not associated with n-back task test scores. Thus we conclude that increasing orthostatic stress combined with a cognitive challenge impairs the neurocognitive abilities of working memory, accuracy and information processing in CFS/POTS, but that this is not related to changes in CBFV. Individuals with CFS/POTS should be aware that orthostatic stress may impair their neurocognitive abilities.
Oh SJ, Kim YH, Kim SK, Kim MW.	Department of Rehabilitation Medicine, Incheon St. Mary's Hospital, The Catholic University of Korea, Incheon 403-720, Korea.	Painful os peroneum syndrome presenting as lateral plantar foot pain.	Ann Rehabil Med. 2012 Feb;36(1):163-6. doi: 10.5535/arm.2012.36.1.163.	Lateral plantar foot pain can be caused by various entities, and the painful os peroneum syndrome should be considered in the differential diagnosis. Recent developments in musculoskeletal ultrasonography are very useful for initial diagnosis. We discuss a 69-year-old female who experienced lateral plantar foot pain for over one month. Through physical examination, radiography, ultrasound and magnetic resonance imaging, she was diagnosed with the painful os peroneum syndrome with a chronic fatigue fracture of multipartite os peroneum and peroneus longus tenosynovitis, for which she underwent surgery. We herein report this rare condition and reviewed the relevant literature.
Okamoto LE, Raj SR, Peltier A, Gamboa A, Shibao C, Diedrich A, Black BK, Robertson D, Biaggioni I.	Vanderbilt Autonomic Dysfunction Center, Vanderbilt University School of Medicine, Nashville, TN, U.S.A.	Neurohumoral and haemodynamic profile in postural tachycardia and chronic fatigue syndromes.	Clin Sci (Lond). 2012 Feb;122(4):183-92. doi: 10.1042/CS20110200.	Several studies recognized an overlap between CFS (chronic fatigue syndrome) and POTS (postural tachycardia syndrome). We compared the autonomic and neurohormonal phenotype of POTS patients with CFS (CFS-POTS) to those without CFS (non-CFS-POTS), to determine whether CFS-POTS represents a unique clinical entity with a distinct pathophysiology. We recruited 58 patients with POTS, of which 47 were eligible to participate. A total of 93% of them reported severe fatigue [CIS (Checklist of Individual Strength), fatigue subscale >36], and 64% (n=30) fulfilled criteria for CFS (CFS-POTS). The prevalence of CFS symptoms (Centers for Disease Control and Prevention criteria) was greater in the CFS-POTS group, but the pattern of symptoms was similar in both groups. Physical functioning was low in both groups (RAND-36 Health Survey, 40±4 compared with 33±3; P=0.153), despite more severe fatigue in CFS-POTS patients (CIS fatigue subscale 51±1 compared with 43±3; P=0.016). CFS-POTS patients had greater orthostatic tachycardia than the non-CFS-POTS group (51±3 compared with 40±4 beats/min; P=0.030), greater low-frequency variability of BP (blood pressure; 6.3±0.7 compared with 4.8±1.0 mmHg2; P=0.019), greater BP recovery from early to late phase II of the Valsalva manoeuvre (18±3 compared with 11±2 mmHg; P=0.041) and a higher supine (1.5±0.2 compared with 1.0±0.3 ng/ml per·h; P=0.033) and upright (5.4±0.6 compared with 3.5±0.8 ng/ml per h; P=0.032) PRA (plasma renin activity). In conclusion, fatigue and CFS-defining symptoms are common in POTS patients. The majority of them met criteria for CFS. CFS-POTS patients have higher markers of sympathetic activation, but are part of the spectrum of POTS. Targeting this sympathetic activation should be considered in the treatment of these patients.
Oosterheert JJ, Kampschreur L,	Universitair Medisch Centrum Utrecht, afd.	Fatigue after Q fever: nothing new. [Article	Ned Tijdschr Geneeskd. 2012;156(48):A5474.	New guidelines for the diagnosis and treatment of Q-fever related fatigue syndrome have been proposed. However, we argue that Q-fever related fatigue syndrome is

Hoepelman AI.	Interne Geneeskunde en Infectieziekten, Utrecht.	in Dutch]		only just another description of a chronic fatigue syndrome in which a specific micro-organism is implicated. We feel that development of this guideline comes too soon and may be redundant, as relevant diagnosis and treatment protocols for patients with chronic fatigue, without somatic or psychiatric cause, are already available and current evidence does not support a distinct guideline for fatigue after Q fever. Rather, chronic infection with Coxiella Burnetii should be ruled out. Introducing the term 'Q-fever related fatigue syndrome' may only cause confusion, may lead to increased health-care costs, rather than improve patient management.
Op De Beéck K, Maes L, Van den Bergh K, Derua R, Waelkens E, Van Steen K, Vermeersch P, Westhovens R, De Vlam K, Verschueren P, Hooijkaas H, Blockmans D, Bossuyt X.	Catholic University of Leuven, and Experimental Laboratory of Medicine, Immunology, University Hospitals Leuven, Leuven, Belgium.	Heterogeneous nuclear RNPs as targets of autoantibodies in systemic rheumatic diseases.	Arthritis Rheum. 2012 Jan;64(1):213-21. doi: 10.1002/art.33327.	OBJECTIVE: To investigate the abundance of autoantibodies to heterogeneous nuclear RNPs (hnRNPs) in systemic rheumatic diseases. METHODS: Recombinant human hnRNPs A1, B1, C1, E1, F, Gi, H1, I, K, and P2 were prepared. Antibodies to these antigens were determined by Western blotting and by enzyme-linked immunosorbent assay (ELISA) (for hnRNPs B1, E1, F, and H1) in serum samples obtained from patients with chronic fatigue syndrome (control subjects) and from patients with various connective tissue diseases. RESULTS: Western blotting analysis in 106 control subjects and 298 patients with a connective tissue disease revealed that antibodies to all tested hnRNP antigens, except hnRNP Gi, were significantly more prevalent in patients with Sjögren's syndrome (SS) than in control subjects. The highest reactivity was observed for hnRNPs B1, E1, F, and H1 (reactivity in >45% of patients with SS and in 2.8% of control subjects). Reactivity with hnRNPs B1, E1, F, and H1 was also evaluated by ELISA in 89 control subjects and 228 patients with a connective tissue disease. Reactivity with at least 2 of the 4 tested antigens was observed in 1.1% of control subjects, 16% of patients with systemic lupus erythematosus (SLE), and 18% of patients with SS. Reactivity with at least 3 of the 4 antigens was observed in 0% of the control subjects, 3.2% of patients with SLE, and 15% of patients with SS. CONCLUSION: Several hnRNPs are target antigens in SS. The combined presence of antibodies to several hnRNPs was strongly associated with connective tissue disease in general and with SS in particular.
Op De Beéck K, Vermeersch P, Verschueren P, Westhovens R, Mariën G, Blockmans D, Bossuyt X.	Experimental Laboratory Immunology, Catholic University Leuven, Leuven, Belgium.	Antinuclear antibody detection by automated multiplex immunoassay in untreated patients at the time of diagnosis.	Autoimmun Rev. 2012 Dec;12(2):137-43. doi: 10.1016/j.autrev.2012.02.013.	Fully automated multiplex immunoassays are increasingly used as first line screening for antinuclear antibodies. The diagnostic performance of such multiplex assays in untreated patients at the time of diagnosis has not been reported. Antinuclear antibodies were measured by indirect immunofluorescence (IIF) (dilution 1:160) and by BioPlex 2200 ANA screen (antibodies to dsDNA, chromatin, ribosomal protein, SSA-52, SSA-60, SSB, Sm, SmRNP, RNP-A, RNP-68, Scl-70, Jo-1, and centromere B) in 236 patients with a systemic rheumatic disease at the time of diagnosis, 149 blood donors, 139 patients with chronic fatigue syndrome (CFS), and 134 diseased controls. BioPlex ANA screen and IIF were positive in, respectively, 79% and 90% of patients with systemic lupus erythematosus (SLE), 60% and 60% with cutaneous lupus, 72% and 93% with systemic sclerosis (SSc), 100% and 100% with mixed connective tissue disease (MCTD), 89% and 56% with primary Sjögren's (SS) syndrome, 36% and 36%

				with polymyositis/dermatomyositis, 5.4% and 6% of blood donors, 7.2% and 3.6% of patients with CFS, and 11% and 18% of diseased controls. BioPlex test result interval specific likelihood ratios increased with increasing antibody concentration. The simultaneous presence of at least three antibodies by BioPlex was found in 35% of patients with SLE, 4% with SSc, 100% with MCTD, 64% with SS, 7% with inflammatory myopathy, 0.7% of CFS and diseased controls, and none of the blood donors. In conclusion, test result specific likelihood ratios and the presence of multiple autoantibodies help with the interpretation of data generated by multiplex immunoassays.
Ormen B, Türker N, Vardar I, Kaptan F, El S, Ural S, Kaya F, Coşkun NA.	İzmir Atatürk Training and Research Hospital, Clinic of Infectious Diseases and Clinical Microbiology, İzmir, Turkey. bormen2002@yahoo.com	Attitudes and side effects related to pandemic influenza A (H1N1) vaccination in healthcare personnel. [Article in Turkish]	Mikrobiyol Bul. 2012 Jan;46(1):57-64.	The aims of this study were to evaluate the attitudes towards H1N1 vaccination and to determine the safety and side effects following 2009 pandemic influenza A (H1N1) vaccination. Pandemic influenza vaccine had been administered to the healthcare personnel in our research and training hospital in December 2009. The rate being vaccinated was established as 40% (800/2000). Four months following vaccination, the opinions about vaccination were asked to the healthcare workers, and also side effects were questioned to the vaccinated group. Two different questionnaires (for vaccinated and unvaccinated subjects) were delivered to the volunteers who agreed to participate in the study. Demographic features, reasons related to being vaccinated or not, were questioned. The vaccinated group was also questioned for the presence of chronic diseases, previous vaccinations (pandemic/seasonal influenza), local or systemic reactions that develop after vaccination. A total of 332 volunteers participated in the questionnaire. Of them 247 (74.4%) were vaccinated and 85 (25.6%) were unvaccinated. Male/female ratio of the participants was 1.2, and 55.7% of them were older than 30-year-old. Most of the participants (82.8%) were highly educated (high school and faculty-graduated). Vaccination rates were found statistically significant in advanced age group compared to young adults (p= 0.042); in male gender compared to females (p= 0.001) and in parents compared to subjects who didn't have children (p= 0.021). Vaccination rates were observed to be higher (57.5%) in non-medical staff (cleaning employers, administrative personnel, etc.) than the physicians (29.1%) and nurses (13.4%), and the rate was also high (54.7%) in personnel who worked in intensive care units, emergency department and administrative units than the personnel who worked in the clinics of internal medicine (22.3%) and surgery (23.1%) (p= 0.001). The most important causes of rejecting vaccination were being afraid of the side effects (69.4%) and not believing the effectiveness of the vaccine (56.4%). The leading causes of accepting vaccination were worries about infecting their family (60.3%) and being in a risk group (54.3%). After vaccination, local reactions (pain, swelling and redness at the vaccination site) were described in 43.3% and systemic reactions (weakness, fatigue, muscle aches, influenza-like symptoms, etc.) were described in 43.7% of the subjects. Severe side effects such as vasculitis, neuritis, encephalomyelitis, Guillian-Barre syndrome and

				anaphylactic reaction were not observed in any of the vaccinated cases. It was detected that worries about the safety of vaccine had negative impact for vaccination. Since no serious side effects were detected related to vaccination, it was concluded that the vaccine was safe. In spite of the scientific proofs, negative concerns about the safety of the vaccines can unfavorably affect the vaccination campaigns and can jeopardize efforts of influenza control. As a result, data collection systems about the safety and side effects of the vaccine all over the country and regular reports about these data may more efficiently guide vaccination programs in the future.
Pacini S, Fiore MG, Magherini S, Morucci G, Branca JJ, Gulisano M, Ruggiero M.	Department of Anatomy, Histology and Forensic Medicine, University of Firenze, Viale Morgagni 85, 50134 Firenze, Italy. stefania.pacini@unifi.it	Could cadmium be responsible for some of the neurological signs and symptoms of Myalgic Encephalomyelitis/Chronic Fatigue Syndrome.	Med Hypotheses. 2012 Sep;79(3):403-7. doi: 10.1016/j.mehy.2012.06.007.	According to the World Health Organization, Myalgic Encephalomyelitis/Chronic Fatigue Syndrome (ME/CFS) is a neurological disease characterized by widespread inflammation and multi-systemic neuropathology. Aetiology and pathogenesis are unknown, and several agents have been proposed as causative agents or as factors perpetuating the syndrome. Exposure to heavy metals, with particular reference to mercury and gold in dental amalgams, has been considered among the triggers of ME/CFS. Here we hypothesize that cadmium, a widespread occupational and environmental heavy metal pollutant, might be associated with some of the neurological findings described in ME/CFS. In fact, ME/CFS patients show a decrease of the volume of the gray matter in turn associated with objective reduction of physical activity. Cadmium induces neuronal death in cortical neurons through a combined mechanism of apoptosis and necrosis and it could then be hypothesized that cadmium-induced neuronal cell death is responsible for some of the effects of cadmium on the central nervous system, i.e. a decrease in attention level and memory in exposed humans as well as to a diminished ability for training and learning in rats, that are symptoms typical of ME/CFS. This hypothesis can be tested by measuring cadmium exposure in a cohort of ME/CFS patients compared with matched healthy controls, and by measuring gray matter volume in un-exposed healthy controls, exposed non-ME/CFS subjects, un-exposed ME/CFS patients and exposed ME/CFS patients. In addition, we hypothesize that cadmium exposure could be associated with reduced cerebral blood flow in ME/CFS patients because of the disruptive effects of cadmium on angiogenesis. In fact, cadmium inhibits angiogenesis and low global cerebral flow is associated with abnormal brain neuroimaging results and brain dysfunction in the form of reduced cognitive testing scores in ME/CFS patients. This hypothesis can be tested by measuring cerebral cortex blood flow in un-exposed healthy controls, exposed non-ME/CFS subjects, un-exposed ME/CFS patients and exposed ME/CFS patients. If our hypothesis is demonstrated correct, the consequences could affect prevention, early diagnosis, and treatment of ME/CFS. Implications in early diagnosis could entail the evaluation of symptoms typical of ME/CFS in cadmium-exposed subjects as well as the search for signs of exposure to cadmium in subjects diagnosed with ME/CFS. Nutritional supplementation of magnesium and zinc could then be considered, since these elements have been

				proposed in the prophylaxis and therapy of cadmium exposure, and magnesium was demonstrated effective on ME/CFS patients' symptom profiles.
Paolucci S, Piralla A, Zanello C, Minoli L, Baldanti F.	Fondazione IRCCS Policlinico San Matteo, Pavia, Italy.	Xenotropic and polytropic murine leukemia virus-related sequences are not detected in the majority of patients with chronic fatigue syndrome.	New Microbiol. 2012 Jul;35(3):341-4.	XMRV and polytropic MLV-related virus have been controversially associated with chronic fatigue syndrome (CFS). Subsequent reports failed to detect XMRV and MLV-related virus in CFS patients, and the previous results have been interpreted as a massive laboratory contamination by mouse DNA sequences. Among 12 sequential CFS patients, two were positive for XMRV/MLV sequences. In contrast, 40 selected control subjects were negative. CSF patients and controls were negative for mitochondrial mouse-specific DNA sequences. These findings do not confirm the high frequency of MLV-related viruses infection in CFS patients, but also contrast the widespread laboratory contamination previously suggested.
Passeri E, Villa C, Couette M, Itti E, Brugieres P, Cesaro P, Gherardi RK, Bachoud-Levi AC, Authier FJ.	Paris Est-Creteil University & Henri-Mondor University Hospital (APHP): Reference Center for Neuromuscular Diseases Garches-Necker-Mondor-Hendaye, Creteil, F-94010, France.	Long-term follow-up of cognitive dysfunction in patients with aluminum hydroxide-induced macrophagic myofasciitis (MMF).	J Inorg Biochem. 2011 Nov;105(11):1457-63. doi: 10.1016/j.jinorgbio.2011.08.006. Epub 2011 Aug 22.	Macrophagic myofasciitis (MMF) is characterized by specific muscle lesions assessing long-term persistence of aluminum hydroxide within macrophages at the site of previous immunization. Affected patients are middle-aged adults, mainly presenting with diffuse arthromyalgias, chronic fatigue, and cognitive dysfunction. Representative features of MMF-associated cognitive dysfunction (MACD) include (i) dysexecutive syndrome; (i) visual memory; (iii) left ear extinction at dichotic listening test. In present study we retrospectively evaluated the progression of MACD in 30 MMF patients. Most patients fulfilled criteria for non-amnestic/dysexecutive mild cognitive impairment, even if some cognitive deficits seemed unusually severe. MACD remained stable over time, although dysexecutive syndrome tended to worsen. Long-term follow-up of a subset of patients with 3 or 4 consecutive neuropsychological evaluations confirmed the stability of MACD with time, despite marked fluctuations.
Payne B, Hateley C, Ong E, Premchand N, Schmid M, Schwab U, Newton J, Price D.	Department of Infection and Tropical Medicine, Royal Victoria Infirmary, Newcastle-upon-Tyne, UK; Institute of Genetic Medicine, Newcastle University, Newcastle-upon-Tyne, UK.	HIV-associated fatigue in the era of highly active antiretroviral therapy: novel biological mechanisms?	HIV Med. 2012 Sep 23. doi: 10.1111/j.1468-1293.2012.01050.x.	OBJECTIVE: The aim of the study was to determine the prevalence and risk factors for HIV-associated fatigue in the era of highly active antiretroviral therapy (HAART). METHODS: A cross-sectional survey of 100 stable HIV-infected out-patients was carried out. Severity of fatigue was measured using the Fatigue Impact Scale (FIS). Symptoms of orthostatic intolerance (dysautonomia) were evaluated using the Orthostatic Grading Scale (OGS). Data for HIV-infected patients were compared with those for 166 uninfected controls and 74 patients with chronic fatigue syndrome (CFS)/myalgic encephalomyelitis (encephalopathy) (ME). RESULTS: Ninety-one per cent of HIV-infected patients were on HAART and 78% had suppressed plasma HIV viral load (≤ 40 HIV-1 RNA copies/mL). Fifty-one per cent of HIV-infected patients reported excessive symptomatic fatigue (FIS ≥ 40), and 28% reported severe fatigue symptoms (FIS ≥ 80). The mean FIS score among HIV-infected patients was 50.8 [standard deviation (SD) 41.9] compared with 13.0 (SD 17.6) in uninfected control subjects, and 92.9 (SD 29.0) in CFS patients ($P < 0.001$ for comparison of HIV-infected patients and uninfected controls). Among HIV-infected patients, fatigue severity was not significantly associated with current or nadir CD4 lymphocyte count, HIV plasma viral load, or whether on HAART. Prior dideoxynucleoside analogue (d-drug) exposure

				(P = 0.016) and the presence of clinical lipodystrophy syndrome (P = 0.011) were associated with fatigue. Additionally, fatigue severity correlated strongly with symptomatic orthostatic intolerance (r = 0.65; P < 0.001). CONCLUSIONS: Fatigue is very common and often severe in HIV-infected out-patients, despite viral suppression and good immune function. In a subgroup of patients, prior d-drug exposure may contribute to fatigue, suggesting a metabolic basis. Dysautonomia may also drive fatigue associated with HIV infection, as in other chronic diseases, and CFS/ME, and should be further evaluated with the potential for a shared therapeutic approach.
Payne C, Wiffen PJ, Martin S.	Faculty of Life and Health Sciences, University of Ulster at Jordanstown, Belfast, UK. c.payne@ulster.ac.uk	Interventions for fatigue and weight loss in adults with advanced progressive illness.	Cochrane Database Syst Rev. 2012 Jan 18;1:CD008427. doi: 10.1002/14651858.CD008427.pub2.	BACKGROUND: Fatigue and unintentional weight loss are two of the commonest symptoms experienced by people with advanced progressive illness. Appropriate interventions may bring considerable improvements in function and quality of life to seriously ill people and their families, reducing physical, psychological and spiritual distress. OBJECTIVES: To conduct an overview of the evidence available on the efficacy of interventions used in the management of fatigue and/or unintentional weight loss in adults with advanced progressive illness by reviewing the evidence contained within Cochrane reviews. METHODS: We searched the Cochrane Database of Systematic Reviews (CDSR) for all systematic reviews evaluating any interventions for the management of fatigue and/or unintentional weight loss in adults with advanced progressive illness (The Cochrane Library 2010, Issue 8). We reviewed titles of interest by abstract. Where the relevance of a review remained unclear we reached a consensus regarding the relevance of the participant group and the outcome measures to the overview. Two overview authors extracted the data independently using a data extraction form. We used the measurement tool AMSTAR (Assessment of Multiple SysTemAtic Reviews) to assess the methodological quality of each systematic review. MAIN RESULTS: We included 27 systematic reviews (302 studies with 31,833 participants) in the overview. None of the included systematic reviews reported quantitative data on the efficacy of interventions to manage fatigue or weight loss specific to people with advanced progressive illness. All of the included reviews apart from one were deemed of high methodological quality. For the remaining review we were unable to ascertain the methodological quality of the research strategy as it was described. None of the systematic reviews adequately described whether conflict of interests were present within the included studies.Management of fatigue Amyotrophic lateral sclerosis/motor neuron disease (ALS/MND) - we identified one systematic review (two studies and 52 participants); the intervention was exercise.Cancer - we identified five systematic reviews (116 studies with 17,342 participants); the pharmacological interventions were eicosapentaenoic acid (EPA) and any drug therapy for the management of cancer-related fatigue and the non pharmacological interventions were exercise, interventions by breast care nurses and psychosocial interventions.Chronic obstructive pulmonary disease (COPD) - we identified three systematic reviews (59 studies and 4048 participants); the

				interventions were self management education programmes, nutritional support and pulmonary rehabilitation.Cystic fibrosis - we identified one systematic review (nine studies and 833 participants); the intervention was physical training.Human immunodeficiency virus/acquired immune deficiency syndrome (HIV/AIDS) - we identified two systematic reviews (21 studies and 748 participants); the interventions were progressive resistive exercise and aerobic exercise.Multiple sclerosis (MS) - we identified five systematic reviews (23 studies and 1502 participants); the pharmacological interventions were amantadine and carnitine. The non pharmacological interventions were diet, exercise and occupational therapy.Mixed conditions in advanced stages of illness - we identified one systematic review (five studies and 453 participants); the intervention was medically assisted hydration.Management of weight loss ALS/MND - we identified one systematic review but no studies met the inclusion criteria for the systematic review; the intervention was enteral tube feeding.Cancer - we identified three systematic reviews with a fourth systematic review also containing extractable data on cancer (66 studies and 5601 participants); the pharmacological interventions were megestrol acetate and eicosapentaenoic acid (EPA) (this systematic review is also included in the cancer fatigue section above). The non pharmacological interventions were enteral tube feeding and non invasive interventions for patients with lung cancer.COPD - we identified one systematic review (59 studies and 4048 participants); the intervention was nutritional support. This systematic review is also included in the COPD fatigue section.Cystic fibrosis - we identified two systematic reviews (three studies and 131 participants); the interventions were enteral tube feeding and oral calorie supplements.HIV/AIDS - we identified four systematic reviews (42 studies and 2071 participants); the pharmacological intervention was anabolic steroids. The non pharmacological interventions were nutritional interventions, progressive resistive exercise and aerobic exercise. Both of the systematic reviews on exercise interventions were also included in the HIV/AIDS fatigue section.MS - we found no systematic reviews which considered interventions to manage unintentional weight loss for people with a clinical diagnosis of multiple sclerosis at any stage of illness.Mixed conditions in advanced stages of illness - we identified two systematic reviews (32 studies and 4826 participants); the interventions were megestrol acetate and medically assisted nutrition. AUTHORS' CONCLUSIONS: There is a lack of robust evidence for interventions to manage fatigue and/or unintentional weight loss in the advanced stage of progressive illnesses such as advanced cancer, heart failure, lung failure, cystic fibrosis, multiple sclerosis, motor neuron disease, Parkinson's disease, dementia and AIDS. The evidence contained within this overview provides some insight into interventions which may prove of benefit within this population such as exercise, some pharmacological treatments and support for self management.Researchers could improve the methodological quality of future studies

				by blinding of outcome assessors. Adopting uniform reporting mechanisms for fatigue and weight loss outcome measures would also allow the opportunity for meta-analysis of small studies.Researchers could also improve the applicability of recommendations for interventions to manage fatigue and unintentional weight loss in advanced progressive illness by including subgroup analysis of this population within systematic reviews of applicable interventions.More research is required to ascertain the best interventions to manage fatigue and/or weight loss in advanced illness. There is a need for standardised reporting of these symptoms and agreement amongst researchers of the minimum duration of studies and minimum percentage change in symptom experience that proves the benefits of an intervention. There are, however, challenges in providing meaningful outcome measurements against a background of deteriorating health through disease progression. Interventions to manage these symptoms must also be mindful of the impact on quality of life and should be focused on patient-orientated rather than purely disease-orientated experiences for patients. Systematic reviews and primary intervention studies should include the impact of the interventions on standardised validated quality of life measures.
Peters S, Wearden A, Morriss R, Dowrick CF, Lovell K, Brooks J, Cahill G, Chew-Graham C; FINE Trial Group. Collaborators: Bennett C, Bentall R, Booth L, Brooks J, Cahill G, Chapman A, Chew-Graham C, Connell S, Dowrick C, Dunn G, Fleetwood D, Ibbotson L, Jerman D, Lovell K, Mann J, Morriss R, Peters S, Powell P, Quarmby D, Richardson G, Riste L, Wearden A, Williams J.	School of Psychological Sciences, University of Manchester, Manchester, UK. Sarah.peters@manchester.ac.uk	Challenges of nurse delivery of psychological interventions for long-term conditions in primary care: a qualitative exploration of the case of chronic fatigue syndrome/myalgic encephalitis.	Implement Sci. 2011 Dec 22;6:132. doi: 10.1186/1748-5908-6-132.	BACKGROUND: The evidence base for a range of psychosocial and behavioural interventions in managing and supporting patients with long-term conditions (LTCs) is now well-established. With increasing numbers of such patients being managed in primary care, and a shortage of specialists in psychology and behavioural management to deliver interventions, therapeutic interventions are increasingly being delivered by general nurses with limited training in psychological interventions. It is unknown what issues this raises for the nurses or their patients. The purpose of the study was to examine the challenges faced by non-specialist nurses when delivering psychological interventions for an LTC (chronic fatigue syndrome/myalgic encephalomyelitis [CFS/ME]) within a primary care setting. METHODS: A qualitative study nested within a randomised controlled trial [ISRCTN 74156610] explored the experiences and acceptability of two different psychological interventions (pragmatic rehabilitation and supportive listening) from the perspectives of nurses, their supervisors, and patients. Semi structured in-depth interviews were conducted with three nurse therapists, three supervisors, and 46 patients. An iterative approach was used to develop conceptual categories from the dataset. RESULTS: Analyses identified four sets of challenges that were common to both interventions: (i) being a novice therapist, (ii) engaging patients in the therapeutic model, (iii) dealing with emotions, and (iv) the complexity of primary care. Each challenge had the potential to cause tension between therapist and patient. A number of strategies were developed by participants to manage the tensions. CONCLUSIONS: Tensions existed for nurses when attempting to deliver psychological interventions for patients with CFS/ME in this primary care trial. Such tensions should be addressed before implementing

				psychological interventions within routine clinical practice. Similar tensions may be found for other LTCs. Our findings have implications for developing therapeutic alliances and highlight the need for regular supervision.
Petrov D, Marchalik D, Sosin M, Bal A.	UMDNJ/Robert Wood Johnson Medical School, New Brunswick, NJ, USA.	Factors affecting duration of chronic fatigue syndrome in pediatric patients.	Indian J Pediatr. 2012 Jan;79(1):52-5. doi: 10.1007/s12098-011-0463-4.	OBJECTIVE: To determine factors affecting duration of chronic fatigue syndrome (CFS) in pediatric patients. METHODS: This Retrospective cohort consisted of patients with CFS at the regional referral infectious disease clinic for evaluation of fatigue in children and adolescents. Demographic, clinical, and laboratory data were analyzed to identify the impact on duration and severity of pediatric CFS. RESULTS: A total number of 53 predominantly white (98.1%) patients with CFS, aged 9-18 years, were included in the study. Other than fatigue, headaches and sleep disturbance were the most common symptoms of pediatric CFS. Seropositive status for Borrelia burgdorferi (B. burgdorferi) and Epstein-Barr virus (EBV) was identified in 66% of the patients with the diagnosis of CFS by CDC criteria. No association was found between the CFS symptoms, gender, or age at diagnosis and duration of fatigue symptoms. Duration of CFS was associated with high Body-Mass Index (BMI) in a regression model after adjustment for patient's age, gender, and seropositive status for B. burgdorferi and/or EBV (0.34 ± 0.15, $P < 0.04$). CONCLUSIONS: BMI is significantly associated with prolonged duration of CFS.
Pinquart M.	Department of Psychology, Philipps University, Marburg, Germany	Self-esteem of children and adolescents with chronic illness: a meta-analysis.	Child Care Health Dev. 2012 Jun 19. doi: 10.1111/j.1365-2214.2012.01397.x.	Chronic illness may be a risk factor for low self-esteem; however, previous meta-analyses are inconclusive whether children with a chronic illness have lower self-esteem than their healthy peers. The goal of the present study was to summarize available research in order to compare the self-esteem of children and adolescents with a chronic illness with that of healthy children. Random-effects meta-analysis was used to integrate the results of 621 empirical studies that compare levels of self-esteem of children with a chronic physical illness with healthy peers or general test norms. Studies were identified via the electronic databases Adolesc, Embase, Google Scholar, MEDLINE, PSNYDEX, PSYCINFO, and cross-referencing. Children with chronic illnesses have lower self-esteem than healthy peers or test norms ($g=-0.18$ standard deviation units). The lowest levels of self-esteem were observed in children with chronic fatigue syndrome and chronic headaches. Lower levels of self-esteem in children with a chronic illness were found in girls than in boys, in adolescents than in children, in children from developing or threshold countries, when results were collected from observer ratings rather than child reports, in studies published in the 1990s, and when children with chronic illnesses were directly compared with healthy children instead of test norms. Paediatricians, parents, and teachers should promote experiences of success and positive peer-relations, which are important sources of self-esteem. In addition, psychosocial interventions for children with chronic illnesses should be offered for children with reduced self-esteem.
Poppe C, Crombez G, Hanoulle I,	Department of General Internal Medicine,	Mental quality of life in chronic fatigue is	Qual Life Res. 2012 Oct;21(8):1337-45. doi:	PURPOSE: An accommodative coping style (e.g. acceptance) is related to a better mental health-related quality of life (MHQL) in patients with chronic fatigue syndrome

Vogelaers D, Petrovic M.	Ghent University Hospital, De Pintelaan 185, 9000, Ghent, Belgium. Carine.Poppe@ugent.be	associated with an accommodative coping style and neuroticism: a path analysis.	10.1007/s11136-011-0048-8.	(CFS). We want to explore whether neuroticism is predictive for this coping style and MHQL. Secondly we want to explore the relation between acceptance and physical health-related quality of life (PHQL) and expect that illness-related variables such as fatigue severity and duration are related to PHQL. METHOD: In this cross-sectional study, 117 patients with chronic fatigue syndrome from an outpatient internal medicine clinic completed self-report questionnaires on quality of life (SF-36), acceptance (ICQ), personality traits (NEO-FFI) and fatigue severity (CIS). RESULTS: Regression analyses showed that neuroticism and acceptance are predictors of MHQL (38% of the variance was explained). The path analysis showed that acceptance mediates between neuroticism and MHQL and that PHQL is related to MHQL. PHQL is related to fatigue severity and duration, but not to neuroticism and acceptance. CONCLUSION: Stimulating an 'accepting accommodative coping style' within the treatment for CFS is important in improving mental quality of life. Our results suggest that neuroticism may be negatively related to acceptance and MHQL. This findings support the idea that a psychological diagnostic workout with special attention to personality traits in relation to their coping style is recommended in order to choose the most appropriate therapeutic approach in this population.
Pranjić N, Nuhbegović S, Brekalo-Lazarević S, Kurtić A.	Service of Occupational Health Tuzla in Tuzla Canton, Department of Occupational Pathology and Toxicology, Tuzla, Bosnia and Herzegovina. pranicnurka@hotmail.com	Is adrenal exhaustion synonym of syndrome burnout at workplace?	Coll Antropol. 2012 Sep;36(3):911-9.	The objective of this study is the assessment of the association of burnout syndrome with adrenal exhaustion specific symptoms and signs among 116 patients who were exposed to violence or mobbing at workplace and who were treated during 2005 to 2008 in Department of Occupational Pathology and Toxicology Tuzla; to detect symptoms and signs of adrenal exhaustion differences between patients who were exposed to act of violence as acute catastrophic event and patients who were long-term exposed to mobbing or chronic distress at workplace.MATERIAL AND METHODS: Data of 86 employees who were exposed to mobbing > 1 years (chronic distress syndrome) and data of 30 employees who were exposed to act of violence as acute traumatic crisis situation (evaluation in first week after acute stress situation and post control observation 6 months later). TOOLS FOR ASSESSMENT WERE CLINICAL EXAMINATION AND QUESTIONNAIRES: Occupational stress questionnaire (OSQ short version), self-constructed Questionnaire about symptoms and signs of Adrenal exhaustion; self-constructed mobbing questionnaire; and Maslach--Burnout Inventory.
Prinsen H, Bleijenberg G, Zwarts MJ, Hopman MT, Heerschap A, van Laarhoven HW.	Department of Medical Oncology, Radboud University Nijmegen Medical Centre, Nijmegen, the Netherlands. h.prinsen@onco.umcn.nl	Physiological and neurophysiological determinants of postcancer fatigue: design of a randomized controlled trial.	BMC Cancer. 2012 Jun 18;12:256. doi: 10.1186/1471-2407-12-256.	BACKGROUND: Postcancer fatigue is a frequently occurring, severe, and invalidating problem, impairing quality of life. Although it is possible to effectively treat postcancer fatigue with cognitive behaviour therapy, the nature of the underlying (neuro)physiology of postcancer fatigue remains unclear. Physiological aspects of fatigue include peripheral fatigue, originating in muscle or the neuromuscular junction; central fatigue, originating in nerves, spinal cord, and brain; and physical deconditioning, resulting from a decreased cardiopulmonary function. Studies on physiological aspects of postcancer fatigue mainly concentrate on deconditioning.

				Peripheral and central fatigue and brain morphology and function have been studied for patients with fatigue in the context of chronic fatigue syndrome and neuromuscular diseases and show several characteristic differences with healthy controls. METHODS/DESIGN: Fifty seven severely fatigued and 21 non-fatigued cancer survivors will be recruited from the Radboud University Nijmegen Medical Centre. Participants should have completed treatment of a malignant, solid tumour minimal one year earlier and should have no evidence of disease recurrence. Severely fatigued patients are randomly assigned to either the intervention condition (cognitive behaviour therapy) or the waiting list condition (start cognitive behaviour therapy after 6 months). All participants are assessed at baseline and the severely fatigued patients also after 6 months follow-up (at the end of cognitive behaviour therapy or waiting list). Primary outcome measures are fatigue severity, central and peripheral fatigue, brain morphology and function, and physical condition and activity. DISCUSSION: This study will be the first randomized controlled trial that characterizes (neuro)physiological factors of fatigue in disease-free cancer survivors and evaluates to which extent these factors can be influenced by cognitive behaviour therapy. The results of this study are not only essential for a theoretical understanding of this invalidating condition, but also for providing an objective biological marker for fatigue that could support the diagnosis and follow-up of treatment. TRIAL REGISTRATION: The study is registered at http://ClinicalTrials.gov (NCT01096641).
Prinsen H, de Vries IJ, Torensma R, Pots JM, Mulder SF, van Herpen CM, Elving LD, Bleijenberg G, Stelma FF, van Laarhoven HW.	Department of Medical Oncology, Radboud University Nijmegen Medical Centre, Geert Grooteplein Zuid 8, 6525, GA, Nijmegen, the Netherlands. h.prinsen@onco.umcn.nl.	Humoral and cellular immune responses after influenza vaccination in patients with chronic fatigue syndrome.	BMC Immunol. 2012 Dec 17;13:71. doi: 10.1186/1471-2172-13-71.	ABSTRACT:BACKGROUND: Chronic fatigue syndrome (CFS) is a clinical condition characterized by severe and disabling fatigue that is medically unexplained and lasts longer than 6 months. Although it is possible to effectively treat CFS, the nature of the underlying physiology remains unclear. Various studies have sought evidence for an underlying disturbance in immunity. The aim of this study was to compare the humoral and cellular immune responses upon influenza vaccination in CFS patients and healthy controls. RESULTS: Identical antibody titers were observed in CFS patients and healthy controls. Patients and controls demonstrated similar seroprotection rates against all three virus-strains of the influenza vaccine, both pre- and post-vaccination. Functional T cell reactivity was observed in both CFS patients and healthy controls. CFS patients showed a non-significant, numerically lower cellular proliferation at baseline compared to controls. Vaccination induced a significant increase in cellular proliferation in CFS patients, but not in healthy controls. Cytokine production and the number of regulatory T cells were comparable in patients and controls. CONCLUSIONS: The humoral and cellular immune responses upon influenza vaccination were comparable in CFS patients and healthy controls. Putative aberrations in immune responses in CFS patients were not evident for immunity towards influenza. Standard seasonal influenza vaccination is thus justified and, when indicated, should be recommended for patients suffering from CFS.
Puri BK, Jakeman	Department of	Regional grey and	Br J Radiol. 2012	OBJECTIVE: It is not established whether myalgic encephalomyelitis/chronic fatigue

PM, Agour M, Gunatilake KD, Fernando KA, Gurusinghe AI, Treasaden IH, Waldman AD, Gishen P.	Imaging, Hammersmith Hospital, London, UK. basant.puri@imperial.ac.uk	white matter volumetric changes in myalgic encephalomyelitis (chronic fatigue syndrome): a voxel-based morphometry 3 T MRI study.	Jul;85(1015):e270-3. doi: 10.1259/bjr/93889091	syndrome (CFS) is associated with structural brain changes. The aim of this study was to investigate this by conducting the largest voxel-based morphometry study to date in CFS. METHODS: High-resolution structural 3 T cerebral MRI scanning was carried out in 26 patients with CFS and 26 age- and gender-matched healthy volunteers. Voxel-wise generalised linear modelling was applied to the processed MR data using permutation-based non-parametric testing, forming clusters at t>2.3 and testing clusters for significance at p<0.05, corrected for multiple comparisons across space. RESULTS: Significant voxels (p<0.05, corrected for multiple comparisons) depicting reduced grey matter volume in the CFS group were noted in the occipital lobes (right and left occipital poles; left lateral occipital cortex, superior division; and left supracalcrine cortex), the right angular gyrus and the posterior division of the left parahippocampal gyrus. Significant voxels (p<0.05, corrected for multiple comparisons) depicting reduced white matter volume in the CFS group were also noted in the left occipital lobe. CONCLUSION: These data support the hypothesis that significant neuroanatomical changes occur in CFS, and are consistent with the complaint of impaired memory that is common in this illness; they also suggest that subtle abnormalities in visual processing, and discrepancies between intended actions and consequent movements, may occur in CFS.
Qiu X, Swanson P, Tang N, Leckie GW, Devare SG, Schochetman G, Hackett J Jr.	Infectious Diseases R&D, Abbott Diagnostics, Abbott Park, Illinois 60064, USA. xiaoxing.qiu@abbott.com	Seroprevalence of xenotropic murine leukemia virus-related virus in normal and retrovirus-infected blood donors.	Transfusion. 2012 Feb;52(2):307-16. doi: 10.1111/j.1537-2995.2011.03395.x.	BACKGROUND: Xenotropic murine leukemia virus-related virus (XMRV) has been reported in patients with prostate cancer and chronic fatigue syndrome. Although results have been conflicting, the potential of XMRV as an infectious human retrovirus has raised concerns about transfusion safety. To address this issue, normal and retrovirus-infected blood donors were screened for evidence of XMRV infection. STUDY DESIGN AND METHODS: Plasma from 1000 US, 100 human immunodeficiency virus Type 1-infected Cameroonian, and 642 human T-lymphotropic virus Type I (HTLV-I)-infected or uninfected Japanese blood donors as well as 311 sexually transmitted disease diagnostic specimens were screened for antibodies to XMRV gp70 and p15E using chemiluminescent immunoassays (CMIAs). CMIA-reactive samples were evaluated by p30 CMIA, Western blot, and real-time reverse transcriptase polymerase chain reaction. RESULTS: XMRV seroreactivity was low (0%-0.6%) with the exception of the HTLV-I-infected donors (4.9%). Antibody was detected against only a single XMRV protein (p15E or gp70); none of the seroreactive samples had detectable XMRV pol or env sequences. The elevated seroreactivity in HTLV-I-infected donors was due to an increased p15E seroreactive rate (4.1%). Inspection of XMRV and HTLV sequences revealed a high level of conservation within the immunodominant region (IDR) of the transmembrane protein. In some cases, HTLV IDR peptide competitively reduced the XMRV p15E signal. CONCLUSIONS: Based on the low prevalence of seroreactivity, detection of antibody to only a single XMRV protein and the absence of XMRV sequences, this study finds no compelling evidence of XMRV in normal or retrovirus-infected blood donors. The increased p15E seroreactivity observed in HTLV

				infection is likely due to cross-reactive antibodies.
Ragnarsson O, Berglund P, Eder DN, Johannsson G.	Institute of Medicine, Sahlgrenska Academy, University of Gothenburg, SE-413 45 Göteborg, Sweden. oskar.ragnarsson@medic.gu.se	Long-term cognitive impairments and attentional deficits in patients with Cushing's disease and cortisol-producing adrenal adenoma in remission.	J Clin Endocrinol Metab. 2012 Sep;97(9):E1640-8. doi: 10.1210/jc.2012-1945	CONTEXT: Cognitive function is impaired in patients with active Cushing's syndrome (CS). OBJECTIVE: The aim was to study cognitive function in patients with CS in long-term remission. DESIGN: We conducted a cross-sectional, case-controlled, single center study. PATIENTS: Fifty-five patients previously treated for Cushing's disease (n = 43) and cortisol-producing adrenal adenoma (n = 12) and 55 controls matched for age, gender, and educational level participated in the study. METHODS: Working memory, attention, information-processing speed, verbal fluency, and reading speed were studied using standardized neuropsychological testing and alerting, orienting, and executive control using the Attentional Network Test. Fatigue impact scale and the comprehensive psychopathological rating scale were used to evaluate fatigue and affective disorder. RESULTS: Median (interquartile range) duration of remission was 13 (5-19) yr and the mean ± SD age at follow-up was 54 ± 14 yr. Compared to controls, patients had a higher score on the fatigue impact scale, indicating greater burdens of fatigue, and a higher score on the comprehensive psychopathological rating scale subscales for depression and anxiety. In a multivariate analysis, attention, spatial orienting, alerting, working memory, verbal fluency, and reading speed were all diminished in comparison to controls, independent of scores for affective disorder and fatigue. No overall difference in outcome was seen between patients in long-term remission for Cushing's disease and cortisol-producing adrenal adenoma. CONCLUSION: Patients with CS in remission have impaired cognitive function that cannot be explained by the coexistence of affective disorder or chronic fatigue. The pattern of cognitive and attentional deficits suggests a more global involvement of the brain function than has previously been suggested.
Reme SE, Archer N, Chalder T.	Harvard School of Public Health, Harvard University, Boston, Massachusetts, USA.	Experiences of young people who have undergone the Lightning Process to treat chronic fatigue syndrome/myalgic encephalomyelitis - a qualitative study.	Br J Health Psychol. 2012 Sep 19. doi: 10.1111/j.2044-8287.2012.02093.x	OBJECTIVES: Chronic fatigue syndrome/myalgic encephalomyelitis (CFS/ME) is a serious condition characterized by debilitating but unexplained fatigue. Treatment alternatives are few, and especially so for young people. The aetiology of CFS/ME is still unclear and controversial, but rehabilitative interventions seem so far most promising. The Lightning Process is a 3-day training programme that has recently become available, but no outcome studies have yet been published. It is a non-medical training programme that combines concepts from Neuro-Linguistic Programming, Life Coaching and Osteopathy. The aim of this study was to explore the experiences of young people with CFS/ME after they had undergone the Lightning Process. DESIGN: Qualitative research study. METHODS: Semi-structured interviews were conducted with an opportunistic sample recruited through open advertisements of nine young people, aged 14-26, who had undergone the treatment, and three of their parents. Inductive thematic analysis was used to evaluate the content of the interviews. RESULTS: Mostly positive experiences were reported of the Lightning Process. Two reported dissatisfaction and no improvement, while seven were satisfied and were much improved. Particular helpful aspects were the

				theoretical rationale, practical exercises, and the technique they learned. Less helpful aspects were the intensity and short duration of the treatment with little follow-up, the secrecy surrounding it, and feelings of being blamed if the treatment did not work. CONCLUSIONS: As this is the first report of young people's experiences with the Lightning Process, it will be important to consider the helpful and unhelpful treatment components for future refinement of interventions for CFS/ME. STATEMENT OF CONTRIBUTION: What is already known on this subject? Treatment alternatives for people with CFS/ME are few, especially for young people. The Lightning Process is a popular treatment programme that has recently become available, but no studies involving the treatment have yet been published. Feelings of blame or dismissal in CFS/ME patients lead to withdrawal or disengagement from professionals. What does this study add? The Lightning Process for young people with CFS/ME encompasses many positive aspects, particularly the practical aspects of the treatment programme. The more extreme position taken by the Lightning Process in denying the limitations of the illness seem to produce divergent results in various young people; some found it liberating and therapeutic, whilst others did not respond well to it and were left feeling guilty and blamed.
Reyes Del Paso GA, Pulgar A, Duschek S, Garrido S.	Department of Psychology, University of Jaén, Jaen, Spain. greyes@ujaen.es	Cognitive impairment in fibromyalgia syndrome: the impact of cardiovascular regulation, pain, emotional disorders and medication.	Eur J Pain. 2012 Mar;16(3):421-9. doi: 10.1002/j.1532-2149.2011.00032.x	This study investigated cognitive performance in fibromyalgia syndrome (FMS) and its association with cardiovascular and clinical parameters. Thirty-five patients with FMS and 29 matched healthy controls completed a neuropsychological test measuring attention and arithmetic processing. As possible factors underlying the expected cognitive impairment, clinical pain intensity, co-morbid depression and anxiety disorders, sleep complaints, medication use, as well as blood pressure parameters were investigated. The patients' test performance was substantially reduced, particularly in terms of lower speed of cognitive processing and restricted improvement of performance in the course of the task. While the extent of depression, anxiety, fatigue and sleep complaints was unrelated to test performance, better performance was observed in patients showing lower pain ratings and those using opiate medication. The data corroborate the presence of substantial cognitive impairment in FMS. While the experience of chronic pain is crucial in mediating the deficits, co-morbid depression, anxiety, fatigue and sleep complaints play only a subordinate role. In the control group, but not in the patients, blood pressure was inversely associated with mental performance. This finding is in line with the well known cognitive impairment in hypertension. The lack of this association in FMS confirms previous research showing aberrances in the interaction between blood pressure and central nervous function in the affected patients.
Rico-Villademoros F, Rodriguez-Lopez CM, Morillas-Arques P, Vilchez	Instituto de Neurociencias, Universidad de Granada, Avda de	Amisulpride in the treatment of fibromyalgia: an uncontrolled study.	Clin Rheumatol. 2012 Sep;31(9):1371-5. doi: 10.1007/s10067-012-2012-6.	Some antipsychotics, including amisulpride, have shown to be effective in the treatment of various painful conditions, lessening pain as well as symptoms of anxiety and/or depression. In this open-label, 12-week study, we explored the efficacy and tolerability of amisulpride in patients with fibromyalgia. We recruited 40 patients, 1

JS, Hidalgo J, Calandre EP.	Madrid 11, 18012 Granada, Spain. fernando.ricovillademoros@gmail.com			male and 39 females, aged 46.2 ± 6.8 years, who met the ACR criteria for fibromyalgia and had a score equal to or greater than 4 in the pain severity item of the Fibromyalgia Impact Questionnaire (FIQ). Amisulpride was added to their current treatment regimen at an initial dose of 25 mg/day and titrated according to the clinical response and tolerability (mean final dose, 87.5 ± 41.3 mg/day). In the intent-to-treat analysis (i.e., all recruited patients), using a baseline-observation-carried-forward approach, the mean score in the FIQ decreased from 75.7 ± 10.6 to 73.2 ± 15.4, but this change was not statistically significant. Pain severity, as measured with the visual analogue scale from the FIQ, remained unchanged. Nonsignificant improvements were observed in depressive or anxiety symptoms using the Beck Depression Inventory and the State-Trait Anxiety Inventory, respectively. Twenty-six patients either withdrew from the study, mainly due to adverse reactions, or were lost to follow-up (n = 11, 27.5 %, for each category). Despite its promising results in some chronic painful conditions and in a related illness, such as chronic fatigue syndrome, amisulpride does not seem to provide any benefit to patients with fibromyalgia. Amisulpride was poorly tolerated by our participants.
Robinson MJ, Erlwein O, McClure MO.	Section of Infectious Diseases, Jefferiss Research Trust Laboratories, Imperial College London, St Mary's Campus, London, W2 1PG, UK.	Xenotropic murine leukaemia virus-related virus (XMRV) does not cause chronic fatigue.	Trends Microbiol. 2011 Nov;19(11):525-9. doi: 10.1016/j.tim.2011.08.005.	The xenotropic murine leukaemia virus-related virus (XMRV), a gammaretrovirus, was discovered in prostate cancer tumours by Virochip technology in 2006. It was subsequently detected in chronic fatigue patients in 2009. The association between XMRV and chronic fatigue has proved to be controversial. No study has confirmed these findings and many have refuted them. Here, we present the evidence for our contention that XMRV is not a human pathogen.

Rosenblum H, Shoenfeld Y, Amital H.	Department of Medicine B, Sheba Medical Center, Sackler Faculty of Medicine, Tel Aviv University, Ramat Aviv, Tel-Hashomer 52621, Israel.	The common immunogenic etiology of chronic fatigue syndrome: from infections to vaccines via adjuvants to the ASIA syndrome.	Infect Dis Clin North Am. 2011 Dec;25(4):851-63. doi: 10.1016/j.idc.2011.07.012.	Chronic fatigue syndrome (CFS) is characterized by unexplained fatigue that lasts for at least 6 months with a constellation of other symptoms. Most cases start suddenly, and are usually accompanied by a flu-like illness. It is a symptom-based diagnosis of exclusion, the pathogenesis of which is unknown. Studies have examined and hypothesized about the possible biomedical and epidemiologic characteristics of the disease, including genetic predisposition, infections, endocrine abnormalities, and immune dysfunction and psychological and psychosocial factors. Recently, the AISA (autoimmune/inflammatory syndrome induced by adjuvants) syndrome was recognized, indicating the possible contribution of adjuvants and vaccines to the

				development of autoimmunity.

Rovigatti U.	Department of Oncology, Transplantation and New Biomedical Technologies, University of Pisa Medical School, Pisa, Italy. Electronic address: profrovigatti@gmail.com.	Chronic Fatigue Syndrome (CFS) and Cancer Related Fatigue (CRF): two "fatigue" syndromes with overlapping symptoms and possibly related aetiologies.	Neuromuscul Disord. 2012 Dec;22 Suppl 3:S235-41. doi: 10.1016/j.nmd.2012.10.018.	In July 2010, at the Muscle Fatigue Meeting, I presented an overview of Chronic Fatigue Syndrome and Cancer Related Fatigue, emphasizing a critical interpretation of the potential association between Chronic Fatigue Syndrome and Cancer Related Fatigue and a newly discovered retrovirus: Xenotropic Murine Related Virus. Since this association was hotly debated at that time, I suggested at the Meeting that it was wrong and most likely due to the identification of the wrong virus culprit. Today, 20months after the Meeting, the first part of our prediction has turned out to be correct, as Xenotropic Murine Related Virus was shown to be a laboratory-created artefact. Still, the potential association of fatigue-syndromes with an infection (most likely viral) is sustained by a plethora of evidence and this overview will initially summarize data suggesting prior viral infection(s). The principal hypothesized mechanisms for both peripheral and central Chronic Fatigue Syndrome/Cancer Related Fatigue will be then summarized, also indicating plausible associations and triggering factors. All evidence accrued so far suggests that further research work should be performed in this interesting area and in order to identify an infectious agent for Chronic Fatigue Syndrome/Cancer Related Fatigue. One candidate RNA virus, Micro-Foci inducing Virus, will be described in this overview.
Sáez-Francàs N, Alegre J, Calvo N, Antonio Ramos-Quiroga J, Ruiz E, Hernández-Vara J, Casas M.	Psychiatry and Legal Medicine Department, Hospital Universitari Vall d'Hebron, Institut de Recerca (VHIR), Universitat Autònoma de Barcelona, CIBERSAM, Barcelona, Spain. Electronic address: nasaez2@gmail.com.	Attention-deficit hyperactivity disorder in chronic fatigue syndrome patients.	Psychiatry Res. 2012 Dec 30;200(2-3):748-53. doi: 10.1016/j.psychres.2012.04.041.	Psychopathological disorders are frequent in chronic fatigue syndrome patients. The present study examines the presence of attention-deficit hyperactivity disorder (ADHD) in a sample of adult chronic fatigue syndrome (CFS) patients, and evaluates its clinical consequences in this population. CFS patients were assessed for childhood and adult ADHD by clinical interview and ADHD-specific scales. Psychopathological comorbidities were evaluated by clinical examination and questionnaires. Forty-seven of 158 CSF patients (29.7%) were diagnosed of childhood ADHD and in 33 (20.9%), the condition persisted into adulthood. CFS patients with adult ADHD had an earlier CSF onset, more severe anxiety and depression symptoms, and a higher risk of suicide than CFS patients without ADHD. Using lineal regression analysis, we found that depressive symptoms and ADHD
Sakudo A, Kuratsune H, Kato YH, Ikuta K.	Department of Virology, Center for Infectious Disease Control, Research Institute for Microbial Diseases, Osaka University, Yamadaoka, Suita, Osaka 565-0871,	Visible and near-infrared spectra collected from the thumbs of patients with chronic fatigue syndrome for diagnosis.	Clin Chim Acta. 2012 Oct 9;413(19-20):1629-32. doi: 10.1016/j.cca.2012.05.004.	BACKGROUND: Currently, diagnosis of chronic fatigue syndrome (CFS) is based on clinical symptoms and therefore relies on the experience and skill of the doctors. Here, we have examined the possible diagnosis of CFS based on spectral information and chemometrics analysis, such as principal component analysis (PCA) and soft modeling of class analogy (SIMCA). METHODS: Visible and near-infrared (Vis-NIR) spectroscopy was used to examine possible changes in the region of 600-1100 nm in thumbs and assessed. RESULTS: The Vis-NIR spectra of thumbs from 57 CFS patients and 74 healthy volunteers were subjected to PCA and SIMCA to develop multivariate

	Japan. sakudo@biken.osaka-u.ac.jp			models to discriminate between CFS patients and healthy individuals. The model was further assessed by the prediction of 120 determinations (60 in the healthy group and 60 in the CFS patient group). The PCA model predicted a discrimination of the masked samples; specifically the SIMCA model correctly predicted 51 of 60 (83.3%) healthy volunteers and 42 of 60 (70%) CFS patients. CONCLUSIONS: Despite the relatively small number of subjects involved in this trial, who were exclusively Japanese, our results imply that Vis-NIR spectroscopy of the thumb combined with chemometrics analysis may provide a valuable tool for diagnosing CFS.
Sakuma T, Tonne JM, Malcolm JA, Thatava T, Ohmine S, Peng KW, Ikeda Y	Department of Molecular Medicine, Mayo Clinic, Rochester, Minnesota, United States of America.	Long-term infection and vertical transmission of a gammaretrovirus in a foreign host species.	PLoS One. 2012;7(1):e29682. doi: 10.1371/journal.pone.0029682.	Increasing evidence has indicated natural transspecies transmission of gammaretroviruses; however, viral-host interactions after initial xeno-exposure remain poorly understood. Potential association of xenotropic murine leukemia virus-related virus (XMRV) in patients with prostate cancer and chronic fatigue syndrome has attracted broad interests in this topic. Although recent studies have indicated that XMRV is unlikely a human pathogen, further understanding of XMRV xenoinfection would allow in vivo modeling of the initial steps of gammaretroviral interspecies transmission, evolution and dissemination in a new host population. In this study, we monitored the long-term consequences of XMRV infection and its possible vertical transmission in a permissive foreign host, wild-derived Mus pahari mice. One year post-infection, XMRV-infected mice showed no notable pathological changes, while proviral DNA was detected in three out of eight mice. XMRV-infected mice remained seropositive throughout the study although the levels of gp70 Env- and p30 capsid-specific antibodies gradually decreased. When vertical XMRV transmission was assessed, no viremia, humoral immune responses nor endogenization were observed in nine offspring from infected mothers, yet one offspring was found PCR-positive for XMRV-specific sequences. Amplified viral sequences from the offspring showed several mutations, including one amino acid deletion in the receptor binding domain of Env SU. Our results therefore demonstrate long-term asymptomatic infection, low incidence of vertical transmission and limited evolution of XMRV upon transspecies infection of a permissive new host, Mus pahari.
Sato E, Yoshikawa R, Miyazawa T.	Laboratory of Signal Transduction, Department of Cell Biology, Institute for Virus Research, Kyoto University, 53 Shogoin-Kawaharacho, Sakyo-ku, Kyoto 606–8507, Japan.	Comparison of two quantitative assays for xenotropic murine leukemia virus-related virus.	J Vet Med Sci. 2012 Feb;74(2):255-8.	Xenotropic murine leukemia virus-related virus (XMRV), a novel gammaretrovirus in humans, was found in patients with prostate cancer (PC) and chronic fatigue syndrome (CFS). However, there has been controversy whether XMRV is directly associated with human diseases. In this study, we developed a LacZ marker rescue assay using human embryonic kidney 293T cells and a focus assay using a feline fibroblastic sarcoma-positive leukemia-negative QN10S cells. XMRV induced prominent foci in QN10S cells and the viral titer determined by the focus assay was as high as that by the LacZ marker rescue assay. Because the focus assay is simple and sensitive, it will be useful for monitoring infectious XMRVs in CFS and PC patients and virological studies for XMRV.
Schreurs KM,	University of Twente,	Cognitive	Behav Res Ther. 2011	Cognitive behavioural therapy (CBT) was combined with graded exercise therapy

Veehof MM, Passade L, Vollenbroek-Hutten MM.	Enschede, The Netherlands. k.m.g.schreurs@utwente.nl	behavioural treatment for chronic fatigue syndrome in a rehabilitation setting: effectiveness and predictors of outcome.	Dec;49(12):908-13. doi: 10.1016/j.brat.2011.09.004.	(GET) for patients with chronic fatigue syndrome (CFS) in an uncontrolled implementation study of an inpatient multidisciplinary group therapy. During the intake procedure, 160 CFS patients completed a questionnaire on fatigue related measurements, physical impairment, depression, somatic and psychological attributions, somatic focus, and sense of control over symptoms. Pre-treatment physical activity level was measured with an actometer. At baseline, post-treatment and 6-month follow-up individual strength, subjective fatigue and physical impairment, were reassessed. Large effect sizes were found on subjective fatigue (1.2 post-treatment; 1.2 follow-up) and physical impairment (-.9 post-treatment; -.9 follow-up), Clinically significant improvement was found in 33.8% of the participants at post-treatment and 30.6% at follow-up. Individual strength at post-treatment was predicted by level of physical activity before treatment, and by sense of control over symptoms and physical activity at follow-up. Clinically significant improvement in subjective fatigue was predicted by not receiving a disablement insurance benefit, shorter duration of fatigue, higher sense of control over symptoms and, at follow-up by more pre-treatment physical activity. In conclusion, the intervention was effective for CFS patients. Cognitive behavioural factors that perpetuate fatigue symptoms are also predictors of treatment outcome.
Schrier M, Amital D, Arnson Y, Rubinow A, Altaman A, Nissenabaum B, Amital H.	Department of Medicine 'B', Sheba Medical Center, 52621 Tel-Hashomer, Ramat-Gan, Israel.	Association of fibromyalgia characteristics in patients with non-metastatic breast cancer and the protective role of resilience.	Rheumatol Int. 2012 Oct;32(10):3017-23.	Cancer patients often complain about weakness, fatigue, and pain. The aim of this study was to assess the features of the fibromyalgia syndrome (FMS) characteristics in patients with non-metastatic breast cancer. The study group included 40 women whose age ranged from 40 to 70 years with Stages 0-3 breast cancer. The control group included 40 healthy women matched by age. A diagnosis of FMS was established based on medical history, physical examination, and the Fibromyalgia Impact Questionnaire (FIQ). Pain measures and functional factors were evaluated by the Brief Pain Inventory and the Sheehan Questionnaire. Resilience was assessed by Antanovsky's Sense of Coherence Questionnaire. Psychiatric disturbances were tested by the MINI Questionnaire and Hamilton questionnaires for depression and anxiety. The prevalence of chronic pain was higher in the study group. Statistically significant differences were also found between the group regarding pain, fatigue, and functional measures. The prevalence of depressive or anxious mood, measured by the Hamilton questionnaires, was strongly related to FMS characteristics reflected by FIQ scores (r = 0.79 between FIQ and the Hamilton Depression Index and r = 0.75 between FIQ and the Hamilton Anxiety Scale). The sense of coherence measure for these patients demonstrated an inverse correlation with pain, fatigue, and functional capability. Women with breast cancer tend to develop chronic widespread pain syndromes more often than do healthy women.
Selmi C, Mix E, Zettl UK.	Division of Rheumatology, Allergy, and Clinical	A clear look at the neuroimmunology of multiple sclerosis	Autoimmun Rev. 2012 Jan;11(3):159-62. doi: 10.1016/j.autrev.2011.05.006.	The term neuroimmunology was first coined to refer to a generic involvement of the immune system in the pathogenesis of neurological diseases, particularly of the central nervous system. Since then, the neuroimmunology spectrum has steadily

	Immunology, University of California, Davis, United States.	and beyond.		grown and currently spans from classical autoimmune diseases of the central and peripheral nervous systems to previously unsuspected conditions such as autism spectrum disorders or chronic fatigue syndrome. Multiple sclerosis remains the predominant entity in terms of research efforts and social pressure as well as a good model of organ-specific autoimmune disease with limited therapeutic options. While the fast-pace genome-wide association studies reported a number of genes to be significantly associated with multiple sclerosis, these currently explain only a minor part of disease susceptibility. Further, clinicians are continuously challenged with the clinical classifications of immune-mediated or autoimmune central and peripheral conditions and with other pragmatic questions such as the roles of vaccination and physical therapy. For these reasons the present collection of Autoimmunity Reviews is timely as it will address these major issues related to neuroimmunology.
Senel K, Baygutalp F, Baykal T, Erdal A, Ugur M.	Department of Physical Medicine and Rehabilitation, Atatürk University Medical Faculty, Erzurum, Turkey, kazimsenel@gmail.com .	Melatonin levels in premenopausal women with fibromyalgia syndrome.	Rheumatol Int. 2011 Dec 23.	The fibromyalgia syndrome (FMS) is a chronic, widespread pain disorder of unknown etiology. It has been suggest that familial component, environmental factors, endocrine and neurotransmitter alterations, and psychological factors may contribute to the development of FMS. The role of melatonin in FMS is unclear. Some studies describe a lower nocturnal peak and a decreased secretion of melatonin in women with FMS when compared with healthy matched controls. The aim of the present study was to determine the possible role of melatonin in FMS patients. We examined the characteristics and levels of melatonin in 25 consecutive premenopausal women with FMS. Serum blood samples were collected from 25 patients and 20 the age and gender matched healthy controls. Melatonin levels were measured by enzyme-linked immunosorbent assay. Then, the results were compared with those from healthy subjects. Serum melatonin levels of FMS patients were not statistically different from those of controls ($P > 0.05$). No association was observed between melatonin levels of patients with FMS and disease duration, sleep disturbances, fatigue, and pain scores. Our results demonstrate that melatonin levels were similar in patients with FMS and healthy controls. Further studies are needed to determine the possible role of melatonin.
Seshadri N, Sonoda LI, Lever AM, Balan K.	Department of Nuclear Medicine, Addenbrookes Hospital, Cambridge CB2 0QQ, United Kingdom. s_n_bhushan@yahoo.com	Superiority of 18F-FDG PET compared to 111In-labelled leucocyte scintigraphy in the evaluation of fever of unknown origin.	J Infect. 2012 Jul;65(1):71-9. doi: 10.1016/j.jinf.2012.02.008.	AIM: To compare the accuracy of positron emission tomography (PET) using (18)F-FDG (Fluorodeoxyglucose) PET with (111)In-labelled leucocytes scintigraphy (LS) in patients with fever of unknown origin (FUO). METHODS: Twenty-three consecutive patients with FUO were prospectively studied using whole-body LS and PET. Performance of the two modalities for identifying a cause of FUO was evaluated. Final diagnosis was based on biopsy, microbiological tests, clinical and imaging follow-up. RESULTS: Abnormal tracer uptake was seen in 3/23(13%) and 14/23(61%) patients on LS and PET respectively, suggesting a higher sensitivity ($p < 0.01$) for the latter. All LS positive cases were identified on PET and confirmed as infection. The causes of FUO in the other PET positive patients were: infection (n = 3), vasculitis (n = 3), non-infectious inflammatory conditions (n = 2) and cancer (n = 1). No specific

				diagnosis was reached in 2 patients. Of 13 patients without a definite diagnosis following PET and LS, 10 made a spontaneous recovery during the follow-up period and no definite cause for FUO was found on investigation. Still's disease, Polymyalgia rheumatica and Chronic fatigue syndrome/Myalgic encephalomyelitis were diagnosed in the remaining three patients during follow-up. The results thus showed an overall sensitivity of 86% for PET and 20% for LS ($p < 0.01$). The overall specificity for FDG PET was 78% as against 100% for LS. PET had a PPV of 86% and a NPV of 78% whereas LS had a PPV of 100% and a NPV of 40%. CONCLUSION: PET has a higher sensitivity than LS in identifying the aetiology of FUO. PET/PET-CT, where available, should be used as the non-invasive investigation of choice in the assessment of patients with FUO.
Shin SR, Han AL.	Department of Family Medicine, Wonkwang University College of Medicine, Iksan, Korea.	Improved chronic fatigue symptoms after removal of mercury in patient with increased mercury concentration in hair toxic mineral assay: a case.	Korean J Fam Med. 2012 Sep;33(5):320-5. doi: 10.4082/kjfm.2012.33.5.320	Clinical manifestations of chronic exposure to organic mercury usually have a gradual onset. As the primary target is the nervous system, chronic mercury exposure can cause symptoms such as fatigue, weakness, headache, and poor recall and concentration. In severe cases chronic exposure leads to intellectual deterioration and neurologic abnormality. Recent outbreaks of bovine spongiform encephalopathy and pathogenic avian influenza have increased fish consumption in Korea. Methyl-mercury, a type of organic mercury, is present in higher than normal ranges in the general Korean population. When we examine a patient with chronic fatigue, we assess his/her methyl-mercury concentrations in the body if environmental exposure such as excessive fish consumption is suspected. In the current case, we learned the patient had consumed many slices of raw tuna and was initially diagnosed with chronic fatigue syndrome. Therefore, we suspected that he was exposured to methyl-mercury and that the mercury concentration in his hair would be below the poisoning level identified by World Health Organization but above the normal range according to hair toxic mineral assay. Our patient's toxic chronic fatigue symptoms improved after he was given mercury removal therapy, indicating that he was correctly diagnosed with chronic exposure to organic mercury.
Shungu DC, Weiduschat N, Murrough JW, Mao X, Pillemer S, Dyke JP, Medow MS, Natelson BH, Stewart JM, Mathew SJ.	Department of Radiology, Weill Medical College of Cornell University, New York, NY 10021, USA. dcs7001@med.cornell.edu	Increased ventricular lactate in chronic fatigue syndrome. III. Relationships to cortical glutathione and clinical symptoms implicate oxidative stress in disorder pathophysiology.	NMR Biomed. 2012 Sep;25(9):1073-87. doi: 10.1002/nbm.2772.	Chronic fatigue syndrome (CFS) is a complex illness, which is often misdiagnosed as a psychiatric illness. In two previous reports, using (1)H MRSI, we found significantly higher levels of ventricular cerebrospinal fluid (CSF) lactate in patients with CFS relative to those with generalized anxiety disorder and healthy volunteers (HV), but not relative to those with major depressive disorder (MDD). In this third independent cross-sectional neuroimaging study, we investigated a pathophysiological model which postulated that elevations of CSF lactate in patients with CFS might be caused by increased oxidative stress, cerebral hypoperfusion and/or secondary mitochondrial dysfunction. Fifteen patients with CFS, 15 with MDD and 13 HVs were studied using the following modalities: (i) (1)H MRSI to measure CSF lactate; (ii) single-voxel (1)H MRS to measure levels of cortical glutathione (GSH) as a marker of antioxidant capacity; (iii) arterial spin labeling (ASL) MRI to measure regional cerebral blood flow (rCBF); and (iv) (31)P MRSI to measure brain high-energy phosphates as objective

				indices of mitochondrial dysfunction. We found elevated ventricular lactate and decreased GSH in patients with CFS and MDD relative to HVs. GSH did not differ significantly between the two patient groups. In addition, we found lower rCBF in the left anterior cingulate cortex and the right lingual gyrus in patients with CFS relative to HVs, but rCBF did not differ between those with CFS and MDD. We found no differences between the three groups in terms of any high-energy phosphate metabolites. In exploratory correlation analyses, we found that levels of ventricular lactate and cortical GSH were inversely correlated, and significantly associated with several key indices of physical health and disability. Collectively, the results of this third independent study support a pathophysiological model of CFS in which increased oxidative stress may play a key role in CFS etiopathophysiology.
Simmons G, Glynn SA, Komaroff AL, Mikovits JA, Tobler LH, Hackett J Jr, Tang N, Switzer WM, Heneine W, Hewlett IK, Zhao J, Lo SC, Alter HJ, Linnen JM, Gao K, Coffin JM, Kearney MF, Ruscetti FW, Pfost MA, Bethel J, Kleinman S, Holmberg JA, Busch MP; Blood XMRV Scientific Research Working Group (SRWG). Collaborators: Glynn S, Holmberg JA, Bianco C, Busch MP, Dodd RY, Katz LM, Kleinman SH, Komaroff AL, Mikovits JA, Simmons G, Stramer SL, Tobler LH, Vernon SD, Alter H, Coffin J,	Blood Systems Research Institute and University of California, San Francisco, San Francisco, CA 94118, USA.	Failure to confirm XMRV/MLVs in the blood of patients with chronic fatigue syndrome: a multi-laboratory study.	Science. 2011 Nov 11;334(6057):814-7. doi: 10.1126/science.1213841.	Murine leukemia viruses (MLVs), including xenotropic-MLV-related virus (XMRV), have been controversially linked to chronic fatigue syndrome (CFS). To explore this issue in greater depth, we compiled coded replicate samples of blood from 15 subjects previously reported to be XMRV/MLV-positive (14 with CFS) and from 15 healthy donors previously determined to be negative for the viruses. These samples were distributed in a blinded fashion to nine laboratories, which performed assays designed to detect XMRV/MLV nucleic acid, virus replication, and antibody. Only two laboratories reported evidence of XMRV/MLVs; however, replicate sample results showed disagreement, and reactivity was similar among CFS subjects and negative controls. These results indicate that current assays do not reproducibly detect XMRV/MLV in blood samples and that blood donor screening is not warranted.

Singh PK, Chopra K, Kuhad A, Kaur IP.	University Institute of Pharmaceutical Sciences, UGC Centre of Advanced Study, Panjab University, Chandigarh 160014, India.	Role of Lactobacillus acidophilus loaded floating beads in chronic fatigue syndrome: behavioral and biochemical evidences.	Neurogastroenterol Motil. 2012 Apr;24(4):366-e170. doi: 10.1111/j.1365-2982.2011.01861.x. Epub 2012 Feb 1.	BACKGROUND: In recent years the interface between neuropsychiatry and gastroenterology has converged in to a new discipline referred to as enteric neuroscience. Implications of brain-gut communication in the pathogenesis of psychiatric disorders indicate a possible role of suitably packaged/delivered probiotics as newer therapeutic options. In the present study probable role of per-oral administration of free Lactobacillus acidophilus (LAB) and LAB loaded alginate beads in attenuation of the symptoms associated with chronic fatigue syndrome (CFS) were evaluated. METHODS: Chronic fatigue syndrome following physical fatigue was induced in rats by forcing them to swim (forced swim test; FST) in water till exhaustion, after weighing them down with 10% their body weight, daily for 28 days. Immobility (I) and postswim fatigue time (PSF) were taken as suitable markers. Free LAB and LAB loaded floating beads (FBs) were administered, from 21 to 28 days. KEY RESULTS: Immobility and PSF were found to increase considerably in FST rats (665 ± 22 s and 196 ± 6 s) as compared with the naïve (32 ± 7 s and 22 ± 2 s) at 20 days, establishing severe fatigue like behavior. FST control group exhibited significant ($P < 0.05$) hypertrophy of spleen, hypotrophy of thymus, and increased oxido-nitrosative stress in brain and tumor necrosis factor-α (TNF-α) levels in serum. Treatment with LAB and LAB FBs significantly decreased I and PSF and attenuated ($P < 0.05$) oxido-nitrosative stress and TNF-α levels. Spleen and thymus were also restored to their original size in this group. CONCLUSIONS & INFERENCES: The findings suggest a valuable therapeutic role of LAB especially when incorporated into alginate beads for the treatment of CFS.
Skelly JR, Edge D, Shortt CM, Jones JF, Bradford A, O'Halloran KD.	UCD School of Medicine and Medical Science, University College Dublin, Belfield, Dublin 4, Ireland. richskelly@yahoo.com	Respiratory control and sternohyoid muscle structure and function in aged male rats: decreased susceptibility to chronic intermittent hypoxia.	Respir Physiol Neurobiol. 2012 Mar 15;180(2-3):175-82. doi: 10.1016/j.resp.2011.11.004.	Obstructive sleep apnoea syndrome (OSAS) is a common respiratory disorder characterized by chronic intermittent hypoxia (CIH). We have shown that CIH causes upper airway muscle dysfunction in the rat due to oxidative stress. Ageing is an independent risk factor for the development of OSAS perhaps due to respiratory muscle remodelling and increased susceptibility to hypoxia. We sought to examine the effects of CIH on breathing and pharyngeal dilator muscle structure and function in aged rats. Aged (18-20 months), male Wistar rats were exposed to alternating cycles of normoxia and hypoxia (90 s each; F(I)O(2)=5% O(2) at nadir) or sham treatment for 8h/day for 9 days. Following CIH exposure, breathing was assessed by

				whole-body plethysmography. In addition, sternohyoid muscle contractile and endurance properties were examined in vitro. Muscle fibre type and cross-sectional area, and the activity of key oxidative and glycolytic enzymes were determined. CIH had no effect on basal breathing or ventilatory responses to hypoxia or hypercapnia. CIH did not alter succinate dehydrogenase or glycerol phosphate dehydrogenase enzyme activities, myosin heavy chain fibre areal density or cross-sectional area. Sternohyoid muscle force and endurance were unaffected by CIH exposure. Since we have established that this CIH paradigm causes sternohyoid muscle weakness in adult male rats, we conclude that aged rats have decreased susceptibility to CIH-induced stress. We suggest that structural remodelling with improved hypoxic tolerance in upper airway muscles may partly compensate for impaired neural regulation of the upper airway and increased propensity for airway collapse in aged mammals.
Smith C, Wessely S.	Department of Psychological Medicine, Institute of Psychiatry, Weston Education Centre, , London, UK.	Unity of opposites? Chronic fatigue syndrome and the challenge of divergent perspectives in guideline development.	J Neurol Neurosurg Psychiatry. 2012 Nov 17.	Guideline development by its nature is a process and method of integration and synthesis of information, be it originating from research, evidence-based medicine, clinical findings, patient experience and/or individual narratives of an illness or disease. In the majority of cases, it can be assumed that this information and these ideas are travelling in the same direction; however, it is possible that the objective and subjective cannot be synthesised, and appear mutually contradictory. In this commentary, an example of where this might be the case has been analysed: a report published by the Scottish Public Health Network, a Health Care Needs Assessment of Services for people living with myalgic encephalomyelitis (ME)/chronic fatigue syndrome (CFS). It appears from reflection and analysis of this document that this process may indeed have gone awry. We propose that, if followed, this document would lead to the adoption of dangerous diagnostic criteria for ME/CFS, as well as preventing patients from making informed decisions about treatment options, and discouraging clinicians from following evidence-based medicine and recommending proven treatments for ME/CFS, because of potential implications for future commissioning. This commentary seeks to highlight some of the problems, contradictions and unintended consequences of a divergence between patient perspectives and evidence-based medicine despite probably sharing the same aim, that of improving patient care and striving for better understanding and better treatments for disease.
Smith HS, Elliott JA.	Albany Medical College, Albany, NY, USA.	Opioid-induced androgen deficiency (OPIAD).	Pain Physician. 2012 Jul;15(3 Suppl):ES145-56.	Opioid therapy is one of the most effective forms of analgesia currently in use. In the past few decades, the use of opioids as a long-term treatment for chronic pain has increased dramatically. Accompanying this upsurge in the use of long-term opioid therapy has been an increase in the occurrence of opioid associated endocrinopathy, most commonly manifested as an androgen deficiency and therefore referred to as opioid associated androgen deficiency (OPIAD). This syndrome is characterized by the presence of inappropriately low levels of gonadotropins (follicle stimulating hormone and luteinizing hormone) leading to inadequate production of sex hormones,

				particularly testosterone. Symptoms that may manifest in patients with OPIAD include reduced libido, erectile dysfunction, fatigue, hot flashes, and depression. Physical findings may include reduced facial and body hair, anemia, decreased muscle mass, weight gain, and osteopenia or osteoporosis. Additionally, both men and women with OPIAD may suffer from infertility. While the literature regarding OPIAD remains limited, it is apparent that OPIAD is becoming increasingly prevalent among chronic opioid consumers but often goes unrecognized. OPIAD can have a significant negative impact on the the quality of life of opioid users, and clinicians should anticipate the potential for its occurrence whenever long-term opioid prescribing is undertaken. Once diagnosed, treatment for OPIAD may be offered utilizing a number of androgen replacement therapy options including a variety of testosterone preparations and, for female patients with OPIAD, dehydroepiandrosterone (DHEA) supplementation. Follow-up evaluation of patients receiving androgen replacement therapy should include a review of any unresolved symptoms of hypogonadism, laboratory evaluation, and surveillance for potential adverse effects of androgen replacement therapy including prostate disease in males.:
Son CG.	Liver and Research Center, Daejon Oriental Hospital of Daejon University, Republic of Korea. ckson@dju.ac.kr	Safety of 4-week indirect-moxibustion therapy at CV4 and CV8.	J Acupunct Meridian Stud. 2011 Dec;4(4):262-5. doi: 10.1016/j.jams.2011.09.018.	PURPOSE: Moxibustion therapy is a commonly used treatment in Oriental medicine. Here, we provide evidence for the safety of long-term moxibustion therapy. SUBJECTS: and design: Forty-five subjects (10 men and 35 women) who complained of chronic fatigue were divided into control (5 men and 15 women) and experimental groups (5 men and 20 women) in a randomized double-blind setting. The experimental group was treated with moxibustion to CV4 and CV8 for 4 weeks (administered three times per week); the control group was exposed to simulated burning of moxibustion. Complete blood counts, blood chemistry, and urinalysis results were analyzed before and after each trial. RESULTS: The absolute and relative number of peripheral blood cells did not differ between the pre- and posttreatment measurements of either group. No significant changes in blood chemistry or urinalysis data were observed in either group. CONCLUSIONS: These results suggest that indirect moxibustion has no effect on blood chemistry or urine and is safe for clinical use. These data could be used as reference data for further moxibustion studies.
Spindler J, Hackett J Jr, Qiu X, Wiegand A, Boltz VF, Swanson P, Bream JH, Jacobson LP, Li X, Rinaldo CR, Wolinsky SM, Coffin JM, Kearney MF, Mellors JW.	HIV Drug Resistance Program, National Cancer Institute, Frederick, MD 21702-1201, USA.	Prevalence of XMRV nucleic acid and antibody in HIV-1-Infected men and in men at risk for HIV-1 Infection.	Adv Virol. 2011;2011:268214. doi: 10.1155/2011/268214.	Xenotropic MLV-Related Virus (XMRV) was recently reported to be associated with prostate cancer and chronic fatigue syndrome (CFS). Infection was also reported in 3.7% of healthy individuals. These highly reported frequencies of infection prompted concerns about the possibility of a new, widespread retroviral epidemic. The Multicenter AIDS Cohort Study (MACS) provides an opportunity to assess the prevalence of XMRV infection and its association with HIV-1 infection among men who have sex with men. Reliable detection of XMRV infection requires the application of multiple diagnostic methods, including detection of human antibodies to XMRV and detection of XMRV nucleic acid. We, therefore, tested 332 patient plasma and PBMC samples obtained from recent visits in a subset of patients in the MACS cohort

				for XMRV antibodies using Abbott prototype ARCHITECT chemiluminescent immunoassays (CMIAs) and for XMRV RNA and proviral DNA using a XMRV single-copy qPCR assay (X-SCA). Although 9 of 332 (2.7%) samples showed low positive reactivity against a single antigen in the CMIA, none of these samples or matched controls were positive for plasma XMRV RNA or PBMC XMRV DNA by X-SCA. Thus, we found no evidence of XMRV infection among men in the MACS regardless of HIV-1 serostatus.
St Clair K, Maguire JD.	Center Portsmouth, Portsmouth, VA, USA.	Role of fluconazole in a case of rapid onset ritonavir and inhaled fluticasone-associated secondary adrenal insufficiency.	Int J STD AIDS. 2012 May;23(5):371-2. doi: 10.1258/ijsa.2009.009339.	A 52-year-old man with well-controlled HIV infection taking ritonavir and increasing doses of inhaled fluticasone for chronic bronchitis developed thrush. Within days of discontinuing fluticasone and initiating fluconazole, he presented with fatigue, malaise, lower-extremity oedema and orthostasis. Testing confirmed exogenous Cushing's syndrome and secondary adrenal insufficiency. Although ritonavir-fluticasone interactions have been previously reported as a cause for adrenal insufficiency, we propose that fluconazole increased the rapidity of onset and severity of symptoms through synergistic inhibition of the adrenal axis.
Staud R.	Division of Rheumatology and Clinical Immunology, University of Florida, PO Box 100221, Gainesville, FL 32610-0221, USA. staudr@ufl.edu	Peripheral and central mechanisms of fatigue in inflammatory and noninflammatory rheumatic diseases.	Curr Rheumatol Rep. 2012 Dec;14(6):539-48. doi: 10.1007/s11926-012-0277-z.	Fatigue is a common symptom in a large number of medical and psychological disorders, including many rheumatologic illnesses. A frequent question for health care providers is related to whether reported fatigue is "in the mind" or "in the body"-that is, central or peripheral. If fatigue occurs at rest without any exertion, this suggests psychological or central origins. If patients relate their fatigue mostly to physical activities, including exercise, their symptoms can be considered peripheral. However, most syndromes of fatigue seem to depend on both peripheral and central mechanisms. Sometimes, muscle biopsy with histochemistry may be necessary for the appropriate tissue diagnosis, whereas serological tests generally provide little reliable information about the origin of muscle fatigue. Muscle function and peripheral fatigue can be quantified by contractile force and action potential measurements, whereas validated questionnaires are frequently used for assessment of mental fatigue. Fatigue is a hallmark of many rheumatologic conditions, including fibromyalgia, myalgic encephalitis/chronic fatigue syndrome, rheumatoid arthritis, systemic lupus, Sjogren's syndrome, and ankylosing spondylitis. Whereas many studies have focused on disease activity as a correlate to these patients' fatigue, it has become apparent that other factors, including negative affect and pain, are some of the most powerful predictors for fatigue. Conversely, sleep problems, including insomnia, seem to be less important for fatigue. There are several effective treatment strategies available for fatigued patients with rheumatologic disorders, including pharmacological and nonpharmacological therapies.
Staud R.	Division of Rheumatology and Clinical Immunology, University of Florida,	Abnormal endogenous pain modulation is a shared characteristic	Expert Rev Neurother. 2012 May;12(5):577-85. doi: 10.1586/ern.12.41.	The intensity of acute and chronic pain depends on interactions between peripheral impulse input and CNS pain mechanisms, including facilitation and inhibition. Whereas tonic pain inhibition is a characteristic of most pain-free individuals, pain facilitation can be detected in many chronic pain patients. The capability to inhibit

	PO Box 100221, Gainesville, FL 32610-0221, USA. staudr@ufl.edu.	of many chronic pain conditions.		pain is normally distributed along a wide continuum in the general population and can be used to predict chronic pain. Accumulating evidence suggests that endogenous pain inhibition depends on activation of the prefrontal cortex, periaqueductal gray and rostral ventral medulla. Quantitative sensory test paradigms have been designed to acquire detailed information regarding each individual's endogenous pain inhibition and facilitation. Such tests include: temporal summation of pain, which is mostly used to assess facilitatory pain modulation by measuring the change in pain perception during a series of identical nociceptive stimuli; and conditioned pain modulation, which tests pain inhibition by utilizing two simultaneously applied painful stimuli (the 'pain inhibits pain' paradigm). Considerable indirect evidence seems to indicate that not only increased pain facilitation but also ineffective pain inhibition represents a predisposition for chronic pain. This view is supported by the fact that many chronic pain syndromes (e.g., fibromyalgia, temporomandibular joint disorder, irritable bowel syndrome, headache and chronic fatigue syndrome) are associated with hypersensitivity to painful stimuli and reduced endogenous pain inhibition. However, future prospective studies will be necessary to provide definitive evidence for this relationship. Such research would not only provide important information about mechanisms relevant to chronic pain but would also permit identification of individuals at high risk for future chronic pain.
Steffen I, Tyrrell DL, Stein E, Montalvo L, Lee TH, Zhou Y, Lu K, Switzer WM, Tang S, Jia H, Hockman D, Santer DM, Logan M, Landi A, Law J, Houghton M, Simmons G.	Blood Systems Research Institute, San Francisco, California, United States of America.	No evidence for XMRV nucleic acids, infectious virus or anti-XMRV antibodies in Canadian patients with chronic fatigue syndrome.	PLoS One. 2011;6(11):e27870. doi: 10.1371/journal.pone.0027870.	The gammaretroviruses xenotropic murine leukemia virus (MLV)-related virus (XMRV) and MLV have been reported to be more prevalent in plasma and peripheral blood mononuclear cells of chronic fatigue syndrome (CFS) patients than in healthy controls. Here, we report the complex analysis of whole blood and plasma samples from 58 CFS patients and 57 controls from Canada for the presence of XMRV/MLV nucleic acids, infectious virus, and XMRV/MLV-specific antibodies. Multiple techniques were employed, including nested and qRT-PCR, cell culture, and immunoblotting. We found no evidence of XMRV or MLV in humans and conclude that CFS is not associated with these gammaretroviruses.
Stewart JM, Medow MS, Messer ZR, Baugham IL, Terilli C, Ocon AJ.	Departments of Physiology, New York Medical College, Valhalla, New York. USA. julian_stewart@nymc.edu	Postural neurocognitive and neuronal activated cerebral blood flow deficits in young chronic fatigue syndrome patients with postural tachycardia syndrome.	Am J Physiol Heart Circ Physiol. 2012 Mar 1;302(5):H1185-94. doi: 10.1152/ajpheart.00994.2011.	Neurocognition is impaired in chronic fatigue syndrome (CFS). We propose that the impairment relates to postural cerebral hemodynamics. Twenty-five CFS subjects and twenty control subjects underwent incremental upright tilt at 0, 15, 30, 45, 60, and 75° with continuous measurement of arterial blood pressure and cerebral blood flow velocity (CBFV). We used an n-back task with n ranging from 0 to 4 (increased n = increased task difficulty) to test working memory and information processing. We measured n-back outcomes by the number of correct answers and by reaction time. We measured CBFV, critical closing pressure (CCP), and CBFV altered by neuronal activity (activated CBFV) during each n value and every tilt angle using transcranial Doppler ultrasound. N-back outcome in control subjects decreased with n valve but was independent of tilt angle. N-back outcome in CFS subjects decreased with n value

				but deteriorated as orthostasis progressed. Absolute mean CBFV was slightly less than in control subjects in CFS subject at each angle. Activated CBFV in control subjects was independent of tilt angle and increased with n value. In contrast, activated CBFV averaged 0 in CFS subjects, decreased with angle, and was less than in control subjects. CCP was increased in CFS subjects, suggesting increased vasomotor tone and decreased metabolic control of CBFV. CCP did not change with orthostasis in CFS subjects but decreased monotonically in control subjects, consistent with vasodilation as compensation for the orthostatic reduction of cerebral perfusion pressure. Increasing orthostatic stress impairs neurocognition in CFS subjects. CBFV activation, normally tightly linked to cognitive neuronal activity, is unrelated to cognitive performance in CFS subjects; the increased CCP and vasomotor tone may indicate an uncoupling of the neurovascular unit during orthostasis.
Strauss B, Löschau M, Seidel T, Stallmach A, Thomas A.	Jena University Hospital, Friedrich-Schiller University, Institute of Psychosocial Medicine and Psychotherapy, Germany. Bernhard.strauss@med.uni-jena.de	Are fatigue symptoms and chronic fatigue syndrome following Q fever infection related to psychosocial variables?	J Psychosom Res. 2012 Apr;72(4):300-4. doi: 10.1016/j.jpsychores.2012.01.010.	OBJECTIVE: Fatigue is known as one of the most common long-term sequelae of Q fever infections. The study aimed to determine the prevalence of fatigue symptoms, chronic fatigue, and chronic fatigue syndrome (CFS) in a sample of patients who were exposed to Q fever (Coxiella burnetii) infection compared to controls, and to contrast Q fever patients with and without fatigue symptoms related to somatoform symptoms, hypochondriacal worries and beliefs, psychosocial complaints, and social support. METHODS: Cross-sectional study of 84 Q fever exposed patients from a specific region in Jena (Germany) and 85 matched controls using standardized questionnaires (MFI, SF-12, CDC-SI, SOMS, Whiteley Index, OQ-45 and F-Sozu). Diagnostic interviews were performed to validate questionnaire results in a smaller subsample. RESULTS: Patients who were exposed to a Q fever infection in the past indicated more fatigue symptoms and chronic fatigue than controls (54.8 vs. 20%, 32.1 vs. 4.7%) but did not show more criteria for a CFS (1 patient in each group). Q fever patients showing fatigue symptoms revealed significantly higher scores in the SOMS, the Whiteley-Index, and higher psychosocial complaints measured with the OQ-45. Their health related Quality of Life was reduced, no differences were found related to perceived social support. CONCLUSION: Although in our sample fatigue symptoms were common among Q fever patients, we found no increased prevalence of CFS in contrast to several other studies. The combination of fatigue symptoms with other psychosocial symptoms/problems support the view of a biopsychosocial etiology of fatigue symptoms.
Strayer DR, Carter WA, Stouch BC, Stevens SR, Bateman L, Cimoch PJ, Lapp CW, Peterson DL; Chronic Fatigue	Hemispherx Biopharma, Inc., Philadelphia, Pennsylvania, United States of America. david.strayer@hemispherx.net	A double-blind, placebo-controlled, randomized, clinical trial of the TLR-3 agonist rintatolimod in severe cases of chronic fatigue	PLoS One. 2012;7(3):e31334. doi: 10.1371/journal.pone.0031334.	BACKGROUND: Chronic fatigue syndrome/myalgic encephalomyelitis (CFS/ME) is a severely debilitating disease of unknown pathogenesis consisting of a variety of symptoms including severe fatigue. The objective of the study was to examine the efficacy and safety of a TLR-3 agonist, rintatolimod (Poly I: C(12)U), in patients with debilitating CFS/ME. METHODS AND FINDINGS: A Phase III prospective, double-blind, randomized, placebo-controlled trial comparing twice weekly IV rintatolimod versus placebo was conducted in 234 subjects with long-standing, debilitating CFS/ME at 12

Syndrome AMP-516 Study Group, Mitchell WM.		syndrome.		sites. The primary endpoint was the intra-patient change from baseline at Week 40 in exercise tolerance (ET). Secondary endpoints included concomitant drug usage, the Karnofsky Performance Score (KPS), Activities of Daily Living (ADL), and Vitality Score (SF 36). Subjects receiving rintatolimod for 40 weeks improved intra-patient placebo-adjusted ET 21.3% (p = 0.047) from baseline in an intention-to-treat analysis. Correction for subjects with reduced dosing compliance increased placebo-adjusted ET improvement to 28% (p = 0.022). The improvement observed represents approximately twice the minimum considered medically significant by regulatory agencies. The rintatolimod cohort vs. placebo also reduced dependence on drugs commonly used by patients in an attempt to alleviate the symptoms of CFS/ME (p = 0.048). Placebo subjects crossed-over to receive rintatolimod demonstrated an intra-patient improvement in ET performance at 24 weeks of 39% (p = 0.04). Rintatolimod at 400 mg twice weekly was generally well-tolerated. CONCLUSIONS/SIGNIFICANCE: Rintatolimod produced objective improvement in ET and a reduction in CFS/ME related concomitant medication usage as well as other secondary outcomes. TRIAL REGISTRATION: ClinicalTrials.gov NCT00215800.
Sulheim D, Hurum H, Helland IB, Thaulow E, Wyller VB.	Department of Paediatric Medicine, Oslo University Hospital, Rikshospitalet, Oslo, Norway. dag.sulheim@medisin.uio.no.	Adolescent chronic fatigue syndrome; a follow-up study displays concurrent improvement of circulatory abnormalities and clinical symptoms.	Biopsychosoc Med. 2012 Mar 21;6:10. doi: 10.1186/1751-0759-6-10.	BACKGROUND: The pathophysiology of chronic fatigue syndrome (CFS) in adolescents is unknown, and the clinical course and prognosis is still questioned. Recent research indicates that abnormalities of autonomic cardiovascular control may play an important role. The aim of this research project was to perform a follow-up study of adolescents with chronic fatigue syndrome, focusing on clinical symptoms and autonomic cardiovascular control. METHODS: 47 adolescents (12-18 years old) with CFS were recruited from the outpatient clinic at the Department of Pediatrics, Oslo University Hospital. In a primary visit and a follow-up visit (3-17 months later), we evaluated: a) a wide range of complaints and symptoms and b) cardiovascular variables at baseline and during a 20° head-up tilt-test (HUT). RESULTS: At the second visit, patients reported significant improvement regarding functional impairments, fatigue severity, muscular pain, concentration problems, post-exertional malaise and the problem of non-relieving rest. Also, at the second visit, baseline heart rate (HR), blood pressure, total peripheral resistance index (TPRI) and LF/HF (low-frequency:high-frequency heart rate variability ratio, an index of sinus node sympathovagal balance derived from spectral analyses of heart rate) were significant lower, and the increases in HR, mean blood pressure (MBP), diastolic blood pressure (DBP) and TPRI during tilt were significantly less pronounced as compared to the first visit. There was a significant correlation between changes in autonomic symptom score, fatigue severity score and functional impairment score from the first to the second visit. CONCLUSIONS: The majority of adolescents with CFS experienced an improvement over time in functional impairment, self-reported fatigue and additional symptoms, and a concurrent improvement of autonomic cardiovascular control. A possible connection between clinical symptoms and abnormal autonomic control in

				CFS might represent a focus for further research.
Suma S, Veerendra Kumar B.	Department of Oral and Maxillofacial Pathology, DA Pandu Memorial RV Dental College and Hospital, No. CA 37, 24th Main, JP Nagar I Phase, Bangalore, Karnataka, India.	Temporomandibular disorders and functional somatic syndromes: Deliberations for the dentist.	Indian J Dent Res. 2012 Jul;23(4):529-36. doi: 10.4103/0970-9290.104965	Temporomandibular disorder (TMD) is an umbrella term for a collection of disorders affecting the temporomandibular joint (TMJ) and associated tissues. TMD is not a rare pathology for the dentist. The most common presenting symptom is pain, which causes the patient seek immediate treatment. Management is dictated by the cause. The most 'famed' causes include trauma, inflammation, aging, parafunctional habits, infections, neoplasms, and stress; and these are always considered in the differential diagnosis of TMJ pain. There are some less 'famed' causes of TMD, which are characterized by increased pain sensitivity due to psychosocial factors; these include myofascial pain syndrome and functional somatic syndromes (FSS) such as fibromyalgia and chronic fatigue syndrome. They present with chronic pain, fatigue, disability, and impairment in ability to perform daily activities. A non-systematic search in the English literature revealed numerous studies describing the occurrence of TMD in these conditions, along with few other oral manifestations. TMD has been even considered to be a part of the FSS by some. In these patients, TMD remains a recurring problem, and adequate management cannot be achieved by traditional treatment protocols. Awareness of these conditions, with correct diagnosis and modification of management protocols accordingly, may resolve this problem.
Surapaneni DK, Adapa SR, Preeti K, Teja GR, Veeraragavan M, Krishnamurthy S.	Neurotherapeutics Lab, Department of Pharmaceutics, Indian Institute of Technology (Banaras Hindu University), Varanasi 221005 U.P., India.	Shilajit attenuates behavioral symptoms of chronic fatigue syndrome by modulating the hypothalamic-pituitary-adrenal axis and mitochondrial bioenergetics in rats.	J Ethnopharmacol. 2012 Aug 30;143(1):91-9. doi: 10.1016/j.jep.2012.06.002.	ETHNOPHARMACOLOGICAL RELEVANCE: Shilajit has been used as a rejuvenator for ages in Indian ancient traditional medicine and has been validated for a number of pharmacological activities. AIM OF THE STUDY: The effect of processed shilajit which was standardized to dibenzo-α-pyrones (DBPs;0.43% w/w), DBP-chromoproteins (DCPs; 20.45% w/w) and fulvic acids (56.75% w/w) was evaluated in a rat model of chronic fatigue syndrome (CFS). The mitochondrial bioenergetics and the activity of hypothalamus-pituitary-adrenal (HPA) axis were evaluated for the plausible mechanism of action of shilajit. MATERIALS AND METHODS: CFS was induced by forcing the rats to swim for 15mins for 21 consecutive days. The rats were treated with shilajit (25, 50 and 100mg/kg) for 21 days before exposure to stress procedure. The behavioral consequence of CFS was measured in terms of immobility and the climbing period. The post-CFS anxiety level was assessed by elevated plus maze (EPM) test. Plasma corticosterone and adrenal gland weight were estimated as indices of HPA axis activity. Analysis of mitochondrial complex chain enzymes (Complex I, II, IV and V) and mitochondrial membrane potential (MMP) in prefrontal cortex (PFC) were performed to evaluate the mitochondrial bioenergetics and integrity respectively. RESULTS: Shilajit reversed the CFS-induced increase in immobility period and decrease in climbing behavior as well as attenuated anxiety in the EPM test. Shilajit reversed CFS-induced decrease in plasma corticosterone level and loss of adrenal gland weight indicating modulation of HPA axis. Shilajit prevented CFS-induced mitochondrial dysfunction by stabilizing the complex enzyme activities and the loss of MMP. Shilajit reversed CFS-induced mitochondrial oxidative stress in terms of NO concentration

				and, LPO, SOD and catalase activities. CONCLUSION: The results indicate that shilajit mitigates the effects of CFS in this model possibly through the modulation of HPA axis and preservation of mitochondrial function and integrity. The reversal of CFS-induced behavioral symptoms and mitochondrial bioenergetics by shilajit indicates mitochondria as a potential target for treatment of CFS.
Suskind AM, Berry SH, Suttorp MJ, Elliott MN, Hays RD, Ewing BA, Clemens JQ	Department of Urology, University of Michigan Health System, University of Michigan, 1500 E. Medical Center Drive, Ann Arbor, MI, 48109, USA.	Health-related quality of life in patients with interstitial cystitis/bladder pain syndrome and frequently associated comorbidities.	Qual Life Res. 2012 Oct 7.	PURPOSE: To estimate the association of chronic non-urologic conditions [i.e., fibromyalgia (FM), chronic fatigue syndrome (CFS), and irritable bowel syndrome (IBS)] with health-related quality of life (HRQOL) in patients with interstitial cystitis/bladder pain syndrome (IC/BPS). METHODS: A total of 276 women with established diagnoses of IC/BPS completed a telephone interview which included demographics, self-reported medical conditions, the SF-36 health survey, and the interstitial cystitis symptom index (ICSI). Multivariate linear regression analysis was used to identify correlates of SF-36 physical and mental component summary scores. RESULTS: Mean patient age was 45.1 (SD 15.9) years, and 83 % of the subjects were white. Mean values for the SF-36 Physical Component Score (PCS) and Mental Component Score (MCS) means were 39 (SD 14) and 45 (SD 12), respectively, indicating significant HRQOL reductions. Mean ICSI score was 11.27 (SD = 4.86). FM and IBS were significantly associated with worse SF-36 scores: -8 points on the PCS ($p < 0.001$) and -6 points on the MCS ($p < 0.001$). CFS and the presence of other pelvic conditions (overactive bladder, vulvodynia, endometriosis) were not significantly associated with SF-36 PCS and MCS scores. CONCLUSIONS: In patients with IC/BPS, the presence of FM, CFS, and IBS has a significant association with HRQOL, equivalent in impact to the bladder symptoms themselves. These results emphasize the importance of a multidisciplinary approach to treating patients with IC/BPS and other conditions.
Switzer WM, Zheng H, Simmons G, Zhou Y, Tang S, Shankar A, Kapusinszky B, Delwart EL, Heneine W.	Laboratory Branch, Division of HIV/AIDS Prevention, National Center for HIV/AIDS, Viral Hepatitis, STD, and TB Prevention, Centers for Disease Control and Prevention, Atlanta, Georgia, USA. bswitzer@cdc.gov	No evidence of murine leukemia virus-related viruses in live attenuated human vaccines.	PLoS One. 2011;6(12):e29223. doi: 10.1371/journal.pone.0029223.	BACKGROUND: The association of xenotropic murine leukemia virus (MLV)-related virus (XMRV) in prostate cancer and chronic fatigue syndrome reported in previous studies remains controversial as these results have been questioned by recent data. Nonetheless, concerns have been raised regarding contamination of human vaccines as a possible source of introduction of XMRV and MLV into human populations. To address this possibility, we tested eight live attenuated human vaccines using generic PCR for XMRV and MLV sequences. Viral metagenomics using deep sequencing was also done to identify the possibility of other adventitious agents. RESULTS: All eight live attenuated vaccines, including Japanese encephalitis virus (JEV) (SA-14-14-2), varicella (Varivax), measles, mumps, and rubella (MMR-II), measles (Attenuvax), rubella (Meruvax-II), rotavirus (Rotateq and Rotarix), and yellow fever virus were negative for XMRV and highly related MLV sequences. However, residual hamster DNA, but not RNA, containing novel endogenous gammaretrovirus sequences was detected in the JEV vaccine using PCR. Metagenomics analysis did not detect any adventitious viral sequences of public health concern. Intracisternal A particle

				sequences closest to those present in Syrian hamsters and not mice were also detected in the JEV SA-14-14-2 vaccine. Combined, these results are consistent with the production of the JEV vaccine in Syrian hamster cells. CONCLUSIONS: We found no evidence of XMRV and MLV in eight live attenuated human vaccines further supporting the safety of these vaccines. Our findings suggest that vaccines are an unlikely source of XMRV and MLV exposure in humans and are consistent with the mounting evidence on the absence of these viruses in humans.
Szu-Ting Fu T, Koutstaal W, Poon L, Cleare AJ. J Behav Ther Exp Psychiatry. 2012 Jun;43(2):699-704. doi: 10.1016/j.jbtep.2011.09.014.	BACKGROUND AND OBJECTIVES: According to the negativity hypothesis, depressed individuals are over-pessimistic due to negative self-concepts. In contrast, depressive realism suggests that depressed persons are realistic compared to their nondepressed controls. However, evidence supporting depressive realism predominantly comes from judgment comparisons between controls and nonclinical dysphoric samples when the controls showed overconfident bias. This study aimed to test the validity of the two accounts in clinical depression and dysphoria. METHODS: Sixty-eight participants, including healthy controls (n = 32), patients with DSM-IV major depression (n = 20), and dysphoric participants with CDC-defined chronic fatigue syndrome (n = 16) performed an adjective recognition task and reported their item-by-item confidence judgments and post-test performance estimate (PTPE). RESULTS: Compared to realistic PTPE made by the controls, patients with major depression showed significant underconfidence. The PTPE of the dysphoric participants was relatively accurate. Both the depressed and dysphoric participants displayed less item-by-item overconfidence as opposed to significant item-by-item overconfidence shown by the controls. LIMITATIONS: The judgment-accuracy patterns of the three groups need to be replicated with larger samples using non-memory task domains. CONCLUSION: The present study confirms depressive realism in dysphoric individuals. However, toward a more severe depressive emotional state, the findings did not support depressive realism but are in line with the prediction of the negativity hypothesis. It is not possible to determine the validity of the two hypotheses when the controls are overconfident. Dissociation between item-by-item and retrospective confidence judgments is discussed.
Takada S, Shimizu T, Hadano Y, Matsumoto K, Kataoka Y, Arima Y, Inoue T, Sorano S.	Department of General Medicine, Osaka City General Hospital, Miyakojima-ku, Osaka, Japan.	Cryoglobulinemia (review).	Mol Med Report. 2012 Jul;6(1):3-8. doi: 10.3892/mmr.2012.861.	Cryoglobulins are immunoglobulins that precipitate at low temperatures and redissolve upon rewarming. Cryoglobulinemia refers to the presence of circulating cryoglobulins in serum, and generally leads to a systemic inflammatory syndrome characterized by fatigue, arthralgia, purpura, neuropathy and glomerulonephritis. The disease mainly involves small to medium-sized blood vessels and causes vasculitis due to cryoglobulin-containing immune complexes. Cryoglobulinemia is classified into three types (I, II and III) on the basis of immunoglobulin composition. Predisposing conditions include lymphoproliferative disease, collagen disease and hepatitis C virus (HCV) infection. The diagnosis of cryoglobulinemic syndrome is predominantly based on the laboratory demonstration of serum cryoglobulins. Treatment is often directed

				towards the underlying disease state. For patients with chronic HCV infection, anti-viral therapy is indicated. Intense immunosuppressive or immunomodulatory therapy, including steroids, plasmapheresis and cytotoxic agents, is reserved for organ-threatening or recalcitrant disease. In this review, we discuss the clinical characteristics of the three types of cryoglobulinemia.
Tanaka Y.	Health Research Institute, National Institute of Advanced Industrial Science and Technology (AIST).	Biomarkers of stress and fatigue. [Article in Japanese]	Nihon Rinsho. 2012 May;70(5):880-6.	A questionnaire based survey has been commonly used for the assessment of psychological stress and stress-related diseases. Development of a quantitative approach using a non-invasive sample (i.e., saliva, hair or nails) is highly desirable to measure chronic stress. This paper gives a brief explanation of subjective and objective (i.e., physiological signals, and biological markers) methods for stress assessment. Furthermore, it focuses particularly on the current knowledge about the biomarker candidates of chronic psychological stress and chronic fatigue syndrome (CFS). Psychological stress is known to stimulate the autonomic nervous, endocrine, and immune systems. Since chronic stress is associated with suppression of a variety of immune parameters, some immune markers are potentially useful.
Tang N, Frank A, Leckie G, Hackett J Jr, Simmons G, Busch M, Abravaya K.	Abbott Molecular Inc., Des Plaines, IL 60018, USA. ning.tang@abbott.com	Development of sensitive single-round pol or env RT-PCR assays to screen for XMRV in multiple sample types.	J Virol Methods. 2012 Jan;179(1):127-34. doi: 10.1016/j.jviromet.2011.10.010.	The potential association between xenotropic murine leukemia virus-related virus (XMRV) and prostate cancer and chronic fatigue syndrome (CFS) has been much debated. To help resolve the potential role of XMRV in human disease, it is critical to develop sensitive and accurate reverse transcriptase (RT)-PCR assays to screen for the virus. Single-round RT-PCR assays were developed on the automated m2000™ system for detection of the pol or env regions of XMRV in whole blood, plasma, urine cell pellets and urogenital swab samples. Assay performance was assessed by testing two blinded panels, one comprised of whole blood and the other of plasma spiked with serial dilutions of XMRV-infected tissue culture cells and supernatant, respectively, prepared by the Blood XMRV Scientific Research Working Group (SRWG). For both whole blood and plasma panel testing, the assays showed excellent specificity and sensitivity as compared to the other tests included in the SRWG phase I study. Analytical specificity of the assays was also evaluated. Neither pol nor env PCR assays detected a panel of potential cross-reactive microorganisms, although some cross-reaction was observed with mouse genomic DNA. Screening of 196 normal human blood donor plasma, 214 HIV-1 seropositive plasma, 20 formalin-fixed paraffin-embedded (FFPE) prostate cancer specimens, 4 FFPE benign prostate specimens, 400 urine pellets from prostate cancer patients, 166 urine pellets from non-prostate cancer patients, and 135 cervical swab specimens, detected no samples as unequivocally XMRV positive.
Tang S, Zhao J, Haleyur Giri Setty MK, Devadas K, Gaddam D, Viswanath R,	Lab of Molecular Virology, Center for Biologics Evaluation and Research, Food and Drug	Absence of detectable XMRV and other MLV-related viruses in healthy blood donors	PLoS One. 2011;6(11):e27391. doi: 10.1371/journal.pone.0027391.	BACKGROUND: Preliminary studies in chronic fatigue syndrome (CFS) patients and XMRV infected animals demonstrated plasma viremia and infection of blood cells with XMRV, indicating the potential risk for transfusion transmission. XMRV and MLV-related virus gene sequences have also been detected in 4-6% of healthy individuals including blood donors in the U.S. These results imply that millions of persons in the

Wood O, Zhang P, Hewlett IK.	Administration, Bethesda, Maryland, United States of America. tangshixing@hotmail.com	in the United States.		U.S. may be carrying the nucleic acid sequences of XMRV and/or MLV-related viruses, which is a serious public health and blood safety concern. METHODOLOGY/PRINCIPAL FINDINGS: To gain evidence of XMRV or MLV-related virus infection in the U.S. blood donors, 110 plasma samples and 71 PBMC samples from blood donors at the NIH blood bank were screened for XMRV and MLV-related virus infection. We employed highly sensitive assays, including nested PCR and real-time PCR, as well as co-culture of plasma with highly sensitive indicator DERSE cells. Using these assays, none of the samples were positive for XMRV or MLV-related virus. CONCLUSIONS/SIGNIFICANCE: Our results are consistent with those from several other studies, and demonstrate the absence of XMRV or MLV-related viruses in the U.S. blood donors that we studied.
Tian H, Lin JM, Reeves WC.	Chronic Viral Diseases Branch, Division of High-Consequence Pathogens and Pathology, Centers for Disease Control and Prevention, Atlanta, Georgia 30333, USA. ejq7@cdc.gov	Utilization of two web-based continuing education courses evaluated by Markov chain model.	J Am Med Inform Assoc. 2012 May-Jun;19(3):489-94. doi: 10.1136/amiajnl-2011-000287.	OBJECTIVES: To evaluate the web structure of two web-based continuing education courses, identify problems and assess the effects of web site modifications. DESIGN: Markov chain models were built from 2008 web usage data to evaluate the courses' web structure and navigation patterns. The web site was then modified to resolve identified design issues and the improvement in user activity over the subsequent 12 months was quantitatively evaluated. MEASUREMENTS: Web navigation paths were collected between 2008 and 2010. The probability of navigating from one web page to another was analyzed. RESULTS: The continuing education courses' sequential structure design was clearly reflected in the resulting actual web usage models, and none of the skip transitions provided was heavily used. The web navigation patterns of the two different continuing education courses were similar. Two possible design flaws were identified and fixed in only one of the two courses. Over the following 12 months, the drop-out rate in the modified course significantly decreased from 41% to 35%, but remained unchanged in the unmodified course. The web improvement effects were further verified via a second-order Markov chain model. CONCLUSIONS: The results imply that differences in web content have less impact than web structure design on how learners navigate through continuing education courses. Evaluation of user navigation can help identify web design flaws and guide modifications. This study showed that Markov chain models provide a valuable tool to evaluate web-based education courses. Both the results and techniques in this study would be very useful for public health education and research specialists.
Tjensvoll AB, Harboe E, Gøransson LG, Beyer MK, Greve OJ, Kvaløy JT, Omdal R.	Department of Neurology, Stavanger University Hospital, Stavanger, Norway.	Headache in primary Sjøgren's syndrome: a population-based retrospective cohort study.	Eur J Neurol. 2012 Nov 28. doi: 10.1111/ene.12033	BACKGROUND: We investigated whether the prevalence of primary headaches was higher in patients with primary Sjøgren's syndrome (PSS) than in healthy individuals. METHODS: This retrospective cohort study included 71 patients with PSS (patients) based on the American European Consensus Classification criteria, and 71 age- and gender-matched healthy subjects (controls). Headaches were classified according to the International Classification of Headache Disorders. We measured depression with the Beck Depression Inventory, and fatigue with the Fatigue Severity Scale. RESULTS: Fifty-one patients and 42 controls had headaches in the previous 12 months (71.8% vs. 59.2%, P = 0.10). Thirty-eight patients and 28 controls had tension type headaches

				(TTHs) (53.5% vs. 39.4%, P = 0.12). Eight patients (11.3%) and one control had chronic TTHs (P = 0.05). Migraines and migraines with aura were equally prevalent in patients (26.8% and 11.3%, respectively) and controls (28.2% and 15.5%, respectively; P = 0.61). CONCLUSIONS: In general, patients did not have more migraines or headaches than controls. However, patients had more chronic TTHs than controls. Chronic TTHs were not associated with PSS-related autoantibodies, fatigue, depression, abnormalities on magnetic resonance imaging or abnormalities in the cerebrospinal fluid. Patients with PSS did, however, have higher depression and fatigue scores than controls.
Tomic S, Brkic S, Maric D, Mikic AN.	Clinic for Infectious Diseases, Clinical Center Vojvodina, Novi Sad, Serbia.	Lipid and protein oxidation in female patients with chronic fatigue syndrome.	Arch Med Sci. 2012 Nov 9;8(5):886-91. doi: 10.5114/aoms.2012.31620.	INTRODUCTION: Chronic fatigue syndrome (CFS) is a widely recognized problem, characterized by prolonged, debilitating fatigue and a characteristic group of accompanying symptoms, that occurs four times more frequently in women than in men. The aim of the study was to determine the existence of oxidative stress and its possible consequences in female patients with CFS. MATERIAL AND METHODS: Twenty-four women aged 15-45 who fulfilled the diagnostic criteria for CFS with no comorbidities were recruited and were age matched to a control group of 19 healthy women. After conducting the routine laboratory tests, levels of the lipid oxidation product malondialdehyde (MDA) and protein oxidation protein carbonyl (CO) were determined. RESULTS: The CFS group had higher levels of triglycerides (p = 0.03), MDA (p = 0.03) and CO (p = 0.002) and lower levels of HDL cholesterol (p = 0.001) than the control group. There were no significant differences in the levels of total protein, total cholesterol or LDL cholesterol. CONCLUSIONS: The CFS group had an unfavorable lipid profile and signs of oxidative stress induced damage to lipids and proteins. These results might be indicative of early proatherogenic processes in this group of patients who are otherwise at low risk for atherosclerosis. Antioxidant treatment and life style changes are indicated for women with CFS, as well as closer observation in order to assess the degree of atherosclerosis.
Tomš J.	Univerzita Karlova v Praze, Lekarska fakulta v Hradci Kralove. toms.jan@seznam.cz	Updated view of fibromyalgia. [Article in Czech]	Cas Lek Cesk. 2012;151(9):415-9.	Fibromyalgia is a chronic syndrome characterized by dysfunction of pain processing and regulation. Although the definite etiology has not been recognized yet, the key role in the pathogenesis of this syndrome probably plays the central sensitization process with the development of chronic (central) pain and other associated symptoms (fatigue, stiffness, sleep disorders, cognitive and vegetative disturbance). The absence of objective diagnostic tests often results in delayed diagnosis and patient fluctuation among a number of specialists with uncertainty and fear of a serious disease. The treatment is based on the individually adjusted and multidisciplinary approach to the patient, combining pharmacological and non-pharmacological therapy. New drugs introduced to the therapy in the recent years can have positive effect on symptom reduction and improvement of patients quality of life.
Tort S, Urrútia G,	Iberoamerican	Monoamine oxidase	Cochrane Database Syst Rev.	BACKGROUND: Fibromyalgia (FM) syndrome is a chronic condition of unknown

Nishishinya MB, Walitt B.	Cochrane Centre, Institute of Biomedical Research (IIB Sant Pau), Barcelona, Spain. sera.tort@cochrane.es	inhibitors (MAOIs) for fibromyalgia syndrome.	2012 Apr 18;4:CD009807. doi: 10.1002/14651858.CD009807.	aetiology characterised by musculoskeletal pain that often co-exists with sleep disturbance, cognitive dysfunction and fatigue. Patients often report high disability levels and poor quality of life. Since there is no specific treatment that alters the pathogenesis of FM, drug therapy focuses on pain reduction and improvement of other bothersome symptoms. OBJECTIVES: The objective of this review was to assess the effectiveness and safety of monoamine oxidase inhibitors (MAOIs) in the treatment of FM syndrome. SEARCH METHODS: We searched the Cochrane Central Register of Controlled Trials (CENTRAL) (The Cochrane Library 2010, Issue 10), MEDLINE (1966 to November 2010), EMBASE (1980 to November 2010) and the reference lists of reviewed articles. SELECTION CRITERIA: We selected all randomised, double-blind trials of MAOIs used for the treatment of FM pain in adult participants. DATA COLLECTION AND ANALYSIS: Two authors assessed risk of bias and extracted data independently onto a specially designed pro forma and a third review author cross-checked them. MAIN RESULTS: We included two studies of inconsistent risk of bias with a total of 230 patients diagnosed with FM. We evaluated two MAOIs: pirlindole and moclobemide. Pirlindole showed statistically significant results compared with placebo for several outcomes (pain, tender points and overall assessment by the patient and the physician), whereas moclobemide did not show statistically significant differences between groups. Pooled results of the two studies displayed a modest effect size in pain (mean difference (MD) -1.45 (121 patients; 95% confidence interval (CI) -2.71 to -0.20; number needed to treat (NNT) 2 (95% CI 1 to 12); I(2) = 59%)), implying a minimal clinically important difference (MCID) and a small effect on tender points (standardised mean difference (SMD) -0.36 (121 patients; 95% CI -0.72 to -0.00; I(2) = 31%)). No effect was seen on global assessment by patient. Physical function and sleep disturbance were not measured. The most frequent adverse events were nausea and vomiting, with statistically significant differences between groups (risk ratio (RR) 7.82 (89 patients; 95% CI 1.02 to 59.97; NNT 7 (95% CI 4 to 33)). AUTHORS' CONCLUSIONS: Data suggest that the effectiveness of MAOIs for the treatment of FM symptoms is limited. Although we observed a moderate effect size on pain and a small one on tender points, these results should be taken with caution as they are only based on two studies with a small number of patients and inconsistent risk of bias among them.
Tosun E, Topaloğlu O, Akkalyoncu B.		As a rare cause of drug-induced cough: topiramate.	J Trace Elem Med Biol. 2012 Oct;26(4):291-3. doi: 10.1016/j.jtemb.2012.02.005.	The most common causes of chronic cough in nonsmokers are postnasal drip syndrome, asthma, and gastroesophageal reflux disease. Drugs are also important in the etiology of resistant cough. Most common drugs inducing cough are the ACE inhibitors. Many drugs other than ACE inhibitors can also cause dry cough and one among them is topiramate. It is a new generation, efficacy-proved antiepileptic drug that is used widely for migraine prophylaxis in many countries. Most common adverse events of topiramate are paresthesia, cognitive symptoms, fatigue, insomnia, nausea, loss of apetite, anxiety, and dizziness. There is only one case report about

				topiramate associated cough in the literature. The present report refers to a patient, presenting with cough who is on topiramate treatment for migraine prophylaxis.
Toussaint LL, Whipple MO, Abboud LL, Vincent A, Wahner-Roedler DL.	Department of Psychology, Luther College, Decorah, IA 52101, USA. touslo01@luther.edu	A mind-body technique for symptoms related to fibromyalgia and chronic fatigue.	Explore (NY). 2012 Mar-Apr;8(2):92-8. doi: 10.1016/j.explore.2011.12.003.	CONTEXT: A novel mind-body approach (amygdala retraining) is hypothesized to improve symptoms related to fibromyalgia and chronic fatigue. OBJECTIVE: To examine the use of a mind-body approach for improving symptoms related to fibromyalgia and chronic fatigue. DESIGN: This was a single-blind, randomized controlled trial. SETTING: The study was conducted in a tertiary-care fibromyalgia and chronic fatigue clinic. PATIENTS: Patients with fibromyalgia, chronic fatigue, or both were included. INTERVENTIONS: Patients were randomly assigned to receive amygdala retraining along with standard care or standard care alone. Standard care involved attending a 1.5-day multidisciplinary program. The amygdala retraining group received an additional 2.5-hour training course in which the key tools and techniques adapted from an existing program were taught to the patient. A home-study video course and associated text were provided to supplement the on-site program. Both groups received telephone calls twice a month to answer questions related to technique and to provide support. MAIN OUTCOME MEASURES: Validated self-report questionnaires related to general health, well-being, and symptoms, including Short Form-36, Measure Yourself Medical Outcome Profile, Multidimensional Fatigue Inventory, Epworth Sleepiness Scale, and Fibromyalgia Impact Questionnaire. RESULTS: Of the 44 patients randomly assigned who completed baseline assessments, 21 patients completed the study (14 in the standard care group and 7 in the study group). Median age was 48 years (range, 27-56 years), and female subjects comprised 91% of the group. Analyses demonstrated statistically significant improvements in scores for physical health, energy, pain, symptom distress, and fatigue in patients who received the amygdala retraining compared with standard care.
Trabal J, Leyes P, Fernández-Solá J, Forga M, Fernández-Huerta J.	Servei d´Endocrinología i Nutrició, Hospital Clínic, Barcelona, Spain. joantrabal@gmail.com	Patterns of food avoidance in chronic fatigue syndrome: is there a case for dietary recommendations?	Nutr Hosp. 2012 Mar-Apr;27(2):659-62. doi: 10.1590/S0212-16112012000200046.	OBJECTIVES: To assess the dietary habits and food avoidance-behavior in patients with Chronic Fatigue Syndrome (CFS). METHODS: Cross-sectional pilot study with 28 patients diagnosed with severe CFS. Eating habits were assessed with a food frequency questionnaire and 3-day food records. We analyzed variables related to dietary restrictions induced by symptoms or external information. RESULTS: The most prevalent restrictions were for dairy products and gluten-containing grains, with 22 and 15 restricting patients, respectively. Patients reported different digestive symptoms, which did not improve with the use of exclusion diets. Thirteen patients had received information against the intake of certain foods through different sources. Six cases of grains restriction and 11 of dairy were compatible with a counseling-induced pattern of exclusion. CONCLUSIONS: There is not a homogeneous pattern of food avoidance. Dietary restrictions should be based on a proven food allergy or intolerance. Dietary counseling should be based on sound nutritional knowledge.

Tracy M.	Pump House Surgery, Earls Colne, Essex.	Chronic fatigue syndrome.	Nurs Stand. 2012 Sep 26-Oct 2;27(4):57.	
Trivedi PJ, Chapman RW.	Centre for Liver Research and NIHR Biomedical Research Unit, University of Birmingham, Wolfson Drive, Edgbaston, Birmingham, B15 2TT United Kingdom. doctortrivedi@doctors.org.uk	PSC, AIH and overlap syndrome in inflammatory bowel disease.	Clin Res Hepatol Gastroenterol. 2012 Oct;36(5):420-36. doi: 10.1016/j.clinre.2011.10.007.	Primary sclerosing cholangitis (PSC) is a progressive, cholestatic disorder characterised by chronic inflammation and stricture formation of the biliary tree. Symptoms include pruritus, fatigue and in advanced cases ascending cholangitis, cirrhosis and end-stage hepatic failure. Patients are at an increased risk of malignancy arising from the bile ducts, gallbladder, liver and colon. The majority (>80%) of Northern European patients with PSC also have inflammatory bowel disease (IBD), usually ulcerative colitis (UC). IBD commonly presents before the onset of PSC, although the opposite can occur and the onset of both conditions can be separated by many years. The colitis associated with PSC is characteristically mild although frequently involves the whole colon. Despite the majority of patients having relatively inactive colonic disease, paradoxically the risk of colorectal malignancy is substantially increased. Patients may also develop dominant, stenotic lesions of the biliary tree which may be difficult to differentiate from cholangiocarcinoma and the coexistence of IBD may influence the development of this complication. Ursodeoxycholic acid may offer a chemoprotective effect against colorectal malignancy and improve liver biochemical indices. Evidence of any beneficial effect on histological progression of hepatobiliary disease is less clear. High doses (~25-30 mg/kg/d) may be harmful and should be avoided. Autoimmune hepatitis (AIH) is less common in patients with IBD than PSC, however, an association has been observed. A small subgroup may have an overlap syndrome between AIH and PSC and management should be individualised dependant on liver histology, serum immunoglobulin levels, autoantibodies, degree of biochemical cholestasis and cholangiography.
Tsang BK, Macdonell R.	Department of Neurology, Austin Hospital, Melbourne, Victoria, Australia. bktsang@optusnet.com.au	Multiple sclerosis-diagnosis, management and prognosis.	Aust Fam Physician. 2011 Dec;40(12):948-55.	BACKGROUND: Multiple sclerosis is the most common chronic disabling disease of the central nervous system in young adults. OBJECTIVE: This article summarises the diagnosis, management and prognosis of multiple sclerosis. DISCUSSION: Multiple sclerosis usually starts with an acute episode of neurological disturbance, termed a 'clinically isolated syndrome', followed by an illness phase punctuated by relapses and remissions which may transition after 10 years to a phase of progressive accumulation of disability without relapses.
Tsibris AM.	[No address quoted]	The end of the association between XMRV, MLV-like viruses and chronic fatigue syndrome.	Virulence. 2011 Nov-Dec;2(6):493-4. doi: 10.4161/viru.2.6.18518.	[No abstract given]
Tummers M, Knoop H, van Dam A, Bleijenberg G	Expert Centre for Chronic Fatigue, Radboud University Nijmegen Medical	Implementing a minimal intervention for chronic fatigue syndrome in a	Psychol Med. 2012 Oct;42(10):2205-15. doi: 10.1017/S0033291712000232.	BACKGROUND: Cognitive behaviour therapy (CBT) for chronic fatigue syndrome (CFS) is an effective but intensive treatment, requiring trained therapists. A minimal intervention based on CBT for CFS, guided self-instruction, was shown to be an effective treatment when delivered in a tertiary treatment centre. Implementing this

	Centre, The Netherlands.	mental health centre: a randomized controlled trial.		intervention in a community-based mental health centre (MHC) will increase the treatment capacity for CFS patients. This study evaluated the effectiveness of guided self-instruction for CFS implemented in an MHC, delivered by nurses. Method One hundred and twenty-three patients were randomly assigned to either guided self-instruction (n=62) or a waiting list (n=61). Randomization was computer generated, with allocation by numbered sealed envelopes. Group allocation was open to all those involved. Patients fulfilled US Centers for Disease Control and Prevention (CDC) criteria for CFS. Primary outcome variables were fatigue severity and physical and social functioning, measured with the Checklist Individual Strength (CIS) and the Medical Outcomes Survey Short Form-36 (SF-36) respectively. RESULTS: After 6 months, patients who followed guided self-instruction reported a significantly larger decrease in fatigue compared to the waiting list [mean difference -8.1, 95% confidence interval (CI) -3.8 to -12.4, controlled effect size 0.70]. There was no significant difference in physical and social functioning. However, post-hoc analyses showed a significant decrease in fatigue and physical disabilities following the intervention in a subgroup of patients with physical disabilities at baseline (SF-36 physical functioning $\leqslant$70). CONCLUSIONS: Implementation of guided self-instruction in a community-based MHC was partially successful. The minimal intervention can be effectively implemented for CFS patients with physical impairments.

[No address quoted]	Graded exercise therapy GET/cognitive behavioural therapy (CBT) is often counterproductive in myalgic encephalomyelitis (ME) and chronic fatigue syndrome (CFS).	Eur J Clin Invest. 2012 Nov;42(11):1255-6; author reply 1257-8. doi: 10.1111/j.1365-2362.2012.02718.x.	Comment on Eur J Clin Invest. 2012 Oct;42(10):1136-44.
Ulus Y, Akyol Y, Tander B, Durmus D, Bilgici A, Kuru O.	Department of Physical Medicine and Rehabilitation, Medical Faculty, Ondokuz Mayis University, Samsun, Turkey. yaseminulus@gmail.com	Sleep quality in fibromyalgia and rheumatoid arthritis: associations with pain, fatigue, depression, and disease activity.	Clin Exp Rheumatol. 2011 Nov-Dec;29(6 Suppl 69):S92-6.	OBJECTIVES: The aim of this study was to compare the sleep quality in patients with rheumatoid arthritis (RA) and fibromyalgia syndrome (FMS); and to evaluate the relationship between sleep quality and pain, fatigue, depression, and disease activity in patients with RA and FMS. METHODS: Forty RA, 40 FMS and 40 healthy controls were enrolled in the study. Disease activity and disease duration were reported in patients. Pain by visual analogue scale (VAS), fatigue by Multidimensional Assesment of Fatigue (MAF), depression by Beck Depression Index (BDI), and sleep quality by Pittsburgh Sleep Quality Index (PSQI) were gathered in all participants. RESULTS: All participants were aged between 20 and 65 years, with a mean age of 42.97±10.75 years. There was no significant difference with respect to demographic characteristics

				among the three study groups. Patients reported more depression than controls, but BDI scores were similar in FMS and RA patients. VAS pain scores and MAF scores were significantly different in the three groups (p<0.001). FMS and RA patients had poor sleep quality (p<0.001). FMS patients had daytime dysfunction due to sleep disorder and had worse habitual sleep efficiency than RA patients (p<0.05). In patients, positive correlations were found between PSQI and clinic assessment variables except disease duration. CONCLUSIONS: FMS and RA may have poor sleep quality when compared to subjects without rheumatologic disorders. The quality of sleep can be impaired by pain, fatigue, depression, and disease activity in such patients.
Van Cauwenbergh D, De Kooning M, Ickmans K, Nijs J.	Chronic Pain and Chronic Fatigue Research Group (CHROPIVER), Department of Human Physiology, Faculty of Physical Education & Physiotherapy, Vrije Universiteit Brussel, Belgium. jo.nijs@vub.ac.be	How to exercise people with chronic fatigue syndrome: evidence-based practice guidelines.	Eur J Clin Invest. 2012 Oct;42(10):1136-44. doi: 10.1111/j.1365-2362.2012.02701.x. Comment in Eur J Clin Invest. 2012 Nov;42(11):1255-6; author reply 1257-8.	BACKGROUND: Despite the large number of studies emphasizing the effectiveness of graded exercise therapy (GET) and cognitive behavioural therapy (CBT) for people with chronic fatigue syndrome (CFS), clinicians are left wondering how exactly to apply exercise therapy to their patients with CFS. The aim of this literature review is to identify the appropriate exercise modalities (i.e. exercise duration, mode, number of treatment sessions, session length, duration of treatment, exercise intensity and whether or not to apply home exercise program) for people with CFS. MATERIALS AND METHODS: All studies that were identified through electronic databases (PubMed and PEDro) were assessed for methodological quality by using selection criteria (Delphi score). RESULTS: In this literature review, 12 studies fulfilled all study requirements. One study had a low methodological quality. The parameters used in the GET and CBT interventions were divided into subgroups: (i) time or symptom contingent, (ii) exercise frequency and (iii) exercise modality. CONCLUSION: The lack of uniformity in outcome measures and CFS diagnostic criteria make it difficult to compare the findings across studies. Based on the available evidence, exercise therapy for people with CFS should be aerobic and must comprise of 10-11 sessions spread over a period of 4-5 months. A time-contingent approach is preferred over a symptom-contingent way of exercising. In addition, people with CFS can perform home exercises five times a week with an initial duration of 5-15 min per exercise session. The exercise duration can be gradually increased up to 30 min.

Vaughan AE, Mendoza R, Aranda R, Battini JL, Miller AD.	Human Biology Division, Fred Hutchinson Cancer Research Center, Seattle, Washington, USA.	Xpr1 is an atypical G-protein-coupled receptor that mediates xenotropic and polytropic murine retrovirus neurotoxicity.	J Virol. 2012 Feb;86(3):1661-9. doi: 10.1128/JVI.06073-11.	Xenotropic murine leukemia virus-related virus (XMRV) was first identified in human prostate cancer tissue and was later found in a high percentage of humans with chronic fatigue syndrome (CFS). While exploring potential disease mechanisms, we found that XMRV infection induced apoptosis in SY5Y human neuroblastoma cells, suggesting a mechanism for the neuromuscular pathology seen in CFS. Several lines of evidence show that the cell entry receptor for XMRV, Xpr1, mediates this effect, and chemical cross-linking studies show that Xpr1 is associated with the Gβ subunit of the G-protein heterotrimer. The activation of adenylate cyclase rescued the cells from XMRV toxicity, indicating that toxicity resulted from reduced G-protein-mediated cyclic AMP (cAMP) signaling. Some proteins with similarity to Xpr1 are involved in phosphate uptake into cells, but we found no role of Xpr1 in phosphate uptake or its regulation. Our results indicate that Xpr1 is a novel, atypical G-protein-coupled receptor (GPCR) and that xenotropic or polytropic retrovirus binding can disrupt the cAMP-mediated signaling function of Xpr1, leading to the apoptosis of infected cells. We show that this pathway is also responsible for the classic toxicity of the polytropic mink cell focus-forming (MCF) retrovirus in mink cells. Although it now seems clear that the detection of XMRV in humans was the result of sample contamination with a recombinant mouse virus, our findings may have relevance to neurologic disease induced by MCF retroviruses in mice.
Verhaeghe J, Van Den Eede F, Van Den Ameele H, Sabbe BG.	Johanna.Verhaeghe@hotmail.com	Neuro-endocrine correlates of burnout. [Article in Dutch]	Tijdschr Psychiatr. 2012;54(6):517-26.	BACKGROUND: The symptoms of burnout are similar to those of depression on the one hand and chronic fatigue syndrome on the other hand. However, the neuro-endocrine correlates of these two syndromes are the opposite, the former being a hyperfunction of the hypothalamic-hypophysial-cortical axis (HPA) and the latter being a hypofunction of the hpa-axis. AIM: To find out, via a systematic review of the literature, whether burnout is associated with either a hyperfunction or a hypofunction of the HPA-axis. METHOD: We searched PubMed using the following search terms: 'burnout syndrome and burnout', 'adrenocorticotropic hormone', 'corticotropin releasing factor', 'hypothalamic pituitary adrenal axis' and 'cortisol'. We retrieved 16 original articles en one meta-analysis were included in the study. RESULTS: Functional stress testing showed hypersuppression of the HPA-axis after dexamethasone. Basal cortisol values were found to be less conclusive, although a meta-analysis pointed to a negative association between burnout and cortisol. We did not find any studies that were carried out with the help of physiological, physical or psychological stress factors in burnout. CONCLUSION: Burnout is associated primarily with a hypofunction of the HPA-axis, which is a neuro-endocrine

				characteristic of exhaustion, rather than of depression. However, further studies involving functional stress testing are needed in order to map the neuro-endocrine profile fully and to clarify the link with the deregulation of the immune system.
Vierck CJ.	Department of Neuroscience and Comprehensive Center for Pain Research, Colleges of Medicine and Dentistry, University of Florida, P.O. Box 100444, 1600 S.W. Archer Road, Gainesville, FL 32610, USA.	A mechanism-based approach to prevention of and therapy for fibromyalgia.	Pain Res Treat. 2012;2012:951354. doi: 10.1155/2012/951354.	Fibromyalgia syndrome (FMS) is characterized by pain referred to deep tissues. Diagnosis and treatment of FMS are complicated by a variable coexistence with regional pain, fatigue, sleep disruption, difficulty with mentation, and depression. The widespread, deep pain of FMS can be a consequence of chronic psychological stress with autonomic dysregulation. Stress acts centrally to facilitate pain and acts peripherally, via sympathetic vasoconstriction, to establish painful muscular ischemia. FMS pain, with or without a coexistent regional pain condition, is stressful, setting up a vicious circle of reciprocal interaction. Also, stress interacts reciprocally with systems of control over depression, mentation, and sleep, establishing FMS as a multiple-system disorder. Thus, stress and the ischemic pain it generates are fundamental to the multiple disorders of FMS, and a therapeutic procedure that attenuates stress and peripheral vasoconstriction should be highly beneficial for FMS. Physical exercise has been shown to counteract peripheral vasoconstriction and to attenuate stress, depression, and fatigue and improve mentation and sleep quality. Thus, exercise can interrupt the reciprocal interactions between psychological stress and each of the multiple-system disorders of FMS. The large literature supporting these conclusions indicates that exercise should be considered strongly as a first-line approach to FMS therapy.
Vincent A, Brimmer DJ, Whipple MO, Jones JF, Boneva R, Lahr BD, Maloney E, St Sauver JL, Reeves WC.	Fibromyalgia and Chronic Fatigue Clinic, Mayo Clinic, Rochester, MN; Division of General Internal Medicine, Mayo Clinic, Rochester, MN. Electronic address: RSTFCFC@mayo.edu.	Prevalence, incidence, and classification of chronic fatigue syndrome in olmsted county, Minnesota, as estimated using the Rochester epidemiology project.	Mayo Clin Proc. 2012 Dec;87(12):1145-52. doi: 10.1016/j.mayocp.2012.08.015.	OBJECTIVE: To estimate the prevalence and incidence of chronic fatigue syndrome in Olmsted County, Minnesota, using the 1994 case definition and describe exclusionary and comorbid conditions observed in patients who presented for evaluation of long-standing fatigue. PATIENTS AND METHODS: We conducted a retrospective medical record review of potential cases of chronic fatigue syndrome identified from January 1, 1998, through December 31, 2002, using the Rochester Epidemiology Project, a population-based database. Patients were classified as having chronic fatigue syndrome if the medical record review documented fatigue of 6 months' duration, at least 4 of 8 chronic fatigue syndrome-defining symptoms, and symptoms that interfered with daily work or activities. Patients not meeting all of the criteria were classified as having insufficient/idiopathic fatigue. RESULTS: We identified 686 potential patients with chronic fatigue, 2 of whom declined consent for medical record review. Of the remaining 684 patients, 151 (22%) met criteria for chronic fatigue syndrome or insufficient/idiopathic fatigue. The overall prevalence and incidence of chronic fatigue syndrome and insufficient/idiopathic fatigue were 71.34 per 100,000 persons and 13.16 per 100,000 person-years vs 73.70 per 100,000 persons and 13.58 per 100,000 person-years, respectively. The potential cases included 482 patients (70%) who had an exclusionary condition, and almost half the patients who met either criterion had at least one nonexclusionary comorbid

				condition. CONCLUSION: The incidence and prevalence of chronic fatigue syndrome and insufficient/idiopathic fatigue are relatively low in Olmsted County. Careful clinical evaluation to identify whether fatigue could be attributed to exclusionary or comorbid conditions rather than chronic fatigue syndrome itself will ensure appropriate assessment for patients without chronic fatigue syndrome.
Volterrani M, Rosano G, Iellamo F.	Cardiovascular Research Unit, Department of Medical Sciences, Centre for Clinical and Basic Research, Istituto di Ricovero e Cura a Carattere Scientifico San Raffaele Pisana, via della Pisana 235, 00163 Rome, Italy. maurizio.volterrani@sanraffaele.it	Testosterone and heart failure.	Endocrine. 2012 Oct;42(2):272-7.	Testosterone deficiency is a generalized phenomenon seen in the course of chronic heart failure (CHF). Reduction in circulating testosterone level is a predictor of deterioration of functional capacity over time, underscoring the role of testosterone deficiency in CHF. Anabolic hormones are determinants of exercise capacity and circulating levels of anabolic hormones strongly determine muscle mass and strength. Testosterone deficiency is involved in the pathophysiology of CHF, contributing to some features of this syndrome, such as the reduced muscle mass, abnormal energy handling, fatigue, dyspnea and, finally, cachexia. This review summarizes current knowledge on the role of testosterone deficiency in the pathophysiology of CHF, gaining insights from the potential implications of testosterone as supplementation therapy.
Vos-Vromans DC, Smeets RJ, Rijnders LJ, Gorrissen RR, Pont M, Köke AJ, Hitters MW, Evers SM, Knottnerus AJ.	Revant Rehabilitation Centre Breda, Brabantlaan 1, 4817, JW, Breda, The Netherlands. d.vos@revant.nl.	Cognitive behavioural therapy versus multidisciplinary rehabilitation treatment for patients with chronic fatigue syndrome: study protocol for a randomised controlled trial (FatiGo).	Trials. 2012 May 30;13:71. doi: 10.1186/1745-6215-13-71.	ABSTRACT:BACKGROUND: Patients with chronic fatigue syndrome experience extreme fatigue, which often leads to substantial limitations of occupational, educational, social and personal activities. Currently, there is no consensus regarding the treatment. Patients try many different therapies to overcome their fatigue. Although there is no consensus, cognitive behavioural therapy is seen as one of the most effective treatments. Little is known about multidisciplinary rehabilitation treatment, a combination of cognitive behavioural therapy with principles of mindfulness, gradual increase of activities, body awareness therapy and pacing. The difference in effectiveness and cost-effectiveness between multidisciplinary rehabilitation treatment and cognitive behavioural therapy is as yet unknown. The FatiGo (Fatigue-Go) trial aims to compare the effects of both treatment approaches in outpatient rehabilitation on fatigue severity and quality of life in patients with chronic fatigue syndrome. METHODS: One hundred twenty patients who meet the criteria of chronic fatigue syndrome, fulfil the inclusion criteria and sign the informed consent form will be recruited. Both treatments take 6 months to complete. The outcome will be assessed at 6 and 12 months after the start of treatment. Two weeks after the start of treatment, expectancy and credibility will be measured, and patients will be asked to write down their personal goals and score their current performance on these goals on a visual analogue scale. At 6 and 14 weeks after the start of treatment, the primary outcome and three potential mediators-self-efficacy, causal attributions and present-centred attention-awareness-will be measured. Primary outcomes are fatigue severity and quality of life. Secondary outcomes are physical activity,

				psychological symptoms, self-efficacy, causal attributions, impact of disease on emotional and physical functioning, present-centred attention-awareness, life satisfaction, patient personal goals, self-rated improvement and economic costs. The primary analysis will be based on intention to treat, and longitudinal analysis of covariance will be used to compare treatments. DISCUSSION: The results of the trial will provide information on the effects of cognitive behavioural therapy and multidisciplinary rehabilitation treatment at 6 and 12 months follow-up, mediators of the outcome, cost-effectiveness, cost-utility, and the influence of treatment expectancy and credibility on the effectiveness of both treatments in patients with chronic fatigue syndrome. TRIAL REGISTRATION: Current Controlled Trials ISRCTN77567702.
Wang X, Tu F, Zhu Y, Gao G.	Key Laboratory of Infection and Immunity, Institute of Biophysics, Chinese Academy of Sciences, Beijing, China.	Zinc-finger antiviral protein inhibits XMRV infection.	PLoS One. 2012;7(6):e39159. doi: 10.1371/journal.pone.0039159.	BACKGROUND: The zinc-finger antiviral protein (ZAP) is a host factor that specifically inhibits the replication of certain viruses, including Moloney murine leukemia virus (MoMLV), HIV-1, and certain alphaviruses and filoviruses. ZAP binds to specific viral mRNAs and recruits cellular mRNA degradation machinery to degrade the target RNA. The common features of ZAP-responsive RNA sequences remain elusive and thus whether a virus is susceptible to ZAP can only be determined experimentally. Xenotropic murine leukemia virus-related virus (XMRV) is a recently identified γ-retrovirus that was originally thought to be involved in prostate cancer and chronic fatigue syndrome but recently proved to be a laboratory artefact. Nonetheless, XMRV as a new retrovirus has been extensively studied. Since XMRV and MoMLV share only 67.9% sequence identity in the 3'UTRs, which is the target sequence of ZAP in MoMLV, whether XMRV is susceptible to ZAP remains to be determined. FINDINGS: We constructed an XMRV-luc vector, in which the coding sequences of Gag-Pol and part of Env were replaced with luciferase-coding sequence. Overexpression of ZAP potently inhibited the expression of XMRV-luc in a ZAP expression-level-dependent manner, while downregulation of endogenous ZAP rendered cells more sensitive to infection. Furthermore, ZAP inhibited the spreading of replication-competent XMRV. Consistent with the previously reported mechanisms by which ZAP inhibits viral infection, ZAP significantly inhibited the accumulation of XMRV-luc mRNA in the cytoplasm. The ZAP-responsive element in XMRV mRNA was mapped to the 3'UTR. CONCLUSIONS: ZAP inhibits XMRV replication by preventing the accumulation of viral mRNA in the cytoplasm. Documentation of ZAP inhibiting XMRV helps to broaden the spectrum of ZAP's antiviral activity. Comparison of the target sequences of ZAP in XMRV and MoMLV helps to better understand the features of ZAP-responsive elements.
Warren JW, Clauw DJ, Langenberg P.	Department of Medicine Department of Epidemiology and Public Health,	Prognostic factors for recent-onset interstitial cystitis/painful	BJU Int. 2012 Aug 9. doi: 10.1111/j.1464-410X.2012.11422.x.	Study Type - Prognosis (case series) Level of Evidence 4 What's known on the subject? and What does the study add? Interstitial cystitis/painful bladder syndrome (IC/PBS) comprises pain perceived to be from the bladder, urinary urgency and frequency, and nocturia. As diagnosed at present, it is primarily identified in adult

	University of Maryland School of Medicine, Baltimore, MD Departments of Anesthesiology and Medicine, University of Michigan School of Medicine, Ann Arbor, MI, USA.	bladder syndrome.		women. It is a chronic disease yet its natural history has not been well studied. In a prospective study of 304 incident female IC/PBS cases followed for a median of 33 months after onset, women with baseline chronic fatigue syndrome had a worse prognosis for IC/PBS. Mild IC/PBS at baseline was the only variable that was directly associated with a good prognosis. OBJECTIVE: • To identify baseline variables that predict the prognosis of interstitial cystitis/painful bladder syndrome (IC/PBS) in women seeking medical care for recent onset of this syndrome. SUBJECTS AND METHODS: • In a prospective study of women with incident IC/PBS (≤12 months of symptoms), we contacted patients at intervals and asked standardized questions about IC/PBS symptoms in the previous week. • Logistic regression analyses assessed baseline variables as predictors of mild vs more severe IC/PBS at the last follow-up. RESULTS: • Median length of follow-up was 33 months after onset of IC/PBS; 304 (97%) patients had at least one follow-up assessment. • Mild IC/PBS at baseline was the only variable that was directly associated with a mild IC/PBS endpoint. • Conversely, a history of chronic fatigue syndrome (CFS) was inversely associated with a mild endpoint of IC/PBS (i.e. individuals with CFS had a worse prognosis for their IC/PBS symptoms). CONCLUSIONS: • At a median of nearly 3 years after onset, baseline mild IC/PBS was directly associated with a milder disease severity. • Baseline co-morbid CFS was associated with more severe disease. • Whether CFS was uniquely associated or represented several co-morbid non-bladder syndromes (NBSs) could not be determined.
Warren JW, Clauw DJ.	Department of Medicine and of Epidemiology, University of Maryland School of Medicine, Baltimore, MD 21201, USA. jwarren@medicine.umaryland.edu	Functional somatic syndromes: sensitivities and specificities of self-reports of physician diagnosis.	Psychosom Med. 2012 Nov-Dec;74(9):891-5. doi: 10.1097/PSY.0b013e31827264aa. Comment in Psychosom Med. 2012 Nov-Dec;74(9):882.	OBJECTIVE: Functional somatic syndromes have no laboratory or pathologic abnormalities and so are diagnosed by symptom-based case definitions. However, many studies, including recent ones, have used self-reports of physician diagnosis rather than the case definitions. Our objective was to determine the sensitivities and specificities of self-report of physician diagnosis for chronic fatigue syndrome (CFS), fibromyalgia (FM), irritable bowel syndrome (IBS), panic disorder, and migraine. METHODS: Each of 312 female patients with incident interstitial cystitis/bladder pain syndrome and matched population-based controls were queried on self-report of physician diagnosis and separately on established case definitions for each of these syndromes. RESULTS: Using the symptom-based case definitions as standards, we found that self-report of physician diagnosis did not identify 90% of the controls who had CFS, 77% who had FM, 69% who had IBS, 43% who had panic disorder, and 23% who had migraine. In addition, it missed most individuals with multiple syndromes. Findings in one cohort (controls) were confirmed in another (patients with interstitial cystitis/bladder pain syndrome). CONCLUSIONS: Self-report of physician diagnosis did not identify most of the three most venerable functional somatic syndromes, IBS, FM, and, especially, CFS; nor did it identify substantial minorities of individuals with panic disorder and migraine. Self-report of physician diagnosis was particularly poor in recognizing persons with multiple syndromes. The insensitivity of this diagnostic test

				has effects on not only prevalence and incidence estimates but also correlates, comorbidities, and case recruitment. To reveal individuals with these syndromes, singly or together, queries of symptoms, not diagnoses, are necessary.
Warren JW, Langenberg P, Clauw DJ.	Department of Medicine, University of Maryland School of Medicine, Baltimore, MD, USA; Department of Epidemiology and Public Health, University of Maryland School of Medicine, Baltimore, MD, USA. Electronic address: jwarren@medicine.umaryland.edu.	The number of existing functional somatic syndromes (FSSs) is an important risk factor for new, different FSSs.	J Psychosom Res. 2013 Jan;74(1):12-7. doi: 10.1016/j.jpsychores.2012.09.002. Epub 2012 Sep 26.	OBJECTIVE: The objective of this study is to test the hypothesis that the number of functional somatic syndromes (FSSs) predicts new, additional FSSs. METHODS: In a recent case-control study of interstitial cystitis/painful bladder syndrome (IC/PBS), we used symptom-based consensus definitions to identify these FSSs: fibromyalgia (FM), chronic fatigue syndrome (CFS), irritable bowel syndrome (IBS), chronic pelvic pain, migraine, sicca syndrome and panic disorder. Those present before the incidence year were called antecedent FSSs; those with onset during the incidence year were called incident FSSs. In each of two groups, 312 IC/PBS cases and 313 controls, rates of incident FSSs were compared among those with 0, 1, 2, or ≥3 antecedent FSSs. Confounding was assessed using logistic regression analyses that included the individual antecedent FSSs, published correlates of these FSSs, and demographic variables. RESULTS: The incidence of a new FSS increased with the number of antecedent FSSs, as did that of incident FM, CFS and IBS studied separately. These findings were not confounded by other variables. The presence of multiple antecedent FSSs generally had the highest odds ratio for new, different, incident FSSs. CONCLUSIONS: This study revealed that the number of antecedent FSSs was among the strongest risk factors for other FSSs, especially incident FM, CFS and IBS. This suggests that the FSSs are linked through a polysyndromic phenotype. If each FSS is heterogeneous, to seek a pathogenesis common to all FSSs, individuals with multiple FSSs should be sought; to seek a pathogenesis unique to a specific FSS, mature persons who have only that FSS should be studied.
Watt T, Oberfoell S, Balise R, Lunn MR, Kar AK, Merrihew L, Bhangoo MS, Montoya JG.	Division of Infectious Diseases and Geographic Medicine, Department of Medicine, Stanford University Medical Center, Palo Alto, CA, USA.	Response to valganciclovir in chronic fatigue syndrome patients with human herpesvirus 6 and Epstein-Barr virus IgG antibody titers.	J Med Virol. 2012 Dec;84(12):1967-74. doi: 10.1002/jmv.23411.	Valganciclovir has been reported to improve physical and cognitive symptoms in patients with chronic fatigue syndrome (CFS) with elevated human herpesvirus 6 (HHV-6) and Epstein-Barr virus (EBV) IgG antibody titers. This study investigated whether antibody titers against HHV-6 and EBV were associated with clinical response to valganciclovir in a subset of CFS patients. An uncontrolled, unblinded retrospective chart review was performed on 61 CFS patients treated with 900 mg valganciclovir daily (55 of whom took an induction dose of 1,800 mg daily for the first 3 weeks). Antibody titers were considered high if HHV-6 IgG ≥ 1:320, EBV viral capsid antigen (VCA) IgG ≥ 1:640, and EBV early antigen (EA) IgG ≥ 1:160. Patients self-rated physical and cognitive functioning as a percentage of their functioning prior to illness. Patients were categorized as responders if they experienced at least 30% improvement in physical and/or cognitive functioning. Thirty-two patients (52%) were categorized as responders. Among these, 19 patients (59%) responded physically and 26 patients (81%) responded cognitively. Baseline antibody titers showed no significant association with response. After treatment, the average change in physical and cognitive functioning levels for all patients was +19% and +23%, respectively (P <

				0.0001). Longer treatment was associated with improved response (P = 0.0002). No significant difference was found between responders and non-responders among other variables analyzed. Valganciclovir treatment, independent of the baseline antibody titers, was associated with self-rated improvement in physical and cognitive functioning for CFS patients who had positive HHV-6 and/or EBV serologies. Longer valganciclovir treatment correlated with an improved response.
Wearden AJ, Dunn G, Dowrick C, Morriss RK.	University of Manchester, School of Psychological Sciences, Coupland 1 Building, Oxford Road, Manchester M13 9PL, UK. Alison.wearden@manchester.ac.uk	Depressive symptoms and pragmatic rehabilitation for chronic fatigue syndrome.	Br J Psychiatry. 2012 Sep;201(3):227-32. doi: 10.1192/bjp.bp.111.107474.	BACKGROUND: Previous research has suggested that depressed mood may predict outcome and moderate response to treatment in chronic fatigue syndrome, although findings have differed between studies. AIMS: To examine potential moderators of response to pragmatic rehabilitation v. general practitioner treatment as usual in a recent randomised trial for patients with chronic fatigue syndrome in primary care (IRCTN74156610). METHOD: Simple regressions, with weighting adjustments to allow for missing data, were calculated. Demographic, medical and psychological variables, and treatment arm, were entered separately and as an interaction term. The outcome variable in each case was change in Chalder Fatigue Scale scores, from baseline to 1-year follow-up, our primary outcome point. RESULTS: Longer illness durations predicted poorer outcome across the two treatment arms. For patients allocated to pragmatic rehabilitation compared with those allocated to treatment as usual, higher levels of depressive symptoms at baseline were associated with smaller improvements in fatigue (P = 0.022). CONCLUSIONS: For patients in primary care with higher levels of depressive symptoms, either more intensive or longer pragmatic rehabilitation, or cognitive-behavioural therapy, may be required in order to show a significant improvement in fatigue.
Webb CM, Collin SM, Deave T, Haig-Ferguson A, Spatz A, Crawley E.	St George's University of London, Cranmer Terrace, London, UK.	What stops children with a chronic illness accessing health care: a mixed methods study in children with Chronic Fatigue Syndrome/Myalgic Encephalomyelitis (CFS/ME).	BMC Health Serv Res. 2011 Nov 11;11:308. doi: 10.1186/1472-6963-11-308.	BACKGROUND: Paediatric Chronic Fatigue Syndrome/Myalgic Encephalomyelitis (CFS/ME) is relatively common and disabling with a mean time out of school of more than one academic year. NICE guidelines recommend referral to specialist services immediately if severely affected, within 3 months if moderately affected and within 6 months if mildly affected. However, the median time-to-assessment by a specialist service in the UK is 18 months. This study used a mixed-methods approach to examine factors associated with time taken to access specialist services. METHODS: Time-to-assessment was analysed as a continuous "survival-time" variable in Cox regression models using data from self-completed assessment forms for children attending a regional specialist CFS/ME service between January 2006 and December 2009. Semi-structured interviews about barriers experienced in accessing healthcare for their child were conducted with nine parents of children aged < 17 years (8 individual and one parent couple). Interviews were digitally recorded and analysed using "thematic analysis". RESULTS: 405 children were assessed between 2006 and 2009 and information on school attendance was available on 388. Only 1/125 with severe CFS/ME and 49/263 (19%) with mild to moderate CFS/ME were seen within NICE recommended timeframe. Increased fatigue was associated with shorter time to

				assessment (HR = 1.15; 95% CI 1.03, 1.29 per unit increase in Chalder fatigue score; P = 0.01). Time-to-assessment was not associated with disability, mood, age or gender. Parents described difficulties accessing specialist services because of their own as well as their GP's and Paediatrician's lack of knowledge. They experienced negative attitudes and beliefs towards the child's condition when they consulted GPs, Paediatricians and Child Psychiatrists. Parents struggled to communicate an invisible illness that their child and not themselves were experiencing. CONCLUSIONS: GPs, Child Psychiatrists and Paediatricians need more knowledge about CFS/ME and the appropriate referral pathways to ensure timeliness in referral to specialist services.
Weis J, Faller H.	Klinik für Tumorbiologie an der Universität Freiburg, Breisacher Str. 117, 79106, Freiburg, Deutschland. weis@tumorbio.uni-freiburg.de	Psychosocial issues of long-term cancer survivors. [Article in German]	Bundesgesundheitsblatt Gesundheitsforschung Gesundheitsschutz. 2012 Apr;55(4):501-8. doi: 10.1007/s00103-012-1458-7.	Although cancer incidence rates are increasing, recent statistical studies suggest that cancer patients are showing higher cure rates as well as improved overall survival rates for most cancer locations. These advances are explained by improved strategies in early diagnoses as well as improved cancer therapies. Therefore, the number of long-term cancer survivors has also increased, but only few studies, especially within the last years, have focused on psychosocial issues of this subgroup. Some studies show that overall quality of life of long-term cancer survivors is quite high and comparable to that of the normal population. Nevertheless, a substantial percentage of former patients shows reduced quality of life and suffers from various sequelae of cancer and its treatment. This review focuses on the most common psychosocial issue of long-term survivors such as reduced psychological wellbeing, neuropsychological deficits and cancer-related fatigue syndrome. Finally, recommendations for problem-oriented interventions as well as improvement of psychosocial care of long-term survivors are given.
Wensaas KA, Langeland N, Hanevik K, Mørch K, Eide GE, Rortveit G.	Department of Public Health and Primary Health Care, University of Bergen, Bergen, Norway. knut-arne.wensaas@uni.no	Irritable bowel syndrome and chronic fatigue 3 years after acute giardiasis: historic cohort study.	Gut. 2012 Feb;61(2):214-9. doi: 10.1136/gutjnl-2011-300220. Comment in Nat Rev Gastroenterol Hepatol. 2011 Nov;8(11):597.	BACKGROUND: Giardia lamblia is a common cause of gastroenteritis worldwide, but there is limited knowledge about the long-term complications. OBJECTIVE: To estimate the relative risk of irritable bowel syndrome (IBS) and chronic fatigue 3 years after acute giardiasis. DESIGN: Controlled historic cohort study with 3 years' follow-up. Data collected by mailed questionnaire. SETTING: Waterborne outbreak of giardiasis in the city of Bergen, Norway. PARTICIPANTS: 817 patients exposed to Giardia lamblia infection verified by detection of cysts in stool samples and 1128 matched controls. MAIN OUTCOME MEASURES: IBS and chronic fatigue. RESULTS: The prevalence of IBS in the exposed group was 46.1%, compared with 14.0% in the control group, and the adjusted RR=3.4 (95% CI 2.9 to 3.8). Chronic fatigue was reported by 46.1% of the exposed group and 12.0% of the controls, the adjusted RR was 4.0 (95% CI 3.5 to 4.5). IBS and chronic fatigue were associated and the RR for the exposed group of having a combination of the two outcomes was 6.8 (95% CI 5.3 to 8.5). The RR was also increased for having just one of the two syndromes, 1.8 for IBS (95% CI 1.4 to 2.3) and 2.2 for chronic fatigue (95% CI 1.7 to 2.8). CONCLUSIONS: Infection with Giardia lamblia in a non-endemic area was associated with a high prevalence of IBS and chronic fatigue 3 years after acute illness, and the risk was

				significantly higher than in the control group. This shows that the potential consequences of giardiasis are more serious than previously known. Further studies are needed, especially in areas where giardiasis is endemic.
Wessely SC.	Department of Psychological Medicine, Institute of Psychiatry, King's College London, London, UK. simon.wessely@kcl.ac.uk	Impact Commentaries. The nature of fatigue: a comparison of chronic "postviral" fatigue with neuromuscular and affective disorders.	J Neurol Neurosurg Psychiatry. 2012 Jan;83(1):4-5. doi: 10.1136/jnnp-2011-301216. White AT, Light AR, Hughen RW, Vanhaitsma TA, Light KC.	Department of Anesthesiology, University of Utah, 30 N 1900 E, Room 3C444, Salt Lake City, UT 84132-2501, USA.	Differences in metabolite-detecting, adrenergic, and immune gene expression after moderate exercise in patients with chronic fatigue syndrome, patients with multiple sclerosis, and healthy controls.	Psychosom Med. 2012 Jan;74(1):46-54. doi: 10.1097/PSY.0b013e31824152ed.	OBJECTIVE: Chronic fatigue syndrome (CFS) and multiple sclerosis (MS) are characterized by debilitating fatigue, yet evaluation of this symptom is subjective. We examined metabolite-detecting, adrenergic, and immune gene expression (messenger ribonucleic acid [mRNA]) in patients with CFS (n = 22) versus patients with MS (n = 20) versus healthy controls (n = 23) and determined their relationship to fatigue and pain before and after exercise. METHODS: Blood samples and fatigue and pain ratings were obtained at baseline and 0.5, 8, 24, and 48 hours after sustained moderate exercise. Leukocyte mRNA of four metabolite-detecting receptors (acid-sensing ion channel 3, purinergic type 2X4 and 2X5 receptors, and transient receptor potential vanilloid type 1) and four adrenergic (α-2a, β-1, and β-2 receptors and catechol-O-methyltransferase) and five immune markers (CD14, toll-like receptor 4 [TLR4], interleukin [IL] 6, IL-10, and lymphotoxin α) was examined using quantitative polymerase chain reaction. RESULTS: Patients with CFS had greater postexercise increases in fatigue and pain (10-29 points above baseline, $p < .001$) and greater mRNA increases in purinergic type 2X4 receptor, transient receptor potential vanilloid type 1, CD14, and all adrenergic receptors than controls (mean ± standard error = 1.3 ± 0.14- to 3.4 ± 0.90-fold increase above baseline, $p = .04$-$.005$). Patients with CFS with comorbid fibromyalgia (n = 18) also showed greater increases in acid-sensing ion channel 3 and purinergic type 2X5 receptors ($p < .05$). Patients with MS had greater postexercise increases than controls in β-1 and β-2 adrenergic receptor expressions (1.4 ± 0.27- and 1.3 ± 0.06-fold increases, respectively, $p = .02$ and $p < .001$) and greater decreases in TLR4 ($p = .02$). In MS, IL-10 and TLR4 decreases correlated with higher fatigue scores. CONCLUSIONS: Postexercise mRNA increases in metabolite-detecting receptors were unique to patients with CFS, whereas both patients with MS and patients with CFS showed abnormal increases in adrenergic receptors. Among patients with MS, greater fatigue was correlated with blunted immune marker expression.

Wiborg JF, Knoop H, Frank LE, Bleijenberg G.	Expert Centre for Chronic Fatigue, Radboud University Nijmegen Medical Centre, The Netherlands. j.wiborg@nkcv.umcn.nl	Towards an evidence-based treatment model for cognitive behavioral interventions focusing on chronic fatigue syndrome.	J Psychosom Res. 2012 May;72(5):399-404. doi: 10.1016/j.jpsychores.2012.01.018.	OBJECTIVE: The purpose of the present study was to develop a treatment model for cognitive behavioral interventions focusing on chronic fatigue syndrome (CFS) based on the model of perpetuating factors introduced by Vercoulen et al. [Journal of Psychosomatic Research 1998;45:507-17]. METHODS: For this purpose, we reanalyzed the data of a previously conducted randomized controlled trial in which a low intensity cognitive behavioral intervention was compared to a waiting list control group. Structural equation modeling was used to test a treatment model in which changes in focusing on symptoms, perceived problems with activity, and sense of control over fatigue were hypothesized to mediate the effect of our intervention on fatigue severity and disability. RESULTS: In the final model, which had a good fit to the data, the effect of treatment was mediated by a decrease in perceived problems with activity and an increase in sense of control over fatigue. CONCLUSION: Our findings suggest that cognitive behavioral interventions for CFS need to change the illness perception and beliefs of their patients in order to be effective.
Wiborg JF, Knoop H, Wensing M, Bleijenberg G.	Expert Centre for Chronic Fatigue, Radboud University Nijmegen Medical Centre, The Netherlands. J.Wiborg@nkcv.umcn.nl	Therapist effects and the dissemination of cognitive behavior therapy for chronic fatigue syndrome in community-based mental health care.	Behav Res Ther. 2012 Jun;50(6):393-6. doi: 10.1016/j.brat.2012.03.002.	OBJECTIVE: The purpose of the present study was to explore the role of the therapist in the dissemination of manualized cognitive behavior therapy (CBT) for chronic fatigue syndrome (CFS) outside specialized treatment settings. METHOD: We used the routinely collected outcome data of three community-based mental health care centers (MHCs) which implemented and sustained CBT for CFS during the course of the study. Ten therapists, who all received the same training in CBT for CFS, and 103 patients with CFS were included. RESULTS: Random effects modeling revealed a significant difference in mean post-treatment fatigue between therapists. The effect of the therapist accounted for 21% of the total variance in post-treatment fatigue in our sample. This effect could be explained by the therapists' attitude toward working with evidence-based treatment manuals as well as by the MHC where CBT for CFS was delivered. CONCLUSION: The context in which CBT for CFS is delivered may play an important role in the accomplishment of established therapy effects outside specialized treatment settings. Due to the small sample size of MHCs and the different implementation scenarios in which they were engaged, our findings should be interpreted as preliminary results which are in need for replication.
Wiborg JF, Wensing M, Tummers M, Knoop H,	Expert Centre for Chronic Fatigue, Radboud University Nijmegen Medical	Implementing Evidence-Based Practice for Patients with Chronic Fatigue	Clin Psychol Psychother. 2012 Dec 11. doi: 10.1002/cpp.1827	The aim of our study was to explore whether community-based mental health care centres (MHCs) are able to implement and sustain cognitive behaviour therapy (CBT) for chronic fatigue syndrome (CFS) with the help of an implementation manual. We monitored the implementation process and treatment outcome data of three Dutch

Bleijenberg G.	Centre, The Netherlands; Department of Psychosomatic Medicine and Psychotherapy, University Medical Center Hamburg-Eppendorf & Schön Klinik Hamburg-Eilbek, Hamburg, Germany. j.wiborg@nkcv.umcn.nl.	Syndrome.		MHCs that implemented or sustained CBT for CFS, one in the context of a stepped care programme. We compared these data with findings of other treatment studies conducted in the context of CBT for CFS. All three MHCs included at least 40 patients with dropout rates between 15% and 35% from intention-to-treat to second assessment. Effect sizes ranged between 0.88 and 1.76 for changes in fatigue severity and 0.43 and 1.23 for changes in physical functioning. With one exception, these outcomes were within the range of our benchmark. Contrary to original expectations, we provided additional implementation support to the two MHCs new with CBT for CFS. We concluded that our implementation manual does not seem to substitute external support for team leaders and associated professions during initial implementation of CBT for CFS but may have the potential to make this assistance more efficient. Particular attention should be paid to challenges of implementing stepped care for CFS. ation of CBT for CFS in community-based MHCs was monitored. External support was provided in addition to an implementation manual during initial implementation of CBT for CFS. Participating MHCs were generally capable of successfully implementing and delivering CBT for CFS. Implementation of low-intensity interventions for CFS might better be postponed until therapists have sufficient experience with conventional CBT for CFS.
Wilkinson K, Shapiro C.	Department of Cell and Systems Biology, University of Toronto, 25 Harbord Street, Toronto, ON M5S 3G5, Canada. katewilk@gmail.com	Nonrestorative sleep: symptom or unique diagnostic entity?	Sleep Med. 2012 Jun;13(6):561-9. doi: 10.1016/j.sleep.2012.02.002. Comment in Sleep Med. 2012 Jun;13(6):557-8.	Nonrestorative sleep (NRS) refers to the subjective experience of sleep as insufficiently refreshing, often despite the appearance of normal sleep according to traditionally assessed objective parameters. This has led researchers to pursue alternative physiological markers of nonrestorative or unrefreshing sleep, though much of this research remains controversial and inconclusive. This review summarizes the recent findings on NRS in the literature and discusses some of the issues inherent in current efforts to define and measure NRS. We offer a summary of recommended clinical approaches to NRS and discuss a new potential paradigm for the assessment of NRS-an approach modelled on current diagnosis of insomnia.
Williams DK, Galvin TA, Ma H, Khan AS.	Laboratory of Retroviruses, Division of Viral Products, Center for Biologics Evaluation and Research, U.S. Food and Drug Administration, 8800 Rockville Pike, Bethesda, MD 20892, USA.	Investigation of xenotropic murine leukemia virus-related virus (XMRV) in human and other cell lines.	Biologicals. 2011 Nov;39(6):378-83. doi: 10.1016/j.biologicals.2011.08.011.	Xenotropic murine leukemia virus-related virus (XMRV) was discovered in human prostate tumors and later in some chronic fatigue syndrome (CFS) patients. However, subsequent studies have identified various sources of potential contamination with XMRV and other murine leukemia virus (MLV)-related sequences in test samples. Biological and nucleotide sequence analysis indicates that XMRV is distinct from known xenotropic MLVs and has a broad host range and cell tropism including human cells. Therefore, it is prudent to minimize the risk of human exposure to infection by evaluating XMRV contamination in cell lines handled in laboratory research and particularly those used in the manufacture of biological products. Nested DNA PCR assays were optimized for investigating XMRV gag and env sequences in various cell lines, which included MRC-5, Vero, HEK-293, MDCK, HeLa, and A549, that may be used in the development of some vaccines and other cell lines broadly used in research. The sensitivity of the DNA PCR assays was <10 copies in approximately 1.8 x

				10(5) cells equivalent of human DNA. The results indicated the absence of XMRV in the cell lines tested; although in some cases DNA fragments identified as cellular sequences were seen following the first round of PCR amplification with the env primer pair.
Wright B, Beverley D.	Child, Adolescent & Family Unit, York, England, UK. Barry.Wright@nyypct.nhs.uk	Pervasive refusal syndrome.	Clin Child Psychol Psychiatry. 2012 Apr;17(2):221-8. doi: 10.1177/1359104511403680.	We report here on a case of severe pervasive refusal syndrome. This is of interest for three reasons. Firstly, most reported cases are adolescent girls; our case is regarding an adolescent boy. Secondly, he was successfully treated at home and thirdly, the serology showed an apparent infective pre-cursor to the illness with evidence of possible autoimmune serology. A 14-year old boy deteriorated from a picture where diagnosed CFS/ME developed into Pervasive Refusal Syndrome. This included the inability to move or speak, with closed eyes, multiple tics, facial grimacing, heightened sensitivity to noise (hyperacusis) and touch (hyperaesthesia), and inability or unwillingness to eat anything except small amounts of sloppy food. Successful rehabilitation is reported. Finally the issue of nomenclature is discussed, raising the question whether Pervasive Refusal Syndrome would be better renamed in a way that does not imply that the condition is always volitional and oppositional, as this can distract focus away from an alliance between family and clinicians.
Wu HS, Davis JE, Natavio T.	College of Nursing, Wayne State University, Detroit, MI, USA. wuh@wayne.edu	Fatigue and disrupted sleep-wake patterns in patients with cancer: a shared mechanism.	Clin J Oncol Nurs. 2012 Apr;16(2):E56-68. doi: 10.1188/12.CJON.E56-E68.	The strong and potentially reciprocal relationship between cancer-related fatigue (CRF) and disrupted sleep-wake patterns suggests a possible shared physiologic pathway. A growing body of evidence supports this and shows that abnormalities in the 24-hour rhythm of stress-related hormones may be related to chronic fatigue and sleep disturbances. Aberrations in the hypothalamic-pituitary-adrenal (HPA) axis, the primary neuroendocrine interface responding to stress, induce important biologic and behavioral consequences. HPA aberrations have long been associated with chronic fatigue syndrome. Many overlapping symptoms exist between chronic fatigue syndrome and CRF, including sleep disruption. Therefore, in the absence of knowledge about CRF mechanisms, emerging biologic models from chronic fatigue syndrome may assist in understanding the cause of CRF. Cancer-associated stressors also may alter the circadian functions of HPA-associated neuroendocrine activities, which result in the symptoms of fatigue and disrupted sleep-wake patterns in patients with cancer. Exploring promising physiologic models furthers the knowledge about CRF and disrupted sleep and may foster hypothesis-based studies of mechanisms that underlie apparent overlapping symptoms, providing the basis for new management to improve sleep and lessen fatigue.
Xu W, Zhou RH, Li L, Jiang MW.	Acupuncture and Moxibustion Department, The Third People's Hospital of Hangzhou City, Hangzhou 310009,	Observation on therapeutic effect of chronic fatigue syndrome treated with coiling dragon needling and moving	Zhongguo Zhen Jiu. 2012 Mar;32(3):205-8.	OBJECTIVE: To compare the differences of therapeutic effect of chronic fatigue syndrome treated with the combined therapy of coiling dragon needling and cupping on back and the western medicine therapy with Prednisone. METHODS: Seventy-two cases were randomly divided into an acupuncture and cupping group (37 cases) and a Prednisone group (35 cases). In acupuncture and cupping group, Jiaji (EX-B 2) points of T1--L5 were applied with coiling dragon needling (once a day), combined with

	Zhejiang Province, China. xwxw217@163.com	cupping on back. [Article in Chinese]		moving cupping on back (once every two days); in Prednisone group, Prednisone tablets were orally taken for 10 mg at 8:00 am. Seven days made one course, and 2 courses were carried on totally. FS-14 scale and BELL's chronic fatigue syndrome integral table were applied to evaluate the fatigue degree of patients before and after treatment, and the therapeutic effects of both groups were compared. RESULTS: After one course of treatment, the BELL's scores of both groups were obviously improved (both P < 0.01), but there was no significant difference between groups (P > 0.05); after two courses of treatment, the BELL's score in acupuncture and cupping group improved more obviously than that in Prednisone group, and the total effective rate of 91.9% (34/37) in acupuncture and cupping group was superior to that of 71.4% (25/35) in Prednisone group (P < 0.05). CONCLUSION: The therapeutic effect of chronic fatigue syndrome treated with coiling dragon needling and moving cupping on back is positive, superior to that of Prednisone with oral administration.
Yamamoto S, Ouchi Y, Nakatsuka D, Tahara T, Mizuno K, Tajima S, Onoe H, Yoshikawa E, Tsukada H, Iwase M, Yamaguti K, Kuratsune H, Watanabe Y. Reduction of [(11)C](+)3-MPB Binding in Brain of Chronic Fatigue Syndrome with Serum Autoantibody against Muscarinic Cholinergic Receptor.	PLoS One. 2012;7(12):e51515. doi: 10.1371/journal.pone.0051515.	BACKGROUND: Numerous associations between brain-reactive antibodies and neurological or psychiatric symptoms have been proposed. Serum autoantibody against the muscarinic cholinergic receptor (mAChR) was increased in some patients with chronic fatigue syndrome (CFS) or psychiatric disease. We examined whether serum autoantibody against mAChR affected the central cholinergic system by measuring brain mAChR binding and acetylcholinesterase activity using positron emission tomography (PET) in CFS patients with positive [CFS(+)] and negative [CFS(-)] autoantibodies. METHODOLOGY: Five CFS(+) and six CFS(-) patients, as well as 11 normal control subjects underwent a series of PET measurements with N-[(11)C]methyl-3-piperidyl benzilate [(11)C](+)3-MPB for the mAChR binding and N-[(11)C]methyl-4-piperidyl acetate [(11)C]MP4A for acetylcholinesterase activity. Cognitive function of all subjects was assessed by neuropsychological tests. Although the brain [(11)C](+)3-MPB binding in CFS(-) patients did not differ from normal controls, CFS(+) patients showed significantly lower [(11)C](+)3-MPB binding than CFS(-) patients and normal controls. In contrast, the [(11)C]MP4A index showed no significant differences among these three groups. Neuropsychological measures were similar among groups. CONCLUSION: The present results demonstrate that serum autoantibody against the mAChR can affect the brain mAChR without altering acetylcholinesterase activity and cognitive functions in CFS patients.
Yancey JR, Thomas SM.	Fort Belvoir Community Hospital, Fort Belvoir, VA 22060, USA. joe.yancey@us.army.mil	Chronic fatigue syndrome: diagnosis and treatment.	Am Fam Physician. 2012 Oct 15;86(8):741-6.	Chronic fatigue syndrome is characterized by debilitating fatigue that is not relieved with rest and is associated with physical symptoms. The Centers for Disease Control and Prevention criteria for chronic fatigue syndrome include severe fatigue lasting longer than six months, as well as presence of at least four of the following physical symptoms: postexertional malaise; unrefreshing sleep; impaired memory or concentration; muscle pain; polyarthralgia; sore throat; tender lymph nodes; or new headaches. It is a clinical diagnosis that can be made only when other disease processes are excluded. The etiology of chronic fatigue syndrome is unclear, is likely

				complex, and may involve dysfunction of the immune or adrenal systems, an association with certain genetic markers, or a history of childhood trauma. Persons with chronic fatigue syndrome should be evaluated for concurrent depression, pain, and sleep disturbances. Treatment options include cognitive behavior therapy and graded exercise therapy, both of which have been shown to moderately improve fatigue levels, work and social adjustment, anxiety, and postexertional malaise. No pharmacologic or alternative medicine therapies have been proven effective.

Young JL.	Wayne State University School of Medicine, Detroit, MI, USA; William Beaumont Hospital, Royal Oak, MI, USA; Rochester Center for Behavioral Medicine, Rochester Hills, MI, USA. Electronic address: jyoung@rcbm.net.	Use of Lisdexamfetamine dimesylate in treatment of executive functioning deficits and chronic fatigue syndrome: A double blind, placebo-controlled study.	Psychiatry Res. 2012 Oct 9. pii: S0165-1781(12)00503-3. doi: 10.1016/j.psychres.2012.09.007.	The purpose of this study was to assess the efficacy of lisdexamfetamine dimesylate (LDX) for the treatment of executive functioning deficits in adults (ages 18-60) with chronic fatigue syndrome (CFS). The study's primary outcome measure was the Behavior Rating Inventory of Executive Function-Adult (BRIEF-A). Secondary outcome measures were standardized assessments of fatigue, pain and global functioning. Twenty-six adults who met criteria for CFS and had clinically significant executive functioning deficits were randomly assigned to a flexible morning dose (30, 50, 70mg/day) of either placebo or LDX for a six-week trial. The data were analyzed with standard analysis of variance (ANOVA) procedures. Participants in the LDX group showed significantly more positive change in BRIEF-A scores (M(change)=21.38, SD=15.85) than those in the placebo group (M(change)=3.36, SD=7.26), p=0.005, d=1.46. Participants in the active group also reported significantly less fatigue and generalized pain relative to the placebo group. Although future studies with LDX should examine whether these benefits generalize to larger, more diverse samples of patients, these results suggest that LDX could be a safe and efficacious treatment for the executive functioning deficits often associated with CFS. The possibility that dopaminergic medications could play an important role addressing the symptoms of CFS is also discussed.
Yunus MB.	Section of Rheumatology, Department of Medicine, University of Illinois College of Medicine at Peoria, One Illini Drive, Peoria, IL 61605, USA.	The prevalence of fibromyalgia in other chronic pain conditions.	Pain Res Treat. 2012;2012:584573. doi: 10.1155/2012/584573.	Central sensitivity syndromes (CSS) include fibromyalgia syndrome (FMS), irritable bowel syndrome, temporomandibular disorder, restless legs syndrome, chronic fatigue syndrome, and other similar chronic painful conditions that are based on central sensitization (CS). CSS are mutually associated. In this paper, prevalence of FMS among other members of CSS has been described. An important recent recognition is an increased prevalence of FMS in other chronic pain conditions with structural pathology, for example, rheumatoid arthritis, systemic lupus, ankylosing spondylitis, osteoarthritis, diabetes mellitus, and inflammatory bowel disease. Diagnosis and proper management of FMS among these diseases are of crucial importance so that unwarranted use of such medications as corticosteroids can be

				avoided, since FMS often occurs when RA or SLE is relatively mild.
Zhang HY, Liu ZD, Hu CJ, Wang DX, Zhang YB, Li YZ.	Department of Rheumatology and Clinical Immunology, Peking Union Medical College Hospital, Chinese Academy of Medical Science, No. 1 Shuaifuyuan, Beijing, China.	Up-regulation of TGF-β1 mRNA expression in peripheral blood mononuclear cells of patients with chronic fatigue syndrome.	J Formos Med Assoc. 2011 Nov;110(11):701-4. doi: 10.1016/j.jfma.2011.09.006.	BACKGROUND/PURPOSE: It has been shown that the abnormality in immune cells in chronic fatigue syndrome (CFS) patients is closely associated with the participation of TGF-β. In order to study the relationship between TGF-β1 and CFS, we investigated the mRNA levels of TGF-β1 in peripheral blood mononuclear cells (PBMCs) in patients with CFS. METHODS: Fluorescent quantitative real time reverse-transcription polymerase chain reaction (FQ-RT-PCR) was performed to test TGF-β1 mRNA expression in PBMCs in 63 cases of CFS, 50 cases of disease controls, and 50 cases of healthy controls. RESULTS: The mean value of TGF-β1 mRNA expression in CFS patients was ΔΔCt=1.17±0.58, which was significantly higher than the disease controls (ΔΔCt=0.07±1.08, df=111, $p < 0.01$) and the healthy controls (ΔΔCt=0.00±1.63, df=111, $p < 0.01$). No significant difference was detected between disease and healthy controls ($p > 0.05$). CONCLUSION: The expression of TGF-β1 in PBMCs is significantly elevated in patients with CFS. It might be correlated to the pathogenesis of the disease.
Zhang W, Liu ZS, Xu HR, Liu YS.	Guang'anmen Hospital, China Academy of Chinese Medical Sciences, Beijing 100053, China. zhangwei_7108@sohu.com	Observation on therapeutic effect of acupuncture of Back-shu acupoints for chronic fatigue syndrome patients. [Article in Chinese]	Zhen Ci Yan Jiu. 2011 Dec;36(6):437-41, 448.	OBJECTIVE: To observe the therapeutic effect and safety of acupuncture of Back-shu points [Xinshu (BL 15), Pishu (BL 20), etc.] in the treatment of chronic fatigue syndrome (CFS). METHODS: A total of 120 CFS patients were equally randomized Into acupuncture and control groups. Acupuncture needles were inserted into bilateral Xinshu (BL 15), Pishu (BL 20), and Gaohuang (BL 43) points, once daily for 4 weeks except weekends. For patients of the control group, acupuncture needles were inserted into the shallow layer of the non-acupoints (two mid-points of the horizon lines passing through the crossing-points of the 1st and 2nd branches of the Gallbladder Meridian and the crests of 4th, 5th and 11th thoracic vertebrae). General health scale (SF-20) and Chalder fatigue scale were used to measure the CFS patients' degree of general health. A follow-up survey was carried out 3 months after the last treatment. RESULTS: In comparison with pre-treatment, the scores of Chalder fatigue scale were decreased significantly in both treatment and control groups ($P < 0.01$), while the scores of physiological function (PF) and general health (GH) of SF-20 in both acupuncture groups and those of the role function (RF), social function (SF), mental health (MH) and pain sensation (PS) in the treatment group were increased apparently after the treatment ($P < 0.05$, $P < 0.01$). The scores of Chalder Scale and PF, RF, SF, GH, MH, PS and the CFS patients' satisfication degrees 4 weeks (64.4% and 36.7%) and 3 months (62.3% and 32%) after the treatment in the treatment group were significantly superior to those of the control group ($P < 0.05$). CONCLUSION: Acupuncture at Back-shu point has a good therapeutic effect (including immediate and midterm effect) in the treatment of chronic fatigue syndrome patients.
Zheng H, Jia H, Shankar A, Heneine W,	Laboratory Branch, Division of HIV/AIDS Prevention, National	Detection of murine leukemia virus or mouse DNA in	PLoS One. 2011;6(12):e29050. doi: 10.1371/journal.pone.002905	The xenotropic murine leukemia virus (MLV)-related viruses (XMRV) have been reported in persons with prostate cancer, chronic fatigue syndrome, and less frequently in blood donors. Polytropic MLVs have also been described in persons with

Switzer WM.	Center for HIV/AIDS, Viral Hepatitis, STD, and TB Prevention, Centers for Disease Control and Prevention, Atlanta, Georgia, United States of America.	commercial RT-PCR reagents and human DNAs.	0.	CFS and blood donors. However, many studies have failed to confirm these findings, raising the possibility of contamination as a source of the positive results. One PCR reagent, Platinum Taq polymerase (pol) has been reported to contain mouse DNA that produces false-positive MLV PCR results. We report here the finding of a large number of PCR reagents that have low levels of MLV sequences. We found that recombinant reverse-transcriptase (RT) enzymes from six companies derived from either MLV or avian myeloblastosis virus contained MLV pol DNA sequences but not gag or mouse DNA sequences. Sequence and phylogenetic analysis showed high relatedness to Moloney MLV, suggesting residual contamination with an RT-containing plasmid. In addition, we identified contamination with mouse DNA and a variety of MLV sequences in commercially available human DNAs from leukocytes, brain tissues, and cell lines. These results identify new sources of MLV contamination and highlight the importance of careful pre-screening of commercial specimens and diagnostic reagents to avoid false-positive MLV PCR results.
Zhou Y, Steffen I, Montalvo L, Lee TH, Zemel R, Switzer WM, Tang S, Jia H, Heneine W, Winkelman V, Tailor CS, Ikeda Y, Simmons G.	Blood Systems Research Institute, Department of Laboratory Medicine, University of California at San Francisco, San Francisco, California 94118, USA.	Development and application of a high-throughput microneutralization assay: lack of xenotropic murine leukemia virus-related virus and/or murine leukemia virus detection in blood donors.	Transfusion. 2012 Feb;52(2):332-42. doi: 10.1111/j.1537-2995.2011.03519.x.	BACKGROUND: Xenotropic murine leukemia virus (MLV)-related virus (XMRV) and other related MLVs have been described with chronic fatigue syndrome and certain types of prostate cancer. In addition, prevalence rates as high as 7% have been reported in blood donors, raising the risk of transfusion-related transmission. Several laboratories have utilized microneutralization assays as a surrogate marker for detection of anti-MLV serologic responses--with up to 25% of prostate cancer patients reported to harbor neutralizing antibody responses. STUDY DESIGN AND METHODS: We developed a high-throughput microneutralization assay for research studies on blood donors using retroviral vectors pseudotyped with XMRV-specific envelopes. Infection with these pseudotypes was neutralized by sera from both macaques and mice challenged with XMRV, but not preimmune serum. A total of 354 plasma samples from blood donors in the Reno/Tahoe area were screened for neutralization. RESULTS: A total of 6.5% of donor samples gave moderate neutralization of XMRV, but not control pseudotypes. However, further testing by Western blot revealed no evidence of antibodies against MLVs in any of these samples. Furthermore, no evidence of infectious virus or viral nucleic acid was observed. CONCLUSION: A microneutralization assay was developed for detection of XMRV and can be applied in a high-throughput format for large-scale studies. Although a proportion of blood donors demonstrated the ability to block XMRV envelope-mediated infection, we found no evidence that this inhibition was mediated by specific antibodies elicited by exposure to XMRV or MLV. It is likely that this moderate neutralization is mediated through another, nonspecific mechanism.

[No authors listed]	[no address given]	[No title given]	IACSF/ME. 19 (2). Fall 2011. Abstracts from IACFS/ME Biennial International Conference. Poster Presentations. P152	Objective: We present case studies/ case series of Fibromyalgia (FMS) patients treated with an interdisciplinary approach. Method: The 4 component model (Klinghardt) for treating chronic pain and disease helps to conceptualize an approach for FMS. This involves identifying and treating underlying root causes for pain and dysfunction in 4 areas: Structural – Biochemical – Psychoemotional – Neurological. This approach as a model for multi-modal/ multi-disciplinary treatment will be illustrated. Results Structural: A case series of 25 FMS patients treated effectively with Botulinum Toxin-A injections will be presented. Such injections into myofascial trigger points and tender points often do not work and may exacerbate FMS pain. Injections do work when done on a biomechanical basis (correcting postural misalignments and upper/ lower crossed syndromes) and when combined with specialized manual therapy and exercise. (Ko G, Whitmore S et.al. J Musculoskel Pain 2007;15(4):55-66.). Preliminary results from a double-blind randomized controlled pilot study may also be presented. Platelet-rich Plasma Prolotherapy for sacroiliac ligament laxity were also helpful in posttraumatic (motor-vehicle accident) cases. (Ko G. Pract Pain Manage 2010;10(7):55-68) Biochemical: Case studies of FMS-CFS patients improved with Functional Medicine and Bioidentical Hormone replacement therapy will be presented. This includes the use of omega 3 fatty acids (at a high dose) to improve pain and mood. (Ko G, Arseneau L et.al. Clin J Pain 2010; 26(2):168-72. Psychoemotional: A FMS case study using EEG biofeedback / neurotherapy will be presented. This patient was followed over 5 years and had significant amelioration of pain, improvement in “fibrofog” and in sleep. (Ko G, Gottfried B et.al Crit Rev Phys Rehabil Med 2005;17:1-30) Neurological: Case series of recalcitrant FMS patients with allodynia who responded to unique multimodal combinations of neuropathic pain medications will be presented. This included combinations of Pregabalin, SNRIs, tramadol and cannabinoids. (Hum A et.al. Pain Res Manage 2008;13:137). Topical medication use from essential oils (J Musculoskel Pain 2007;15(1):11-20) to compounded pain gels will be described as well. Conclusion: These cases demonstrate the diversity in assessment for underlying causes and the need for individualized treatment in FMS. Randomized clinical trials may need to focus on specific subgroups of FMS patients to demonstrate clinical effectiveness.
Alegre, J; DeMeirleir, K; Frémont, M;	Chronic Fatigue Syndrome Unit, Hospital Universitari	Effects of Alpha1-Proteinase Inhibitor in Peripheral Blood	IACSF/ME. 19 (2). Fall 2011. Abstracts from IACFS/ME Biennial International	Introduction: Immune dysregulation of 2-5A oligoadenylate synthetase/ribonuclease (RNase) L antiviral pathway has been widely reported in chronic fatigue syndrome (CFS). Proteolytic cleavage of RNase L (83 kDa) by elastase generate hyperactivated

Campuri, S	Vall d'Hebron, Barcelona Spain.	Mononuclear Cells of Chronic Fatigue Syndrome Patients	Conference. Poster Presentations. P167-168.	low molecular weight forms of RNase L (37 kDa) and ankyrin-like fragments in peripheral blood mononuclear cells (PBMC) of CFS patients. Ankyrin-like RNase L domain might disrupt ABC transporter function, accounting for physiological symptoms of CFS [1]. We hypothesized that alpha1-proteinase inhibitor (A1PI) could inhibit intracellular elastase activity to prevent RNase L proteolytic cleavage in PBMC of CFS. Objectives: To demonstrate that A1PI is capable of inhibiting intracellular elastase activity of cultured PBMC from CFS patients. Methods: Peripheral blood was drawn from 7 CFS patients fulfilling Fukuda criteria [2] and 5 healthy subjects. Extracts of freshly isolated PBMC were prepared and PBMC cultures were grown in RPMI medium without serum or antibiotics for 12 hours. One third of cultured cells were left untreated and the rest was treated with human plasma-derived A1PI at two different doses (3 g/l and 6 g/l) for 12 hours. After that, cells were harvested to obtain cytoplasmatic extracts. Elastase activity [3] was measured in all samples (mean ± SD). Results: PBMC extracts showed mean baseline elastase activity levels of 86±33 U/mg in healthy subjects and 323±106 U/mg in CFS patients. After PBMC culture, a marked increase of intracellular elastase activity was observed in both healthy subjects and CFS patients (up to 757 U/mg and 1503 U/mg, respectively). PBMC cultures in presence of A1PI 3 g/l showed significantly lower intracellular elastase activity, with mean values of 70±14 U/mg in healthy subjects and 132±90 U/mg in CFS patients. Similar results were obtained in presence of A1PI 6 g/l, with mean values of 62±10 U/mg in healthy subjects and 73±18 U/mg in CFS patients. Conclusion: In this study it was observed that A1PI strongly inhibited intracellular elastase activity in PBMC of CFS patients. Further research should examine the A1PI effect on proteolytic cleavage of RNase L. Nevertheless, the results indicate that the use human A1PI can be a promising therapeutic agent in the management of CFS.
Alegre, J; Garcia Quintana, AM; Karaki, M; Aliste, E; Montaner, L; Saez, N; Fernandez de Sevilla, T	Unidades del CFS. Hospital Vall d´Hebrón y Centro Médico Delfos. Barcelona. Spain.	Profile of the Patient with Chronic Fatigue Syndrome, Experience with a Population-Based Registry	IACSF/ME. 19 (2). Fall 2011. Abstracts from IACFS/ME Biennial International Conference. Poster Presentations. P185-186.	Objectives: In Spain, there are no epidemiologic studies analyzing the characteristics of patients diagnosed with chronic fatigue syndrome (CFS) according to the criteria of Fukuda. Thus, the prevalence and incidence of this nosologic condition, which causes considerable disability in personal, social, and work-related activity, is currently unknown. This study determines the sociodemographic, clinical, and therapeutic characteristics of a large series of CFS patients in our setting. Patients and Method: All patients who consulted for disabling chronic fatigue and met the diagnostic criteria of Fukuda were included. Patients underwent a diagnostic protocol that included complete laboratory analyses, chest x-ray, abdominal ultrasound, and psychiatric assessment. Sociodemographic data, symptoms, work situation, and treatments prescribed at the time of the diagnosis were recorded. Results: The study included 981 patients with CFS (91 men and 890 women), with a mean age of 47.9 years, 66% were married, 60% carried out specialized work, and 7% were housewives. Among the total, 60% had a secondary school or university education. There was a family background of CFS in 12%, fibromyalgia in 10%, and other immunological diseases in

				26.4%. The mean age at the onset of symptoms was 37.5 years and the mean interval from the onset of fatigue to the diagnosis was 116,5 months. The onset was sudden in 20% and gradual in 61%. An evident trigger was documented in 60% (infection, delivery, and a stressful life event). At the time of the diagnosis, 62.5% of patients were not working (sick leave 34% and work disability 37%). The treatment received at diagnosis included medication for the symptoms (analgesic, anxiolytic, and antidepressive agents) in 78.3%, alternative treatments in 3%, and programmed physical exercise and/or cognitive behavioural therapy in 5%. Conclusions: When evaluating a patient with incapacitating chronic fatigue, it is essential to identify cases that meet the criteria for CFS. In our setting, this condition predominantly affects middle-aged women who have a secondary or university education and work at specialized jobs. The onset of symptoms often occurs following an identifiable trigger. The condition leads to severe dysfunction in the personal, social, and work-related activities of daily life.
Alegre, J; Garcia-Quintana, AM; Ruiz, E; Aliste, L; Javierre, C; De Meirleir, K; Saez, N; Suarez, A; Fernández de Sevilla, T	Unidades del CFS Vall d´Hebron y Centro Médico Delfos de Barcelona (Spain)	Impact of Neurovegetative Symptoms on Patients Who Are Diagnosed With CFS And Have No History of Syncope	IACSF/ME. 19 (2). Fall 2011. Abstracts from IACFS/ME Biennial International Conference. Poster Presentations. P196.	Objective: Neurovegetative symptoms, such as dizziness, syncope, abnormal intestinal and bladder rhythms, sweating, and accommodation, were not initially contemplated in the diagnostic criteria of Fukuda for CFS. They acquired more importance later, when the Canadian criteria were established. In this study, the impact of neurovegetative symptoms is investigated in a group of patients with no prior history of syncope and a diagnosis of CFS. Patients and Method: The study included patients with no history of syncope, diagnosed with CFS according to the Fukuda criteria. Sociodemographic and work-related variables, symptoms, and comorbid phenomena were recorded. The impact of fatigue was assessed with the fatigue impact scale (FIS), SF-36 quality of life questionnaire, hospital anxiety and depression scale (HADS), and the maximum oxygen consumption, maximum cardiac output, maximum heart rate, and energy expenditure on stress testing. Biological markers were determined in peripheral blood monocytes (RNase L ratio, RNase L activity and elastase activity), and serum nitric oxide concentration was measured. Symptoms from the neurovegetative, neurocognitive, muscular, and immunological groups were categorized using the Cronbach alpha value. Associations between neurovegetative symptoms and the remaining variables were studied. Results: Thirty-seven CFS patients (4 men, 33 women), with a mean age of 48 years were studied. Among the total, 60% had a middle school educational level and specialized jobs, 65% reported a gradual symptoms onset, and the interval from symptoms onset to the diagnosis was 136 months. Neurocognitive, muscular, and immunologic symptoms were present in 95%, 87%, and 78% of patients, respectively. Neurovegetative symptoms were documented in 90%. Myofascial syndrome was found in 84%, dry syndrome 86%, and tendinopathy 62%. The total FIS score was 131.8, physical subscale 35.6, psychosocial 62.3, and cognitive 40. The SF-36 physical health score was 25.7 and mental health 36.1. The anxiety-depression component was 11.3. In

				addition, maximum oxygen consumption 57.1%, maximum cardiac output 67.1, maximum heart rate, 115.6 bpm and energy expenditure 4.6. RNase L ratio 0.54, RNase L activity 16.9, elastase activity 198.3, and nitric oxide 7.35. There was a significant association between neurovegetative dysfunction and the presence of painful lymph nodes (p=0.012), food intolerance (p=0.013), and monocyte elastase levels (p=0.02). Discussion: In CFS patients with no prior history of syncope, a considerable deterioration in quality of life and physical functional capacity was found, as well as high scores on the fatigue and anxiety-depression scales. Neurovegetative symptoms were common and showed a significant association with immunological symptoms and intracellular parameters of inflammatory activity.
Alegre, J; Moya, A; Garcia-Quintana, AM; Javierre, C; De Meirleir, K; Aliste, L; Fernández de Sevilla, T	Unidades del CFS Vall d´Hebron y Centro Médico Delfos de Barcelona (Spain)	Heart Rate Variability Evaluated with the LF/HF Ratioi of Sympatetic-Parasympathetic Activity in the Assessment of Neurovegetative Dysfunction in Patients with Chronic Fatigue Syndrome and No History of Syncope	IACSF/ME. 19 (2). Fall 2011. Abstracts from IACFS/ME Biennial International Conference. Poster Presentations. P195-196.	Objective: In chronic fatigue syndrome (CFS) neurovegetative symptoms have acquired relevance through the Canadian diagnostic criteria. As is the case of other highly disabling symptoms of this condition, resources are needed to quantify these neurovegetative manifestations. We propose assessment of heart rate variability by means of the LF/HF ratio determined on orthostatic positioning with tilt table testing in CSF patients with no prior history of syncope. Patients and Method: The study included patients with no history of syncope, diagnosed with CFS according to the Fukuda criteria. Neurovegetative, muscular, neurocognitive, and immunologic symptoms were recorded. Patients were evaluated with the fatigue impact scale (FIS), SF-36 quality of life questionnaire, hospital anxiety and depression scale (HADS), and stress testing (maximum oxygen consumption, maximum cardiac output, maximum heart rate, and energy expenditure). Biological markers were determined (RNase L ratio, RNase L activity, elastase activity, and serum nitric oxide concentration). The LF, HF and LF/HF ratio were evaluated on tilt table testing, with 3 determinations 5 minutes apart in supine position and 8 in orthostatic position. The *t*-test for paired samples was used to analyze trends. Associations between variables were examined with the chi-square test, *t* test, or Mann- Whitney test. Results: Thirty-seven CFS patients were studied (4 men, 33 women), with a mean age of 48 years; 65% had a gradual fatigue onset, and the interval from onset to diagnosis was 136 months. Neurocognitive, muscular, and immunologic symptoms were present in 95%, 87%, and 78% of patients, and neurovegetative symptoms in 90%. The total FIS score was 131.8, physical subscale 35.6, psychosocial 62.3, and cognitive 40. The SF-36 physical health score was 25.7 and mental health 36.1. The anxiety-depression component was 11.3. In addition, maximum oxygen consumption 57.1%, maximum cardiac output 67,1, maximum heart rate, 115.6 bpm and energy expenditure 4,6. RNase L ratio was 0.54, RNase L activity 16,9 elastase activity 198,3, and nitric oxide 7.35. Differences in the heart rate variability parameters (LF, HF and LF/HF ratio) were found between supine position and at 5 minutes of orthostatism, with an increase in the LF or sympathetic component. During the next 30 minutes in orthostasis, no changes were observed in the LF/HF ratio, with persistence of the excess sympathetic response. The

				mean LF/HF ratio was 4.88 and a significant association was found with the presence of Raynaud phenomenon, altered libido, SF-36 role-emotional and total mental health, and the depressive component on the HADS, as well as considerable (but non-significant) associations with the FIS psychosocial subscale (p=0.08) and RNase L (p=0.09) ratio. Discussion: In patients with CFS and neurovegetative symptoms without prior syncope, a maintained, predominantly sympathetic neurovegetative response, as assessed with the LF/HF ratio of heart rate variability, was seen on tilt table testing.
Alegre, J; Moya, A; Garcia-Quintana, AM; Javierre, C; De Meirleir, K; Aliste, L; Ruiz, E; Fernández de Sevilla, T	Unidades del CFS Vall d´Hebron y Centro Médico Delfos de Barcelona (Spain)	TILT Testing to Assess Neurovegetative Dysfunction in Patients with Chronic Fataigue Syndrome (CFS) and No History of Syncope	IACSF/ME. 19 (2). Fall 2011. Abstracts from IACFS/ME Biennial International Conference. Poster Presentations. P197.	Objective: Neurovegetative symptoms are very debilitating in CFS patients and there are few available resources to measure, quantify, or treat them. In this study we investigate the neurovegetative response to orthostatic positioning with the use of a tilt table in CFS patients with no prior history of syncope. Patients and Method: The study included patients diagnosed with CFS according to the Fukuda criteria, with no history of syncope. Data were compiled on patients' neurovegetative symptoms, scores on the fatigue impact scale (FIS), hospital anxiety and depression scale (HADS), and SF-36 quality of life questionnaire, physical capacity results (maximum oxygen consumption, maximum cardiac output, maximum heart rate, and energy expenditure) during stress testing, biological markers including monocyte RNase L ratio, RNase L activity, and elastase activity, and serum nitric oxide concentration. The following variables were evaluated on tilt table testing: heart rate, systolic blood pressure, diastolic blood pressure, mean blood pressure, systolic volume, and peripheral vascular resistance (PVR), with 3 determinations 5 minutes apart in the supine position and 8 in orthostatic position. Results: Thirty-seven CFS patients were studied (4 men, 33 women), with a mean age of 48 years at diagnosis, 65% with a gradual onset, and an interval from onset to the diagnosis of 136 months. Neurovegetative symptoms were documented in 90%. The total FIS score was 131.8, physical subscale 35.6, psychosocial 62.3, and cognitive 40. The SF-36 physical health score was 25.7 and mental health 36.1. The anxiety-depression component was 11.3. In addition, maximum oxygen consumption was 57.1%, maximum cardiac output 67,1, maximum heart rate, 115.6 bpm and energy expenditure 4.6. RNase L ratio was 0.54, RNase L activity 16.9, elastase activity 198,3 and nitric oxide 7,35. Tilt table testing was positive in one patient with a mixed cardiovascular response. There were no asymptomatic cardiovascular responses, such as orthostatic intolerance, postural tachycardia or hypertensive tachycardia. Significant differences in the cardiovascular parameters were found between supine position and at 5 minutes of orthostasis, with a pattern characterized by a considerable increase in the PVR, and a smaller increase in systolic blood pressure, with a decrease in the systolic volume and cardiac output. Once the orthostatic position was stabilized, there were no changes in the cardiovascular parameters over the next 30 minutes, with persistence of this predominantly sympathetic response. Discussion: In patients with CFS,

				neurovegetative symptoms, and no prior history of syncope, a predominantly sympathetic noradrenergic response is elicited with tilt table testing.
Alegre, J; Sáez Francàs, N; Calvo, N; Ruiz E; Valero, S; López, MV; Olivreas B; Fernández de Sevilla, T; Casas, M	Unidad del CFS. Hospital Vall d´Hebron, Barcelona. Spain. Servicio de Psiquiatria. Hospital Vall d´Hebrón. Barcelona. Spain.	Adverse Childhood Experiences as a Risk Factor for Chronic Fatigue Syndrome	IACSF/ME. 19 (2). Fall 2011. Abstracts from IACFS/ME Biennial International Conference. Poster Presentations. P174.	Introduction: Chronic Fatigue Syndrome (CFS) is characterized by severe, disabling fatigue and other symptoms, including musculoskeletal pain, sleep disturbance, attentional impairment, and anxiety. Although its etiology is not completely understood, it is considered that it is determined by biological, psychological and social factors. Adverse childhood experiences have been described as one of the major environmental risk factors for CFS. Aim: To evaluate the prevalence of different childhood traumas in a sample of adult CFS patients and the contribution of them in CFS symptoms profile. Methods: The initial sample consisted of 142 patients, of whom 9 were excluded because of severe psychopathology or incomplete evaluation. All the patients (age 48±8,9; 92,9% women) received CFS diagnoses according to Fukuda criteria. Childhood traumatic events were assessed by clinical interview in a dichotomous pattern. The scales FIS- 40 and HAD were administrated. Results: 74 (40,4%) patients reported some adverse childhood experience (ACE) [19 (10,4%) physical abuse, 19 (10,4%) sexual abuse, 25 (13,7%) emotional neglect, 27 (14,8%) bulling]. When comparing those with some ACE with those without it, there were no differences in Fukuda criteria profile, FIS-40 (124,47±24,56 vs 124,08±26,26; p=0,94), HAD-Anxiety (10,38±4,95 vs 10,65±5,08; p=0,81) and HAD-Depression (10,54±5,50)
Alegre, Jose; Ruiz, E; Quintana, AM; Karaki, M; Aliste, E; Montaner, L; Saez, N; de Sevilla, T;	Unidades del CFS Hospital Vall d´Hebrón y Centro Médico Delfos, Barcelona. Spain	Profile of the Patient with Chronic Fatigue Syndrome; Experience with a Population Based Registry	IACSF/ME. 19 (2). Fall 2011. Abstracts from IACFS/ME Biennial International Conference.p131.	Objectives: In Spain, there are no epidemiologic studies analyzing the characteristics of patients diagnosed with chronic fatigue syndrome (CFS) according to the criteria of Fukuda. Thus, the prevalence and incidence of this nosologic condition, which causes considerable disability in personal, social, and work-related activity, is currently unknown. This study determines the sociodemographic, clinical, and therapeutic characteristics of a large series of CFS patients in our setting. Patients and Method: All patients who consulted for disabling chronic fatigue and met the diagnostic criteria of Fukuda were included. Patients underwent a diagnostic protocol that included complete laboratory analyses, chest x-ray, abdominal ultrasound, and psychiatric assessment. Sociodemographic data, symptoms, work situation, and treatments prescribed at the time of the diagnosis were recorded. Results: The study included 981 patients with CFS (91 men and 890 women), with a mean age of 47.9 years, 66% were married, 60% carried out specialized work, and 7% were housewives. Among the total, 60% had a secondary school or university education. There was a family background of CFS in 12%, fibromyalgia in 10%, and other immunological diseases in 26.4%. The mean age at the onset of symptoms was 37.5 years and the mean interval from the onset of fatigue to the diagnosis was 116,5 months. The onset was sudden in 20% and gradual in 61%. An evident trigger was documented in 60% (infection, delivery, and a stressful life event). At the time of the diagnosis, 62.5% of patients were not working (sick leave 34% and work disability 37%). The treatment received at diagnosis included medication for the symptoms (analgesic, anxiolytic, and

				antidepressive agents) in 78,3%, alternative treatments in 3%, and programmed physical exercise and/or cognitive behavioral therapy in 5%. Conclusions: When evaluating a patient with incapacitating chronic fatigue, it is essential to identify cases that meet the criteria for CFS. In our setting, this condition predominantly affects middle-aged women who have a secondary or university education and work at specialized jobs. The onset of symptoms often occurs following an identifiable trigger. The condition leads to severe dysfunction in the personal, social, and work related activities of daily life.
Alegre, Jose; Santamarina-Perez, P, Eiroa-Orosa, FJ; Jacas, C; Ruiz, E; Casas, M; Fernández de SEvilla, T	Psychiatry Department and Unidad del CFS. Hospital Universitari Vall d´Hebron, Barcelona. Spain	Validation of a Neuropsychological Battery in a Sample of Patients with Chronic Fatigue Syndrome	IACSF/ME. 19 (2). Fall 2011. Abstracts from IACFS/ME Biennial International Conference. Poster Presentations. P174-175.	Objectives: Some cognitive deficits have been identified, although the findings are inconsistent and hindered by methodological heterogeneities. One of these limitations is the used neuropsychological battery. Some studies show that cognitive measures that share variance in healthy people can dissociate and contribute to unique variance in people with some cognitive impairment. They suggest that the validity in neuropsychological measures should be tested in homogeneous samples. The aim of this study was to test the validity of a neuropsychological battery in a sample of patients with CFS. Methods: Sixty-eight women, aged between 29 and 67 years-old and diagnosed with CFS according to the criteria of Fukuda were enrolled. We excluded patients with mental disorders (except depression reactive to illness) and organic diseases that can course with cognitive impairment. Patients were assessed with the following neuropsychological test: Mental Control, Paced Auditory Serial Addition Test, Digit Span, Symbol Digit Modalities Test, Stroop Test, Trail-Making Test, verbal fluency test, Tower of London test, Rey Auditory Verbal Learning test, Rey-Osterreith Complex Figure and Grooved pegboard. Twenty-five cognitive measures were obtained. Because the multidimensionality of the cognitive functions studied, principal components analyses including all the measures were carried in order to assure that each one was comprised of only one cognitive dimension. Results: The neuropsychological measures were categorized into 7 specific cognitive domains: Attention/concentration, divided attention, verbal memory, visual memory, executive functioning, problem solving and motor functioning. The Cronbach´s alpha for all analyses was upper than .05. Conclusion: This study proposes a validation of a neuropsychological battery in a homogeneous sample of CFS. This proposition could reduce one of the main limitations in the studies about CFS and cognitive functioning, such as the inconsistent findings associated to the different neuropsychological test used.
Anbu, AT	Dr Anbarasu Theodore Anbu, Consultant General Paediatrician and Clinical lead for Paediatric CFS/ME service, Alder Hey	Audit of Paediatric Chronic Fatigue Syndrome (CFS/ME) specialist service in Alder Hey Children's NHS Foundation	IACSF/ME. 19 (2). Fall 2011. Abstracts from IACFS/ME Biennial International Conference. Poster Presentations. P184.	Background: Alder Hey Children's NHS Foundation Trust is a teaching hospital in the North West of England. The Paediatric Multidisciplinary (MDT) CFS/ME specialist service was established in 2003 as part of the Department of Health initiative on developing services specifically for children of all ages with CFS/ME. The MDT team included Consultant Paediatrician as the lead, CFS/ME specialist nurse, senior physiotherapist, psychologist, consultant psychiatrist and a medical secretary. There

	Children's NHS Foundation Trust, Eaton Road, Liverpool, L12 2AP. UK. theo.anbu@alderhey.nhs.uk	Trust		were 91 children managed by this service in weekly dedicated CFS/ME MDT clinics by early 2008. This service was delivered based on the already existing guidance from the Chief Medical Officers report, National Service Framework for children, General Medical Council's good medical practice and the RCPCH publication. However in 2007 the National Institute of Clinical Excellence (NICE) published specific evidence based guidelines on the management of adults and children with CFS/ME (CG53) which is being actively followed now. Objectives: The objective of this audit was to review the standard of our care towards children and young people with CFS/ME based on the NICE guidelines CG53. Methods: This was a retrospective case notes audit of 50 children seen by our CFS/ME service between December 2003 and July 2008. The lead clinician completed the audit with the help from the Hospital audit committee. Results: There were 40 female and 10 male children with CFS/ME. The mean age of our study population was 12.3 years (range 7-16 years). 60% of the children were referred by other paediatricians. In 96% of the study population the symptoms persisted for more than 3 months. 62% had missed school at some time during their illness. The diagnosis was established by the MDT team in 42/50 and by other paediatrician in 6/50. Appropriate investigations were undertaken, other underlying diagnosis excluded, child and family focussed treatment plans initiated and additional information on the illness and support was provided to all patients as suggested by the CG53. However only in 93% of patients early symptom advice was provided. The mean duration from referral to the time seen in clinic was 7.4 weeks. Only 49% were seen within 6 weeks of referral as suggested by the CG53. All but one patient were managed as outpatients by the specialist team. Conclusion: Review of clinical care based on established evidence based standards has helped us in identifying areas for improvement and deliver high quality service to our children with CFS/ME. This could be used as a regular exercise on a regular basis.
Anbu, AT	Dr Anbarasu Theodore Anbu, Consultant General Paediatrician and Clinical lead for Paediatric CFS/ME service, Alder Hey Children's NHS Foundation Trust, Eaton Road, Liverpool, L12 2AP. UK. theo.anbu@alderhey.nhs.uk	Patient and Parent Survey in a Specialist Paediatric Chronic Fatigue Syndrome/Myalgic Encephalomyelitis (CFS/ME) Service in Alder Hey Children's NHS Foundation Trust	IACSF/ME. 19 (2). Fall 2011. Abstracts from IACFS/ME Biennial International Conference. Poster Presentations. P184-185.	Background: In the last 2 decades there is an increasing awareness and recognition of CFS/ME in children. The National Health Service in UK has established several specialist CFS/ME centres across the country to treat children with this severe debilitating illness. Unfortunately not all are able to access these services. Even if they access the quality of service delivery is variable. This is primarily due to inequality in service provision, lack of understanding of the aetiology of this condition and varied clinical knowledge and expertise of the clinical teams. In Alder Hey following the Department of Health initiative a local Multi Disciplinary Team (MDT) specialist service was set up in 2003. The team consisted of a consultant paediatrician, specialist nurse, physiotherapist, psychologist and a consultant psychiatrist. As it was relatively new area of practice it was believed that there were lot more to listen and learn from the children and their families how a high quality service could be delivered. Hence in 2008 patient and parent experiences survey was undertaken. Aim: To obtain qualitative information on patients and parents experiences of the CFS/ME service.

				Methods: The Commission for Healthcare Improvement (currently the Care Quality Commission) questionnaire was given to all families who attended the weekly clinics between February and April 2008. They were completed both by the child and the parent. The completed questionnaires were posted in a box to ensure confidentiality. The results were analysed by the audit department. Results: There were 52 children actively being managed at that time. The questionnaires were given to 25 families. 25 (48%) of patient population and 24 (46%) of their parents completed questionnaires. 13 (54%) children were between 16-18yrs of age. 18 (75%) of them were girls. 96% to 100% of the children and parent rated either certainly true or partly true with regards to the attitude and clinical knowledge of the health professionals. Only 83% to 87% of children and parent agreed that their appointments were at a suitable time. When specifically asked about *'what was good about the service'* 16/24 children and 18/24 parent felt that the team listened to them, was very patient, had good knowledge and understanding of the condition, sympathetic, very helpful, concerns taken seriously and believed them. When asked about *'things needed to be improved'* 9/24 children and 9/24 parents felt that they preferred information on alternative therapies and improved communication amongst ward staff and the CFS/ME team if admitted to hospital. Conclusion: It is encouraging to see the families' having positive healthcare experience. This survey focussed on the quality of the service delivery. It is vital that in future survey on the effectiveness of the different modalities of treatment they receive would overall improve how we manage children with CFS/ME.
Arroll, Megan A; Senior, Victoria	Department of Psychology, University of Surrey, Guildford, Surrey GU2 7XH Email: m.arroll@surrey.ac.uk	Symptom Typology and Sub-grouping in Chronic Fatigue Syndrome	Bulletin of the IACSF/ME. 17 (2). Summer 2009.	Background: Chronic Fatigue Syndrome (CFS) is a condition of unknown aetiology with a heterogeneous population. The variability in symptomatology produces difficulties in studying CFS, therefore this study aimed to establish symptom typology and sub-groups within a sample of participants by use of data reduction techniques. Methods: Two-hundred and forty-six participants completed two symptom measures (one of which evaluated CFS-specific symptoms and the other a general symptom checklist) which were subsequently combined and analysed. Symptom types were established with factor analysis, whereas sub-groups within the sample were determined by cluster analysis. Results: Five symptom types resulted from the factor analysis which were labelled *FMS-like, depression/anxiety, fatigue/post-exertional malaise, cognitive/neurological* and *IBS-like symptoms,* with the *FMS-like* accounting for the majority of the variance in the data. Cluster analysis illustrated that the sample could be divided into three sub-groups based upon the symptom reports. The clusters that emerged were formed of a low symptomatology sub-group (LSS-G), a medium symptomatology sub-group (MSS-G) and a high symptomatology sub-group (HSS-G), which, as the names suggests, signified symptom severity. Notably, these sub-groups did not differ in respect to age, sex, illness duration or time taken to gain a diagnosis which infers that the groupings were not influenced by demographic concerns. Conclusion: This study illustrated that symptomatology in CFS can be divided into

				distinct categories that concur with the most recent guidelines for the condition. Additionally, the illness can be separated into discrete sub-groups, although these groupings are linked to overall severity, rather than symptom types.
Baken, Don	Massey University, Palmerston North, NZ	The Third IiME International ME/CFS Conference 2008	Bulletin of the IACSF/ME. 16 (3). Fall 2008. P11-14.	I was lucky enough to attend this conference by adding it on to a previously planned work trip to Europe. I was invited to attend a dinner the night before with most of the speakers. I was struck by their enthusiasm about the issues associated with ME/CFS and their willingness to talk to others about these. This summary is an attempt to provide some of the information presented at the conference to people who were not able to be present.
Baraniuk, J; Raksit, M; Merck, S; RAvindran, M; Zheng, Y; Esteitie, R; Timbol, C; Van Meter, J	Megna Raksit, B.S. Center for Functional and Molecular Imaging, Georgetown UniversityMedical Center, LM 14 3900 Reservoir Road, Washington DC 20007 USA megna.raksit@gmail.com	Gulf War Illness: Effects of Exercise on Working Memory	IACSF/ME. 19 (2). Fall 2011. Abstracts from IACFS/ME Biennial International Conference. Poster Presentations. P194-195.	Objectives: Over 25% of the active duty military personnel from the First Persian Gulf War developed chronic multisymptom complexes that included Chronic Fatigue Syndrome, Multiple Chemical Sensitivity, and Post Traumatic Stress Disorder. These overlapping disorders form Gulf War Illness (GWI). This heterogeneous disorder presents challenges to delineating underlying causes as well as targeted treatment. We used fMRI to examine the effects of an exercise stressor on working memory to help phenotype subtypes of GWI. Methods: Veterans were eligible if they were active military duty for at least 30 days from 1990-1991. 18 veterans (average age 50; 12 male) were included. Subjects had identical fMRI protocols before and after VO2max bicycle ergometer stress tests that were done on consecutive days. Participants were trained outside of the scanner until proficient in the N-Back paradigm, which requires continual encoding and retrieval of information. Stimuli consisted of single letters (A, B, C, or D) presented randomly. The task was presented using a block design alternating between 0-Back and 2-Back. For 0-Back, participants pressed the correct button corresponding to the letter presented. 2-Back required pressing the button corresponding to the letter presented 2 letters earlier. Accuracy scores were used to separate participants into two groups: those who performed better after exercise and those who performed worse. Functional MRI data was acquired on a 3.0 T Siemens TIM Trio MRI scanner. Data were analyzed using SPM5 using a mixed-effects statistical analysis examining the brain activity for 2-Back>0-Back during the pre- and post-stressor sessions for each group. Results: Ten participants had increased accuracy: 0-Back by +3.12% (ceiling effect) and 2-Back by +19.8%. 8 subjects had decreased performance: 0-Back by -9.74% and 2-Back by -11.1%. The increased accuracy group showed greater activation after exercise in the caudate ($p<0.001$) and precuneus($p<0.001$). These are task related areas, indicating that this group of subjects recruited more cognitive resources to perform better after exercise. In contrast, those with decreased accuracy after exercise had less activation ($p<0.001$) in the dorso-lateral prefrontal cortex (DLPFC). While this area is also reliably activated by the N-Back, decreased DLPFC activation reflects cognitive inefficiency and failure to recruit additional resources. Conclusion: The group that demonstrated improved

				accuracy also showed increased activation in task-related areas, indicating that this group received cognitive benefits from exercise. However, the group of GW patients that suffered exercise related working memory deficits showed decreased DLPFC activation after exercise. This significant change points to their inability to recruit cognitive recourses during exercise-induced fatigue. These two distinct responses to exercise are one indication that the heterogeneous GWI can be subdivided for more targeted treatment.
Baraniuk, James N	James N. Baraniuk, M.D. Room 3004F 3-PHC Building, 3800 Reservoir Road, N.W.,Washington DC 20007-2197 USA cfsresearch@georgetown.edu	A Chronic Fatigue Syndrome (CFS) Severity Score Questionnaire	IACSF/ME. 19 (2). Fall 2011. Abstracts from IACFS/ME Biennial International Conference. Poster Presentations. P172-173.	Objective: Validate a CFS Severity Score based on the 1994 Fukuda criteria in order to have an instrument to compare subject complaints between groups and over time. Method: Two Cohorts of CFS, and healthy control (HC) subjects had history and physical examinations to see if they met clinical CFS case designation criteria. Subjects with previous psychiatric, chemotherapy, or chronic illness where fatigue was an element were excluded. After Cohort 1 was examined (n=329), different protocols but the same questionnaire were used with, Cohort 2 (n=212). Subjects scored the severities of the 9 Fukuda criteria for the previous 6 months on a 5 point anchored ordinal scale of: *No Complaints* (score=0); *Trivial* (1, symptom present but negligible impact); *Mild* (2); *Moderate* (3); and *Severe* (4). Fatigue scores of 3 or 4 defined CFS and chronic idiopathic fatigue (CIF). HC had Fatigue Scores of 0, 1 or 2. The sum of the 8 minor criteria (Sum8) was tested as a surrogate marker of the overall severity of adjunctive complaints. The distributions of Sum8 were explored to see if the 95th percentile (mean+2σ) for non-CFS groups could be used as a threshold to identify CFS subjects. Results: Fatigue Scores of 0, 1 or 2 defined 236 HC (bars on the left). 305 subjects had Fatigue Scores of 3 or 4. Putative CIF (n=36) had ≤ 3 positive minor criteria. CFS with Fatigue Scores of 3 had a mode for Sum8 at 15 to 19; the mode was 24 when 4 was the Fatigue Score. ROC tests found that Sum8=12 had 98.5% for specificity and sensitivity of 97.8% for CFS in this population. Hierarchical clustering found 4 clades each for CFS and HC. The largest CFS clade (CFS II; n=184) had high severity scores for fatigue, muscle pain, sleep & exertional malaise. The 2nd largest clade (CFS IV, n=51) had lower fatigue, memory, sleep myalgia and exertional malaise scores. CFS clade III (n=30) had fatigue, memory, muscle or joint pain. CFS clade I was an outlier group with fatigue and headache. The largest HC clade (I; n=168, 67% of HC) had low scores for all symptoms. HC II (n=49) had modestly elevated sleep scores (2.4). Myalgia and arthralgia in the mild to moderate range were present in HC III (n=25). HC IV (n=13) had moderate to severe headaches plus sleep and memory problems. These clades of co-existing complaints were highly dissimilar between the CFS and HC groups. Conclusion: The CFS Severity Score was robust for discriminating CFS from HC subjects in this population. Mechanisms underlying the clades are under investigation.

Y; Surian, A; Esteitie, R; RAvindran, M; Merck, SJ; Rayan, R; Adewuyi, O; O'Brien, S	PHC Building, 3800 Reservoir Road, N.W.,Washington DC 20007-2197 USA gwiresearch@georgetown.edu	Rate Bicycle Stress Test Performed on Two Consecutive Days	Biennial International Conference. Poster Presentations. P199-200.	testing. Methods: Subjects exercised on a Schwinn bicycle ergometer. Cardiopulmonary function was measured using mouthpieces and Vmax software. 27 GWI and 8 HC participated in 3 bicycle exercise stress test protocols: #1. 13 GWI and 2 HC had standardized ramped VO2max tests with exercise until physical limitations caused the test to end (*85%HR*). #2. 6 GWI and 4 HC cycled at 70% of maximum predicted heart rate for 25 min then accelerated to 85% without cardiopulmonary testing (*70%+85%*). #3. 11 GWI and 5 HC had VO2max tests that began with 25 min at 70% maximum heart rate that was followed by acceleration to 85% (*70%+85%* plus VO2max). Symptomatic Responses: Borg Dyspnea Scores were significantly higher for GWI subjects on DAY 1 (3.9; 2.8 to 4.9 [mean; 95% C.I.]; n=25) and DAY 2 (4.1; 3.1 to 5.0) than HC (1.4; 0.1 to 2.6; n=9; p=0.016 by t-test; and 1.3; -0.1 to 2.6; p=0.0053; n=8; respectively). On DAY 1, whole body pain and fatigue scores at rest and after exercise were in the 3 to 15 range on the 20 point anchored ordinal Gracely Scale for GWI (n=15) compared to 0 to 3 for HC (0.032≥p≥0.00005; n=8). DAY 2 results were marginally higher at 6 to 16 for GWI and 0 to 5 for HC (0.043≥p≥0.0000004). None of the HC subjects complained of pain or fatigue on either day. Adverse Events: Protocol #1. Three GWI had to stop because of fatigue and dyspnea with VO2max at 25%, 32% and 50% of predicted. A fourth had dyspnea and oxygen desaturation (88% by pulse oximetry). A fifth GWI subject stopped because their systolic blood pressure dropped by 22% as they neared 70% HR. Protocol #2. Two GWI had to stop after 25 min at 70% of maximum HR because of fatigue or muscle pain. A third GWI subject increased their HR by only 29% before stopping. Protocol #3. One GWI became so exhausted after 70% HR that within 15 minutes he had fallen asleep for 1 hour. One veteran who was otherwise healthy on examination could only exercise to VO2max of 48% of predicted before stopping because of dyspnea on both DAYs. This subject and another otherwise healthy appearing veteran both demonstrated orthostatic tachycardia (ΔHR>30 bpm). Energy Expenditures: In the two *70%+85%* protocols, HC expended more METs to reach 85%HR (7.95; 7.08 to 8.82) than GWI (4.94; 4.16 to 5.72; p=0.0015). On DAY 2, this significant difference was found for 70% HR in HC (5.00; 4.26 to 5.74; n=4 vs. 3.17; 2.54 to 3.80; n=6; p=0.0064). At 85% HR the variance of the GWI data was too large for a significant difference to be detected. Expenditures by GWI subjects were different on DAY 2 from DAY 1. Watts needed to reach 85% HR in ramped exercise for GWI were higher on DAY 1 (202; 160 to 245; n=13) than DAY 2 (170; 138 to 202; n=12; p=0.015 by paired t-test). In contrast, the 70%+85% protocol required more calories on DAY 2 (179; 155 to 203; n=12) than DAY 1 (162; 132 to 191; p=0.033) in a different group of GWI subjects. HC had no differences in energy requirements between DAY 1 and DAY 2. Conclusion: The 70%+85% VO2max test was the optimal provocation.
Baranuik, J; Zheng, Y; Ravindran, M;	Yin Zheng, M.S., Research Assistant	Effects of Exercise on Systemic	IACSF/ME. 19 (2). Fall 2011. Abstracts from IACFS/ME	Objectives: Thumb pressure tenderness (TPT) is an indicator of systemic hyperalgesia. Post exercise malaise is a chief complaint of Chronic Fatigue Syndrome (CFS). We

Timbol, C; Esteitie, R; Adewuyi, O	3800 Reservoir Rd NW, 3PHC 3004F, Washington DC 20007, USA yz46@georgetown.edu	Hyperalgesia in Gulf War Illness Patients with Chronic Fatigue Syndrome	Biennial International Conference. Poster Presentations. P197-198.	expect two days of bicycle exercise stress test to increase systemic hyperalgesia in Gulf War Illness (GWI) patients with Chronic Fatigue Syndrome. Method: We tested changes in systemic hyperalgesia in 14 GWI patients with CFS. Systemic hyperalgesia was measured by applying precisely controlled pressures to the thumb nail bed. Pressures were applied in ascending and descending fashion for 3 complete cycles, then 1 randomized cycle to eliminate patient expectation of pain levels. After each pressure, subjects reported their level of pain on a 0 to 20 point anchored ordinal scale. TPT test started at 5 pounds per square inch (psi) and ascended by 5 psi increments until subjects rated pain levels of at least 12 out of 20. Then, starting from the last highest psi, decreasing pressures by 5 psi increments were applied until a final pressure of 5 psi. Subjects completed two days of 25minute 70% maximum heart rate submaximal bicycle exercise stress test. TPT testing was performed on the first day (d1), before first exercise stress test on the second day (d2), and after second bicycle exercise stress test on the third day (d3). The plots of ascending/descending painpressure curves and random pain pressures were plotted and analyzed using Microsoft Excel. Results: A hysteresis pattern was observed in the ascending and descending cycle of the pain as function of pressure plots (PfPP). Patients consistently reported higher pain levels on the descending limb of the cycle compared to the ascending limb at the same pressures. The decreasing pressure limb generally had consistent, high pain ratings, even though the pressures were decreasing. Pain reports subsequently dropped rapidly to near 0 at 5 psi. The area between the ascending and descending limb of the PfPP generally decreased from d1 to d3 ($P<0.01$). This may indicate a learning effect by the subject being able to assess and report pain levels more reproducibly on d3 compared to d1. PfPP of randomized TPT testing on each day showed lower slope values postexercise compared to d1 preexercise ($P<0.0002$). A lower slope indicates lower pain levels at same pressure. This demonstrates a decrease in systemic hyperalgesia after two days of exercise stress testing. Conclusion: Thumb pressure tenderness testing effectively measures systemic hyperalgesia. Subjects perceived their nociceptive input on d3 more accurately than d1. This may indicate a spinal or supraspinal adaptation. *Decrease* in systemic hyperalgesia post exercise may indicate mechanism for benefit of exercise to GWI with CFS.
Baranuik, JM; Le, U; Petrie, K; Ali, M; Merck, SJ; Ravindran, M; Zheng, Y; Timbol, CR; Estieitie, R; Rayhan, R; Adewuyi, O	Uyenphuong Le, M.D. Room 3004F 3-PHC Building, 3800 Reservoir Road, N.W., Washington DC 20007-2197 USA cfsresearch@georgetown.edu	Blunted Nasal and Systemic Sympathetic Reflexes in Chronic Fatigue Syndrome	IACSF/ME. 19 (2). Fall 2011. Abstracts from IACFS/ME Biennial International Conference. Poster Presentations. P198-199.	Objective: Almost 73% of chronic fatigue syndrome (CFS) subjects have a form of nonallergic rhinitis that may be due to autonomic dysfunction. Isometric handgrip was used as a stimulus for sympathetic cardiovascular effects including tachycardia and the vasoconstriction of peripheral and nasal mucosal blood vessels that leads to hypertension. Methods: Isometric handgrip tests were performed in 41 CFS and 42 healthy control (HC) subjects. Nasal acoustic rhinometry to measure the volume of the nasal airspace and minimum cross-sectional area at the anterior nasal valve, and vital signs were

				measured during a sham period of no contraction, and during forearm and hand contraction to 30% of maximum strength. Results: Although HC were stronger then CFS, there were no differences in duration, pain intensity or tolerance of the handgrip. Incremental changes in vital signs were significant ($p<0.0005$) at exhaustion for both groups. However, only HC had significant increases in nasal Volume and Amin from sham. The % change was significantly greater for HC than CFS for Volume, Amin, SBP, DBP and HR. Some CFS subjects had paradoxical decreases in Volume and Amin, and no changes in vital signs. The study was repeated in 104 CFS and 60 HC (87 CFS and 55 HC had acoustic rhinometry). Significant differences were found for Amin%Δ, SBP%Δ, DBP%Δ and HR%Δ. Gender differences were present. DBP%Δ was significantly greater for HC females (29%; 20% to 38%) than CFS females (13%; 10% to 16%; $p=0.00005$). HR%Δ was significantly greater for HC males (20%; 11% to 29%) than CFS males (9%; 6% to 12%; $p=0.018$). Conclusions: CFS had significantly lower sympathetic effects on heart rate, blood pressure, and nasal vascular vasoconstriction than HC subjects in response to isometric exercise. Averaged acoustic rhinometry results were variable for CFS suggesting subsets with normal and hyporesponsive effects. One pattern of interest was found in CFS subjects who had immediate increases in all measurements when isometric contractions began, but decayed to smaller or negative %Δ with time. Frequency distributions of these responses may identify CFS subsets with dysfunctional "on demand" sympathetic discharge. These data support neurological dysfunction of mucosal and systemic sympathetic reflexes in the pathogenesis of CFS and the nonallergic rhinitis of CFS.
Baranuik, JN	James N. Baraniuk, M.D. Room 3004F 3-PHC Building, 3800 Reservoir Road, N.W.,Washington DC 20007-2197 USA cfsresearch@georgetown.edu	Distinct Cerebrospinal Fluid Proteomic Patterns in Clusters of CFS and Healthy Subjects	IACSF/ME. 19 (2). Fall 2011. Abstracts from IACFS/ME Biennial International Conference. Poster Presentations. P191-192.	Objective: The protein constituents of cerebrospinal fluid are its proteome. If central nervous system dysfunction contributes to CFS pathophysiology, then proteomes from CFS subjects should differ from healthy controls (HC). If CFS is a homogenous illness, then the patterns of proteins should be similar for all CFS subjects. However, if CFS is a heterogenous disorder, then different patterns of proteins may be found for subsets of CFS subjects. Method: Informed consent was obtained from CFS (n=59) and HC (n=18) subjects to have lumbar punctures. Cerebrospinal fluid was digested with trypsin for mass spectrometry. Of the 4,543 ion peaks detected, 880 were peptide ions that matched to 79 proteins (MASCOT software). Unsequenced ion peaks may be complex metabolites, have posttranslational modifications, or be technical artifacts. Subjects used our CFS Severity Score to estimate the severity of fatigue and the 8 minor (1994 Fukuda) criteria for the previous 6 months. The anchored ordinal scale of scored 0 for no symptoms, 1 for trivial, 2 mild, 3 moderate and 4 severe. Unsupervised hierarchical clustering of Severity Score created a phylogenetic tree with 4 predominant subsets of CFS subjects. Results: CFS clades were clade 1 (*C1*; n=31; 41% female; 47 yr), *C2* (n=9; 78% female, 52 yr), *C3* (n=11; 91% female; 46 yr), and *C4* (n=8; 62% female; 48 yr). The healthy control group (*H1*; n=18) had 44% females and average age of 41 yr. The average signal intensity for all peptide ions in a

				protein were compared between *H1* and the 4 CFS clades by 2-tailed Student's t-tests ($p<0.005$ for significance in this pilot analysis) after ANOVA ($p<0.05$). Proteins with the highest ion counts were NRAP (2 peptides), PTGDS, CAMKK2, ALB (81 peptides), TTR, CST3, TF and CLU. CFS clade 1 (*C1*) had higher levels of CST3, APOE, HP/HPR, APLP1, KLK6, APP, CP and FGA than *H1*. *C2* had 36 proteins with significantly higher average signal intensities than H1. These included the brain proteins AGT, B3GNT1, GSN, XIRP2, FBLN1, EFEMP1, SPARCL1, CLSTN1, NRCAM, NCAM1, and FN1. Complement proteins included CLU, C3, C4A,B, CFB, and CFH/CFHR1. Serine protease inhibitors were common (SERPINs F1, A3, and D1). The pattern suggested that *C2* had higher levels of brain-derived proteins than *H1*. TTR, SERPINA1 and the neural growth inhibitor DKK3 were significantly higher in *C3* than *H1*. These may also have had predominantly brain origins. ALB counts were highest in *H1*, and significantly higher than *C3*. *H1* also had significantly higher immunoglobulin peptides, HPX, APOA1, SERPINC1, and SERPINF2 than *C4*. Half of the proteins that were higher in *C1* or *C2* than *H1* were also higher in *H1* than *C4*. Conclusion: CFS phenotypes were defined by hierarchical clustering of CFS Severity Score results. These clades were associated with significantly different panels of proteins. The 4 CFS clades suggest at least 4 pathophysiologically distinct states. Factors that may enrich the brain protein fraction include brain injury with protein release into cerebrospinal fluid (e.g. *C1* and *C2*), and decreased plasma flux across the blood brain barrier (e.g. *C3*).
Baranuik, JN; Varghese, R; Adewuyi, O; DiPoto, C; Pannell, L; Ravindran, M; Merck, S; Zheng, Y; Timbol, C; Esteitie, R; Rayan, R	Rency Varghese, M.S., Biostatistics, Room 3004F 3-PHC Building, 3800 Reservoir Road, N.W., Washington DC 20007-2197 USA, cfsresearch@georgetown.edu	Distinct Clustering of Cerebrospinal Fluid Peptides and Other Ion Peaks in Clusters of CFS and Healthy Subjects	IACSF/ME. 19 (2). Fall 2011. Abstracts from IACFS/ME Biennial International Conference. Poster Presentations. P189-190.	Objective: Determine if proteomic differences were present between subsets of CFS. Method: Informed consent was obtained from CFS (n=59) and HC (n=18) subjects to have lumbar punctures. Subjects used our CFS Severity Score to estimate the severity of fatigue and the 8 minor (1994 Fukuda) criteria for the previous 6 months. The anchored ordinal scale of scored 0 for no symptoms, 1 for trivial, 2 mild, 3 moderate and 4 severe. Cerebrospinal fluid proteins were digested into peptides with trypsin before Orbitrap mass spectrometry. Ion peaks from mass spectrometry and CFS subjects' Severity Scores were grouped using "two-dimensional" unsupervised hierarchical clustering (MatLab). Results: The heatmap defined four clades of CFS subjects (*C1* to *C4*, columns) and five clades of ion peaks (*P1* to *P5*, rows) (Figure 1). Clade *P1* ion peaks were equivalent for all CFS clades and *H1* (Table 1). The exception was a subset of C4 (upper right). *P2* ion peaks were ranked *C3≈C4>H1>C1≈C2*. *P3* ions ranked CFS in the opposite way: *C1≈C2>H1>C3≈C4*. *C4* was significantly different from *H1* for peaks in *P4*. Ions in *P5* were ranked *C3≈C2>H1>C2*. Each ion clade had unique results Conclusions: These distinctive cerebrospinal fluid proteomic patterns for CFS subgroups suggest that distinctive pathophysiological mechanisms that lead to unique protein biosignatures may be associated with clinically defined subsets of CFS subjects.

Baranuik. JN; Esteitie, R; Adewuyi, O; Ravindran, M; Merck, S; Zheng, Y; Timbol, C; DiPoto, C; Rayhan, R	James N. Baraniuk, M.D., Room 3004F 3-PHC Building, 3800 Reservoir Road, N.W., Washington DC 20007-2197 USA cfsresearch@georgetown.edu	Medication Responses in Chronic Fatigue Syndrome (CFS) And Non-CFS Subjects	IACSF/ME. 19 (2). Fall 2011. Abstracts from IACFS/ME Biennial International Conference. Poster Presentations. P187-188.	Objective: There is a clinical perception that Chronic Fatigue Syndrome (CFS) subjects have greater drug sensitivity and "allergy" than the rest of the population. This perception was tested by assessing the symptoms associated with medication use in a group stratified by CFS status and gender. Method: 194 subjects answered a binary (yes-no) questionnaire (Simon GE, Daniell W, Stockbridge H, Claypoole K, Rosenstock L. *Immunologic, psychological, and neuropsychological factors in multiple chemical sensitivity.* Ann Intern Med 1993;119:97–100) to determine if "medications" (not further subdivided by drug class) caused any of 25 symptoms from the neurological (6 symptoms); musculoskeletal (5); airways (7); gastrointestinal (5); and skin (2) systems. Gastrointestinal- nausea, vomiting, diarrhea, abdominal pain, and heartburn; Neurologic- headache, dizziness, confusion, memory loss, nervousness, and visual change; Musculoskeletal- joint pain, joint swelling, muscle pain, weakness, and fatigue; Pulmonary- cough, runny nose, shortness of breath, sneezing, wheezing, sinusitis & chest pain; Dermatologic- skin rash and itching. Subjects used our CFS Severity score to estimate the severity of fatigue and the 8 minor criteria for the previous 6 months. The anchored ordinal scale scored 0 for no symptoms, 1 for trivial, 2 mild, 3 moderate and 4 severe. Fisher's Exact Test and T-tests were used to assess significant effects of gender and CFS status. Result: The subgroup of ALL CFS females had more frequent nausea (32% vs. 13%; p=0.013) and visual changes (19% vs. 4%; p=0.018) than ALL non-CFS females. ALL CFS males had nausea (26%; p=0.003) and dizziness (23%; p=0.006) compared to zero in ALL non-CFS males. However, these differences were misleading because many individuals had no symptoms, and so would not have adverse complaints or contact their physicians. Therefore, the 47% of CFS and 72% of non-CFS subjects with zero symptoms were removed. The remaining 65 CFS subjects had 5.6 symptoms (4.2 to 7.0, 95% CI). The 20 non-CFS subjects had 3.5 symptoms (1.8 to 5.2; not significant by t-test). Females in these subsets had no significant differences in symptoms frequencies. However, CFS males (n = 22) had more nausea (54.5% vs. 0%; p=0.067) and dizziness (50% vs. 0%; p=0.091) for non-CFS males (n = 4). Conclusion: The apparent higher prevalence of medication-related symptoms in CFS than non-CFS was biased by the large number of subjects with zero symptoms. When subjects with no complaints were excluded, there was no difference between CFS and non-CFS females, but a trend for CFS males to have had more gastrointestinal and neurologic symptoms than the non-CFS males. Overall, the equivalence of symptoms in CFS and non-CFS suggests that Multiple Chemical Sensitivity (MCS) may be an independent syndrome. These methods will direct our analysis of other irritants in this multiple chemical sensitivity questionnaire.
Bateman, Lucinda	[No address quoted]	CFS and the Exercise Conundrum	Bulletin of the IACSF/ME. Fall, 2006	Summary: Find a range of well tolerated physical conditioning activities and doggedly stick with it, even if it seems ridiculously insignificant. Learn to pace, assess, and re-adjust the type, intensity and duration of activity day by day to stay under the relapse threshold and avoid post-exertional malaise. Observe any pattern of activity at least a

				week before increasing the duration or intensity. Be careful about advancing any aspect of physical conditioning unless gradual increases are well tolerated. Recognize and respect the reality that CFS patients may have a point at which, physiologically, they will become more ill from physical activity and experience a substantial set back, even if the mechanisms are not entirely clear.

Medicine, Internal Medicine University of Utah; and Director, Fatigue Consultation Clinic, 1002 East South Temple, Suite 408, Salt Lake City UT 84102 USA. fcclinic@xmission.com	Gene Expression of Sensory Ion Channels, Adrenegic Receptors and Cytokines: Potential Biomarkers for CFS and Fibromyalgia	IACSF/ME. 19 (2). Fall 2011. Abstracts from IACFS/ME Biennial International Conference. P133-134.	Objectives: To determine whether baseline and/or post-exercise expression of genes involved in signaling and modulating sensory fatigue and muscle pain are potential biomarkers for distinguishing patients with Chronic Fatigue Syndrome (CFS) and Fibromyalgia Syndrome (FM) from healthy controls. Methods: Forty eight Patients with CFS-only or CFS with comorbid FM, 18 Patients with FM that did not meet criteria for CFS, and 49 healthy Controls underwent moderate exercise (25 min at 70% of age-predicted maximum heart rate on Air-Dyne). Blood samples were taken before and 0.5, 8, 24, and 48 hours after exercise. Leukocytes were immediately isolated in buffer, number coded for blind processing, and flash frozen. Using real-time, quantitative PCR, the amount of mRNA for 13 genes (relative to control gene) involved in sensory ion channel, adrenergic, and immune functions was compared between groups at baseline and following exercise. Visual-analogue measures of fatigue and pain were taken before, during, and after exercise, including concurrently with all blood samples. Changes in amounts of mRNA were correlated with these measures, with history of orthostatic intolerance and with blinded ratings of disorder severity by the treating physician derived from multiple clinics. Results: No gene expression changes occurred following exercise in Controls except for inconsistent increases in β-1 adrenergic receptor. In 71% of CFS patients, moderate exercise increased most sensory ion channels and adrenergic receptors and one cytokine gene for 48 hours. These post-exercise increases correlated with numerical ratings of fatigue and pain, and greater increases were shown by patients with higher physician ratings of disorder severity. In contrast, for the other 29% of CFS patients, adrenergic α-2A receptor expression was decreased at all time points after exercise; other genes were not altered. History of orthostatic intolerance was significantly more common in the α-2A decrease subgroup. FM only patients showed no post-exercise alterations in gene expression, but their pre-exercise baseline mRNA for two sensory ion channels and one cytokine were significantly higher than Controls. Conclusions: At least two subgroups of CFS patients can be identified by gene expression changes following exercise. The larger subgroup showed increases in mRNA for sensory ion channels and adrenergic receptors and a cytokine. Both self rated and physician-rated symptom severity was associated with greater post-exercise increases in these genes. The smaller subgroup contained most of the CFS patients with orthostatic intolerance, showed no post-exercise increases in any gene, and was defined by decreases in mRNA for α-2A adrenergic receptor. FM only patients can be identified by baseline

				increases in 3 genes. Post-exercise increases for 4 genes meet published criteria as an objective biomarker for CFS, and could be useful in guiding treatment selection for different subgroups.
Bazzichi, L; SErnissi, F; Scarpellini, P; Conseni, A; Giacomelli, C; DeFeo. F; Rossi, A; Bombardieri, S	Laura Bazzichi, Reumatologia - Ospedale Santa Chiara, Via Roma, 67, 56126 Pisa – Italy l.bazzichi@gmail.com	Neurocognitive Impairment in Chronic Fatigue Syndrome: Complained Symptom or Real Deficit? - An Objective Method of Evaluation	IACSF/ME. 19 (2). Fall 2011. Abstracts from IACFS/ME Biennial International Conference. Poster Presentations. P193.	Objective: Several symptoms reported by chronic fatigue syndrome (CFS) patients - including fatigue, headache, impaired concentration, attention and memory - suggest that the central nervous system may be involved in the pathophysiology of the syndrome. Coexisting psychological distress or a psychiatric disorder also may contribute to neurocognitive (NC) deficits. Since CFS shows a significant overlap with Fibromyalgia syndrome (FM), a comparison of the two groups of patients could be important to understand the relationship between fatigue and NC disorders. The aim of the present study is to investigate the prevalence of NC deficits in CFS patients compared to FM patients, using a standardized set of validated tests, and to understand how psychiatric disorders and intake of psychoactive drugs may interfere. Methods: 49 patients with a diagnosis of CFS (based on Fukuda criteria, 1994) and 26 patients with a diagnosis of FM (ACR criteria, 1990) were consecutively recruited. Patients with axis I current psychiatric diagnosis was excluded. Each CFS or FM patient was asked to fill a set of questionnaires on paper and perform a battery of NC computerized tests after blood analysis (9:00 am). CNS Vital Signs© (CNSVS)1 is a NC test battery developed as a routine clinical screening instrument. It is composed of 7 tests for the evaluation of Composite Memory, Verbal and Visual Memory, Processing Speed (PrS), Executive Function (EF), Psychomotor Speed (PsS), Reaction Time, Complex Attention (CA) and Cognitive Flexibility (CF). It returns a score for each item and a composite NC global score named Neurocognition Index (NCI), normalized for patient's age, school attendance and computer usage frequency. Results: Patients with CFS (♀ 26/49) had a mean age (SD) of 37.8 (11.5) years, while patients with FM (♀ 24/26) had a mean age (SD) of 43.0 (10.3) years (p=0.017). On a total of 75 patients, only 20 (26,6%) did not complain about NC problems. NCI was higher in CFS subjects (p= 0.02) and 16 CFS patients (32.7%) showed a real NC impairment, vs 12 (46.2%) with FM, considering a real deficit with a low or very low NCI. The items that differed the most were the PsS, the EF and the CG. PsS of all the patients correlated with disease duration (p=0.0004). Of the 55 patients with CFS and FM who complained about NC disorders, less than half showed low or very low NCI. Thirty-five patients out of 75 had not a psychiatric lifetime comorbidity, 20 patients (26.7%) had a mood disorder and 20 (26.7%) an anxiety disorder. Patients with such a comorbidity had a lower NCI (p=0.0044), in particular lower CA, PrS, CG, PsS and EF, independently on the diagnosis. Moreover, 23 out of 75 patients were taking antidepressant drugs (AD) and 18 benzodiazepines (BDZ). Between patients treated with BDZ and those treated with AD there were not significant differences. Conclusion: The 32.7% of CFS patients showed a real NC deficit, although the 68.6% complained about it. FM showed more severe NC impairments respect to CFS patients, independently on drug

				assumption and age. A deficit of neurocognitive functions seemed to be predominant in patients with psychiatric lifetime comorbidity, independently on the assumption of antidepressant or anxiolytic drugs and the diagnosis. Thus, CNSVS has proven to be a useful and easy tool for the assessment of NC impairments in clinical trials as well as in routine practice.
Bell, David S	Board Member, AACFS	Sleep Abnormalities in Chronic Fatigue Syndrome	Bulletin of the IACSF/ME. **Winter 2005 - 6**	Conclusion: Sleep symptoms should be pursued aggressively, and only if there is a good clinical response should the diagnosis be changed. Too often the patient with CFS hears the medical provider say, Aha, we have finally found the cause of your symptoms, only to be disappointed when treatment has little or no effect. This treatment failure then encourages alienation of the patient from the medical provider and increases both the frustration and confusion of the patient which, by itself, leads to greater distress.
Bell, David S	Board Member IACFS	Medical Literature Review	Bulletin of the IACSF/ME. Spring 2006	Pilot study of gene expression carrelates of post-infectious fatigue following infection with EBV in 5 subjects compared to 5 HLA-matched controls. Peripheral blood mononuclear cells harvested at diagnosis, every 2 weeks for 3 months then every 3 months for a year. Extracted RNA hybridized to microarrays spotted with 3,800 oligonucleotides. Gene transcription patterns following acute EBV infection in patients who developed prolonged fatigue differed from the matched controls, and some of these genes expressed differently related to immune function. Overall, gene expression during the acute illness was different for twenty three genes, and eight of these remained different after 6 months in cases. Four genes were more highly expressed in controls than post-viral cases. Of the genes expressed differently from controls, and 12 related to mitochondrial functions "including fatty acid oxidation, apoptosis, DNA repair and mitochondrial membrane." The authors concluded that despite a small number of genes evaluated, and small number of cases, "our preliminary results implicate mitochondrial dysfunction as a plausible physiologic perturbation in post-infective fatigue."
Bell, David S	dsbellmd@yahoo.com	Review of the Two-day Exercise Test with a Pediatric Case Report	Bulletin of the IACSF/ME. 16 (1). Spring 2008.	In the most recent *Journal of Chronic Fatigue Syndrome* there are two articles which may be the first to offer an objective proof of disability in ME/CFS. More importantly, if shown to be correct, they may give us an avenue to test and measure the biochemical abnormality which causes the symptom pattern.
Boneva, Roumiana; Jones, James F; Unger, Elizabeth R	Roumiana S. Boneva MD, PhD, Chronic Viral Diseases BranchDivision of High-Consequence Pathogens and	Evidence for Reduced Aldosterone in Persons with Chronic Fatigue Syndrome	IACSF/ME. 19 (2). Fall 2011. Abstracts from IACFS/ME Biennial International Conference. p136	Objectives: Aldosterone, a mineralocorticoid hormone of the adrenal gland, controls the absorption of salt and water in the kidneys and the intestine and thus the overall blood volume. Mineralocorticoid receptors in the brain are involved in regulation of blood volume and sympathetic outflow regulation. A few studies have suggested lower blood volume and lower heart stroke volume in persons with chronic fatigue syndrome (CFS) and some persons with CFS experience postural hypotension.

	Pathology, NCEZID, Centers for Disease Control and Prevention, 1600 Clifton Road, MS A15, Atlanta,GA 30333, USA rboneva@cdc.gov			Because altered cortisol secretion has been found in a number of CFS studies, adrenal dysfunction has been suggested. Surprisingly, only one prior study examined aldosterone in CFS, finding lower aldosterone in CFS compared to controls. The current study was performed to explore the hypothesis that aldosterone levels in persons with CFS may differ from those in controls of similar age, sex, and race. Methods: Participants were identified from a population-based study including 70 CFS cases who met the international 1994 CFS case definition and 212 controls of similar age and race. A morning blood sample, collected after participants rested 30 minutes in supine position, was used to test for serum aldosterone. Testing was performed at Quest Diagnostics using liquid chromatography tandem mass spectrometry (analytical sensitivity 1 ng/dL). The Wilcoxon nonparametric test was used for comparison of non-normally distributed numeric variables (aldosterone). Chi square test and logistic regression were used to assess magnitude of associations; for these tests aldosterone was dichotomized at its median value 4 ng/dL in controls, which also equaled the lowest normal lab reference value. Results: Cases and controls did not differ significantly in mean age (47.8 and 47.7, respectively) or race distribution (78.3% and 80.7% Whites, respectively). The CFS group had a higher proportion of women (91.3% vs 67.5%) and a higher mean body mass index than the control group (BMI, 28.9 vs 26.9), p<0.005 for both. The CFS group had lower aldosterone levels compared to controls (mean 4.46, median 3, range 1 to 19 ng/dL vs mean 6.05, median 4, range 1to 76 ng/dL, respectively), p<0.0001 (Wilcoxon non-parametric test). Persons with CFS were 65% more likely to have aldosterone level of <4 ng/dL, OR=1.65 (95% CI, 0.95-2.85), p=0.07. The OR changed slightly after adjusting for BMI, OR=1.58 (0.93-2.74), p=0.11, but minimally after adjusting for sex, OR= 1.69 (95% CI, 0.96- 2.97), p=0.07. A limitation of the study is that aldosterone was measured only in supine position (less sensitive for identifying alterations in aldosterone secretion) and information on dietary salt intake was not available. Conclusions: These results support a previous study's finding of relatively lower aldosterone levels in CFS subjects compared to controls. Further studies of aldosterone in CFS should measure its response to challenge such as salt restriction and changes in aldosterone levels from recumbent to upright position.
Boneva, RS; Jin-Mann, SL; Unger, E	Roumiana S. Boneva MD, PhD, Chronic Viral Diseases Branch, Division of High-Consequence Pathogens and Pathology, NCEZID, Centers for Disease	Risk Factors for CFS in Women: A Case-Control Study of Gynecologic History	IACSF/ME. 19 (2). Fall 2011. Abstracts from IACFS/ME Biennial International Conference. Poster Presentations. P187.	Objective: Chronic fatigue syndrome (CFS) is more common in females and is predominantly diagnosed in middle-age. We have previously found, in a Mid-Western population, that CFS in women was associated with endometriosis and hysterectomy and a tendency for earlier menopause. In this study, we used a different female population to examine sex-specific risk factors for CFS in women. Methods: A population-based survey in several counties in Georgia, USA, followed up by a nested case-control study. The reproductive histories of 84 women identified as having CFS either at a baseline (2007) and/or follow-up clinical study (2008) were

	Control and Prevention, 1600 Clifton Road, MS A15, Atlanta,GA 30333, USA rboneva@cdc.gov			compared to those of 73 women who were well and non-fatigued (controls) both at baseline and follow up. We used Chi square test for comparison of proportions and calculated odds ratios (OR) with 95% confidence intervals (95% CI) to measure the magnitude of associations between CFS and reproductive history variables. Results: CFS cases and controls were similar in demographic characteristics and had similar mean age at menarche (12 years). However, women from the CFS group reported significantly more gynecologic problems and surgeries than controls. These included: excessive menstrual bleeding [73.8% vs. 26.2%, OR 3.82 (1.95-7.48), p<0.001], bleeding between periods [48.8% vs 23.3%, OR 3.14, p=0.001], endometriosis [30.6% vs. 12.3%, OR= 3.01 (95% CI, 1.30-6.98), p<0.05], being menopausal [62% vs 37% of controls, OR=2.77, 95% CI, 1.38-5.59, p=0.002] and earlier age at menopause [mean±SEM, 37.6±1.3 vs 48.6±0.9 years, p=0.001. Compared to controls, women with CFS were significantly more likely to report: any gynecologic surgery [OR=4.12 (95% CI, 2.11-8.04), p<0.05], especially hysterectomy [OR=5.10 (2.47-10.52), p<0.05], removal of both tubes [OR =2.67 (95% CI,1.14-6.34), p<0.01], removal of ovaries [OR=2.07 (0.97-4.41), p=0.06]. Gynecologic surgeries in the CFS group occurred at a younger mean age than in controls: mean (±sd) 35. 9 (6.8) vs 41.5 (6.3) years for hysterectomy, 38.7 (sd 8.4) vs 45.1 (3.5) years for removal of both ovaries. Onset of fatigue occurred after surgery in 55% of cases (of those with data available) suggesting that not only removal of the uterus and/or ovaries but also pre-existing gynecologic conditions and hormonal abnormalities that lead to these surgeries may predispose to CFS. Conclusions: The high prevalence of excessive menstrual bleeding and bleeding between periods among women with CFS as well as the association between CFS and early menopause suggest that hormonal abnormalities with involvement of the hypothalamo-pituitary-gonadal axis may be contributing to the pathogenesis of CFS in women. The possible mechanism of these associations and their implications for diagnosing and treatment of CFS in women remain to be clarified.
Booth, NE; Myhill, S; McLaren-Howard	Applegate Orchard Lane, East Hendred, Wantage OX12 8JW, UK norman.booth@mansfield.ox.ac.uk	Mitochondrial Medicine for the Treatment of CFS/ME	IACSF/ME. 19 (2). Fall 2011. Abstracts from IACFS/ME Biennial International Conference. Poster Presentations. P150-151.	In 2009 we showed that 70 out of 71 patients with CFS/ME (Fukuda 1994 criteria) attending a private clinic had measureable mitochondrial dysfunction and were clearly separated from a control group of 53 normal, healthy people 1. The dysfunction was determined by the ATP Profile, a set of 5 different biochemical measurements of white blood cells (neutrophils) and their mitochondria. The degree of dysfunction, the Mitochondrial Energy Score, correlated strongly with the functional ability of the patients as measured on the Bell CFS Ability Scale. The Objectives of the present audit are to see if the mitochondrial dysfunctions can be corrected by a therapeutic protocol consisting of 1) pacing, 2) changes in diet, 3) nutritional supplements known to be essential to the biochemical processes of energy transformation by mitochondria, and 4) detoxification to remove toxic heavy metals and biochemical toxins causing or associated with the dysfunctions. Methods After

				the initial ATP Profile and recording of the CFS Ability patients participated in the basic treatment protocol. Depending upon the progress of each patient and other factors, patients whose results are reported here had the ATP Profile tests carried out a second time and for 4 patients a third time. We can therefore measure changes in mitochondrial function and functional Ability during the treatment protocol. Results All patients improved by at least 1 unit on the Bell Ability Scale (0-10) and some by as much as 6 units. About 25% moved into the normal region in both Mitochondrial Energy Score and CFS Ability, and the strong correlation between these quantities is maintained by the treatment protocol. The results of a patient who had the ATP Profile 3 times clearly demonstrate the importance of the detoxification part of the protocol. Conclusions Whatever the cause of CFS/ME, mitochondrial dysfunction which can affect every cell of the body is a major factor. Improved mitochondrial function produces improved functional ability and these can be achieved by a protocol of targeting mitochondria to give them their essential nutrients and to remove toxins that attack them.
Brenu, E; Marshall-Gradisnik, S; Staines, DR; Van Driel, M; Ashton, KA; Petersen, D	Ekua Weba Brenu, Faculty of Health Science and Medicine, Bond University, Gold Coast,Queensland 4229. Australia Email: ebrenu@student.bond.edu.au	The Effects of Vaccination on Immune Function in Chronic Fatigue Syndrome	IACSF/ME. 19 (2). Fall 2011. Abstracts from IACFS/ME Biennial International Conference. Poster Presentations. P171.	Objective: Flu like symptoms are a hallmark of Chronic Fatigue Syndrome/Myalgic Encephalomyelitis (CFS/ME). Additionally, most CFS/ME patients experience severe symptoms of toxin intolerance and hypersensitivity. As CFS/ME is associated with periodic immune dysfunction, patients may be more susceptible to influenza episodes compared to the normal population. Conversely, their inability to tolerate certain toxins and hypersensitivity responses may affect their immune response to routine vaccines. The purpose of this study is to examine the effects of routine vaccination on immune function in patients with CFS/ME. Method: CFS patients were selected based on the Centre for Disease Prevention and Control (CDC) case definition of CFS/ME. A total of 20 CFS/ME patients and 20 health controls were recruited for this study. Blood samples were collected from all participants prior to vaccinations, and 7 and 28 days post vaccinations. Immune parameters that were assessed on the samples included Natural Killer (NK) cytotoxic activity, NK phenotypes, cytokine secretion and the expression of lytic proteins. ANOVA and repeated measures were the statistical methods employed to analyse the data with p-value set to 0.05 as the criterion for significance. Result: Preliminary findings suggest a potential role of vaccines in the pathophysiology of CFS/ME. Conclusion: These results may be important for developing effective therapies for the management of CFS/ME and establishment of guidelines for immunization of this population.
Brenu, E; Tajouri, L; Marshall-Gradisnik, S; Staines, DR; Petersen, D	Ekua Weba Brenu HBSc, Grad Dip BMed, Faculty of Health Science and Medicine, Bond University, Gold Coast, Queensland	The Relationship between Steroid Hormones and Chronic Fatigue Syndrome	IACSF/ME. 19 (2). Fall 2011. Abstracts from IACFS/ME Biennial International Conference. Poster Presentations. P170-171.	Objective: Autoimmune diseases are known to affect more females than males. During pregnancy women with autoimmune diseases such as Multiple Sclerosis and Rheumatoid Arthritis tend to experience an improvement in their symptoms. In Chronic Fatigue Syndrome/Myalgic Encephalomyelitis (CFS/ME) which may resemble an autoimmune disorder, a similar observation has been made. Currently, there are limited data on the relationship between pregnancy and CFS/ME symptomatology;

	4229. Australia Email: ebrenu@student.bond.edu.au			however, this may be an important clue to understanding the mechanism of CFS/ME. The purpose of this study is to ascertain the role of gestational period in patients diagnosed with CFS/ME. Method: The study involves 55 patients diagnosed with CFS/ME based on the Centre for Disease Prevention and Control (CDC). Gene expression analyses using quantitative real time reverse transcriptase polymerase chain reaction (qRT-PCR) and genotyping protocols were used in assessing all PBMC collected from these patients. Result: Our preliminary results elucidated differential expression of genes involved in the gestational process in CFS/ME participants. These genes have also been implicated in some aspects of immune function. Conclusion: These results suggest a role of the gestational process in the mechanism of CFS/ME. These findings may be important for diagnostic and therapeutic purposes.
Brenu, Eku; Van Driel, M; Ashton, KJ; Ramos, SB; Keane, J; Staines, DR; Marshall-Gradnisnik S	Ekua Weba Brenu HBSc Grad Dip BMed, Faculty of Health Science and Medicine, Bond University Gold Coast, Queensland 4229, Australia ebrenu@student.bond.edu.au	Disparities In Innate and Adaptive Immune Cell Activities in Chronic Fatigue Syndrome	IACSF/ME. 19 (2). Fall 2011. Abstracts from IACFS/ME Biennial International Conference. p125.	Objective: Cell specific immune investigations have demonstrated a possible link between Chronic Fatigue Syndrome (CFS) and failure to maintain immunological homeostasis. The most common immune cells with known dysfunction in CFS are cytotoxic cells, Natural killer cells and CD8+T cells. This study examined cytotoxic function and markers in CFS patients at 6 months intervals to determine the stability of these observations over time. Methods: 90 CFS patients (mean age 46.5yrs ±11.7) and 50 healthy controls (mean age 41.9yrs ± 9.6) participated in the study. Flow cytometeric protocols were used in the assessment of cytotoxic activity and cell phenotypes and RTqPCR analysis in screening for levels of cytoxic molecules that depict the various cytotoxic pathways. These molecules include, granzymes, perforin, interferon (IFN)-γ and tumour necreosis (TNF-α). Results: Preliminary results indicate that compared to the healthy controls, CFS patients demonstrate significant decreases in cytotoxic activity at baseline, at 6 and at 12 months. Additionally, NK CD56 bright cells remained decreased in the CFS participants. Cytotoxic, molecules were also differentially expressed in these cells in comparison to the healthy group. Conclusion: This study demonstrates and confirms reduced immune function in patients with CFS. These findings substantiate the use of NK cell cytotoxic function as a potential biomarker for CFS.
Brenu, Ekua W; Ashton, KJ; Atkinson, G; Van Driel, M; Staines, DR; Marshall-Gradisnik, S	Ekua Weba Brenu,Faculty of Health Science and Medicine, Bond University, Gold Coast, Queensland 4229, Australia ekbrenu@bond.edu.au	Expression Patterns of miRNAs in Lymphocytes in Patients with Chronic Fatigue Syndrome	IACSF/ME. 19 (2). Fall 2011. Abstracts from IACFS/ME Biennial International Conference.p132.	Objective: MicroRNAs (miRNAs) and transcription factors regulate gene expression and thus are important in modulating the immune responses. Changes in these molecules may be implicated in diseases such as Chronic Fatigue Syndrome (CFS). A number of transcription factors have been shown to be upregulated in CFS patients. However, the role of miRNAs remains to be determined. As cytotoxic activity is decreased in Natural Killer (NK) cells and CD8+T cells, this study assesses the role of miRNAs molecules in CD8+T cells and NK cells in CFS patients. Methods: 30 CFS patients meeting the CDC case definition (45.3±11.7 yrs) and 30 healthy controls (41.8±9.6 yrs) were recruited into the study. Blood samples were collected from all participants following which lymphocytes were preferentially isolated via a negative isolation system to yield a pure sample of NK and CD8+T cells. RNA was extracted and

				converted into cDNA and miRNAs of interest were assessed using RT-qPCR. Statistical analysis was performed using the t-test. Results: Of the fifteen miRNAs investigated six were found to be down regulated in both the NK and CD8+T cells in CFS patients compared with healthy controls. Most of these miRNAs target genes that are involved in cell cycle regulation, apoptosis and toll like receptor expression. Conclusion: This study confirms changes in miRNA expression in cytotoxic cells that may be related to the poor function of these cells in CFS patients.
Brenu, Ekua; Ashton, KJ; Van Driel, M; Hardcastle, S; Staines, DR; Marshall-Gradisnik, S	Ekua Weba Brenu, Faculty of Health Science and Medicine, Bond University, Gold Coast, Queensland 4229, Australia ebrenu@student.bond.edu.au	Longitudinal Assessment of Adaptive Immune Regulation in Chronic Fatigue Syndrome	IACSF/ME. 19 (2). Fall 2011. Abstracts from IACFS/ME Biennial International Conference.p125-126.	Objective: Chronic Fatigue Syndrome (CFS) is known to persist for more than 6 months with a very slow recovery rate. It is not known whether immunological abnormalities in CFS remain stable over time or change during the course of the disease. Additionally cytokine measurements have not been consistent across studies which may be associated with the fluctuating pattern of the disease. This longitudinal study assesses proteins and receptors secreted and expressed by CD4+T lymphocytes in CFS patients over time, at baseline, 6 and 12 months. Method: 50 CFS meeting the CDC case definition and 30 non-CFS control participants were recruited from two states in Australia. Peripheral blood mononuclear cells were preferentially isolated from whole blood samples collected from participants. The samples were then assessed for the expression of Th1, Th2, Th17 cytokines, IL-1α, IL-1β and TGF-β using cytometric bead array and flex set kits. Result: At baseline there was an increase in IL-10, TNF-α and IFN-γ in the CFS group compared to the healthy control group. However, after 6 months IL-2 was significantly increased and IL-10 and IL-17A were significantly decreased in the CFS group while after 12 months only IL-2 was observed to be significantly increased in the CFS group. Conclusion: These results suggest that the cytokine profile in CFS changes during disease progression. This may be associated with disease severity and/or concurrent environmental stressors. Hence there is a need to match experimental findings with data on clinical disease progression.
Brenu, EW; Marshall-Gradisnik, S; Staines, DR; Petersen, D	Ekua Weba Brenu, Faculty of Health Science and Medicine, Bond University, Gold Coast, Queensland 4229. Australia Email: ebrenu@student.bond.edu.au	Assessment of Natural Killer Cell Function in Chronic Fatigue Syndrome/ME	IACSF/ME. 19 (2). Fall 2011. Abstracts from IACFS/ME Biennial International Conference. Poster Presentations. P171-172.	Objective: Immunological abnormalities are recognized as an important component of Chronic Fatigue Syndrome (CFS). Natural Killer (NK) cell dysfunction is the most common immunological finding across studies. It has been suggested that these reductions in NK cell function is caused by decreases in the expression pattern of perforin and granzyme molecules. However, other factors may be involved in NK cell dysfunction. Hence the purpose of this study is to investigate other potential mechanisms of NK cell dysfunction in Methods: This study examined samples collected from 20 CFS/ME subjects and 5 normal controls. CFS participants were preselected by demonstration of low NK cell function and diminished VO2 max on stress testing. Using flow cytometry and real time quantitative PCR, samples were assessed for levels of cytokines, lytic molecules and expression of miRNAs. Results: Preliminary data demonstrated differential expression of cytokines, miRNAs and cytotoxic molecules in the CFS/ME participants compared to healthy controls. Additionally, cytokines, perforin and granzymes were differentially expressed

				between groups for both the serum and CSF. Conclusion: These results confirm the observation of impaired NK cell function in, CFS/ME patients which may be related to alterations in cytokines and lytic proteins.
Brenu, EW; Marshall-Gradisnik, S; Staines, DR; Petersen, D	Ekua Weba Brenu, Faculty of Health Science and Medicine, Bond University, Gold Coast, Queensland 4229Australia Email: ebrenu@student.bond.edu.au	Purinergic Signaling in Chronic Fatigue Syndrome/ME	IACSF/ME. 19 (2). Fall 2011. Abstracts from IACFS/ME Biennial International Conference. Poster Presentations. P191.	Objective: Chronic Fatigue Syndrome (CFS) is a multi-factorial disease that involves abnormalties of neuro-endocrine immune function. Presently, a number of neuropeptides have been associated with CFS. This may be attributed to their role in regulating immune function. These neuropeptides are involved in purinergic signaling and their compromise may be associated with receptor differences or other derangements of the adenosine pathway. This study examines the expression pattern of purinergic receptors and the molecules in involved in the signaling pathways. Method: Cerebrospinal fluid (CSF) and peripheral blood mononuclear cells (PBMCs) collected from 20 CFS/ME and 5 normal control participants were examined for the expression pattern of the various purinergic receptors and second messenger systems using ELISA and gene expression protocols. Statistical analysis used in this study is ANOVA with p-value set at 0.05. Result: Preliminary data demonstrated differential distribution of purinergic receptors in CFS participants compared to the healthy controls. Similarly, ATP, cAMP and adenosine were also differentially expressed in the CFS/ME participants compared to the controls. Conclusion: These results suggest potential involvement of the CNS in the mechanism of CFS/ME. Further studies are required to assess the potential significance of these findings in CFS/ME.
Broderick, G; Ben Hamo, R; Efroni, Ma; Fletcher, Ma; Nathanson, L; Vernon, SD; Klimas, NG	Gordon Broderick, Ph.D., Associate Professor, Department of Medicine, University of Alberta, Suite 225B CollegePlaza, 8215 112 Street NW, Edmonton, AB, T6G 2C8, Canada; gordon.broderick@ualberta.ca	Prefential Pathway Activation in Gulf War Veterans with Unexplained Neuroendocrine-Immune Imbalances	IACSF/ME. 19 (2). Fall 2011. Abstracts from IACFS/ME Biennial International Conference. Poster Presentations. P178.	Objectives: Though potentially linked to the basic physiology of stress response we still have no clear understanding of GulfWar Illness (GWI). Indeed clinical presentation of GWI overlaps strongly with that of another stress-mediated illness: Chronic Fatigue Syndrome (CFS). Recent efforts by our group have cast individual molecular messages in the greater context of immune signaling and cellular demographics. Here, we extend this approach by incorporating *a priori* knowledge of biological pathways to support molecular discrimination of these sister illnesses. Methods: *Cohort*. Male CFS (n=7), GWI (n=20) and healthy veterans (n=11), comparable in age, body mass index (BMI) and ethnicity, were assessed using Fukuda criteria. Stress response was stimulated by way of a standard Graded Exercise Test (GXT) and blood drawn 30 minutes prior to exercise, at peak effort (VO2 max) and 4-hours post exercise while controlling for diurnal variation. Gene expression in circulating immune cells was measured using the Affymetrix HG U133 plus 2.0 microarray. *Computation*. Using a novel method we first assessed compatibility in the expression of genes supporting a pathway segment with the expected molecular association dictated by known biochemistry. For pathway segments supported consistently in the data we then estimated the likelihood that these step reactions were active in a specific sample. Pathway segment activity levels were computed in every sample in the response time course and then compared across patient groups using standard non-parametric tests. Results: Even at rest CFS and GWI patients were distinguished from each other

				and from controls with an accuracy of >85% with fewer than 3 pathways. Using progression across all 3 time points, single pathways were sufficient to separate groups. CFS and control subjects were distinguished with 85% accuracy by suppression of *alanine and aspartate metabolism* (KEGG) alone (pWilcoxon<0.0001). Similarly a classification accuracy of close to 80% was obtained for GWI subjects on the basis of activity in the *1- and 2-methylnaphthalene degradation* pathway (KEGG) (pWilcoxon=0.05), which appeared chronically suppressed in this group. Finally, CFS and GWI subjects were best distinguished with activity in *chondroitin sulfate biosynthesis* (KEGG) (accuracy >85%; pWilcoxon<0.0001). Complete separation of these illness groups was achieved with the addition of *aurora A signaling* (NCI/Nature) (pWilcoxon<0.0001) and signaling mediated by transmembrane protein *syndecan-1* (NCI/Nature) (pWilcoxon=0.024). Aurora A activity is a key component in mitosis and meiosis. It has been associated with a range of malignancies and is significantly increased in GWI vs. CFS. Conversely syndecan-1 has been used as a marker of effector B cell activity and is significantly depressed in GWI compared to CFS patients. Conclusion: Together these pathway segments supporting immune signaling, cytotoxic function and metabolism offer not only a framework for molecular diagnosis but also a glimpse into fundamental imbalances in immune cell signaling and metabolism in each illness.
Broderick, Gordon; Ben Hamo, R; Efroni, S; Katz, BZ; O'Gorman, MRG; Nathanson, L; Fletcher, MA; Vernon, SD; Taylor, R	Gordon Broderick, Ph.D, Associate Professor, Department of Medicine, University of Alberta, Suite 225B College Plaza, 8215 112 Street NW, Edmonton, AB, T6G 2C8, Canada gordon.broderick@ualberta.ca	Linking Lymphocyte Metabolites with Clinical Course in Post-Infectious Fatigue	IACSF/ME. 19 (2). Fall 2011. Abstracts from IACFS/ME Biennial International Conference. P127-128.	Objectives: Chronic Fatigue Syndrome (CFS) affects between 1 and 4 million individuals and costs an estimated $35 billion per year in lost productivity and health care. As CFS can follow Epstein-Bar virus (EBV) and other systemic infections, our objective was to describe differences in immune activation in post-infective CFS (PI-CFS) patients compared to recovered controls. Methods: We studied 301 Chicago-area adolescents prospectively over 24 months following diagnosis of monospot-positive infectious mononucleosis (IM). Cluster analysis of subjects chronically fatigued at 24 months (4.3% of cohort) revealed 3 clinical courses: i) a sustained increase in fatigue after an early partial remission (C1), ii) a monotonic decrease in fatigue (C2), or iii) a slow decrease in fatigue after a peak at 12 months (C3). Cryopreserved samples of peripheral blood mononuclear cells (PBMC) were also recovered from 7 PI-CFS subjects and matched recovered controls. Duplicate gene expression profiles were obtained in these samples using the GeneChip Human Gene 1.0 ST microarray (Affymetrix, Santa Clara, CA). A novel computational method was used to assign probabilities of discrete up and down-expressed states for each gene in every individual sample. These probabilities were then combined to identify consistent representation of known molecular interactions and quantify the activity level of close to 600 cellular pathways catalogued in the National Cancer Institute (NCI)/Nature Pathway Interaction Database (PID) and the KEGG database. Patients and patient groups were then compared statistically on the basis of the estimated activity levels of these pathways. Results: Previous analysis of plasma cytokines in this

				cohort indicated immune signaling anomalies specific to PI-CFS subjects and present to different extents in each fatigue sub-group. Consistent with this, 20% of expressed genes (of 92 with fold change>2, p<0.05) supported cell signaling and/or immune function. Close to half however (47%) supported cell metabolic function. Derivation of pathway activity levels in individual subjects greatly reduced the false discovery rates (FDRs) isolating 5 pathways with significantly altered activity in PI-CFS (FDR<0.10, p< 0.005). Phenylalanine metabolism and Trk neuronal receptor signaling were significantly suppressed in PI-CFS (p=0.002, 0.004; FDR=0.08, 0.09) while starch metabolism, glycolysis and pentose phosphate metabolism were up-regulated (p=0.000, 0.001, 0.003; FDR=0.04, 0.07, 0.09). Of these, phenylalanine metabolic activity also supported the separation of fatigue sub-groups, with higher activity being linked to a more favorable prognosis. Conclusion: These preliminary results suggest that observed differences in cytokine expression are consistent with altered metabolic activity in circulating lymphocytes in PI-CFS patients. These differences may also inform on the course and underlying causes of this illness.
Campbell-Smith, Dianna	[no address given]	Whole Body Vibration Used with Positive Psychology Strategies - New and Vital Component of Multi-Modal Treatment for Decreasing the Pain of Fibromyalgia/Chronic Fatigue While Improving Happiness Levels	IACSF/ME. 19 (2). Fall 2011. Abstracts from IACFS/ME Biennial International Conference. Poster Presentations. P148.	From a psychological perspective, working with clients who have been diagnosed with Fibromyalgia or Chronic Fatigue can be a challenging task in that there are both difficult physiological implications as well as a tendency towards concurrent depression. Using Cognitive Behavioural Therapy (CBT) with these clients has been researched and found to be somewhat effective. There is evidence that using a CBT approach is most effective when combined with exercise therapy and at times, pharmacotherapy as well. From an anecdotal point of view, using CBT alone does not always allow the individual with Fibromyalgia or Chronic Fatigue to move out of their pain enough to learn and integrate new ways of thinking or behaving. The pain is often described by clients as sapping all their energy such that there is little ability to undertake anything but the basics of their day to day requirements. When given homework which may well be able to help clients often say they just do not have the energy to do anything new. The research on multimodal approaches has been encouraging. To move out of depression requires that a client focus on new techniques and strategies but in order to utilize this focus some reduction in the pain and fatigue would more easily allow integration of new materials. There are a handful of research articles looking at the value of WBV to ease pain for Fibromyalgia and Chronic Fatigue clients. One such study used exercise alone as compared to exercise supplemented with whole body vibration. The conclusion of the study showed that exercise supplemented with whole body vibration was beneficial whereas exercise alone was not. Another study concluded that WBV helped with the balance aspects often a problem with Fibromyalgia. Further research into use of whole body vibration machines as part of a multi-modal approach is warranted. In this multi-modal approach it is suggested that clients would be taught how to use of techniques to

				increase their level of happiness while decreasing their experience of pain and fatigue. Given the research into pain reduction through use of wbv, as scant as it is, it suggests a number of sessions on a whole body vibration machine throughout the week. Each session would be increased from a few minutes up to ten minutes three times each week. Pain assessed on a weekly basis to ensure continued reduction would be required. Clients would learn how to integrate new ways of thinking that discover and take advantage of their own strengths such as creativity, love of learning, bravery and valour as determined from the Character Strengths (Peterson and Seligman, 2007). The research into pain reduction through use of WBV, as scant as it is, suggests a number of sessions on a whole body vibration machine throughout the week. In addition, counseling sessions could be used to displace habitual negative thinking by helping clients to integrate positive psychology thinking and activities. As is the case in counseling, a single style of therapy does not work for every client. Some are helped by Cognitive Behavioural Therapy, some by Narrative therapy and others may be helped by Art therapy. It is likely that in order to help a broader range of clients with Fibromyalgia or Chronic Fatigue that a number of different multi-modal strategies should be considered. Given some of the positive studies of whole body vibration, use of this equipment in conjunction with positive psychology techniques to increase happiness levels should be considered. Further research in this area is certainly warranted as anecdotal reports suggest that they may be some benefit.
Carruthers, Bruce M	[no address given]	The New International Consensus Criteria for ME: Content and Context	IACSF/ME. 19 (2). Fall 2011. Abstracts from IACFS/ME Biennial International Conference. P121.	Contents- the general thrust of the 2003 Canadian Consensus Criteria was retained and developed further. Several changes were made- e.g. the 6 month waiting period was no longer required, but left to clinical judgment. The symptom pattern of Post-Exertional- Neuroimmune-Exhaustion (PENE) was kept criterial and further articulated. Symptoms and symptom interactive patterns arising from the following subsystems- neurocognitive, pain processing, sleep disturbances, neurosensory and motor, immune, gastrointestinal, genitourinary and endocrine subsystems as well as energy transport impairments (cardiovascular, microvascular, respiratory, thermostatic homeostasis, intolerance of temperature extremes and stress intolerance) are noted if present. Interactive dynamical pattern matches between PENE symptom patterns and those from pathophysiologial subsystems for individuals and groups of patients are noted for causal projectability over time will be mutually confirmative as real kinds. Modifications for paediatric cases were added. The past historical context is described as well as future implications of this case definition plus any descendents are discussed regarding future research directions, case segregation, and treatments. In conclusion, it is hoped that this case definition and its descendents will continue to emphasize both the clinical/epidemiological/research realms of observation and challenge all participants to integrate them into a mutual confirmation/disconfirmation process that characterizes both clinical medicine, epidemiology and science in general.

Cheney, Paul R	[no address given]	Compassionate Use Treatment of CFS with GcMAF	IACSF/ME. 19 (2). Fall 2011. Abstracts from IACFS/ME Biennial International Conference. Poster Presentations. P151-152.	Introduction: GcMAF is a partially deglycosylated vitamin D binding protein (VDBP) also known as Gc protein. The functional change in the Gc protein caused by deglycosylation is known as GcMAF. GcMAF is extremely potent and will at very low concentrations activate, regulate and expand macrophages which are the central processing unit of the immune system and capable of modulating and controlling both the innate and cognate immune systems. Methods: Twenty-five CFS patients meeting the 1994 CDC criteria were selected from a national referral practice and under informed consent were self-treated with a semi-synthetic GcMAF administered by sub-lingual route. Previous reports from clinicians in The Netherlands using this commercial-grade version of human GcMAF suggested significant bioactivity and promising clinical responses in CFS cases in The Netherlands. Patients were monitored for blood chemistry, CBC, active and non-active forms of vitamin D as well as Nagalase activity. VDR polymorphisms determined from restriction enzyme products of BsmI and FokI were determined and a clinical instrument for symptom assessment of the seven key CFS symptoms was used to evaluate patient response. The protocol called for administering initially low doses of GcMAF at 20 ng SL every five days for the first 30 days followed by a q 5 day ramp to 100 ng SL using 20 ng increments. The study length was scheduled for 5 months but is being extended on a case-by-case basis. Results: Results are reported here for those eighteen CFS patients who have received a minimum of two months of sub-lingual GcMAF. 6/18 or 33.3% had a significant to clinically resolved response in at least two of seven critical CFS symptoms and two of those were functional cures at 80 KPS units or better. 5/18 or 27.8% failed to respond at all or even got worse over those same seven key symptoms. The remainder or 38.9% (7/18) had a mild to moderate improvement in two or more significant symptoms. A total of 72.2% (13/18) responded to GcMAF. VDR polymorphism data in 11 of 18 patients are known and the balance pending. Of these 11 with known VDR results, 3 of 4 who were non-responders were either BB or ff genotypes suggesting that if you had a BB or ff, you had a 75% chance of being a non-responder. On the other hand, there were no BB's in the best responding group of four suggesting that if you had a BB, there was no chance at all of being a significant responder or cure though there was a 33% chance of being a mild to moderate responder but only a 14% chance of being a member of the combined response group (1 chance in 7). Analysis of calcitriol levels demonstrated that there were three response patterns to GcMAF that were predictive of clinical response. All those with low to normal calcitriol to start with who then had a modest rise in calcitriol in response to GcMAF responded clinically (6/6). All those whose calcitriol was initially low to normal that did not respond at all to initial doses of GcMAF failed to respond clinically (4/4). In those with elevated initial calcitriol (>68) had a mixed response with 5 of 7 responding and 2 of 7 not responding. Initial D3 levels were variable and did not predict response nor did their response to GcMAF predict response. Nagalase activity was elevated in all study

				participants (average 3.4, range 1.3-6.5). 87.5% of the patients tested for XMRV were positive (14/16). In 6 of 8 with known response data, Nagalase activity declined with therapy and one patient declined to zero and is one of the recovered patients (KPS > 80). Conclusions: GcMAF appears to be a relatively benign and generally effective treatment for CFS. Most patients, however, had early though short bouts of what appeared to be exacerbations of CFS symptoms regardless of the eventual outcome. Two patients who were deemed responders developed clinical vitamin D toxicity later in their treatment heralded by a rapid rise in calcitriol above 90 as Nagalase dropped but responded very well to GcMAF dose reduction or elimination with no lasting effect on their previously good responses. Nagalase activity generally fell especially in the best responders and initial calcitriol response was predictive of outcome in most patients.VDR genomic data appears to also be a predictor of the relative chance of response vs. non-response to GcMAF.
Cheney, Paul R	[no address given]	Nagalase Activity is Inversely Correlated with CFS Clinical Status (KPS)	IACSF/ME. 19 (2). Fall 2011. Abstracts from IACFS/ME Biennial International Conference. Poster Presentations. P181-182.	Introduction: The sera of patients with HIV and cancer possess alpha-N-acetylgalatosidase enzyme activity known as Nagalase activity. This glycosidase activity appears to reside in the proteolytically cleaved gp160 envelope protein of HIV and also found in the similarly cleaved envelope protein of influenza virus and possibly possessed by other classes of virus that probably induces viral virulence as this glycosidase activity appears to be important in both cellular entry by virus-to-membrane fusion and immunosuppression. Nagalase activity specifically destroys the Gc protein (VDBP) precursor capacity for GcMAF activity leading to direct immunosuppression. Cancer cells also secret Nagalase activity that may come from genomic activation of HERV's within these cells or other viruses active within such cancer cells. In metastatic breast cancer, Nagalase activity correlates with tumor burden and Nagalase values dropping to control ranges near zero correlate with eradication of tumor cells resulting in a prolonged cancer free state lasting years. Nagalase has also correlated even better than CD4 counts for clinical status of HIV patients. Methods: We measured Nagalase activity in 50 consecutive CFS cases with an average age of 47.7 years. There were 20 males and 30 females from a national CFS referral center meeting the 1994 CDC CFS case definition. Serum Nagalase activity was measured in nmoles/min/mg protein by a commercial laboratory (ELN Labs, NJ). The idea to measure Nagalase was suggested by the detection of XMRV in the great majority of patients in this national practice (> 75% positive for XMRV with one measurement and > 95% if measured more than once at a CLIA certified laboratory, VIP Dx, NV). All patients during their office visits at this clinic are routinely given a physician assigned functional capacity score known as the Karnofsky Performance Score or KPS which has been well validated in both CFS and other chronic diseases. This clinic has had two decades of experience using this physician applied functional score including FDA sponsored clinical trials. Patients were sent kits for Nagalase testing and then assigned a KPS score in their charts. Inter-assay measures of KPS

				typically can vary plus or minus 5 KPS units over time by chance alone in CFS unless there is a significant shift in clinical status which usually occurs slowly over time. KPS is not a symptom score and expresses what the patient can and cannot do with respect to activities of daily living. Results: The Nagalase activity of 50 consecutive CFS cases reported here averaged 3.0 nmoles/min/mg protein, range 0.8 – 6.7. The Nagalase mean of CFS cases is comparable to HIV and comparable to breast cancer in respect to both mean and range. Average KPS was 59, range 40-90. Correlation statistics were developed for Nagalase vs. KPS. KPS was found to be negatively correlated with an r-square of 0.3, $p < 0.00005$, $N = 50$. The only two CFS cases with a KPS > 80 were at control values for Nagalase and one was our best responder to GcMAF (see GcMAF Abstract). XMRV detection rate in this 50 patient cohort was 77%, mostly single measures by culture and/or serology. Conclusion: Nagalase activity has been previously demonstrated to be an excellent clinical status marker in HIV and cancer. This data supports the hypothesis that Nagalase activity is also a good clinical status marker for CFS. The origin of Nagalase activity in CFS remains unknown but its finding in all disabled cases to date and that it correlates with clinical status along with the finding that almost all of the same cases are XMRV positive supports the hypothesis that XMRV may be the cause or contributes to Nagalase activity in CFS.
Chester. AC;	Alexander C. Chester, MD, Clinical Professor of Medicine, Georgetown University Medical Center, Washington, DC, 3301 New Mexico Ave, NW, Washington DC 20016, achester@foxhallinternists.com	Chronic Rhinosinusitis as an Overlooked Chronic Fatigue Syndrome Exclusionary Condition	IACSF/ME. 19 (2). Fall 2011. Abstracts from IACFS/ME Biennial International Conference. Poster Presentations. P177-178.	Objectives: To search for symptom similarities between chronic rhinosinusitis (CRS), a chronic fatiguing illness, and unexplained chronic fatigue (UCF). Methods: A MEDLINE literature search of the symptoms and natural history of CRS was performed. Results: Fatigue is one of eight symptom criteria formulated by the American Academy of Otolaryngology–Head and Neck Surgery Rhinosinusitis Task Force to establish the diagnosis of CRS. Chronic rhinosinusitis–related fatigue is associated with symptom severity scores approximating those of other CRS-related symptoms, including facial pressure, headache, and nasal discharge. In one series of patients with CRS, 86% of those surveyed noted fatigue, which was described as severe or very severe in 32% of patients surveyed and as the most disabling CRS symptom in 14% of patients surveyed. In the only meta-analysis comparing CRS vitality scores on the 36-Item Short Form Health Survey (SF-36) before and after sinus surgery, all preoperative vitality scores were below local norms. In the only series comparing CRS vitality scores with other disease norms, vitality scores were significantly lower (worse) than those of patients with congestive heart failure, chronic obstructive pulmonary disease, or chronic back pain. Fatigue associated with CRS improves after sinus surgery. Patients with CRS and severe fatigue demonstrate greater improvement in fatigue than the improvement noted in patients with less severe fatigue after surgery. Similarly, patients with CRS and concurrent fibromyalgia demonstrate greater improvement in fatigue than the fatigue improvement noted in patients without fibromyalgia. In a study of patients with UCF, CRS symptoms were significantly more common than in patients without UCF. Odds ratios (95% confidence intervals) for CRS symptoms in

				that study were 9.7 (5.2-18.2) for facial pressure, 21.9 (10.9- 44.0) for heavy-headedness, 3.1 (1.5-6.6) for sore throat, and 9.2 (4.3-19.7) for tender cervical lymph nodes. In a meta-analysis comparing CRS bodily pain scores on the SF-36 before and after sinus surgery, all preoperative bodily pain scores were below (worse than) local norms. Bodily pain associated with CRS improves after sinus surgery. Chronic rhinosinusitis usually begins with a significant upper respiratory tract infection, as is often observed with UCF. All UCF symptom criteria have been documented in CRS. Like UCF, CRS is not associated with objective findings. In patients with CRS, no abnormalities are noted on routine or specialized blood tests. Although sinus computed tomographic (CT) images can document sinusitis, symptoms usually do not correlate with CT findings, and the extent of abnormalities noted is often similar in patients with and without CRS symptoms. Conclusions: Chronic rhinosinusitis is a fatiguing illness usually unassociated with objective findings and defined by symptoms similar to those of UCF. Therefore, CRS should be considered a possible cause of otherwise unexplained fatigue and should be studied for atypical mechanisms that cause fatigue. In addition, CRS, a treatable illness, may easily be misdiagnosed as UCF.
Chia, John K; Chia, Andrew; El-Habbal, Rabiha;	John K. Chia, M.D., 23560 Crenshaw Blvd., #101, Torrance, Ca 90505, evmed@sbcglobal.net	Pathogenesis of Chronic Enterovirus Infection in Myalgic Encephalomyelitis(ME/CFS) –in vitro and in vivo Studies of Infected Stomach Tissues	IACSF/ME. 19 (2). Fall 2011. Abstracts from IACFS/ME Biennial International Conference. Poster Presentations. P142.	Objectives: Chronic enterovirus infection has been implicated in the pathogenesis of ME/CFS. Previously, we demonstrated enteroviral protein (VP1), RNA and non-cytopathic viruses from the stomach biopsies of ME/CFS patients. The basis of viral persistence has not been clearly defined. Enterovirus can form double-stranded RNA (dsRNA) in tissue cultures and in muscles of infected mice and human. We evaluated the presence of dsRNA in the stomach biopsies and possible infectivity of stomach tissues in SCID mice. Method: Archived, paraffin-embedded stomach biopsies from CFS patients and controls were stained for dsRNA using antidsRNA monoclonal antibody and immunoperoxidase technique. 9 cryopreserved ,VP1+ and dsRNA+ stomach biopsy samples were injected ip into SCID mice; and 2 boiled RNA+ samples, 4 VP1-neg and dsRNA-neg samples and one sample of culture medium were injected ip into other 7 SCID mice as controls. Mice were sacrificed 3-4 weeks after infection, and organs processed for viral cultures, EV RNA and viral protein staining. Results: 108/132 (82%) and 84/132 (64%) of the stomach biopsies from ME/CFS patients stained positive for VP1 and dsRNA respectively, whereas 4/40 (10%) of the control specimens were positive for dsRNA ($p<0.01$, $\chi 2$ test). Pretreatment with RNase III of selective samples diminished or abolished the dsRNA staining; higher concentrations of enzyme and incubation period were required for specimens from sicker patients. 21/23 (91%) of stomach biopsies previously tested positive for EV RNA by RT-PCR or had grown non-cytopathic virus were positive for dsRNA. Of organs taken from SCID mice injected with stomach biopsies, 7/9 (78%) spleen specimens were positive whereas 0/7 controls were positive for VP1 protein by immunoperoxidase staining ($p<0.01$, $\chi 2$ test). 4/9 lung specimens 0/8 of heart, liver and kidney sections demonstrated VP1 staining. All tissue homogenates were negative for EV RNA or

				growth of virus in BGMK-DAF and WI-38 cells. Conclusion: DsRNA was frequently demonstrated in the VP 1+ stomach biopsies taken from ME/CFS patients, and most EV RNA+ samples had detectable dsRNA. In pilot experiments, dsRNA+ samples were infectious in SCID mice, as compared to control samples. Enteroviral dsRNA may play a central role in the pathogenesis of chronic EV infection and ME/CFS, and the mechanism should be further investigated.
Chia,John K; Chia,Andrew	[no address given]	Rifampin Augments the Effects of Oxymatrine/Equilibrant (oxm/equi) In Patients with Myalgic Encephalomyelitis/CFS	IACSF/ME. 19 (2). Fall 2011. Abstracts from IACFS/ME Biennial International Conference. P117-118.	Objectives: Chronic enterovirus infection has been implicated in the immunopathogenesis of ME/CFS. Previously, we demonstrated the benefit of oxm/equi, an herbal immune booster, in 50% of ME/CFS patients. Concomitant administration of rifampin in one patient resulted in flu-like symptoms and ulceration of infected pharyngeal tissues, which was followed by symptomatic improvement and decrease of chronically elevated Coxsackievirus B3, 4 antibodies. We evaluated the adjunctive effect of rifampin in patients who were taking oxm/equi. Method: 46 patients who fulfilled the CDC criteria for ME/CFS were treated with rifampin 300 mg po bid for 7 days while taking oxm/equi (32 responders and 14 non-responders, duration 1.32±0.86 years). 45 patients treated with oxm/equi without rifampin, and 45 outpatients treated with doxycycline and rifampin for MRSA (methicillinresistant Staphylococcus aureus) infections served as controls. Laboratory studies including CBC, chemistry panel, CPK were obtained before and during treatment if patient had flu-like symptoms. Cytokine gene expression of peripheral blood was performed before and during rifampin treatment for 10 ME/CFS treatments. Results: 31/46 (67%) patients developed significant flu-like symptoms lasting few days during or after the one-week rifampin treatment. 23/33 (70%) of responders and 0/13 non-responders had additional improvement of fatigue and other symptoms ($p < 0.01$, X2 test). 21/33 (64%) responders who had taken oxm/equi ≥ 1-2 years were able to discontinue the herbs within weeks or months of flu-like symptoms and remained in remission. 0/45 ME/CFS patients on oxm/equi alone and 0/45 MRSA-infected patients on doxycycline and rifampin developed flu-like symptoms. Laboratory studies showed no significant changes, and gene expression study of 12 cytokines demonstrated increase of TNF-α and IL-1α,β mRNA while on rifampin and oxm/equi. Conclusion: Flu-like symptoms were commonly observed in patients who took oxm/equi concomitantly with rifampin, as compared to controls. Subsequent symptomatic improvement was observed in > 60% of oxm/equi responders. Short course of rifampin may be beneficial in ME/CFS patients who are responding to oxm/equi. The possible mechanism of enhanced immune response will be discussed and further investigated.
Claw, Daniel J	[no address given]	Session: FIBROMYALGIA: Are tender points necessary? A debate	IACSF/ME. 19 (2). Fall 2011. Abstracts from IACFS/ME Biennial International Conference. P119.	[no abstract available]

		Tender points are Unneccessary		
Coffin, J	Department of Molecular Biology and Microbiology, Tufts University, Boston, MA 02111,USA	The Case AGAINST Human Gamma Retroviruses (HGRV) in CFS/ME	IACSF/ME. 19 (2). Fall 2011. Abstracts from IACFS/ME Biennial International Conference. P116.	Xenotropic MLV-related retrovirus (XMRV) was first reported about 5 in a few cases of prostate cancer, but did not attract much attention until its reported association with a large fraction of chronic fatigue syndrome cases about 2 years ago. The publication of the XMRV-CFS connection created a ripple of excitement and interest in the scientific, medical, and patient communities reminiscent of the reports of the association of another retrovirus— HIV--with AIDS some 25 years previously. However, most of the results of the XMRV paper – isolation of infectious virus from patients, frequent detection of virus in plasma and PBMCs by PCR, detection of antiviral antibodies - remain to be replicated outside of the laboratories that authored the original report despite considerable effort worldwide. Indeed, XMRV is now considered by most virologists to be the consequence of a collection of artifacts originating from endogenous murine leukemia viruses prevalent in laboratory and wild mice. There are several related, but distinct, issues that need to be considered. First, various mouse (*Mus musculus*) subspecies carry over a hundred different endogenous proviruses closely (>90%) related to XMRV in their DNA. Second, mice are extremely widespread, as is their DNA, which can be found sporadically on laboratory surfaces, as well as contaminants of common reagents and materials. Sensitive PCR assays can detect "XMRV" related sequences in DNA from tiny fractions of one cell. To detect such contamination, we developed a more sensitive assay based on mouse IAP sequences present in thousands of copies per cell. Third, although only a few of the endogenous MLV proviruses encode infectious virus, it has been known since the 1970s that some of them can give rise to virus that can infect human tumor lines when passaged through nude mice. Indeed, A virus identical to XMRV is produced by the 22RV1 prostate cancer line that was derived in just this way. In initial reports, however, XMRV did not appear to be sufficiently similar to known proviruses to have been derived this way. However, we have recently shown that this is exactly how it did arise, but not from infection of the precursor CWR22 xenograft with a single virus, but rather with a recombinant between the progeny of two previously undescribed proviruses found in the nude mice used for passage. Since the predicted recombinant is ancestral to all XMRV isolates, and cannot have arisen more than once, it must have found its way into many laboratories as the 22Rv1 cell line was distributed worldwide and, by means that remain to be worked out, into clinical samples from CFS patients.
De Meileir, K; Rowe, C; Frémont, M	Himmunitas Foundation, Brussels, Belgium	*Naglase Activity is A Good Marker For ME/CFS*	IACSF/ME. 19 (2). Fall 2011. Abstracts from IACFS/ME Biennial International Conference. Poster Presentations. P192.	Objectives: The GcProtein or Vit. D binding protein is naturally transformed in the body by intervention of sialidase of T cells and beta-galactosidase of B cells thus removing 2 sugars from the Gc's protein's trisaccharide group, leaving a single sugar at the threonine location. The protein is now GcMAf and can activate macrophages. Previous research has shown that the enzyme alpha-N-acetylgalactosaminidase, called Nagalase, removes the entire trisaccharide group. Deglycosylated GcProtein

				cannot activate macrophages. Because ME/CFS patients often have reduced macrophage / NK cell function we hypothesized that Nagalase activity would be elevated in these patients. Methods Serum Nagalase activity was determined in 395 ME/CFS patients who met both the Canadian clinical criteria for ME (2003) and the Fukuda criteria for CFS (1994). The Nagalase assay was performed on serum. The blood was centrifuged within one hour of venous blood drawl and serum was frozen immediately till assayed. The assay method used is described in J. Med. Virol. 81:p.9 (2009) by Yamamoto et al. Healthy control sera exhibit very low enzyme activities. Statistical Analysis: A one-sided t test was used to test the hypothesis that the mean value of the ME group is significantly different from the middle of the normal range (representing the normal population). Results: Average serum Nagalase activity was 1.72 nmol/min/mg (range 0.28-4.0). This is significantly higher compared to levels in normal controls (0.35-0.68 nmol/min/mg) (Yamamoto, 2009). Only 12 of 395 patients had a Nagalase activity below 0.69 nmol/min/mg, or 3 % of the study population. Conclusion: When tested in a large cohort of ME/CFS patients, serum Nagalase is increased in 97 % of the study population. Irrespectively of the cause of these findings, serum Nagalase activity is a good marker to distinguish healthy people from ME/CFS patients. These data provide indirect evidence for low macrophage activity in ME patients.
De Meirleir, K	Vrije Universiteit Brussel & Himmunitas Foundation, Brussels, Belgium	Compassionate Use of GcMAF IN ME/CFS Patients	IACSF/ME. 19 (2). Fall 2011. Abstracts from IACFS/ME Biennial International Conference. Poster Presentations. P142-143	Objectives: Immune dysregulation is an established feature of ME/CFS, reflected in the altered balance of immune activity, allowing reduced protection from certain infections, viral re-activation, excess Th2/Th17 activity causing increased inflammatory symptoms and autoimmunity. This is the foundation for symptom expression as well as additional consequences of reduced immune protection (intracellular infection, fungal overgrowth, parasitic infestation, mould sensitivity). Recently the detection of gamma Retroviral (GRV) Infection involving Murine Leukaemic Virus (MLV) and Xenotropic Murine Retrovirus (XMRV) is shown in a majority ME/CFS and in 3-5% controls (Lombardi et al.). The resultant multisystem illness opens the door to a variety of treatment protocols, but despite this approach, the treatment response is slow, may plateau or not occur. GcMAF has been shown to enhance immune activity and has been used in the role of cancer therapy and in HIV. Its use in addressing the immune dysregulation in ME/CFS and complications has recently started (on compassionate grounds) in those in whom there is no significant response to other therapies, and who suffer marked limitation due to this illness. Methods: Patients (age 18-65) were selected in whom a diagnosis of ME/CFS was made, based upon history, physical examination, routine and specific investigations, and the fulfilment of the Canadian Clinical Criteria and who were diagnosed with XMRV and/or MLV. These included immune and viral studies. They were all XMRV and/or MLV positive. In those patients in whom there was serious illness, were refractory to other treatment protocols and marked limitation due to symptoms

				severity were administered GcMAF. It was used in a concentration of 100 nanograms/ml of physiological serum and administered by weekly injections of 0.25 ml to 1.0 ml by intravenous route or subcutaneously. There was regular follow-up throughout the treatment with review of symptom expression and investigations were performed to monitor treatment response. Duration of Treatment was for 5-40 weeks. *Table 1*- The effectiveness of treatment was assessed by symptom change and expression; monitoring of the condition by routine investigations; measurement of immune response (nagalase, CD57, Perforin, C4A, and comparison with other individual immune parameters shown to be abnormal at the initiation of therapy). Results: - *Table 2: Preliminary data on the outcome: 68/108 (63%) report noticeable improvement.* Side effects were present in 18 %; these mainly, were but not restricted to headaches and sleep disturbances. This was managed by lowering the dose, which usually solved the problem. Therapy was ceased in 7 % because of severe headaches and/or sleep disturbances. Delay in response may be attributed to VDR genotype and so effect of therapy may yet to be expressed amongst those regarded at this stage as non-responders. Conclusion: The use of GCMAF in XMRV+ and/or MLV+ patients ME/CFS patients for whom other treatments were refractory, has been shown to safely produce symptomatic relief when administered weekly for specific periods of time. These "positive" preliminary data need to be confirmed in a double-blind placebo controlled GcMAF study.
De Meirleir, K; Frémont, M	Vrije Universiteit Brussel & Himmunitas Foundation, Brussels, Belgium	GVDR-Fok1 and GVDR-Bsm1 Polymorphisms in ME/CFS Patients	IACSF/ME. 19 (2). Fall 2011. Abstracts from IACFS/ME Biennial International Conference. Poster Presentations. P190.	Objectives: Several researchers have demonstrated abnormalities in Vitamin D metabolism in ME/CFS patients. The individual degree of responsiveness of Vit. D binding protein – macrophage activating factor (GcMAF) is according to Ruggiero et al. dependent on Vit. D receptor (VDR) gene polymorphism, which can be identified by Bsm1 and Fok1, two SNPs (single nucleotide polymorphisms). VDR is also involved in skeletal metabolism, modulation of immune response and regulation of cell proliferation and differentiation. Fok1 is a T-C polymorphism; the T allele leads to a protein which is less effective in transduction of the Vit. D signal, the C allele with a higher response. Bsm1 is a C-T polymorphism. The C allele is associated with Th1 suppression and breast cancer, the T allele with SLE and RA. Given the published scientific studies on the immune system in ME/CFS, we hypothesized that both for Fok1 and Bsm1, the incidence of low responders to GcMAF is higher than in the general population, thus predisposing to a lower natural defense to viruses, intracellular bacteria, mycoses and parasites (low Th1/Th2 ratio). Methods: 185 ME/CFS patients were included in this study. GVDR-Fok1 & Bsm1 were determined. Based on Ruggiero's work we know that related to GcMAF: Fok1: C/C genotype: high responder (FF genotype) T/C genotype: moderate responder (Ff genotype) T/T genotype: low responder (ff genotype) Bsm1: C/C genotype: high responder (bb genotype) T/C genotype: moderate responder (Bb genotype) T/T genotype: low responder (BB genotype) Results: A one sided t-test was used to test the hypothesis

				that the mean % of the Bsm1 BB/Bb/bb and Fok1 FF/Ff/ff groups is statistically different from the average in the normal population according to reference percentages. For Fok1/Bsm1 ff/BB fenotypes (low responder) were significantly higher than in controls and FF/bb (high responder) were significantly higher in controls ($p < 0.001$). Discussion: When compared to the general population, more ME/CFS patients seem to be genetically low GcMAF responders, possibly explaining higher susceptibility for persistent infection. This finding can be added to the list of genetic predisposition factors which may predispose to the development of ME/CFS.
De Meirleir,K; Frémont, M; Metzger,K; Roelant, C	Vrije Universiteit Brussel, Belgium	Systemic Immune Actication in XMRV Positive CFS/ME Patients	IACSF/ME. 19 (2). Fall 2011. Abstracts from IACFS/ME Biennial International Conference. Poster Presentations. P140.	Objectives: Chronic activation of the immune system is present in progressive HIV infection and is a better predictor of disease outcome than plasma viral load. Several studies suggest that XMRV is involved in the pathophysiology of CFS/ME. We wanted to test the hypothesis that the systemic immune activation in XMRV positive CFS patients is similar to the one observed in HIV. Methods: Sixteen CFS patients fulfilling the Canadian criteria for CFS and were found positive for XMRV by co-culture technique were included in the study. Reference data were used from a large cohort of healthy individuals. Complete immunophenotyping was performed on venous blood and also elastase activity, C4a, IgG3, cytokines, sCD14, perforin were measured. Stool IgA was also determined. Statistical analysis was performed independently from our group by Professor D. Coomans (Vrije Universiteit Brussel / James Cook University). Results: The number of CD3+ and CD57+ lymphocytes was significantly lower compared to the reference values. C4a and elastase were significantly higher in the XMRV positive CFS population. Soluble CD14 (which codes for LPS in plasma) was significantly higher at $p < 0.001$ as compared to the reference population. The cytokine panel showed increased IL-10, MCP-1, MIP-1 beta and IL-8 serum levels. Other lymphocyte subsets showed no difference from the reference in the XMRV positive patients. Stool IgA and IgG3 were statistically lower in the MRV positive patients. Discussion: The results of this study show that XMRV positive patients have lymphocyte numbers and CD57+ lymphocytes below normal as is observed in HIV. XMRV positive CFS patients have an activated innate immune system (elastase activity and C4a are increased) which could be related to microbial translocation as their sCD14 is significantly higher than expected; sCD14 strongly correlates with plasma LPS. Low stool IgA also indicates dysfunctional mucosa-associated lymphomal tissue (MALT) in XMRV positive CFS patients. Furthermore their IgG3 serum levels are lower than in the controls. Serum levels of the cytokines IL-8, IL-10, MCP-1 and MIP-1beta are increased in the patients and might constitute a biological signature for the viral infection. These observations and other unpublished data on serum LPS in CFS patients, provide evidence for microbial translocation being part of the pathophysiology of XMRV positive CFS patients.
Donalek, Julie G	DePaul University Department of Nursing	Living with a Parent with Chronic Fatigue	Bulletin of the IACSF/ME. 16 (2). Summer 2008. P5-11.	Individuals experiencing ME-CFS are often parents. Yet the responses of family members to the parent's illness have not previously been explored. In this study, eight

		syndrome		children living or having lived in a family with a parent with ME-CFS talked about their lives. They described attempting to make some sense of their parent's illness, at times with limited information and support, attempting to deal with decisions around telling others outside the family, all while carrying increased responsibility within the family. Suggestions are made for assistance to these children and support for the family as a whole.
Dyke, JP; Weiduschat, N; Mao, X; Pillemer, S; Murrough, JW; Natelson, B; Mathew, SJ; Shungu, DC	Jonathan P. Dyke, Ph.D., Assistant Professor of Physics in Radiology, Weill Cornell Medical College, 516 E 72nd St., New York, NY 10065 jpd2001@med.cornell.edu	Assessment of Regional Cerebral Blood Flow in CFS Using Arterial Spin Labeling MRI	IACSF/ME. 19 (2). Fall 2011. Abstracts from IACFS/ME Biennial International Conference. P138-139	Objectives: Chronic Fatigue Syndrome (CFS) is an unexplained illness characterized by debilitating fatigue that is not ameliorated by sleep [1,2]. In two previous independent samples of CFS, we found increased ventricular lactate, which we had postulated to be due to oxidative stress, a secondary mitochondrial dysfunction and/or decreased regional cerebral blood flow (rCBF). To investigate the latter possibility, we used arterial spin labeling MRI[3] to compare rCBF in patients with CFS, and in age-and sex-matched patients with major depressive disorder (MDD) and healthy volunteers (HV). Methods: Fourteen CFS [31.9±8.6 yrs, 3M/11F], 13 MDD [31.4±9.9 yrs, 5M/8F] and 13 HV [27.6±7.4 yrs, 6M/7F] subjects were recruited for this study. The two patient groups were psychotropic medication-free for at least 1 week prior to scanning. rCBF was measured in each participant using ASL on a 3.0T GE MRI system. The resulting rCBF images were reconstructed on-line and normalized to the Montreal Neurological Institute (MNI) PET template. Groupwise voxel-based analysis of the ASL data was performed using SPM version 5, followed by between-group ANCOVA comparisons in which age and gender were covariates. Results: Significantly decreased rCBF values were found in the left anterior cingulate cortex (ACC) [p=0.039] and the right lingual region [p=0.016] in CFS compared to HV, while a trend toward significantly lower rCBF was found in the left ACC region in MDD subjects compared to HV [p = 0.08]. rCBF values for CFS and MDD did not differ significantly [p>0.05]. Conclusion: The present finding of decreased rCBF in CFS is consistent with prior measurements using 111Xe-CT[4] or ASL[5], although less pervasive and more spatially focused, which might be due to methodological differences. Our observation of a trend toward hypoperfusion in the ACC in MDD, a region where we had previously reported finding amino acid neurotransmitter abnormalities[6], provides further evidence for the involvement of this brain structure in the disorder. Due to the relatively limited spatial extent of the rCBF decrease in CFS, it is unclear whether the resulting hypoperfusion would account for our previous observation of elevated ventricular lactate in the disorder. However, it should be noted that the rCBF values in individual voxels throughout the brain were largest in HV and lowest in CFS, which could cumulatively lead to global hypoperfusion and to lactate increases. Larger studies in well-characterized subjects are warranted to confirm this possibility, as well as the overall results of this pilot study. [1] Mathew et al, NMR Biomed 2009; 22:251. Enlander, Derek; Riedman, Thomas	[no address given]	Enhanced External Counterpulsation in the Treatment of Chronic Fatigue Syndrome by Improving Cardiac Output	IACSF/ME. 19 (2). Fall 2011. Abstracts from IACFS/ME Biennial International Conference. Poster Presentations. P148-150	Introduction: The etiology of Chronic Fatigue Syndrome (CFS) is unknown and has been related to many different pathophysiological disorders including virological, immunological, neuroendocrine, genetic and psychiatric sources.[1-9] . In 2003, Peckerman and coworkers [10-12] suggested CFS may be related to impaired circulation, specially reduced stroke volume (SV) and cardiac output (CO) [10]. The more severe patients suffered from postexertional fatigue, the more serious was their CFS, and proportionally the lower their CO. We hypothesized that a treatment that can increase CO may then improve the CFS symptoms. It has been known for many years that abnormal venous return will lead to reduced cardiac output, orthostatic tachycardia and in turn failure.[10-12]. It has been suggested that this disturbance is at a cellular or subcellular mitochondrial level. [13-21] or a carnitine metabolic problem [22-28] Enhanced external counterpulsation (EECP) is a circulatory assist device.[15] . EECP operates by wrapping three sets of cuffs around the lower extremities, compressed during diastole to squeeze both arterial and venous blood back to the heart, increasing coronary perfusion and right ventricular filling pressure. The compression is released during systole, effectively increases peripheral arterial capacitance and lowers the impedance to cardiac ejection as well as systolic workload. The counterpulsing action to the heart by the EECP system has been shown to increase SV, CO, systemic blood flow velocity, and shear stress acting on the endothelial cells, stimulate endothelial function, including release of angiogenesis factors that promote collateral and improve microcirculation. Currently in the United States EECP Therapy has been FDA approved for use in unstable and stable angina pectoris, acute myocardial infarction, congestive heart failure and cardiogenic shock. Objective: The primary objectives of this study were to examine the changes in stroke volume, heart rate, and cardiac output measured by thoracic electrical impedance cardiography (ICG) after a course of EECP therapy in patients suffering from CFS without evidence of coronary artery disease , and to evaluate whether EECP therapy reduced the severity of CFS. EECP treatment has been shown to increase CO in patients with refractory angina, and in patients with heart failure, it has not been used in CFS patients with reasonable normal SV and CO. CFS patients with coronary artery disease were excluded from this study in order to eliminate an important variable. If there were improvements in the functional capabilities of the patients, it is due to reduction in the severity of CFS and not their cardiac functions. Another objective for this study was to identify whether there are any relationships between SV and CO and CFS severity, particularly any relations in the changes in SV and CO to changes in CSF severity after EECP treatment. Methods Patient Selection: This study enrolled twenty patients seeking treatment between 2009 to 2010 in a New York city clinics satisfying the Fukuda case definition of CFS by the Centers for Disease Control

				and Prevention National Center for Infectious Diseases and Canadian Consensus definition [16,17,18] with unexplained persistent or relapsing chronic fatigue that is not the result of ongoing exertion, is not substantially alleviated by rest, and results in substantial reduction in previous levels of occupational, educational, social, or personal activities, and concurrently suffering from four or more of the following symptoms: substantial impairment in short-term memory or concentration; sore throat; tender lymph nodes; muscle pain; multi-joint pain without swelling or redness; headaches of a new type, pattern, or severity; unrefreshing sleep; and post-exertional malaise lasting more than 24 hours. These symptoms must have persisted or recurred during 6 or more consecutive months of illness and must not have predated the fatigue. Conditions that exclude a diagnosis of CFS include any active medical condition that may explain the presence of chronic fatigue, such as untreated hypothyroidism, sleep apnea and narcolepsy, and iatrogenic conditions such as side effects of medications, any past or current diagnosis of a major depressive disorder with psychotic or melancholic features; bipolar affective disorders; schizophrenia of any subtype; delusional disorders of any subtype; dementias of any subtype; anorexia nervosa; or bulemia nervosa, and alcohol or other substance abuse that occurred within 2 years of the onset of chronic fatigue and any time afterwards. Study Design: CFS severity measure: After signing an informed consent form, patients without evidence of coronary artery disease and satisfying the enrollment criteria of suffering from CFS were asked to complete a battery of questionnaires concerning their demographics, medical history, family risk factors, medications and were assigned by a physician Karnofsky Performance Status scores (KPS) to assess their CFS severity levels. KPS is a general activity and medical care requirements measure to evaluate patient's ability to carry on normal daily activity and work or require custodial care using a 0-100 point scale, ranging from 0-30 as severely disable, unable to care for self, 50-70 as unable to work but able to live at home with varying amount of assistance needed, and 80-100 as patients who were able to carry on normal activity and to work. CFS severity levels were reassessed by the physician at the end of the last EECP treatment hour. Cardiac stroke volume and output: The SV and CO of each patient were measured using an impedance cardiography device (Casmed, Lifegard® ICG Non-Invasive Hemodynamic Monitor, Branford, CT, USA). The device sends out a constant electrical current via electrodes in the neck and abdominal to quantify the heart’s mechanical activity by measuring the changes in impedance to the current which is proportional to the resulting change in blood volume (stroke volume) and velocity in the aorta (cardiac output) with each cardiac cycle. Patients were asked not to consume anything with caffeine for 4 hours before measurement performed in a quiet temperature controlled room in the supine position. The means of two recordings of 30 seconds data were used for analysis. Heart rates were measured using an electrocardiograph unit. The SV and CO measurements were done at

				baseline before the first hour of EECP and repeated post-EECP after the last hour of treatment. Enhanced External Counterpulsation: The treatment is administered to patients on an outpatient basis. EECP therapy systems are Food and Drug Administration (FDA) cleared for marketing in the treatment of stable and unstable angina, congestive heart failure, acute myocardial infarction, and cardiogenic shock. Patients The EECP treatment system (Vasomedical, AngioNew VI, Westbury, NY) consists of three sets of inflatable pressure cuffs wrapped around the calves, the lower and upper thighs, including the buttocks. The cuffs are rapidly and sequentially inflated, starting from the calves and proceeding upward to the buttocks at the beginning of diastole of each cardiac cycle, creating an arterial retrograde flow along the aorta towards the heart and significantly increasing blood flow to the coronary arteries at a time when resistance to coronary blood flow is at its lowest level. The inflation of the cuffs also simultaneously increases the volume of venous blood returned to the right side of the heart providing greater filling of the right and left ventricles. Just prior to the next heartbeat, when the heart begins to contract, all three cuffs simultaneously deflate, leaving an empty vascular space in the lower extremities to receive blood ejecting from the heart, thereby significantly reducing the workload of the heart. The inflation/deflation activity is monitored constantly and coordinated by a microprocessor that interprets electrocardiogram signals, monitors heart rhythm and rate information, and actuates the inflation and deflation in synchronization with the cardiac cycle. The inflation/deflation cycle is repeated for every heartbeat, increasing energy supply to the heart, improving SV and CO, while at the same time reducing the workload of the heart. Patients in this study received 35 hours of EECP treatment, one hour daily, five days per week over seven weeks for a total of 35 sessions. Statistical Analysis: The severity of CFS as evaluated by KPS scores as well as SV and CO measured by ICG before and after EECP treatment were compared using 2-tailed paired Student t-test. Changes in CFS severity versus changes in SV and CO were analyzed using a paired-difference t-test. Correlation between CFS severity levels versus SV and CO were analyzed using Pearson R values as well as linear regression analysis. All data are reported as mean ± SD with p values < 0.05 being accepted as statistically significant in all analyses. Results: This study enrolled 20 patients, 5 males and 15 females, average age 46.4 ± 14.0 (range 29 to 75) years old. All patients had no evidence of coronary artery disease (CAD), but 35% had immediate family history of CAD. All patients reported suffering from massive fatigue during the past 9 months to 30 years, 85% with difficulty sleeping and serious depression. All patients completed the 7 weeks EECP treatment without any adverse events or complications due to the application of pressure to their lower extremities. Effects of EECP treatment in CFS and hemodynamic functions. The severity levels of CFS as measured by KPS before and after 35 hours of EECP therapy improved significantly from 56.2 ± 8.3 to 62.1 ± 9.6 ($p<0.05$) while the SV also increased

				significantly from 50.2 ± 10.6 to 58.5 ± 11.9 ml (p=0.02), as shown in Figure 1. The heart rate did not change from 79.2 ± 10.2 before EECP to 77.7 ± 8.5 beats/min after EECP treatment. CO also increased significantly from 3.9 ± 0.7 to 4.5 ± 0.8 L/min (p=0.017), also shown in Figure1.
Evangård, Birgitta	Professor of Infectious Diseases, Umeå University, Sweden	When the American Association of Chronic Fatigue Syndrome turned international	Bulletin of the IACSF/ME. 16 (4). Winter 2008/2009. P3-6.	We have known for many years that Chronic Fatigue Syndrome, CFS, can be found in all countries. It was already described in 1869 as a syndrome by the American neurologist George Beard and has since been described as occurring in epidemic form in the US (1934) , Iceland (1948) and in the UK during the 1950ths. In the 1980's an outbreak was described in the Lake Tahoe area in the US and at the end of last century researchers recognised the size of the problem in Japan. After the outbreak in Nevada, the US government funded American researchers through the Centers for Disease Control (CDC) and the National Institutes of Health (NIH) to research the syndrome. Except for the outbreaks described, cases have been reported as sporadically occurring. Epidemiological research has shown similar prevalence rates in the US, Japan, and Europe with CFS occurring in around 0.5% of the population.
Falkenberg, Virginia R; Whistler, Toni; Murray, Janna; Unger, Elizabeth R; Mangalathu, S	Virginia R. Falkenberg PhD, Chronic Viral Diseases Branch, Division of High-Consequence Pathogens and Pathology, NCEZID, Centers for Disease Control and Prevention, 1600 Clifton Road, MS G-41, Atlanta, GA 30333, USA fse9@cdc.gov	Promoter DNA Methylation and Expression of Perforin in CFS and Controls	IACSF/ME. 19 (2). Fall 2011. Abstracts from IACFS/ME Biennial International Conference. P126-127.	Objectives: Perforin plays a key role in immune surveillance and several studies report decreased perforin protein and mRNA in peripheral blood of patients with chronic fatigue syndrome (CFS). Factors that modulate gene-environmental interaction and thus the pathophysiology of disease include gene silencing by DNA methylation. The objectives of this study were to determine the pattern of perforin gene methylation in conjunction with perforin gene expression and whether these features were altered in CFS. Methods: Subjects (34 CFS and 47 non-fatigued, NF) selected from a population based study underwent the Trier Social Stress Test (TSST), a standardized psychosocial test that induces stress, and is known to influence cortisol secretion. Blood samples were collected prior to (10:30am, T1), and after the TSST (3:05 pm, T2). DNA extracted from peripheral blood mononuclear cells (PBMC) was used to examine site-specific CpG methylation levels in the methylation sensitive region (MSR) of the promoter (sites -876, -776, -744, -720, -691, -670 and -650). This was quantified by bisulfite treatment of DNA followed by pyrosequencing. RNA from PBMCs collected at the same time points was used to quantify perforin mRNA expression by LightCycler real-time RT-PCR. Total RNA from peripheral blood collected at the same time points was used in the Affymetrix Human Exon Array 1.0 platform. Results: Methylation of the MSR ranged from 38%-79% and no differences in CpG site-specific methylation of perforin was detected between CFS and NF at T1 or T2. In PBMC, there was no difference in the perforin expression between CFS and NF at T1 but expression was significantly higher in CFS than NF (1.4 fold, p=0.02) at T2. NF subjects had reduced perforin expression (0.8 fold, p=0.008) and methylation levels were increased by 4% (range 2.6-4.3, p= 0.01-0.05) at four CpG sites (-876, -744, -691, and -670) at T2 compared to T1. However in CFS subjects, methylation levels were increased by 6%

				(range 4.7-6.8, p=0.02-0.03) at T2 compared to T1 at two positions (-776 and -744) without a corresponding change in expression. Expression results by real-time RT-PCR and exon arrays were concordant. Conclusion: While increased promoter DNA methylation correlated with reduced perforin expression in NF, this relationship was not seen in CFS. The small but statistically significant differences in methylation were detected over the course of the day were different for the NF and CFS groups. Further studies are needed to confirm these results and to evaluate explanations (changes in cell population, circadian rhythm or stress) for the observed dynamics in perforin DNA methylation and expression.
Fennell, P	Patricia Fennell, MSW, LCSW-R, President, Albany Health Management Associates, Inc., 582 New Loudon Rd., Latham NY 11210, USA; communications@albanyhealthmanagement.com	Working the Third Phase: 5 Capacities For Coping With Trauma and Loss In CFS/ME and Fibromyalgia	IACSF/ME. 19 (2). Fall 2011. Abstracts from IACFS/ME Biennial International Conference. Poster Presentations.	Objectives: To live a full life with CFS/ME, fibromyalgia, or other chronic illnesses, individuals and families must learn to accept their circumstances and find meaning in the experience. The arts -- music, humor, movement, writing, painting, or other methods -- helps individuals with chronic conditions develop this acceptance and meaning for enhanced coping. Methods: An online program was launched in mid-2010 that uses the arts to help people develop a healthy response to chronic illness. This program helps people with chronic illnesses use five capacities of improvisation that are explored through the arts and that people coping with chronic illnesses need to acquire to establish acceptance and meaning. These capacities are 1) Tolerate ambiguity, 2) Take risks, 3) Become curious, 4) Improvise, and 5) Innovate. The program, initiated in May 2010 in collaboration with the DePaul Chronic Illness Initiative, is derivative of the evidence-based Fennell Four-Phase Model, which has established that people experience Four Phases – 1) Crisis, 2) Stabilization, 3) Resolution, and 4) Integration -- on their way to defining a new self and a new life with chronic illness. It is in the Resolution Phase where individuals begin to find meaning in their experience and develop a supportive, meaningful philosophy. Creativity and the arts are a mechanism for using improvisation to progress toward and through the Third Phase. Results: The tools of improvisation offer a pathway toward establishing meaning in the chronic illness experience for enhanced coping. Conclusion: Improvisation, the skill of top artists, can offer new ways to respond better to change. In improvisation, we use our existing knowledge and skills to create something new in an unplanned, innovative way. The web-based community offers an effective method for developing these capacities with people with disabling chronic illnesses, such as CFS/ME and fibromyalgia, who may find it difficult to travel to group meetings on a regular basis. Relationship to Conference Theme: A pre- and post-intervention instrument, under development, combined with the validated Fennell Four Phase Inventory, can assess how participants use the five capacities and how they influence their current Phase placement and the development of meaning. By learning the principles of the five capacities of improvisation, patients can emerge with tools to cull prior experiences for better assessment of present circumstances

				and create innovative ways to respond to change.
Fennell, P;	Patricia Fennell, MSW, LCSW-R, President, Albany Health Management Associates, Inc., 582 New Loudon Rd., Latham NY 11210, USA; E-mail: communications@albanyhealthmanagement.com	Six Functional Capacities That Impact People with CFS/ME and/or Fibromyalgia	IACSF/ME. 19 (2). Fall 2011. Abstracts from IACFS/ME Biennial International Conference. Poster Presentations. P173-174.	Objectives: CFS/ME, fibromyalgia and related chronic illnesses have a significant impact on educational, work, and social success, as well as on activities of daily living, including self care, school, work and socialization. Workplaces, schools, social communities and other systems are challenged to provide appropriate accommodations to help people with chronic illnesses succeed to their highest capacity. A unique challenge is that, because these chronic illnesses relapse and remit, the accommodations must be flexible enough to change along with the person's health status. Methods: This presentation will outline the six functions that that are impacted by chronic illness and that affect the patient's participation in work or school. These are: 1. Pain; 2. Fatigue ("tired and wired," sleepy); 3. Sleep Quality; 4. Mood/Presentation; 5. Cognition/Mental Focus; and 6. Ambulation/Movement. It will also explain the Fennell Four Phase Model of chronic illness, an empirically validated model that describes four phases of adaptation that occur in chronic illnesses and trauma. These phases -- 1. Crisis; 2. Stabilization; 3. Resolution; 4. Integration -- describe a predictable passage that patients navigate on their way to defining a new self and a new life after the onset of chronic illness. Results: Research shows that people with CFS/ME and fibromyalgia pass through Four Phases as they learn to manage and cope with their decreased or impaired function, and the individual's health, functional status and Phase placement impact one another over time. Conclusion: By assessing a person's functional status and Phase placement, professionals can implement accommodations that give the patient the highest likelihood of success in the workplace, classroom and other environments. Relationship to Conference Theme: By conceptualizing the experiences of people with chronic illnesses with the functional capacity and phase placement concepts, professionals across disciplines can step outside of a medical/clinical framework and describe commonly shared human experiences in a substantive and meaningful manner that supports the individual's success. In addition, patients and families can utilize these functional area and phase placement concepts as a personal insight tool that helps them understand their current abilities and limitations, work within the parameters they are experiencing, and allow them to make better decisions about how to utilize their time, schedule and energy, on any given day.
Fennell, Patricia A	[No address quoted]	CFS/ME in the Chronic Illness Era	Bulletin of the IACSF/ME. Spring 2007.	There is a paradigm shift occurring in medicine, from models focused on treating acute illnesses to those concerned with managing chronic conditions. This shift coincides with the higher prevalence of chronic illnesses resulting from factors such as lower mortality from formerly fatal illnesses and an aging population. The chronically ill do not fare well in an acute care model and, as a result, it has become imperative to develop new models of care and comprehensive, coordinated case management models that will be effective for these chronic conditions. This shift in medicine toward chronic conditions will force CFS/ME to compete to an even higher degree for

				already limited research dollars and attention, but may provide benefits in the clinical arena, as health care adapts to serve the expanding universe of the chronically ill.
Fernandez Solà, A; Colilles, R; Gilibets, S	Centre Sanitari del Solsonès (CSS) Solsonés Central Catalonia	Usefulness of a Joint and Multidisciplinary Unit for the Diagnosis, and Management of Chronic Fatigue Syndrome (CFS), Multiple Chemical Sensitivity (MCS) and Fibromyalgia	IACSF/ME. 19 (2). Fall 2011. Abstracts from IACFS/ME Biennial International Conference. Poster Presentations. P173.	We present the structure and functioning of our unit as an example of multidisciplinary and co-management of the central sensitization syndromes. The Centre Sanitari del Solsonès (CSS) is a public medical center serving the region of Solsonés, an area of Central Catalonia around 15000 inhabitants. In 2010 we created a unit for the diagnosis and management of the diseases that has an internal medicine physician expert on the three diseases, a nurse, a psychologist and a physiotherapist. The patient arrives at the unit referred by primary care physicians. The nurse manages and cites the patients for the first medical visit where the doctor takes the patient's medical history. Subsequently, the patient is sent to the nurse who performs the nursing history, assessment tests of fatigue (FT. SF-36), pain (FIQ) and chemical sensitivity (QEESI). The patient is then referred to the psychologist who performed psychological and neurocognitive assessment. Subsequently, clinical meetings are held together for determining the diagnosis, the degree of impairment and the proper course of action. The unit has also a group of cognitive-behavioural treatment involving all the professionals of the same. Diagnosed patients enter the patient registry that records the incidence and prevalence of the three diseases as well as clinical and epidemiological parameters. Currently, and after a year of operation the registry has more than 50 patients. Conclusion: We believe that the joint multidisciplinary units that treat the three diseases are the best tool for correct diagnosis, grading, handling and study of these pathologies.
Frémont, Marc; Coomans, Danny; DeMeirleir	Marc Frémont, Ph.D., R.E.D Laboratories, Z.1 Researchpark 100, 1731 Zellik Belgium email: mfremont@redlabs.com	High-Throughput 16s rDNA Sequencing Reveals Alterations of Intestinal Microflora in Myalgic Encephalomyelitis/Chronic Fatigue Syndrome Patients	IACSF/ME. 19 (2). Fall 2011. Abstracts from IACFS/ME Biennial International Conference. Poster Presentations. P158-159.	Objectives: Human intestinal microflora plays an important role in the maintenance of host health by providing energy, nutrients, and immunological protection. Intestinal dysfunction is a frequent complaint in ME-CFS patients, and previous reports suggest that dysbiosis, i.e. the overgrowth of abnormal populations of bacteria in the gut, is linked to the pathogenesis of the disease. Recently developed technologies are able to provide a comprehensive overview of the gut bacterial populations (metagenomics approach). We used high-throughput 16s rDNA sequencing to investigate the presence of specific alterations in the gut flora of ME-CFS patients from Belgium and Norway. Methods: 39 ME-CFS patients and 35 healthy controls were included in the study. Bacterial DNA was extracted from stabilized stool samples and PCR amplification was performed on conserved 16S rDNA regions. PCR amplicons were then sequenced using Roche FLX 454 genome sequencer (6000-10000 sequences per sample). Bacteria were classified by phylum, family and genus; diversity indexes (Chao and Shannon) were also calculated. Data were analyzed using Mann-Whitney test and step-wise linear discriminant analysis. Results: ME-CFS patients presented altered levels of specific bacterial populations: Prevotella, Asaccharobacter, Lactonifactor, Eubacterium. Linear discriminant analysis showed that a significant (p<0,001) discrimination between control and patient populations could be achieved by using a

				combination of Asaccharobacter, Turicibacter, Ruminococcus and Enterococcus as variables. Differences could be seen between males and females, as well as between people from different geographical origins (Belgium vs. Norway). Conclusions: ME-CFS patients present significant alterations of their gut flora composition. More research has to be done to fully understand how intestinal bacteria can contribute to the pathogenesis of the disease (production of toxic metabolites, interaction with host immune cells…), but also how host factors (especially genetic factors) and external factors like diet or viral infections can influence the response of the body to gut bacteria. Metagenomics is a useful tool to diagnose dysbiosis in ME-CFS patients and to help designing treatments based on gut flora modulation (antibiotics, pre- and probiotics supplementation).
Friedberg, Fred	[No address quoted]	Ultra-Brief Self-Management of CFS in Medical Care	Bulletin of the IACSF/ME. Spring 2007.	This article will highlight background studies demonstrating the efficacy of behavioural self-management for many illness conditions, including CFS. I will also suggest how physicians and other professionals can advise their CFS patients about healthy lifestyle change and stress reduction in order to lessen illness severity and, for some patients, promote significant improvement.
Friedberg, Fred	Stony Brook University, New York	Cognitive-Behavioural Intervention in Chronic Fatigue Syndrome: Benefits, Limitations, and Open Questions	Bulletin of the IACSF/ME. 16 (4). Winter 2008/2009. P22-27.	The cognitive-behavioral model of chronic fatigue syndrome (CFS) postulates fear-based avoidance behavior and physical deconditioning to explain symptoms and impairments. This article examines these assumptions and provides a brief critical perspective of CBT trials in patients with CFS. Although CBT is effective to varying degrees in reducing symptoms and improving functioning, published reports often do not address (a) the influence of baseline functioning on intervention rationale; (b) clinical vs. statistical significance of outcomes; (c) patient non-response to CBT; and (d) the potential role of biological variables in predicting response to intervention. A balanced assessment of the effectiveness of CBT in CFS is important in providing accurate information to both professionals and patients
Friedberg, Fred; Coronel, Janna	Department of Psychiatry, Putnam Hall/South Campus, Stony Brook University, Stony Brook NY 11794-8790. fred.friedberg@stonybrook.edu	Brief Self-Management of UCF/CFS in Primary Care: A Randomized Trial	IACSF/ME. 19 (2). Fall 2011. Abstracts from IACFS/ME Biennial International Conference. P118.	Objective: The objective of this study was to test a brief self-management protocol in a primary care setting, in people with medically unexplained chronic fatigue (UCF) and chronic fatigue syndrome (CFS). An effective self-management plan has the potential (1) to improve the generally poor outcomes for UCF and CFS patients in primary care, (2) to greatly expand the availability of behavioral health care for UCF and CFS, and (3) to reduce medical and behavioral utilization for UCF and CFS. The proposed study is an extension of an efficacious two-session self-management clinical trial for CFS in secondary care (Powell et al., 2001). The hypothesis was tested that a brief self-management- focused cognitive-behavioral intervention will yield improvements in fatigue, physical and role functioning, and psychological distress in comparison to the two control conditions: standard medical care alone or standard medical care plus an attention control symptom monitoring condition. Methods: We

				tested the efficacy of a two - session self-management-focused cognitive-behavioral intervention in a target sample of 108 persons with UCF or CFS. Participants were randomly assigned to one of three study conditions: (1) standard medical care alone; (2) standard medical care plus a nurse-delivered attention control condition of symptom monitoring; or (3) standard medical care plus a nurse-delivered self-management cognitive behavioural treatment delivered by a nurse. Results: At the three month follow-up, sample sizes were as follows: fatigue self-management (FSM) = 21; Symptom Monitoring (SM) = 26; and Usual care (UC) = 21. Forty percent met Fukuda criteria for CFS. Controlling for age, sex and illness duration at the three-month follow-up assessment, a significant reduction was found on the fatigue severity scale ($p<.05$). No significant changes were found on diary fatigue ratings, the SF-36PF, Beck Anxiety Inventory or the Beck Depression Inventory. Actigraphy significantly declined across all conditions ($p<.05$). Patient global impression of change (PGIC) ratings were as follows for the three conditions (FSM/SM/UC): Improved (13/ 6/4); Unchanged (5/9/11); Worse (2/5/2). Despite little change on our standard measures, brief interviews with study participants revealed that both worsened and unchanged patients across conditions attributed their PGIC ratings to external negative events or lack of healthy activities, whereas improved patients reported increased awareness of their behaviors and affirmative steps to pursue healthy activities. Conclusion: A brief, standardized illness management service for UCF/CFS showed modest improvement in fatigue severity and PGIC ratings. PGIC ratings of improved, unchanged, and worsened overall appeared to reflect different attitude toward the illness and/or differential exposures to negative major life events. These findings indicate a role for self-management activities in generating improved outcomes.
Garcia, Lina; Kerr, Jonathon; Fletcher, Mary Ann; Sol, Connie; Klimas, Nancy;	University of Miami Miller School of Medicine and Miami VA Medical Center. klimas@miami.edu	Comparing Gene Expression Patterns in CFS and GWI Using the Kerr ME/CFS Platform	IACSF/ME. 19 (2). Fall 2011. Abstracts from IACFS/ME Biennial International Conference. P134-135.	There have been a number of studies utilizing genomics to better understand and define CFS/ME. Jonathan Kerr's group published a series of studies that defined 79 genes associated with this illness, then used the same method to develop biologically defined subgroups (1). The Miami group has been studying both GWI and CFS/ME using gene activation patterns and proteomics, before during and after an exercise challenge to better understand the mediators of persistence and relapse. In this study we collaborated with Dr Kerr, comparing CFS/ME (n=25), control (n=53) and GWI samples (n=25), the GWI samples studied were drawn prior to the exercise challenge. The data from the CFS/ME cohort confirmed the findings from Dr. Kerr's earlier studies. There were significant differences when compared to controls in expression of genes that regulate intracellular pathways mitochondrial function, cell wall and signaling pathways. Genes which regulate cytokine regulation were also significantly different than controls, particularly the pro-inflammatory cytokines TNFa and IL6; antiviral pathways Interferon alpha, beta and omega, and the anti-inflammatory cytokine IL10. When compared to Gulf War Illness there are some important overlaps:

				EB12, an EBV induction gene is 6 fold higher than controls in CFS/ME, 2 fold higher in GWI, both significant differences (p<.005) ETS1, a viral oncogene was also upregulated in both groups. (p<.-0005) Transcription factor 3, which regulates immunoglobulin production, was markedly elevated in GWI, less so though significantly elevated in CFS/ME. (p<.005) Apoptosis genes were markedly upregulated in both groups though GWI saw elevations were 400 fold higher than CFS/ME. (p<.0005). However, the overall trend was that most of the gene regulation abnormalities that are associated with CFS in the Kerr platform were not significantly different in GWI than in controls , and often moved in the opposite direction down regulating intracellular processes in GWI that were upregulated in CFS (73 of 87 genes studied). Using a comprehensive platform, additional genes specific for GWI have been identified by the Miami group (presented separately). 1. Kerr JR, et al. 2008. Gene expression subtypes in patients with chronic fatigue syndrome/myalgic encephalomyelitis. J Infect Dis 197(8):1171-84.

E-Mail johan.gottfries@chem.umu.se Address for correspondence: Carl-Gerhard Gottfries, Professor emeritus Gottfries Clinic, Krokslätts Torg 5, SE-	Immunotherapy of Fibromyalgia and Chronic Fatigue Syndrome by a Staphylococcus Toxoid Vaccine	Bulletin of the IACSF/ME. 17 (4). Winter 2009/2010.	Background In previous clinical double blind investigations a significant effect is recorded in patients with fibromyalgia and/or chronic fatigue syndrome when treated with a staphylococcus vaccine. The aim of this study is to report long-term efficacy and safety of this immunotherapy. Methods One hundred and sixty patients with fibromyalgia and chronic fatigue syndrome who had previously participated in vaccine treatment studies were continuously observed during one year in a follow up study. At inclusion mean age was 53±11 years and mean treatment time 22±10 months. In a subgroup of 97 younger patients (48±10 years) with a mean treatment time of 50.4±17.8 months a Principal Components Analysis (PCA) was performed. The patients were on immunotherapy by a staphylococcus vaccine administered subcutaneously in a dose of 1 mL every 3rd to 4th week. Medically educated and trained staff using the rating scale CPRS-15 evaluated efficacy. Safety was evaluated continuously. Results Ratings showed improvement from start of treatment and further improvement was recorded during the follow-up period. The total mean rating CPRS-15 score was reduced by more than 50 %. Five items (Concentration difficulties, Failing memory, Irritability, Sadness and Autonomic disturbances) had mean levels below one at the time of the last rating, indicating that these symptoms on a group level were within the range of normality. The PCA also indicated improvement in the subgroup of 97 middle- aged patients. Adverse events were few and the adherence to the treatment was surprisingly fine. During the observation period of one year 14% withdrew from treatment. Conclusions The result was considered impressive and in view of the lack of effective treatment in fibromyalgia and chronic fatigue syndrome the results are of interest but need to be confirmed.

Goudsmit, Ellen M[1]; Stouten, Bart[2]; Howes, Sandra[2]	*[1]Health Psychologist, 23 Melbourne Road, Teddington, Middlesex, TW11 9QX, UK[2],Co-editor, ME and CFS References, ellengoudsmit@hotmail.com*	Fatigue in Myalgic Encephalomyelitis	Bulletin of the IACSF/ME. 16 (3). Fall 2008. P4-10.	**Background:** The objectives of this study were to measure fatigue in patients with well-defined Myalgic Encephalomyelitis (ME) and to assess if there are any problems associated with the Chalder Fatigue Scale, which has been widely used to assess fatigue in patients with chronic fatigue syndrome (CFS). **Methods:** Twenty-six patients were recruited from a local support group. All had been diagnosed by physicians and met research criteria for ME. They completed the 11-item Chalder Fatigue Scale and were also asked to rate the severity of their illness. The fatigue scores were calculated using both the Likert method (0, 1, 2,3) and the bimodal method (0,0,1,1,). **Results:** The mean Likert score was 26.65 (SD 5.36) and the mean bimodal score was 9.81 (SD 2.04). Fifty per cent of the patients recorded the maximum score using the bimodal method and 77% recorded the two highest scores. Moreover, there was a marked overlap between those who rated themselves as moderately or severely ill. These findings are indications of a low ceiling. **Conclusions:** The findings from this study using the Chalder Fatigue Scale show that the low ceiling associated with the bimodal method means that this scoring system is not suitable for use in clinical trials. Researchers may wish to consider alternative instruments to obtain a more accurate measure of fatigue in patients with moderate to severe ME and similar conditions.
Hallman, G	Geoffrey Hallmann, PhD Candidate, Southern Cross University, School of Exercise Science & Sport Management, PO Box 157 East Lismore, NSW 2480, geoffhallmann@yahoo.com	ME/CFS and Bullying in Context of Social Interactions	IACSF/ME. 19 (2). Fall 2011. Abstracts from IACFS/ME Biennial International Conference. Poster Presentations. P179.	Objectives: To examine the nature and impact of bullying of persons with ME/CFS when engaged in an institutional encounter. Method: The initial phase of the research involved a thorough review of the available literature to establish the interaction of those with ME/CFS with social institutions. A focus for this paper was made on the incidence of bullying behaviour that participants reported as having experienced during such interactions and attention was paid to the consequences of such experiences. In the data collection phase, a pilot study involving an investigation of the Australian perspective of the experience of ME/CFS was obtained. This was expanded in the main study and participants were provided the opportunity to reveal their stories. Participants were required to have a diagnosis of CFS, ME or ME/CFS from a medical practitioner and self-select themselves as compliant to the Fukuda CFS Criteria, Canadian ME/CFS Criteria and Ramsay ME Criteria. A background questionnaire was provided to give an insight into the history of the participant, particularly interactions with social institutions and pathways to diagnosis. The interview drew upon the questionnaire for guidance, with the primary questions derived from information gained from the literature review. The interviews were transcribed, coded and the relationships and issues identified in order to guide the second phase of the research which was conducted further into the study. The pilot study involved 3 participants, followed by a second, more comprehensive phase

				comprising 16 participants. Stories emerged from within those interviews with respect to interactions with society and these were broken down to reveal particular themes relevant to those experiences. Results: A total of 19 interviews were conducted. The average age of participants was 91.95 with all 14 females and 5 male participants. The mean duration of the condition was 17.66 years, with 8.35 years from onset until diagnosis. A number of issues arose, revealing an insight into the nature of the relationships that exist between persons with ME/CFS and various social institutions. Relationships of power, politics, policies, practices and social relations were revealed to play an important role in the experience of ME/CFS. Bullying appeared to occur across every facet of the participant's lives, particularly in dealings with the medical profession, insurance companies, educators, employment, family, friends and the media. Whilst apparently present such behaviour was not named as such nor addressed. Conclusion: Persons with ME/CFS are subject to bullying directly or indirectly because of their diagnosis and the contested nature of the condition. This experience has an adverse impact upon the person – both physically and emotionally. Patients reveal that such encounters can influence their dealings with people within social institutions and impact adversely upon their condition and manner in which they address future interactions. Rarely is bullying identified, nor is action taken against the perpetrators. Knowledge of steps to be taken and inability to pursue action against perpetrators due to illness prevented protection of rights and self. Providing a more settled understanding of the condition and education within society is indicated as a counter measure to identify and prevent the incidence of bullying.
Hallman, G	Geoffrey Hallmann, PhD Candidate, Southern Cross University, School of Exercise Science & Sport Management, PO Box 157, East Lismore NSW 2480 geoffhallmann@yahoo.com	ME/CFS: First Do No Harm	IACSF/ME. 19 (2). Fall 2011. Abstracts from IACFS/ME Biennial International Conference. Poster Presentations. P179-180.	Objectives: To examine the nature and impact of the medical encounter by persons with ME/CFS. Method: The initial phase of the research involved a thorough review of the available literature to establish the interaction of those with ME/CFS with social institutions. A focus for this paper was made on the interactions between doctors and medical staff with persons with ME/CFS to establish the current evidence. In the data collection phase, a pilot study involving an investigation of the Australian perspective of the experience of ME/CFS was obtained. This was expanded in the main study and participants were provided the opportunity to reveal their stories. Participants were required to have a diagnosis of CFS, ME or ME/CFS from a medical practitioner and selfselect themselves as compliant to the Fukuda CFS Criteria, Canadian ME/CFS Criteria and Ramsay ME Criteria. A background questionnaire was provided to give an insight into the history of the participant, particularly interactions with social institutions and pathways to diagnosis. The interview drew upon the questionnaire for guidance, with the primary questions derived from information gained from the literature review. The interviews were transcribed, coded and the relationships and issues identified in order to guide the second phase of the research which was conducted further into the study. The pilot study involved 3 participants, followed by a second, more comprehensive phase comprising 16 participants. Stories emerged

				from within those interviews with respect to interactions with the medical community and these were broken down to reveal particular themes relevant to those experiences. Results: A total of 19 interviews were conducted. The average age of participants was 91.95 with all 14 females and 5 male participants. The mean duration of the condition was 17.66 years, with 8.35 years from onset until diagnosis. A number of issues arose, revealing an insight into the nature of the relationships that exist between persons with ME/CFS and medical staff. Relationships of power, politics, policies, practices and social relations were revealed to play an important role in the experience of ME/CFS. Positive and negative experiences revealed issues relating to belief, awareness, education, research, school of thought, attitude, investigation, historical analysis, guidelines, personal experience, finances, and politics. Thematically the participants identified empathy, knowledge, and management as attributes that pointed towards what patients consider to be best practice when dealing with medical practitioners. The stories provide a significant insight into the various medical personnel and medical settings that participants have encountered and how that interaction impacted upon their perceptions and the status of their condition. Conclusion: The relationship between persons with ME/CFS and medical staff, particularly doctors is very important to the progress of the patient. The experiences reveal the importance of knowledge, empathy and management to the patient-doctor relationship. Poor experiences have led patients to adverse reactions within their condition and led them look to alternative therapies due to a lack of faith in the medical profession. Beliefs, knowledge and understanding of their condition also had bearing upon the experience.
Hallmann, G	Geoffrey Hallmann, PhD Candidate, Southern Cross University, School of Exercise Science & Sport Management, PO Box 157, East Lismore NSW 2480, geoffhallmann@yahoo.com	ME/CFS: Harsh Realities of the Real World	IACSF/ME. 19 (2). Fall 2011. Abstracts from IACFS/ME Biennial International Conference. Poster Presentations. P183-184.	Objectives: To conduct a preliminary examination of the experiences of persons with ME/CFS when dealing with society and the social institutions that form the fabric of day to day interactions. Method: The initial phase of the research involved a thorough review of the available literature to establish the interaction of those with ME/CFS with social institutions. A focus for this paper was made on the experiences of dealing with social institutions on a daily basis when the diagnosis was known. In the data collection phase, a pilot study involving an investigation of the Australian perspective of the experience of ME/CFS was obtained. This was expanded in the main study and participants were provided the opportunity to reveal their stories. Participants were required to have a diagnosis of CFS, ME or ME/CFS from a medical practitioner and self-select themselves as compliant to the Fukuda CFS Criteria, Canadian ME/CFS Criteria and Ramsay ME Criteria. A background questionnaire was provided to give an insight into the history of the participant, particularly interactions with social institutions and pathways to diagnosis. The interview drew upon the questionnaire for guidance, with the primary questions derived from information gained from the literature review. The interviews were transcribed, coded and the relationships and issues identified in order to guide the second phase of the research which was

				conducted further into the study. The pilot study involved 3 participants, followed by a second, more comprehensive phase comprising 16 participants. Stories emerged from within those interviews with respect to interactions with society and these were broken down to reveal particular themes relevant to those experiences. Results: A total of 19 interviews were conducted. The average age of participants was 91.95 with all 14 females and 5 male participants. The mean duration of the condition was 17.66 years, with 8.35 years from onset until diagnosis. A number of issues arose, revealing an insight into the nature of the relationships that exist between persons with ME/CFS and various social institutions. Relationships of power, politics, policies, practices and social relations were revealed to play an important role in the experience of ME/CFS. Positive and negative experiences arose. The contested nature of the condition, its invisibility, lack of community awareness, lack of education, misrepresentation in the media, name, vulnerability of those affected, lack of evidence, barriers to justice and limited support systems all play a role in the way those with the condition experience the social world. Conclusion: Persons with ME/CFS are faced with major difficulties when they deal with social institutions. The various factors that play a role in the absence of knowledge and understanding the condition have perpetuated misconceptions within the community. This experience has an adverse impact upon the person – physically, emotionally and financially. Patients reveal that such encounters can influence their dealings with society and can impact adversely upon their condition. Whilst there are mechanisms that can address issues that arise during their life, there exist barriers that prevent protection of rights, access to appropriate investigation, management and care, and little assistance for day to day issues.
Hanson, M; Lee,LL; Lin,L; Bell,DE; Ruppert,D; Levine,S; Bell, DS	Maureen R. Hanson, Ph.D., Liberty Hyde Bailey Professor ,Dept. of Molecular Biology and Genetics, Cornell University, Biotech. Bldg., Ithaca, NY 14853 USA E-mail - mrh5@cornell.edu	*Detection of MLV-like gag Sequences in Blood and Cell Lines Incubated With Plasma From CFS Patients and Controls*	IACSF/ME. 19 (2). Fall 2011. Abstracts from IACFS/ME Biennial International Conference. P114.	Objectives: To determine whether viruses related to XMRV could be detected in peripheral blood from adult subjects who are either ill with CFS, are recovered from CFS, or have no history of a CFS diagnosis. Methods: Subjects were divided into five groups. Ten subjects were severely ill with CFS, ten met Fukuda criteria at one time but now considered themselves recovered, and ten subjects from the same geographic area in Western New York were healthy and had never been diagnosed with CFS. Standard instruments were administered to assess the health status of the subjects in these three groups. An additional ten ill subjects and ten control subjects lacking any CFS history were recruited from a physician's practice in New York City and a different region of upstate New York, respectively. Blood was collected in EDTA tubes and nucleic acids made from PBMCs or whole blood. Plasma was incubated with human cells in culture. Nested PCR with USB Hot-Start IT FideliTaq was performed with *gag* primers. Any PCR products of expected sizes were sequenced. Samples were tested for mouse contamination with primers to IAP and/or mouse mitochondrial DNA. Control experiments in which human nucleic acid samples were spiked with mouse DNA were performed to determine the sensitivity of the assays for

				mouse contamination. Results: The SF-36 scores of the ten individuals who considered themselves recovered were significantly lower than ten members of the healthy control group from the same Western New York area, according to Hotelling's T2 test. Tukey's multiple comparison of means indicates that there are highly significant differences between the scores of the Western New York "severe" and controls on all 7 instruments. *gag* sequences were detected in CFS subjects' blood as well as in some healthy controls. *gag* sequences were detected that were more similar to the MLV-like sequences reported by Lo et al. (2010) than to the XMRV sequences reported by Lombardi et al. (2009). MLV-like *gag* sequences could be detected in nucleic acids prepared from whole and fractionated blood that were negative for the presence of mouse DNA when sensitive assays were performed. Possible reasons for false positive and false negative results when performing highly sensitive PCR assays will be presented. Conclusion: *gag* sequences were detected by PCR in whole blood genomic DNAs that were negative for mouse IAP and mitochondrial DNA. *gag* sequences similar to polytropic MLVs were obtained. The sensitivity of the PCR assays used requires extreme caution in interpreting results.
Hardcastle, SL; Brenu, EW; Staines, DR; Van Driel, M; Petersen, D; Marshall-Gradisnik, S	Sharni Lee Hardcastle , Faculty of Health Science and Medicine, Bond University, Gold Coast, Queensland 4229 Australia Email: Sharni.Hardcastle@student.bond.edu.au	Assessment of Natural Killer Cell Receptors in Severe and Moderate Chronic Fatigue Syndrome / Myalgic Encephalomyelitis	IACSF/ME. 19 (2). Fall 2011. Abstracts from IACFS/ME Biennial International Conference. Poster Presentations. P170.	Objective: A common finding within sufferers of Chronic Fatigue Syndrome (CFS/ME) is abnormalities in the immune system. One of the most consistent findings from a variety of studies to date is that CFS/ME subjects have compromised Natural Killer (NK) cell function. The exact cause of reduced NK function is unknown although there are indications for an involvement in cytolytic proteins. Additionally it is unknown whether decreases NK function is related to NK receptors especially within severely affected CFS/ME patients. Therefore, the purpose of this study is to examine NK phenotypes and lysis as well as receptors within moderate and severely affected CFS/ME subjects in comparison to normal controls. Method: Blood samples from 20 normal control participants, 20 moderately affected CFS/ME subjects and 20 severely affected CFS/ME patients. The CFS/ME participants were firstly pre-screened for decreased NK function. Using flow cytometry isolated NK cells were assessed for NK receptor expression and NK phenotypes. Result: Preliminary data from CFS/ME patients showed differences within NK cell receptor function when compared to the healthy control group. Conclusion: Results suggest that NK cell receptor function may be dysfunctional in CFS/ME patients which could potentially explain why these patients have a decrease in NK lysis function.
Harvey, Jeanna M; Barnes, ZM; Sol, C; Zend, MA; Klimas, N	Jeanna M. Harvey, M.D. Candidate, UM Miller School of Medicine. 1600 NW 10th Ave, Miami, FL 33135, USA. jharvey3@med.miami.	Exercise Effects on Biomarkers in GWI, CFS and Healthy Controls	IACSF/ME. 19 (2). Fall 2011. Abstracts from IACFS/ME Biennial International Conference. Poster Presentations. P164-165.	Objective: To determine the effects of an aerobic exercise challenge on potential biomarkers in Gulf War Illness (GWI), Chronic Fatigue Syndrome (CFS0 and healthy controls (HC).

Hyde, Byron M; Chor, Allie	Byron M. Hyde, BA(Chem), MD, Chairman, Nightingale Research Foundation, 121 Iona Street Ottawa, Ontario, Canada, K1Y 3M1 bhyde@nightingale.ca	Canadian Techniques of Investigation of M.E. / CFS & FS Patients and Resulting Anatomical, Patho-Physiological and Genetic Findings	IACSF/ME. 19 (2). Fall 2011. Abstracts from IACFS/ME Biennial International Conference. Poster Presentations. P157.	The Canadian health care system, provides free physicians, investigation and non-pharmaceutical treatment to all patients. Tests include all blood, urine, tissue and technological testing such as cardiovascular, ultrasound, MRI, PET, SPECT, Nerve Conduction, Radiological or Nuclear Medicine examinations. Any corrective surgery, procedural care or hospitalization are also provided free of charge. Unlike in the UK, Australia and many other European countries any physician in Canada can order any test available in Canada. Unlike US physicians, we do not have to ask whether the patient has insurance coverage since all are covered. M.E. and CFS Patients: This system allows an understanding of the patho-physiological basis of why a patient is chronically ill with either a fatigue, cognitive or pain syndrome or a combination of these symptoms. This free assessment has resulted in a significant difference in the understanding of the cause of M.E. and CFS illness. Chronic Fibromyalgia & Fibromyalgia Syndromes (FS): Due to long term follow up and the ability to do significant testing over years at no cost to the patient, we have shown that a majority of chronically ill fibromyalgia patients actually suffer from developing rheumatoid, arthritic, structural, medication induced or genetic illnesses. How to examine & test M.E. and CFS patients: This paper will demonstrate the techniques and difficulties of total body (system and organ) assessment over the past 26 years. The paper will demonstrate the reasons why patients with M.E. and CFS, irrespective of the initiating cause(s), remain chronically ill with brain and fatigue dysfunctions. The Multiple Pathologies of M.E., CFS and FS Patients: This paper will also demonstrate the findings which suggest many patients diagnosed with M.E. or CFS are treatable and many require more specific treatment research.
Hyde, Byron M; Chor, Allie	Byron M. Hyde, BA(Chem), MD, Chairman, Nightingale Research Foundation, 121 Iona Street Ottawa, Ontario, Canada, K1Y 3M1 bhyde@nightingale.ca	Ten Important Facts Derived from M.E./CFS History That Can Improve M.E./CFS Research	IACSF/ME. 19 (2). Fall 2011. Abstracts from IACFS/ME Biennial International Conference. Poster Presentations. P157.	An increasing number of world experts are contributing to M.E./CFS research, but many do not have a good understanding of the historical lessons already learned in these epidemic illnesses. A better understanding of M.E./CFS history will contribute to more efficient research in understanding, virology, cognitive and brain dysfunction. For instance, a recent published discovery of an abnormal protein in spinal fluid of CFS patients was already demonstrated by Harvard's Dr Charles Poser in 1990. For 26 years, since 1984 to 2011 my medical practice has been limited to the full time investigation of M.E., CFS & FS patients. During the earlier period I visited multiple epidemic sites, interviewed & examined patients & discussed & at times resided with many of the chief investigators of these epidemics. The patients & epidemic sites personally investigated include: (a) Los Angeles County General Hospital epidemic 1934, (b) Akureyri Epidemic Iceland 1947-48, (c) Royal Free Hospital Epidemics 1955-1956, (d) Cumberland Epidemic 1955, (e) Newton-le-Willow Epidemic 1956. The earlier researchers include Drs. Melvin Ramsay, Betty Dowsett, John Richardson, Eleanor Bell, James Mowbray, Andrew Wallis family, J. Gordon Parish. W.H. Lyle, Charles Poser, Alberto Marinacci, Ismael Mena, Sheila Bastien, Alexis Shelokov, Peter

				Snow & Clem Boughton to name a few. Dr Byron Hyde will review ten important largely forgotten facts learned from 26 years of investigating various world epidemics and questioning the experts who investigated these epidemics that will assist M.E., CFS &Fibromyalgia researchers..
Hyde, Byron; Green, Tracy	Byron M. Hyde, BA(Chem), MD, Chairman, Nightingale Research Foundation, 121 Iona Street Ottawa, Ontario, Canada, K1Y 3M1 bhyde@nightingale.ca	Thyroid Malignancy Associated with Severe Cognitive Dysfunction, Cortical & Subcortical NeuroSPECT changes in Patients Presenting with a Myalgic Encephalomyelitis / Chronic Fatigue Syndrome (ME/CFS)	IACSF/ME. 19 (2). Fall 2011. Abstracts from IACFS/ME Biennial International Conference. Poster Presentations. P156.	In our investigations, thyroid malignancy in ME/CFS patients greatly exceeds the normal incidence in any known subgroup. Various published studies over recent years have suggested an increasing incidence in the general public from 15 up to 30 per 100,000. However in 100 consecutive patients with M.E./CFS evaluated in our clinic by total body investigation, the malignancy incidence exceeds 6,000 per 100,000. Each patient's evaluation includes ultrasound and needle biopsy of suspicious nodules. Malignant nodules are usually noted as solitary, hypervascular nodules 1 cc in diameter or larger, although all hypervascular nodules have been biopsied. We suggest that as part of their investigation, all ME/CFS patients should be examined by thyroid ultrasound for evidence of thyroid pathology and malignancy. Thyroid pathology may be missed in this group of patients if investigation relies only upon serum testing for TSH, FT3, FT4, microsomal and thyroglobulin antibodies, which are usually normal in the case of malignancy. Unfortunately, corrective treatment by surgical and / or nuclear techniques plus appropriate hormonal replacement medication has not improved the symptoms of fatigue, cognitive and pain syndromes nor the SPECT brain changes. A newly recognized syndrome may exist in ME/CFS patients characterized by: (a) thyroid malignancy, (b) persistent pathological cortical and subcortical SPECT brain scans (NeuroSPECT), (c) failure of thyroidectomy surgery and hormone replacement to correct the fatigue syndrome, (d) an unusual high incidence of cervical v ertebrae pathophysiology. The question remains unresolved as to whether the NeuroSPECT changes consistent with a chronic low grade encephalopathy that we associate with cognitive dysfunction, precedes the thyroid malignancy and may provoke increased malignancy. A long term follow up of these M.E./CFS patients with NeuroSPECT evidence of encephalopathy but without thyroid malignancy is in progress to evaluate whether this group of patients is more prone to developing thyroid and other malignancies. We have also found a significant higher rate of development of all thyroid disease in this same group of M.E./CFS patients. This and other anomalies will be discussed with SPECT brain images of these patients.
Jason, Leonard A; Porter, Nicole; Brown, Molly; Anderson, Valerie; Brown, Abigail; Hunnell, Jessica; Lerch, Athena	Leonard A. Jason, Ph.D., Director, Center for Community Research, 990 W. Fullerton Ave., Suite 3100, Chicago, IL, 60614 email:	CFS: A Review of Epidemiology and Natural History Studies	Bulletin of the IACSF/ME. 17 (3). Fall 2009.	Almost all studies with samples of patients who have chronic fatigue syndrome (CFS) have relied on referrals from physicians or health facilities. Under-served minorities, who not only tend to manifest higher levels of chronic illness, but are also less likely to seek and receive adequate medical care, have not been represented in these studies (1). This may have contributed to an under-estimation of CFS among minority groups (2). Few studies have derived their samples from socioeconomically and ethnically diverse community-based populations. A technical report issued by the

	Ljason@depaul.edu			Agency for Healthcare Research and Quality (3) concluded that estimating rates of recovery/improvement or relapse from CFS are not possible because there are so few natural history studies and those that are available have involved selected referral populations. This paper provides a review of epidemiologic studies of CFS followed by a discussion of diagnostic issues and risk factors for the illness. Findings from Jason et al.'s (4) epidemiologic study in a multi-ethnic, economically diverse urban area are highlighted as this research group is now examining the natural course of CFS over the past 10 years with this community-based sample. The current study will add to current epidemiologic and risk factors research by assessing the course, progression, and risk factors of CFS among a demographically diverse sample of participants who are unbiased by illness, help-seeking behaviors, or differential access to the health care system
Jason, Leonard A; Porter, Nicole; Okasinski, Jennifer; and Benton, Mary	DePaul University	Issues Involved in Name Change Recommendations	Bulletin of the IACSF/ME. Spring 2007	Summary: Many feel that there is considerable benefit of maintaining the name Myalgic Encephalomyelitis, which is the most consistently used and most widely recognized name worldwide, with an established neurological WHO ICD code and a well-documented history of outbreaks along with extensive epidemiological investigations. Researchers and clinicians need to be aware of the strong sentiments that patients have for Myalgic Encephalomyelitis, which is a historically correct (Ramsay, 1981) and has been used internationally (Hyde, Goldstein, & Levine, 1992).
Jason, Leonard; Brown, Abigail; Clyne, Erin; Bartgis, Lindsey; Meredyth, Evans; Brown, Molly	Leonard A. Jason, Ph.D., Director, Center for Community Research, DePaul University, 990, W. Fullerton Ave, Suite3100, Chicago Il. 60614. E-mail - Ljason@depaul.edu	Contrasting Case Definitions	IACSF/ME. 19 (2). Fall 2011. Abstracts from IACFS/ME Biennial International Conference. P122.	Objectives: There has been considerable debate about what case definition to use with the illness commonly known as CFS. For example, some have speculated that the initial definitions of ME ((Dowsett et al., 1994; Goudsmit et al., 2009; Ramsay, 1988)) and later on the Canadian criteria of ME/CFS (Carruthers et al., 2003) select a group of patients that have more severe functional impairments than the Fukuda et al. (1994) criteria. This presentation contrasts individuals diagnosed with the Myalgic Encephalomyelitis/chronic fatigue syndrome (ME/CFS) Canadian case definition (Carruthers et al., 2003) with those that did not meet these criteria (Non-ME/CFS) but met the Fukuda et al. (1994) chronic fatigue syndrome (CFS) criteria. The study also compared individuals diagnosed with another case definition involving Myalgic Encephalomyelitis (ME) (based on criteria from Dowset et al., 1994; Goudsmit et al., 2009; Hyde, 2007; Ramsay, 1988) with those that did not meet these criteria (Non-ME), but met the Fukuda et al. criteria. Methods: The sample of patients had been diagnosed with CFS by the Fukuda et al. criteria and were later categorized as meeting ME/CFS and/or ME criteria. Results: In general, the ME/CFS criteria identified a group of patients with more functional impairments and physical, mental and cognitive problems than the Non-ME/CFS criteria. The ME criteria identified patients with more functional impairments, and more severe physical and cognitive symptoms than the Non-ME condition. Katon and Russo (1992) have argued that a requirement of more symptoms to meet criteria could inadvertently select for individuals with psychiatric

				problems. Similarly, Kroenke (2003) found similar results examining 15 variables within a fatigued sample. It is certainly possible that the differences on so many measures between the ME/CFS and the Non-ME/CFS groups was due to the larger number of symptoms of higher frequency and severity who met the ME/CFS criteria. Conclusion: The current CFS case definition of Fukuda et al. (1994) has been used internationally by researchers for over 15 years. It is possible that some patients meeting these criteria do not have core symptoms such as post-exertional malaise or memory/concentration problems. By specifying 7 symptoms as with the ME/CFS criteria or by specifying 4 symptoms with the ME criteria, it may be possible to identify a more homogenous and impaired group of patients. The current study suggests that these other ME and ME/CFS criteria might be used to identify patients with possibly more homogenous and severe symptomatology and functional impairment. Both ME/CFS and ME criteria appear to select a more severe group of patients than those that only meet the Fukuda et al. criteria.
Jason, Leonard; Porter, Nicole; Hunnell, Jessica; Rademaker, Alfred; Richman, Judith A;	Leonard A. Jason, Ph.D, Director, Center for Community Research, DePaul University, 990 W. Fullerton Ave, Suite 3100, Chicago, Il. 60614. Ljason@depaul.edu	Natural History	IACSF/ME. 19 (2). Fall 2011. Abstracts from IACFS/ME Biennial International Conference. P129-130.	Objectives: Despite growing knowledge about long-term predictors of chronic fatigue syndrome (CFS) outcomes, many followup studies are not prospective in that they either rely on retrospective self-report at a single point in time or they consist of longitudinal data that are analyzed in a cross-sectional manner without taking into account the influence of baseline findings. Clearly, there is a need for more research on the incidence and course of CFS in ethnically and socioeconomically diverse, community populations. Methods: The present project was carried out in two stages. In Stage 1, we attempted to re-contact the 213 adults who were medically and psychiatrically evaluated from 1995-1997. These adults were previously evaluated in our original Wave 1 CFS epidemiology project (Jason, Jordan et al., 1999). Stage 2 of the study encompasses a structured psychiatric assessment and a complete physical examination and a structured medical history. The original Wave 1 sample is a stratified random sample of several neighborhoods in Chicago specifically selected to contain individuals from different ethnic and socioeconomic profiles. Although the CFS group had a high rate of follow-up, those in the other groups were much more difficult to track over time. Fortunately, we did not find significant sociodemographic differences at Wave 1 between those we retained in the sample versus those that we were not able to re-contact, and this provides support for the generalizability of the outcomes to the larger sample. Results: The study's major finding was that rates of CFS appear to have been relatively stable over the period of time from Wave 1 to 2. As rates of CFS were .42% in Wave 1 (Jason, Richman et al., 1999), estimates from our current natural history study suggest that these rates have stayed relatively constant over the past decade. Sixty-seven percent of participants with CFS at Wave 1 continued to have CFS in our sample at Wave 2. Of the new cases of CFS over time, 75% came from the ICF group, suggesting that this group is at higher risk of developing CFS. In addition, 50% of the remitters went from a CFS diagnosis to the ICF

				group, indicating that while remitters no longer met CFS case definition, half were still suffering from chronic severe fatigue. Among all the variables in this study, only for post-exertional malaise did the CFS group significantly differ from the other conditions. This reaffirms the importance of this being a cardinal and critical symptom for CFS, and all of the individuals in the CFS group had this symptom either at Waves 1 or 2. Finally, a high level of mortality was found (18% of those with medical or psychiatric exclusions group, 12.5% for the CFS group). Conclusion: There are few studies that have been able to provide estimates of long term CFS outcomes, particularly in culturally diverse, community-based samples. In the present 10 year natural history study, the CFS group for the most part remained rather ill over time.
Jason, Leonard; Skendrovia, Beth; Furst, Jacob; Brown, Molly; Evans, Meredyth; Brown, Abbey	Leonard A. Jason, Ph.D., Director, Center for Community Research, DePaul University 990 W. Fullerton Ave, Suite 3100, Chicago, Il. 60614 E-mail - Ljason@depaul.edu	Data Mining	IACSF/ME. 19 (2). Fall 2011. Abstracts from IACFS/ME Biennial International Conference. P122-123	Objectives: Data mining may be a useful tool in aiding in the diagnosis of ME/CFS. There are many challenges in diagnosing ME/CFS. Some symptoms associated with it are common of other illnesses, and there are competing definitions that investigators may use. More work with data mining in ME/CFS research could aid in further identification of cardinal symptoms, leading to better diagnostic ability. This would also combine an objective, computer driven decision with a physician's medically influenced decision to come up with a better and more reliable way to diagnose and treat ME/CFS. This article contrasts two case definitions for Myalgic Encephalomyelitis/chronic fatigue syndrome (ME/CFS). We compared the empiric CFS case definition (Reeves et al., 2005) and the Canadian ME/CFS Clinical case definition (Carruthers et al., 2003) with a sample of individuals with CFS as defined by the Fukuda et al. (1994) criteria versus those without CFS from a community-based sample. Methods: Data mining with decision trees was used to identify the best items to identify patients with CFS. Data mining is a statistical technique that was used to help determine which of the survey questions were most effective for accurately classifying cases as defined by the two case definitions versus others contained by the study. Results: The empiric criteria identified 79% of patients with CFS and the Canadian criteria identified 87% of patients with CFS. Items identified by the Canadian criteria had more construct validity. ME/CFS is often thought to include post-exertional malaise and neurocognitive disorders, and both did emerge as predictive factors for the Canadian criteria, but not when using the Reeves et al. (2005) empiric case criteria. In addition, sleeping disorders and pain symptoms, other key symptoms of ME/CFS, did emerge for the Canadian criteria as well as in the immune areas (i.e., sore throat and multiple chemical sensitivities), and this supports evidence for the Canadian criteria. In contrast, the empiric criteria tended to identify more general areas, including less activity, social and role functioning problems, and some pain issues. However, critical symptoms such as post-exertional malaise, neurocognitive symptoms and sleep disorders were not identified as discriminating symptoms with the Reeves et al. (2005) criteria. Conclusion: The study's overall findings were that the Reeves et al. (2005) criteria were not as capable of identifying cases from non-cases

				as the Canadian criteria (Carruthers et al., 2003). The Reeves criteria have been criticized as being more general and broader than the Fukuda et al. (1994) criteria, and the results of this study suggest that these criteria are only able to discriminate 79% of cases from others, whereas the Canadian criteria were able to 87% of cases. In addition, when examining the items selected in both analyses, it is apparent that the Canadian criteria appear to select cardinal and central features of the illness.
Johdoi, Takako[1]; Kawatani, Junko[1]; Shiraish, Seisi[1]; Tomota, Akemi[1]; Miike, Teruhisa[2]	1. Department of Child Development, Faculty of Medical and Pharmaceutical Sciences, Kumamoto University Graduate School, 1-1-1 Honjo, Kumamoto 860-8556, Kumamoto, Japan. 2. Hyogo Children's Sleep and Development Medical Research Center 1070 Akebono-cho, Nishi-ku, kobe 651-2181, Hyogo, Japan	Childhood Chronic Fatigue Syndrome and School Phobia in Junior High Students in Japan	Bulletin of the IACSF/ME. 17 (3). Fall 2009.	The Japanese Ministry of Education, Culture, Sports, Science and Technology reported in 2007 that 105,000 junior high school students (2.91% of all students) had "school phobia". Over the last 15 years, a considerable number of students diagnosed with school phobia have been found to fulfill diagnostic criteria for childhood chronic fatigue syndrome (CCFS). Symptoms of CCFS are similar to those seen in adult chronic fatigue syndrome. In this study, 128 junior high school students with the chief complaint of school non-attendance were presented to the Department of Child Development Outpatient Clinic at Kumamoto University (Jan.-Dec. 2008). They were medically examined using the 2007 international CCFS case definition, and given a Performance Status Score, a measure of functional status. Results showed that 72 (56.3%) students fulfilled CCFS criteria for severe or moderate illness, and 35 students (27.3%) were diagnosed with atypical CCFS or CCFS- like disorder. Twenty one patients (16.4%) either met criteria for other conditions including hyperthyroidism, major depression and narcolepsy or were without clear diagnosis. The results suggest that a diagnosis of CCFS is often associated with school non-attendance or school phobia in Japan.
Jolly, Ken	kjols@xtra.co.nz	Information Sheet: Trying Out Alternative Treatments	Bulletin of the IACSF/ME. 16 (1). Spring 2008.	Most people with ME/CFS at some time or other will try alternative treatments in order to get better. This would seem a reasonable and understandable approach, considering how difficult this illness can be at times... However this doesn't mean that patients should necessarily blindly accept such treatments. A reasoned and careful approach is in order.
Kaseeska, Kristen; Brown, Molly; Jason, Leonard	Leonard Jason, Center for Community Research, 990 W. Fullerton Ave., Suite 3100, Chicago, IL 60614 email: ljason@depaul.edu	Comparing Two Fibromyalgia Diagnostic Criteria in a Cohort of Chronic Fatigue Syndrome Patients	IACSF/ME. 19 (1). Summer 2011.	Two different diagnostic criteria for Fibromyalgia, 1, 2 produced by The American College of Rheumatology were compared with a chronic fatigue syndrome (CFS) sample. While the original Wolfe et al[1] criteria included a patient's tender points, the newer Wolfe et al[2] criteria introduced a total of 44 somatic symptoms in addition to areas of pain throughout the body. The original criteria identified fewer patients with CFS as having co-occurring Fibromyalgia than the newer criteria. In addition, the 1990 criteria better differentiated physical functioning limitations among those with and without Fibromyalgia. The implications of these findings are discussed.
Katz, Benjamin; O'Gorman, Maurice; Wang,	Ben Z. Katz, MD, Professor of Pediatrics, Northwestern	Natural Killer Cell Number and Function in a	IACSF/ME. 19 (2). Fall 2011. Abstracts from IACFS/ME Biennial International	Introduction: Chronic fatigue syndrome (CFS) is a complex condition involving severe fatigue and disabling musculoskeletal and cognitive symptoms. Whether immunologic dysfunction accompanies CFS is controversial. Arguably the most consistent

Deli; Mears, Cynthia; Shiraishi, Yukiko; Taylor, Renee	University Feinberg, School of Medicine, Attending Physician, Division of Infectious Diseases, Children's Memorial Hospital 2300 Children's Plaza, Chicago,IL60614 bkatz@northwestern.edu	Prospective Cohort of Adolescents with Chronic Fatigue Syndrome and Controls Following Mononucleosis	Conference. P124-125	immunologic disturbance associated with CFS is reduced function of natural killer (NK) cells. Objectives: We examined NK function in our cohort of adolescents following infectious mononucleosis (IM) and recovered controls matched for age, sex and Tanner stage. Methods: Nine adolescents with CFS and 9 matched, recovered controls had blood drawn for NK cell quantitation and functional analysis that was performed blinded at 6, 12 and 24 months following IM. At each time point, NK cell quantification was ascertained by flow cytometry as %CD56+ cells, and NK cell function was determined using K562 cells and 3 different dilutions of patient lymphocytes. NK cell numbers were scored as high, normal or low. NK cell function was scored as normal, low or borderline by pre-determined parameters by an investigator blinded as to the patient's diagnosis. Statistical analysis was conducted using generalized linear mixed model with repeated measurements and linear mixed model with SAS 9.2. Results: There were 27 evaluable time points for the CFS patients and 25 for the controls. There was no difference in NK numbers between cases and recovered controls. NK function was significantly higher in case patients with CFS 6 months following IM than in recovered controls (p=0.02). Conclusion: We could not confirm decreased NK cell function in adolescents with CFS following IM.
Kaur, Manraj; Mehta, Saurabh	Manraj Kaur, MSc Rehabilitation Science Student, McMaster University, IAHS, Room 308, 1400 Main St. W. Hamilton ON, L8S 1C7 kaurmn@mcmaster.ca	Are Walls Better Than ill-Defined Bridges? Revisiting Descartes' Biomedical Model From a Biopsychosocial Perspective in Chronic Pain Due to Osteoarthritis	IACSF/ME. 19 (2). Fall 2011. Abstracts from IACFS/ME Biennial International Conference. Poster Presentations. P158.	Introduction: Biopsychosocial and biomedical model are two remarkably different and most argued perspectives on chronic pain. In contrast to biomedical model, biopsychosocial model facilitated greater understanding of the contribution of mental and social health to chronic pain experience. This led to a theoretical and practical shift from traditional unidimensional towards integrated models of chronic pain. However, these multidimensional models have failed to offer a uniform definition, classification system, diagnostic criteria or treatment strategies to manage chronic pain especially in that observed in osteoarthritis (OA) population. Instead, it has faced criticism for ill-defined integrating links which foster no standardization of research or clinical practice and therefore no future directions. Objectives: The purposes of the paper were i) to re-visit the philosophical underpinnings of the Descartes' biomedical model, ii) to discuss and critique the contributions of the biopsychosocial model over the biomedical model in chronic pain related to OA. Methods: A topical review of the studies concerning biopsychosocial and/or biomedical model and chronic musculoskeletal pain published in peer reviewed journals since 1960 was conducted. Patient population was restricted to osteoarthritis in the elderly age group. Results: Re-examining Descartes' philosophy reveals that much of the interpretation of his work does not reflect or elucidate the aspects of chronic pain as experienced by those with OA. Using the example of chronic pain in OA, this paper proposes that biopsychosocial model is essentially biomedical model with some additions and does

				not offer any significant advancement over the biomedical model. Conclusion: Efforts are to be directed towards a more absolute conceptualisation of chronic pain with collaboration of researchers and trans-disciplinary healthcare teams leading to explicit models that could possibly unravel the mind body dilemma in healthcare field.
Keller, Betsy A; Micale, FG	Betsy A. Keller, PhD, Professor Exercise & Sport Sciences Ithaca College, 318 Center for Health Sciences, Ithaca, NY 14850	Exercise Testing to Quantify Effects of Fatigue on Functional Capacity in Patients With CFS	IACSF/ME. 19 (2). Fall 2011. Abstracts from IACFS/ME Biennial International Conference. P123-124.	Objective: The purpose of this study was to assess the effects of post-exertional malaise (PEM) on functional capacity and anaerobic threshold in subjects diagnosed with chronic fatigue syndrome (CFS). Methods: Subjects were 10 females and 2 males (41.3+1.11 yrs) diagnosed with CFS by a physician experienced in the diagnosis of CFS. To induce PEM, each subject completed a maximum exercise test on a cycle ergometer. A second maximum exercise test was performed 24 hrs later to assess the effects of exercise-induced PEM on functional capacity. Maximum oxygen consumption (VO2max), maximum heart rate (HRmax), anaerobic threshold (AT), maximum workload (Wmax), workload at AT (ATwork), and respiratory exchange ratio (RER) were measured. RER is an objective indicator of substrate utilization and subject effort during exercise. Results: Significant decreases from test 1 to test 2 were 13.5% for VO2max (21.5 to 18.6 ml.kg-1.min-1; p<0.01), 8 bpm for HRmax (p<0.01), 18.8% for AT (12.0 to 9.7 ml.kg-1.min-1; p<0.05), 9.4% for Wmax (121 to 109 W, p<0.05), and 17.3% for ATwork (58.3 to 48.2 W; p<0.05). However, there was no change in maximum RER indicating that subject effort was maximum and also comparable during both tests. Conclusion: Results indicate that PEM decreased maximum functional capacity by more than 13% to below 5 METS; a level at or below that which is required by many job-related activities and IADLs. To compare, VO2max in healthy individuals is highly reproducible over days and even months (r>.95)1, with a SEM of < 6%1,2. Thus, for subjects in this study, an expected variation between tests would be ±1.29 ml.kg-1.min-1 in contrast to the observed decrease of 2.9 ml.kg-1.min-1. Furthermore, PEM decreased AT to below 3 METS (e.g., light-moderate speed walking), which is a level of many activities considered to be sedentary in nature. Thus, completion of sedentary ADLs and IADLs for those with CFS requires production of energy via anaerobic processes that will further contribute to PEM and exacerbate symptoms of CFS. Since many daily activities fall into the 3-5 MET range, individuals with CFS will exacerbate symptoms associated with PEM simply by completing normal daily activities.
Kindlon, T	Information Officer (voluntary position), **Irish ME/CFS Association,** PO Box 3075, Dublin 2, Rep. of Ireland, Email: tkindlon@maths.tcd.ie	Reporting of Harms Associated with Graded Exercise Therapy and Cognitive Behavioural Therapy in Myalgic	IACSF/ME. 19 (2). Fall 2011.	Across different medical fields, authors have placed a greater emphasis on the reporting of efficacy measures than harms in randomised controlled trials (RCTs), particularly of nonpharmacologic interventions. To rectify this situation, the Consolidated Standards of Reporting Trials (CONSORT) group and other researchers have issued guidance to improve the reporting of harms. Graded Exercise Therapy (GET) and Cognitive Behavioural Therapy (CBT) based on increasing activity levels are often recommended for Myalgic Encephalomyelitis/Chronic Fatigue Syndrome

	or info@irishmecfs.org	Encephalomyelitis/Chronic Fatigue Syndrome		(ME/CFS). However, exercise-related physiological abnormalities have been documented in recent studies and high rates of adverse reactions to exercise have been recorded in a number of patient surveys. Fifty-one percent of survey respondents (range 28-82%, n=4338, 8 surveys) reported that GET worsened their health while 20% of respondents (range 7-38%, n=1808, 5 surveys) reported similar results for CBT. Using the CONSORT guidelines as a starting point, this paper identifies problems with the reporting of harms in previous RCTs and suggests potential strategies for improvement in the future. Issues involving the heterogeneity of subjects and interventions, tracking of adverse events, trial participants' compliance to therapies, and measurement of harms using patient-oriented and objective outcome measures are discussed. The recently published PACE (Pacing, graded activity, and cognitive behaviour therapy: a randomised evaluation) trial which explicitly aimed to assess "safety", as well as effectiveness, is also analysed in detail. Healthcare professionals, researchers and patients need high quality data on harms to appropriately assess the risks versus benefits of CBT and GET.
Kindlon, Tom	Information Officer (voluntary position) Irish ME/CFS Association, PO Box 3075, Dublin 2, Rep. of Ireland	Letter to the Editor Re: A pilot study of the process of change in a group Chronic Fatigue Syndrome management programme. Bulletin of the IACFS/ME. 2009;17(2):53-68	Bulletin of the IACSF/ME. 17 (3). Fall 2009.	Group interventions based around encouraging CFS patients to increase activity levels have shown modest results. Royle and Pimm (1) state "cognitive-behavioural therapy [CBT] and graded exercise therapy [GET] are efficacious therapies in patients with Chronic Fatigue Syndrome (CFS)". But is this true for group programmes? See also: Royle, G, and Pimm,J. Response to letter from Tom Kindlon. Bulletin of the IACSF/ME. 17 (3). Fall 2009.
Klapow, LA; Nathan, N	Klapow Bioscience and Gordon Medical Associates, Santa Rosa, California	Live, Moving Varestrongylus klapowi: an Atypical, Chronic Nematode Parasite in the Nasal Washings of CFS Patients	IACSF/ME. 19 (2). Fall 2011. Abstracts from IACFS/ME Biennial International Conference. Poster Presentations. P176-177.	Objectives: • Obtain "proof of life" evidence for the atypical *V. klapowi* (Vk) parasite by documenting the vital movements of living worms. • Develop a rapid accurate method for diagnosing the infection by analyzing washings from nasal membranes.• Determine the ethanol concentration for effective nasal spray disinfectants. Methods: A nasal irrigation bottle was used to force warm physiological saline (0.9% NaCl, ~90°F) up one nostril to collect fluid (~60 ml) through the other nostril of CFS patients who were previously shown to be positive for the Vk parasite by sputum analysis. Vk specimens were allowed to settle to the bottom of a 50 ml test-tube suspended in warm water (~90°F), gently pipetted to a warm dish and video-graphed under a stereo-microscope. Moving worms were also video-graphed using intense halogen lighting on a compound microscope equipped with two polarizers (one in the illumination, the other in the image path) to reduce glare. Four Vk positive patients previously diagnosed by sputum analysis (inhalation of 1% ethanol for 30 minutes, then self induce coughing) were re-tested by the nasal washing method. Two patients

				inhaled the fumes of 40% ethanol through the nose for 10 breaths just prior to the nasal washing which my have helped release live worms. Results: Video-graphs showed gross body locomotion as well as rhythmic movements of internal organs. Repeated thrusting movements of the head were seen in the tissue boring fourth stage larva. Whole body contractions were seen in males. Rapid repeated rhythmic contractions of the digestive track (esophagus and intestine) and associated glands were seen in these and other stages. All four patients who were positive by sputum analysis were also positive by the nasal washing method. Previous experiments had shown that inhalation of one percent nebulized ethanol for 30 minutes sterilized sputum from the lungs. Higher concentrations, currently being studied, will likely achieve more rapid sterilization of nasal membranes. Conclusions: *Varestrongylus klapowi* is an anatomically specialized nematode, not an artifact, as evidenced by the vital movements of live specimens showing both gross locomotion and rhythmic movements of internal organs. It has recently been isolated from nasal washings of CFS patients who were previously positive by sputum analysis. The infections are chronic and widely disseminated as they occur in the same individuals over many years, in sputum, intestinal, and now, nasal washings. A study using the nasal washing method is being planned which will attempt to confirm previously reported, statistically significant, blinded sputum analysis linking the infection to CFS. Dilute ethanol sprays can kill the Vk parasite on mucus membranes.
Klimas, Nancy (Chair), Case Presentations by: Lapp, Charles Bateman, Lucinda Vallings, Rosamund Enlander, Derek	[no address given]	Session: DIAGNOSING CFS/ME; DIFFICULT CLINICAL CASES	IACSF/ME. 19 (2). Fall 2011. Abstracts from IACFS/ME Biennial International Conference. P119-121	In this workshop, experts will present difficult cases, and discuss the diagnostic and management implications. Cases may include “look alike cases” that presented with the signs and symptoms of ME, but in fact were found to be caused by another disorder; complex management issues; medication use and medication intolerance and other issues of interest to the practicing clinician. Related conditions such as Gulf War Illness will be included in the case discussion. The workshop will welcome interchange with the clinicians attending the session. Basic scientists may also hear in this discussion some of the issues that trigger further research ideas. Charles Lapp, M.D., Lucinda Bateman, MD, Rosamund Vallings, MNZM, MB BS, and Derek Enlander, M.D. will present cases that will serve as a platform for discussion.
Knight, K	Kim Knight, Certified Mickel Therapist and Mickel Therapy trainer for Australasia, BA (Hons), Director of the Art of Health and Mickel Therapy Clinic (New Zealand), PO Box 84318, Westgate, Massey 0657,	To Show How the Propensity for Chronic Fatigue Is Set Up During Infancy and Childhood	IACSF/ME. 19 (2). Fall 2011. Abstracts from IACFS/ME Biennial International Conference. Poster Presentations. P182.	Objectives: To show how the seeds and propensity for chronic fatigue and related syndromes are sown during infancy and childhood via the mental patterning and emotional conditioning set in place in the environment. So-said patterns and conditions result in the formation of limiting self-beliefs and ensuing disempowering behaviours which put the body into an abnormal and perpetual state of stress. This eventually rewires the cells into illness. Methods: By taking a detailed case history from birth to the present with more than 500 clients and noting in particular the mental and emotional perceptions or responses to upsetting and traumatic events. Results: In every case, without fail, unconscious negative and self-limiting beliefs were set up in childhood which in turn led to disempowering behaviours towards self. This

	Auckland, New Zealand info@artofhealth.co.nz			put the body into a perpetual state of stress (sympathetic response) from a very early age which over time resulted in physical depletion such as adrenal exhaustion and a weakened immune system which opened itself up to viruses. This in turn eventually led to chronic fatigue. Conclusion: The propensity for chronic fatigue is set up in childhood via environmental factors, in particular mental belief systems and emotional patterns which lead the client to perpetuate life-depleting behaviours which result in illness. Therefore it is essential when looking for solutions to take into account the person's current and past history in its totality. The ongoing evidence can then be used again in practice.
Kozak,C	Laboratory of Molecular Microbiology, National Institute of Allergy and Infectious Diseases, Bethesda, MD, 20892-0460, USA	Gammaretroviruses of Mice and Their Links to Prostate Cancer and CFS/ME	IACSF/ME. 19 (2). Fall 2011. Abstracts from IACFS/ME Biennial International Conference. P112.	Gammaretroviruses of three distinct host range tropisms have been isolated from the laboratory mouse. These viruses differ in receptor usage, distribution among wild mouse species and strains of laboratory mice, pathogenicity and sensitivity to host restriction factors. Two of these three host range groups, the xenotropic and polytropic mouse leukemia viruses (together termed XP-MLVs) are widely distributed in house mouse species, mice that live in closest contact with humans. XP-MLVs rely on the XPR1 receptor for entry into cells as does the xenotropic murine leukemia virus-related virus (XMRV) initially identified in human patient samples. Despite their initial description as viruses incapable of infecting mouse cells, the xenotropic viruses have the broadest host range of the MLVs. Nearly all nonrodent mammals are susceptible to X-MLVs, as are all wild mouse species and some inbred strains of laboratory mice. Their XPR1 receptor is highly polymorphic, and there are 5 functional variants of *Xpr1* in *Mus* species and laboratory mouse strains that differ in their ability to support entry of XMRV and various isolates of XP-MLVs. The distribution of XP-MLVs and *Xpr1* variants in wild mouse populations provides a good example of how diversifying selection can be driven by genetic conflicts. Restrictive receptor variants evolved in Eurasian house mouse populations exposed to XP-MLV infection suggesting that positive selection favors antiviral alleles in virus-infected species. The ecotropic and polytropic MLVs have long been linked to disease induction in mice, and the discovery that all wild mice and some laboratory strains are also susceptible to X-MLV has made it possible to examine the disease inducing potential of these viruses in mice as well as in other model systems. X-MLVs are capable of establishing infection in mice carrying permissive XPR1 alleles, but X-MLV does not induce or accelerate disease in mice with permissive receptors inoculated as adults or neonates, and X-MLVs do not readily establish productive infection in monkeys. Host factors that restrict retroviruses effectively limit virus spread and disease induction in mice and other species.
Kuratsune, H; Nojima, Junzo	Kansai University of Welfare Science, Osaka e-mail: kura@fuksi-kagk-u.ac.jp	Objective Biomarkers For The Fatigue State -The Changes Of Oxidation Stress	IACSF/ME. 19 (2). Fall 2011. Abstracts from IACFS/ME Biennial International Conference. Poster	Background: It is well known that the accurate evaluation of fatigue states in each subject is quite difficult, because the levels of fatigue depend on the subjective feeling. Since 2009, the study group (head: Hirohiko Kuratsune) supported by Japanese Ministry of Health, Labor and Welfare has been working for the

			Presentations. P180-181.	establishment of objective biomarkers to diagnose the fatigue states in Japan. We present here the relationship between the fatigue states and the changes of oxidation stress. Materials and Methods: To investigate the role of oxidative stress in the pathogenesis of fatigue states, we measured both oxidation and anti-oxidation activities simultaneously in sera from 303 patients with chronic fatigue syndrome (CFS), 24 people with severe industrial fatigue, 20 healthy students before and after 3 hour mental workload and 312 healthy volunteers by using the d-ROMs test and the BAP test (Diacron; Grosseto, Italy). The oxidation stress index (OSI) was calculated by the following formula: OSI = (d-ROMs / BMP) × 8・85 (a coefficient for standardization to set the mean of healthy individuals to 1.0). Results: The oxidation activities (d-ROMs) in 312 healthy controls are 286.9 ± 50.1 unit (mean ± SD), and the d-ROMs are related to their age. The d-ROMs are higher in female than in male. On the other hand, the anti-oxidation activities (BAP) in 312 healthy volunteers are 2541 ± 60.8 μmol/L, and the BAP are not related to the age and sex. In the CFS group, the d-ROMs and the BAP are 328.8 ± 81.3 units and 2508 ± 102.6 μmol/L, respectively. The d- ROMs are significantly higher in the CFS group than in the control group ($p<0.001$), and the BAP are significantly lower in the CFS group than in the control group ($p<0.001$). The OSI are related to the Performance Status in the CFS patients ($p<0.005$). In the severe industrial fatigue group, the d-ROMs are 410.0 ± 67.0 units, and they are significantly higher in the severe industrial fatigue group than in the control group ($p<0.001$). The BAP are 2527 ± 115.5 μmol/L, and there is no significant difference in the BAP between the severe industrial fatigue group and the control group. When we studied the d-ROMs and the BAP before and after 3 hour mental workload in 20 healthy students, the d-ROMs and the BAP are 301.3 ± 23.6 unit and 2389.6 ± 81.2 μmol/L before workload, and 321.2 ± 33.0 unit and 2438.8 ± 92.9 μmol/L after workload, respectively. After mental workload, both the d-ROMs and the BAP are significantly increased as compared to those before mental workload, and there is no difference in the OSI between before and after workload. Conclusion: The evaluation of oxidation and anti-oxidation activities by using the d-ROMs test and the BAP test reflects not only the clinical condition with or without fatigue state, but also the etiology of fatigue state. Therefore, these evaluations might make useful objective markers for diagnostic evaluation of fatigue states.
Lange, Gudrun	Pain and Fatigue Study Centre, UMDNJ-New Jersey Medical School	Multi-tasking: A challenge for patients with CFS	Bulletin of the IACSF/ME. 17 (1). Spring 2009. P32-36	As a researcher and a practicing clinical neuropsychologist my task is to assess cognitive function in CFS patients. Once the test measures given are scored and the results interpreted, I provide feedback about my findings. Very often the findings are consistent with decreased information processing speed and poor working memory while overall intellectual function is usually intact. These results are not uncommon in CFS and are supported by increasing research evidence (1, 2). During feedback sessions, I aim to explain the deficits found, but are frequently asked the question: "How do these findings relate to what I am experiencing in my daily life and what, if

				anything, can I do about it?" I will use this brief essay to begin to address these questions.
Larson, B; Davenport, TE; Stevens, SR; Steens, J; Van Ness, JM; Snell, CR	Benjamin M. Larson , 895 El Paseo St. Undergraduate Researcher, Pacific Fatigue Laboratory Turlock, CA 95380 b_larson2@u.pacific.edu	Effort Perception in Chronic Fatigue Syndrome Is Not Impaired	IACSF/ME. 19 (2). Fall 2011. Abstracts from IACFS/ME Biennial International Conference. Poster Presentations. P182-183.	Background and Objectives: Activity pacing is one cornerstone of rehabilitation management for CFS. Optimal criteria for pacing are currently unclear, because patients with CFS may have an impaired ability to self-assess their level of physical exertion. However, this hypothesis has yet to be directly tested. The purpose of this study was to determine the association between subjective and objective indicators of physical effort in patients with CFS and matched controls. Materials and Methods: Sixteen patients with CFS and 14 age- and sex-matched non-disabled, sedentary individuals were tested. Each subject received 2 maximal cardiopulmonary exercise tests (CPETs) on a braked bicycle ergometer that were administered 24 hours apart. Heart rate (HR) was measured continuously and rating of perceived exertion (RPE) was assessed at each minute from rest and unloaded cycling until peak exercise. Descriptive statistics (mean ± standard deviation) were calculated for all dependent variables (DVs), including peak HR (HRpeak), HR at VT (HRVT), peak RPE (RPEpeak) and RPE at VT (RPVT). 2x2 analysis of variance (ANOVA) was used to assess the main and interaction effects of group and test on DV measurements. Repeated measures ANOVA was used to assess group and time main and interaction effects on DV measurements. Pearson's correlations (r) were calculated to determine the within-groups associations between HR and RPE during each CPET. Criterion for statistical significance of differences was $\alpha \leq .05$. Results: All subjects met standard criteria for maximal effort during each CPET. HRpeak was significantly lower for patients with CFS (CPET1: 158±15 beats per minute [bpm]; CPET2: 156±17bpm) compared to controls (CPET1: 182±13bpm; CPET2: 183±11bpm) on both CPETs ($p<.01$). HRVT also was significantly lower for patients with CFS (CPET1: 113±21bpm; CPET2: 111±14bpm) compared to controls (CPET1: 122±15bpm; CPET2: 131±17bpm) on both CPETs ($p<.01$). RPEpeak was significantly greater in patients with CFS (CPET1: 19.4±1.0; CPET2: 19.6±0.07) compared to controls (CPET1: 19.4±0.8; CPET2: 18.7±2.1) on both CPETs ($p<.01$). RPEVT also was significantly greater patients with CFS (CPET1: 13.2±2.5; CPET2: 12.7±2.6) compared to controls (CPET1: 10.2±2.5; CPET2: 11.2±2.4) on both CPETs ($p<.01$). Time series analysis revealed significant group effects for HR ($p<.01$) and significant group and group x time effects for RPE ($p<.01$). HR and RPE demonstrated moderate to high correlation in subjects with CFS (CPET1: $r=.769$, $r2=.591$; $p<.001$; CPET2: $r=.765$, $r2=.591$; $p<.001$) and control subjects (CPET1: $r=.742$, $r2=.551$; $p<.001$; CPET2: $r=.688$, $r2=.473$; $p<.001$). Conclusion: Subjects with CFS demonstrated significantly greater effort ratings than control subjects during each CPET. HR and RPE were significantly correlated in subjects with CFS and matched control subjects. Clinical Relevance: The significant association between HR and RPE indicates patients with CFS can accurately perceive their level of physical exertion. Thus, patients' perceptions of physical exertion can be used with confidence as a basis

				for pacing self-management programs.
Leonard A. Jason[1]; Judith Richman[2]; Nicole Porter[1]; Mary Benton[3]	DePaul University [1]; University of Illinois, Chicago[2]; Wichita State University[3]	Why the Name of An Illness is of Importance	Bulletin of the IACSF/ME. Fall 2006.	Despite its chronicity and severity, CFS remains highly controversial (Richman, & Jason, 2001). A particularly high percentage of patients with this illness have experienced disrespect and poor treatment by the health care system. Below, we review an issue involving the name given to this illness, which may have contributed to the diagnostic scepticism and stigma that those with this illness encounter.
Letcher, MA; Klimas, NG	Mary Ann Fletcher, Ph.D. Professor, University of Miami Miller School of Medicine.1600 NW 10th Ave, Miami, FL 33135, USA mfletche@med.miami.edu	Biomarkers in CFS/ME	IACSF/ME. 19 (2). Fall 2011. Abstracts from IACFS/ME Biennial International Conference. Poster Presentations. P169-170.	Objectives: Validated laboratory tests are essential for diagnosis and for monitoring therapy of CFS/ME. Diagnosis using the case definition [Fukuda, et al, 1994] requires the exclusion of any other medical explanation for these symptoms, yielding an inefficient, slow, error prone process. This is also costly because the current clinical diagnosis typically involves tertiary care specialists. The search for biomarkers included lymphocyte functions as well as molecules associated with lymphocyte activation, with stress and with inflammation. Methods: CFS/ME patients were drawn from the University of Miami (UM) Miller School of Medicine CFS/ME and Immunodeficiency Clinic. All were participants in funded studies (NIH, DOD, Chronic Fatigue Immunodeficiency Syndrome Association (CFIDS) or the Veterans Affairs Merit grant). Prospective biomarkers included natural killer cell cytotoxicity (NKCC), T lymphocyte proliferation in vitro in response to mitogen (LPA), lymphocyte activation markers (CD26, CD38), 16 plasma cytokines and neuropeptide Y. All laboratory evaluations of prospective biomarkers were done in the UM/VA clinical immunology laboratories. The diagnostic accuracy of biomarkers was assessed in terms of true positive (sensitivity) versus true negative (specificity) rates using nonparametric receiver operating characteristics (ROC) curve analyses. Results: These studies provided credible biomarker status for NKCC, LPA, and markers of lymphocyte activation in CFS/ME. A significant elevation in the relative amounts of 4 of 5 pro-inflammatory cytokines in peripheral blood plasma of patients with CFS/ME was found when compared with the controls Only tumor necrosis factor (TNF)a was unchanged. In cases, lymphotoxin (LT)a was elevated by 257% and IL-6 by 100% over the controls. Both interleukin (IL)-4 and IL-5 were elevated in CFS/ME, with the median of IL-4 240% and of IL-5 95% higher in cases over controls. The anti-inflammatory cytokine IL-13 was significantly lower (15%) in CFS/ME patients while IL-10 was not different. Plasma levels of IL-2 and IFN. in CFS were similar to those in controls. However, IL-12 was significantly elevated (120%) and IL-15 decreased 15% in cases compared to controls. IL-8 (CXCL8) was 42% lower in the CFS/ME patients. IL-17 and IL-23 were not significantly different in CFS cases compared to controls. ROC analyses calculating area under the curve (AUC) for IL-5 (0. 84), LTa (0.77), IL-4 (0.77), IL-12 (0.76) indicated good biomarker potential. The AUC of IL-6 (0.73), IL-15 (0.73), IL-8 (0.69), IL-13 (0.68) IL-1a (0.62), IL-1ß (0.62) showed fair potential as biomarkers. The stress hormone, NPY, was elevated in plasma of CFS/ME cases and positively

				correlated with perceived stress, anger, depression, negative thoughts and maladaptive coping. ROC analysis indicated that the predictive ability of plasma NPY was significantly better than chance alone in distinguishing patients with CFS/ME from healthy controls. Conclusions: Fifteen useful biomarkers were identified in these studies. The differences of these markers in CFS/ME compared to controls also give important information regarding the pathophysiology of the disorder. The association of low LPA response, elevated proportion of activated CD4 and CD8 T cells, defective NKCC, elevated TH2 cytokines with CFS/ME cases suggests that T cells are metabolically limited in performing their helper function. All but one of the inflammatory cytokines measured were elevated as was the stress hormone, NPY – supporting the hypotheses that inflammation and abnormal stress responses are important components in the pathophysiology of CFS/ME.
Levine, SM; Sterling,M	Susan Levine, MD 115 East 72nd Street, Suite 1A, New York, NY 10021, e-mail cfssuelev@earthlink.net	Results of Head Upright Tilt Table Test as a Predictor of Disability in a Group of Chronic Fatigue Syndrome Patients	IACSF/ME. 18 (1). Spring 2010.	*Background:* Chronic Fatigue Syndrome (CFS) is a complex illness characterized by the presence of debilitating fatigue, myalgias, sore throats, headaches and cognitive disturbances. Autonomic dysfunction or orthostatic intolerance (OI) characterized by the presence of dizziness, palpitations and frank syncope has been implicated as a cause of some of the debility experienced by a subgroup of CFS patients. *Methods:* Using the results of Head Upright Tilt Table Testing (HUT), in addition to the frequency of symptoms of both CFS and OI reported by 15 subjects chosen randomly from S.L.'s private practice, we sought to determine whether the presence of autonomic dysfunction was associated with a likelihood of disability among these patients. *Results:* Of the CFS patients studied 13/15 had a positive HUT. Twelve of the thirteen patients who had a positive outcome on HUT were fully disabled and receiving disability benefits. Three of the thirteen patients who were positive had a history of syncopal episodes and demonstrated syncope on HUT. *Conclusion:* Results of this study suggest that HUT in addition to a strong history of autonomic symptoms, especially syncope, may be useful in determining disability status among CFS patients. It is important to note that methodological differences among testing sites including experience with the method in general, angle of tilt, and monitoring of ambient conditions during HUT, may affect the interpretability of the HUT data. In addition, variability among CFS patients including comorbid medical conditions, such as presence of Mitral Valve Prolapse or Asthma or the use of vasoactive medications prior to testing, may influence the outcome of this procedure.
Martin Lerner, A; Ariza, M; Williams, M; Jason, L; Beqaj, S; Glaser, R	A. Martin Lerner, M.D., 32804 Pierce Street, Beverly Hills, MI 48025, www.treatmentcenterforcfs.com	Epstein-Barr Virus Latent Abortive Reactivation Replication of the Encoded Gene Products	IACSF/ME. 19 (2). Fall 2011. Abstracts from IACFS/ME Biennial International Conference. Poster Presentations. P141-142	Methods: With a specific ME/CFS diagnostic panel, 6 patients with Epstein-Barr Virus (EBV) subset were treated with valacyclovir (14.3 mg/Kg q 6 h) for greater than or equal to 12 consecutive months. EBV assays were repeated every 6-12 weeks in each patient. ELISA assays included EBV, Early Antigen (Diffuse) EBV EA(D), Viral Capsid Antigen (VCA) IgM. Neutralization assays included EBV dUTPase and EBV/DNA polymerase. Results: a) EBV VCA, IgM: 51 separate sera were tested for EBV VCA IgM.

		Deoxyuridine Triphosphate (dUTPase) and Deoxyribonucleotide polymerase (DNA polymerase) in Myalgia Encephalomyelitis Chronic Fatigue Syndrome (ME/CFS)		All were negative. b) EBV EA(D): 48 separate sera were tested for EBV EA(D). 46 of 48 assays (95.8%) were positive c) EBV dUTPase: three of 9 (33.3%) positive assays; patient one: five of 7 (71.4%) positive assays; patient two: three of 10 (30%) positive assays; patient three: eight of 10 (80%) positive assays; patient four: three of 8 (37.5%) positive assays; patient five: two of 7 (28.6%) positive assays. Therefore, all 6 patients had positive assays for elevated antibody titers to dUTPase, d) EBV/DNA polymerase: Eight of 10 (80%) patient one: four of 7 (57.1%) patient two: seven of 10 (70%) patient three: nine of 10 (90%) patient four: seven of 8 (88%) patient five:six of 7 (71.4%) were positive assays for EBV DNA polymerase. Therefore, all 6 patients had positive assays fpr elevated antibody titers to EBV DNA polymerase. Conclusions: There was no evidence of EBV lytic replication in these ME/CFS patients. There were 47/50 (94%) EBV EA(D) positive assays, 24/51 (47%) dUTPase positive assays, and the 41/52 (78.8%) DNA polymerase positive assays. These data document EBV latent abortive reactive replication in these six ME/CFS patients and suggest a possible etiologic relationship to the ME/CFS.
Meirleir,KD; Frémont, M; Khaliboulina, S; Lombardi,VC; Puccinelli, C; Metzger,K; Mikovits,JA	Department of Human Physiology, Vrije Universiteit Brussel, Pleinlaan 2, B- 1051 Brussels Belgium, Email: de.meirleir@telenet.be	Detection Of Anti-XMRV Antibodies In Serum of CFS Patients and Healthy Blood Donors in Belgium	IACSF/ME. 19 (2). Fall 2011. Abstracts from IACFS/ME Biennial International Conference. P113-114.	Objectives: Xenotropic murine leukemia virus–related virus (XMRV) is a new human gammaretrovirus originally identified in prostate cancer patients with a deficiency in the antiviral enzyme RNase L. An association has been made between XMRV and Chronic Fatigue Syndrome (CFS), with a 2009 study reporting the presence of XMRV DNA in the blood of 67% of CFS patients, whereas only 3,7% of healthy controls tested positive. In 2010 another study detected murine leukemia virus (MLV)-like GAG sequences in 86.5% of CFS patients, versus only 6,8% of healthy blood donors. A number of other studies, however, have failed to detect XMRV DNA in the blood of CFS patients. The objectives of this study were to investigate the association between CFS and XMRV in a Belgian population of patients, and to estimate the prevalence of XMRV infections in the general population in Belgium. Methods: A flow cytometry-based assay was used to detect the presence of circulating anti-XMRV antibodies in the serum of 84 Belgian CFS patients. A subgroup of these patients (21) developed CFS after receiving a blood transfusion. Serum obtained from 44 Red Cross healthy blood donors was also tested. Samples were collected in Belgium and sent, blinded, to the Whittemore Peterson Institute in Reno for analysis. Results: 48 out of 84 patients (57%) presented circulating antibodies against XMRV (10 out of the 21 patients who received a transfusion). In contrast, only 7 out of 44 controls had anti-XMRV antibodies (16%). Conclusions: The higher prevalence of serology positives in the patient population, compared to the controls, supports the idea that XMRV is involved in the pathogenesis of CFS. The finding that 16% of healthy blood donors present evidence of infection with XMRV or a related virus raises questions regarding the need to screen blood donors for asymptomatic XMRV infections.

Miike, Terusha; Ymamashita, Nobuyuki	Teruhisa Miike, M.D. Ph.D, Chief of Hyogo Children's Sleep and Development Medical Research Center, 1070, Akebono-Cho Nishi-Ku Kobe, Hyogo, 651-2181, Japan E-mail: t_miike@hwc.or.jp	A Trial for Prevention of CCFS Onset from The View Point of Sleep Issue	IACSF/ME. 19 (2). Fall 2011. Abstracts from IACFS/ME Biennial International Conference. P128.	Objectives: We have been considering that CCFS has been completed with the following order. 1) In spite of night active modern type daily life, people should keep classical morning active daily life, 2) which causes chronic sleep deprivation, 3) developed failure of neuronal function maintenance, 4) induced the derangement of the biological clock which is important and necessary for a human social life and life itself, 5) resulted neuronal fatigue and loss of neurons,6) these conditions connected with each other, finally complete the failure of the everyday life, 7) resulted in school non-attendance and/or so called CCFS. Therefore we think that we will be able to prevent CCFS by reading sleep deficient sign from everyday life of children. Methods: Then we investigated the habit of the sleep-wake rhythm for 5,100 students (ranged 6-15 years of age) in Yawatacity, Kyoto to get actual information to contribute to our purpose. We asked all students to record the consecutive 14 days sleep-wake log and studied following subjects, 1) total sleep time, 2) sleep onset time, 3) wake-up time and 4) sleep-wake pattern. The sleep log was classified into the 8 kinds of patterns, which was made beforehand. (1: holiday sleep supply, 2:short sleep, 3:long sleep, 4:irregular sleep, 5:sleep after get home, 6:sleep fragmentation, 7:overlapping, 8:normal sleep) Results and Conclusion: Average bed time (First grader: 9:14, Second 9:15, Third 9:16, Fourth 9:33, Fifth 10:03, Sixth 10:21, Seventh 10:49, Eighth 11:15, Ninth 11:51 pm).. Average rise time (First grader: 6:58, Second 7:01, Third 7:01, Fourth 7:00, Fifth 7:06, Sixth 7:10, Seventh 7:03, Eighth 7:14, Ninth 7:31am). Average total sleep time (First grader: 9.8, Second 9.7, Third 9.7, Fourth 9.5, Fifth 9.0, Sixth 8.8, Seventh 8.2, Eighth 8.0, Ninth 7.7 hrs). In addition we found that prolonged short sleep and irregular sleep pattern are the strong risk factors that suggest a difficulty of performing daily school life, in this study. It is considered that sleep deprivation and irregular life style has a direct connection to the CCFS. According to these data we conceived that it may be possible to prevent CCFS by observing a lifestyle, especially a sleep-wake rhythm of children.
Mikovits, Judy	Judy A Mikovits, PhD, Research Director, Whittemore Peterson Institute, University of Nevada, Reno MS 0552, 1664 N Virginia St Reno NV 89557-0552	The Case FOR XMRV/Human Gammaretroviruses (HGRVs) in ME/CFS	IACSF/ME. 19 (2). Fall 2011. Abstracts from IACFS/ME Biennial International Conference. P115-116.	In 2009 using a classical virology approach of viral isolation and transmission, electron microscopy, serology and PCR, Lombardi et al demonstrated the first isolation of XMRV from blood from patients with chronic fatigue syndrome (CFS) predominately from the west coast of the United States. In 2010, Lo et al. extended these studies by detecting nucleic acids of MLV-related variants in the peripheral blood mononuclear cells of CFS from the northeastern United States suggesting additional strains capable of infecting humans exist. In a study of 300 CFS patients, 13 developed lymphoproliferative disorders. Of those tested, 11/11 were positive for XMRV and 9/9 positive for clonal TCR gamma rearrangements. Spontaneous development of four immortalized B cells lines occurred during culture of cells from CFS patients. Three developed from B cells isolated from the peripheral blood (two of whom had B cell lymphoma) and one from a bone marrow biopsy. The B cell lines have a mature CD20+, CD23+ phenotype and produce infectious XMRV. Virus production occurred

				despite extensive hypermutation of the proviruses in these cells by APOBEC3G. Therefore, XMRV infection may accelerate the development of B cell malignancies by either indirect chronic stimulation of the immune system and/or by direct infection of the B-cell lineage. Since viral load in peripheral blood is low, these data suggest that B cells in tissues such as spleen and lymph nodes could be an *in vivo* reservoir for XMRV. We have also identified an inflammatory cytokine and chemokine signature that distinguishes XMRV infected CFS patients from healthy controls with 94% sensitivity and specificity. Monitoring immune dysfunction affords the opportunity to begin to understand the pathogenesis of XMRVs. In addition to these data, recent advances in developing tests for detection and characterization of variants of XMRV will be also be discussed
Miller, Andrew H; Jones, JF; Drake, Df; Tian, H; Unger, ER; Pagnoni, G	Andrew H. Miller, M.D., Department of Psychiatry and BehavioralSciences, Emory University School of Medicine, 1365-B Clifton Rd., 5th Floor, Room B5101, Atlanta, GA, 30322, USA, amill02@emory.edu	Decreased Basal Ganglia Activation in CFS Subjects is Associated With Increased Fatigue	IACSF/ME. 19 (2). Fall 2011. Abstracts from IACFS/ME Biennial International Conference.p137-138	Objectives: Altered basal ganglia function has been associated with fatigue in a number of neurologic disorders, as well as in patients exposed to chronic immune stimulation. Patients with chronic fatigue syndrome (CFS) have been shown to exhibit symptoms suggestive of decreased basal ganglia function as reflected by psychomotor slowing on neurocognitive testing, which in turn correlated with fatigue. In addition, CFS patients have been found to have increased markers of immune activation. In order to directly test the hypothesis of decreased basal ganglia function in CFS, we conducted a functional magnetic resonance (fMRI) study on a sample of CFS patients and matched controls, using a reward-processing experimental protocol. Methods: A community-derived sample of 59 male and female subjects, including 18 patients diagnosed with CFS according to 1994 CDC criteria and 41 non-fatigued healthy controls, participated in the study. All subjects were free of psychotropic medications as well as significant depressive symptoms, as determined by a Zung Depression score <60. Groups were similar in age, sex, and race. While undergoing fMRI scanning, subjects performed a monetary gambling task previously shown to strongly activate basal ganglia in the 'win versus lose' condition. To focus our analysis on the specific basal ganglia regions activated by the task, the following procedure was employed: (1) a whole-brain group analysis revealing the general activation pattern for the win-lose contrast across all subjects was performed; (2) the resultant statistical parametric brain map thresholded at $p<0.05$, corrected for multiple comparisons, was intersected with a set of basal ganglia regions of interest (ROIs: caudate nucleus, putamen, and globus pallidus), obtained from a probabilistic cytoarchitectonic brain atlas included in the SPM Anatomy Toolbox; (3) for each subject, the average value of win-lose activation contrast in each ROI was extracted for group comparisons and correlational analyses. Results: Compared to non-fatigued controls, patients with CFS exhibited significantly decreased activation in the right caudate ($p=0.01$) and right globus pallidus ($p=0.02$). Decreased activation in the right globus pallidus was significantly correlated with increased mental fatigue ($r2=0.49$, $p=0.001$), general fatigue ($r2=0.34$, $p=0.01$) and reduced activity ($r2=0.29$, $p=0.02$), as measured by the Multidimensional

				Fatigue Inventory. No such relationships were found in control subjects. Conclusions: These data suggest that reduced basal ganglia activation may contribute to symptoms of fatigue in CFS subjects. Given the central role of dopamine in basal ganglia regulation, these data also indicate that alterations in dopamine metabolism may be involved. Further understanding of potential alterations of dopamine transmission and metabolism in basal ganglia, due to activated immune pathways or other causes, may lead to new pharmacologic strategies targeting dopamine and the basal ganglia for the treatment of CFS symptoms.
Miller, Andrew H; Jones, JF; Rajendra, J; Drake, D; Miller, A; Under, ER; Tian, H; Pagnoni, G	James F. Jones, 1600 Clifton Rd, MS-A15, Atlanta GA, 30333, USA, jaj9@cdc.gov	Interaction of Self-And Illness-Related Cognitive Processing in the Right Anterior Insula of CFS Patients: An MRI study	IACSF/ME. 19 (2). Fall 2011. Abstracts from IACFS/ME Biennial International Conference. P136-137	Objectives: Based on the core clinical complaints of CFS patients several groups have suggested that CFS symptoms may be at least partially linked to altered cognitive or pre-cognitive processing in the central nervous system. Targeting the identification of the neural substrates of alterations of internal body signals and self-related information seems warranted. This study investigates brain responses to self- and illness-related semantic information in a sample of CFS patients compared to matched control subjects, using functional magnetic resonance imaging (fMRI). We focus on the right anterior insula (rAIC), for its purported role in interoceptive processing and awareness (Craig 2002, 2009, Nat Rev Neurosci), and on the interaction of the self-related and illness-related semantic processing. Methods: Twenty-one subjects meeting the 1994 International criteria for CFS, and 42 non-fatigued (NF) subjects performed a semantic processing task while undergoing an fMRI scan. The stimuli consisted of visually presented short sentences requiring the participants to provide a "true" or "false" answer. The semantic content was arranged according to a 2 x 2 x 2 factorial design, where the three factors were (a) Self-related: yes/no, (b) Illness-related: yes/no, and (c) Valence: negative/positive. We assessed the effect of processing Self-related versus Non self-related semantic information, across the two groups of CFS and NF subjects in a single acquisition run of functional images by examining a set of regions of interest. Results: In both CFS and NF subjects: 1) the insular response to self-related sentences tended to decrease compared to response to non- self-related sentences, in both CFS and NF subjects; 2) the insular response to non-self sentences did not differ with respect to illness-related material or not; 3) the insular response to self-related/illness-related sentences was greater than that for self-related/non illness-related only in CFS subjects. A qualitatively similar pattern was observed for the response time data. The statistical significance for the group difference in the interaction effect (3-way ANOVA: Group x Self-related x Illness-related) was p=0.0034 for the rAIC activation data and p=0.0022 for the reaction time data. Conclusions: Self is a multifaceted construct that relies in part on interoception (monitoring of internal physiology and consequences of external stimuli) via the anterior insular cortex through recognition of subjective feelings (Craig). The changes observed here in CFS subjects indicate responses to an increased mental load or to a cognitive conflict within the semantic dimensions of self and illness. This is evidence

				that (1) there is a real alteration of body physiology underlying the CFS symptoms, and the observed altered rAIC response reflects the (normal) cognitive and pre-cognitive acquisition of an abnormal physiological landscape in the body; or (2) the actual interoceptive landscape is acquired cognitively and pre-cognitively in an altered way in CFS subjects, enhancing the prominence of normal bodily signals related to fatigue.
Moldofsky, H; Patchai J	[No address quoted]	Chronic Widespread Musculoskeletal Pain, Fatigue, Depression and Disordered Sleep in Chronic Post- SARS Syndrome; A Case-Controlled Study	IACSF/ME. 19 (2). Fall 2011. Abstracts from IACFS/ME Biennial International Conference. P115.	The long term adverse effects of Severe Acute Respiratory Syndrome (SARS), a viral disease, are poorly understood. Methods: Sleep physiology, somatic and mood symptoms of 22 Toronto subjects, 21 of whom were healthcare workers, (19 females, 3 males, mean age 46.29 yrs.+/- 11.02) who remained unable to return to their former occupation (mean 19.8 months, range: 13 to 36 months following SARS) were compared to 7 healthy female subjects. Because of their clinical similarities to patients with fibromyalgia syndrome (FMS) these post-SARS subjects were similarly compared to 21 drug free female patients, (mean age 42.4 +/- 11.8 yrs.) who fulfilled criteria for fibromyalgia. Results: Chronic post-SARS is characterized by persistent fatigue, diffuse myalgia, weakness, depression, and non-restorative sleep with associated REM-related apneas/hypopneas, an elevated sleep EEG cyclical alternating pattern, and alpha EEG sleep anomaly. Post- SARS patients had symptoms of pre and post-sleep fatigue and post sleep sleepiness that were similar to the symptoms of patients with FMS, and similar to symptoms of patients with chronic fatigue syndrome. Both post-SARS and FMS groups had sleep instability as indicated by the high sleep EEG cyclical alternating pattern rate. The post-SARS group had a lower rating of the alpha EEG sleep anomaly as compared to the FMS patients. The post-SARS group also reported less pre-sleep and post-sleep musculoskeletal pain symptoms. Conclusions: The clinical and sleep features of chronic post-SARS form a syndrome of chronic fatigue, pain, weakness, depression and sleep disturbance, which overlaps with the clinical and sleep features of FMS and chronic fatigue syndrome. Publication: Moldofsky and Patcai: Chronic widespread musculoskeletal pain, fatigue, depression and disordered sleep in chronic post-SARS syndrome; a case-controlled study. BMC Neurology 2011 11:37. See: http://www.biomedcentral.com/1471-2377/11/37
Moriya,J; Yamakawa, J; Motoo, Y	Junji Moriya (Assistant Professor.), Department of General Medicine, Kanazawa Medical University, 1-1 Daigaku, Uchinada-machi,Kahoku-gun, Ishikawa 920-0293, Japan	Resveratrol Improves Hippocampal Atrophy in Mice with Chronic Fatigue	IACSF/ME. 19 (2). Fall 2011. Abstracts from IACFS/ME Biennial International Conference. Poster Presentations. P144-145	Abstract: Neuroimaging evidence showed structural and/or functional abnormalities existing in the central nervous system, especially the hippocampus, in chronic fatigue syndrome (CFS) patients. However, its pathophysiologic mechanisms are unclear in part due to the lack of an applicable animal model. We established a chronic fatigue murine model by six repeated injections of *Brucella abortus* antigen to mice, which was manifested as reduced daily running activity and hippocampal atrophy. Thereafter, resveratrol, a polyphenolic activator of sirtuin 1, was used for treatment in this model. Daily running activity was increased by more than 20%, and the hippocampus was enlarged after 4-week resveratrol therapy. Furthermore,

	moriya@kanazawa-med.ac.jp			resveratrol inhibited neuronal apoptosis and expression of hippocampal acetylated p53 in the fatigue mice. Resveratrol also improved neurogenesis and expression of brain-derived neurotrophic factor mRNA in the hippocamous. We concluded that repeated injection of *B. abortus* antigen could induce hypoactivity and hippocampal atrophy in mice. Resveratrol may be effective for improving fatigue symptoms and enlarging the atrophic hippocampus by repressing apoptosis and promoting neurogenesis. Objectives: Neuroimaging indicates that structural and/or functional abnormalities exist in the central nervous system, especially in the hippocampus of patients with chronic fatigue syndrome (CFS). However, the pathophysiological mechanisms of CFS are still unclear, which is partly because of the lack of a suitable animal model. Methods: In the present study, we established a mouse model of chronic fatigue by six repeated injections of *Brucella abortus* antigen into Balb/c mice. Results: Which was manifested as a significant reduction in daily spontaneous running activity, and hippocampal atrophy. Thereafter, resveratrol (RSV), a polyphenolic activator of sirtuin 1 (Sirt1) was used for the treatment of this model. The daily spontaneous running activity was increased by more than 20%, and the hippocampus was enlarged after 4 weeks RSV therapy. Furthermore, RSV inhibited neuronal apoptosis and the expression of hippocampal acetylatedp53 in the chronic fatigue mice model, which may have contributed to the upregulated deacetylation of p53 by Sirt1. In addition, RSV improved neurogenesis and expression of brain-derived neurotrophic factor mRNA in the hippocampus. In conclusion, six repeated injections of *B. abortus* antigen induced hippocampal hypoactivity and atrophy in Balb/c mice. Conclusion: It is speculated that RSV is an effective agent for improving fatigue symptoms and enlarging the atrophic hippocampus, by repressing apoptosis and promoting neurogenesis, which might be one possible mechanism for recovery from fatigue.
Murvska, M; Chapenko, S; Krumina, A; Logina, I; Rasa, S; Chistyakov, M; Sultanova, A; Viksna, L	Modra Murovska, M.D., Ph.D., Director, August Kirchenstein Institute of Microbiology and Virology, Riga, Stradins University, Ratsupites St. 5, Riga, Latvia, LV-1067, e-mail: modra@latnet.lv; Modra.Murovska@rsu.lv	*Presence of Active HHV-6, HHV-7 and Parvovirus B19* Infection/Co-Infection In Patients With Chronic Fatigue Syndrome/Myalgic Encephalomyelitis	IACSF/ME. 19 (2). Fall 2011. Abstracts from IACFS/ME Biennial International Conference. Poster Presentations. P140-141.	Introduction: CFS/ME is a chronic neuro-immune illness defined by combination of non-specific symptoms of uncertain cause and pathogenesis. Immunomodulating viruses (HHV-6, HHV-7, parvovirus B19) are considered as possible trigger factors for CFS/ME development. The aim of this study was to evaluate frequency of HHV-6, HHV-7 and B19 infection activation/co-activation and association with clinical findings in CFS/ME patients. Methods: 108 patients (71 females and 37 males, mean age 37 years) with clinically diagnosed CFS/ME corresponding to CDC definition criteria were enrolled in the study. Plasma/serum samples were tested for HHV-6 and B19 IgG and IgM antibodies using ELISA. Qualitative and quantitative PCRs were used for viral genomic sequences detection in PBL and cell-free plasma DNA samples. Results: HHV-6 specific IgG and IgM antibodies were detected in 81.5% and 14.8% patients, respectively, B19 specific IgG and IgM antibodies - in 73.1% and 26.9% patients, respectively. Virus specific sequences were detected in 70/108 (64.8%) patients

				plasma DNA samples, from them single virus sequence - in 41 (38.0%) DNA samples (HHV-6 - 2, HHV-7 - 28, B19 - 11) and double or triple virus sequences - in 29 (27.0%) samples (HHV-6+HHV-7 - 10, HHV-7+B19 - 15, HHV-6+HHV-7+B19 - 4). HHV-6-PBL load was higher in patients with active HHV-6 and HHV-7 co-infection then in patients with single HHV-6 infection (1007.8±367.1x103, 133.0±10.3x103, copies/µg DNA, respectively). Severe chronic fatigue for at least six months or longer was recognized in all patients independently from the causation of the active infection. Subfebrility, tender cervical or axillary lymph nodes and post-exertional malaise were not revealed in patients with single B19 infection but were detected in patients with single HHV-7 infection (50.0%, 75.0%, 100%, respectively) and HHV-6+HHV-7 co-infection (68.9%, 83.4%, 88.9%, respectively). Persistent muscle and muscular weakness were detected in all patients with manifestation more severe in patients with HHV-6, HHV- 7 and HHV-6+HHV-7 infection. Multi-joint pain also was determined in all patients with stronger symptoms in HHV- 7+B19 (82.5%) and HHV-6+HHV-7+B19 (100%) co-infection cases. Neuropsychological disturbances were detected in all patients: impaired memory – in 85.0% patients with active HHV-7 and HHV-6+HHV-7 infection, and impaired concentration – in all patients with active B19, HHV-7+B19 and HHV-6+HHV-7+B19 infection. Unrefreshing sleep was revealed in all patients with sleepiness more characteristic in patients with HHV-7, HHV 6+HHV-7 (87.5%) and HHV-6+HHV-7+B19 infection, and sleepless – in all patients with HHV-6, B19 and HHV-7+B19 infection. Headaches of new type were reported from all patients with B19 infection versus 41.7% in patients with HHV-7 and HHV- 6+HHV-7 infection. Conclusion: High rate of active HHV-6, HHV-7, B19 infection or in combination suggest that each from these immunomodulating pathogens could be trigger factor for CFS/ME development. The association between high frequency of active coinfection and distinctive types of clinical symptoms show necessity of simultaneous study of these viral infections to define possible subsets of CFS/ME.
Nacul, Luis Carlos[1]; Lacerda, Eliana Mattos[1]; Sakellariou, Dikaios[2]	[1] Nutrition and Public Health Interventions Research Unit, London School of Hygiene and Tropical Medicine, Keppel Street, London WC1E 7HT [2]Department of Occupational Therapy, School of Healthcare Studies, Cardiff University, Cardiff CF14 4XN.	Is there an association between the exposure to chemicals and chronic fatigue syndrome? Review of the evidence.	Bulletin of the IACSF/ME. 17 (1). Spring 2009. P3-15	Background: Chronic fatigue syndrome or myalgic encephalomyelitis (CFS/ME) is characterised by persistent or recurrent incapacitating fatigue which can have a considerable impact on the function of the patients. A number of chemical substances have been reported to be associated with fatigue. However, it remains uncertain whether exposure to chemicals at levels usually considered safe is related to chronic fatigue. This paper provides an overview of the existing evidence of association between chemical exposures, particularly in low levels, and CFS/ME. Methods: The Pubmed and the Scopus databases were searched using combinations of relevant terms, including 'chronic fatigue', 'chronic fatigue syndrome', 'chemicals', 'toxicants' and the names of specific 'toxicants' and classes of toxicants. Standard toxicology textbooks were also reviewed. Results: The existing studies were in small number and had many limitations. Most studies were descriptive and only a handful of analytic studies were located, which seldom compared cases of CFS/ME with healthy controls.

	Correspondence:*Dr Luis C Nacul, Department of Epidemiology and Public Health, Nutrition and Public Health Research Unit (NPHIRU), London School of Hygiene and Tropical Medicine, Keppel Street, London WC1E 7HT Email: luis.nacul@lshtm.ac.uk			None of them was prospective and they were commonly prone to selection and information biases. The results are presented under the subheadings: organophosphates and other pesticides/insecticides; carbon monoxide (CO); heavy metals; solvents, ciguatera and other chemicals; and multiple exposures, including in Gulf War troops. Conclusions: The existing evidence remains inconclusive as to the association between exposure to chemicals and chronic fatigue syndrome, and there is therefore a need for further well designed epidemiological studies.
Oldfield, Margaret	MEDes, PhD Candidate, 407-550 Ontario St., Toronto, Ontario,M4X 1X3 Canada. Email: margaret.oldfield@utoronto.ca	You're Too Sick to Work: Messages about Fibromyalgia and Paid Work in Information Materials on the Web	IACSF/ME. 19 (2). Fall 2011. Abstracts from IACFS/ME Biennial International Conference. Poster Presentations. P153.	Messages about fibromyalgia (FM) infuse clinician-patient relationships. Both parties bring these messages into their understandings of FM: its diagnosis, symptoms, treatments, and prognosis. This poster will describe a study that examined messages about FM in information targeted to people with fibromyalgia on the Web. It is important to understand how these messages shape the clinical relationship: First, if clinicians and their patients develop an awareness of these messages, they can examine their usefulness for each individual patient care plan. Second, understanding these messages can help foster trust in the clinical relationship, thereby promoting clinician-patient collaboration to improve treatment efficacy. This trust and collaboration can reduce the likelihood of conflicts between clinical and lay understandings of FM. Objectives: This study examined messages about doing paid work with fibromyalgia (FM) in information materials targeted to people with FM. Methods: This qualitative study used Critical Discourse Analysis to examine text in self-help, rehabilitation, and medical websites that women with FM in the Canadian province of Ontario might access in seeking information. Results: Many of the messages about FM in information materials offer little hope for feeling better and returning to work. Indeed, few information materials mention work. Materials that do mention work focus on individuals' responsibility for managing their FM in the workplace, rather than accommodation of FM-related disability by employers. Conclusion: Staying in the workforce offers women with FM many benefits, among them decent income, sense of self-worth, social relationships, daily routine, and distraction from pain. Encouragement to remain in the workplace, or to return after short-term disability leave, is needed. Workplace accommodations of FM-related disability may be required.
Pall, Martin	Washington state University	The NO/ONOO- Cycle as the Cause of CFS	Bulletin of the IACSF/ME. 16 (1). Spring 2008.	CFS and such related illnesses as fibromyalgia and multiple chemical sensitivity have been puzzling illnesses. There has not been any accepted mechanism for how cases of

	martin_pall@wsu.edu	and Related Illnesses		these illnesses get initiated, why they are chronic, how the diverse symptoms are generated, why these illnesses tend to be comorbid and, most importantly, how they should be treated. I have published a series of 16 papers in the scientific literature, developing a mechanism for these in CFS and other diseases/illnesses that provides answers to these features and many other previously puzzling features for these illnesses.
Patricia Fennell	Patricia Fennell, MSW, LCSW-R, President, Albany Health Management Associates, Inc., 582 NewLoudon Rd., Latham NY 11210, USA; communications@albanyhealthmanagement.com	Riding the CFS/ME Research Rollercoaster	IACSF/ME. 19 (2). Fall 2011. Abstracts from IACFS/ME Biennial International Conference. Poster Presentations. P146.	Objectives: Research advances, such as the potential association of CFS with XMRV, bring knowledge, excitement, and scientific validation to patients, families and professionals working in this field. But these developments also have the potential to cause confusion and distress, as conflicting findings emerge and new research is published that may clarify or further muddy understanding of CFS/ME and fibromyalgia. As media attention to CFS increases as a result of this research, patients gain much-needed validation of the severity of their illness, but also find themselves having to explain to family members, friends, healthcare providers, media, and concerned members of the community how this research relates to their lives, including addressing fears associated with potential contagion. At the same time, patients must continue to cope with the CFS rollercoaster itself, which brings relapses and remittances and demands flexibility in coping strategies, depending on their current health status. As the research rollercoaster rolls on, patients need strategies to cope effectively as they continue their daily lives, and healthcare professionals need tools to help their patients interpret the impact of research findings on their own lives. Methods: There are twin rollercoasters at play in CFS/ME patients' lives -- one caused by increased media and research attention and the other related to the ongoing illness and its relapsing remitting patterns. Gaining an understanding of these rollercoasters is essential in helping patients develop coping strategies for both. The Fennell Four-Phase Model of chronic illness (1. Crisis; 2. Stabilization; 3. Resolution; 4. Integration) describes a predictable passage that patients navigate on their way to defining a new self and a new life after the onset of chronic illness. Results: The FFPM helps patients gain new coping skills, enhances quality of life, generates meaning, and improves responses to community, medical, family, media, and other concerns. Conclusion: Understanding FFPM and the twin rollercoasters of CFS/ME research, as well as how they are influenced by the media, the community and health status, improves patients' ability to cope with variable patterns, and also assists clinicians in helping patients navigate complex, confusing circumstances.
Perdomo, D; Antoni, M; Czaja, SJ; Lattie, E; Sala-Guerrero, A	Dolores Perdomo, Ph.D. Department of Psychiatry and Behavioral Sciences, Center on Aging1695 N.W. 9th Avenue, Suite	*The TeleHealth Study: Memory Problems in Patients with Chronic Fatigue and Their Psychosocial Impact*	IACSF/ME. 19 (2). Fall 2011. Abstracts from IACFS/ME Biennial International Conference. Poster Presentations. P193-194.	Objectives: Present preliminary findings from the TeleHealth Study, a 4-year randomized trial that evaluated a technology based intervention for individuals diagnosed with Chronic Fatigue Syndrome (CFS). This presentation will focus on the prevalence of memory problems in individuals with CFS and their impact on psychosocial outcomes such as social interaction/engagement and depression. Methods: Baseline interview data was evaluated from a sample of 116 CFS

	3204L, Miami, Fl 33136, USA dperdomo@med.miami.edu			participants including 19 males and 97 females who ranged in age from 23 years to 73 years. The sample was primarily Caucasian (78.4%) and most participants had beyond a high school education (89.6%). Two independent variables were analyzed to evaluate possible cognitive deficits reported by study sample, in particular memory problems such as forgetfulness and confusion. Frequency of forgetfulness was obtained from the CDC Symptom Inventory and reported feelings of confusion bewilderment from the Profile of Mood States (POMS) confusion- bewilderment subscale. The psychosocial impact of these cognitive problems was further analyzed by examining the relationship between these cognitive problems and the participant's levels of social interaction/engagement and symptoms of depression. The Sickness Impact Profile (SIP) subscales measuring disruption in social interaction and engagement in recreation/past times, and the Center for Epidemiologic Studies Depression (CES-D) score and the POMS depression-dejection subscale were used as dependent variables in the analyses. Results: The analyses revealed that nearly 88% of the study sample (N = 102) reported having experienced forgetfulness/memory problems that caused them to substantially cut back on activities since the onset of CFS. Of those who reported experiencing forgetfulness/memory problems, 65% indicated experiencing these symptoms everyday at moderate (45.1%) to severe (33.3%) levels. A one-way ANOVA demonstrated that those participants who experienced forgetfulness/memory problems reported greater social isolation scores, $F(1,114)=11.215$, $p=0.001$, and less engagement in leisure activities, $F(1,114)=5.912$, $p=0.017$. Higher scores on the POMS confusion bewilderment subscale were also correlated with greater social isolation, $r(114)=.448$, $p<.001$ and less leisure activities, $r(114)=2.16$, $p=.020$. Greater amounts of confusion-bewilderment was also related to high levels of depression symptomatology as measured by the CES-D, $r(114)=.653$,$p<.001$ and the POMS depression-dejection scale, $r(114)=.674$,$p<.001$. Conclusion: A significant number of CFS patients report having memory problems that interfere with their daily activity and affect their mood and ability to engage in social activities. Those patients with memory problems are particularly at risk of being socially isolated and depressed. Overall these results suggest that future interventions for these patients should also focus on strategies to help remediate memory problems.
Pheby, Derek[1]; Sneddon, Peter[2]; Heinrich, Inge[3]	[1]Derek Pheby, Project Coordinator, National ME Observatory Visiting Professor, Faculty of Society and Health, Buckinghamshire New University, 106, Oxford	Severe ME/CFS in Adults – A report from the CHROME Database	Bulletin of the IACSF/ME. 17 (4). Winter 2009/2010.	Background: Case History Research on ME (CHROME) was established in 1994 to undertake research on severely affected patients. Since 1995 CHROME has collected data on volunteers with severe ME/CFS. All are medically diagnosed, conform to Fukuda criteria, are or were house-bound, and ill for at least two years. Participants complete initial and annual follow-up questionnaires, and report their condition at onset of illness, a year previously, on recruitment, and annually thereafter. Method: We report symptom severity and ability to undertake activities of daily living in 324 participants recruited between 1995 and 1998, their evolution through time, and, for

	Road, Uxbridge, Middlesex, UB8 1NA, UKTel.: e-mail : derekpheby@btinternet.com [2]Dr. Peter Sneddon, M.A., PhD. School of Health and Social Sciences, Middlesex University and CHROME Research Group 7 Wilderton Road, London, N16 5QY, UK e-mail : Peter.Sneddon@btinternet.com [3]Dr. Inge Heinrich, MSc, PhD, Medical Statistician (retired), "Thurne", Gore Road, Eastry, Sandwich, Kent, CT13 0LP, UK. e-mail : inge.heinrich@virgin.net			later onset (age 17+) subjects, changes occurring between recruitment and the latest questionnaire. Significance was assessed using the McNemar test or its binomial equivalent. Results: For most features, subjects deteriorated between onset and recruitment, with subsequent improvement, often slow and uneven, among later onset cases. Complete recovery was unusual. There were marked individual variations, and many subjects remained severely incapacitated or deteriorated. All features examined were more prevalent and severe in patients with a younger age of onset. Age at onset was bimodal, with peaks at 11-20 and 31-40. Most subjects, at recruitment, had been ill for 2-10 years. The proportion of early onset cases rose significantly in the mid-1980s. Conclusions: Caution is necessary in interpreting the results, given problems of self- selection, recall bias, and subjective interpretations of symptom ratings. It is unclear whether the reported trends are inevitable features of ME/CFS, or perhaps due to poor management at the outset.
Pinxsterhuis, Irma	Irma Pinxsterhuis, ME/CFS-Centre, Oslo University Hospital, Postboks 4956 Nydalen, 0424 Oslo, Norway. E-mail: irpi@uus.no	Illness Course in Chronic Fatigue Syndrome – What Can Be Done To Prevent Deterioration and Promote Improvement of Occupational Performance?	IACSF/ME. 19 (2). Fall 2011. Abstracts from IACFS/ME Biennial International Conference. Poster Presentations. P186.	Objectives: Chronic fatigue syndrome (CFS) often leads to extensive problems with occupational performance. Different disciplines disagree about what treatment strategy is best with regard to improving occupational performance. Few studies are based on the patients' opinion about this issue. This study focuses therefore on CFS patients' understanding of which factors and processes which influence their occupational performance, both before and after they were diagnosed. Methods: Semi-structured interviews were used for data collection. The sample consists of 15 women with mean age 42 years (range 31 to 58) that were diagnosed with CFS between 9 months and 17 years ago. All participants met the CDC criteria for CFS. Eight participants had been severely ill and were totally bedridden between 15 months and 7-8 years. All participants still had a mild to severe degree of CFS at the time they were interviewed, but all had improved. Results: The participants were diagnosed with CFS from 6 months to 20 years after they became ill. Symptoms changed and fluctuated over time, while they experienced an increasing intolerance

				for physical and mental activity. Lack of support and understanding, expectations and demands from themselves and others, as well as financial insecurity caused stress and over-exertion that influenced their occupational performance negatively over time. Two participants got bedridden before they got diagnosed. The CFS-diagnosis made it possible to find information about how to cope with the illness. They experienced that pacing activities, energy conservation, rest/relaxation, stress management, lower expectations to themselves, social support, changes in nutrition, financial security, as well as acceptance improved their occupational performance and reduced symptom-fluctuation over time. Some continued with over-exertion after they got diagnosed with CFS and got bedridden. While bedridden they learnt that it was important to be nursed by a few persons, according to routines they had agreed upon and with respect for their symptoms and needs. They needed above all peace of mind, and a feeling that they and their family were taken care of, so that they could use all their energy on getting better. When they started to feel better, they felt that it was important to mobilize in their own pace and not to be pushed by anyone. They improved very much in the same way as those who weren't bedridden, but had to start at a very low activity level. Their intolerance for physical and mental activity improved over time. Some improved quicker after Lightning Process, while others didn't have any effect or just a temporary effect. Conclusion: Diagnosing CFS at an early stage may prevent deterioration over time. In addition, patients need information and help in order to cope with CFS in an adequate way. Those who are able to avoid over-exertion stabilise, and improve their occupational performance over time. At the ME/CFS-centre, a multidisciplinary team applies the results of this study when they give advice to CFS-patients about how to deal with the illness at all stages of the illness course.
Pinxsterhuis, Irma; Sveen, Unni	Irma Pinxsterhuis, ME/CFS-Centre, Oslo University Hospital, Postboks, 4956 Nydalen, 0424 Oslo, Norway. E-mail: irpi@uus.no.	Chronic Fatigue Syndrome – Three Case Studies Concerning the Very Severely Ill	IACSF/ME. 19 (2). Fall 2011. Abstracts from IACFS/ME Biennial International Conference. Poster Presentations. P154.	Objectives: Chronic fatigue syndrome (CFS) often leads to extensive problems with occupational performance, and some get bedridden for a period of time. No studies so far have focused on the very severely ill. This study focuses therefore on CFS patients', as well as their relatives' and health care workers' understanding of how CFS patient' can be helped to prevent them from becoming bedridden and to promote improvement over time. Methods: Semi-structured interviews were used for data collection. The sample consists of three women, and from each of these women: One close relative or friend, and one health care worker, a total of 9 participants. All three patients met the CDC criteria for CFS. Anita (age 35), Sarah (age 44) and Helen (age 48) were totally bedridden from 15 months to 2.5 years. Sarah and Helen had a mild degree of CFS at the time they were interviewed, while Anita still had a severe degree of CFS. Results: Anita, Sarah and Helen had vague, fluctuating symptoms, and experienced an increasing intolerance for physical and mental activity. Over-exertion caused deterioration over time. When they got diagnosed with CFS, Helen was already bedridden. Sarah and Anita continued with over-exertion and got bedridden

				after some time. While bedridden they learned that it was important to be nursed by a few persons, according to routines they had agreed upon, and with respect for their symptoms and needs. They needed above all peace of mind and a feeling that they and their family were taken care of, so that they could use all their energy on getting better. When they started to feel better, they mobilised themselves with the support of health care workers and others, but in their own pace. They started at a very low activity level, but their intolerance for physical and mental activity improved over time. Pacing activities, energy conservation, rest/relaxation, lower expectations to themselves, stress management, social support, changes in nutrition, as well as acceptance improved their occupational performance over time. Sarah got much better after Lightning Process, while Anita just had a temporary effect. They all needed psychological help to cope with their illness-experiences. The patients' husbands, children, and close friends were affected by the illness too. Husbands and close friends got an overload of tasks, obligations and concerns, while the children were concerned about their mothers' condition and experienced that both their parents became less available. The situation deteriorated for Anita and Helen, and their families, while waiting for adequate help. Some of their children needed professional help to cope with psychological reactions. Sarah and her family got adequate help as soon as Sarah got bedridden. She stabilised and improved much quicker, and her family members did cope much better. Conclusion: Diagnosing CFS at an early stage may prevent deterioration over time. In addition, patients and their families need information and help to cope with CFS in an adequate way. Those who are able to avoid over-exertion stabilise and improve over time. At the ME/CFS-centre, a multidisciplinary team applies the results of this study to give advice to patients, their families and health care workers about how to deal with CFS at all stages of the illness course.
Porter, Nicole; Paavola, Erin; Jason, Leonard A	DePaul University	Content Analysis of ME/CFS in Medical Training Textbooks	Bulletin of the IACSF/ME. Spring 2007.	Medical textbooks serve as a cornerstone for the training of medical students and residents, as well as providing authoritative references for experienced healthcare providers (Rabow et al., 2000). Given the importance of medical textbooks in codifying best practices, several authors have engaged in textbook analyses on topics such as end of life issues (Lynn, 1997) and nurses' assessment of symptoms (Ferrell, 1999). However, no reviews have analyzed the content of medical textbook references for ME/CFS.
Rajeevan, Mangalathu; Dimulescu, Irina; Murray, Janna; Khin, Maung M; Falkenberg,	Mangalathu S. Rajeevan PhD, Chronic Viral Diseases Branch, Division of High-Consequence, Pathogens and	Pathway-focused Genetic Evolution of Immune and Inflammation Related Genes in CFS	IACSF/ME. 19 (2). Fall 2011. Abstracts from IACFS/ME Biennial International Conference. P132-133.	Objectives: There is evidence that immune and inflammatory alterations are important in CFS. The objective of this study was to determine if genetic variants in inflammation and immune pathways could be linked to CFS as well as to quantitative measures of functional impairment, fatigue and symptom inventory. Methods: Participants were identified from a population-based study. This analysis included 362 Caucasian subjects: 121 non-fatigued (NF); 50 CFS with no medical/psychiatric

Virginia; Unger, Elizabeth R	Pathology, NCEZID, Centers for Disease Control and Prevention, 1600 Clifton Road, MS G-41,Atlanta, GA 30333, USA mor4@cdc.gov			exclusions (CFS); 129 fatigued but insufficient symptoms or fatigue for CFS (ISF) with no medical or psychiatric conditions; and 62 CFS except for medical/psychiatric exclusions (CFS-exclusions). We used a pathway-focused genetic analysis of immune and inflammation related genes with the Affymetrix Immune and Inflammation Chip that covers 11K single nucleotide polymorphisms (SNP) in 1000 genes representing 38 sub-pathways in immune response and inflammation. The manufacturer's protocol was followed for genotyping and accuracy was validated by pyrosequencing. Golden Helix SVS software was used for genetic analysis. SNP functional annotation was done using SPOT and GenomePipe programs. Results: Compared to NF controls, CFS was associated with 34 functionally relevant SNPs (p=2.68 x10-2 – 1.31 x10-5). Twelve of these SNPs are in genes playing a role in pathways related to complement cascade (*SERPINA5*, *CFB*, *CFH*, *MASP1* and *C6*), chemokines (*CXCL16*, *CCR4*, *CCL27*), cytokines/cytokine signaling (*IL18*, *IL17B*, *IL2RB*), and Toll-like receptor signaling (*TIRAP*, *IRAK4*). While 11 out of 34 SNPs remained associated with ISF compared to NF, only 4 of the 34 SNPs remained associated with CFS-exclusions. A polymorphism (rs11214105) in the 5'upstream regulatory region of *IL18* was associated with both CFS and ISF (CFS, p=1.52 x 10-2; ISF, p=2.03 x 10-2). In CFS, this SNP associated with MFI subscale of physical fatigue (p=7.1 x10-3), SF-36 subscale of body pain (p=9.7 x10-3) and summary score for CFS case defining symptoms (2.6 x 10-5). With all these associations, the minor allele increased the risk of the associated phenotype. Similarly, the minor allele of rs7616342 in *KCNH8,* representing the p38/MAPK signaling pathway, increased the risk for CFS (p=1.31 x 10-5), and was also associated with MFI mental fatigue subscale (p=9.0 x 10-3). Conclusion: This study identified a number of novel and functionally relevant genetic variants in complement cascade, chemokine and cytokine signaling pathways associated with CFS. Differences in these associations found for subjects with exclusionary conditions otherwise meeting criteria for CFS (CFS-exclusions) suggests important differences between these groups. Further replication and functional studies are needed to support the results of this study.
Roelant, C; De Meirleir, K	Chris Roelant, Ph.D., CEO Protea Biopharma N.V., De Tyraslaan 111, 1120 Neder-Over-Heembeek, Belgium. croelant@proteabiopharma.com	Easy Monitoring of the Th1/Th2 Balance Status in Health and Disease with Special Emphasis on CFS/ME	IACSF/ME. 19 (2). Fall 2011. Abstracts from IACFS/ME Biennial International Conference. Poster Presentations. P175.	Objective: It is generally agreed that CFS/ME is a Th2 shifted condition. However, simple self-tests allowing physicians and CFS/ME patients to follow-up on Th1/Th2 balance during therapy are lacking and therefore it still remains very difficult for an individual to evaluate whether the treatment he or she is undergoing is really effective. In addition, the effectiveness of over the counter sold products claiming to balance Th1/Th2 status such as antioxidants, pro-biotics and other should be evaluable on a personal basis. A lot of CFS/ME patients are trying to improve their condition by exploring so-called neutraceuticals by "trial and error" without realizing the potential risk of further deterioration of their health by randomly taking products that may even further disturb their Th1/Th2 balance. Therefore we developed a simple "self-test" principle allowing patients to determine their Th1/Th2 profile over

				short periods of time and to follow-up on the effect of therapy and intake of drugs and neutraceuticals or any other strategy to balance Th1/Th2 status. Methods: By analyzing a massive number of first morning urine samples obtained from patients facing conditions associated with an overactive Th2 arm (ulcerative colitis, autism, blastocystis, mercury poisoning, viral infection) we came across a reaction principle that uses a colorimetric substrate changing color upon reaction with metabolites contained in the urine samples from yellow (neutral) over light green and brown (moderate Th2) to deep purple and black (strongly Th2 shifted). The development of the color is time-dependent and quantitative. Results: More than 80% of urine samples obtained from CFS/ME patients produced a time-dependent quantitative change in color compared to 4% of the controls (perfectly healthy population). Conclusion: The urine test principle we've developed offers an easy way to determine and to follow-up on Th1/Th2 balance in health and disease and more in particular at the same time provides further evidence that CFS/ME is a condition merely associated with an overactive Th2 arm.
Roelant, C; De Meirleir, K	Chris Roelant, Ph.D., CEO Protea Biopharma N.V., De Tyraslaan 111, 1120 Neder-Over-Heembeek, Belgium. croelant@proteabiopharma.com	Role of Cellular Prion Proteins (PrPc) in CFS/ME and other Chronic Diseases	IACSF/ME. 19 (2). Fall 2011. Abstracts from IACFS/ME Biennial International Conference. Poster Presentations. P176.	Objective: Cellular prion proteins (PrPc) are small glycoproteins attached to the outer leaflet of the plasmamembrane of mammalian cells by a glycosylphosphatidyl anchor. The isoform of the prion protein is expressed in hematopoietic stem cells, neuronal cells, T and B lymphocytes, natural killer cells, muscle, intestinal tract, spleen, adrenal glands, endothelial cells, platelets. PrPc binds copper, plays a role in calcium uptake, protects cells against oxidative stress, prevents cells from apoptosis, interacts with viruses (binds gp-120), is involved in neuroprotection and plays an important role in immune and angiogenic responses. Therefore we estimated that hallmarks of CFS/ME such as oxidative stress, calcium channelopathy, T-cell dysfunction, copper uptake changes, altered red blood cells and oxygen transport, coagulation and hormonal responses (HPA-axis) as well as viral entry could be attributed to aberrant PrPc function which could than ultimately explain the "multi-system" character of the CFS/ME disorder. In order to investigate PrPc function in CFS/ME, we first needed to develop a test allowing to measure "activity" of PrPc in "real time". Methods: We have developed a cell-based chemiluminometric (CL) assay accordingly to the following principle: cells or tissue under study are incubated in an appropriate buffer in the presence of a chemiluminometric probe (CLP). Next a PrPc redox-trigger is added that stimulates PrPc-mediated reactive oxygen species (ROS) production which is proportional to the active state of the PrPc and which ROS react with CLP to produce a basal glow of light (Lb) that can be detected in front of a photomultiplier. Next, to an identical sample and CLP an additional trigger is added that stimulates cells to produce ROS at maximum capacity, producing maximum glow type chemiluminescence (Lmax). Lmax/Lb defines a PrPc functional stimulation index (SI) that can be compared for different tissues and cells obtained from controls and patient populations. Results: Peripheral blood mononuclear cells (PBMC's) obtained

				from CFS/ME patients show aberrant SI's (extremely low SI<3 or extremely high SI>20 compared to controls (SI=10 +/- 3). In addition we could demonstrate the influence of heparin, minocyclin, metals (copper, mercury) and other agents on PrPc function by means of this luminometric technique Conclusion: PrPc functionality of PBMC's is altered in CFS/ME. Chemiluminometric analysis provides a useful tool to further develop and explore PrPc functional tests and PrPc drug interaction platforms (drug discovery) in CFS/ME and other chronic diseases (fibromyalgia, rheumatoid arthritis, autism, cancer).
Roesner, Nicole; Porter, Nicole; Holiday, Patrick; Delucca, Gina; Robinson, Ashley; Walano, Nicolette; Natanek, Ian; Clautier, Catherine; Jason, Leonard A	DePaul University, Center for Community Research, Email-nroesner@depaul.edu	An Alternative Way to Help People with ME/CFS	Bulletin of the IACSF/ME. 16 (4). Winter 2008/2009. P12-21.	In 1996, a Buddy program began at DePaul University. Participants with ME/CFS were provided a Buddy, who was a volunteer DePaul University student. Over the years, we have found that both participants and Buddies have been able to gain from their participation. This report provides information about this Buddy program as well as qualitative data from both participants and the Buddies.
Rowe, Katherine; Moon, Judith	Royal Children's Hospital, Melbourne, Australia	What is the Natural History of Chronic Fatigue Syndrome in Young People?	IACSF/ME. 19 (2). Fall 2011. Abstracts from IACFS/ME Biennial International Conference. P129.	Objectives: To follow up consecutive patients referred to the CFS clinic at the Royal Children's Hospital between 1991 and 2009 regarding their level of functioning, self-reported perception of recovery, duration of illness and the usefulness of management strategies. Methods: Seven hundred and eighty eight young people age 6-18 years (mean 15 years) (M:F 1:3), were referred from family doctors or consultant pediatricians for diagnosis and management or secondary consultation. Diagnosis required a defined onset over hours or days of persistent or relapsing, debilitating fatigue, which was exacerbated with exercise and did not resolve with bed rest, duration of illness greater than 6 months, and fulfilling the criteria of Holmes et al (1988) and Fukuda et al., (1994). Standardised historical, symptom and psychological data were obtained from 398 and standardised history only, from an additional 390. 398 were followed up prospectively with questionnaires approximately each 2 years, while the second group were contacted by phone during 2010 and 2011, and a questionnaire sent if consent was obtained. The follow up questionnaire recorded functional outcomes, demographics, duration of illness, use of alternative health practitioners and reported usefulness of management strategies. Results: Questionnaire follow up data were obtained on at least one occasion for 342 of the 398 (86%). Six occasions between 1996 and 2008 provided 804 returns allowing more accurate timing of reported recovery with multiple data points. 78% of the additional 390 were able to be traced and provided information. The follow up for both groups ranged from 1.7 years to 21 years. The average duration of illness was reported as 5 years with range 1-15 years. By 5 years 60% reported recovery. By 12 years, 88%

				reported recovery (n=256), although in approximately 1/3 there was an indication that they were conscious of monitoring their workload. Less than 5% were not either studying or working part or full time, often due to other factors than CFS. Many had married (n=38) and those with children (n=15) reported being well. 90% completed or intended to complete post-secondary training. The only alternative practitioners that were deemed helpful were those that provided some relief for muscle pain with massage, or who provided good dietary advice. Restrictive diets and supplements did not reach placebo levels of response. Symptom management and the strategy of balancing social contact, physical activity, educational input and a commitment to regularly attend at least one activity each week as the most useful assistance. Every young person devised a different balance of activities and program depending on severity of illness, stage of education, family circumstances and life interests. Engagement in education was best predictor of functional outcome. Conclusion: The outcomes for young people in Australia are generally positive although prolonged. Ongoing support particularly in navigating the education system was highlighted by them as an essential contributor to the quality of their life and their ability to cope.
Royle, Genevieve H; Pimm, John T	*Requests for reprints should be addressed to Dr Genevieve H Royle, Durdans, Elm Green Lane, Danbury, Essex, CM3 4DR, UK., [1]Oxford Doctoral Course in Clinical Psychology, Oxford, UK, Address: 5 Belmont Terrace, Remuera, Auckland 1050, New Zealand Email: genaikman@hotmail.com [2]Community Neurological Rehabilitation Services, Buckinghamshire Primary Care Trust, Aylesbury, UK, Address: Rayners Hedge, Croft Road, Aylesbury, Bucks, HP21 7RD, United Kingdom	A Pilot Study of the Process of Change in a Group Chronic Fatigue Syndrome Management Programme	Bulletin of the IACSF/ME. 17 (2). Summer 2009.	Background: Cognitive-behavioural therapy and graded exercise therapy are efficacious therapies in patients with Chronic Fatigue Syndrome (CFS). There is some evidence for the efficacy of group programmes that employ the same principles of rehabilitation. Little is known about the process of change with these interventions, however it is important to understand why change occurs in order to improve outcomes. Objectives: To investigate the process of change and related outcomes in participants in a CFS group management programme. Method: Task analysis was used to generate a health professionals' model specifying the psychological shifts thought necessary for participants to improve. Following this, data from participant interviews were analysed to see whether they matched the shifts specified in the model. Results: Participants were able to identify 'key moments' which they thought were involved in change. One commonly cited key moment involved participants coming to the realization that they were not unique in their difficulties and there were others in the group who understood, and had experienced similar problems. Four of the six shifts identified by health professionals were also identified as key moments by participants. Conclusions: This study highlights the potential benefits of group work for people with CFS/ME including opportunities for validation from peers, sharing and modelling, all of which are suggested to be important in the process of change. Royle, Genevieve; Pimm, John	[No address quoted]	Response to letter from Tom Kindlon. Re: A pilot study of the process of change in a group Chronic Fatigue Syndrome management programme. Bulletin of the IACFS/ME. 2009;17(2):53-68	Bulletin of the IACSF/ME. 17 (3). Fall 2009.	One of the aims of our study was to investigate whether a number of interventions (i.e. CBT & GET), shown to be effective when delivered in an individualized format, could also be effectively delivered in a group format. We know from the literature (referenced in our original article) that patients report particular benefits from group-based therapies and it would therefore seem logical to investigate whether any of these benefits could be used to increase the efficacy of interventions for CFS/ME. While Kindlon rightly points out that the current NICE guidelines recommend individual treatment only, this is due to the fact that NICE guidelines are based on the literature as it stands at the time and as yet there is only emerging evidence for group treatments for CFS/ME. The group-based studies referenced in our original article do indicate some benefits for group-based interventions (1, 2), however there is no doubt that there is clearly a need for more research in this area. Our study sought to contribute to this.
Rusu, C; Bancej, C; Roberts, KC	Corneliu Rusu, Analyst, Chronic Disease Surveillance and Monitoring Division, Centre for Chronic Disease Preventionand Control, Public Health Agency of Canada, 785 Carling Avenue, Ottawa, Ontario, K1A 0K9, Canada, corneliu.rusu@phac-aspc.gc.ca	The Epidemiology of Self-Reported Chronic Fatigue Syndrome in Canada	IACSF/ME. 19 (2). Fall 2011. Abstracts from IACFS/ME Biennial International Conference. Poster Presentations. P188-189.	Objective To determine for the first time the prevalence of Chronic Fatigue Syndrome (CFS) in the household population of Canadians 12 years of age and over, and to explore its relationship with various key determinants of health. Methods Data were obtained from the Canadian Community Health Survey, Cycle 3.1 (2005). Weighted prevalence rates (PRs) for CFS in the Canadian population and specific sub-groups based on various key determinants of health were calculated. The 95% confidence intervals (CIs) around PRs were calculated using exact standard errors generated through bootstrap re-sampling techniques. Results In 2005, 331525 Canadians reported having CFS (PR 1.22%, 95%CI: 1.13-1.31), with a female-to-male PR ratio of roughly two to one. The prevalence of CFS among women peaked in the 45-64 age group and fell thereafter, whereas the increase among men was monotonic across all ages. Women in the 45-64 age group accounted for more than a third of all reported cases of CFS. Sub-group analyses based on various key determinants of health showed that people who reported lower income, altered employment status or living in food-insecure households were more likely to report having CFS. A greater PR of CFS was found among people who reported being inactive, dealing with activity limitations, needing help with daily tasks, having difficulty with social situations as well as among those facing discrimination or unfair treatment due to their health condition. Finally, heavy users of health care services as well as those with unmet health care or home care needs showed increased PRs of self-reported CFS. Conclusions To our knowledge, this is the first study examining the prevalence of CFS in the household Canadian population and among various sub-groups based on key determinants of health. The PR of self-reported CFS was several-fold higher than the national PR among sub-groups with poorer measures on a variety of health determinants, including

				determinants of unmet health needs and access to care. Further investigations are required to decipher the true nature of these associations, in order to develop effective preventive and/or disease management measures.
Ryll,ED	**Erich D. Ryll, M.D. 383l San Juan Avenue, Carmichael, CA 95608, Email:** Eryll@sbcglobal.net	A 30-year Historic Review of a Community Hospital Epidemic Outbreak	IACSF/ME. 19 (1). Summer 2011.	A 1975 outbreak, characterized by severe venous involvement, affected nurses and staff of a California community hospital spreading to other health care workers and unrelated persons. Spread from epidemic to quintary cases was noted. The purpose of this report is to delineate the hallmark symptoms of the outbreak and determine the functional state of affected patients 30 years later. Methods Sixty-one hospital epidemic cases were reviewed, and 30-year follow-up assessed by questionnaire, interview, and physical examination. Results Painful veins; flu-like symptoms; and severe generalized pain, exhaustion, weakness, cognitive disturbances, and nervous system abnormalities marked the outbreak. In 2006, 30 patients were available for follow-up, 14 were deceased, and 17 were lost to follow-up. Of the living, 29 never became well citing generalized pain; energy absence; confusion, memory loss, other neurologic problems; and leg discomfort. Only eight were able to return to work, five of who functioned with difficulty. Of those deceased, 11 never worked after onset. Conclusions A severe viral-like epidemic, apparently communicable and carried latently with pronounced venous inflammation resulted in permanent disability in 75% of those surveyed 30 years later.
Sampson, D	[No address quoted]	Letter to Editor: Response to Professor White's comments	IACSF/ME. 18 (4). Winter 2011.	Firstly I welcome Prof. White's acknowledgement that broad based definitions of ME/CFS that include co-morbid mood disorder/psychiatric illness are predicted by different factors than those that do not, and that subjects with purely psychiatric disorders were included in broad based definitions of ME/CFS such as the Oxford criteria. However he seems not to have grasped the main focus of my paper—the inclusion of patients with psychiatric reasons for their fatigue alongside those with bona fide ME/CFS. It is patently clear from my analysis of his own data and the risk factors that accompany these two groups of patients that they are completely different illnesses/conditions. This is at best tautology and at worst very poor science. Not only in the study he refers to showing Graded Exercise as an effective treatment for CFS/ME (which ostensibly excluded patients with co-morbid mood disorder) were 30% of the participants receiving normal dose antidepressant therapy or low dose tricyclic antidepressant hypnotic medication but furthermore those with appreciable sleep disturbance (one of the hallmarks of CFS/ME) were excluded. As nearly 90% of even CDC defined CFS sufferers report profound sleep disturbance) this was clearly not a study of ME/CFS but of psychogenic fatigue with no physical basis. Finally he refers to the PACE trial, the largest ever trial of Graded Exercise of which he is Principal Investigator—the results of which have not yet been announced. It is of interest that the ME/CFS criteria selected for use in this study are the Oxford Criteria, which preferentially select patients with psychiatric reasons for their fatigue as his own data clearly demonstrate. No other researchers examining ME/CFS in the world

				currently utilize such broad criteria as they clearly fail to exclude patients with primary psychiatric diagnosis in the absence of physical symptoms.
Sampson, D	[No address quoted]	Letter to Editor: Comment on the Results of the PACE trial	IACSF/ME. 18 (4). Winter 2011.	The results of the PACE trial in terms of treatment efficacy for both Cognitive Behavioural Therapy (CBT) and Graded Exercise Therapy (GET) are extremely modest to say the least and certainly not by any stretch of the imagination remotely curative—a decrease in fatigue score (range 0-33) at 52 weeks of 3.4 and 3.2 points respectively, and an increase in physical function score (range 0-100) of 7.1 and 9.4 points for each treatment respectively, compared with standard medical care. (1) This despite the adoption of the Oxford criteria, which are so broad that they clearly fail to exclude patients with primary psychiatric diagnosis in the absence of physical symptoms. (2) Conversely the results of a another large scale evaluation of the efficacy of both CBT and GET conducted in Spain and published earlier this year demonstrated that after 12 months, intervention with CBT and GET not only failed to improve health-related quality of life HRQL scores but led to worse SF-36 physical function and bodily pain scores in the group receiving these treatments compared with standard medical care alone. (3) It is of interest that two such similar studies both utilising comparable timescales, interventions and measures of outcome should produce such discrepant and diametrically opposed results. Even if we take the results of the PACE trial at face value, of the 3158 patients presenting with fatigue at specialist Chronic Fatigue Syndrome clinics for potential inclusion in the PACE trial, only 641 were eventually selected for inclusion in the study. This means that 4 out of every 5 potential participants were excluded. This is remarkable—given the obvious delay between primary outpatient appointment and specialist hospital CFS clinic attendance most if not all would naturally meet Oxford criteria in the absence of major psychosis, organic brain disease and substance abuse. How only 1 in 5 of these were eventually selected for inclusion in the study and the exact criteria for such exclusion leading to such an unusual/unrepresentative ME/CFS sample are questions that must warrant further investigation.
Sampson, DP	9 Cherry Tree Road, London N2 9QL Email: davidsamps@aol.com	Close Analysis of a Large Published Cohort Trial into Fatigue Syndromes and Mood Disorders That Occur After Documented Viral Infection	IACSF/ME. 18 (2). Summer 2010.	This paper presents a close analysis of a large published cohort trial into predictors (risk factors) for developing a fatigue syndrome or mood disorder following either infectious mononucleosis or an upper respiratory tract infection - White et al (16). Critically, in addition to utilising broad based definitions of ME/CFS, such as the Oxford and CDC CFS criteria, White et al also utilise a further definition, Empirical Fatigue Syndrome, which excludes current psychiatric illness. This provides important additional insights into the results, leading to conclusions which are materially different to those that the author draws, in relation to the inherent validity of broad based definitions of CFS and in relation to the significance of deconditioning as a perpetuating factor in this illness. Examination of the data shows that the highest risk factor for developing a non-psychiatrically defined Fatigue Syndrome (i.e. Empirical

				Fatigue Syndrome), even 6 months later, is documented clinical evidence of viral infection (infectious mononucleosis) not previous psychiatric morbidity. Furthermore under the Empirical definition, no significant correlation exists between bed rest at onset and subsequent development of a fatigue syndrome; this suggests that deconditioning is not an important perpetuating factor under this definition. Conversely, wider definitions of ME/CFS that do not exclude individuals with psychological/psychiatric reasons for their fatigue (such as the Oxford and CDC criteria) reduce the importance of clinical factors (infectious mononucleosis) and increase the importance of factors such as G.P. attendance in year before onset, mood disorder at 2 months and past psychiatric illness, which are consistent predictors of subsequent mood disorder quite independently of the existence or otherwise of a fatigue syndrome. This analysis and the original data in the White et al. paper strongly calls into question the validity of broad based definitions of ME/CFS, such as the Oxford (and to lesser extent CDC) criteria. This is in large part due to the clear inclusion within such criteria of significant numbers of patients with primarily mood disorder/psychiatric illness in addition to those with ME/CFS. See also: White,P. Reply to Sampson. IACSF/ME. 18 (3). Fall 2010.
Scott, A; Norton, M; Mabillard, H; Newton, JL	Professor Julia L Newton, Institute for Ageing and Health Medical School, Framlington Place, Newcastle-upon-Tyne, NE2 4HH, Email: julia.newton@ncl.ac.uk	Brief Report: Shortened QTc interval in chronic fatigue syndrome	IACSF/ME. 19 (3/4). Summer 2012.	Abstract Chronic fatigue syndrome (CFS) is a common, debilitating disease that is frequently associated with autonomic dysfunction. One previous study of a selected population using a manual measurement technique suggested CFS is associated with a shortened QTc interval. Here we assessed QTc in a large UK population of CFS patients using automated, clinically applicable, measurement techniques and confirmed that QTc is significantly shortened in CFS patients compared to non-CFS fatigued and control populations. Automated measurement of QTc in clinical practise has potential utility as a diagnostic biomarker in CFS.
Shoemaker, RC	Center for Research on Biotoxin Associated Illnesses Pocomoke, Md	Vasoactive Intestinal Polypeptide (VIP) Lowers C4a and TGF beta-1, Corrects Refractory Symptoms and Normalizes Abnormal Biomarkers in Patients with CFS	IACSF/ME. 19 (2). Fall 2011. Abstracts from IACFS/ME Biennial International Conference. Poster Presentations. P144.	Background: CFS patients invariably have low levels of vasoactive intestinal polypeptide (VIP). In two case series of patients meeting the case definition for adult CFS (N=1682), deficiency of VIP occurred in 98% of patients. Less than 10% of controls were VIP deficient. VIP raises cAMP; lowers pulmonary artery (PASP) responses to exercise, blocks peripheral innate immune activation; reduces apoptosis of glial cells undergoing oxidative stress; raises VEGF; restores circadian rhythm; regulates response to olfactory stimuli in the suprachiasmatic nucleus; regulates dendritic cells; regulates Th17 function in autoimmunity; enhances IL-10 production; and modulates innate immunity. In a pilot study in 2010, use of VIP was shown to be safe in human volunteers, providing (1) marked reduction in symptoms and (2) blunted accentuated pulmonary artery response to exercise. We studied the clinical responses in 100 consecutive CFS patients with refractory illness to intranasally administered VIP. Methods: After informed consent, patients with symptoms meeting the Fukuda definition of CFS were treated with 50 mcg of VIP given four times a day via nasal aerosol for two months. There were no dropouts in the study. Pre- and post- VIP

				measures included symptoms; visual contrast sensitivity (VCS); levels of VIP, VEGF, MSH, C4a, TGF beta-1, MMP9, testosterone, estradiol, lipase, vitamin D 25-OH, CBC and CMP. Exclusion criteria included three indicators known to be associated with reduced benefit (1) depressed visual contrast sensitivity; (2) ERMI > 2; (3) presence of multiply antibiotic resistant biofilm-forming coagulase negative staphylococci in deep nasal aerobic spaces. Results: Patients tolerated the drug well. Symptom reduction occurred in all patients with normalization of mean VEGF, MMP9, C4a and TGF beta-1. Testosterone rose and estradiol fell in males with no changes in females. No adverse effects on CBC and CMP were noted. Abnormal vitamin D 25-OH normalized. One person developed an elevated level of lipase without abdominal pain. Discussion: Treatment with VIP provided restored clinical functioning in a cohort of patients with severe CFS illness. As a regulatory neuropeptide, VIP has multiple salutary effects on human physiology. Replenishment of deficiency states returns quality of life and stabilizes inflammatory responses. Conclusions: Evaluation of clinical use of VIP will require additional clinical trials but early results show safety and marked benefit in severely affected CFS patients.
Shoemaker, Ritchie C	Center for Research on Biotoxin Associated Illnesses; Pocomoke, Md	T Regulatory Cell Abnormalities in CFS: Another Varying Biomarker is Unveiled That Adds to Understanding of Pathophysiology, Diagnosis and Treatment	IACSF/ME. 19 (2). Fall 2011. Abstracts from IACFS/ME Biennial International Conference. Poster Presentations. P168-169.	Background: Deficiency of T regulatory (Treg) cells is now recognized in a number of chronic fatiguing illnesses including Post- Lyme, “mold illness” (chronic inflammatory response syndrome from water-damaged buildings, CIRS-WDB), chronic lymphocytic lymphoma and multiple sclerosis (MS) among many others. Correction of Treg deficiency is associated with clinical benefit. Data from this clinic and others internationally have shown that CFS is marked by absence of neuropeptide (MSH and VIP) control of innate immune inflammatory mediators, especially C4a, MMP9 and TGF beta-1. Successful treatment of affected patients requires correction of these abnormalities, but even with that successful treatment, we noted a subset of patients that remained persistently affected. Because of the known effects of high TGF beta-1 on populations of CD4+CD25+ T reg cells, and in an effort to establish the role of abnormal Treg in CFS, levels in CFS patients were stratified by clinical condition. Methods: 150 patients in a single practice were identified as controls, untreated cases, treated cases, VIP-treated cases and relapses. CD4+CD25+ levels were measured by flow cytometry by Quest Diagnostics. Patients with symptoms not responsive to standard interventions of reduction of inflammatory markers (N=43) were treated with 50 mcg VIP administered by nasal aerosol QID. Results: CD4+CD25+ levels in controls were 16.8; untreated cases 6.2; treated cases 17.1; vasoactive intestinal polypeptide (VIP)-treated cases 22.6 and relapses 5.3. Those with the lowest CD4+CD25+ levels were the most symptomatic. Treatment of low CD4+CD25+ with VIP by nasal aerosol led to symptom reduction with rising levels of CD4+CD25+. Use of VIP without correction of underlying innate immune abnormalities did not show significant benefit. In 12 patients, prospective exposure of CFS patients with MSH < 35 pg/ml to WDB with an Environmental Relative Mold Index (ERMI) of > 2 was

				associated with relapse of symptoms and fall in CD4+CD25+. Discussion: Rising levels of TGF beta-1 induces production of CD4+CD25+ regulatory T cells. In inflamed tissue, CD4+CD25+ cells are reported to be altered in situ creating pathogenic T cells which in turn release additional TGF beta-1. Correction of (1) deficiency of CD4+CD25+ cells; and (2) elevated TGF beta-1 result in clinical benefit. Preexisting CFS is a risk factor for relapse of illness and reduction of Tregs after exposure to WDB. Conclusions: Cellular immunity plays an important role in CFS. Reduced levels of Treg cells can be corrected by treatment of inflammatory mediators, with persistent illness responding to use of replacement VIP. CFS patients are at risk for acquisition of additional inflammatory and cellular immune injuries due to exposure to WDB.
Shoemaker, Ritchie C; Maizel, Margaret S	Center for Research on Biotoxin Associated Illnesses, 500 Market St, Suite 102, Pocomoke, D, 21851 Corresponding author: RC Shoemaker MD, ritchieshoemaker@msn.com.	Exposure to Interior Environments of Water-Damaged Buildings Causes a CFS-like Illness in Pediatric Patients: a Case/Control Study	Bulletin of the IACSF/ME. 17 (2). Summer 2009.	The case definition for pediatric chronic fatigue syndrome (CFS) is symptom based, with a defined set of exclusions for confounding illnesses. These exclusions form a differential diagnosis of chronic fatiguing illnesses; the list of exclusions will grow as potential confounders are newly confirmed. Patients sickened by exposure to water-damaged buildings (WDB) have a multi-system, multisymptom illness, but only recently has fatigue become commonly accepted in WDB literature as a common symptom. Published data on symptoms in patients with WDB illness show fatigue is present in over 90% of adult patients. Physiologic disturbances in these patients are densely present and contribute to form a case definition for WDB illness in adults that demonstrates that each patient has a chronic, systemic inflammatory response syndrome (CIRS), with abnormalities in regulatory neuropeptides; markers of pro-inflammatory cytokine response; genetic association shown by HLA DR; TGF beta-1; autoimmunity; and split products of complement activation. We reviewed our pediatric cases of WDB illness comparing cases to a roster of controls, a group of well patients seen in the practice for well-child or well-adolescent care. Each case, but no controls, met the current pediatric case definition of CFS; each case, but no controls, had CIRS. We propose that (1) the pediatric case definition of CFS be modified to specifically exclude patients with exposure to WDB that lasts more than 30 days (2) environmental exposure to WDB be included in a pediatric CFS history (3) laboratory testing in all potential pediatric CFS patients include assessment of CIRS (4) pediatric patients currently diagnosed with CFS be reviewed to exclude WDB illness as shown by exposure and CIRS markers.
Shor, S	Samuel Shor, MD, FACP, Associate Clinical Professor, George Washington University Health Care Sciences, Internal Medicine of Northern Virginia, 1860	Retrospective Analysis of a Cohort of Internationally Case Defined Chronic Fatigue Syndrome Patients in a Lyme Endemic Area	IACSF/ME. 18 (4). Winter 2011.	**Background** Chronic fatigue syndrome is a diagnosis of exclusion for which there are no markers. Lyme disease is the most common vector borne illness in the United States for which chronic fatigue is a frequent clinical manifestation. Intervention of patients with Lyme disease with appropriately directed antimicrobials has been associated with improved outcomes. **Methods** An arbitrary date was chosen such that all patients registered in the database of the practice of the PI, which is located in the Lyme endemic area of Northern Virginia area were reviewed. The diagnosis of

	Town Center Drive #230, Reston, Virginia 20190 E mail - samshormd@gmail.com			clinically significant fatigue > 6 months was chosen. Inclusion criteria required fulfilling the International Case Definition for CFS. **Results** Of the total 210 included in the analysis, 209 or 99% were felt to represent a high likelihood of "seronegative Lyme disease." Initiating various antimicrobial regimen, involved at least a 50% improvement in clinical status in 130 or 62%. Although not achieving the 50% threshold according to the criteria discussed, another 55 patients subjectively identified a beneficial clinical response to antimicrobials, representing a total of 188 or 88% of the total identified as having a high potential for seronegative Lyme disease. **Conclusions** A potentially substantial proportion of patients with what would otherwise be consistent with internationally case defined CFS in a Lyme endemic environment actually have a perpetuation of their symptoms driven by a persistent infection by Borrelia burgdorferi. By treating this cohort with appropriately directed antimicrobials, we have the ability to improve outcomes.
Shor, Samuel	Associate Clinical Professor, George Washington University, Health Care Sciences	Retrospective Analysis of a Cohort of Internationally Case Defined Chronic Fatigue Syndrome Patients in a Lyme Endemic Erea	IACSF/ME. 19 (2). Fall 2011. Abstracts from IACFS/ME Biennial International Conference. Poster Presentations. P159-164.	Goals: a. To determine the prevalence of seronegative Lyme in a CFS clinic in a Lyme endemic region, that actually represented persistent borrelial infection. b. To determine if antimicrobial intervention as an integral part of treatment was able to assist in the delineation of this potential cohort. Chronic Fatigue Syndrome represents a symptom complex often including in addition to clinically significant fatigue, the co-morbidities of fractured nonrestorative sleep, endocrinopathies [such as decreased cortisol production], autonomic dysfunction [such as neurally mediated hypotension and postural orthostatic tachycardia] [8]. It is the interpretation of the author that this "CFS like complex" represents a valid model for the management of many patients with chronic persistent Lyme infection [9]. The adverse societal impact of CFS was reported by Reynolds et al in 2004. Estimates were of a 37% decline in household productivity and a 54% reduction in labor force productivity among people with CFS. The annual total value of lost productivity in the United States was $9.1 billion which represents about $20,000 per person with CFS or approximately one-half of the household and labor force productivity of the average person with this syndrome [2]. The following data would suggest that we have the capacity to better characterize a substantial number of "CFS" patients as having "seronegative" persistent Lyme infection for which adjustments in intervention are shown to improve outcomes. Thus, we are attempting to provide evidence to the etiology of Chronic Fatigue Syndrome, while also providing input as to the clinical manifestation of persistent Lyme infection. The management of Lyme disease regarding diagnosis and treatment unfortunately is wrought with controversy. There is one evidence based school of thought that Lyme disease is easily diagnosed and easily treated [10-11]. This set of guidelines has had questions raised as to the quality of the evidence with which the recommendations have been generated: "…The IDSA guideline recommendations are primarily based on low-quality evidence derived from nonrandomized studies or expert opinion. These findings highlight the limitations of current clinical infectious

				diseases research that can provide high-quality evidence…"[12-14]. There is an alternative, evidence based position that suggests that the diagnosis of Lyme disease is associated with insensitivities and that the management of those identified with this condition regularly have protracted, and relapsing courses often requiring prolonged antimicrobial therapy [15].

Fall 2011. Abstracts from IACFS/ME Biennial International Conference. P112-113.	Background: The Blood XMRV Scientific Research Working Group was established to design and coordinate collaborative studies to investigate the prevalence of XMRV in blood donors using standardized XMRV assays. Materials And Methods: A multi-phase study has been designed to evaluate XMRV nucleic acid and serological detection assays in terms of sensitivity, specificity and reproducibility; assess assay performance on various specimen types represented in existing blood donor/recipient repositories, and determine the prevalence of XMRV in blood donors. Phase I involved production of whole blood (WB) and plasma analytical performance panels spiked with XMRV infected cells or virus, respectively. These panels were tested in a blinded fashion using XMRV nucleic acid amplification testing (NAT) developed by seven participating laboratories. Phase II represented pilot studies to compare XMRV detection using frozen PBMCs, WB and plasma derived from individuals identified as XMRV viremic in a previous study. Additionally, serology was performed on plasma by two laboratories. Phase III involves further evaluation of the clinical sensitivity and specificity of candidate NAT, serology and culture assays by using a blinded panel of 15 pedigreed positive samples, together with pedigreed negative samples and spiked positive controls Results: In phase I, all laboratories detected at least 136 proviral copies/ml and 5/7 assays demonstrated even more sensitive limits of detection. 5/7 plasma RNA assays performed similarly, with limits of detection of 80 RNA copies/ml or less. The initial unblinded pilot study in phase II resulted in two laboratories detecting MLV-like sequences in the plasma, but not PBMCs or WB, from all four subjects. A third laboratory detected no viral sequences. A second, blinded, pilot study using the same four subjects and two validated negative controls was less conclusive, with three laboratories detecting no viral sequences with any of the samples. A FACS-based serological assay detected antibodies in 3/4 XMRV-positive individuals, but also in 1/2 negative controls. A western-based assay found no evidence of serology in any sample. Results from Phase III are expected soon. Conclusions: The Blood XMRV SRWG has established a collaboration between many of the laboratories conducting research into XMRV and its detection in blood and has initiated steps to compare performance of XMRV assays using analytical and clinical panels comprised of blood samples from XMRV-positive and negative pedigreed subjects.

Snell, Christopher	[no address given]	The Importance of Exercise Challenge	IACSF/ME. 19 (2). Fall 2011. Abstracts from IACFS/ME Biennial International Conference. P124.	The absence of reliable diagnostic laboratory tests or biomarkers presents significant problems for persons with Myalgic Encephalomyelitis/Chronic Fatigue Syndrome (ME/CFS), treating physicians, and the ME/CFS research community alike. Typically ME/CFS diagnoses rely on self-report measures. An alternative to this approach is to employ direct, objective multi-system, measures of physical function that may also provide insights to the underlying pathophysiology of ME/CFS. One such methodology is cardiopulmonary exercise testing (CPET). The principles underlying CPET are simple. Physical exertion requires that the cardiovascular system supply oxygen (O2) to active muscles and the pulmonary system remove carbon dioxide (CO2) from the blood. Taxing these systems has the capacity to reveal abnormalities that may not be apparent at rest and thus elucidate the mechanisms underlying exercise intolerance in ME/CFS. Some key measures available from CPET include: maximal aerobic capacity (Peak VO2 or VO2 max); ventilatory or anaerobic threshold (VT); and peak respiratory exchange ratio (RER). CPET permits accurate comparison of subjects across serial exercise tests and should be of prime consideration for any clinical intervention trial with functional endpoints. CPET data also allow for the more reliable interpretation of results when an exercise challenge is used to elicit ME/CFS symptoms. As a quantifiable measure of both physiological stress and effort, CPET enables direct comparison between patients and controls on these measures. CPET also has the capacity to objectively document PEM in ME/CFS patients. A significant change in exercise capacity over consecutive tests, it could be argued, is clear evidence of PEM.
Staines, DR; Brenu, EW; Marshall-Gradisnik, S	Ekua Weba Brenu, Faculty of Health Science and Medicine Bond University Queensland 4229,	Novel pathomechanisms in Chronic Fatigue Syndrome/Myalgic Encephalomyelitis:	IACSF/ME. 18 (1). Spring 2010.	CFS/ME is, in some cases, a serious fatigue-related condition exhibiting a range of neurological, immunological and metabolic dysfunctions in symptom presentation. The present paper explores the possibility of perturbations of purinergic signalling (PS) as a pathomechanism of CFS/ME involving glial cell dysfunction, disruption of neuronal transmission, neuroinflammation and possible disturbances in the

	Australia Email: ebrenu@student.bond.edu.au Dr Donald R. Staines Associate Professor and Public Health Physician, Gold Coast Population Health Unit, 10-12 Young Street, Southport 4215, Queensland, Australia E-mail: Don_Staines@health.qld.gov.au Dr Sonya Marshall , Associate Professor Biochemistry Faculty of Health Sciences and Medicine ,Bond University, Queensland 4229, Australia Email: smarshal@bond.edu.au	Do purinergic signalling perturbations and gliosis play a role?		functioning of the blood-brain and blood-spinal barriers (BBB/BSB). This paper discusses the possibility that the putative neuroinflammatory processes may occur through perturbations of PS involving vasoactive neuropeptide (VN) dysfunction (e.g. through autoimmune mechanisms). Pituitary adenylate cyclase-activating polypeptide (PACAP) and vasoactive intestinal peptide (VIP) function as neurotransmitters, vasodilators and regulators of immunity, nociception and hypoxic injury. They are important in the central nervous system (CNS) by activating adenylate cyclase (AC) to produce cAMP from ATP. Compromise of ATP metabolism may promote neuronal and glial toxicity through impaired cAMP production or impaired ATP metabolism and these may alter BBB/BSB function. Although speculative, diagnostic and therapeutic implications may exist for CFS/ME if VN compromise, along with perturbations of PS, do indeed disrupt neurological and glial cell functioning. Treatment opportunities involving phosphodiesterase inhibitors (PDEIs) and purinergic modulators may plausibly exist.
Staud, Ronald	[no address given]	Session: FIBROMYALGIA: Are tender points necessary? A debate Tender points are Important	IACSF/ME. 19 (2). Fall 2011. Abstracts from IACFS/ME Biennial International Conference. P118-119.	Population studies have demonstrated moderately strong associations (odds ratios range 1.3-3.1) between the presence of pain in a body segment and the presence of tender points within that segment. Further, there is evidence of increasing number of tender points with increasing number of painful segments. The reporting of non-Bulletin of the specific pain, aching, or stiffness, is also associated with high tender point counts. Importantly, there is no unique cut off at which local pains and tender points occur concurrently in a widespread form. This is consistent with the observation that fibromyalgia (FM) represents one end of a spectrum of musculoskeletal pain and tender points, and that both traits are continuous in the general population. Tender points have been successfully used for the definition of study populations like fibromyalgia. For clinical purposes, however, tender points seem to provide little mechanistic information about individuals' pain and associated symptoms.
Steele, Lea	Lea Steele, Ph.D.,	Gene-Exposure	IACSF/ME. 19 (2). Fall 2011.	Objectives: Epidemiologic and clinical studies have implicated wartime exposures to

	Research Professor of Biomedical Studies, Baylor University, Director, Baylor Complex Illness Research Initiative, One Bear Place, Box # 97224, Waco, TX 76798, Email: Lea_Steele@baylor.edu	Interactions in the Etiology of Gulf War Illness: Evidence of Increased Vulnerability to Neurotoxicants in Identifiable Veteran Subgroups	Abstracts from IACFS/ME Biennial International Conference. P134.	neurotoxicants (pyridostigmine anti-nerve gas pills, pesticides, and low-level nerve agents) as risk factors for Gulf War illness (GWI), but it is unclear why some troops developed GWI after the 1991 Gulf War (GW) while others, with similar experiences and exposures, remained healthy. This study investigated whether genotype or activity of paraoxonase (PON1), a circulating enzyme whose isoforms differentially hydrolyze pesticides and nerve agents, is associated with variable risk for GWI in veterans of the 1991 Gulf War. Methods: Case-control study of a population-based sample of 91 veterans who served in the Army as enlisted personnel during the 1991 Gulf War: 49 Gulf War veterans with GWI, 19 GW veteran controls, and 23 nondeployed veteran controls. Veterans provided information on wartime experiences and exposures, and blood samples for determining PON1 genotype at position 192, and PON1 activity in three substrates: paraoxon, phenyl acetate, and diazoxon. In addition to general case-control comparisons, exploratory analyses evaluated interactions between genotype and exposures in the risk for GWI. Results: Overall, a somewhat higher proportion of GW cases (22%) than GW controls (6%) were PON1192 RR homozygotes (p=0.09). PON1 activity in paraoxon was significantly lower in GW controls than in GWI cases (p=0.04) and nondeployed controls (p=0.05), with no significant differences noted in other substrates. In exploratory evaluation of GWI risk in PON1192 genetic subgroups, QQ homozygotes were at significantly increased risk for GWI if they reported wearing pesticide-treated uniforms (OR = 21.0, exact p<0.01) or prolonged use of pyridostigmine bromide (OR=11.2, exact p<0.01), although these exposures were not associated with GWI in veterans with QR and RR genotypes. Among veterans with QR and RR genotypes, the only significant GWI risk factor was hearing chemical alarms in theater (OR=7.6, exact p=0.04), while hearing alarms was not a risk factor for QQ homozygotes (OR= 0.75, exact p=0.34). Conclusions: Findings support earlier indicators that GWI may be associated with PON1 genotype and activity levels, with GW PON1192RR homozygotes at somewhat increased risk for GWI overall. Detailed investigations from our small sample provided significant results in support of the following hypotheses: 1) GW veterans whose PON1 genotype (QQ) is known to provide slower hydrolysis of some organophosphate pesticides were at increased risk for GWI in relation to reported use of pesticides and prolonged use of pyridostigmine bromide during deployment, and 2) GW veterans who carry the R allele at PON1192, which is known to provide inefficient hydrolysis of sarin, were at increased GWI risk if they heard chemical alarms in theater. These preliminary findings identify significant gene exposure interactions in the directions expected for substrates preferentially hydrolyzed by PON1192 Q and R isozymes, and warrant further evaluation in a larger sample.
Stein, Eleanor	Private practice psychiatry; Calgary,	Diagnosing psychiatric disorder	Bulletin of the IACSF/ME. **Winter 2005 - 6**	A frequently voiced concern of physicians in clinical practice is how to accurately diagnose and treat psychiatric disorders in people with chronic fatigue syndrome

	Alberta , Canada	in patients with ME/CFS		(ME/CFS). The objective of this paper is to suggest some simple ways to differentiate between ME/CFS and primary depression and anxiety, as well as how to approach secondary psychiatric issues when they are present. These guidelines are based on close reading of the diagnostic criteria of ME/CFS, a review of the literature and clinical experience with both discrete and mixed populations.
Stein, Eleanor	Myalgic Encepahalomyelitis/Chronic Fatigue Syndrome and related disorders, Psychiatrist in Private Practice, Clinical Assistant Professor Dept of Psychiatry, University of Calgary, 4523 – 16 A Street SW Calgary, Alberta T2T 4L8 e-mail: espc@shaw.ca	Development of Standardised Patient Scenarios as a Teaching Tool for ME/CFS	IACSF/ME. 19 (2). Fall 2011. Abstracts from IACFS/ME Biennial International Conference. Poster Presentations. P155-156	Objectives: 1. To describe the process of developing two "standardized patient" clinical teaching tools for ME/CFS 2. To evaluate the effectiveness of these tools in a mixed health care professional audience attending an educational workshop on Methods: The process started with two focus groups of physicians who were unfamiliar with ME/CFS. The groups identified their top learning priorities with regards to ME/CFS. Clinical cases were developed to address these identified needs based on the Canadian Consensus Guidelines. The cases were then "workshopped" extensively by expert clinicians and patient focus groups and standardized patient trainers. The final standardized scenarios will be presented in vivo at an accredited CME medical education workshop April 30, 2011. Evaluations of the April 30th, 2011 workshop will provide data on the acceptability of these tools to health care professionals. Results: Patient feedback to the two scenarios: 1. diagnosis and 2. symptom management was extremely positive. Patient input ensured that the scenarios reflect that ME/CFS is a biomedical condition which due to its severity, variability and uncertain prognosis can cause depression, anxiety and stress. They also stressed the importance of clinicians asking about the lived experience of patients with ME/CFS. This is a qualitative evaluation of new teaching tools. The presentation will include verbatim comments from participants, evaluation data and may include video clips. Conclusions: These standardized clinical scenarios are well received by patients with ME/CFS and have promise as teaching tools for health care professionals
Stein, Eleanor; Stormorken, Eva	Eleanor Stein MD FRCP(C), Myalgic Encepahalomyelitis/Chronic Fatigue Syndrome and related disorders, Psychiatrist in Private Practice, Clinical Assistant Professor, Dept of Psychiatry, University of Calgary, 4523 – 16 A Street SW	Working Successfully With Patients Who Have Contested Conditions: The Case of Myalgic Encephalomyelitis/Chronic Fatigue Syndrome	IACSF/ME. 19 (2). Fall 2011. Abstracts from IACFS/ME Biennial International Conference. Poster Presentations. P153-154	Objectives: 1. To provide an understanding of the impact on the therapeutic relationship of ME/CFS being a contested condition - one in which there is no proven etiology, diagnostic test or treatment. 2. To recommend solutions to the challenges and misunderstanding that arise in the relationships between patients with ME/CFS and their health care practitioners as a result of the contested status. Methods: Non-systematic literature review and clinical experience. Results: Therapeutic relationships between patients with ME/CFS and their medical practitioners are impacted by contextual issues including: debate about causality, lack of recognition, and lack of objective diagnostic markers. These issues lead to common therapeutic challenges including: debate over validity of the condition, the need to differentiate ME/CFS from primary psychiatric disorders, frustration due to lack of symptom improvement, altered power balance between the patient and practitioner, interaction with patients who feel unheard, and the need to close the gap between needed and available services. Strategies which deserve further research include: keeping an open mind,

				clarifying symptom profiles, collaboratively searching for hope, clarifying expertise of patient and practitioner, listening to the whole story and building a coalition to advocate for needed services. Conclusions: Identifying and openly discussing contextual issues which impact the therapeutic relationship allows patient and practitioner to form a working relationship against the illness and societal stigma rather than fighting each other. This collaboration may improve the quality of therapeutic relationships thereby improving patient care and outcomes.
Stevens, SR; Davenport,TE	1 Executive Director, Pacific Fatigue Laboratory, Department of Sport Sciences, University of the Pacific, Stockton, CA, USA 2 Assistant Professor, Department of Physical Therapy, Thomas J. Long School of Pharmacy and Health Sciences, University of the Pacific, Stockton, CA, USA	Functional Outcomes of Anaerobic Rehabilitation in a Patient with Chronic Fatigue Syndrome: Case Report with 1-year follow-up	IACSF/ME. 18 (3). Fall 2010.	This case study aimed to document the effect of pacing self-management and short-duration exercise on physiological functioning and disability in an individual with chronic fatigue syndrome/myalgic encephalomyelitis (CFS/ME). A 28-year-old woman with CFS/ME received a rehabilitation program that involved: (1) pacing self-management using a heart rate monitor to maintain heart rate below ventilatory threshold and (2) a pragmatic approach to restorative strengthening and flexibility exercises conducted at an intensity below anaerobic threshold, which were completed 3 times weekly. Cardiopulmonary exercise testing (CPET) with analysis of expired gases and functional self-report were obtained before and 1 year after initiation of intervention. At 1-year follow-up, the patient reported she was able to complete daily activities without reproducing symptoms and 75% improvement in time to recover from CPET. Prior to intervention, patient demonstrated impaired cardiovascular and pulmonary responses at peak and anaerobic threshold, which improved at 1-year follow-up. Pacing self-management combined with short-duration restorative exercise resulted in a favorable clinical outcome in this patient with CFS/ME. Additional research is necessary to determine the efficacy and mechanism of action for this treatment.
Stouten, B[1]; Goudsmit, EM[2]	1. Einsteindreef 67A, Utrecht, The Netherlands 2. University of East London, UK	How Valid id the Model Behind Cognitive Behaviour Therapy For Chronic Fatigue Syndrome? An Evaluation of the Additional Data from the Trial by Pins et al	IACSF/ME. 18 (2). Summer 2010.	The cognitive behavior therapy (CBT) program studied by Prins et al. is based on a model of chronic fatigue syndrome that posits that fatigue and functional impairment are perpetuated by physical inactivity, somatic attributions, focusing on bodily symptoms and a low sense of control. A recent analysis of the data from three trials based on a model devised by Vercoulen et al. concluded that the effect of CBT on fatigue could not be attributed to a persistent increase in physical activity. We therefore examined the effect of treatment on the remaining three variables in the model using data from one of the trials, available in the public domain. The results from the groups given CBT, Guided Support and treatment as usual revealed that CBT had no significant impact on somatic attributions and focusing on bodily symptoms, and that in line with established guidelines, these two variables were not mediating factors. The only variable in the model showing an effect of CBT was sense of control. We submit that there is now sufficient evidence to warrant a review of CFS guidelines which advocate interventions aimed particularly at increasing physical activity and challenging somatic attributions, and that more flexible programs which address loss

				of control deserve further consideration and evaluation.
Strayar, DR; Mikovits, JA[2]; Vurimindi, V[1]; Carter, WA[1];	[1]Hemispherx Biopharma, Inc., Philadelphia, PA [2]Whittemore Peterson Institute, Reno, NV	Health/Performance and Response Status of XMRV/pMRV Antibody Positive vs. Negative Chronic Fatigue Syndrome (CFS) Subjects in a Phase III Clinical Trial	IACSF/ME. 19 (2). Fall 2011. Abstracts from IACFS/ME Biennial International Conference. P116-117.	Background: CFS is a severe disorder consisting of profound fatigue and a variety of other debilitating symptoms that affects up to 4 million Americans. Recently, one of us (JAM) identified DNA from a human gamma retrovirus (XMRV) in 67% of CFS subjects. Evidence also suggested that approximately 50% of the CFS infected subjects mounted a specific antibody response against XMRV (Science 326, 585-589 (2009)). The objective of this study was to compare demographic parameters, health/performance status and response of XMRV/pMRV antibody positive vs. negative CFS subjects enrolled in a Phase III clinical trial evaluating the safety and efficacy of a toll-like receptor 3 (TLR3) agonist, rintatolimod (PolyI:PolyC12U, Ampligen®). Materials and Methods: Two-hundred-eight (208) evaluable subjects, who met the 1988/1994 Case Definitions for CFS, participated in this randomized, placebo-controlled, double-blinded, multicenter study. Only severely debilitated patients were selected for this study. The primary endpoint was exercise treadmill duration. Subjects received rintatolimod (200-400 mg) or an equivalent volume of placebo twice weekly by IV infusion for 40 weeks. Baseline (or earliest available specimen) serum samples from all 208 subjects were analyzed for antibodies directed against XMRV/pMRV. Results: Seventy (33.7%) of the 208 CFS subjects were positive for antibodies directed against XMRV/pMRV, while 138 (66.3%) were negative. There was no significant difference in the number of CFS subjects positive or negative for antibody with regard to age, gender, duration of CFS, cognitive dimension (SCL90-R), exercise treadmill duration, or SF-36 vitality score (p>0.3). However, the subjects negative for antibody had a lower Activity of Daily Living score (66.9 vs.71.2, p=0.010, ANOVA) and a lower overall activity level based upon a lower activity monitor score (183K vs. 210K, p=0.033, ANOVA). The percent of subjects with a >25% increase in exercise treadmill tolerance (ETT) at Week 40 compared to Baseline was significantly greater for subjects receiving rintatolimod (39%) vs. placebo (23%), p=0.016 (2 tailed Fisher's Exact Test). Although, there was a trend for greater improvement in exercise duration with rintatolimod treatment for both the XMRV/pMRV antibody cohorts receiving rintatolimod, the antibody positive subgroup had a greater relative percent of subjects showing a >25% increase in ETT with rintatolimod compared to placebo than the antibody negative cohort. An analysis of concomitant medications utilized by CFS subjects to help treat symptoms of CFS showed that, when compared to placebo, the rintatolimod treated cohort positive for antibodies had a greater percentage of subjects with a decrease in CFS-related medication use at the end of the study (24%), p=0.039 vs. the antibody negative subjects (13%), p>0.10. Conclusions: These results indicate that approximately 1/3 of the CFS subjects have a detectable immune response directed against XMRV/pMRV and that this antibody positive group may respond more favorably to rintatolimod, an antiviral and immune modulator, than the antibody negative cohort. Additional studies to further evaluate XMRV/pMRV in this

				CFS population are underway.
Sugino, T; Ishigami, K; Kajimoto,O	Tomohiro Sugino, Representative Director, Soiken Inc., Master of Science in Biology, Senri Life Science Center 13F, 1-4-2, Shinsenri-higashimachi, Toyonaka, Osaka, 560-0082, Japan sugino@soiken.com	Supplementation of Imidazole Dipeptides Attenuates Fatigue Induced by Various Causes in Human	IACSF/ME. 19 (2). Fall 2011. Abstracts from IACFS/ME Biennial International Conference. Poster Presentations. P147-148	Objective: Oxidative stress is known to cause physical and mental fatigue, so antioxidants are potential candidates for antifatigue agents. Imidazole dipeptides (carnosine and anserine) which chicken breast is rich in, are reported to have strong antioxidative effects. This is the reason migratory birds can fly thousands of miles without rest? Here, we investigated the effect of imidazole dipeptides derived from chicken breast on fatigue induced by physical task or by daily activities in human. Methods: (Study I) In a double-blinded, placebo-controlled, crossover study, 17 subjects took dipeptides 400 mg/day or placebo for 29 days. As a fatigue-inducing physical task, subjects performed workload trials on a cycle ergometer at fixed workloads for 4 hours and then rested for 4 hours. We evaluated physical performance by 10-second high power test, subjective sensation of fatigue by visual analogue scale (VAS) and antioxidant and its related effects by biochemical parameters in blood and urine. (Study II) In a double-blinded, placebo-controlled, parallel study, 207 subjects who have fatigue feeling from daily activities were randomly divided into three groups; and provided with imidazole dipeptides 200 mg/day, 400 mg/day, or placebo for 8 weeks. We evaluated the subjective sensation of fatigue primarily by VAS. Results: (Study I) Oral imidazole dipeptides administration inhibited the impaired physical performance and the increased level of fatigue sensation, and suppressed the increased levels of the urinary oxidative stress parameters [8- isoprastane and 8-hydroxy-deoxy-guanosine (8-OHdG)] and plasma transforming growth factor (TGF)-b by physical task. (Study II) The VAS score was significantly lower in the imidazole dipeptides 200 and 400 mg/day groups compared with that in the placebo group. The effect was remarkable especially in the 400/day group. Conclusion: These results suggest that the antioxidant effect of imidazole dipeptides inhibited tissue damage and attenuated fatigue by physical task, moreover the dipeptides decreased in fatigue sensation from daily activities. Imidazole dipeptides have the effects on attenuating fatigue induced by various causes, so supplementation of the dipeptides (drink, capsule, tablet etc.) is one of the promising remedies for fatigue in human.
Tajima, Seiki; Matsuzawa, Shigeyuki; Takai, Kazumi; Miike, Teruhisa	Seiki Tajima, MD., 1070 Akebono-cho, Nishi-ku Kobe, 651-2181, Japan. s_tajima@hwc.or.jp	Therapeutic Outcome by Two-months Intensive Sleep-Wake Circadian Rhythm Treatments in Japanese Children and Adolescents with Chronic Fatigue	IACSF/ME. 19 (2). Fall 2011. Abstracts from IACFS/ME Biennial International Conference. P128-129.	Objectives: In the last two decades, we have reported relationship between biological clock system and childhood chronic fatigue (CCF). Biological clock dysfunction is associated with energy metabolism, immune system and frontal lobe dysfunction. Based on these evidences, we have treated patients with CCF at new medical research center for CCF and developmental disorder since April 2009. Here we show the therapeutic outcome of our first year trial for translating evidence into practice. Methods: 30 patients (15 boys and 15 girls, age 11 to 25) with chronic fatigue caused by sleep deprivation were admitted in the first year of our center. All patients were treated for 8 weeks with bright light therapy, thermal therapy, medication, cognitive behavioral therapy and lifestyle teaching. Self-sleep-logs (S-log) have been recorded

				during hospitalization. 48hr core body temperature (CBT) monitoring was performed at the beginning and the end of therapy. Delay of circadian rhythm (≥60min.), poor daily variation (ΔCBT<1.0°C) and totally high CBT (1.0°C higher than control) were detected in CBT recordings. Long total sleep time (≥10hr), delayed sleep phase (sleep onset later than 24:00), irregularity of sleep onset and offset (larger variation than 90min.) and sleep segmentation (segmented more than 7 days per 2 weeks) were also detected in S-log recordings. With or without these factors were compared between the beginning and the end of therapy using fisher's exact test. Results: Delay of CBT circadian rhythm ($p<0.01$), long total sleep time ($p<0.0001$), delayed sleep phase ($p<0.05$) and irregularity of sleep onset and offset ($p<0.0001$) were significantly improved at the end of therapy. Conclusion: Intensive sleep-wake circadian rhythm treatments were effective to improve circadian rhythm. However, recoveries of other chronic fatigue related symptoms and poor performances were insufficient at the time of discharge. Therefore, just a part of patients has resumed normal activity yet. Recovery from sleep disturbance is not the goal but the first stage of improvement for the patients with chronic fatigue. From this point of view, more clinical trials will be needed.
Torres-Harding, Susan[1]; Sorenson, Matthew[2]; Jason, Leonard A[2]; Maher, Kevin[3]; Fletcher, Mary Ann[4]	[1]Roosevelt University; [2]DePaul University; [3]Labcorp and University of Miami, [4]University of Miami	Evidence for T-helper 2 Shift and Association with Illness Parameters in Chronic Fatigue Syndrome (CFS)	Bulletin of the IACSF/ME. 16 (3). Fall 2008. P19-33.	Few immunological markers have been consistently reported in CFS. However, a shift to a T-helper 2 (Th2) type immune response has been hypothesized for individuals with CFS. The current study investigated whether individuals with CFS who exhibited a stronger shift towards a Th2 type of immune response would also exhibit more severe symptoms, poorer neurocognitive functioning, and poorer physical and psychosocial functioning. The current investigation measured the percentage of Th1-like and Th2-like memory cells using cell surface flow cytometry in 114 individuals with CFS. The associations between the ratio of Th1 and Th2 memory cells and various illness parameters measures were then examined, including symptom severity, psychiatric functioning, neurocognitive functioning, salivary cortisol levels, and chronic pain status. Results indicated that individuals who exhibited a more extreme shift towards a Th2 immune response also exhibited poorer sleep and high levels of basal salivary cortisol. The implications of these findings are discussed.
Treasdaden, IH; Puri, BK	Dr. Ian H. Treasaden, Consultant Psychiatrist and Honorary Clinical Senior Lecturer, West London MHT and Imperial College London; Head of Forensic Neuroscience, Department of	Regional Grey and White Matter volumetric changes in Chronic Fatigue Syndrome (Myalgic Encephalomyelitis): A Voxel-based Morphometry 3T MRI Study	IACSF/ME. 19 (2). Fall 2011. Abstracts from IACFS/ME Biennial International Conference. P135-136	Objectives: It is not established whether or not myalgic encephalomyelitis/chronic fatigue syndrome (CFS) is associated with structural brain changes. The aim of this study was to investigate this by conducting the largest voxel-based morphometry study to date in CFS. Methods: High-resolution structural 3-T cerebral MRI scanning was carried out in 26 CFS patients and 26 age- and gendermatched healthy volunteers. Voxel-wise generalized linear modeling was applied to the processed MR data using permutation-based non-parametric testing, forming clusters at $t > 2.3$ and testing clusters for significance at $p < 0.05$, corrected for multiple comparisons across space. Results: Significant voxels ($p < 0.05$, corrected for multiple comparisons),

	Imaging, Imperial College, UK.Three Bridges Unit, West London Mental Health NHS Trust, Uxbridge Road, Southall, Middlesex UB1 3EU, England,UK. E-mail: ian.treasaden@wlmht.nhs.uk			depicting reduced grey matter volume in the CFS group, were noted in the occipital lobes (right and left occipital poles; left lateral occipital cortex, superior division; and left supracalcrine cortex); the right angular gyrus; and the posterior division of the left parahippocampal gyrus. Significant voxels ($p < 0.05$, corrected for multiple comparisons), depicting reduced white matter volume in the CFS group, were also noted in the left occipital lobe. Conclusion: These data support the hypothesis that significant neuroanatomical changes occur in CFS, and are consistent with the complaint of impaired memory that is common in this illness; they also suggest that subtle abnormalities in visual processing, and discrepancies between intended actions and consequent movements, may occur in CFS.
Unger, Elizabeth	Elizabeth R. Unger PhD, MD, Chronic Viral Diseases Branch, Division of High-Consequence Pathogens and Pathology, NCEZID Centers for Disease Control and Prevention, 1600 Clifton Road, MS G41 Atlanta,GA 20222, USA. eunger@cdc.gov	Pathways to Pathogenesis: Standardized Measures of CFS/ME Illness Domains	IACSF/ME. 19 (2). Fall 2011. Abstracts from IACFS/ME Biennial International Conference. P123.	Case definitions are used in at least two different circumstances. First, a case definition, when simply and easily applied, may be used as a substitute for a specific diagnostic test to measure disease in a population. This would be done when use of the diagnostic test is impractical for delivering information in a timely and cost-effective manner. An example of this situation is use of “flu-like illness” determined by telephone interview as a surrogate to monitor seasonal or pandemic influenza. A second circumstance occurs when there is no diagnostic test, and case identification requires the use of specific descriptive measures. This is the current situation with CFS/ME, a complex and heterogeneous disorder likely to involve multiple pathways to pathogenesis. Case definitions are essential for public health agencies to determine burden of illness, for clinicians to appropriately diagnose and manage patients, and for researchers to identify risk factors and the underlying biologic basis for illnesses. Limitations in the ability of case definitions to identify homogenous patient populations could be addressed by standardizing how the definitions are applied, or by narrowing the definitions through increased criteria needed to meet the definition, or both. An alternative approach is to improve measures of illness domains (questionnaires and biologic) to allow patients identified by any case definition to be phenotypically sub-grouped in a way that allows the underlying biology to be discovered.
Unger, Elizabeth; Brimmer, Dana J; Boneva, Roumiana S; Jones, James F;	Dana J. Brimmer, Ph.D., M.P.H, Behavioral Scientist, McKing and CDC, 1600 Clifton Road, MS-A15, Atlanta, Georgia, 30333 dyv4@cdc.gov	CFS Knowledge and Illness Management Behavior Among US Healthcare Providers and The Public	IACSF/ME. 19 (2). Fall 2011. Abstracts from IACFS/ME Biennial International Conference. P130-131.	Objectives: Chronic fatigue syndrome (CFS) is a challenge because of unknown etiology and diagnostic biomarkers, and treatment relies on symptom management. Previous research has shown positive CFS knowledge, attitudes and beliefs among physicians and awareness among the public. We compared CFS knowledge and illness management behavior between healthcare providers (HCP) and the public in order to identify gaps and need for educational interventions. Methods: We used DocStyles, a 2009 web-based panel survey of primary care physicians, OB/GYNs, pediatricians, dermatologists, and nurse practitioners, and HealthStyles, a 2010 public consumer mail survey to ask questions about CFS knowledge and illness management behavior.

				The HCP sample is drawn from an opt-in, verified Epocrates Honors panel. HealthStyles used stratified random sampling to match the national population on region, income, age, and household size. Both surveys asked about CFS awareness, CFS symptoms, and if CFS is a medical or psychiatric condition. HCP were also asked if they have ever made a CFS diagnosis and how they treat and manage CFS. HealthStyles respondents were asked if they knew someone diagnosed with CFS, and then also if they or someone they knew thought they had CFS, what they would do to find out more about the illness. Results: The response rate was 46% for DocStyles and 67% for HealthStyles with a sample size of 2,000 and 4,184 participants, respectively. Males comprised 65% of DocStyles physicians and 48% of the HealthStyles sample. Among HCP, 94% heard of CFS compared to 57% of the public. HCP had two to three times higher recognition rates on eight CFS symptom criteria as compared to the general public. When asked if CFS were both medical and psychiatric, 71% of HCP agreed as compared to 30% of the public. Two percent of the public considered CFS a psychiatric condition vs 14% of HCP. A higher proportion of the public considered CFS a medical condition: 27% vs 8% of HCP. Uncertainty whether CFS was either a medical or a psychiatric condition was higher among the public (42%) compared to HCP (8%). Thirty-seven percent of HCP reported ever making a diagnosis of CFS and nearly 10% of the public knew someone diagnosed with CFS. HCP who reported ever diagnosing CFS were more likely to categorize CFS as a medical condition (Chi-square = 98.6, $p<0.01$). Top three ways in which HCP manage CFS were: referring to a medical specialist (35%), prescribing medications (29%), and referring to a psychologist (26%) or prescribing graded exercise therapy (26%). If diagnosed with CFS, the public would seek information by talking to a family doctor (72%), searching the Internet (54%), and talking to medical specialist (25%). Only 7% would join a support group. Conclusion: Our results are consistent with findings that HCP have high awareness and knowledge of CFS, and nearly 80% of HCP classified CFS as a medical or as both medical and psychiatric condition. However, HCP and public view of medical or psychiatric conditions differed. History of CFS diagnosis for HCP may influence this classification. More than 1/3 of HCP had ever diagnosed CFS, which is notable considering the relatively low prevalence of CFS. Study results support development and maintenance of CFS educational materials for the Internet and providing family doctors with tools to engage patients in conversations about CFS.
Vallings, Rosamund	vallings@xtra.co.nz	The Current CFS/ME Situation in NZ	Bulletin of the IACSF/ME. 16 (1). Spring 2008.	Here in New Zealand we are fortunate that our government accepts without question the diagnosis of CFS/ME in assessments for social welfare benefits. But many patients do fell between the cracks and have difficulty accessing home help, suitable housing and other extra health needs.
Vallings, Rosamund	vallings@xtra.co.nz	ME CFS Conference – May 2008 –	Bulletin of the IACSF/ME. 16 (2). Summer 2008. P12-19.	On May 6, 2008 I attended the International Conference on ME/CFS Biomedical Research at Hinxton, Cambridge, UK. 130 people attended and cutting edge research

		Cambridge, UK		was presented from around the globe. The conference was sponsored jointly by ME Research UK and the Irish ME Trust. Sadly, Vance Spence, who had organised the conference and was going to give an introductory overview, was too ill to attend.
Vallings, Rosamund	New Zealand ME/CFS Association vallings@xtra.co.nz	Skepticism in CFS/ME	Bulletin of the IACSF/ME. 16 (2). Summer 2008. P29-33.	One of the hardest things for those with CFS/ME has been the issue of "no-one seems to believe I am ill". Fortunately I am hearing this less and less these days because I think this illness is becoming better understood and validated by current research thinking did change, as we entered the era of mind-body medicine. ... Thankfully with the emergence and development of sciences such as immunology, genetics and biochemistry, illnesses such as CFS/ME are becoming validated and acknowledged by the wider medical and research community. ... It is just like any other illness with physical and mental aspects. So why do patients still have problems with convincing doctors and others in their lives that they have a "real" illness and are seriously afflicted?
Vallings, Rosamund	[No address quoted]	A Little Bit of History	Bulletin of the IACSF/ME. 16 (3). Fall 2008. P15-18.	On a recent visit to the United Kingdom to attend the Cambridge conference, I spent some time in London and decided to experience a little CFS/ME history again. I had done my medical training at the London Hospital, soon after the flu like epidemic that had affected many at the Royal Free Hospital, another of the 12 big London teaching hospitals, situated in Gray's Inn Road. In 1955, nearly 300 of the medical and nursing staff had remained seriously ill following this epidemic, and as we were a nearby teaching hospital, we had many of these people as inpatients for investigation.
Vallings,R	140, North Road, RD2 Papakura, 2582, New Zealand	Letter to Editor: CFS following H1N1 Flu	IACSF/ME. 18 (3). Fall 2010.	In early 2009 I had a case study published in the *Journal of Clinical Pathology* (1). This involved a young teenage boy who was diagnosed as suffering from Chronic Fatigue Syndrome (CFS) following an attack of swine flu (HIN1). His initial illness was severe, and he developed many symptoms in the following weeks. Three months later he was still very ill, and a diagnosis of CFS was deemed appropriate, according to the pediatric version of the Canadian criteria (2, 3). Since that time he has gradually improved although is still unwell and unable to participate fully in everyday activities or attend school regularly. Here in New Zealand we have just emerged from another winter and already I have seen a further 5 patients with CFS following HIN1 swine flu. I feel that primary care physicians need to be alerted to this possibility, and to identify at risk patients, so that suitable intervention can be instated. Early recognition of diagnostic vulnerability should give a better chance of earlier recovery. Any person suffering a very prolonged recovery following acute infection needs careful follow up. Suitable intervention would include: adequate rest, freedom from stress, cautious gentle exercise and a sensible diet. Most of these patients will have problems with sleep, necessitating regular bedtime routine, and medication may be needed. As pain is also a frequent symptom, a low dose tricyclic such as nortriptyline 5mg a few hours before bedtime may be appropriate. These simple measures can enhance an earlier

				recovery. Another associated issue for patients already suffering from CFS, or those who have recovered, is whether to have annual influenza immunisation. The immunisation here does incorporate HIN1 also. In general I recommend avoidance of any immunisation unless deemed absolutely necessary, as there seems to be accompanying risk of relapse for some patients. I have seen several patients each year who have relapsed after various immunisations, and I also have documented a number of CFS patients whose illness actually began following an immunisation. This does indeed produce a dilemma for both patient and physician. It would be interesting to hear from other physicians regarding their experiences, and hopefully this letter could generate some useful research to help guide us in future recommendations.
Van Hoof, Elke LS; De Becker, Pascale J; Lapp, Charles; De Meirleir, Kenny L	Elke Van Hoof, Department of cognitive and biological psychology, Faculty of psychological and educational sciences, Vrije Universiteit Brussel, Pleinlaan 2, 1050 Brussels - Belgium	How do adolescents with chronic fatigue syndrome perceive their social environment? A quantitative study.	Bulletin of the IACSF/ME. 17 (1). Spring 2009. P16-31	Some concern has been raised regarding the inappropriateness of the adult Center for Disease Control criteria for use in children. This resulted in a pediatric case definition being published in 2006. Unfortunately, the case definition does not prevent confusion and doubt with regards to the experienced symptoms in school personnel who deal with young persons with chronic fatigue syndrome (CFS). In order to provide more insight into pediatric chronic fatigue syndrome, twenty-seven chronic fatigue syndrome adolescents were interviewed by means of questionnaires. Results showed that it took about one and a half years before children received a diagnosis of chronic fatigue syndrome. Their symptom pattern seems comparable with that of an adult sample, except for stomach aches. The majority experienced conflicts at school due to their condition. Almost every adolescent with chronic fatigue syndrome abandoned their leisure activities. Adolescents with chronic fatigue syndrome were frequently confronted with negative remarks if they attempted their usual leisure activities.
Van Konynenburg, Richard A	Livermore, CA	The Glutathione Depletion – Methylation Cycle Block Hypothesis for CS/ME, Implications for treatment	Bulletin of the IACSF/ME. 16 (2). Summer 2008. P20-28.	At the January, 2007, IACFS/ME Scientific Conference in Fort Lauderdale, I presented a poster paper describing a new biochemical hypothesis for the etiology, pathogenesis, pathophysiology and symptomatology of CFS/ME, which I call the "Glutathione Depletion—Methylation Cycle Block (GD—MCB)" hypothesis. This hypothesis is able to explain many of the biochemical and symptomatic features of CFS/ME in a straightforward, specific and testable manner. Since the conference, I have continued to develop this hypothesis, and a clinical research study using a treatment protocol based on it is currently underway. The GD--MCB hypothesis has not yet been described in a peer-reviewed publication, and controlled clinical trials of treatment based on it have not yet been performed. Nevertheless, I believe it is in the best interest of the CFS/ME community for IACFS/ME members to receive an update on this hypothesis and the implications for treatment at this time.
Van Konynenburg,R	Richard A. Van Konynenburg, Ph.D.,	A Comprehensive Biochemical Model	IACSF/ME. 19 (2). Fall 2011. Abstracts from IACFS/ME	Objective: To build a comprehensive model for the pathogenesis and pathophysiology of ME/CFS that will lead to accurate diagnosis and effective treatment in clinical

	444 Ontario Drive, Livermore, CA 94550, USA, richvank@aol.com	for the Pathogenesis and Pathophysiology of ME/CFS, and Effective Treatment Based on It	Biennial International Conference. Poster Presentations. P145-146	practice. Methods: This paper builds on work presented at the previous three conferences of the IACFS/ME and its predecessors. In 2004, the author emphasized the importance of glutathione depletion in the pathogenesis and pathophysiology of ME/CFS (1). In 2007, he linked this to a partial block in the methylation cycle (2). In 2009, he and a physician presented evidence from a clinical study of a treatment based on this mechanism in a private practice, which was found to produce significant benefits for most of the patients, in terms of both symptomatic improvement and normalization of lab measured parameters (3). Results: Since the previous conference, further progress has been made in developing a comprehensive model of the pathogenesis and pathophysiology of ME/CFS at the biochemical level, which is consistent with available research on this disorder, clinical experience, and patient health histories, symptoms, and treatment outcomes. To the author's knowledge, this hypothesis is the only proposed model at the biochemical level that is capable of explaining the wide variety of features of this disorder in a straightforward manner. It draws together the specialized work of other researchers in epidemiology, genomics, nutrition, allopathic load, toxicology, gastroenterology, metabolism, exercise science, sleep science, gene expression, cardiology, neuroendocrinology, immunology and virology. It offers measurable biomarkers and guidance for effective clinical treatment. This model also has the potential to mesh well with retroviral involvement in ME/CFS, owing to the known silencing of gene expression by methylation. A significant number of patients, under the care of several clinicians, are currently receiving treatment based on this work, and most are experiencing improvement. A small number of what appear to be complete recoveries have been reported. Conclusion: Treatment to lift the partial methylation cycle block appears to be an important component of an overall treatment protocol for ME/CFS.
Vera, MA; Garcia, L; Valencia, W; Barnes, Z; Fletcher, M-A; Klimas, NG	Maria A. Vera-Nunez, MD, PG-Y 3 Internal Medicine Resident, University of Miami, Clinical Research Building, University of Miami Miller School of Medicine, 1150 N.W. 14th Street, Miami FL 33136, mveranunez@med.miami.edu	Abnormal Cytokine Levels in Patients with CFS Regardless of Metabolic Syndrome	IACSF/ME. 19 (2). Fall 2011. Abstracts from IACFS/ME Biennial International Conference. Poster Presentations. P166.	Background: Metabolic Syndrome (MetSd) is a known risk factor for significant morbidity and mortality, including cardiovascular and cerebrovascular disease. It has been described that inflammation plays an important role in the pathogenesis of MetSd, with up-regulation of both TH1 and TH2 cytokines. Previous studies have shown that patients with CFS were 2-fold as likely to have metabolic syndrome compared with healthy controls. Objective: To compare cytokine levels in patients with Chronic Fatigue Syndrome (CFS) with and without metabolic syndrome. Methods: With a cross-sectional study design, we evaluated the data from participants of the National Institutes of Health funded "Good Day, Bad Day" research study, and collected information on demographics: age, gender, race; anthropometrics: weight, height, waist circumference. Using a multiplex method (Quansys), plasma cytokines:Interleukin (IL) 1α, IL-1β, IL-2, IL-4, IL-5, IL-6, IL-8, IL-10, IL-12, IL-13, IL-15, IL-17, IL-23, Interferon gamma (IFNγ), Tumor necrosis factor alpha (TNFα) were measured. Metabolic syndrome (MetSd) was defined according to the Adult Treatment Panel III criteria. Normal values for cytokines were obtained from 93

				healthy controls. We used independent sample t test to compare means of continuous variables. Results: 66 charts of patients with CFS contained available information and pertinent data to complete the analysis of this study. Demographics: age 53±11.5, 85% female, 72.8% non-hispanic white, 18.2% Hispanic, 3% black, 1.5% Asian, and more than 1 ethnicity 4.5%. MetSd was present in 17 patients (26%), 71% female, 82% white. MetSd was not present in 49 (74%) Cytokine levels were compared between these two groups and no statistical differences were found. Further cytokine level comparison was made between CFS with MetSd and 93 healthy controls, 75% female. Here we found statistically significant differences in IL1α, IL-4, IL-5, IL-6, IL-8, IL-15, IFNγ and TNFα. Conclusion: The prevalence of metabolic syndrome in a CFS population was 26%. Plasma cytokine levels in CFS patients with and without co-morbid MetSd were not different. Similarly to our previously reported findings in CFS, CFS + MetSd patients had abnormalities in proinflamatory, Th2, Th1 and IL-8 when compared to healthy controls. Affected individuals would be biased towards a T-helper (TH) 2 type, or humoral immunity-oriented cytokine pattern accompanied by autoantibody production, inappropriate fatigue, myalgia and arthralgia, as well as changes in mood and sleep patterns. Large longitudinal studies should be performed to determine the contributing factors to this increased risk, and whether the course of metabolic syndrome is altered in this inflammatory state.
Vera, MA; Rey, I; Garcia, L; Harvey, J; Eugene, G; Barnes, Z; Fletcher, M-A; Klimas, NG	Maria A.Vera, MD, PG-Y 3 Internal Medicine Resident, University of Miami, Clinical Research Building, University of Miami Miller School of Medicine, 1150 N.W. 14th Street, Miami FL 33136, mveranunez@med.miami.edu	Vitamin D and IL 10 in Chronic Fatigue Syndrome	IACSF/ME. 19 (2). Fall 2011. Abstracts from IACFS/ME Biennial International Conference. Poster Presentations. P165-166.	Chronic Fatigue Syndrome (CFS) is considered a state of chronic inflammation. Vitamin D inhibition of pro-inflammatory processes has been observed and one of the proposed mechanisms is the ability to modulate T regulatory cell (Treg) function. Also a possible effect of vitamin D in IL-10 pathway (which is an anti-inflammatory cytokine) has been shown as IL-10-secreting T regs can be induced following activation in the presence of vitamin D. Objective: To determine vitamin D levels in a group of CFS patients and also evaluate if this level correlates with IL-10 levels. Methods: Data of subjects evaluated at the Center for Multidisciplinary Research on CFS, was obtained in a cross-sectional manner, from January to June 2010, in which vitamin D and IL-10 were measured in their first visit before therapeutic intervention. Collected data include demographics (age, gender), vitamin D and IL-10 levels and natural killer cytotoxic activity. Vitamin D deficiency was considered if its level was less or equal to 30ng/mL (75nmol/L), based on the recommendation of the International Osteoporosis Foundation Statistic analysis included descriptive statistics and correlation calculated with Pearson's r. Results: There were 54 people (13 men and 41 women) with pertinent available information, age 47.78±14.9, vit D 33.68 ±16.6, IL-10 15.7±16.1, nk activity 9%±5.6. The prevalence of vitamin D deficiency in this group was 57.4% (46.2% in men and 58.5% in women). Correlation between vitamin D and IL-10 levels was 0.228 (p=0.048). There was no correlation between vitamin D and NK activity or age in the studied group. Conclusion: The prevalence of Vitamin D deficiency was 57.4% and there was a significant correlation between VitD

				and IL-10 levels in this group of CFS patients. Clinical randomized-controlled studies that evaluate the immunomodulatory effect of vitamin D in patients with CFS are necessary.
Vogelsberger, W; Kamp, M; Blätter, G; Arends, W; Gringinger, F; Colizoli, L	[no address given]	Healing On The Spiritual Path Through The Teachings of Bruno Groening – Medically Verifiable: Three Documented Healings of ME and Two Documented Healings ofFybromyalgie	IACSF/ME. 19 (2). Fall 2011. Abstracts from IACFS/ME Biennial International Conference. Poster Presentations. P155.	In a time of world-wide health crisis with steadily growing numbers of chronically sick people, an interest in handed down traditional healing is growing. Natural healing, Homeopathy, Acupuncture, Phytotherapy and others have achieved ever growing significance in the last decade in medical practice. But also the oldest form of healing, the picking up and passing on of life energy or bio-energy, very often referred to as spiritual healing, finds more and more attention among medical specialists. Already in the 50's The British Council of Medical Doctors stated the fact that, "through spiritual healing the regaining of health is possible, which by today´s perception must be looked at as inexplicable."1 Since that time more and more hospitals of the Public Health Service have opened their doors to spiritual healing. The happenings around Bruno Gröning (1906-1959) in Germany, who is regarded as one of the most significant healers, has become the foundation-stone for a unique work of enlightenment by doctors of many countries in our time.1, 2 Thanks to the systematic work of our working group a great number of medically inexplicable progressions of healing from the most varied diseases could be recorded.3,4,5 Documentation is taking place world-wide by means of detailed recordings and analyses of the existing diseases and of the changes that have led to the healing. By means of a certain physical and mental attitude it was possible for the observed persons, mostly after a few minutes to sense a light feeling of energizing in their bodies. Often there occurred characteristic reactions in the body as a forerunner to the healing. It was interesting to observe in many cases an increase in the existing symptoms or pain appeared mostly in the exact topographic region of the affected organ in the body. Frequently it happened that in clear timely connection with these reactions chronic disorders ceased to exist. It is interesting that these phenomena have been described by such important representatives of medical science of the last centuries, such as Paracelsus (Switzerland), and by the well -known European doctor of the beginning of modern times, Hahnemann of Germany, the founder of Homeopathy. Similar knowledge exists in the Asian culture. The perceptions of our working group are presented in publications, in congresses, in different universities with medical students, and passed on in public lectures worldwide. In the last decade over 100.000 people in more than seventy countries have attended these lectures. The Focal point of the lecture will be the personal healing report of Mrs Anneke Hagen-de Waal from Germany. Mrs Hagen-de Waal received the healing after seven and a half years of suffering by putting into practical terms the teachings of Bruno Groening. This particular healing and two additional healings of ME and two healings of Fybromylagie will be presented and commented on by a medical doctor.
Whistler, T;	Toni Whistler, PhD.	Transient	IACSF/ME. 19 (2). Fall 2011.	Objective: Studies have shown that individuals differ appreciably in their

Kryston, C; Panicker, G; Unger, ER	Research Microbiologist, Centers for Disease Control and Prevention, 1600 Clifton Rd, G41,Atlanta, GA, 30333. USA. taw6@cdc.gov.	Responsiveness of Inflammatory Cytokines to an Acute Stressor: Comparisons Between CFS and NF	Abstracts from IACFS/ME Biennial International Conference. Poster Presentations. P167.	inflammatory responses to acute psychosocial stress, and as cytokines have been implicated in the pathogenesis and clinical manifestations of CFS, we wanted to determine if stress-induced immune-modulation was altered between CFS and non-fatigued controls. Methods: Subjects with CFS and matched well controls identified from the general population participated in a 3-day in hospital study. On the final day, participants were exposed to a standardized psychosocial stressor (the Trier Social Stress Test, TSST), which included free speech and mental arithmetic tasks in front of an audience. Blood was collected at nine time points before, during and after the test. Plasma was assayed for 10 cytokines (IL1b, IL4, IL5, IL6, IL8, IL10, IL12p70, IL15, TNFα and IFNγ) in a multiplexed high-sensitivity assay for the Meso Scale Discovery platform. All analyses was performed on log2-transformed data to correct for non-normal distributions, and analysis of covariance for repeated measures were performed co-varying for age, sex, race and BMI. Area under the curve (AUCs) for each cytokine was computed using the trapezoidal rule on the raw data and response AUCs were calculated by subtracting baseline from post-baseline AUCs. The data was then log-transformed and used to look at factors such as length of illness, MFI and SF36 scores using Pearson correlation coefficients. Results: Significant baseline differences between CFS and NF were noted for IFNγ and IL8, with levels of each being higher in the well controls. Data for IL1b was not included in the analyses as many measures were below the 0.35 pg/ml lower limit of detection. For all cytokines, the TSST elicited a significant increase in cytokine secretion as determined by a paired t-test of each subject's peak level after baseline compared to baseline. All analytes showed a significant change after multiple test correction. Repeated measure MANOVA's were computed for overall TSST differences between CFS cases and well controls (group-effect) which showed differences for IFNg, IL15 and IL6. Differences were seen in response profiles (group by time-effects) for IL15 and IL12p70. Conclusions: We show that a psychosocial stressor modulates inflammatory activity. The precise mechanism of this is not known, it could possibly be attributed to the transient mobilization of leukocytes to the periphery caused by sympathetic nervous activation. The mechanism becomes important if we are to understand the differences evident between CFS subjects and well controls in their response to a stressor. The different response profiles between CFS people and NF controls for IL15 and IL12p70 are interesting as IL15 regulates T- and natural killer (NK) cell activation and proliferation, and IL12 plays an important role in the activities of T- and NK-cells. This study attempts to further our understanding of the pathophysiology of CFS using a new paradigm to look at differences between well controls, the application of a stressor and monitoring the response over time.
White,P	Barts and the London School of Medicine,	Letter to Editor: Reply to Sampson	IACSF/ME. 18 (3). Fall 2010.	Dear Editor, In the last edition of the *Bulletin*, Sampson published a criticism (1) of a cohort study

	Queen Mary University of London, St Bartholomew's Hospital, London, EC1A 7BE, UK E-mail - p.d.white@qmul.ac.uk			of patients recovering from infectious mononucleosis (IM), written by myself and colleagues (2). He suggests that our conclusion was wrong, and even suggests that part of our analysis was incorrect and misleading. Sampson concluded essentially that our data suggest that broad based definitions of CFS that include comorbid psychiatric disorders are predicted by different factors than those that do not. That is also what we concluded: "The predictors of a prolonged fatigue syndrome after an infection differ with both definition and time, depending particularly on the presence or absence of comorbid mood disorders."(2) He also implies that we included some subjects with psychiatric disorders without declaring this. We did not: all subjects received a standardised psychiatric interview and full details were published in the paper (2). Finally he suggests that we did not find that lack of physical fitness predicted CFS. We did, no matter how we defined CFS (2). Sampson went on to develop an argument that graded exercise therapy (GET) is not an effective treatment for CFS in the absence of comorbid mood disorders. It is: the first published trial of GET excluded patients with comorbid mood disorders (3). The PACE trial, which is the largest ever trial of graded exercise therapy, compared to other rehabilitative interventions, for people with CFS will report next year (4). This will provide the most definitive test so far of both the efficacy and safety of this treatment. See also: IACSF/ME. 18 (4). Winter 2011. Sampson, Reply to White; and White, Response to Sampson

Cardiac and skeletal muscle defects in a mouse model of human Barth syndrome.	J Biol Chem. 2011 Jan 14;286(2):899-908. Epub 2010 Nov 9.	Barth syndrome is an X-linked genetic disorder caused by mutations in the tafazzin (taz) gene and characterized by dilated cardiomyopathy, exercise intolerance, chronic fatigue, delayed growth, and neutropenia. Tafazzin is a mitochondrial transacylase required for cardiolipin remodeling. Although tafazzin function has been studied in non-mammalian model organisms, mammalian genetic loss of function approaches have not been used. We examined the consequences of tafazzin knockdown on sarcomeric mitochondria and cardiac function in mice. Tafazzin knockdown resulted in a dramatic decrease of tetralinoleoyl cardiolipin in cardiac and skeletal muscles and accumulation of monolysocardiolipins and cardiolipin molecular species with aberrant acyl groups. Electron microscopy revealed pathological changes in mitochondria, myofibrils, and mitochondrion-associated membranes in skeletal and cardiac muscles. Echocardiography and magnetic resonance imaging revealed severe cardiac abnormalities, including left ventricular dilation, left ventricular mass reduction, and depression of fractional shortening and ejection fraction in tafazzin-deficient mice. Tafazzin knockdown mice provide the first mammalian model system for Barth syndrome in which the pathophysiological relationships between altered content of mitochondrial phospholipids, ultrastructural abnormalities, myocardial and mitochondrial dysfunction, and clinical outcome can be completely investigated.
Alberts B.	Editor-in-Chief, Science, American Association for the Advancement of Science, 1200 New York Avenue NW, Washington, DC 20005, USA.	Editorial Expression of Concern.	Science. 2011 Jun 2. [Epub ahead of print]	In the issue of 23 October 2009, Science published a study by Lombardi et al. purporting to show that a retrovirus called XMRV (xenotropic murine leukemia virus-related virus) was present in the blood of 67% of patients with chronic fatigue syndrome (CFS) compared with 3.7% of healthy controls. A number of studies published elsewhere have failed to replicate these findings. In conjunction with two new Reports that strongly support the growing view that the association between XMRV and CFS likely reflects contamination of laboratories and research reagents with the virus, Science is publishing an Editorial Expression of Concern about the Lombardi et al. Report.

Alberts B.		Editorial expression of concern.	Science. 2011 Jul 1;333(6038):35. Comment on Science. 2009 Oct 23;326(5952):585-9.

Science is fully retracting the report "Detection of an infectious retrovirus, XMRV, in blood cells of patients with chronic fatigue syndrome" (V. C. Lombardi et al., Science 326, 585 (2009); 10.1126/science.1179052)
Albright F, Light K, Light A, Bateman L, Cannon-Albright LA.	Pharmacotherapy Outcomes Research Center, Department of Pharmacotherapy, College of Pharmacy, University of Utah, USA. frederick.albright@pharm.utah.edu	Evidence for a heritable predisposition to Chronic Fatigue Syndrome.	BMC Neurol. 2011 May 27;11:62.	BACKGROUND: Chronic Fatigue Syndrome (CFS) came to attention in the 1980s, but initial investigations did not find organic causes. Now decades later, the etiology of CFS has yet to be understood, and the role of genetic predisposition in CFS remains controversial. Recent reports of CFS association with the retrovirus xenotropic murine leukemic virus-related virus (XMRV) or other murine leukemia related retroviruses (MLV) might also suggest underlying genetic implications within the host immune system. METHODS: We present analyses of familial clustering of CFS in a computerized genealogical resource linking multiple generations of genealogy data with medical diagnosis data of a large Utah health care system. We compare pair-wise relatedness among cases to expected relatedness in the Utah population, and we estimate risk for CFS for first, second, and third degree relatives of CFS cases. RESULTS: We observed significant excess relatedness of CFS cases compared to that expected in this population. Significant excess relatedness was observed for both close ($p < 0.001$) and distant relationships ($p = 0.010$). We also observed significant excess CFS relative risk among first (2.70, 95% CI: 1.56-4.66), second (2.34, 95% CI: 1.31-4.19), and third degree relatives (1.93, 95% CI: 1.21-3.07). CONCLUSIONS: These analyses provide strong support for a heritable contribution to predisposition to Chronic Fatigue Syndrome. A population of high-risk CFS pedigrees has been identified, the study of which may provide additional understanding.
Ali MA, Dale JK, Kozak CA, Goldbach-Mansky	Medical Virology Section, Laboratory of	Xenotropic murine leukemia virus-related virus is not	Virol J. 2011 Sep 24;8:450.	BACKGROUND: In 2009, xenotropic murine leukemia virus-related virus (XMRV) was reported in 67% of patients with chronic fatigue syndrome (CFS) compared to 4% of controls. Since then numerous reports failed to detect XMRV in other cohorts of CFS

R, Miller FW, Straus SE, Cohen JI.	Infectious Diseases, National Institute of Allergy and Infectious Diseases, National Institutes of Health, Bethesda, Maryland, USA.	associated with chronic fatigue syndrome in patients from different areas of the us in the 1990s.		patients, and some studies suggested that XMRV sequences in human samples might be due to contamination of these samples with mouse DNA. RESULTS: We determined the prevalence of XMRV in patients with CFS from similar areas in the United States as the original 2009 study, along with patients with chronic inflammatory disorders and healthy persons. Using quantitative PCR, we initially detected very low level signals for XMRV DNA in 15% of patients with CFS; however, the frequency of PCR positivity was no different between patients with CFS and controls. Repeated attempts to isolate PCR products from these reactions were unsuccessful. These findings were supported by our observations that PHA and IL-2 stimulation of peripheral blood mononuclear cells from patients with apparently low levels of XMRV, which induced virus replication in the 2009 report, resulted in the disappearance of the signal for XMRV DNA in the cells. Immunoprecipitation of XMRV-infected cell lysates using serum from patients from whom we initially detected low levels of XMRV DNA followed by immunoblotting with antibodies to XMRV gp70 protein failed to detect antibody in the patients, although one control had a weak level of reactivity. Diverse murine leukemia virus (MLV) sequences were obtained by nested PCR with a similar frequency in CFS patients and controls. Finally, we did not detect XMRV sequences in patients with several chronic inflammatory disorders including rheumatoid arthritis, Bechet's disease, and systemic lupus erythematosus. CONCLUSIONS: We found no definitive evidence for XMRV DNA sequences or antibody in our cohort of CFS patients, which like the original 2009 study, included patients from diverse regions of the United States. In addition, XMRV was not detected in a cohort of patients with chronic inflammatory disorders.
Alraek T, Lee MS, Choi TY, Cao H, Liu J.	National Research Center for Complementary and Alternative Medicine, University of Tromsø, Norway. terje.alrak@uit.no	Complementary and alternative medicine for patients with chronic fatigue syndrome: a systematic review.	BMC Complement Altern Med. 2011 Oct 7;11:87.	BACKGROUND: Throughout the world, patients with chronic diseases/illnesses use complementary and alternative medicines (CAM). The use of CAM is also substantial among patients with diseases/illnesses of unknown aetiology. Chronic fatigue syndrome (CFS), also termed myalgic encephalomyelitis (ME), is no exception. Hence, a systematic review of randomised controlled trials of CAM treatments in patients with CFS/ME was undertaken to summarise the existing evidence from RCTs of CAM treatments in this patient population. METHODS: Seventeen data sources were searched up to 13th August 2011. All randomised controlled trials (RCTs) of any type of CAM therapy used for treating CFS were included, with the exception of acupuncture and complex herbal medicines; studies were included regardless of blinding. Controlled clinical trials, uncontrolled observational studies, and case studies were excluded. RESULTS: A total of 26 RCTs, which included 3,273 participants, met our inclusion criteria. The CAM therapy from the RCTs included the following: mind-body medicine, distant healing, massage, tuina and tai chi, homeopathy, ginseng, and dietary supplementation. Studies of qigong, massage and tuina were demonstrated to have positive effects, whereas distant healing failed to do so. Compared with placebo, homeopathy also had insufficient evidence of symptom improvement in CFS.

				Seventeen studies tested supplements for CFS. Most of the supplements failed to show beneficial effects for CFS, with the exception of NADH and magnesium. CONCLUSIONS: The results of our systematic review provide limited evidence for the effectiveness of CAM therapy in relieving symptoms of CFS. However, we are not able to draw firm conclusions concerning CAM therapy for CFS due to the limited number of RCTs for each therapy, the small sample size of each study and the high risk of bias in these trials. Further rigorous RCTs that focus on promising CAM therapies are warranted. © 2011 Alraek et al; licensee BioMed Central Ltd.
Anderson VR, Jason LA, Hlavaty LE, Porter N, Cudia J.	Department of Psychology, Michigan State University, East Lansing, USA.	A review and meta-synthesis of qualitative studies on Myalgic Encephalomyelitis/chronic fatigue syndrome.	Patient Educ Couns. 2012 Feb;86(2):147-55. Epub 2011 May 14.	OBJECTIVE: To review and synthesize findings across qualitative studies on Myalgic Encephalomyelitis/chronic fatigue syndrome (ME/CFS). METHODS: Articles were systematically reviewed and analyzed within a meta-analytic framework. Analyses included a multi-perspective examination of ME/CFS, as well as a comparative analysis of ME/CFS versus other chronic conditions. RESULTS: Thirty-four qualitative studies on ME/CFS were included. Findings include three substantive thematic areas that focus on: (1) experiences of people with ME/CFS, (2) experiences of physicians, and (3) themes that intersect both of these groups. For patients, illness development influenced identity, reductions in functioning, and coping. Physician-specific themes described lack of awareness about ME/CFS and recommended improvement in educational resources. Intersecting themes expressed issues with diagnosis creating tensions and fueling the stigmatization of ME/CFS. CONCLUSIONS: Findings indicate multilayered, context-specific experiences and ways in which both people with ME/CFS, as well as those involved in their lives (e.g., family or the medical community), interpret this illness. Future qualitative studies should recognize the various facets of the ME/CFS experience, the network members of people with ME/CFS, and the sociocultural environment through which the illness is understood. PRACTICE IMPLICATIONS: Health care professionals can gain unique insight from patient experiences, allowing for more accurate diagnoses and treatment recommendations. Antiel RM, Caudill JS, Burkhardt BE, Brands CK, Fischer PR.	Department of Pediatric & Adolescent Medicine, Division of General Pediatric and Adolescent Medicine, Mayo Clinic, Rochester, MN 55905, USA. antiel.ryan@mayo.edu	Iron insufficiency and hypovitaminosis D in adolescents with chronic fatigue and orthostatic intolerance.	South Med J. 2011 Aug;104(8):609-11.	OBJECTIVES: More than 10% of adolescents suffer from severe fatigue and/or orthostatic intolerance. Adult studies show correlations between iron insufficiency and fatigue as well as between hypovitaminosis D and non-specific pain. We sought to determine whether there were correlations between nutritional factors (iron status, and serum vitamin D levels) and chronic ill health. METHODS: We reviewed records of 188 adolescents with symptoms of fatigue and/or orthostatic intolerance and who underwent autonomic reflex screening. RESULTS: Of the 188 patients, 130 patients (69%) had excessive postural tachycardia (PT) with a heart rate (HR) change of ≥30 bpm. 62 patients (47%, n = 131) had iron insufficiency with low iron stores, and 29 patients (22%, n = 131) were iron deficient. HR change did not correlate to ferritin level (P = 0.15). 21 patients (22%, n = 95) had hypovitaminosis D (25-hydroxyvitamin D ≤20 ng/mL). There was a significant association with hypovitaminosis D and

				orthostatic intolerance (P = 0.024). CONCLUSION: In patients presenting with chronic fatigue and/or orthostatic intolerance, low ferritin levels and hypovitaminosis D are common, especially in patients with PT.
Anty R, Marjoux S, Bekri S, DeGalleani L, Dainese R, Gelsi E, Cherikh F, Tran A, Piche T.	INSERM U895, Centre Hospitalier Universitaire of Nice-Digestive Center, Nice Cedex 3, France.	Plasma carnitine is associated with fatigue in chronic hepatitis C but not in the irritable bowel syndrome.	Aliment Pharmacol Ther. 2011 Apr;33(8):961-8. doi: 10.1111/j.1365-2036.2011.04608.x. Epub 2011 Mar 2. Comment in Aliment Pharmacol Ther. 2011 Jun;33(11):1252-3. Nat Rev Gastroenterol Hepatol. 2011 May;8(5):246.	BACKGROUND: Fatigue is an important determinant of altered quality of life in patients affected by chronic hepatitis C or the irritable bowel syndrome (IBS). AIM: In this study, we aimed at determining the contributory role of plasma levels of leptin and carnitine on fatigue in chronic hepatitis C and IBS. METHODS: We enrolled 81 patients with chronic hepatitis C, 42 with IBS and 44 healthy subjects. Fatigue was evaluated using the Fatigue Impact Scale questionnaire. Body composition was assessed through impedance analysis. Plasma carnitine and leptin were measured. RESULTS: Fatigue scores were significantly more elevated in patients with chronic hepatitis C and IBS than in healthy subjects. Patients with chronic hepatitis C but not IBS, had significant lower plasma levels of total and free carnitine adjusted for fat mass compared with healthy subjects. In patients with chronic hepatitis C and not with IBS, fatigue scores were negatively correlated with plasma levels of carnitine. Levels of free carnitine were significantly and independently associated with the severity of fatigue in patients with chronic hepatitis C [OR=2.019, P=0.02, CI 95% (1.01-1.23)]. CONCLUSIONS: In patients with chronic hepatitis C, the severity of fatigue is associated with a low level of carnitine, suggesting that an oral supplementation may be effective to relieve fatigue in chronic hepatitis C. The underlying mechanism of fatigue in IBS does not seem to involve carnitine. © 2011 Blackwell Publishing Ltd.
Arnett SV, Alleva LM, Korossy-Horwood R, Clark IA.	Research School of Biology, Australian National University, Australia. simon.arnett@anu.edu.au	Chronic fatigue syndrome--a neuroimmunological model.	Med Hypotheses. 2011 Jul;77(1):77-83. Epub 2011 Apr 6.	The aetiological and pathophysiological basis of chronic fatigue syndrome (CFS) remains a controversial field of inquiry in the research community. While CFS and similar disease conditions such as fibromyalgia (FM) and post-infectious encephalopathy have been the focus of intense scrutiny for the past 20 years, results of research were often contradictory and a cohesive pathological model has remained elusive. However, recent developments in understanding the unique immunophysiology of the brain may provide important clues for the development of a truly comprehensive explanation of the pathology of CFS. We argue that CFS pathogenesis lies in the influence of peripheral inflammatory events on the brain and the unique immunophysiology of the central nervous system. There is also evidence that CFS patients have a relative immunodeficiency that predisposes to poor early control of infection that leads to chronic inflammatory responses to infectious insults. The neurological and endocrine changes have been described in CFS patients support the view that CFS has an inflammatory pathogenesis when considered as a whole. An inflammatory model of disease also provides an explanation for the marked female sex bias associated with CFS. This review therefore posits the hypothesis that CFS as a disease of long-term inflammatory processes of the brain. We will also provide an investigative framework that could be used to justify the use of anti-TNF biological

				agents as a reliable and effective treatment approach to CFS, a syndrome that to date remains frustratingly difficult for both patients and health care professionals to manage. Copyright © 2011 Elsevier Ltd. All rights reserved.
Arredondo M, Hackett J, de Bethencourt FR, Treviño A, Escudero D, Collado A, Qiu X, Swanson P, Soriano V, de Mendoza C.	Hospital Carlos III, Infectious Diseases, Madrid, Spain; arredondo.miguel@gmail.com.	Prevalence of XMRV infection in different risk populations in Spain.	AIDS Res Hum Retroviruses. 2011 Dec 29. [Epub ahead of print]	Human infection with the xenotropic murine leukemia virus-related virus (XMRV) has been associated controversially with prostate cancer and chronic fatigue syndrome. Information is lacking about the mechanisms of transmission and potential risk groups for XMRV infection. Plasma and peripheral blood mononuclear cells (PBMCs) from individuals with retroviral infections, chronic viral hepatitis, autoimmune diseases, prostate cancer, chronic fatigue syndrome and blood donors were tested for XMRV markers. Antibodies to XMRV proteins p15E and gp70 were examined using research assays. DNA extracted from PBMCs was tested for the presence of XMRV gag and env sequences. A total of 1103 specimens belonging to individuals with chronic fatigue syndrome and/or fibromyalgia (437), prostate cancer (69), HIV-1 (149), HTLV-1/2 (31), chronic hepatitis B (81), chronic hepatitis C (72), autoimmune diseases (18) and blood donors (246) were examined. Overall, 3 samples (0.3%) were p15E seroreactive (2 HTLV-1 and 1 HCV patient). Another 15 (1.4%) were gp70 seroreactive (6 chronic fatigue syndrome-fibromyalgia, 4 blood donors, 2 HIV-1, 1 prostate cancer, 1 HBV and 1 HCV). Four specimens were initially positive for XMRV gag sequences, but none could be confirmed by repeated testing. In summary, no evidence of XMRV infection was found in populations with retroviral and viral hepatitis infections in Spain. Likewise, XMRV was not recognized in patients with autoimmune diseases, chronic fatigue syndrome-fibromyalgia, prostate cancer or healthy blood donors.

Atzeni F, Cazzola M, Benucci M, Di Franco M, Salaffi F, Sarzi-Puttini P.	Rheumatology Unit, L. Sacco University Hospital, Milan, Italy. atzenifabiola@hotmail.com	Chronic widespread pain in the spectrum of rheumatological diseases.	Best Pract Res Clin Rheumatol. 2011 Apr;25(2):165-71.	Fibromyalgia (FM) is a rheumatic disease characterised by musculoskeletal pain, chronic diffuse tension and/or stiffness in joints and muscles, fatigue, sleep and emotional disturbances and pressure pain sensitivity in at least 11 of 18 tender points. There are currently no instrumental tests or specific diagnostic markers, and the characteristic symptoms of the disease overlap those of many other conditions classified in a different manner. FM is often associated with other diseases that act as confounding and aggravating factors, including primary Sjögren's syndrome (pSS), systemic lupus erythematosus (SLE) and rheumatoid arthritis (RA). It has been

				reported to coexist in 25% of patients with RA, 30% of patients with SLE and 50% of patients with pSS. Its clinical diagnosis is not easy because FM-like symptoms are frequent, and its differential diagnosis with other causes of chronic diffuse pain is difficult. This is even more true in the case of patients who are positive for antinuclear antibodies (ANAs) because, although sensitive, ANA positivity is not specific for SLE or connective tissue diseases, and can also be found in 10-15% of FM patients. Furthermore, composite indices such as the disease activity score (DAS)-28, which are widely used in everyday clinical practice and clinical trials, may be insufficient to evaluate real inflammatory activity in patients with RA associated with chronic pain syndromes such as FM, and can lead to an overestimate of disease activity in RA. The presence of diffuse pain in autoimmune rheumatic diseases compromises the quality of life of the patients, although overall mortality is not increased. A misdiagnosis harms the patients and the community. Rheumatologists should be able to recognise and distinguish primary and secondary FM, and need new guidelines and instruments to avoid making mistakes.

Bakker RJ, van de Putte EM, Kuis W, Sinnema G.	Department of Pediatrics, Antonius Ziekenhuis, Sneek, The Netherlands. robhelbz@telfort.nl	Effects of an educational video film in fatigued children and adolescents: a randomised controlled trial.	Arch Dis Child. 2011 May;96(5):457-60. Epub 2010 Sep 22.	BACKGROUND: In many cases standard management for chronic fatigue syndrome (CFS) in children and adolescents is ineffective. OBJECTIVE: To evaluate the efficacy of a video film intervention in preventing the development of persistent fatigue and significant school absence in fatigued children and adolescents. DESIGN: Randomised controlled trial. PARTICIPANTS: 91 patients with fatigue; 50 were randomly assigned to receive the intervention (video film plus usual care) and 41 to usual care only. INTERVENTION: A video film on CFS and coping behaviour. MAIN OUTCOME MEASURES: Self-reported fatigue severity, physical activity, motivation, concentration and school absence. RESULTS: 79 patients had complete data at 12 months (42 in the video film and 37 in the usual care group). Mean fatigue severity and school absenteeism scores did not differ significantly, but in the intervention group the score for reduced motivation was higher (difference 2.9 (CI 0.1 to 5.7), p=0.038). 18% more patients in the intervention compared to the usual care group also had persistent fatigue with significant school absence. The odds of developing persistent fatigue and of missing >50% of school classes was 3.3 times higher in the intervention than in the usual care group (OR 3.3 (CI 1.0 to 11.3), p=0.046). CONCLUSION: This particular video

				film intervention plus usual care in children and adolescents with unexplained fatigue did not prevent an unfavourable outcome and possibly had an adverse effect in that it reduced motivation and increased the incidence of persistent fatigue with significant school absence. The use of this particular film is not recommended.
Balada E, Castro-Marrero J, Felip L, Vilardell-Tarrés M, Ordi-Ros J.	Research Unit in Systemic Autoimmune Diseases, Vall d'Hebron Research Institute, Vall d'Hebron Hospital, Autonomous University of Barcelona, Barcelona, Spain. ebalada@ir.vhebron.net	Xenotropic murine leukemia virus-related virus (XMRV) in patients with systemic lupus erythematosus.	J Clin Immunol. 2011 Aug;31(4):584-7. Epub 2011 Apr 21.	OBJECTIVES: Xenotropic murine leukemia virus-related virus (XMRV)-specific proviral DNA has been recently detected in peripheral blood mononuclear cells of patients with chronic fatigue syndrome. Since chronic fatigue is commonly reported in patients with systemic lupus erythematosus (SLE) we aimed at testing the presence of this virus in these patients. METHODS: Ninety-five SLE patients, 45 of whom had a Fatigue Severity Scale score higher than 3, were included. Molecular analyses were performed by PCR from DNA obtained from the whole blood of both SLE patients and 50 healthy controls. RESULTS: None of the 145 samples analyzed yielded the specific XMRV PCR product. CONCLUSIONS: We conclude that XMRV is not detected in blood neither from SLE patients nor from healthy controls. It leads to infer that other environmental and biological triggers (different from XMRV) may account for the increased levels of fatigue over the course of SLE.
Ballantyne AJ, Rogers WA.	Department of Primary Health Care and General Practice, School of Medicine and Health Sciences, Otago University Wellington, Wellington, New Zealand. angela.ballantyne@otago.ac.nz	Sex bias in studies selected for clinical guidelines.	J Womens Health (Larchmt). 2011 Sep;20(9):1297-306. Epub 2011 Aug 8.	OBJECTIVE: To determine the proportions of female participants in research studies selected to inform the development of national clinical guidelines and to assess these against the proportions of women affected by the conditions. METHODS: We assessed 392 published articles, involving a total of 5.2 million participants, cited as references in five influential clinical guidelines addressing the use of antiarrhythmics, chronic fatigue, depression, diabetes, and colorectal cancer. For each article, we extracted the number of female participants to determine any discrepancies in the sex of participants and if the proportion of female participants as research subjects reflected the sex distribution of patients affected by the condition. RESULTS: The overall and median percentages (per study) of females per guideline were: use of antiarrhythmics (35%, median 38%), chronic fatigue (70%, median 73%), colorectal cancer (67%, median 46%), depression (66%, median 66%), and diabetes (63%, median 50%). The baseline prevalence rates used for comparison purposes were (percentage female): antiarrhythmics (60% of patients 75(+) years); chronic fatigue (66%), colorectal cancer (46%), depression (66%), and diabetes (46%). CONCLUSIONS: The colorectal cancer, depression, and chronic fatigue guidelines were based on research populations that accurately reflected the sex distribution of the condition in the general population. Women were slightly overrepresented in the research studies supporting the diabetes guidelines and were significantly underrepresented in the research studies supporting the guidelines on the use of antiarrhythmics. Guideline developers should be aware of and comment on the potential impact of sex. Where

				the evidence base is lacking, guideline developers should highlight this and, where necessary, limit their specific conclusions to populations on whom the research was performed.
Bansal AS, Bradley AS, Bishop KN, Kiani-Alikhan S, Ford B.	Dept. of Immunology, Epsom and St. Helier University Hospitals NHS Trust, Carshalton, Surrey, SM5 1AA and Chronic Illness Research Team, Stratford Campus, University of East London, London E15 4LZ, UK. Amolak.Bansal@ESTH.nhs.uk	Chronic fatigue syndrome, the immune system and viral infection.	Brain Behav Immun. 2012 Jan;26(1):24-31. Epub 2011 Jul 2.	The chronic fatigue syndrome (CFS), as defined by recent criteria, is a heterogeneous disorder with a common set of symptoms that often either follows a viral infection or a period of stress. Despite many years of intense investigation there is little consensus on the presence, nature and degree of immune dysfunction in this condition. However, slightly increased parameters of inflammation and pro-inflammatory cytokines such as interleukin (IL) 1, IL6 and tumour necrosis factor (TNF) α are likely present. Additionally, impaired natural killer cell function appears evident. Alterations in T cell numbers have been described by some and not others. While the prevalence of positive serology for the common herpes viruses appears no different from healthy controls, there is some evidence of viral persistence and inadequate containment of viral replication. The ability of certain herpes viruses to impair the development of T cell memory may explain this viral persistence and the continuation of symptoms. New therapies based on this understanding are more likely to produce benefit than current methods.
Barnden LR, Crouch B, Kwiatek R, Burnet R, Mernone A, Chryssidis S, Scroop G, Del Fante P.	Department of Nuclear Medicine, The Queen Elizabeth Hospital, Adelaide, South Australia. Leighton.Barnden@health.sa.gov.au	A brain MRI study of chronic fatigue syndrome: evidence of brainstem dysfunction and altered homeostasis.	NMR Biomed. 2011 Dec;24(10):1302-12. doi: 10.1002/nbm.1692. Epub 2011 May 11.	To explore brain involvement in chronic fatigue syndrome (CFS), the statistical parametric mapping of brain MR images has been extended to voxel-based regressions against clinical scores. Using SPM5 we performed voxel-based morphometry (VBM) and analysed T(1) - and T(2) -weighted spin-echo MR signal levels in 25 CFS subjects and 25 normal controls (NC). Clinical scores included CFS fatigue duration, a score based on the 10 most common CFS symptoms, the Bell score, the hospital anxiety and depression scale (HADS) anxiety and depression, and hemodynamic parameters from 24-h blood pressure monitoring. We also performed group × hemodynamic score interaction regressions to detect locations where MR regressions were opposite for CFS and NC, thereby indicating abnormality in the CFS group. In the midbrain, white matter volume was observed to decrease with increasing fatigue duration. For T(1) -weighted MR and white matter volume, group × hemodynamic score interactions were detected in the brainstem [strongest in midbrain grey matter (GM)], deep prefrontal white matter (WM), the caudal basal pons and hypothalamus. A strong correlation in CFS between brainstem GM volume and pulse pressure suggested impaired cerebrovascular autoregulation. It can be argued that at least some of these changes could arise from astrocyte dysfunction. These results are consistent with an insult to the midbrain at fatigue onset that affects multiple feedback control loops to suppress cerebral motor and cognitive activity and disrupt local CNS homeostasis, including resetting of some elements of the autonomic nervous system (ANS).

Barregard L, Rekić D, Horvat M, Elmberg L, Lundh T, Zachrisson O.	Department of Occupational and Environmental Medicine, Sahlgrenska Academy, University of Gothenburg, SE 405 30 Gothenburg, Sweden. lars.barregard@amm.gu.se	Toxicokinetics of mercury after long-term repeated exposure to thimerosal-containing vaccine.	Toxicol Sci. 2011 Apr;120(2):499-506. Epub 2011 Jan 20.	The preservative thimerosal contains ethyl mercury (EtHg). Concerns over possible toxicity have re-emerged recently due to its presence in (swine and other) flu vaccines. We examined the potential accumulation of mercury in adults given repeated injections of a thimerosal-preserved vaccine for many years. Fifteen female patients were recruited from an outpatient clinic running a clinical trial with repeated injections (1 ml every 3-4 weeks) of a staphylococcus toxoid vaccine containing 0.01% thimerosal to treat chronic fatigue syndrome. Fifteen untreated female patients with the same diagnoses served as controls. Blood samples were taken before injecting the vaccine, 1 day later, about 2 weeks later, and just before the next injection. In the 15 controls, samples were taken twice. Blood was analyzed for total mercury and EtHg. The toxicokinetics were assessed for each patient separately as well as with a population-based pharmacokinetic model. Total mercury in blood increased on Day 1 in all treated patients (median: 0.33, range: 0.17-1.3 µg/l), as did EtHg (median: 0.14 µg/l, range: 0.06-0.43 µg/l). After a few weeks, levels were back to normal and similar to those in controls. Levels of methyl mercury (MeHg; from fish consumption) were much higher than those of EtHg. After exclusion of an outlier, the mean half-life in a population-based model was 5.6 (95% CI: 4.8-6.3) days. The results indicate that mercury from thimerosal is not accumulated in blood in adults. This is in accordance with short half-lives and rapid metabolism of EtHg to inorganic mercury.
Barros SM, Carvalho JF.	Rheumatology Division, Hospital Naval Marcílio Dias, Rio de Janeiro, Brazil.	Shoenfeld's syndrome after pandemic influenza A/H1N1 vaccination.	Acta Reumatol Port. 2011 Jan-Mar;36(1):65-8.	Recently, reports have suggested grouping different autoimmune conditions that are triggered by external stimuli as a single syndrome called autoimmune/inflammatory syndrome induced by adjuvants (ASIA). This syndrome is characterized by the appearance of myalgia, myositis, muscle weakness, arthralgia, arthritis, chronic fatigue, sleep disturbances, cognitive impairment and memory loss, and the possible emergence of a demyelinating autoimmune disease caused by systemic exposure after vaccines and adjuvants. In the current study, the authors reported the first Brazilian case of a woman who developed ASIA, which was characterized by arthralgia, changes in inflammatory markers, and chronic fatigue, after the pandemic anti-influenza A/H1N1 vaccine without causing any other rheumatic disease, and it had a positive outcome.
Bhui KS, Dinos S, Ashby D, Nazroo J, Wessely S, White PD.	Centre for Psychiatry, Wolson Institute of Preventive Medicine, Barts and the London School of Medicine and Dentistry, Queen Mary University	Chronic fatigue syndrome in an ethnically diverse population: the influence of psychosocial adversity and physical inactivity.	BMC Med. 2011 Mar 21;9:26.	BACKGROUND: Chronic fatigue syndrome (CFS) is a complex multifactorial disorder. This paper reports the prevalence of chronic fatigue (CF) and CFS in an ethnically diverse population sample and tests whether prevalence varies by social adversity, social support, physical inactivity, anxiety and depression. METHODS: Analysis of survey data linking the Health Survey for England (1998 and 1999) and the Ethnic Minority Psychiatric Illness Rates in the Community (EMPIRIC) study undertaken in 2000. The study population comprised a national population sample of 4,281 people ages 16 to 74 years. CF and CFS were operationally defined on the basis of an interview in the EMPIRIC study, alongside questions about psychosocial risk factors. Previous illnesses were reported in the Health Survey for England during 1998 and

	of London, London, UK. k.s.bhui@qmul.ac.uk			1999, as was physical inactivity. RESULTS: All ethnic minority groups had a higher prevalence of CFS than the White group. The lowest prevalence was 0.8% in the White group, and it was highest at 3.5% in the Pakistani group (odds ratio (OR), 4.1; 95% confidence interval (95% CI), 1.6 to 10.4). Anxiety (OR, 1.8; 95% CI, 1.4 to 2.2), depression (OR, 1.4; 95% CI, 1.1 to 1.8), physical inactivity (OR, 2.0; 95% CI, 1.1 to 3.8), social strain (OR, 1.24; 95% CI, 1.04 to 1.48) and negative aspects of social support (OR, 2.12; 95% CI, 1.4 to 3.3) were independent risk factors for CFS in the overall sample. Together these risk factors explained ethnic differences in the prevalence of CFS, but no single risk factor could explain a higher prevalence in all ethnic groups. CONCLUSIONS: The prevalence of CFS, but not CF, varies by ethnic group. Anxiety, depression, physical inactivity, social strain and negative aspects of social support together accounted for prevalence differences of CFS in the overall sample.
Biswal B, Kunwar P, Natelson BH.	Department of Radiology, UMDNJ-New Jersey Medical School, Newark NJ, USA.	Cerebral blood flow is reduced in chronic fatigue syndrome as assessed by arterial spin labeling.	J Neurol Sci. 2011 Feb 15;301(1-2):9-11. Epub 2010 Dec 16.	BACKGROUND: Chronic fatigue syndrome is diagnosed by a set of clinical criteria and therefore is probably heterogeneous. Earlier reports tested the hypothesis that the syndrome had a neurological substrate by doing studies of cerebral blood flow (CBF) but with discrepant results. One possible reason for the discrepancy was that relative CBF was assessed. We found reduced CBF in an earlier study of absolute CBF using xenon-CT. The purpose of this study was to use a second method of assessing CBF and to look within the study group for heterogeneity of responses. METHOD: Eleven CFS patients and 10 age matched healthy controls underwent neuroimaging using arterial spin labeling to determine their regional and global absolute CBF. A template was constructed based on the control data, and individual patient montages were compared on a case by case basis to determine if differences in regions of interest occurred. RESULTS: The patients as a group had significantly lower global CBF than the controls. The reduction in CBF occurred across nearly every region assessed. Nine of the 11 patients showed these reductions compared to the average control data, while two patients showed actual increases relative to the controls. CONCLUSION: The data extend our earlier observation that CFS patients as a group have broad decreases in CBF compared to healthy controls. However, as expected, the effect was not homogeneous in that 2 of the 11 patients studied showed actual increases in CBF relative to controls. Copyright © 2010 Elsevier B.V. All rights reserved.

[Epub ahead of print]	relational problems and may also be associated with the clinical presentation of chronic fatigue syndrome (CFS) symptoms. The objective of this study was (1) to determine whether CFS patients and their partners have similar perceptions of their dyadic adjustment and (2) to evaluate whether the influence of dyadic satisfaction in women with CFS, as well as common psychological parameters such as anxiety, may correlate with physiological responses at rest and/or when performing very low intensity exercise. Forty females with CFS and their partners completed the Dyadic Adjustment Scale, the State-Trait Anxiety Inventory, and the Hospital Anxiety and Depression scale. The cardiovascular adaptation of patients was evaluated during resting conditions and on a precalibrated cycle ergometer while performing very low intensity exercise. Patients and partners had similar perceptions of their marital relationship. Both at rest and during very low workload, various physiological parameters in the patient group showed statistical correlations with certain psychological parameters. Several psychological variables, such as anxiety and dyadic adjustment, were associated with the cardioventilatory response monitored at rest and during very low intensity exercise. Further studies are needed to determine the nature of this association.

Section of Clinical Microbiology, Department of Medical Sciences, Uppsala University, 751 05 Uppsala, Sweden.	Phylogeny-directed search for murine leukemia virus-like retroviruses in vertebrate genomes and in patients suffering from myalgic encephalomyelitis/chronic fatigue syndrome and prostate cancer.	Adv Virol. 2011;2011:341294. Epub 2011 Sep 4.	Gammaretrovirus-like sequences occur in most vertebrate genomes. Murine Leukemia Virus (MLV) like retroviruses (MLLVs) are a subset, which may be pathogenic and spread cross-species. Retroviruses highly similar to MLLVs (xenotropic murine retrovirus related virus (XMRV) and Human Mouse retrovirus-like RetroViruses (HMRVs)) reported from patients suffering from prostate cancer (PC) and myalgic encephalomyelitis/chronic fatigue syndrome (ME/CFS) raise the possibility that also humans have been infected. Structurally intact, potentially infectious MLLVs occur in the genomes of some mammals, especially mouse. Mouse MLLVs contain three major groups. One, MERV G3, contained MLVs and XMRV/HMRV. Its presence in mouse DNA, and the abundance of xenotropic MLVs in biologicals, is a source of false positivity. Theoretically, XMRV/HMRV could be one of several MLLV transspecies infections. MLLV pathobiology and diversity indicate optimal strategies for investigating XMRV/HMRV in humans and raise ethical concerns. The alternatives that XMRV/HMRV may give a hard-to-detect "stealth"

				infection, or that XMRV/HMRV never reached humans, have to be considered.
Boneva RS, Maloney EM, Lin JM, Jones JF, Wieser F, Nater UM, Heim CM, Reeves WC.	Centers for Disease Control and Prevention, Atlanta, GA 30333, USA. rboneva@cdc.gov	Gynecological history in chronic fatigue syndrome: a population-based case-control study.	J Womens Health (Larchmt). 2011 Jan;20(1):21-8. Epub 2010 Nov 20.	BACKGROUND: Chronic fatigue syndrome (CFS) affects disproportionately more women than men, and the condition is more common at perimenopause. We examined gynecological history events as risk factors for CFS. METHODS: In a case-control study from a randomly selected population sample from Wichita, Kansas, 36 women with CFS and 48 nonfatigued controls, of similar age, race, and body mass index (BMI), answered a structured gynecological history questionnaire. RESULTS: CFS cases and controls had the same mean age (51 years) and age at menarche (12 years). Overall, a greater proportion of women with CFS than controls reported pelvic pain unrelated to menstruation (22.2% vs. 1.7%, p = 0.004), endometriosis (36.1% vs. 16.7, %, p = 0.046), and periods of amenorrhea (53.9 % vs. 46.2%, p = 0.06). Compared to controls, women in the CFS group had a higher mean number of pregnancies (2.8 vs 2.0, p = 0.05) and gynecological surgeries (1.8 vs. 1.1, p = 0.05). Similar proportions of the CFS (69.4%) and control (72.9%) groups were menopausal. Although menopausal women in the CFS and control groups had similar mean age (55.5 and 55.8, respectively), menopause occurred about 4.4 years earlier in the CFS group (41.7 years vs. 46.1 years, respectively, p = 0.11). Among menopausal women, 76% of the CFS group reported hysterectomy vs. 54.6% of controls (p = 0.09), and 56% of women with CFS reported oophorectomy vs. 34.3% of controls (p = 0.11). CONCLUSIONS: The higher prevalence of gynecological conditions and gynecological surgeries in women with CFS highlights the importance of evaluating gynecological health in these patients and the need for more research to clarify the chronologic and the pathophysiological relationships between these conditions and CFS.

Braz Ade S, de Paula AP, Diniz Mde F, de Almeida RN.	Universidade Federal da Paraiba, UFPB, Brazil. alessabraz@gmail.com	Non-pharmacological therapy and complementary and alternative medicine in fibromyalgia. [Article in English, Portuguese]	Rev Bras Reumatol. 2011 Jun;51(3):269-82.	Fibromyalgia is a chronic painful syndrome that affects up to 5% of the world population. It is associated with sleep and mood disorders, fatigue, and functional disability. Its pathogenesis involves a disorder of the central modulation of pain, impairment of the descending inhibitory system, and hyperactivity of substance P. Because of the extensive symptomatology of patients with fibromyalgia and its multifactorial pathogenesis, its ideal treatment requires a multidisciplinary approach including the association of pharmacological and non-pharmacological therapies. The pharmacological therapy currently recommended for the syndrome includes antidepressants, calcium-channel modulators, muscle relaxants, and analgesics. In most cases, the non-pharmacological treatment consists of patient education, supervised aerobic physical activity, and cognitive-behavioral therapy. However, many patients do not respond satisfactorily, or have side effects associated with the long-

				term use of drugs, in addition to reporting difficulties in adhering to a therapy based on exercises and physical medicine. Thus, physicians and patients are increasingly interested in an alternative and complementary therapy for fibromyalgia. This review approaches the different therapeutic modalities used in fibromyalgia, emphasizing the evidence of non-pharmacological therapy and use of alternative and complementary medicine for these patients.
Brenu EW, van Driel ML, Staines DR, Ashton KJ, Ramos SB, Keane J, Klimas NG, Marshall-Gradisnik SM.	Population Health and Neuroimmunology Unit, Faculty of Health Science and Medicine, Bond University, Robina, Queensland, Australia.	Immunological abnormalities as potential biomarkers in Chronic Fatigue Syndrome/Myalgic Encephalomyelitis.	J Transl Med. 2011 May 28;9:81.	BACKGROUND: Chronic Fatigue Syndrome/Myalgic Encephalomyelitis (CFS/ME) is characterised by severe prolonged fatigue, and decreases in cognition and other physiological functions, resulting in severe loss of quality of life, difficult clinical management and high costs to the health care system. To date there is no proven pathomechanism to satisfactorily explain this disorder. Studies have identified abnormalities in immune function but these data are inconsistent. We investigated the profile of markers of immune function (including novel markers) in CFS/ME patients. METHODS: We included 95 CFS/ME patients and 50 healthy controls. All participants were assessed on natural killer (NK) and CD8(+) T cell cytotoxic activities, Th1 and Th2 cytokine profile of CD4(+) T cells, expression of vasoactive intestinal peptide receptor 2 (VPACR2), levels of NK phenotypes (CD56(bright) and CD56(dim)) and regulatory T cells expressing FoxP3 transcription factor. RESULTS: Compared to healthy individuals, CFS/ME patients displayed significant increases in IL-10, IFN-γ, TNF-α, CD4(+)CD25(+) T cells, FoxP3 and VPACR2 expression. Cytotoxic activity of NK and CD8(+) T cells and NK phenotypes, in particular the CD56(bright) NK cells were significantly decreased in CFS/ME patients. Additionally granzyme A and granzyme K expression were reduced while expression levels of perforin were significantly increased in the CFS/ME population relative to the control population. These data suggest significant dysregulation of the immune system in CFS/ME patients. CONCLUSIONS: Our study found immunological abnormalities which may serve as biomarkers in CFS/ME patients with potential for an application as a diagnostic tool.
Brkić S, Tomić S, Ruzić M, Marić D.	Hospital for Infectious Diseases, Clinical Centre of Vojvodina, Hajduk Veljkova 1-9, 21000 Novi Sad, Serbia. tomkis@eunet.rs	Chronic fatigue syndrome.	Srp Arh Celok Lek. 2011 Mar-Apr;139(3-4):256-61.	Chronic fatigue syndrome (CFS) is defined by a profound, debilitating fatigue, lasting for at least 6 months and resulting in a substantial reduction of occupational, personal, social and educational status. CFS is a relatively poorly recognized clinical entity, although everyday experience shows that there are many patients with CFS symptoms. The incidence and prevalence of CFS remain unknown in most countries; however, the working population is most affected with predominantly female patients in generative period. Although, CFS was first mentioned four centuries ago, mysterious aethiopathogensis of CFS still intrigues scientists as hundreds of studies are still published every year on the subject. About 80 different aetiological CFS factors are mentioned, which can be classified into five basic groups: genetics, immunology, infectious diseases, endocrinology and neuropsychiatry-psychology. Even today the condition is passed established based on the diagnosis by exclusion of organic and psychiatric disorders, which demands a multidisciplinary approach. As the

				syndrome is often misdiagnosed and mistreated, self-medication is not uncommon in CFS patients'. In addition, such patients usually suffer for years tolerating severe fatigue. Thus, at the moment there are three priorities regarding CFS; understanding pathogenesis, development of diagnostic tests and creating efficient treatment program.
Brooks J, Lycett-Lambert K, Caminiti K, Merks H, McMillan R, Sandstrom P.	National HIV & Retrovirology Laboratories, National Microbiology Laboratory, Public Health Agency of Canada, Ottawa, Canada. james.brooks@phac-aspc.gc.ca	No evidence of cross-species transmission of mouse retroviruses to animal workers exposed to mice.	Transfusion. 2012 Feb;52(2):317-25. doi: 10.1111/j.1537-2995.2011.03463.x. Epub 2011 Dec 30.	BACKGROUND: Although recent data have brought into question the association between xenotropic murine leukemia virus-related virus (XMRV) and chronic fatigue syndrome, one group has reported evidence of human infection with distinct polytropic murine leukemia viruses (MLVs). Occult retroviral infection among humans poses a significant public health risk should it be introduced into the blood supply. To explore the possibility of cross-species transmission of MLVs to humans, we sought molecular and serologic evidence of XRMV/MLV infection among a cohort of animal workers highly exposed to mice. STUDY DESIGN AND METHODS: Before the commencement of the study, the laboratory and equipment were demonstrated to be free of XMRV/MLV DNA sequences. DNA extracted from 43 animal workers was tested using nested polymerase chain reaction (PCR) with published primer sets, targeting regions of XMRV and MLV gag. Negative controls were assayed in a 1:1 ratio with specimens. Serum specimens were tested using a validated immunoblot assay containing cross-reactive XMRV antigens. RESULTS: Initial molecular assays demonstrated that the physical space and laboratory equipment were free of MLV and XMRV DNA sequences. Nested PCR assays using multiple primer sets successfully amplified XMRV and MLV sequences from positive controls with high sensitivity. A single, nonreproducible, false-positive result from one specimen was shown to be the result of subsequent contamination. Immunoblotting of all subjects' sera failed to demonstrate any evidence of seroreactivity to XMRV proteins. CONCLUSIONS: There was no evidence of human infection with XMRV/MLV among a cohort of individuals highly exposed to mice. These data suggest that the likelihood of cross-species transmission events of MLV from mice to humans is low. © 2012 American Association of Blood Banks.
Brooks SK, Rimes KA, Chalder T.	Department of Psychological Medicine, King's College London, UK.	The role of acceptance in chronic fatigue syndrome.	J Psychosom Res. 2011 Dec;71(6):411-5. Epub 2011 Sep 16.	OBJECTIVE: In this paper we consider the role that acceptance plays in fatigue and physical and social functioning. We predicted that lack of acceptance would be positively correlated with fatigue and impairment in functioning; that there would be a significant relationship between perfectionism and acceptance; and cognitive behavioural therapy (CBT) would increase acceptance. METHODS: Two hundred and fifty nine patients with chronic fatigue syndrome (CFS) completed questionnaires measuring fatigue, physical functioning, work and social adjustment, lack of acceptance, perfectionism and depression. Ninety consecutive attenders received a course of CBT and completed further questionnaires at discharge and 3months post-treatment. Correlations and multiple hierarchical regressions were used to determine relationships between acceptance, perfectionism and clinical outcome variables.

				RESULTS: At baseline, lack of acceptance was the key factor associated with impaired physical functioning and work and social adjustment. Lack of acceptance and doubts about actions were associated with fatigue in a multiple regression analysis. At discharge and follow-up patients showed significantly increased acceptance, as well as reduced Concern over Mistakes, less fatigue and impairment of physical functioning, and improved work and social adjustment. CONCLUSION: This is the first study to our knowledge which shows a change in acceptance after CBT and a relationship between acceptance and perfectionism. Acceptance may be an important factor to consider within treatments for CFS. 2011 Elsevier Inc. All rights reserved.
Brown M, Kaplan C, Jason L.	DePaul University, Chicago, USA.	Factor Analysis of the Beck Depression Inventory-ii With Patients With Chronic Fatigue Syndrome.	J Health Psychol. 2011 Nov 21. [Epub ahead of print]	This study examined the properties of the Beck Depression Inventory-II (BDI-II) in a sample of 111 patients with chronic fatigue syndrome (CFS). Exploratory factor analysis identified two factors. The mean score for the Somatic-Affective factor was significantly higher than the Cognitive factor. Convergent and discriminant validity were assessed for BDI-II total score, the two factor scores, and the BDI for Primary Care (BDI-PC). The BDI-PC and Cognitive factor demonstrated superior validity. Results suggest patients endorse BDI-II somatic items that overlap with CFS symptoms at a high rate. Factor scores should be evaluated separately, or the BDI-PC should be utilized with this population.
Brown M, Khorana N, Jason LA.	DePaul University. mbrown59@depaul.edu	The role of changes in activity as a function of perceived available and expended energy in nonpharmacological treatment outcomes for ME/CFS.	J Clin Psychol. 2011 Mar;67(3):253-60. doi: 10.1002/jclp.20744. Epub 2010 Oct 25.	Nonpharmacological interventions for myalgic encephalomyelitis/chronic fatigue syndrome (ME/CFS) often emphasize gradual increases in activity to promote improvement in physical functioning and fatigue. The energy envelope theory may provide a framework for understanding the relationship between changes in activity level and outcomes for patients with ME/CFS. This study examined the relationship between energy envelope and changes in activity after nonpharmacological interventions in a sample of 44 adults with ME/CFS. Results showed that those who were within their energy envelope before treatment showed more improvement in physical functioning and fatigue compared with those outside of their energy envelope. These findings suggest that an assessment of perceived available and expended energy could help guide the development of individualized nonpharmacological interventions for people with ME/CFS. © 2010 Wiley Periodicals, Inc.
Burgess M, Andiappan M, Chalder T.	South London & Maudsley Trust, London, UK.	Cognitive Behaviour Therapy for Chronic Fatigue Syndrome in Adults: Face to Face versus Telephone Treatment - A Randomized Controlled Trial.	Behav Cogn Psychother. 2012 Mar;40(2):175-91. Epub 2011 Sep 20.	Background: Previous research has shown that face to face cognitive behaviour therapy (CBT) is an effective treatment for chronic fatigue syndrome (CFS)/Myalgic Encephalomyelitis (ME). However, some patients are unable to travel to the hospital for a number of reasons. Aims: The aim of this study was to assess whether face to face CBT was more effective than telephone CBT (with face to face assessment and discharge appointment) for patients with CFS. Method: Patients aged 18-65 were recruited from consecutive referrals to the Chronic Fatigue Syndrome (CFS) Research and Treatment Unit at The South London and Maudsley NHS Trust in London. Participants were randomly allocated to either face to face CBT or telephone CBT by a

				departmental administrator. Blinding of participants and care givers was inappropriate for this trial. A parallel-groups randomised controlled trial was used to compare the two treatments. The primary outcomes were physical functioning and fatigue. Results: Significant improvements in the primary outcomes of physical functioning and fatigue occurred and were maintained to one year follow-up after discharge from treatment. Improvements in social adjustment and global outcome were noted and patient satisfaction was similar in both groups. Conclusions: Results from this study indicate that telephone CBT with two face to face appointments is a mild to moderately effective treatment for CFS and may be offered to patients where face to face treatment is not a viable option. Despite these encouraging conclusions, dropout was relatively high and therapists should be aware of this potential problem.
Burkhardt BE, Fischer PR, Brands CK, Porter CB, Weaver AL, Yim PJ, Pianosi PT.	Department of Pediatric Cardiology and Congenital Heart Disease, University Medical Center Freiburg, Freiburg, Germany.	Exercise performance in adolescents with autonomic dysfunction.	J Pediatr. 2011 Jan;158(1):15-9, 19.e1. Epub 2010 Sep 1. Comment in J Pediatr. 2011 Jan;158(1):4-6.	OBJECTIVE: To test the hypothesis that excessive postural tachycardia is associated with deconditioning rather than merely being an independent sign of autonomic dysfunction in patients with postural orthostatic tachycardia syndrome (POTS). STUDY DESIGN: We retrospectively analyzed records from 202 adolescents who underwent both head up-tilt and maximal exercise testing. Patients were classified as POTS if they had ≥ 30 min(-1) rise in heart rate (HR) after tilt-table test; and deconditioned if peak O(2) uptake was < 80% predicted. Changes in HR during exercise and recovery were compared between groups. RESULTS: Two-thirds of patients were deconditioned, irrespective of whether they fulfilled diagnostic criteria for POTS, but peak O(2) uptake among patients with POTS was similar to patients without POTS. HR was higher at rest and during exercise; whereas stroke volume was lower during exercise, and HR recovery was slower in patients with POTS compared with patients without POTS. CONCLUSIONS: Most patients who presented with chronic symptoms of dizziness, fatigue, or pre-syncope, were deconditioned, but, because the proportion of deconditioned patients was similar in POTS vs non-POTS groups, we conclude that HR changes in POTS are not solely because of inactivity resulting in deconditioning. Busch AJ, Webber SC, Brachaniec M, Bidonde J, Bello-Haas VD, Danyliw AD, Overend TJ, Richards RS, Sawant A, Schachter CL.	School of Physical Therapy, University of Saskatchewan, 1121 College Drive, Saskatoon, Saskatchewan S7N 0W3, Canada. angela.busch@usask.ca	Exercise therapy for fibromyalgia.	Curr Pain Headache Rep. 2011 Oct;15(5):358-67.	Fibromyalgia syndrome, a chronic condition typically characterized by widespread pain, nonrestorative sleep, fatigue, cognitive dysfunction, and other somatic symptoms, negatively impacts physical and emotional function and reduces quality of life. Exercise is commonly recommended in the management of people with fibromyalgia, and interest in examining exercise benefits for those with the syndrome has grown substantially over the past 25 years. Research supports aerobic and strength training to improve physical fitness and function, reduce fibromyalgia symptoms, and improve quality of life. However, other forms of exercise (e.g., tai chi, yoga, Nordic walking, vibration techniques) and lifestyle physical activity also have been investigated to determine their effects. This paper highlights findings from recent randomized controlled trials and reviews of exercise for people with fibromyalgia, and includes information regarding factors that influence response and

				adherence to exercise to assist clinicians with exercise and physical activity prescription decision-making to optimize health and well-being.
Bürgel B, Friesland M, Koch A, Manns MP, Wedemeyer H, Weissenborn K, Schulz-Schaeffer WJ, Pietschmann T, Steinmann E, Ciesek S.	Division of Experimental Virology, TWINCORE, Centre for Experimental and Clinical Infection Research, Medical School Hannover (MHH) and Helmholtz Centre for Infection Research (HZI), Hannover, Germany.	Hepatitis C virus enters human peripheral neuroblastoma cells - evidence for extra-hepatic cells sustaining hepatitis C virus penetration.	J Viral Hepat. 2011 Aug;18(8):562-70. doi: 10.1111/j.1365-2893.2010.01339.x. Epub 2010 Jun 23.	Patients with chronic hepatitis C virus (HCV) infection show an increased incidence of nervous system disorders such as chronic fatigue syndrome, depression and cognitive dysfunction. It is unclear whether this is because of HCV replication in the brain and in peripheral neuronal cells or to more indirect effects of HCV infection on the central or peripheral nervous system. The aim of this study was to investigate whether cells originating from these tissues are permissive for HCV cell entry, RNA replication and virus assembly. Among eight cell lines analysed, the human peripheral neuroblastoma cell line SKNMC expressed all HCV entry factors and was efficiently infected with HCV pseudoparticles (HCVpp) independent of the HCV genotype. All remaining cell types including human neuroblastoma and glioblastoma cell lines and microglial cells lacked expression of at least one host factor essential for HCV entry. When transfected with HCV luciferase reporter virus RNA, inoculated with HCV reporter viruses or challenged with high-titre cell culture-derived HCV, none of these cells supported detectable HCV RNA replication. Thus, in conclusion, this comprehensive screening did not reveal evidence directly strengthening the notion that HCV enters and replicates in the central nervous system. However, productive viral entry into the peripheral neuroblastoma cell line SKNMC indicates that HCV may penetrate into certain nonhepatic cell types which may serve as viral reservoirs and could modulate viral pathogenesis. © 2010 Blackwell Publishing Ltd.

Caminero A, Bartolomé M.	Multiple Sclerosis Unit, Department of Neurology, Complejo Asistencial de Ávila, Spain. acaminero@saludcastillayleon.es	Sleep disturbances in multiple sclerosis.	46. J Neurol Sci. 2011 Oct 15;309(1-2):86-91. Epub 2011 Aug 3.	OBJECTIVES: The frequency of sleep disturbances in multiple sclerosis (MS), and their impact on the quality of life of MS patients, have traditionally been underestimated. Here we review the most common sleep disorders seen in this disease, their prevalence, pathophysiology, clinical manifestations and current treatments. METHOD: We begin with a brief description of epidemiological data on sleep disturbances in MS, explain how these disturbances increase potential associated morbidities, and discuss the bidirectional relationship established between these two comorbid conditions (i.e. MS worsens sleep disturbances and vice versa). We then analyze the main dyssomnias and parasomnias described in MS: insomnia, circadian rhythm disorders, drug-induced sleep disturbances, restless legs syndrome (RLS) and periodic leg movements (PLM), respiratory disorders during sleep, narcolepsy-cataplexy syndrome and REM sleep behavior disorder (RBD). We also review the relationship between sleep disturbances and chronic fatigue syndrome, which is very frequent in MS patients. CONCLUSION: Sleep disturbances are more common in MS patients than in the general population and limit these patients' quality of life. Therefore, we believe that these disturbances should be a focal point in any multidisciplinary treatment for MS. Copyright © 2011 Elsevier B.V. All rights reserved.

Cao Y, Hu Y, Liu P, Zhao HX, Zhou XJ, Wei YM.	Department of Clinical Pharmacology, Chinese PLA General Hospital, Beijing 100853, China.	Effects of a Chinese traditional formula Kai Xin San (KXS) on chronic fatigue syndrome mice induced by forced wheel running.	J Ethnopharmacol. 2012 Jan 6;139(1):19-25. Epub 2011 Aug 22.	ETHNOPHARMACOLOGICAL RELEVANCE: In traditional medicine, Kai Xin San (KXS), composed of ginseng (Panax ginseng), hoelen (Wolfiporia cocos), polygala (Polygala tenuifolia) and Acorus gramineus, is famous for the treatment of emotion-thought disease, such as settling fright, quieting the spirit and nourishing the heart. AIM OF THE STUDY: The present study investigated the effect of KXS on chronic fatigue syndrome (CFS) mice induced by forced wheel running. MATERIALS AND METHODS: Seventy two healthy adult male Kunming mice were randomly divided into six groups: home cage control group, CFS group, CFS group with Modafinil treatment at 13 mg/kg/d doge, KXS treatment at 175 mg/kg/d, 350 mg/kg/d and 700 mg/kg/d doge. CFS mice were induced by forced wheel running with higher speed for 4 weeks and then taken an exhausted exercise. The biochemical parameters including serum lactate dehydrogenase (LDH), serum urea nitrogen (SUN), serum testosterone (T), liver glycogen (LG), muscle glycogen (MG) and muscle lactic acid (MLA) were determined by using commercially available kits. The splenocytes proliferation from mice was examined by MTT method. The levels of interleukin-2 (IL-2) and interleukin-4 (IL-4) secreted by splenocytes were determined by ELISA. RESULTS: CFS mice with KXS administration exhibited less electric shock time when compared with CFS group without drug treatment. The effect of KXS has after demonstrated reduction in SUN, LDH and MLA levels and an increase in T, LG and MG levels. CFS mice with KXS could improve the proliferation of splenocytes compared with CFS group without drug treatment. The cultured splenocytes from CFS mice without KXS supplementation produced more interleukin-2 (IL-2) but less interleukin-4 (IL-4) when compared with home cage control mice. The cultured splenocytes of CFS mice with KXS supplementation produced more interleukin-2 (IL-2) but less interleukin-4 (IL-4) when compared with CFS group without drug treatment. CONCLUSIONS: The results of this preliminary study provide evidence that KXS could ameliorate CFS by affecting the physiological markers for fatigue. This study also supported the use of KXS against CFS by improving the proliferation of splenocytes from CFS mice and modulating the disturbance of cytokines induced by CFS. Carruthers BM, van de Sande MI, De Meirleir KL, Klimas NG, Broderick G, Mitchell T, Staines D, Powles AC, Speight N, Vallings R, Bateman L, Baumgarten-	Department of Physiology and Medicine, Vrije University of Brussels, Himmunitas Foundation, Brussels, Belgium. bcarruth@telus.net	Myalgic encephalomyelitis: International Consensus Criteria.	J Intern Med. 2011 Oct;270(4):327-38. doi: 10.1111/j.1365-2796.2011.02428.x. Epub 2011 Aug 22. Comment in J Intern Med. 2012 Jan;271(1):29-31.	The label 'chronic fatigue syndrome' (CFS) has persisted for many years because of the lack of knowledge of the aetiological agents and the disease process. In view of more recent research and clinical experience that strongly point to widespread inflammation and multisystemic neuropathology, it is more appropriate and correct to use the term 'myalgic encephalomyelitis' (ME) because it indicates an underlying pathophysiology. It is also consistent with the neurological classification of ME in the World Health Organization's International Classification of Diseases (ICD G93.3). Consequently, an International Consensus Panel consisting of clinicians, researchers, teaching faculty and an independent patient advocate was formed with the purpose of developing criteria based on current knowledge. Thirteen countries and a wide

Austrheim B, Bell DS, Carlo-Stella N, Chia J, Darragh A, Jo D, Lewis D, Light AR, Marshall-Gradisbik S, Mena I, Mikovits JA, Miwa K, Murovska M, Pall ML, Stevens S.				range of specialties were represented. Collectively, members have approximately 400 years of both clinical and teaching experience, authored hundreds of peer-reviewed publications, diagnosed or treated approximately 50 000 patients with ME, and several members coauthored previous criteria. The expertise and experience of the panel members as well as PubMed and other medical sources were utilized in a progression of suggestions/drafts/reviews/revisions. The authors, free of any sponsoring organization, achieved 100% consensus through a Delphi-type process. The scope of this paper is limited to criteria of ME and their application. Accordingly, the criteria reflect the complex symptomatology. Operational notes enhance clarity and specificity by providing guidance in the expression and interpretation of symptoms. Clinical and research application guidelines promote optimal recognition of ME by primary physicians and other healthcare providers, improve the consistency of diagnoses in adult and paediatric patients internationally and facilitate clearer identification of patients for research studies. © 2011 The Association for the Publication of the Journal of Internal Medicine.
Carvalho EE, Costa DC, Crescêncio JC, Santi GL, Papa V, Marques F, Schmidt A, Marin-Neto JA, Simões MV, Gallo Junior L.	Departamento de Clínica Médica Laboratório de Fisiologia do Exercício, Divisão de Cardiologia, Faculdade de Medicina de Ribeirão Preto, USP, Brazil. carvalhoeev@usp.br	Heart failure: comparison between six-minute walk test and cardiopulmonary test. [Article in English, Portuguese, Spanish]	Arq Bras Cardiol. 2011 Jul;97(1):59-64. Epub 2011 May 6. Comment in Arq Bras Cardiol. 2011 Nov;97(5):440; author reply 440-1.	BACKGROUND: Chronic heart failure (HF) is a syndrome characterized by reduced cardiac output in relation to the metabolic needs of the organism, as well as metabolic and neurohormonal axis abnormalities. Symptoms such as fatigue and dyspnoea are notorious and stress tests are widely used to assess functional capacity, prognosis and effectiveness of therapeutic interventions in this syndrome. OBJECTIVE: To evaluate the reproducibility of the six-minute walk test (6MW) in patients with HF and correlate the magnitude of the variables reached at peak exercise of the 6MWT with a cardiopulmonary exercise test (CPET). METHODS: We studied 16 patients (12 men and 4 women) diagnosed with HF FC I-II (NYHA). The volunteers underwent two 6MWT (6MWT'1 and 6MWT'2) with 30-minute interval between them; then, they underwent a maximum CPET. RESULTS: All variables obtained in the two 6MWT' proved to be significant with high correlations: distance walked (DW) ($r = 0.93$, $p < 0.0001$), heart rate (HR) ($r = 0.89$, $p < 0.0001$), oxygen consumption (VO2) ($r = 0.93$, $p < 0.0001$) and scale of perceived exertion ($r = 0.85$, $p < 0.0001$). In turn, all variables analyzed in the 6MWT' showed significant and moderate correlations with the variables obtained from the CPET, namely: peak HR ($r = 0.66$; $p = 0.005$); VO2 ($r = 0.57$; $p = 0.02$) and VO2 in the CPET and DT in the 6MWT'2 ($r = 0.70$; $p = 0.002$). CONCLUSION: The 6MWT was reproducible in this group of patients with HF (NYHA - I-II) and correlated with the CPET. Therefore, it is a tool for reliable evaluation, and a suitable, safe and low-cost alternative for the prescription of aerobic exercise in patients with HF.
Castori M, Sperduti I, Celletti C, Camerota F, Grammatico P.	Medical Genetics, Department of Molecular Medicine,	Symptom and joint mobility progression in the joint hypermobility	Clin Exp Rheumatol. 2011 Nov-Dec;29(6):998-1005.	OBJECTIVES: To evaluate progression of symptoms and joint mobility in the joint hypermobility syndrome (JHS) in order to identify specific disease pictures by age at presentation. 	Sapienza University, San Camillo-Forlanini Hospital, Rome, Italy. mcastori@scamilloforlanini.rm.it.	syndrome (Ehlers-Danlos syndrome, hypermobility type).		symptoms. Incidence and prevalence rates by age at onset and sex were calculated and compared by chi-square, Fisher's exact test and Mann-Whitney U-test. Relationship between BS and age at examination was evaluated by the Spearman rho correlation. The existence of an age cut-off separating patients with or without a positive BS was analysed by the receiver operating characteristic analysis. Influence of age on the single components of the BS was also investigated. RESULTS: Except for isolated features, the overall clinical presentation was the same between sexes. In the whole sample, statistically significant differences by age at presentation were registered for fatigue, myalgias, muscle cramps, strains/sprains, dislocations, tendon ruptures, tendonitis, gastroesophageal reflux, chronic gastritis, constipation/diarrhoea and abdominal hernias. A clear inverse correlation between age at examination and BS was demonstrated with an age cut-off fixed at 33 years. Among the components of the BS, spine and elbow joints were not significantly influenced by age. CONCLUSIONS: This study confirmed the existence of a protean clinical history of JHS which may be exemplified in different phases with distinguishable presentations. The knowledge of the peculiarities of each of them will help the practitioner in recognising and, hopefully, treating this condition.

Department of Nursing and Physical Therapy, University of Almería (UAL), 04120 Almería, Spain.	Benefits of massage-myofascial release therapy on pain, anxiety, quality of sleep, depression, and quality of life in patients with fibromyalgia.	Evid Based Complement Alternat Med. 2011;2011:561753. Epub 2010 Dec 28.	Fibromyalgia is a chronic syndrome characterized by generalized pain, joint rigidity, intense fatigue, sleep alterations, headache, spastic colon, craniomandibular dysfunction, anxiety, and depression. The purpose of the present study was to determine whether massage-myofascial release therapy can improve pain, anxiety, quality of sleep, depression, and quality of life in patients with fibromyalgia. A randomized controlled clinical trial was performed. Seventy-four fibromyalgia patients were randomly assigned to experimental (massage-myofascial release therapy) and placebo (sham treatment with disconnected magnotherapy device) groups. The intervention period was 20 weeks. Pain, anxiety, quality of sleep, depression, and quality of life were determined at baseline, after the last treatment session, and at 1 month and 6 months. Immediately after treatment and at 1 month, anxiety levels, quality of sleep, pain, and quality of life were improved in the experimental group over the placebo group. However, at 6 months postintervention, there were only significant differences in the quality of sleep index. Myofascial release techniques improved pain and quality of life in patients with fibromyalgia.
Cella M, Sharpe M, Chalder T.	Institute of Psychiatry, King's College London, UK. matteo.cella@kcl.ac.uk	Measuring disability in patients with chronic fatigue syndrome: reliability and validity of the Work and Social Adjustment Scale.	J Psychosom Res. 2011 Sep;71(3):124-8. Epub 2011 Apr 3.	BACKGROUND: Disability is a defining feature of chronic conditions, and it is an increasingly used measure of therapy effectiveness. The Work and Social Adjustment Scale (WSAS) is a simple and clear measure of disability. Although the scale is widely used, no study has yet investigated its psychometric properties in patients with chronic fatigue syndrome (CFS). METHODS: Data from two samples of patients were used, one from a multicenter randomized controlled clinical trial of treatments for CFS (n =639) and the other from a clinic that specializes in CFS (n=384). All patients completed the WSAS as well as other measures. RESULTS: Internal consistency and the Spearman-Brown split-half coefficient values indicated that the scale is reliable. CFS patients who had comorbid diagnoses of depression, anxiety or fibromyalgia had higher WSAS scores. High levels of disability were associated with high number of physical symptoms, severe fatigue, depression, anxiety, poor sleep quality and poor physical fitness, with correlation coefficients ranging between 0.41 and 0.11. Lower scores on the WSAS were modestly associated with better physical functioning as well as higher levels of physical capacity as assessed by a walking test. Sensitivity to change was evaluated in a subgroup of patients who had undergone a course of cognitive behavioral therapy. Disability significantly decreased after therapy and

				remained stable at follow-ups. CONCLUSION: The WSAS is a reliable and valid assessment tool for disability in patients with CFS. Copyright © 2011 Elsevier Inc. All rights reserved.
Cella M, Stahl D, Reme SE, Chalder T.	King's College, Department of Psychological Medicine, Institute of Psychiatry, London, UK.	Therapist effects in routine psychotherapy practice: an account from chronic fatigue syndrome.	Psychother Res. 2011 Mar;21(2):168-78.	The effect of therapists in psychotherapy is a much debated topic, with a number of studies showing therapist variance being large while other studies show little or no variability in outcomes due to therapists. The aim of this study was to investigate therapist effects in a well-defined sample of patients and therapists from an outpatient service which specializes in providing cognitive behaviour therapy (CBT) for patients with chronic fatigue syndrome (CFS). Therapy was provided in a highly specialized clinical setting for CFS and was delivered by qualified CBT therapists with at least 2 years experience with this client group. Three hundred and seventy-four patients with CFS and 12 cognitive behavioural psychotherapists took part. Therapist effects on the primary outcomes of fatigue and disability were investigated with multilevel random effects models and variance component analysis. Different models were computed and compared. Results showed a reduction in fatigue and disability scores after therapy. Variance explained by therapists, when demographic covariates were accounted for, was 0% for fatigue and under 2% for disability. A number of important factors may have played a significant role in minimizing therapist effects in our study. These are: specialist setting, single centre, patients with the same primary diagnosis, therapists of the same orientation and training, shared environment and supervision. Future studies may stress the importance of these factors in the investigation of the therapist effect in psychotherapy.
Cella M, Chalder T, White PD.	Department of Psychological Medicine, Institute of Psychiatry, King's College London, UK. matteo.cella@kcl.ac.uk	Does the heterogeneity of chronic fatigue syndrome moderate the response to cognitive behaviour therapy? An exploratory study.	Psychother Psychosom. 2011;80(6):353-8. Epub 2011 Aug 6.	BACKGROUND: Chronic fatigue syndrome (CFS) is a heterogeneous condition. A few studies have shown that some independent factors predict outcomes after cognitive behaviour therapy (CBT). Two recent systematic reviews suggest that heterogeneity may moderate treatment outcomes. However, no study has explored whether subgroups of CFS predict response to treatment. METHODS: We used both latent class analysis (LCA) and latent class regression (LCR) to clarify the relationship between subgroups of CFS patients (n = 236), diagnosed using the Oxford diagnostic criteria, and the response to CBT. We measured symptoms, demographics, mood, and cognitive and behavioural responses to illness to define subgroups. RESULTS: We found 5 latent classes by LCA, which did not differ in the direction of their response to CBT, with all classes showing improvement. In contrast, an exploratory LCR identified 4 latent classes, 1 of which predicted a poor response to CBT, whereas the other 3 predicted a good outcome, accounting for more than 70% of the patients. The negative outcome class was defined by weight fluctuations and physical shakiness, anxiety, pain and being focused on symptoms. CONCLUSIONS: CBT should be offered to all classes of patients with CFS, when defined by these measures. It may be possible to predict a minority group with a negative outcome, but this exploratory work needs replication. Copyright © 2011 S. Karger AG, Basel.

Chaipan C, Dilley KA, Paprotka T, Delviks-Frankenberry KA, Venkatachari NJ, Hu WS, Pathak VK.	HIV Drug Resistance Program, National Cancer Institute-Frederick, P. O. Box B, Building 535, Room 334, Frederick, MD 21702-1201, USA.	Severe restriction of xenotropic murine leukemia virus-related virus replication and spread in cultured human peripheral blood mononuclear cells.	J Virol. 2011 May;85(10):4888-97. Epub 2011 Feb 16.	Xenotropic murine leukemia virus-related virus (XMRV) is a gammaretrovirus recently isolated from human prostate cancer and peripheral blood mononuclear cells (PBMCs) of patients with chronic fatigue syndrome (CFS). We and others have shown that host restriction factors APOBEC3G (A3G) and APOBEC3F (A3F), which are expressed in human PBMCs, inhibit XMRV in transient-transfection assays involving a single cycle of viral replication. However, the recovery of infectious XMRV from human PBMCs suggested that XMRV can replicate in these cells despite the expression of APOBEC3 proteins. To determine whether XMRV can replicate and spread in cultured PBMCs even though it can be inhibited by A3G/A3F, we infected phytohemagglutinin-activated human PBMCs and A3G/A3F-positive and -negative cell lines (CEM and CEM-SS, respectively) with different amounts of XMRV and monitored virus production by using quantitative real-time PCR. We found that XMRV efficiently replicated in CEM-SS cells and viral production increased by >4,000-fold, but there was only a modest increase in viral production from CEM cells (<14-fold) and a decrease in activated PBMCs, indicating little or no replication and spread of XMRV. However, infectious XMRV could be recovered from the infected PBMCs by cocultivation with a canine indicator cell line, and we observed hypermutation of XMRV genomes in PBMCs. Thus, PBMCs can potentially act as a source of infectious XMRV for spread to cells that express low levels of host restriction factors. Overall, these results suggest that hypermutation of XMRV in human PBMCs constitutes one of the blocks to replication and spread of XMRV. Furthermore, hypermutation of XMRV proviruses at GG dinucleotides may be a useful and reliable indicator of human PBMC infection.
Chandraratne NK, Gunawardena NS.	Public Health Department, Colombo Municipal Council, Sri Lanka. radkamil@yahoo.com	Premenstrual syndrome: the experience from a sample of Sri Lankan adolescents.	J Pediatr Adolesc Gynecol. 2011 Oct;24(5):304-10.	SETTING: Government schools of Colombo. MAIN OUTCOME MEASURES: Premenstrual symptomatology (PMS) was determined by a modified version of Premenstrual Symptom screening tool and American College of Obstetricians and Gynecologists (ACOG) diagnostic criteria were used in categorizing study units as having PMS. Other outcome measures were demographic and reproductive factors thought to be correlates of PMS, health seeking behavior for premenstrual symptoms, and how premenstrual symptoms impact their daily life. RESULTS: Individual premenstrual symptoms were experienced by 65.7% of the population. The most common somatic symptom was fatigue (29.9%) and affective symptom was feeling sad/hopeless (29.6%). Prevalence of PMS was 8.75% (95%CI: 6.43-11.07). Multivariate analysis revealed the presence of: chronic physical illness (P = 0.001); dysmenorrhea (P < 0.0001), and regular menstrual cycles (P = 0.006) as correlates of PMS. Presence of PMS significantly disturbed "in school" activities, relationships and daily routines (P < 0.005) indicating a high negative influence on adolescents' daily life. Only 9.7% sought help from (western) medical practitioners for their premenstrual symptoms and a majority has not perceived it as a condition to report. CONCLUSION: Premenstrual syndrome is a common condition among adolescent schoolgirls with a

				high negative influence on their daily life. The health care seeking behavior is poor, indicating the necessity to address the subject at adolescent reproductive health programs. Check JH, Cohen R.	The University of Medicine and Dentistry of New Jersey, Robert Wood Johnson Medical School at Camden Cooper Hospital/University Medical Center, Department of Obstetrics and Gynecology, Division of Reproductive Endocrinology & Infertility, Camden, NJ, USA. laurie@ccivf.com	Sympathetic neural hyperalgesia edema syndrome, a frequent cause of pelvic pain in women, mistaken for Lyme disease with chronic fatigue.	Clin Exp Obstet Gynecol. 2011;38(4):412-3.	PURPOSE: To show that chronic fatigue syndrome can be mistakenly attributed to Lyme disease rather than considering sympathetic neural hyperalgesia edema syndrome. This common disorder of women, frequently, but not always causing pelvic pain, can present simply as chronic fatigue. METHODS: A water load test was performed in a woman reactive for B-Burgdorferi with chronic fatigue whose symptoms did not improve despite three months of treatment with doxycycline. A water load test was performed. RESULTS: She failed the water load test by excreting only 50% ingested load standing for four hours. She showed marked improvement following treatment with dextroamphetamine sulfate. CONCLUSIONS: This very treatable disorder of the sympathetic nervous system should be considered in women with an unknown cause of chronic fatigue or if the symptoms persist despite treatment of another potential cause.
Chew-Graham C, Brooks J, Wearden A, Dowrick C, Peters S.	School of Community-Based Medicine, University of Manchester, Manchester, UK. cchew@manchester.ac.uk	Factors influencing engagement of patients in a novel intervention for CFS/ME: a qualitative study.	Prim Health Care Res Dev. 2011 Apr;12(2):112-22.	AIM: To establish what factors are important for patients to engage in a new intervention for chronic fatigue syndrome/myalgic encephalomyelitis (CFS/ME) and make recommendations to general practitioners (GPs) on preparing a patient for referral to such a service. BACKGROUND: NICE guidelines recommend a prominent role for primary care in the management of patients with CFS/ME, with prompt diagnosis and appropriate referral for evidence-based treatments. METHODS: A qualitative study nested within a multi-centre randomised controlled trial of two new nurse therapist delivered interventions. Semi-structured interviews carried out with 19 patients who had received pragmatic rehabilitation (PR) in the trial. Interviews were transcribed verbatim and an iterative approach used to develop themes from the data set. FINDINGS: Factors that influence whether or not a patient engages with PR for CFS/ME are ensuring that the patient feels accepted and believed, that they accept the diagnosis, and that the model implicated by the treatment offered to the patient matches the model of illness held by the patient. If patients hold a clearly incompatible model of their illness, it is unlikely that they will engage with, and successfully complete, therapy. It is vital that the GP elicits and explores such illness beliefs either before making a referral to maximise patient engagement in therapy, or that an initial session with the therapist explores attitudes to the treatment model

				offered and then works with the patient's model.
Chia J, Chia A, El-Habbal R.	EV Med Research, Lomita, California 90717, USA. evmed@sbcglobal.net	Carcinoid tumour associated with enterovirus infection.	J Clin Pathol. 2011 Aug;64(8):722-4. Epub 2011 Jan 28.	Enteroviruses commonly infect the gastrointestinal tract, and replication of enteroviruses has been well documented in the Peyer patches of the small bowel. Chronic enterovirus infection has been found in the stomach and terminal ileum of patients with myalgic encephalomyelitis/chronic fatigue syndrome. The authors report the unexpected finding of enterovirus VP1 protein, by immunoperoxidase staining, in carcinoid tumours found in one patient with myalgic encephalomyelitis/chronic fatigue syndrome and another patient with chronic lower quadrant abdominal pain, and suggest a possible association between enteroviruses and tumorigenesis.
Cingöz O, Paprotka T, Delviks-Frankenberry KA, Wildt S, Hu WS, Pathak VK, Coffin JM.	Department of Molecular Biology and Microbiology, Genetics Program, Sackler School of Graduate Biomedical Sciences, Tufts University, Boston, Massachusetts, USA.	Characterization, mapping, and distribution of the two XMRV parental proviruses.	J Virol. 2012 Jan;86(1):328-38. Epub 2011 Oct 26.	Xenotropic murine leukemia virus-related virus (XMRV) was previously reported to be associated with human prostate cancer and chronic fatigue syndrome. Our groups recently showed that XMRV was created through recombination between two endogenous murine retroviruses, PreXMRV-1 and PreXMRV-2, during the passaging of a prostate tumor xenograft in nude mice. Here, multiple approaches that led to the identification of PreXMRV-2, as well as the distribution of both parental proviruses among different mouse species, are described. The chromosomal loci of both proviruses were determined in the mouse genome, and integration site information was used to analyze the distribution of both proviruses in 48 laboratory mouse strains and 46 wild-derived strains. The strain distributions of PreXMRV-1 and PreXMRV-2 are quite different, the former being found predominantly in Asian mice and the latter in European mice, making it unlikely that the two XMRV ancestors could have recombined independently in the wild to generate an infectious virus. XMRV was not present in any of the mouse strains tested, and among the wild-derived mouse strains analyzed, not a single mouse carried both parental proviruses. Interestingly, PreXMRV-1 and PreXMRV-2 were found together in three laboratory strains, Hsd nude, NU/NU, and C57BR/cd, consistent with previous data that the recombination event that led to the generation of XMRV could have occurred only in the laboratory. The three laboratory strains carried the Xpr1(n) receptor variant nonpermissive to XMRV and xenotropic murine leukemia virus (X-MLV) infection, suggesting that the xenografted human tumor cells were required for the resulting XMRV recombinant to infect and propagate.
Clark C, Goodwin L, Stansfeld SA, Hotopf M, White PD.	Centre for Psychiatry, Barts & the London School of Medicine & Dentistry, Queen Mary University of London,	Premorbid risk markers for chronic fatigue syndrome in the 1958 British birth cohort.	Br J Psychiatry. 2011 Oct;199(4):323-9. doi: 10.1192/bjp.bp.110.083956. Epub 2011 Aug 18.	BACKGROUND: Little is known about the aetiology of chronic fatigue syndrome/myalgic encephalomyelitis (CFS/ME); prospective studies suggest a role for premorbid mood disorder. AIMS: To examine childhood and early adult adversity, ill health and physical activity as premorbid risk markers for CFS/ME by 42 years, taking psychopathology into account. METHOD: Data were from the 1958 British birth cohort, a prospective study from birth to 42 years (n = 11 419). The outcomes were self-reported CFS/ME (n = 127) and operationally defined CFS-like illness (n = 241) at 42 years. RESULTS: Adjusting for psychopathology, parental physical abuse (odds ratio

	Charterhouse Square, UK. c.clark@qmul.ac.uk			(OR) = 2.10, 95% CI 1.16-3.81), childhood gastrointestinal symptoms (OR = 1.58, 95% CI 1.00-2.50) and parental reports of many colds (OR = 1.65, 95% CI 1.09-2.50) were independently associated with self-reported CFS/ME. Female gender and premorbid psychopathology were the only risk markers for CFS-like illness, independent of comorbid psychopathology. CONCLUSIONS: This confirms the importance of premorbid psychopathology in the aetiological pathways of CFS/ME, and replicates retrospective findings that childhood adversity may play a role in a minority.
Clauw DJ, Arnold LM, McCarberg BH; FibroCollaborative.	Department of Anesthesiology, University of Michigan, Ann Arbor, MI 48106, USA. dclauw@med.umich.edu	The science of fibromyalgia.	Mayo Clin Proc. 2011 Sep;86(9):907-11.	Fibromyalgia (FM) is a common chronic widespread pain disorder. Our understanding of FM has increased substantially in recent years with extensive research suggesting a neurogenic origin for the most prominent symptom of FM, chronic widespread pain. Neurochemical imbalances in the central nervous system are associated with central amplification of pain perception characterized by allodynia (a heightened sensitivity to stimuli that are not normally painful) and hyperalgesia (an increased response to painful stimuli). Despite this increased awareness and understanding, FM remains undiagnosed in an estimated 75% of people with the disorder. Clinicians could more effectively diagnose and manage FM if they better understood its underlying mechanisms. Fibromyalgia is a disorder of pain processing. Evidence suggests that both the ascending and descending pain pathways operate abnormally, resulting in central amplification of pain signals, analogous to the "volume control setting" being turned up too high. Patients with FM also exhibit changes in the levels of neurotransmitters that cause augmented central nervous system pain processing; levels of several neurotransmitters that facilitate pain transmission are elevated in the cerebrospinal fluid and brain, and levels of several neurotransmitters known to inhibit pain transmission are decreased. Pharmacological agents that act centrally in ascending and/or descending pain processing pathways, such as medications with approved indications for FM, are effective in many patients with FM as well as other conditions involving central pain amplification. Research is ongoing to determine the role of analogous central nervous system factors in the other cardinal symptoms of FM, such as fatigue, nonrestorative sleep, and cognitive dysfunction.

Cobankara V, Unal UO, Kaya A,	Rheumatology Clinic, Internal	The prevalence of fibromyalgia among	Int J Rheum Dis. 2011 Oct;14(4):390-4. doi:	AIM: Fibromyalgia (FM) is characterized by chronic widespread pain, fatigue, reduced sleep quality and multiple tender points. A recent population study from Turkey

Bozkurt AI, Ozturk MA.	Medicine Department, Pamukkale University Faculty of Medicine, Denizli, Turkey.	textile workers in the city of Denizli in Turkey.	10.1111/j.1756-185X.2011.01620.x. Epub 2011 Jun 29.	found the prevalence of FM as 3.6%. A prevalence study among workers has not yet been performed. We performed a prevalence survey among working population in the city of Denizli in Turkey. METHODS: The field survey was done in two stages. In the first stage 655 (523 female, 132 male) textile workers from four factories were asked to fill a screening questionnaire. In the next stage, participants who had widespread pain were examined by an experienced rheumatologist. Patients who had 11 tender points according to ACR 1990 FM classification criteria were diagnosed as FM syndrome and later a detailed clinical and laboratory evaluation was done. RESULTS: Forty-eight patients (7.3%) (one male [0.76% of males], 47 females [9.0% of females]) among 655 textile workers were diagnosed as FM. The clinical features were as follows: all patients had widespread pain, 12.5% had arthralgia, 14.6% had Raynaud's phenomenon, 41.6% had sleep disturbance, 87.5% had headache, 52% had irritable bowel disease. Age, gender, marital status, income level, education level, smoking status, and body mass index level of workers were evaluated by logistic regression analysis; multiple analysis. Only three variables (age, gender and annual income level) were significantly affected FM prevalence. CONCLUSION: This is the first study investigating FM prevalence among workers from Turkey. The prevalence of FM appears higher among females, older workers, and workers with low annual money income. © 2011 The Authors. E, May MT, Sterne JA, Hollingworth W; UK CFS/ME National Outcomes Database. Collaborators: O'Dowd H, Butt K, Dunn D, Pemberton S, White P, Murphy M, Mullick Y, Bansal A.	Community Medicine, Centre for Child & Adolescent Health, University of Bristol, Oakfield House, Oakfield Grove, BS8 2BN, UK.	CFS/ME on employment and productivity in the UK: a cross-sectional study based on the CFS/ME national outcomes database.	2011 Sep 15;11:217.	of employment in patients with CFS/ME or quantified its impact on productivity. METHODS: We used patient-level data from five NHS CFS/ME services during the period 01/04/2006-31/03/2010 collated in the UK CFS/ME National Outcomes Database. We used logistic regression to identify factors associated with discontinuation of employment. We estimated UK-wide productivity costs using patient-level data on duration of illness before assessment by a CFS/ME service, duration of unemployment, age, sex and numbers of patients, in conjunction with Office for National Statistics income and population data. RESULTS: Data were available for 2,170 patients, of whom 1,669 (76.9%) were women. Current employment status was recorded for 1,991 patients (91.8%), of whom 811 patients (40.7%) were currently employed and 998 (50.1%) had discontinued their employment "because of fatigue-related symptoms". Older age, male sex, disability, fatigue, pain, and duration of illness were associated with cessation of employment. In a multivariable model, age, male sex, and disability remained as independent predictors. Total productivity costs among the 2,170 patients due to discontinuation of employment in the years preceding assessment by a specialist CFS/ME service (median duration of illness=36 months) were £49.2 million. Our sample was equivalent to 4,424 UK adults accessing specialist services each year, representing productivity costs to the UK economy of £102.2 million. Sensitivity analyses suggested a range between £75.5-£128.9 million. CONCLUSIONS: CFS/ME incurs huge productivity costs amongst the small fraction of adults with CFS/ME who access specialist services.
Constant EL, Adam S, Gillain B, Lambert M, Masquelier E, Seron X.	Department of Psychiatry, Université Catholique de Louvain, 1200 Brussels, Belgium. Eric.Constant@uclouvain.be	Cognitive deficits in patients with chronic fatigue syndrome compared to those with major depressive disorder and healthy controls.	Clin Neurol Neurosurg. 2011 May;113(4):295-302. Epub 2011 Jan 20.	OBJECT: Chronic fatigue syndrome (CFS) patients report usually cognitive complaints. They also have frequently comorbid depression that can be considered a possible explanation for their cognitive dysfunction. We evaluated the cognitive performance of patients with CFS in comparison with a control group of healthy volunteers and a group of patients with MDD. PATIENTS AND METHODS: Twenty-five patients with CFS, 25 patients with major depressive disorder (MDD), and 25 healthy control subjects were given standardized tests of attention, working memory, and verbal and visual episodic memory, and were also tested for effects related to lack of effort/simulation, suggestibility, and fatigue. RESULTS: Patients with CFS had slower phasic alertness, and also had impaired working, visual and verbal episodic memory compared to controls. They were, however, no more sensitive than the other groups to suggestibility or to fatigue induced during the cognitive session. Cognitive impairments in MDD patients were strongly associated with depression and subjective fatigue; in patients with CFS, there was a weaker correlation between cognition and depression (and no correlation with fatigue). CONCLUSIONS: This study confirms the presence of an objective impairment in attention and memory in patients with CFS but with good mobilization of effort and without exaggerated suggestibility.

Middleton Memorial Veterans Hospital 3School of Physical Education, Sport & Exercise Science, Ball State University 4Graduate School of Education, The University of Tokyo 5Pain and Fatigue Study Center, Beth Israel Medical Center.	Responses to Exercise Differ For Chronic Fatigue Syndrome Patients with Fibromyalgia.	Med Sci Sports Exerc. 2011 Dec 12. [Epub ahead of print]	Chronic fatigue syndrome (CFS) and fibromyalgia (FM) are chronic multisymptom illnesses with substantial clinical and diagnostic overlap. We have previously shown that when controlling for aerobic fitness and accounting for comorbid FM, CFS patients do not exhibit abnormal cardiorespiratory responses during maximal aerobic exercise compared to healthy controls, despite differences in pain and exertion. PURPOSE: The purpose of the present study was to examine cardiac and perceptual responses to steady-state, submaximal exercise in CFS patients and healthy controls. METHODS: Twenty-one CFS patients [13 CFS with comorbid FM (CFS+FM)] and 14 controls completed 20 minutes of submaximal cycling exercise. Impedance cardiography was used to determine cardiac responses during exercise. Systolic blood pressure (SBP), perceived exertion (RPE) and leg-muscle pain were also measured. Data were analyzed using a doubly-multivariate, repeated-measures MANOVA to model the exercise response. RESULTS: There was a significant multivariate Time by Group interaction ($p < 0.05$). The CFS+FM group exhibited an exercise response characterized by higher stoke index, ventilatory equivalents for oxygen and carbon dioxide and RPE, lower SBP and similar HR responses. CONCLUSIONS: The present results extend upon our previous work with maximal exercise and show that CFS and CFS+FM differ in their responses to steady-state exercise. These resultshighlight the importance of accounting for comorbid conditions when conducting CFS research, particularly when examining psychophysiological responses to exercise.
Cool M, Bouchard N, Massé G, Laganière B, Dumont A, Hanna Z, Phaneuf D, Morisset R, Jolicoeur P.	Laboratory of Molecular Biology, Clinical Research Institute of Montreal, Montreal, Quebec, Canada H2W 1R7.	No detectable XMRV in subjects with chronic fatigue syndrome from Quebec.	Virology. 2011 Nov 10;420(1):66-72. Epub 2011 Sep 16.	We investigated the presence of XMRV in a cohort of Quebec patients with chronic fatigue syndrome (CFS). DNA was purified from activated peripheral blood mononuclear cells (PBMCs) and PCR was used to detect XMRV gag and env in 72 patients. Anti-XMRV antibodies were searched in sera of 62 patients by Western blot analysis. Attempts to detect XMRV antigens was made, using immunofluorescence with Gag anti-p30 antiserum on activated PBMC from 50 patients. Plasma viremia was measured by RT-PCR on 9 subjects. Finally, detection of infectious virus in 113 CFS subjects was made by co-culture of PHA+IL-2 activated PBMC with human LNCaP carcinoma cells, and by infecting the same susceptible cells with plasma, using a reverse transcriptase (RT) assay as a readout in both experiments. No detection of XMRV footprints nor infectious virus was detected with any of the approaches, in any of the tested individuals.

Coughlin SS, Kang	Environmental	Alcohol use and	Prev Chronic Dis. 2011	INTRODUCTION: A sizable literature has analyzed the frequency of alcohol

HK, Mahan CM.	Epidemiology Service (135), Office of Public Health and Environmental Hazards, Department of Veterans Affairs, 810 Vermont Ave NW, Washington, DC 20420, USA. steven.coughlin@va.gov	selected health conditions of 1991 Gulf War veterans: survey results, 2003-2005.	May;8(3):A52. Epub 2011 Apr 15.	consumption and patterns of drinking among veterans. However, few studies have examined patterns of alcohol use in veterans of the first Gulf War or factors associated with problem drinking in this population. We examined the frequency and patterns of alcohol use in male and female veterans who served in the 1991 Gulf War or during the same era and the relationships between alcohol use and selected health conditions. METHODS: We analyzed data from a follow-up survey of health information among population-based samples of 15,000 Gulf War and 15,000 Gulf Era veterans. Data had been collected from 9,970 respondents during 2003 through 2005 via a structured questionnaire or telephone survey. RESULTS: Posttraumatic stress disorder (PTSD), major depressive disorder (MDD), unexplained multisymptom illness (MSI), and chronic fatigue syndrome (CFS)-like illness were more frequent among veterans with problem drinking than those without problem drinking. Approximately 28% of Gulf War veterans with problem drinking had PTSD compared with 13% of Gulf War veterans without problem drinking. In multivariate analysis, problem drinking was positively associated with PTSD, MDD, unexplained MSI, and CFS-like illness after adjustment for age, sex, race/ethnicity, branch of service, rank, and Gulf status. Veterans who were problem drinkers were 2.7 times as likely to have PTSD as veterans who were not problem drinkers. CONCLUSION: These findings indicate that access to evidence-based treatment programs and systems of care should be provided for veterans who abuse alcohol and who have PTSD and other war-related health conditions and illnesses.
Coughlin SS, Kang HK, Mahan CM.	Environmental Epidemiology Service (135), Office of Public Health and Environmental Hazards, Department of Veterans Affairs, 810 Vermont Avenue, NW, Washington, DC 20420, USA.	Selected Health Conditions Among Overweight, Obese, and Non-Obese Veterans of the 1991 Gulf War: Results from a Survey Conducted in 2003-2005.	Open Epidemiol J. 2011;4:140-146.	BACKGROUND: Several health conditions and concerns have been reported to be increased among Gulf War veterans including post-traumatic stress disorder (PTSD), chronic fatigue syndrome (CFS), CFS-like illness, and unexplained multi-symptom illness (MSI). As the cohort of Gulf War veterans advance in age, they are likely to be at risk of not only certain deployment-related health conditions but also chronic diseases associated with lifestyle factors. METHODS: To clarify relationships between PTSD, CFS-like illness, MSI, and obesity, we analyzed data from a cross-sectional survey of health information among population-based samples of 15,000 Gulf War veterans and 15,000 veterans who served during the same era. Data had been collected from 9,970 respondents in 2003-2005 via a structured questionnaire or telephone survey. RESULTS: Based upon body mass index (BMI) estimated from self-reported information about height and weight, the percentages of Gulf War and Gulf Era veterans who were overweight (BMI 25 to ≤ 29.9), were 46.8% and 48.7%, respectively. The percentages who were obese (BMI ≥ 30) were 29.6% and 28.3%, respectively. Without adjustment for Gulf deployment status (Gulf War vs Gulf Era), age, sex, or other factors, PTSD, MSI, CFS-like illness, and other chronic health conditions were more common among obese veterans than those who were normal weight (BMI 18.5 to ≤ 24.9). In multivariate analyses, PTSD was positively associated with obesity after adjustment for age, sex, Gulf deployment status, rank, income,

				education, and current smoking. In the model for PTSD, the adjusted odds ratio for obesity was 1.5 (95% CI 1.2-1.8). No associations were observed between BMI categories and CFS-like illness or MSI in multivariate analysis. CONCLUSIONS: Gulf War and Gulf Era veterans who were obese were more likely to have certain chronic health conditions including PTSD. Associations between Gulf status and CFS-like illness and MSI identified in the 2003-2005 follow-up survey were not accounted for by group differences in the prevalence of overweight or obesity.
Crawley EM, Emond AM, Sterne JA.	Centre for Child and Adolescent Health, School of Social and Community Medicine, Bristol, UK.	Unidentified Chronic Fatigue Syndrome/myalgic encephalomyelitis (CFS/ME) is a major cause of school absence: surveillance outcomes from school-based clinics.	BMJ Open. 2011 Dec 12;1(2):e000252. Print 2011.	Objective To investigate the feasibility of conducting clinics for chronic fatigue syndrome/myalgic encephalomyelitis (CFS/ME) in schools. Design School-based clinical project. Participants Children aged 11-16 years were enrolled in three state secondary schools in England. Main outcome measures Number of children newly diagnosed as having CFS/ME. Methods Attendance officers identified children missing ≥20% of school in a 6-week term without a known cause, excluding those with a single episode off school, a known medical illness explaining the absence or known to be truanting. Children with fatigue were referred to a specialist CFS/ME service for further assessment. The authors compared children with CFS/ME identified through school-based clinics with those referred via health services. Outcomes of CFS/ME were evaluated at 6 weeks and 6 months. Results 461 of the 2855 enrolled children had missed ≥20% school over a 6-week period. In 315, of whom three had CFS/ME, the reason for absence was known. 112 of the 146 children with unexplained absence attended clinical review at school; two had been previously diagnosed as having CFS/ME and 42 were referred on to a specialist clinic, where 23 were newly diagnosed as having CFS/ME. Therefore, 28 of the 2855 (1.0%) children had CFS/ME. Children with CFS/ME identified through surveillance had been ill for an amount of time comparable to those referred via health services but had less fatigue (mean difference 4.4, 95% CI 2.2 to 6.6), less disability (mean difference -5.7, 95% CI -7.9 to -3.5) and fewer symptoms (mean difference 1.86, 95% CI 0.8 to 2.93). Of 19 children followed up, six had fully recovered at 6 weeks and a further six at 6 months. Conclusions Chronic fatigue is an important cause of unexplained absence from school. Children diagnosed through school-based clinics are less severely affected than those referred to specialist services and appear to make rapid progress when they access treatment.
Daniels J, Wearden AJ.	Department of Psychology, University of Bath, Claverton Down, Bath, UK. jo.daniels@live.com	Socialization to the model: the active component in the therapeutic alliance? A preliminary study.	Behav Cogn Psychother. 2011 Mar;39(2):221-7. Epub 2010 Nov 22.	BACKGROUND: Therapeutic alliance has been found to be a significant predictor of outcome in psychotherapy yet what constitutes therapeutic alliance remains unclear. Examining the common constructs of therapeutic alliance, it is possible that there may be a conceptual overlap between active components of therapeutic alliance and socialization to the treatment model. Aim: To investigate the relationship between socialization to the model and therapeutic alliance. METHOD: Participants (N = 43) were taken from the active treatment arm in a RCT for the treatment of chronic fatigue syndrome (CFS/ME). Therapeutic alliance was measured using a 5-item questionnaire (brief CALPAS) and socialization to the model was extracted from

				therapy tapes using a novel coding system. RESULTS: Key findings were that when patients and therapists agreed about goals of treatment, there were higher levels of concordance, less evidence of applying principles incongruent to the model, and less resistance during the treatment sessions. CONCLUSIONS: The outcome of this preliminary study contributes to the potential understanding of active components in the therapeutic alliance, and supports further research to achieve a more detailed picture of "non-specific" factors in therapy, including the active process of socialization in therapeutic alliance.
Dansie EJ, Furberg H, Afari N, Buchwald D, Edwards K, Goldberg J, Schur E, Sullivan PF.	Center for Clinical and Epidemiological Research, University of Washington, Seattle, WA 98101, USA. Edansie@uw.edu	Conditions comorbid with chronic fatigue in a population-based sample.	Psychosomatics. 2012 Jan;53(1):44-50. Epub 2011 Sep 22.	BACKGROUND: Chronic fatigue syndrome (CFS) has been found to be comorbid with various medical conditions in clinical samples, but little research has investigated CFS comorbidity in population-based samples. OBJECTIVE: This study investigated conditions concurrent with a CFS-like illness among twins in the population-based Mid-Atlantic Twin Registry (MATR), including chronic widespread pain (CWP), irritable bowel syndrome (IBS), and major depressive disorder (MDD). METHOD: A survey was mailed to participants in the MATR in 1999. Generalized estimating equations were used to estimate odds ratios to assess associations between CFS-like illness and each comorbid condition. RESULTS: A total of 4590 completed surveys were collected. Most participants were female (86.3%); mean age was 44.7 years. Among participants with a CFS-like illness, lifetime prevalences of CWP, IBS, and MDD were 41%, 16%, and 57% respectively. Participants reporting at least one of the three comorbid conditions were about 14 times more likely to have CFS-like illness than those without CWP, IBS, or MDD (95% confidence interval 8.1%-21.3%). Only MDD showed a temporal pattern of presentation during the same year as diagnosis of CFS-like illness. Age, gender, body mass index, age at illness onset, exercise level, self-reported health status, fatigue symptoms, and personality measures did not differ between those reporting CFS-like illness with and without comorbidity. CONCLUSION: These results support findings in clinically based samples that CFS-like illness is frequently cormorbid with CWP, IBS, and/or MDD. We found no evidence that CFS-like illnesses with comorbidities are clinically distinct from those without comorbidities. Copyright © 2012 The Academy of Psychosomatic Medicine. Davenport TE, Stevens SR, Baroni K, Van Ness JM, Snell CR.	Department of Physical Therapy, Thomas J. Long School of Pharmacy and Health Sciences, University of the Pacific, Stockton, California, USA.	Reliability and validity of Short Form 36 Version 2 to measure health perceptions in a sub-group of individuals with fatigue.	Disabil Rehabil. 2011;33(25-26):2596-604. Epub 2011 Jun 20.	PURPOSE: To determine the validity and reliability of Short Form 36 Version 2 (SF36v2) in sub-groups of individuals with fatigue. METHOD: Thirty subjects participated in this study, including n = 16 subjects who met case definition criteria for chronic fatigue syndrome (CFS) and n = 14 non-disabled sedentary matched control subjects. SF36v2 and Multidimensional Fatigue Inventory (MFI-20) were administered before two maximal cardiopulmonary exercise tests (CPETs) administered 24 h apart and an open-ended recovery questionnaire was administered 7 days after CPET challenge. The main outcome measures were self-reported time to recover to pre-challenge functional and symptom status, frequency of post-exertional symptoms and

	tdavenport@pacific.edu			SF36v2 sub-scale scores. RESULTS: Individuals with CFS demonstrated significantly lower SF36v2 and MFI-20 sub-scale scores prior to CPET. Between-group differences remained significant post-CPET, however, there were no significant group by test interaction effects. Subjects with CFS reported significantly more total symptoms ($p < 0.001$), as well as reports of fatigue ($p < 0.001$), neuroendocrine ($p < 0.001$), immune ($p < 0.01$), pain ($p < 0.01$) and sleep disturbance ($p < 0.01$) symptoms than control subjects as a result of CPET. Many symptom counts demonstrated significant relationships with SF36v2 sub-scale scores ($p < 0.05$). SF36v2 and MFI-20 sub-scale scores demonstrated significant correlations ($p < 0.05$). Various SF36v2 sub-scale scores demonstrated significant predictive validity to identify subjects who recovered from CPET challenge within 1 day and 7 days ($p < 0.05$). Potential floor effects were observed for both questionnaires for individuals with CFS. CONCLUSION: Various sub-scales of SF36v2 demonstrated adequate reliability and validity for clinical and research applications. Adequacy of sensitivity to change of SF36v2 as a result of a fatiguing stressor should be the subject of additional study.
Davenport TE, Stevens SR, Baroni K, Van Ness M, Snell CR.	Department of Physical Therapy, Thomas J. Long School of Pharmacy and Health Sciences, University of the Pacific, Stockton, CA 95211, USA. tdavenport@pacific.edu	Diagnostic accuracy of symptoms characterising chronic fatigue syndrome.	Disabil Rehabil. 2011;33(19-20):1768-75. Epub 2011 Jan 6.	PURPOSE: To determine the diagnostic accuracy for single symptoms and clusters of symptoms to distinguish between individuals with and without chronic fatigue syndrome (CFS). METHODS: A cohort study was conducted in an exercise physiology laboratory in an academic setting. Thirty subjects participated in this study ($n = 16$ individuals with CFS; $n = 14$ non-disabled sedentary matched control subjects). An open-ended symptom questionnaire was administered 1 week following the second of two maximal cardiopulmonary exercise tests administered 24 h apart. RESULTS: Receiver operating characteristics (ROC) curve analysis was significant for failure to recover within 1 day (area under the curve = 0.864, 95% confidence interval [CI]: 0.706-1.00, $p = 0.001$) but not within 7 days. Clinimetric properties of failure to recover within 1 day to predict membership in the CFS cohort were sensitivity 0.80, specificity 0.93, positive predictive value 0.92, negative predictive value 0.81, positive likelihood ratio 11.4, and negative likelihood ratio 0.22. Fatigue demonstrated high sensitivity and modest specificity to distinguish between cohorts, while neuroendocrine dysfunction, immune dysfunction, pain, and sleep disturbance demonstrated high specificity and modest sensitivity. ROC analysis suggested cut-point of three associated symptoms (0.871, 95% CI: 0.717-1.00, $p < 0.001$). A significant binary logistic regression model ($p < 0.001$) revealed immune abnormalities, sleep disturbance and pain accurately classified 92% of individuals with CFS and 88% of control subjects. CONCLUSIONS: A cluster of associated symptoms distinguishes between individuals with and without CFS. Fewer associated symptoms may be necessary to establish a diagnosis of CFS than currently described.
Davidson JR, Crawford C, Ives JA, Jonas WB.	Department of Psychiatry and Behavioral	Homeopathic treatments in psychiatry: a	J Clin Psychiatry. 2011 Jun;72(6):795-805.	OBJECTIVE: To systematically review placebo-controlled randomized trials of homeopathy for psychiatric conditions. DATA SOURCES: Eligible studies were identified using the following databases from database inception to April 2010:

	Science, Duke University Medical Center, Durham, North Carolina, USA. jonathan.davidson@duke.edu	systematic review of randomized placebo-controlled studies.		PubMed, CINAHL, PsycINFO, Hom-Inform, Cochrane CENTRAL, National Center for Complementary and Alternative Medicine grantee publications database, and ClinicalTrials.gov. Gray literature was also searched using Google, Google Scholar, the European Committee for Homeopathy, inquiries with homeopathic experts and manufacturers, and the bibliographic lists of included published studies and reviews. Search terms were as follows: (homeopath* or homoeopath*) and (placebo or sham) and (anxiety or panic or phobia or post-traumatic stress or PTSD or obsessive-compulsive disorder or fear or depress* or dysthym* or attention deficit hyperactivity or premenstrual syndrome or premenstrual disorder or premenstrual dysphoric disorder or traumatic brain injury or fibromyalgia or chronic fatigue syndrome or myalgic encephalitis or insomnia or sleep disturbance). Searches included only English-language literature that reported randomized controlled trials in humans. STUDY SELECTION: Trials were included if they met 7 criteria and were assessed for possible bias using the Scottish Intercollegiate Guidelines Network (SIGN) 50 guidelines. Overall assessments were made using the Grading of Recommendations Assessment, Development and Evaluation procedure. Identified studies were grouped into anxiety or stress, sleep or circadian rhythm complaints, premenstrual problems, attention-deficit/hyperactivity disorder, mild traumatic brain injury, and functional somatic syndromes. RESULTS: Twenty-five eligible studies were identified from an initial pool of 1,431. Study quality according to SIGN 50 criteria varied, with 6 assessed as good, 9 as fair, and 10 as poor. Outcome was unrelated to SIGN quality. Effect size could be calculated in 16 studies, and number needed to treat, in 10 studies. Efficacy was found for the functional somatic syndromes group (fibromyalgia and chronic fatigue syndrome), but not for anxiety or stress. For other disorders, homeopathy produced mixed effects. No placebo-controlled studies of depression were identified. Meaningful safety data were lacking in the reports, but the superficial findings suggested good tolerability of homeopathy. A funnel plot in 13 studies did not support publication bias ($\chi(2)(1) = 1.923$, $P = .166$). CONCLUSIONS: The database on studies of homeopathy and placebo in psychiatry is very limited, but results do not preclude the possibility of some benefit. © Copyright 2011 Physicians Postgraduate Press, Inc.
de Carvalho Leite JC, de L Drachler M, Killett A, Kale S, Nacul L, McArthur M, Hong CS, O'Driscoll L, Pheby D, Campion P, Lacerda E, Poland F.	School of Allied Health Professions, University of East Anglia, Norwich, England, United Kingdom, NR4 7TJ, UK. f.poland@uea.ac.	Social support needs for equity in health and social care: a thematic analysis of experiences of people with chronic fatigue syndrome/myalgic encephalomyelitis.	Int J Equity Health. 2011 Nov 2;10(1):46.	ABSTRACT:BACKGROUND: Needs-based resource allocation is fundamental to equitable care provision, which can meet the often-complex, fluctuating needs of people with Chronic Fatigue Syndrome/Myalgic Encephalomyelitis (CFS/ME). This has posed challenges both for those providing and those seeking support providers, in building shared understanding of the condition and of actions to address it. This qualitative study reports on needs for equity in health and social care expressed by adults living with CFS/ME. METHODS: The participants were 35 adults with CFS/ME in England, purposively selected to provide variation in clinical presentations, social backgrounds and illness experiences. Accounts of experienced needs and needs-

	uk.			related encounters with health and social services were obtained through a focus group (n = 6) and semi-structured interviews (n = 35). These were transcribed and needs related topics identified through data-led thematic analysis. FINDINGS: Participants emphasised needs for personalised, timely and sustained support to alleviate CFS/ME impacts and regain life control, in three thematic areas: (1) Illness symptoms, functional limitations and illness management; (2) practical support and social care; (3) financial support. Access of people with CFS/ME to support from health and social services was seen to be constrained by barriers stemming from social, cultural, organisational and professional norms and practices, further heightened for disadvantaged groups including some ethnic minorities. These reduced opportunities for their illness to be explained or associated functional limitations and social disadvantages to be addressed through social support. Participants sought more understanding of bio-psycho-social aspects of CFS/ME, of felt needs of people with CFS/ME and of human rights and disability rights, for providing person-centred, equitable care. CONCLUSIONS: Changes in attitudes of health practitioners, policy makers and general public and more flexibly organised health and social care provision are needed to address equity issues in support needs expressed by people with CFS/ME, to be underpinned by research-based knowledge and communication, for public and professional education. Policy development should include shared decision-making and coordinated action across organizations working for people with CFS/ME, human rights and disadvantaged groups. Experiences of people with CFS/ME can usefully inform an understanding of equity in their health and social care.
De Luca C, Raskovic D, Pacifico V, Thai JC, Korkina L.	Tissue Engineering & Skin Pathophysiology Laboratory and 2nd Dermatology Division, Dermatological Research Institute (IDI IRCCS), Via Monti di Creta 104, Rome 00167, Italy. c.deluca@idi.it	The search for reliable biomarkers of disease in multiple chemical sensitivity and other environmental intolerances.	Int J Environ Res Public Health. 2011 Jul;8(7):2770-97. Epub 2011 Jul 1.	Whilst facing a worldwide fast increase of food and environmental allergies, the medical community is also confronted with another inhomogeneous group of environment-associated disabling conditions, including multiple chemical sensitivity (MCS), fibromyalgia, chronic fatigue syndrome, electric hypersensitivity, amalgam disease and others. These share the features of poly-symptomatic multi-organ cutaneous and systemic manifestations, with postulated inherited/acquired impaired metabolism of chemical/physical/nutritional xenobiotics, triggering adverse reactions at exposure levels far below toxicologically-relevant values, often in the absence of clear-cut allergologic and/or immunologic involvement. Due to the lack of proven pathogenic mechanisms generating measurable disease biomarkers, these environmental hypersensitivities are generally ignored by sanitary and social systems, as psychogenic or "medically unexplained symptoms". The uncontrolled application of diagnostic and treatment protocols not corresponding to acceptable levels of validation, safety, and clinical efficacy, to a steadily increasing number of patients demanding assistance, occurs in many countries in the absence of evidence-based guidelines. Here we revise available information supporting the organic nature of these clinical conditions. Following intense research on gene polymorphisms of phase

				I/II detoxification enzyme genes, so far statistically inconclusive, epigenetic and metabolic factors are under investigation, in particular free radical/antioxidant homeostasis disturbances. The finding of relevant alterations of catalase, glutathione-transferase and peroxidase detoxifying activities significantly correlating with clinical manifestations of MCS, has recently registered some progress towards the identification of reliable biomarkers of disease onset, progression, and treatment outcomes.
de Souza PA, Matheus SM, Castan EP, Campos DH, Cicogna AC, Carvalho RF, Dal-Pai-Silva M.	Department of Morphology, Institute of Biosciences, UNESP, Botucatu, São Paulo, Brazil. pats_souza@yahoo.com.br	Morphological aspects of neuromuscular junctions and gene expression of nicotinic acetylcholine receptors (nAChRs) in skeletal muscle of rats with heart failure.	J Mol Histol. 2011 Dec;42(6):557-65. Epub 2011 Sep 18.	HF is syndrome initiated by a reduction in cardiac function and it is characterized by the activation of compensatory mechanisms. Muscular fatigue and dyspnoea are the more common symptoms in HF; these may be due in part to specific skeletal muscle myopathy characterized by reduced oxidative capacity, a shift from slow fatigue resistant type I to fast less fatigue resistant type II fibers and downregulation of myogenic regulatory factors (MRFs) gene expression that can regulate gene expression of nicotinic acetylcholine receptors (nAChRs). In chronic heart failure, skeletal muscle phenotypic changes could influence the maintenance of the neuromuscular junction morphology and nAChRs gene expression during this syndrome. Two groups of rats were studied: control (CT) and Heart Failure (HF), induced by a single intraperitoneal injection of monocrotaline (MCT). At the end of the experiment, HF was evaluated by clinical signs and animals were sacrificed. Soleus (SOL) muscles were removed and processed for morphological, morphometric and molecular NMJ analyses. Our major finding was an up-regulation in the gene expression of the alpha1 and epsilon subunits of nAChR and a spot pattern of nAChR in SOL skeletal muscle in this acute monocrotaline induced HF. Our results suggest a remodeling of nAChR alpha1 and epsilon subunit during heart failure and may provide valuable information for understanding the skeletal muscle myopathy that occurs during this syndrome.
de Tommaso M, Federici A, Serpino C, Vecchio E, Franco G, Sardaro M, Delussi M, Livrea P.	Neurophysiopathology of Pain Unit, Neurological and Psychiatric Sciences Department, Medical Faculty, Policlinico General Hospital, Aldo Moro University, Neurological Building, Piazza Giulio Cesare 11,	Clinical features of headache patients with fibromyalgia comorbidity.	J Headache Pain. 2011 Dec;12(6):629-38. Epub 2011 Aug 17.	Our previous study assessed the prevalence of fibromyalgia (FM) syndrome in migraine and tension-type headache. We aimed to update our previous results, considering a larger cohort of primary headache patients who came for the first time at our tertiary headache ambulatory. A consecutive sample of 1,123 patients was screened. Frequency of FM in the main groups and types of primary headaches; discriminating factor for FM comorbidity derived from headache frequency and duration, age, anxiety, depression, headache disability, allodynia, pericranial tenderness, fatigue, quality of life and sleep, and probability of FM membership in groups; and types of primary headaches were assessed. FM was present in 174 among a total of 889 included patients. It prevailed in the tension-type headache main group (35%, $p < 0.0001$) and chronic tension-type headache subtype (44.3%, $p < 0.0001$). Headache frequency, anxiety, pericranial tenderness, poor sleep quality, and physical disability were the best discriminating variables for FM comorbidity, with 81.2% sensitivity. Patients presenting with chronic migraine and chronic tension-type

	70124, Bari, Italy. m.detommaso@neurol.uniba.it			headache had a higher probability of sharing the FM profile (Bonferroni test, $p < 0.01$). A phenotypic profile where headache frequency concurs with anxiety, sleep disturbance, and pericranial tenderness should be individuated to detect the development of diffuse pain in headache patients.
Delviks-Frankenberry KA, Chaipan C, Bagni R, Wyvill K, Yarchoan R, Pathak VK.	Viral Mutation Section, HIV Drug Resistance Program, National Cancer Institute at Frederick, National Institutes of Health, Frederick, MD 21702, USA.	Lack of Detection of Xenotropic Murine Leukemia Virus-Related Virus in HIV-1 Lymphoma Patients.	Adv Virol. 2011;2011:797820. Epub 2011 Sep 8.	Xenotropic murine leukemia virus-related virus (XMRV) is a gammaretrovirus reported to be associated with human prostate cancer and chronic fatigue syndrome. Since retroviruses cause various cancers, and XMRV replication might be facilitated by HIV-1 co-infection, we asked whether certain patients with HIV-associated lymphomas are infected with XMRV. Analysis of PMBCs and plasma from 26 patients failed to detect XMRV by PCR, ELISA, or Western blot, suggesting a lack of association between XMRV and AIDS-associated lymphomas.

Dittner AJ, Rimes K, Thorpe S.	South London & Maudsley NHS Trust, Chronic Fatigue Syndrome Unit, London, SE5 8AZ UK.	Negative perfectionism increases the risk of fatigue following a period of stress.	Psychol Health. 2011 Mar;26(3):253-68. Epub 2010 Feb 18.	Cognitive-behavioural models of excessive fatigue suggest that people who believe that failure to meet high standards indicates unacceptability to others (a form of 'negative perfectionism') are at risk of fatigue after a period of illness or stress. The present study investigates this using a prospective design and possible mediating factors between such beliefs and fatigue were also investigated. Undergraduate students completed questionnaires at the beginning of the academic year (time 1; n = 436) and again following a time of academic pressure, 16 weeks later (time 2; n = 206). Participants were significantly more fatigued at time 2 than at time 1. Negative perfectionism was positively associated with all measures of fatigue and predicted subsequent levels of physical fatigue after controlling for time 1 fatigue. Time 1 negative perfectionism was not associated with time 2 perfectionist studying behaviours, distress about academic work or specific health behaviours, but was associated with time 2 depression. Results also indicated that time 2 depression may account for the relationship between baseline negative perfectionism and subsequent fatigue. This is the first prospective study to demonstrate a significant relationship between perfectionism and subsequent fatigue.
Diószeghy P.	Jósa András Oktatókórház Egészségügyi Szolgáltató Nonprofit Kft., Neurológiai	[Diagnosis of immune-mediated neuropathies]. [Article in Hungarian]	Orv Hetil. 2011 Sep 25;152(39):1560-8.	Separate discussion of immune-mediated neuropathies from other neuropathies is justified by the serious consequences of the natural course of these diseases, like disability and sometimes even life threatening conditions. On the other hand nowadays effective treatments already exist, and with timely and correct diagnosis an appropriately chosen treatment may result in significant improvement of quality of life, occasionally even complete recovery. These are rare diseases, and the increasing

	Osztály, Nyíregyháza. dioszeghy@josa.hu			number of different variants makes it more difficult to recognize them. Their diagnosis is based on the precise knowledge of clinical signs and symptoms, and it is verified by the help of neurophysiologic and laboratory, first of all CSF examinations. Description of clinical features of the classic acute immune-mediated neuropathy, characterized by ascending paresis and demyelination is followed by a summary of characteristics of newly recognized axonal, regional and functional variants. Chronic immune-mediated demyelinating polyneuropathies are not diagnosed in due number even today. This paper does not only present the classic form but it also introduces the ever increasing special variants, like distal acquired demyelinating sensory neuropathy, Lewis-Sumner syndrome, multifocal motor neuropathy and paraproteinemic neuropathies. Vasculitic neuropathies can be divided into two groups: systemic and non-systemic ones. The first sign of a vasculitic neuropathy is a progressive, painful mononeuropathy; the classic clinical presentation is the mononeuritis multiplex. It is characterized by general signs like fever, loss of weight, fatigue. In systemic vasculitis organ specific symptoms are also present. From the paraneoplastic diseases the subacute sensory neuropathy and the sensory neuronopathy are members of the immune-mediated neuropathies, being most frequently associated with small cell lung cancer.
Djukic M, Schmidt-Samoa C, Nau R, von Steinbüchel N, Eiffert H, Schmidt H.	Department of Neurology, University of Goettingen, Goettingen, Germany.	The diagnostic spectrum in patients with suspected chronic Lyme neuroborreliosis--the experience from one year of a university hospital's Lyme neuroborreliosis outpatients clinic.	Eur J Neurol. 2011 Apr;18(4):547-55. doi: 10.1111/j.1468-1331.2010.03229.x. Epub 2010 Oct 27.	BACKGROUND AND PURPOSE: Studies addressing the diagnostic relevance of anti-Borrelia burgdorferi (BB) serum antibodies in patients with non-specific symptoms and suspected chronic Lyme neuroborreliosis (LNB) are scarce. METHODS: In this study, we enrolled within 1 year 122 patients with suspected chronic LNB. One hundred and fourteen patients had previously tested positive for BB. All patients had previously received antibiotic treatment. Each patient received a clinical examination and measurement of BB-specific antibodies. The diagnosis of neuroborreliosis was made according to the national guidelines of the German Society of Neurology. Nine patients had acute borreliosis. One of the nine met the criteria of acute LNB. Of the remaining 113 patients, 85 patients underwent a lumbar puncture. Ten seronegative subjects without lumbar puncture were also considered. In 61.8% of these 95 patients the quality of life, of sleep, mood, and anxiety were assessed. RESULTS: Of 95 patients, 25.3% had symptoms without a somatic cause or evidence of borreliosis, 38.9% had a well-defined illness unrelated to BB infection, and 29.5% suffered from symptoms without a detectable somatic cause, displaying antibodies against BB. Six patients were grouped as post-LNB syndrome. Most common symptoms in all categories were arthralgia, myalgia, dysaesthesia, depressive mood and chronic fatigue. CONCLUSION: Patients with persistent symptoms with elevated serum antibodies against BB but without signs of cerebrospinal fluid inflammation require further diagnostic examinations to exclude ongoing infection and to avoid co-infections and other treatable conditions (e.g. autoimmune diseases). One patient with acute LNB, who was treated with ceftriaxone for 3 weeks suffered from LNB with

				new headaches and persistent symptoms 6 months later. These data should encourage further studies with new experimental parameters. © 2010 The Author(s). European Journal of Neurology © 2010 EFNS.
Dodd RY, Hackett J Jr, Linnen JM, Dorsey K, Wu Y, Zou S, Qiu X, Swanson P, Schochetman G, Gao K, Carrick JM, Krysztof DE, Stramer SL.	American Red Cross Holland Laboratory, Rockville, Maryland 20855, USA. dodd@usa.redcross.org	Xenotropic murine leukemia virus-related virus does not pose a risk to blood recipient safety.	Transfusion. 2012 Feb;52(2):298-306. doi: 10.1111/j.1537-2995.2011.03450.x. Epub 2011 Nov 21.	BACKGROUND: When xenotropic murine leukemia virus-related virus (XMRV) was first reported in association with chronic fatigue syndrome, it was suggested that it might offer a risk to blood safety. Thus, the prevalence of the virus among blood donors and, if present, its transmissibility by transfusion need to be defined. STUDY DESIGN AND METHODS: Two populations of routine blood donor samples (1435 and 13,399) were obtained for prevalence evaluations; samples from a linked donor-recipient repository were also evaluated. Samples were tested for the presence of antibodies to XMRV-related recombinant antigens and/or for XMRV RNA, using validated, high-throughput systems. RESULTS: The presence of antibodies to XMRV could not be confirmed among a total of 17,249 blood donors or recipients (0%; 95% confidence interval [CI], 0%-0.017%); 1763 tested samples were nonreactive for XMRV RNA (0%; 95% CI, 0%-0.17%). Evidence of infection was absent from 109 recipients and 830 evaluable blood samples tested after transfusion of a total of 3741 blood components. CONCLUSIONS: XMRV and related murine leukemia virus (MLV) markers are not present among a large population of blood donors and evidence of transfusion transmission could not be detected. Thus, these viruses do not currently pose a threat to blood recipient safety and further actions relating to XMRV and MLV are not justified. © 2012 American Association of Blood Banks.
Dodd RY.	Research & Development, American Red Cross, Holland Laboratory, Rockville, MD 20855, USA. dodd@usa.redcross.org	Chronic fatigue syndrome, XMRV and blood safety.	Future Microbiol. 2011 Apr;6(4):385-9.	In the past few months, there has been public discussion relating to a new perspective on blood safety and specifically upon measures to prevent or discourage donation by individuals with a diagnosis of myalgic encephalopathy-chronic fatigue syndrome. This reflects an intriguing interplay between science, public health and public concern and illustrates some of the difficulties of making decisions in the face of uncertainty and inadequate information.
Duffy FH, McAnulty GB, McCreary MC, Cuchural GJ, Komaroff AL.	Department of Neurology, Children's Hospital Boston and Harvard Medical School, 300 Longwood Ave, Boston, Massachusetts 02115, USA.	EEG spectral coherence data distinguish chronic fatigue syndrome patients from healthy controls and depressed patients--a case control study.	BMC Neurol. 2011 Jul 1;11:82.	BACKGROUND: Previous studies suggest central nervous system involvement in chronic fatigue syndrome (CFS), yet there are no established diagnostic criteria. CFS may be difficult to differentiate from clinical depression. The study's objective was to determine if spectral coherence, a computational derivative of spectral analysis of the electroencephalogram (EEG), could distinguish patients with CFS from healthy control subjects and not erroneously classify depressed patients as having CFS. METHODS: This is a study, conducted in an academic medical center electroencephalography laboratory, of 632 subjects: 390 healthy normal controls, 70 patients with carefully defined CFS, 24 with major depression, and 148 with general fatigue. Aside from fatigue, all patients were medically healthy by history and examination. EEGs were

	fhd@sover.net			obtained and spectral coherences calculated after extensive artifact removal. Principal Components Analysis identified coherence factors and corresponding factor loading patterns. Discriminant analysis determined whether spectral coherence factors could reliably discriminate CFS patients from healthy control subjects without misclassifying depression as CFS. RESULTS: Analysis of EEG coherence data from a large sample (n = 632) of patients and healthy controls identified 40 factors explaining 55.6% total variance. Factors showed highly significant group differentiation ($p < .0004$) identifying 89.5% of unmedicated female CFS patients and 92.4% of healthy female controls. Recursive jackknifing showed predictions were stable. A conservative 10-factor discriminant function model was subsequently applied, and also showed highly significant group discrimination ($p < .001$), accurately classifying 88.9% unmedicated males with CFS, and 82.4% unmedicated male healthy controls. No patient with depression was classified as having CFS. The model was less accurate (73.9%) in identifying CFS patients taking psychoactive medications. Factors involving the temporal lobes were of primary importance. CONCLUSIONS: EEG spectral coherence analysis identified unmedicated patients with CFS and healthy control subjects without misclassifying depressed patients as CFS, providing evidence that CFS patients demonstrate brain physiology that is not observed in healthy normals or patients with major depression. Studies of new CFS patients and comparison groups are required to determine the possible clinical utility of this test. The results concur with other studies finding neurological abnormalities in CFS, and implicate temporal lobe involvement in CFS pathophysiology.

Eglinton R, Chung MC.	Independent Medical and Psychological Services, Taunton,	The relationship between posttraumatic stress disorder, illness	Psychiatry Res. 2011 Jul 30;188(2):245-52. Epub 2011 May 19.	This study investigated, firstly, the rate of posttraumatic stress disorder (PTSD) and the level of psychological well-being amongst people with chronic fatigue syndrome (CFS); and secondly, the extent to which illness cognitions, defence styles and PTSD symptom severity related to fatigue severity and psychological well-being. Seventy-

	United Kingdom.	cognitions, defence styles, fatigue severity and psychological well-being in chronic fatigue syndrome.		eight participants with a diagnosis of CFS completed the Chalder Fatigue Scale, the General Health Questionnaire-28, the Posttraumatic Stress Diagnostic Scale, the Illness Cognition Questionnaire and the Defence Style Questionnaire. Fifty-nine participants were recruited from the general public to form the non-fatigued control group. CFS participants had significantly higher levels of PTSD symptoms, lower levels of psychological well-being and more traumatic life events compared to the non-fatigued controls. Trauma exposure and PTSD severity both predicted CFS status. However, regression analyses demonstrated no significant relationship between PTSD symptoms and fatigue severity or the degree of psychological well-being. 'Helplessness' predicted both physical and mental fatigue and psychological well-being, whilst the 'mature' defence styles predicted fatigue severity only. The results offer support to previous research showing that the rate of traumatic life events and PTSD are significantly higher amongst the CFS population. The lack of relationship between PTSD symptoms and fatigue severity or psychological well-being indicates that these processes may operate independently of one another, via different appraisal processes. This study focused on fatigue severity, but it may be that the role of pain in CFS is a key element in the previously reported association between PTSD and CFS. Copyright © 2011 Elsevier Ireland Ltd. Eichenauer DA, Engert A.	First Department of Internal Medicine, University Hospital of Cologne, Cologne, Germany.	Therapy-related myeloid neoplasms in patients treated for hodgkin lymphoma.	Mediterr J Hematol Infect Dis. 2011;3(1):e2011046. Epub 2011 Oct 24.	Hodgkin lymphoma (HL) is a malignancy of the lymphatic system with an incidence of 2-3/100.000/year in developed countries. With modern multi-agent chemotherapy protocols optionally combined with radiotherapy (RT), 80% to 90% of HL patients achieve long-term remission and can be considered cured. However, current standard approaches bear a considerable risk for the development of treatment-related late effects. Thus, one major focus of current clinical research in HL is reducing the incidence of these late effects that include heart failure, infertility, chronic fatigue and therapy-related myelodysplastic syndrome/acute myeloid leukemia (t-MDS/t-AML). In previous analyses, t-MDS/t-AML after treatment for HL was associated with a poor prognosis. Nearly all patients died rapidly after diagnosis. However, more recent analyses indicated an improved outcome among patients with t-MDS/t-AML who are eligible for modern anti-leukemic treatment and allogeneic stem cell transplantation (aSCT). This article gives an overview of recent reports on the incidence and the treatment of t-MDS/t-AML after HL therapy and describes the efforts currently made to reduce the risk to develop this severe late effect.
Elfaitouri A, Shao X, Mattsson Ulfstedt J, Muradrasoli S, Bölin Wiener A, Golbob S, Ohrmalm C,	Section of Clinical Virology, Department of Medical Sciences, University of Uppsala, Uppsala, Sweden.	Murine gammaretrovirus group G3 was not found in Swedish patients with myalgic encephalomyelitis/chronic fatigue	PLoS One. 2011;6(10):e24602. Epub 2011 Oct 12.	BACKGROUND: The recent report of gammaretroviruses of probable murine origin in humans, called xenotropic murine retrovirus related virus (XMRV) and human murine leukemia virus related virus (HMRV), necessitated a bioinformatic search for this virus in genomes of the mouse and other vertebrates, and by PCR in humans. RESULTS: Three major groups of murine endogenous gammaretroviruses were identified. The third group encompassed both exogenous and endogenous Murine Leukemia Viruses (MLVs), and most XMRV/HMRV sequences reported from patients suffering from

Matousek M, Zachrisson O, Gottfries CG, Blomberg J.		syndrome and fibromyalgia.		myalgic encephalomyelitis/chronic fatigue syndrome (ME/CFS). Two sensitive real-time PCRs for this group were developed. The predicted and observed amplification range for these and three published XMRV/HMRV PCRs demonstrated conspicuous differences between some of them, partly explainable by a recombinatorial origin of XMRV. Three reverse transcription real-time PCRs (RTQPCRs), directed against conserved and not overlapping stretches of env, gag and integrase (INT) sequences of XMRV/HMRV were used on human samples. White blood cells from 78 patients suffering from ME/CFS, of which 30 patients also fulfilled the diagnostic criteria for fibromyalgia (ME/CFS/FM) and in 7 patients with fibromyalgia (FM) only, all from the Gothenburg area of Sweden. As controls we analyzed 168 sera from Uppsala blood donors. We controlled for presence and amplifiability of nucleic acid and for mouse DNA contamination. To score as positive, a sample had to react with several of the XMRV/HMRV PCRs. None of the samples gave PCR reactions which fulfilled the positivity criteria. CONCLUSIONS: XMRV/HMRV like proviruses occur in the third murine gammaretrovirus group, characterized here. PCRs developed by us, and others, approximately cover this group, except for the INT RTQPCR, which is rather strictly XMRV specific. Using such PCRs, XMRV/HMRV could not be detected in PBMC and plasma samples from Swedish patients suffering from ME/CFS/FM, and in sera from Swedish blood donors.
Erlwein O, Robinson MJ, Kaye S, Wills G, Izui S, Wessely S, Weber J, Cleare A, Collier D, McClure MO.	Jefferiss Research Trust Laboratories, Section of Infectious Diseases, Wright-Fleming Institute, Faculty of Medicine, Imperial College London, London, United Kingdom.	Investigation into the presence of and serological response to XMRV in CFS patients.	PLoS One. 2011 Mar 9;6(3):e17592.	The novel human gammaretrovirus xenotropic murine leukemia virus-related virus (XMRV), originally described in prostate cancer, has also been implicated in chronic fatigue syndrome (CFS). When later reports failed to confirm the link to CFS, they were often criticised for not using the conditions described in the original study. Here, we revisit our patient cohort to investigate the XMRV status in those patients by means of the original PCR protocol which linked the virus to CFS. In addition, sera from our CFS patients were assayed for the presence of xenotropic virus envelope protein, as well as a serological response to it. The results further strengthen our contention that there is no evidence for an association of XMRV with CFS, at least in the UK.
Erlwein O, Robinson MJ, Dustan S, Weber J, Kaye S, McClure MO.	Jefferiss Research Trust Laboratories, Section of Infectious Diseases, Imperial College London, London, United Kingdom.	DNA extraction columns contaminated with murine sequences.	PLoS One. 2011;6(8):e23484. Epub 2011 Aug 18.	Sequences of the novel gammaretrovirus, xenotropic murine leukemia virus-related virus (XMRV) have been described in human prostate cancer tissue, although the amounts of DNA are low. Furthermore, XMRV sequences and polytropic (p) murine leukemia viruses (MLVs) have been reported in patients with chronic fatigue syndrome (CFS). In assessing the prevalence of XMRV in prostate cancer tissue samples we discovered that eluates from naïve DNA purification columns, when subjected to PCR with primers designed to detect genomic mouse DNA contamination, occasionally gave rise to amplification products. Further PCR analysis, using primers to detect XMRV, revealed sequences derived from XMRV and pMLVs

				from mouse and human DNA and DNA of unspecified origin. Thus, DNA purification columns can present problems when used to detect minute amounts of DNA targets by highly sensitive amplification techniques.

Evering RM, Tönis TM, Vollenbroek-Hutten MM.	Roessingh Research and Development, Post Box 310, 7500 AH Enschede, The Netherlands. r.evering@rrd.nl	Deviations in daily physical activity patterns in patients with the chronic fatigue syndrome: a case control study.	J Psychosom Res. 2011 Sep;71(3):129-35. Epub 2011 May 18.	OBJECTIVES: Deviations in daily physical activity patterns may play an important role in the development and maintenance of fatigue in the chronic fatigue syndrome (CFS). The aim of this study is to gain insight into the objective daily physical activity pattern of patients with CFS in comparison with healthy controls. The secondary objective is studying the awareness in performing physical activities. METHODS: The objective daily physical activity pattern was measured with a tri-axial accelerometer in 35 patients with CFS and in 35 age- and gender-matched healthy controls. The objective daily physical activity level and distribution of physical activities at low, medium and high intensity levels during the day were measured. Moreover, variability in performing physical activities within and between subjects was computed. Subjective ratings of self-reported daily physical activity levels were assessed at a visual analog scale. RESULTS: CFS patients were significantly less physically active in the afternoon and evening, and spent fewer activities at high intensity levels and more at low intensity levels. Moreover, CFS patients showed more variability in their own physical activity pattern during the afternoon. The heterogeneity in the physical activity pattern between subjects within the CFS and control group did not differ. Finally, CFS patients were more aware about their daily physical activity level than healthy controls. CONCLUSION: CFS patients showed deviations in the objectively measured daily physical activity pattern. Future research should elucidate the relation between impaired balances in daily physical activity patterns and fatigue severity in CFS. Copyright © 2011 Elsevier Inc. All rights reserved.
Evering RM, van Weering MG, Groothuis-Oudshoorn KC, Vollenbroek-Hutten MM.	Roessingh Research and Development, Enschede, The Netherlands. r.evering@rrd.nl	Daily physical activity of patients with the chronic fatigue syndrome: a systematic review.	Clin Rehabil. 2011 Feb;25(2):112-33. Epub 2010 Oct 13.	OBJECTIVE: To give an overview of the physical activity level of patients with chronic fatigue syndrome in comparison with asymptomatic controls. DATA SOURCES: MEDLINE, Web of Science, EMBASE, PsycINFO, Picarta, the Cochrane Controlled Trial Register that is included in the Cochrane Library and reference tracking. REVIEW METHODS: A systematic literature search was conducted focusing on studies concerning physical activity levels of patients with chronic fatigue syndrome compared to controls. A meta-analysis was performed to pool data of the studies. RESULTS: Seventeen studies were included with 22 different comparisons between patients with chronic fatigue syndrome and controls. Fourteen studies, including 18 comparisons, showed lower physical activity levels in patients with chronic fatigue syndrome as compared to controls. Four studies, including four comparisons, showed no differences between both groups. The meta-analysis included seven studies and showed a daily physical activity level in patients with chronic fatigue syndrome of only

				68% of the physical activity level observed in control subjects. The pooled mean coefficient of variation in patients with chronic fatigue syndrome was higher as compared to control subjects (34.3% versus 31.5%), but this difference did not reach significance. CONCLUSION: Patients with chronic fatigue syndrome appear to be less physically active compared with asymptomatic controls. There is no difference in variation of physical activity levels between patients with chronic fatigue syndrome and healthy control subjects, but the validity and reliability of some methods of measuring physical activity is questionable or unknown.
Falkenberg VR, Whistler T, Murray JR, Unger ER, Rajeevan MS.	Division of High-Consequence Pathogens and Pathology, Centers for Disease Control & Prevention, Atlanta, GA, 30333, USA. MRajeevan@cdc.gov.	Identification of Phosphoglycerate Kinase 1 (PGK1) as a reference gene for quantitative gene expression measurements in human blood RNA.	BMC Res Notes. 2011 Sep 6;4:324.	ABSTRACT:BACKGROUND: Blood is a convenient sample and increasingly used for quantitative gene expression measurements with a variety of diseases including chronic fatigue syndrome (CFS). Quantitative gene expression measurements require normalization of target genes to reference genes that are stable and independent from variables being tested in the experiment. Because there are no genes that are useful for all situations, reference gene selection is an essential step to any quantitative reverse transcription-PCR protocol. Many publications have described appropriate genes for a wide variety of tissues and experimental conditions, however, reference genes that may be suitable for the analysis of CFS, or human blood RNA derived from whole blood as well as isolated peripheral blood mononuclear cells (PBMCs), have not been described. FINDINGS: Literature review and analyses of our unpublished microarray data were used to narrow down the pool of candidate reference genes to six. We assayed whole blood RNA from Tempus tubes and cell preparation tube (CPT)-collected PBMC RNA from 46 subjects, and used the geNorm and NormFinder algorithms to select the most stable reference genes. Phosphoglycerate kinase 1 (PGK1) was one of the optimal normalization genes for both whole blood and PBMC RNA, however, additional genes differed for the two sample types; Ribosomal protein large, P0 (RPLP0) for PBMC RNA and Peptidylprolyl isomerase B (PPIB) for whole blood RNA. We also show that the use of a single reference gene is sufficient for normalization when the most stable candidates are used. CONCLUSIONS: We have identified PGK1 as a stable reference gene for use with whole blood RNA and RNA derived from PBMC. When stable genes are selected it is possible to use a single gene for normalization rather than two or three. Optimal normalization will improve the ability of results from PBMC RNA to be compared with those from whole blood RNA and potentially allows comparison of gene expression results from blood RNA collected and processed by different methods with the intention of biomarker discovery. Results of this study should facilitate large-scale molecular epidemiologic studies using blood RNA as the target of quantitative gene expression measurements.
Falkenberg VR, Gurbaxani BM, Unger ER,	Division of Viral and Rickettsial Diseases, Centers	Functional genomics of serotonin receptor 2A (HTR2A):	Neuromolecular Med. 2011 Mar;13(1):66-76. Epub 2010 Oct 13.	Serotonergic neurotransmission plays a key role in the pathophysiology of neuropsychiatric illnesses. The functional significance of a promoter polymorphism, -1438G/A (rs6311), in one of the major genes of this system (serotonin receptor 2A,

Rajeevan MS.	for Disease Control & Prevention, Atlanta, GA 30333, USA.	interaction of polymorphism, methylation, expression and disease association.		HTR2A) remains poorly understood in the context of epigenetic factors, transcription factors and endocrine influences. We used functional and structural equation modeling (SEM) approaches to assess the contributions of the polymorphism (rs6311), DNA methylation and clinical variables to HTR2A expression in chronic fatigue syndrome (CFS) subjects from a population-based study. HTR2A was up-regulated in CFS through allele-specific expression modulated by transcription factors at critical sites in its promoter: an E47 binding site at position -1,438, (created by the A-allele of rs6311 polymorphism), a glucocorticoid receptor (GR) binding site encompassing a CpG at position -1,420, and Sp1 binding at CpG methylation site -1,224. Methylation at -1,420 was strongly correlated with methylation at -1,439, a CpG site that is dependent upon the G-allele of rs6311 at position -1,438. SEM revealed a strong negative interaction between E47 and GR binding (in conjunction with cortisol level) on HTR2A expression. This study suggests that the promoter polymorphism (rs6311) can affect both transcription factor binding and promoter methylation, and this along with an individual's stress response can impact the rate of HTR2A transcription in a genotype and methylation-dependent manner. This study can serve as an example for deciphering the molecular determinants of transcriptional regulation of major genes of medical importance by integrating functional genomics and SEM approaches. Confirmation in an independent study population is required.

Felger JC, Cole SW, Pace TW, Hu F, Woolwine BJ, Doho GH, Raison CL, Miller AH.	Department of Psychiatry and Behavioral Sciences, Emory University, Atlanta, GA, USA.	Molecular signatures of peripheral blood mononuclear cells during chronic interferon-α treatment: relationship with depression and fatigue.	Psychol Med. 2011 Dec 9:1-13. [Epub ahead of print]	BACKGROUND: Interferon-alpha (IFN-α) treatment for infectious disease and cancer causes high rates of depression and fatigue, and has been used to investigate the impact of inflammatory cytokines on brain and behavior. However, little is known about the transcriptional impact of chronic IFN-α on immune cells in vivo and its relationship to IFN-α-induced behavioral changes.MethodGenome-wide transcriptional profiling was performed on peripheral blood mononuclear cells (PBMCs) from 21 patients with chronic hepatitis C virus (HCV) either awaiting IFN-α therapy (n=10) or at 12 weeks of IFN-α treatment (n=11). RESULTS: Significance analysis of microarray data identified 252 up-regulated and 116 down-regulated gene transcripts. Of the up-regulated genes, 2'-5'-oligoadenylate synthetase 2 (OAS2), a gene linked to chronic fatigue syndrome (CFS), was the only gene that was differentially expressed in patients with IFN-α-induced depression/fatigue, and correlated with depression and fatigue scores at 12 weeks (r=0.80, p=0.003 and r=0.70, p=0.017 respectively). Promoter-based bioinformatic analyses linked IFN-α-

				related transcriptional alterations to transcription factors involved in myeloid differentiation, IFN-α signaling, activator protein-1 (AP1) and cAMP responsive element binding protein/activation transcription factor (CREB/ATF) pathways, which were derived primarily from monocytes and plasmacytoid dendritic cells. IFN-α-treated patients with high depression/fatigue scores demonstrated up-regulation of genes bearing promoter motifs for transcription factors involved in myeloid differentiation, IFN-α and AP1 signaling, and reduced prevalence of motifs for CREB/ATF, which has been implicated in major depression. CONCLUSIONS: Depression and fatigue during chronic IFN-α administration were associated with alterations in the expression (OAS2) and transcriptional control (CREB/ATF) of genes linked to behavioral disorders including CFS and major depression, further supporting an immune contribution to these diseases.
Fernández AA, Martínez MI.		[Cognitive impairment: a reality in chronic fatigue syndrome]. [Article in Spanish]	Med Clin (Barc). 2011 Mar 12;136(6):248-9. Epub 2010 Dec 18. Comment in Med Clin (Barc). 2011 Nov 12;137(12):572; author reply 572-3.

Fiest KM, Currie SR, Williams JV, Wang J.	Department of Psychiatry, University of Calgary, Canada.	Chronic conditions and major depression in community-dwelling older adults.	J Affect Disord. 2011 Jun;131(1-3):172-8. Epub 2010 Dec 18.	OBJECTIVES: To estimate (1) the prevalence of long-term medical conditions and of comorbid major depression, and (2) the associations between major depression and various chronic medical conditions in a general population of older adults (over 50 years of age) and in persons who are traditionally classified as seniors (65 years and older). METHODS: Data from the Canadian Community Health Survey- Mental Health and Wellbeing (CCHS-1.2) were analyzed. Non-institutionalized individuals over 15 years of age in the 10 Canadian provinces were sampled in the CCHS-1.2. The entire sample of the CCHS-1.2 consisted of 36,894 individuals, for the main analyses in this study the dataset was restricted to those aged 50 and over (n=15,591). Chronic health conditions were assessed using a self-report method of doctor diagnosis. The World Mental Health-Composite Diagnostic Interview was used to asses major depressive episodes based on DSM-IV criteria. RESULTS: The overall prevalence of having at least one chronic condition in those over 50 years of age was 82.4%, compared to 62.0% in those under 50. The prevalence of a major depressive episode in those over 50 with one chronic condition was 3.7%, compared with 1.0% in those without a long-term

				medical condition. The top 3 chronic health conditions in seniors aged 65 or older were arthritis/rheumatism, high blood pressure and back problems. Chronic Fatigue Syndrome, fibromyalgia and migraine headache had the highest comorbidity with major depression in the senior population. LIMITATIONS: The use of self-report data on chronic health conditions, potential diagnostic overlap between conditions, and the inability to make causal inferences due to the cross-sectional nature of the data are all limitations of the current study. CONCLUSIONS: Differences were found between rates of chronic conditions and major depression between the general population, older adults and seniors in this study. Further research is needed to delineate the direction of these relationships in seniors. Primary and secondary prevention efforts should target seniors who exhibit symptoms of depression or highly prevalent chronic health conditions. Copyright © 2010 Elsevier B.V. All rights reserved.
Fitzgerald K.	Institute for Functional Medicine, USA. kf@drkarafizgerald.com	A case report of a 53-year-old female with rheumatoid arthritis and osteoporosis: focus on lab testing and CAM therapies.	Altern Med Rev. 2011 Sep;16(3):250-62.	A 53-year-old female presented with rheumatoid arthritis and osteoporosis. Additional conditions and symptoms included Raynaud syndrome, fatigue, irritable bowel syndrome associated constipation (IBS-C), gastroesophageal reflux (GERD), menopausal symptoms, chronic urinary tract and upper respiratory infections, and weight gain. She was taking Arthrotec (a combination of diclofenac and misoprostol - for pain and inflammation), Fosamax Plus D (alendronate with vitamin D3 - recently prescribed because of low bone density), and Catapres (clonidine - for menopausal symptoms). Against the advice of her rheumatologist, she had recently discontinued taking Plaquenil (hydroxychloroquine), methotrexate, and prednisone due to significant side effects. Lab tests to identify underlying imbalances and to direct treatment were ordered. Treatment included dietary, nutritional, hormonal, and mind/body support. After one year of therapy, the patient experienced improvement with all of her presenting conditions and symptoms, which enabled her to discontinue several medications. She became versed in identifying and avoiding the environmental triggers of her disease, including foods (dairy, wheat, eggs, and soy), molds, and emotional stress. Antinuclear antibodies were normalized. She experienced a 7.5-percent improvement in left trochanteric bone density - comparable to bisphosphonate therapy. Mild improvements were also noted in the spine and bilateral femoral neck.
Fluge Ø, Bruland O, Risa K, Storstein A, Kristoffersen EK, Sapkota D, Næss H, Dahl O, Nyland H, Mella O.	Department of Oncology and Medical Physics, Haukeland University Hospital, Bergen, Norway. oystein.fluge@gm	Benefit from B-lymphocyte depletion using the anti-CD20 antibody rituximab in chronic fatigue syndrome. A double-blind and placebo-controlled	PLoS One. 2011;6(10):e26358. Epub 2011 Oct 19.	BACKGROUND: Chronic fatigue syndrome (CFS) is a disease of unknown aetiology. Major CFS symptom relief during cancer chemotherapy in a patient with synchronous CFS and lymphoma spurred a pilot study of B-lymphocyte depletion using the anti-CD20 antibody Rituximab, which demonstrated significant clinical response in three CFS patients. METHODS AND FINDINGS: In this double-blind, placebo-controlled phase II study (NCT00848692), 30 CFS patients were randomised to either Rituximab 500 mg/m(2) or saline, given twice two weeks apart, with follow-up for 12 months. Xenotropic murine leukemia virus-related virus (XMRV) was not detected in any of the

	ail.com	study.		patients. The responses generally affected all CFS symptoms. Major or moderate overall response, defined as lasting improvements in self-reported Fatigue score during follow-up, was seen in 10 out of 15 patients (67%) in the Rituximab group and in two out of 15 patients (13%) in the Placebo group (p = 0.003). Mean response duration within the follow-up period for the 10 responders to Rituximab was 25 weeks (range 8-44). Four Rituximab patients had clinical response durations past the study period. General linear models for repeated measures of Fatigue scores during follow-up showed a significant interaction between time and intervention group (p = 0.018 for self-reported, and p = 0.024 for physician-assessed), with differences between the Rituximab and Placebo groups between 6-10 months after intervention. The primary end-point, defined as effect on self-reported Fatigue score 3 months after intervention, was negative. There were no serious adverse events. Two patients in the Rituximab group with pre-existing psoriasis experienced moderate psoriasis worsening. CONCLUSION: The delayed responses starting from 2-7 months after Rituximab treatment, in spite of rapid B-cell depletion, suggests that CFS is an autoimmune disease and may be consistent with the gradual elimination of autoantibodies preceding clinical responses. The present findings will impact future research efforts in CFS. TRIAL REGISTRATION: ClinicalTrials.gov NCT00848692.
Ford AC, Talley NJ.	Leeds Gastroenterology Institute, D Floor, Clarendon Wing, Leeds General Infirmary, Great George Street, Leeds LS1 3EX, UK. alexf12399@yahoo.com	Mucosal inflammation as a potential etiological factor in irritable bowel syndrome: a systematic review.	J Gastroenterol. 2011 Apr;46(4):421-31. Epub 2011 Feb 18.	BACKGROUND: The causes of irritable bowel syndrome (IBS) remain obscure. Some investigators have proposed chronic low-grade mucosal inflammation as a potential etiological factor. We performed a systematic review to examine this issue in detail. METHODS: MEDLINE, EMBASE, and EMBASE classic were searched up to December 2010 to identify studies of case-control design applying tests for low-grade inflammation to either full-thickness intestinal or endoscopic mucosal biopsies from patients with IBS. Controls were required to be healthy individuals, or asymptomatic patients undergoing investigation for reasons other than the reporting of upper or lower gastrointestinal symptoms. Individual study results were summarized descriptively. RESULTS: The literature search identified 1388 citations, of which 16 studies were eligible for inclusion. Individual study results were diverse, partly as a consequence of the different surrogate markers for inflammatory mechanisms studied. Mast cells, T lymphocytes, B lymphocytes, and mucosal cytokine production all appeared altered among cases with IBS in individual studies, while no study demonstrated a significant difference in numbers of plasma cells, neutrophils, or eosinophils. Some studies suggested a relationship between mast cell abnormalities and symptom severity and frequency, as well as co-existent fatigue and depression. Studies were limited by the lack of comparability of controls, and the fact that most were conducted in highly selected groups of patients with IBS. CONCLUSIONS: Low-grade mucosal inflammation, particularly mast cell activation, may be a contributory factor in the pathogenesis of IBS. Mast cell stabilizers warrant further assessment as a potential therapy in the condition.

Frampton D, Kerr J, Harrison TJ, Kellam P.	Department of Infection, Division of Infection and Immunity, University College London, London, United Kingdom.	Assessment of a 44 gene classifier for the evaluation of chronic fatigue syndrome from peripheral blood mononuclear cell gene expression.	PLoS One. 2011 Mar 30;6(3):e16872.	Chronic fatigue syndrome (CFS) is a clinically defined illness estimated to affect millions of people worldwide causing significant morbidity and an annual cost of billions of dollars. Currently there are no laboratory-based diagnostic methods for CFS. However, differences in gene expression profiles between CFS patients and healthy persons have been reported in the literature. Using mRNA relative quantities for 44 previously identified reporter genes taken from a large dataset comprising both CFS patients and healthy volunteers, we derived a gene profile scoring metric to accurately classify CFS and healthy samples. This metric out-performed any of the reporter genes used individually as a classifier of CFS.To determine whether the reporter genes were robust across populations, we applied this metric to classify a separate blind dataset of mRNA relative quantities from a new population of CFS patients and healthy persons with limited success. Although the metric was able to successfully classify roughly two-thirds of both CFS and healthy samples correctly, the level of misclassification was high. We conclude many of the previously identified reporter genes are study-specific and thus cannot be used as a broad CFS diagnostic.
Frost J, Okun S, Vaughan T, Heywood J, Wicks P.	VU Amsterdam, KankerNL, Amsterdam, Netherlands. jeana.frost@gmail.com	Patient-reported outcomes as a source of evidence in off-label prescribing: analysis of data from PatientsLikeMe.	J Med Internet Res. 2011 Jan 21;13(1):e6.	BACKGROUND: Evaluating a new use for an existing drug can be expensive and time consuming. Providers and patients must all too often rely upon their own individual-level experience to inform clinical practice, which generates only anecdotal and unstructured data. While academic-led clinical trials are occasionally conducted to test off-label uses of drugs with expired patents, this is relatively rare. In this work, we explored how a patient-centered online research platform could supplement traditional trials to create a richer understanding of medical products postmarket by efficiently aggregating structured patient-reported data. PatientsLikeMe is a tool for patients, researchers, and caregivers (currently 82,000 members across 11 condition-based communities) that helps users make treatment decisions, manage symptoms, and improve outcomes. Members enter demographic information, longitudinal treatment, symptoms, outcome data, and treatment evaluations. These are reflected back as longitudinal health profiles and aggregated reports. Over the last 3 years, patients have entered treatment histories and evaluations on thousands of medical products. These data may aid in evaluating the effectiveness and safety of some treatments more efficiently and over a longer period of time course than is feasible through traditional trials. OBJECTIVE: The objective of our study was to examine the illustrative cases of amitriptyline and modafinil - drugs commonly used off-label. METHODS: We analyzed patient-reported treatment histories and drug evaluations for each drug, examining prevalence, treatment purpose, and evaluations of effectiveness, side effects, and burden. RESULTS: There were 1948 treatment histories for modafinil and 1394 treatment reports for amitriptyline reported across five PatientsLikeMe communities (multiple sclerosis, Parkinson's disease, mood conditions, fibromyalgia/chronic fatigue syndrome, and amyotrophic lateral sclerosis). In these reports, the majority of members reported taking the drug for off-label uses.

				Only 34 of the 1755 (1%) reporting purpose used modafinil for an approved purpose (narcolepsy or sleep apnea). Only 104 out of 1197 members (9%) reported taking amitriptyline for its approved indication, depression. Members taking amitriptyline for off-label purposes rated the drug as more effective than those who were taking it for its approved indication. While dry mouth is a commonly reported side effect of amitriptyline for most patients, 88 of 220 (40%) of people with amyotrophic lateral sclerosis on the drug reported taking advantage of this side effect to treat their symptom of excess saliva. CONCLUSIONS: Patient-reported outcomes, like those entered within PatientsLikeMe, offer a unique real-time approach to understand utilization and performance of treatments across many conditions. These patient-reported data can provide a new source of evidence about secondary uses and potentially identify targets for treatments to be studied systematically in traditional efficacy trials.
Furuta RA, Miyazawa T, Sugiyama T, Kuratsune H, Ikeda Y, Sato E, Misawa N, Nakatomi Y, Sakuma R, Yasui K, Yamaguti K, Hirayama F.	Department of Research, Japanese Red Cross Osaka Blood Center, 2-4-43 Morinomiya, Joto-ku, Osaka 536-8505, Japan. furuta@osaka.bc.jrc.or.jp	No association of xenotropic murine leukemia virus-related virus with prostate cancer or chronic fatigue syndrome in Japan.	Retrovirology. 2011 Mar 17;8:20.	BACKGROUND: The involvement of xenotropic murine leukemia virus-related virus (XMRV) in prostate cancer (PC) and chronic fatigue syndrome (CFS) is disputed as its reported prevalence ranges from 0% to 25% in PC cases and from 0% to more than 80% in CFS cases. To evaluate the risk of XMRV infection during blood transfusion in Japan, we screened three populations--healthy donors (n = 500), patients with PC (n = 67), and patients with CFS (n = 100)--for antibodies against XMRV proteins in freshly collected blood samples. We also examined blood samples of viral antibody-positive patients with PC and all (both antibody-positive and antibody-negative) patients with CFS for XMRV DNA. RESULTS: Antibody screening by immunoblot analysis showed that a fraction of the cases (1.6-3.0%) possessed anti-Gag antibodies regardless of their gender or disease condition. Most of these antibodies were highly specific to XMRV Gag capsid protein, but none of the individuals in the three tested populations retained strong antibody responses to multiple XMRV proteins. In the viral antibody-positive PC patients, we occasionally detected XMRV genes in plasma and peripheral blood mononuclear cells but failed to isolate an infectious or full-length XMRV. Further, all CFS patients tested negative for XMRV DNA in peripheral blood mononuclear cells. CONCLUSION: Our data show no solid evidence of XMRV infection in any of the three populations tested, implying that there is no association between the onset of PC or CFS and XMRV infection in Japan. However, the lack of adequate human specimens as a positive control in Ab screening and the limited sample size do not allow us to draw a firm conclusion.
Galbraith S, Cameron B, Li H, Lau D, Vollmer-Conna U, Lloyd AR.	School of Mathematics and Statistics, Faculty of Science, University of New South Wales,	Peripheral blood gene expression in postinfective fatigue syndrome following from three different triggering infections.	J Infect Dis. 2011 Nov 15;204(10):1632-40. Epub 2011 Sep 29.	BACKGROUND: Several infections trigger postinfective fatigue syndromes, which share key illness characteristics with each other and with chronic fatigue syndrome (CFS). Previous cross-sectional case-control studies of CFS have suggested that unique gene expression signatures are evident in peripheral blood samples. METHODS: Peripheral blood transcriptomes in samples collected longitudinally, in 18 subjects with a fatigue syndrome lasting ≥ 6 months after acute infection due to Epstein-Barr

	Sydney, Australia.			virus, Ross River virus, or Coxiella burnetii (Q fever), and 18 matched control subjects who had recovered promptly, were studied by microarray (n = 127) and confirmatory quantitative polymerase chain reaction (PCR). Gene expression patterns associated with CFS were sought by univariate statistics and regression modeling. RESULTS: There were 23 genes with modest differential expression (0.6-2.3-fold change) in within-subject comparisons of early, symptomatic time points with late, recovered time points. There were modest differences found in 63 genes, either in cross-sectional comparison of cases and controls at 6 months after infection onset or in the regression model. There were 223 genes significantly correlated with individual symptom domains. Quantitative PCR confirmed 33 (73%) of 45 genes-none were consistent across cohorts. CONCLUSIONS: Although the illness characteristics of patients with postinfective fatigue syndromes have more similarities than differences, no reliable peripheral blood gene expression correlate is evident.
Gardner A, Boles RG.	Karolinska Institutet, Department of Clinical Neuroscience, Stockholm, Sweden. agtorndal@odenhall.se	Beyond the serotonin hypothesis: mitochondria, inflammation and neurodegeneration in major depression and affective spectrum disorders.	Prog Neuropsychopharmacol Biol Psychiatry. 2011 Apr 29;35(3):730-43. Epub 2010 Aug 5.	For many years, a deficiency of monoamines including serotonin has been the prevailing hypothesis on depression, yet research has failed to confirm consistent relations between brain serotonin and depression. High degrees of overlapping comorbidities and common drug efficacies suggest that depression is one of a family of related conditions sometimes referred to as the "affective spectrum disorders", and variably including migraine, irritable bowel syndrome, chronic fatigue syndrome, fibromyalgia and generalized anxiety disorder, among many others. Herein, we present data from many different experimental modalities that strongly suggest components of mitochondrial dysfunction and inflammation in the pathogenesis of depression and other affective spectrum disorders. The three concepts of monoamines, energy metabolism and inflammatory pathways are inter-related in many complex manners. For example, the major categories of drugs used to treat depression have been demonstrated to exert effects on mitochondria and inflammation, as well as on monoamines. Furthermore, commonly-used mitochondrial-targeted treatments exert effects on mitochondria and inflammation, and are increasingly being shown to demonstrate efficacy in the affective spectrum disorders. We propose that interactions among monoamines, mitochondrial dysfunction and inflammation can inspire explanatory, rather than mere descriptive, models of these disorders. Garson JA, Kellam P, Towers GJ.	MRC Centre for Medical Molecular Virology, Division of Infection and Immunity, University College London, 46	Analysis of XMRV integration sites from human prostate cancer tissues suggests PCR contamination rather than genuine human infection.	Retrovirology. 2011 Feb 25;8:13.	XMRV is a gammaretrovirus associated in some studies with human prostate cancer and chronic fatigue syndrome. Central to the hypothesis of XMRV as a human pathogen is the description of integration sites in DNA from prostate tumour tissues. Here we demonstrate that 2 of 14 patient-derived sites are identical to sites cloned in the same laboratory from experimentally infected DU145 cells. Identical integration sites have never previously been described in any retrovirus infection. We propose that the patient-derived sites are the result of PCR contamination. This observation further undermines the notion that XMRV is a genuine human pathogen.

BACKGROUND: Exposure to organic solvents may cause an increase of sleep apnoeas, which may explain the excess of fatigue, concentration and memory problems reported in exposed workers. METHODS: Polysomnography was performed in 21 long-term exposed printers and 27 controls. In addition, a questionnaire regarding sleep related complaints, Q16 questionnaire and computerized neurobehavioral tests were administered. The groups matched well regarding age, weight, neck circumference and schooling level. A semi-quantitative cumulative exposure index was calculated. RESULTS: Excessive sleepiness while watching TV ($p<0.01$) and diminished sexual interest ($p=0.03$) was found in the organic solvent-workers. The sleep complaints score correlated positively with the exposure index and duration (both $p=0.01$). The polysomnography results showed an increase of central apnoeas in the exposed workers (67%) compared to the referents (30%). The presence of central apnoeas was positively correlated with the exposure index ($p<0.05$) in regression models. Of the neurobehavioral test only hand-eye coordination was dose-related impaired in the exposed workers. The co-existence of abnormal values on at least one neurobehavioral test and the presence of central apnoeas was observed in the exposed workers, but did not reach significance. CONCLUSIONS: Workers chronically exposed to low organic solvent levels may experience mild sleeping problems, however, our data do not support the hypothesis that the clinical picture of chronic toxic encephalopathy can be primarily caused by the induction of sleep apnoea syndrome. It seems thus that the risk to experience central apnoeas rather accompanies the risk of impaired neurobehavioral performance with increasing

				exposure in a working population. Copyright © 2010 Elsevier GmbH. All rights reserved.
Goodwin L, White PD, Hotopf M, Stansfeld SA, Clark C.	Centre for Psychiatry, Barts and The London School of Medicine and Dentistry, Queen Mary University of London, London, UK. l.goodwin@qmul.ac.uk	Psychopathology and physical activity as predictors of chronic fatigue syndrome in the 1958 british birth cohort: a replication study of the 1946 and 1970 birth cohorts.	Ann Epidemiol. 2011 May;21(5):343-50.	PURPOSE: In this study, we investigate whether prospective associations between psychopathology, physical activity, and chronic fatigue syndrome/myalgic encephalomyelitis (CFS/ME) observed in the 1946 and 1970 birth cohorts were replicable in the 1958 British birth cohort. METHODS: Prospective study using the 1958 British birth cohort, which included 98.7% of births from 1 week in March 1958 in England, Wales, and Scotland. The outcome was self-reported CFS/ME by the age of 42 years, at which point 11,419 participants remained in the study. Psychopathology was assessed by the Rutter scales in childhood and the Malaise Inventory in adulthood. Physical activity was reported by the cohort member, mother and teacher in childhood and adulthood. RESULTS: The prevalence of CFS/ME was 1.0% (95% confidence interval [CI] = 0.9-1.3) and the median age of onset was 34 years. Premorbid psychopathology at 23 years (odds ratio [OR] = 1.85, 95% CI = 1.06-3.22) and 33 years (OR = 2.81, 95% CI = 1.28-6.18) significantly increased the odds of developing CFS/ME, supporting the 1946 cohort findings. Childhood psychopathology, sedentary behavior in childhood, and persistent exercise in adulthood were not associated with CFS/ME. CONCLUSIONS: In cohort studies premorbid psychopathology in adulthood is a replicated risk marker for CFS/ME, whereas premorbid extremes of physical activity are not. Copyright © 2011 Elsevier Inc. Goudsmit EM, Nijs J, Jason LA, Wallman KE.	School of Psychology, University of East London , Stratford, London, E15 4LZ , UK.	Pacing as a strategy to improve energy management in myalgic encephalomyelitis/chronic fatigue syndrome: a consensus document.	Disabil Rehabil. 2011 Dec 19. [Epub ahead of print]	Purpose: Myalgic encephalomyelitis/chronic fatigue syndrome (ME/CFS) is a debilitating condition characterized by a number of symptoms which typically worsen following minimal exertion. Various strategies to manage the limited energy levels have been proposed. Of these, pacing has been consistently rated as one of the most helpful in surveys conducted by patient groups. This review is a response to the paucity of the information on pacing in the scientific literature. Method: We describe the principle of pacing and how this can be adapted to meet individual abilities and preferences. A critical evaluation of the research was conducted to ascertain the benefits and limitations of this strategy. Results: Based on various studies, it is proposed that pacing can help to stabilize the condition and avoid post-exertional malaise. Conclusion: Pacing offers practitioners an additional therapeutic option which is acceptable to the majority of patients and can reduce the severity of the exertion-related symptoms of ME/CFS.
