Understanding permissions granted by a policy

The IAM console includes *policy summary* tables that describe the access level, resources, and conditions that are allowed or denied for each service in a policy. Policies are summarized in three tables: the [policy summary](#), the [service summary](#), and the [action summary](#). The *policy summary* table includes a list of services. Choose a service there to see the *service summary*. This summary table includes a list of the actions and associated permissions for the chosen service. You can choose an action from that table to view the *action summary*. This table includes a list of resources and conditions for the chosen action.

You can view policy summaries on the **Users** page or **Roles** page for all policies (managed and inline) that are attached to that user. View summaries on the **Policies** page for all managed policies. Managed policies include AWS managed policies, AWS managed job function policies, and customer managed policies. You can view summaries for these policies on the **Policies** page regardless of whether they are attached to a user or other IAM identity.

You can use the information in the policy summaries to understand the permissions that are allowed or denied by your policy. Policy summaries can help you [troubleshoot](#) and fix policies that are not providing the permissions that you expect.

Topics

- [Policy summary \(list of services\)](#)
- [Service summary \(list of actions\)](#)
- [Action summary \(list of resources\)](#)

- [Examples of policy summaries](#)

Policy summary (list of services)

Policies are summarized in three tables: the policy summary, the [service summary](#), and the [action summary](#). The *policy summary* table includes a list of services and summaries of the permissions that are defined by the chosen policy.

The policy summary table is grouped into one or more **Uncategorized services**, **Explicit deny**, and **Allow** sections. If the policy includes a service that IAM does not recognize, then the service is included in the **Uncategorized services** section of the table. If IAM recognizes the service, then it is included under the **Explicit deny** or **Allow** sections of the table, depending on the effect of the policy (Deny or Allow).

Viewing policy summaries

You can view the summaries for any policies that are attached to a user by choosing the policy name on the **Permissions** tab on the user details page. You can view the summaries for any policies that are attached to a role by choosing the policy name on the **Permissions** tab on the role details page. You can view the policy summary for managed policies on the **Policies** page. If your policy does not include a policy summary, see [Missing policy summary](#) to learn why.

To view the policy summary from the Policies page

1. Sign in to the AWS Management Console and open the IAM console at <https://console.aws.amazon.com/iam/>.
2. In the navigation pane, choose **Policies**.
3. In the list of policies, choose the name of the policy that you want to view.
4. On the **Policy details** page for the policy, view the **Permissions** tab to see the policy summary.

To view the summary for a policy attached to a user

1. Sign in to the AWS Management Console and open the IAM console at <https://console.aws.amazon.com/iam/>.
2. Choose **Users** from the navigation pane.
3. In the list of users, choose the name of the user whose policy you want to view.
4. On the **Summary** page for the user, view the **Permissions** tab to see the list of policies that are attached to the user directly or from a group.
5. In the table of policies for the user, expand the row of the policy that you want to view.

To view the summary for a policy attached to a role

1. Sign in to the AWS Management Console and open the IAM console at <https://console.aws.amazon.com/iam/>.
2. In the navigation pane, choose **Roles**.
3. In the list of roles, choose the name of the role whose policy you want to view.
4. On the **Summary** page for the role, view the **Permissions** tab to see the list of policies that are attached to the role.
5. In the table of policies for the role, expand the row of the policy that you want to view.

Editing policies to fix warnings

While viewing a policy summary, you might find a typo or notice that the policy does not provide the permissions that you expected. You cannot edit a policy summary directly. However, you can edit a customer managed policy using the visual policy editor, which catches many of the same errors and warnings that the policy summary reports. You can then view the changes in the policy

summary to confirm that you fixed all of the issues. To learn how to edit an inline policy, see [the section called “Editing IAM policies”](#). You cannot edit AWS managed policies.

To edit a policy for your policy summary using the Visual option

1. Open the policy summary as explained in the previous procedures.
2. Choose **Edit**.

If you are on the **Users** page and choose to edit a customer managed policy that is attached to that user, you are redirected to the **Policies** page. You can edit customer managed policies only on the **Policies** page.

3. Choose the **Visual** option to view the editable visual representation of your policy. IAM might restructure your policy to optimize it for the visual editor and to make it easier for you to find and fix any problems. The warnings and error messages on the page can guide you to fix any issues with your policy. For more information about how IAM restructures policies, see [Policy restructuring](#).
4. Edit your policy and choose **Next** to see your changes reflected in the policy summary. If you still see a problem, choose **Previous** to return to the editing screen.
5. Choose **Save changes** to save your changes.

To edit a policy for your policy summary with the JSON option

1. Open the policy summary as explained in the previous procedures.
2. You can use the **Summary** and **JSON** buttons to compare the policy summary to the JSON policy document. You can use this information to determine which lines in the policy document you want to change.
3. Choose **Edit** and then choose the **JSON** option to edit the JSON policy document.

Note

You can switch between the **Visual** and **JSON** editor options any time. However, if you make changes or choose **Next** in the **Visual** editor option, IAM might restructure your policy to optimize it for the visual editor. For more information, see [Policy restructuring](#).

If you are on the **Users** page and choose to edit a customer managed policy that is attached to that user, you are redirected to the **Policies** page. You can edit customer managed policies only on the **Policies** page.

4. Edit your policy. Resolve any security warnings, errors, or general warnings generated during [policy validation](#), and then choose **Next**. If you still see a problem, choose **Previous** to return to the editing screen.
5. Choose **Save changes** to save your changes.

Understanding the elements of a policy summary

In the following example of a policy details page, the **SummaryAllElements** policy is a managed policy (customer managed policy) that is attached directly to the user. This policy is expanded to show the policy summary.

Policy details

Type Customer managed	Creation time September 13, 2022, 16:37 (UTC-05:00)	Edited time September 13, 2022, 16:40 (UTC-05:00)	ARN arn:aws:iam:::policy/SummaryAllElements
--------------------------	--	--	--

1 **Permissions** Entitles attached Tags Policy versions Access Advisor

2 This policy defines some actions, resources, or conditions that do not provide permissions. To grant access, policies must have an action that has an applicable resource or condition. For details, choose **Show remaining**. [Learn more](#)

3 **Summary** JSON

4 Search

5 **Explicit deny (1 of 338 services)**

Service	Access level	Resource	Request condition
S3	Limited: List, Permissions management, Read, Write, Tagging	Multiple	None

6 **Allow (3 of 338 services)** Show remaining 334 services

Service	Access level	Resource	Request condition
Billing Console	Full: Read Limited: Write	All resources	aws:SourceIp IP Address 203.0.113.0/24
CodeDeploy	Limited: List, Read, Write, Tagging	DeploymentGroupName string like All, region string like us-west-2	None
EC2	Limited: Read	All resources	None

In the preceding image, the policy summary is visible from within the **Policies** page:

1. The **Permissions** tab includes the permissions defined in the policy.
2. If the policy does not grant permissions to all the actions, resources, and conditions defined in the policy, then a warning or error banner appears at the top of the page. The policy summary then includes details about the problem. To learn how policy summaries help you to understand and troubleshoot the permissions that your policy grants, see [the section called “My policy does not grant the expected permissions”](#).

- Use the **Summary** and **JSON** buttons to toggle between the policy summary and the JSON policy document.
- Use the **Search** box to reduce the list of services and find a specific service.
- The expanded view shows additional details of the **SummaryAllElements** policy.

The following policy summary table image shows the expanded **SummaryAllElements** policy on the policy details page.

Explicit deny (1 of 338 services) A			
Service B	Access level C	Resource D	Request condition E
S3	Limited: List, Permissions management, Read, Write, Tagging	Multiple	None

Allow (3 of 338 services) F <input type="checkbox"/> Show remaining 334 services			
Service	Access level	Resource	Request condition
Billing Console	Full: Read Limited: Write	All resources	aws:SourceIp IP Address 203.0.113.0/24
CodeDeploy	Limited: List, Read, Write, Tagging	DeploymentGroupName string like All, region string like us-west-2	None
EC2	Limited: Read	All resources	None

In the preceding image, the policy summary is visible from within the **Policies** page:

- For those services that IAM recognizes, it arranges services according to whether the policy allows or explicitly denies the use of the service. In this example, the policy includes a Deny statement for the Amazon S3 service and Allow statements for the Billing, CodeDeploy, and Amazon EC2 services.
- Service** – This column lists the services that are defined within the policy and provides details for each service. Each service name in the policy summary table is a link to the *service summary* table, which is explained in [Service summary \(list of actions\)](#). In this example, permissions are defined for the Amazon S3, Billing, CodeDeploy, and Amazon EC2 services.
- Access level** – This column tells whether the actions in each access level (List, Read, Write, Permission Management, and Tagging) have Full or Limited permissions defined in the policy. For additional details and examples of the access level summary, see [Understanding access level summaries within policy summaries](#).
 - Full access** – This entry indicates that the service has access to all actions within all four of the access levels available for the service.

- If the entry does not include **Full access**, then the service has access to some but not all of the actions for the service. The access is then defined by following descriptions for each of the access level classifications (List, Read, Write, Permission Management, and Tagging):

Full: The policy provides access to all actions within each access level classification listed. In this example, the policy provides access to all of the Billing Read actions.

Limited: The policy provides access to one or more but not all actions within each access level classification listed. In this example, the policy provides access to some of the Billing Write actions.

D. **Resource** – This column shows the resources that the policy specifies for each service.

- **Multiple** – The policy includes more than one but not all of the resources within the service. In this example, access is explicitly denied to more than one Amazon S3 resource.
- **All resources** – The policy is defined for all resources within the service. In this example, the policy allows the listed actions to be performed on all Billing resources.
- **Resource text** – The policy includes one resource within the service. In this example, the listed actions are allowed on only the DeploymentGroupName CodeDeploy resource. Depending on the information that the service provides to IAM, you might see an ARN or you might see the defined resource type.

 **Note**

This column can include a resource from a different service. If the policy statement that includes the resource does not include both actions and resources from the same service, then your policy includes mismatched resources. IAM does not warn you about mismatched resources when you create a policy, or when you view a policy in the policy summary. If this column includes a mismatched resource, then you should review your policy for errors. To better understand your policies, always test them with the [policy simulator](#).

E. **Request condition** – This column indicates whether the services or actions associated with the resource are subject to conditions.

- **None** – The policy includes no conditions for the service. In this example no conditions are applied to the denied actions in the Amazon S3 service.
- **Condition text** – The policy includes one condition for the service. In this example, the listed Billing actions are allowed only if the IP address of the source matches 203.0.113.0/24.

- **Multiple** – The policy includes more than one condition for the service. To view each of the multiple conditions for the policy, choose **JSON** to view the policy document.

F. **Show remaining services** – Toggle this button to expand the table to include the services that are not defined by the policy. These services are *implicitly denied* (or denied by default) within this policy. However, a statement in another policy might still allow or explicitly deny using the service. The policy summary summarizes the permissions of a single policy. To learn about how the AWS service decides whether a given request should be allowed or denied, see [Policy evaluation logic](#).

When a policy or an element within the policy does not grant permissions, IAM provides additional warnings and information in the policy summary. The following policy summary table shows the expanded **Show remaining services** services on the **SummaryAllElements** policy details page with the possible warnings.

Explicit deny (1 of 338 services)			
Service	Access level	Resource a	Request condition b
S3	Limited: List, Permissions management, Read, Write, Tagging	c Multiple One or more actions do not have an applicable resource.	None

Allow (3 of 338 services)			<input checked="" type="checkbox"/> Show remaining 334 services
Service	Access level	Resource	Request condition
Billing Console	Full: Read Limited: Write	All resources	aws:SourceIp IP Address 203.0.113.0/24
CodeCommit	None	d No resources are defined.	None
CodeDeploy	Limited: List, Read, Write, Tagging	e DeploymentGroupName string like All, region string like us-west-2 One or more actions do not have an applicable resource.	None
EC2	Limited: Read	All resources	None
S3	None	None One or more actions do not have an applicable resource.	f None One or more conditions do not have an applicable action.

In the preceding image, you can see all services that include defined actions, resources, or conditions with no permissions:

- a. **Resource warnings** – For services that do not provide permissions for all of the included actions or resources, you see one of the following warnings in the **Resource** column of the table:

-  **No resources are defined.** – This means that the service has defined actions but no supported resources are included in the policy.
-  **One or more actions do not have an applicable resource.** – This means that the service has defined actions, but that some of those actions don't have a supported resource.
-  **One or more resources do not have an applicable action.** – This means that the service has defined resources, but that some of those resources don't have a supporting action.

If a service includes both actions that do not have an applicable resource and resources that do have an applicable resource, then only the **One or more resources do not have an applicable action.** warning is shown. This is because when you view the service summary for the service, resources that do not apply to any action are not shown. For the `ListAllMyBuckets` action, this policy includes the last warning because the action does not support resource-level permissions, and does not support the `s3:x-amz-ac1` condition key. If you fix either the resource problem or the condition problem, the remaining issue appears in a detailed warning.

b. **Request condition warnings** – For services that do not provide permissions for all of the included conditions, you see one of the following warnings in the **Request condition** column of the table:

-  **One or more actions do not have an applicable condition.** – This means that the service has defined actions, but that some of those actions don't have a supported condition.
-  **One or more conditions do not have an applicable action.** – This means that the service has defined conditions, but that some of those conditions don't have a supporting action.

c. **Multiple |**

One or more actions do not have an applicable resource. – The Deny statement for Amazon S3 includes more than one resource. It also includes more than one action, and some actions support the resources and some do not. To view this policy, see [the section called “SummaryAllElements JSON policy document”](#). In this case, the policy includes all Amazon S3 actions, and only the actions that can be performed on a bucket or bucket object are denied.

d. 

No resources are defined – The service has defined actions, but no supported resources are included in the policy, and therefore the service provides no permissions. In this case, the policy includes CodeCommit actions but no CodeCommit resources.

e. **DeploymentGroupName | string like | All, region | string like | us-west-2 |**

One or more actions do not have an applicable resource. – The service has a defined action, and at least one more action that does not have a supporting resource.

f. **None |**

One or more conditions do not have an applicable action. – The service has at least one condition key that does not have a supporting action.

SummaryAllElements JSON policy document

The **SummaryAllElements** policy is not intended for you to use to define permissions in your account. Rather, it is included to demonstrate the errors and warnings that you might encounter while viewing a policy summary.

Understanding access level summaries within policy summaries

AWS access level summary

Policy summaries include an access level summary that describes the action permissions defined for each service that is mentioned in the policy. To learn about policy summaries, see [Understanding permissions granted by a policy](#). Access level summaries indicate whether the actions in each access level (List, Read, Tagging, Write, and Permissions management) have Full or Limited permissions defined in the policy. To view the access level classification that is assigned to each action in a service, see [Actions, Resources, and Condition Keys for AWS Services](#).

The following example describes the access provided by a policy for the given services. For examples of full JSON policy documents and their related summaries, see [Examples of policy summaries](#).

Service	Access level	This policy provides the following
IAM	Full access	Access to all actions within the IAM service.
CloudWatch	Full: List	Access to all CloudWatch actions in the List access level, but no access to actions with the Read, Write, or Permissions management access level classification.

Service	Access level	This policy provides the following
Data Pipeline	Limited: List, Read	Access to at least one but not all AWS Data Pipeline actions in the List and Read access level, but not the Write or Permissions management actions.
EC2	Full: List, Read Limited: Write	Access to all Amazon EC2 List and Read actions and access to at least one but not all Amazon EC2 Write actions, but no access to actions with the Permissions management access level classification.
S3	Limited: Read, Write, Permissions management	Access to at least one but not all Amazon S3 Read, Write and Permissions management actions.
CodeDeploy	(empty)	Unknown access, because IAM does not recognize this service.
API Gateway	None	No access is defined in the policy.
CodeBuild	 No actions are defined.	No access because no actions are defined for the service. To learn how to understand and troubleshoot this issue, see the section called "My policy does not grant the expected permissions" .

As [previously mentioned](#), **Full access** indicates that the policy provides access to all the actions within the service. Policies that provide access to some but not all actions within a service are further grouped according to the access level classification. This is indicated by one of the following access-level groupings:

- **Full:** The policy provides access to all actions within the specified access level classification.
- **Limited:** The policy provides access to one or more but not all actions within the specified access level classification.

- **None:** The policy provides no access.
- (empty): IAM does not recognize this service. If the service name includes a typo, then the policy provides no access to the service. If the service name is correct, then the service might not support policy summaries or might be in preview. In this case, the policy might provide access, but that access cannot be shown in the policy summary. To request policy summary support for a generally available (GA) service, see [Service does not support IAM policy summaries](#).

Access level summaries that include limited (partial) access to actions are grouped using the AWS access level classifications `List`, `Read`, `Tagging`, `Write`, or `Permissions management`.

AWS access levels

AWS defines the following access level classifications for the actions in a service:

- **List:** Permission to list resources within the service to determine whether an object exists. Actions with this level of access can list objects but cannot see the contents of a resource. For example, the Amazon S3 action `ListBucket` has the **List** access level.
- **Read:** Permission to read but not edit the contents and attributes of resources in the service. For example, the Amazon S3 actions `GetObject` and `GetBucketLocation` have the **Read** access level.
- **Tagging:** Permission to perform actions that only change the state of resource tags. For example, the IAM actions `TagRole` and `UntagRole` have the **Tagging** access level because they allow only tagging or untagging a role. However, the `CreateRole` action allows tagging a role resource when you create that role. Because the action does not only add a tag, it has the `Write` access level.
- **Write:** Permission to create, delete, or modify resources in the service. For example, the Amazon S3 actions `CreateBucket`, `DeleteBucket` and `PutObject` have the **Write** access level. Write actions might also allow modifying a resource tag. However, an action that allows only changes to tags has the `Tagging` access level.
- **Permissions management:** Permission to grant or modify resource permissions in the service. For example, most IAM and AWS Organizations actions, as well as actions like the Amazon S3 actions `PutBucketPolicy` and `DeleteBucketPolicy` have the **Permissions management** access level.

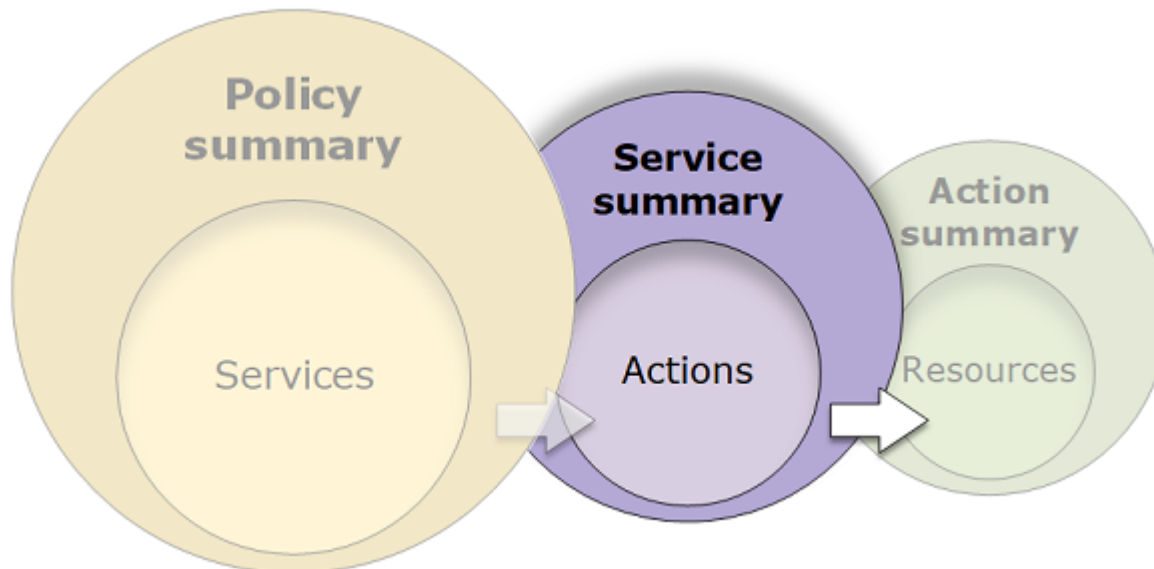

Tip

To improve the security of your AWS account, restrict or regularly monitor policies that include the **Permissions management** access level classification.

To view the access level classification for all of the actions in a service, see [Actions, Resources, and Condition Keys for AWS Services](#).

Service summary (list of actions)

Policies are summarized in three tables: the [policy summary](#), the service summary, and the [action summary](#). The *service summary* table includes a list of the actions and summaries of the permissions that are defined by the policy for the chosen service.

You can view a service summary for each service listed in the policy summary that grants permissions. The table is grouped into **Uncategorized actions**, **Uncategorized resource types**, and access level sections. If the policy includes an action that IAM does not recognize, then the action is included in the **Uncategorized actions** section of the table. If IAM recognizes the action, then it is included under one of the access level (**List**, **Read**, **Write** and **Permissions management**) sections of the table. To view the access level classification that is assigned to each action in a service, see [Actions, Resources, and Condition Keys for AWS Services](#).

Viewing service summaries

You can view the service summary for managed policies on the **Policies** page.

To view the service summary for a managed policy

1. Sign in to the AWS Management Console and open the IAM console at <https://console.aws.amazon.com/iam/>.
2. In the navigation pane, choose **Policies**.
3. In the list of policies, choose the name of the policy that you want to view.
4. On the **Policy details** page for the policy, view the **Permissions** tab to see the policy summary.
5. In the policy summary list of services, choose the name of the service that you want to view.

To view the service summary for a policy attached to a user

1. Sign in to the AWS Management Console and open the IAM console at <https://console.aws.amazon.com/iam/>.
2. In the navigation pane, choose **Users**.
3. In the list of users, choose the name of the user whose policy you want to view.
4. On the **Summary** page for the user, view the **Permissions** tab to see the list of policies that are attached to the user directly or from a group.
5. In the table of policies for the user, choose the name of the policy that you want to view.

If you are on the **Users** page and choose to view the service summary for a policy that is attached to that user, you are redirected to the **Policies** page. You can view service summaries only on the **Policies** page.

6. Choose **Summary**. In the policy summary list of services, choose the name of the service that you want to view.

Note

If the policy that you select is an inline policy that is attached directly to the user, then the service summary table appears. If the policy is an inline policy attached from a group, then you are taken to the JSON policy document for that group. If the policy is a managed policy, then you are taken to the service summary for that policy on the **Policies** page.

To view the service summary for a policy attached to a role

1. Sign in to the AWS Management Console and open the IAM console at <https://console.aws.amazon.com/iam/>.
2. Choose **Roles** from the navigation pane.
3. In the list of roles, choose the name of the role whose policy you want to view.
4. On the **Summary** page for the role, view the **Permissions** tab to see the list of policies that are attached to the role.
5. In the table of policies for the role, choose the name of the policy that you want to view.

If you are on the **Roles** page and choose to view the service summary for a policy that is attached to that user, you are redirected to the **Policies** page. You can view service summaries only on the **Policies** page.

6. In the policy summary list of services, choose the name of the service that you want to view.

Understanding the elements of a service summary

The example below is the service summary for Amazon S3 actions that are allowed from a policy summary. The actions for this service are grouped by access level. For example, 35 **Read** actions are defined out of the total 52 **Read** actions available for the service.

Permissions

Entities attached

The service summary page for a managed policy includes the following information:

1. If the policy does not grant permissions to all the actions, resources, and conditions defined for the service in the policy, then a warning banner appears at the top of the page. The service

- summary then includes details about the problem. To learn how policy summaries help you to understand and troubleshoot the permissions that your policy grants, see [the section called “My policy does not grant the expected permissions”](#).
2. Choose **JSON** to see additional details about the policy. You can do this to view all conditions that are applied to the actions. (If you are viewing the service summary for an inline policy that is attached directly to a user, you must close the service summary dialog box and return to the policy summary to access the JSON policy document.)
 3. To view the summary for a specific action, type keywords into the **Search** box to reduce the list of available actions.
 4. Next to the **Services** back arrow appears the name of the service (in this case **S3**). The service summary for this service includes the list of allowed or denied actions that are defined in the policy. If the service appears under (**Explicit deny**) on the **Permissions** tab, then the actions listed in the service summary table are explicitly denied. If the service appears under **Allow** on the **Permissions** tab, then the actions listed in the service summary table are allowed.
 5. **Action** – This column lists the actions that are defined within the policy and provides the resources and conditions for each action. If the policy grants or denies permissions to the action, then the action name links to the [action summary](#) table. The table groups these actions into at least one or up to five sections, depending on the level of access that the policy allows or denies. The sections are **List**, **Read**, **Write**, **Permission Management**, and **Tagging**. The count indicates the number of recognized actions that provide permissions within each access level. The total is the number of known actions for the service. In this example, 35 actions provide permissions out of 52 total known Amazon S3 **Read** actions. To view the access level classification that is assigned to each action in a service, see [Actions, Resources, and Condition Keys for AWS Services](#).
 6. **Show remaining actions** – Toggle this button to expand or hide the table to include actions that are known but do not provide permissions for this service. Toggling the button also displays warnings for any elements that do not provide permissions.
 7. **Resource** – This column shows the resources that the policy defines for the service. IAM does not check whether the resource applies to each action. In this example, actions in the Amazon S3 service are allowed on only the `developer_bucket` Amazon S3 bucket resource. Depending on the information that the service provides to IAM, you might see an ARN such as `arn:aws:s3:::developer_bucket/*`, or you might see the defined resource type, such as `BucketName = developer_bucket`.

Note

This column can include a resource from a different service. If the policy statement that includes the resource does not include both actions and resources from the same service, then your policy includes mismatched resources. IAM does not warn you about mismatched resources when you create a policy, or when you view a policy in the service summary. IAM also does not indicate whether the action applies to the resources, only whether the service matches. If this column includes a mismatched resource, then you should review your policy for errors. To better understand your policies, always test them with the [policy simulator](#).

8. **Request condition** – This column tells whether the actions associated with the resource are subject to conditions. To learn more about those conditions, choose **JSON** to review the JSON policy document.
9. **(No access)** – This policy includes an action that does not provide permissions.
- 10 **Resource warning** – For actions with resources that do not provide full permissions, you see one of the following warnings:
 - **This action does not support resource-level permissions. This requires a wildcard (*) for the resource.** – This means that the policy includes resource-level permissions but must include "Resource": ["*"] to provide permissions for this action.
 - **This action does not have an applicable resource.** – This means that the action is included in the policy without a supported resource.
 - **This action does not have an applicable resource and condition.** – This means that the action is included in the policy without a supported resource and without a supported condition. In this case, there is also condition included in the policy for this service, but there are no conditions that apply to this action.
- 11 Actions that provide permissions include a link to the action summary.

Action summary (list of resources)

Policies are summarized in three tables: the [policy summary](#), the [service summary](#), and the action summary. The *action summary* table includes a list of resources and the associated conditions that apply to the chosen action.

To view an action summary for each action that grants permissions, choose the link in the service summary. The action summary table includes details about the resource, including its **Region** and **Account**. You can also view the conditions that apply to each resource. This shows you conditions that apply to some resources but not others.

Viewing action summaries

You can view the action summary for managed policies, any policy that is attached to a user, and any policy that is attached to a role on the **Policies** page.

To view the action summary for a managed policy

1. Sign in to the AWS Management Console and open the IAM console at <https://console.aws.amazon.com/iam/>.
2. In the navigation pane, choose **Policies**.
3. In the list of policies, choose the name of the policy that you want to view.
4. On the **Policy details** page for the policy, view the **Permissions** tab to see the policy summary.
5. In the policy summary list of services, choose the name of the service that you want to view.
6. In the service summary list of actions, choose the name of the action that you want to view.

To view the action summary for a policy attached to a user

1. Sign in to the AWS Management Console and open the IAM console at <https://console.aws.amazon.com/iam/>.

2. Choose **Users** from the navigation pane.
3. In the list of users, choose the name of the user whose policy you want to view.
4. On the **Summary** page for the user, view the **Permissions** tab to see the list of policies that are attached to the user directly or from a group.
5. In the table of policies for the user, choose the name of the policy that you want to view.

If you are on the **Users** page and choose to view the service summary for a policy that is attached to that user, you are redirected to the **Policies** page. You can view service summaries only on the **Policies** page.

6. In the policy summary list of services, choose the name of the service that you want to view.

 **Note**

If the policy that you select is an inline policy that is attached directly to the user, then the service summary table appears. If the policy is an inline policy attached from a group, then you are taken to the JSON policy document for that group. If the policy is a managed policy, then you are taken to the service summary for that policy on the **Policies** page.

7. In the service summary list of actions, choose the name of the action that you want to view.

To view the action summary for a policy attached to a role

1. Sign in to the AWS Management Console and open the IAM console at <https://console.aws.amazon.com/iam/>.
2. In the navigation pane, choose **Roles**.
3. In the list of roles, choose the name of the role whose policy you want to view.
4. On the **Summary** page for the role, view the **Permissions** tab to see the list of policies that are attached to the role.
5. In the table of policies for the role, choose the name of the policy that you want to view.

If you are on the **Roles** page and choose to view the service summary for a policy that is attached to that user, you are redirected to the **Policies** page. You can view service summaries only on the **Policies** page.

6. In the policy summary list of services, choose the name of the service that you want to view.
7. In the service summary list of actions, choose the name of the action that you want to view.

Understanding the elements of an action summary

The example below is the action summary for the PutObject (Write) action from the Amazon S3 service summary (see [Service summary \(list of actions\)](#)). For this action, the policy defines multiple conditions on a single resource.

Permissions defined in this policy [Info](#)

Permissions defined in this policy document specify which actions are allowed or denied. To define permissions for an IAM identity (user, user group, or role), attach a policy to it.

[Edit](#) [Summary](#) [JSON](#)

Search

< **Actions** PutObject action in S3

Resource	Region	Account	Request condition
BucketName string like customer, ObjectPath string like All	All regions	All accounts	s3:x-amz-acl = public-read

The action summary page includes the following information:

1. Choose **JSON** to see additional details about the policy, such as viewing the multiple conditions that are applied to the actions. (If you are viewing the action summary for an inline policy that is attached directly to a user, the steps differ. To access the JSON policy document in that case, you must close the action summary dialog box and return to the policy summary.)
2. To view the summary for a specific resource, type keywords into the **Search** box to reduce the list of available resources.
3. Next to the **Actions** back arrow appears the name of the service and action in the format **action name action in service** (in this case **PutObject action in S3**). The action summary for this service includes the list of resources that are defined in the policy.
4. **Resource** – This column lists the resources that the policy defines for the chosen service. In this example, the **PutObject** action is allowed on all object paths, but on only the `developer_bucket` Amazon S3 bucket resource. Depending on the information that the service provides to IAM, you might see an ARN such as `arn:aws:s3:::developer_bucket/*`, or you might see the defined resource type, such as `BucketName = developer_bucket, ObjectPath = All`.
5. **Region** – This column shows the Region in which the resource is defined. Resources can be defined for all Regions, or a single Region. They cannot exist in more than one specific Region.

- **All regions** – The actions that are associated with the resource apply to all Regions. In this example, the action belongs to a global service, Amazon S3. Actions that belong to global services apply to all Regions.
 - **Region text** – The actions associated with the resource apply to one Region. For example, a policy can specify the `us-east-2` Region for a resource.
6. **Account** – This column indicates whether the services or actions associated with the resource apply to a specific account. Resources can exist in all accounts or a single account. They cannot exist in more than one specific account.
- **All accounts** – The actions that are associated with the resource apply to all accounts. In this example, the action belongs to a global service, Amazon S3. Actions that belong to global services apply to all accounts.
 - **This account** – The actions that are associated with the resource apply only in the current account..
 - **Account number** – The actions that are associated with the resource apply to one account (one that you are not currently logged in to). For example, if a policy specifies the `123456789012` account for a resource, then the account number appears in the policy summary.
7. **Request condition** – This column shows whether the actions that are associated with the resource are subject to conditions. This example includes the `s3:x-amz-acl = public-read` condition. To learn more about those conditions, choose **JSON** to review the JSON policy document.

Examples of policy summaries

The following examples include JSON policies with their associated [policy summaries](#), the [service summaries](#), and the [action summaries](#) to help you understand the permissions given through a policy.

Policy 1: DenyCustomerBucket

This policy demonstrates an allow and a deny for the same service.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "FullAccess",
```

```

    "Effect": "Allow",
    "Action": ["s3:*"],
    "Resource": ["*"]
  },
  {
    "Sid": "DenyCustomerBucket",
    "Action": ["s3:*"],
    "Effect": "Deny",
    "Resource": ["arn:aws:s3:::customer", "arn:aws:s3:::customer/*" ]
  }
]
}

```

DenyCustomerBucket Policy Summary:

i This policy defines some actions, resources, or conditions that do not provide permissions. To grant access, policies must have an action that has an applicable resource or condition. For details, choose **Show remaining**. [Learn more](#)

Permissions defined in this policy [Info](#)

Permissions defined in this policy document specify which actions are allowed or denied. To define permissions for an [IAM](#) identity (user, user group, or role), attach a policy to it

[Edit](#) [Summary](#) [JSON](#)

Action	Resource	Request condition	
PutObjectAcl	Multiple	Multiple	

PutObject (Write) Action Summary:

< Actions PutObject action in S3			
Resource	Region	Account	Request condition
Multiple	-	All accounts	Multiple

Policy 4: EC2_troubleshoot

The following policy allows users to get a screenshot of a running Amazon EC2 instance, which can help with EC2 troubleshooting. This policy also permits viewing information about the items in the Amazon S3 developer bucket.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "ec2:GetConsoleScreenshot"
      ],
      "Resource": [
        "*"
      ]
    },
    {
      "Effect": "Allow",
      "Action": [
        "s3:ListBucket"
      ],
      "Resource": [
        "arn:aws:s3:::developer"
      ]
    }
  ]
}
```

EC2_Troubleshoot Policy Summary:

Allow (2 of 370 services) Show remaining 368 services			
Service	Access level	Resource	Request condition
EC2	Limited: Read	All resources	None
S3	Limited: List	BucketName string like developer	None

EC2_Troubleshoot S3 (Allow) Service Summary:

Action	Resource	Request condition
ListBucket	BucketName string like developer	None

ListBucket (List) Action Summary:

Resource	Region	Account	Request condition
BucketName string like developer	-	All accounts	None

Policy 5: CodeBuild_CodeCommit_CodeDeploy

This policy provides access to specific CodeBuild, CodeCommit, and CodeDeploy resources. Because these resources are specific to each service, they appear only with the matching service. If you include a resource that does not match any services in the Action element, then the resource appears in all action summaries.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "Stmt1487980617000",
      "Effect": "Allow",
      "Action": [
        "codebuild:*",
        "codecommit:*",
        "codedeploy:*"
      ],
      "Resource": [
        "arn:aws:codebuild:us-east-2:123456789012:project/my-demo-project",
        "arn:aws:codecommit:us-east-2:123456789012:MyDemoRepo",
        "arn:aws:codedeploy:us-east-2:123456789012:application:WordPress_App",
        "arn:aws:codedeploy:us-east-2:123456789012:instance/AssetTag*"
      ]
    }
  ]
}
```

Permissions required to access IAM resources

Resources are objects within a service. IAM resources include groups, users, roles, and policies. If you are signed in with AWS account root user credentials, you have no restrictions on administering IAM credentials or IAM resources. However, IAM users must explicitly be given permissions to administer credentials or IAM resources. You can do this by attaching an identity-based policy to the user.

Note

Throughout the AWS documentation, when we refer to an IAM policy without mentioning any of the specific categories, we mean an identity-based, customer managed policy. For details about policy categories, see [the section called "Policies and permissions"](#).

Permissions for administering IAM identities

The permissions that are required to administer IAM groups, users, roles, and credentials usually correspond to the API actions for the task. For example, in order to create IAM users, you must have the `iam:CreateUser` permission that has the corresponding API command: [CreateUser](#). To allow an IAM user to create other IAM users, you could attach an IAM policy like the following one to that user:

```
{
  "Version": "2012-10-17",
  "Statement": {
    "Effect": "Allow",
    "Action": "iam:CreateUser",
    "Resource": "*"
  }
}
```

In a policy, the value of the `Resource` element depends on the action and what resources the action can affect. In the preceding example, the policy allows a user to create any user (* is a wildcard that matches all strings). In contrast, a policy that allows users to change only their own access keys (API actions [CreateAccessKey](#) and [UpdateAccessKey](#)) typically has a `Resource` element. In this case the ARN includes a variable (`${aws:username}`) that resolves to the current user's name, as in the following example:

```
{
```

```

"Version": "2012-10-17",
"Statement": [
  {
    "Sid": "ListUsersForConsole",
    "Effect": "Allow",
    "Action": "iam:ListUsers",
    "Resource": "arn:aws:iam::*:*"
  },
  {
    "Sid": "ViewAndUpdateAccessKeys",
    "Effect": "Allow",
    "Action": [
      "iam:UpdateAccessKey",
      "iam:CreateAccessKey",
      "iam:ListAccessKeys"
    ],
    "Resource": "arn:aws:iam::*:user/${aws:username}"
  }
]
}

```

In the previous example, `${aws:username}` is a variable that resolves to the user name of the current user. For more information about policy variables, see [IAM policy elements: Variables and tags](#).

Using a wildcard character (*) in the action name often makes it easier to grant permissions for all the actions related to a specific task. For example, to allow users to perform any IAM action, you can use `iam:*` for the action. To allow users to perform any action related just to access keys, you can use `iam:*AccessKey*` in the Action element of a policy statement. This gives the user permission to perform the [CreateAccessKey](#), [DeleteAccessKey](#), [GetAccessKeyLastUsed](#), [ListAccessKeys](#), and [UpdateAccessKey](#) actions. (If an action is added to IAM in the future that has "AccessKey" in the name, using `iam:*AccessKey*` for the Action element will also give the user permission to that new action.) The following example shows a policy that allows users to perform all actions pertaining to their own access keys (replace `account-id` with your AWS account ID):

```

{
  "Version": "2012-10-17",
  "Statement": {
    "Effect": "Allow",
    "Action": "iam:*AccessKey*",

```

```
"Resource": "arn:aws:iam::account-id:user/${aws:username}"
}
```

Some tasks, such as deleting a group, involve multiple actions: You must first remove users from the group, then detach or delete the group's policies, and then actually delete the group. If you want a user to be able to delete a group, you must be sure to give the user permissions to perform all of the related actions.

Permissions for working in the AWS Management Console

The preceding examples show policies that allow a user to perform the actions with the [AWS CLI](#) or the [AWS SDKs](#).

As users work with the console, the console issues requests to IAM to list groups, users, roles, and policies, and to get the policies associated with a group, user, or role. The console also issues requests to get AWS account information and information about the principal. The principal is the user making requests in the console.

In general, to perform an action, you must have only the matching action included in a policy. To create a user, you need permission to call the `CreateUser` action. Often, when you use the console to perform an action, you must have permissions to display, list, get, or otherwise view resources in the console. This is necessary so that you can navigate through the console to make the specified action. For example, if user Jorge wants to use the console to change his own access keys, he goes to the IAM console and chooses **Users**. This action causes the console to make a [ListUsers](#) request. If Jorge doesn't have permission for the `iam:ListUsers` action, the console is denied access when it tries to list users. As a result, Jorge can't get to his own name and to his own access keys, even if he has permissions for the [CreateAccessKey](#) and [UpdateAccessKey](#) actions.

If you want to give users permissions to administer groups, users, roles, policies, and credentials with the AWS Management Console, you need to include permissions for the actions that the console performs. For some examples of policies that you can use to grant a user for these permissions, see [Example policies for administering IAM resources](#).

Granting permissions across AWS accounts

You can directly grant IAM users in your own account access to your resources. If users from another account need access to your resources, you can create an IAM role, which is an entity that

includes permissions but that isn't associated with a specific user. Users from other accounts can then use the role and access resources according to the permissions you've assigned to the role. For more information, see [Providing access to an IAM user in another AWS account that you own](#).

Note

Some services support resource-based policies as described in [Identity-based policies and resource-based policies](#) (such as Amazon S3, Amazon SNS, and Amazon SQS). For those services, an alternative to using roles is to attach a policy to the resource (bucket, topic, or queue) that you want to share. The resource-based policy can specify the AWS account that has permissions to access the resource.

Permissions for one service to access another

Many AWS services access other AWS services. For example, several AWS services—including Amazon EMR, Elastic Load Balancing, and Amazon EC2 Auto Scaling—manage Amazon EC2 instances. Other AWS services make use of Amazon S3 buckets, Amazon SNS topics, Amazon SQS queues, and so on.

The scenario for managing permissions in these cases varies by service. Here are some examples of how permissions are handled for different services:

- In Amazon EC2 Auto Scaling, users must have permission to use Auto Scaling, but don't need to be explicitly granted permission to manage Amazon EC2 instances.
- In AWS Data Pipeline, an IAM role determines what a pipeline can do; users need permission to assume the role. (For details, see [Granting Permissions to Pipelines with IAM](#) in the *AWS Data Pipeline Developer Guide*.)

For details about how to configure permissions properly so that an AWS service is able to accomplish the tasks you intend, refer to the documentation for the service you are calling. To learn how to create a role for a service, see [Creating a role to delegate permissions to an AWS service](#).

Configuring a service with an IAM role to work on your behalf

When you want to configure an AWS service to work on your behalf, you typically provide the ARN for an IAM role that defines what the service is allowed to do. AWS checks to ensure that you have

permissions to pass a role to a service. For more information, see [Granting a user permissions to pass a role to an AWS service](#).

Required actions

Actions are the things that you can do to a resource, such as viewing, creating, editing, and deleting that resource. Actions are defined by each AWS service.

To allow someone to perform an action, you must include the necessary actions in a policy that applies to the calling identity or the affected resource. In general, to provide the permission required to perform an action, you must include that action in your policy. For example, to create a user, you need add the `CreateUser` action to your policy.

In some cases, an action might require that you include additional related actions in your policy. For example, to provide permission for someone to create a directory in AWS Directory Service using the `ds:CreateDirectory` operation, you must include the following actions in their policy:

- `ds:CreateDirectory`
- `ec2:DescribeSubnets`
- `ec2:DescribeVpcs`
- `ec2:CreateSecurityGroup`
- `ec2:CreateNetworkInterface`
- `ec2:DescribeNetworkInterfaces`
- `ec2:AuthorizeSecurityGroupIngress`
- `ec2:AuthorizeSecurityGroupEgress`

When you create or edit a policy using the visual editor, you receive warnings and prompts to help you choose all of the required actions for your policy.

For more information about the permissions required to create a directory in AWS Directory Service, see [Example 2: Allow a User to Create a Directory](#).

Example policies for administering IAM resources

Following are examples of IAM policies that allow users to perform tasks associated with managing IAM users, groups, and credentials. This includes policies that permit users manage their own passwords, access keys, and multi-factor authentication (MFA) devices.

For examples of policies that let users perform tasks with other AWS services, like Amazon S3, Amazon EC2, and DynamoDB, see [Example IAM identity-based policies](#).

Topics

- [Allow a user to list the account's groups, users, policies, and more for reporting purposes](#)
- [Allow a user to manage a group's membership](#)
- [Allow a user to manage IAM users](#)
- [Allow users to set account password policy](#)
- [Allow users to generate and retrieve IAM credential reports](#)
- [Allow all IAM actions \(admin access\)](#)

Allow a user to list the account's groups, users, policies, and more for reporting purposes

The following policy allows the user to call any IAM action that starts with the string `Get` or `List`, and to generate reports. To view the example policy, see [IAM: Allows read-only access to the IAM console](#).

Allow a user to manage a group's membership

The following policy allows the user to update the membership of the group called *MarketingGroup*. To view the example policy, see [IAM: Allows managing a group's membership programmatically and in the console](#).

Allow a user to manage IAM users

The following policy allows a user to perform all the tasks associated with managing IAM users but not to perform actions on other entities, such as creating groups or policies. Allowed actions include these:

- Creating the user (the [CreateUser](#) action).
- Deleting the user. This task requires permissions to perform all of the following actions: [DeleteSigningCertificate](#), [DeleteLoginProfile](#), [RemoveUserFromGroup](#), and [DeleteUser](#).
- Listing users in the account and in groups (the [GetUser](#), [ListUsers](#) and [ListGroupsWithUser](#) actions).

- Listing and removing policies for the user (the [ListUserPolicies](#), [ListAttachedUserPolicies](#), [DetachUserPolicy](#), [DeleteUserPolicy](#) actions)
- Renaming or changing the path for the user (the [UpdateUser](#) action). The Resource element must include an ARN that covers both the source path and the target path. For more information on paths, see [Friendly names and paths](#).

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "AllowUsersToPerformUserActions",
      "Effect": "Allow",
      "Action": [
        "iam:ListPolicies",
        "iam:GetPolicy",
        "iam:UpdateUser",
        "iam:AttachUserPolicy",
        "iam:ListEntitiesForPolicy",
        "iam:DeleteUserPolicy",
        "iam:DeleteUser",
        "iam:ListUserPolicies",
        "iam:CreateUser",
        "iam:RemoveUserFromGroup",
        "iam:AddUserToGroup",
        "iam:GetUserPolicy",
        "iam:ListGroupsWithUser",
        "iam:PutUserPolicy",
        "iam:ListAttachedUserPolicies",
        "iam:ListUsers",
        "iam:GetUser",
        "iam:DetachUserPolicy"
      ],
      "Resource": "*"
    },
    {
      "Sid": "AllowUsersToSeeStatsOnIAMConsoleDashboard",
      "Effect": "Allow",
      "Action": [
        "iam:GetAccount*",
        "iam:ListAccount*"
      ],
    }
  ]
}
```

```
        "Resource": "*"
    }
]
}
```

A number of the permissions included in the preceding policy allow the user to perform tasks in the AWS Management Console. Users who perform user-related tasks from the [AWS CLI](#), the [AWS SDKs](#), or the IAM HTTP query API only might not need certain permissions. For example, if users already know the ARN of policies to detach from a user, they do not need the `iam:ListAttachedUserPolicies` permission. The exact list of permissions that a user requires depends on the tasks that the user must perform while managing other users.

The following permissions in the policy allow access to user tasks via the AWS Management Console:

- `iam:GetAccount*`
- `iam:ListAccount*`

Allow users to set account password policy

You might give some users permissions to get and update the [password policy](#) of your AWS account. To view the example policy, see [IAM: Allows setting the account password requirements programmatically and in the console](#).

Allow users to generate and retrieve IAM credential reports

You can give users permission to generate and download a report that lists all users in your AWS account. The report also lists the status of various user credentials, including passwords, access keys, MFA devices, and signing certificates. For more information about credential reports, see [Getting credential reports for your AWS account](#). To view the example policy, see [IAM: Generate and retrieve IAM credential reports](#).

Allow all IAM actions (admin access)

You might give some users administrative permissions to perform all actions in IAM, including managing passwords, access keys, MFA devices, and user certificates. The following example policy grants these permissions.

⚠ Warning

When you give a user full access to IAM, there is no limit to the permissions that user can grant to him/herself or others. The user can create new IAM entities (users or roles) and grant those entities full access to all resources in your AWS account. When you give a user full access to IAM, you are effectively giving them full access to all resources in your AWS account. This includes access to delete all resources. You should grant these permissions to only trusted administrators, and you should enforce multi-factor authentication (MFA) for these administrators.

```
{
  "Version": "2012-10-17",
  "Statement": {
    "Effect": "Allow",
    "Action": "iam:*",
    "Resource": "*"
  }
}
```

Code examples for IAM using AWS SDKs

Code examples for IAM using AWS SDKs

The following code examples show how to use IAM with an AWS software development kit (SDK).

Actions are code excerpts from larger programs and must be run in context. While actions show you how to call individual service functions, you can see actions in context in their related scenarios and cross-service examples.

Scenarios are code examples that show you how to accomplish a specific task by calling multiple functions within the same service.

For a complete list of AWS SDK developer guides and code examples, see [Using IAM with an AWS SDK](#). This topic also includes information about getting started and details about previous SDK versions.

Get started

Hello IAM

The following code examples show how to get started using IAM.

.NET

AWS SDK for .NET

Note

There's more on GitHub. Find the complete example and learn how to set up and run in the [AWS Code Examples Repository](#).

```
namespace IAMActions;

public class HelloIAM
{
    static async Task Main(string[] args)
    {
        // Getting started with AWS Identity and Access Management (IAM). List
        // the policies for the account.
        var iamClient = new AmazonIdentityManagementServiceClient();

        var listPoliciesPaginator = iamClient.Paginators.ListPolicies(new
ListPoliciesRequest());
        var policies = new List<ManagedPolicy>();

        await foreach (var response in listPoliciesPaginator.Responses)
```

```
    {
        policies.AddRange(response.Policies);
    }

    Console.WriteLine("Here are the policies defined for your account:\n");
    policies.ForEach(policy =>
    {
        Console.WriteLine($"Created:
{policy.CreateDate}\t{policy.PolicyName}\t{policy.Description}");
    });
}
```

- For API details, see [ListPolicies](#) in *AWS SDK for .NET API Reference*.

C++

SDK for C++

Note

There's more on GitHub. Find the complete example and learn how to set up and run in the [AWS Code Examples Repository](#).

Code for the CMakeLists.txt CMake file.

```
# Set the minimum required version of CMake for this project.
cmake_minimum_required(VERSION 3.13)

# Set the AWS service components used by this project.
set(SERVICE_COMPONENTS iam)

# Set this project's name.
project("hello_iam")

# Set the C++ standard to use to build this target.
# At least C++ 11 is required for the AWS SDK for C++.
set(CMAKE_CXX_STANDARD 11)
```

```
# Use the MSVC variable to determine if this is a Windows build.
set(WINDOWS_BUILD ${MSVC})

if (WINDOWS_BUILD) # Set the location where CMake can find the installed
  libraries for the AWS SDK.
  string(REPLACE ";" "/aws-cpp-sdk-all;" SYSTEM_MODULE_PATH
    "${CMAKE_SYSTEM_PREFIX_PATH}/aws-cpp-sdk-all")
  list(APPEND CMAKE_PREFIX_PATH ${SYSTEM_MODULE_PATH})
endif ()

# Find the AWS SDK for C++ package.
find_package(AWSSDK REQUIRED COMPONENTS ${SERVICE_COMPONENTS})

if (WINDOWS_BUILD)
  # Copy relevant AWS SDK for C++ libraries into the current binary directory
  for running and debugging.

  # set(BIN_SUB_DIR "/Debug") # if you are building from the command line you
  may need to uncomment this
  # and set the proper subdirectory to the executables' location.

  AWSSDK_CPY_DYN_LIBS(SERVICE_COMPONENTS ""
    ${CMAKE_CURRENT_BINARY_DIR}${BIN_SUB_DIR})
endif ()

add_executable(${PROJECT_NAME}
  hello_iam.cpp)

target_link_libraries(${PROJECT_NAME}
  ${AWSSDK_LINK_LIBRARIES})
```

Code for the iam.cpp source file.

```
#include <aws/core/Aws.h>
#include <aws/iam/IAMClient.h>
#include <aws/iam/model/ListPoliciesRequest.h>
#include <iostream>
#include <iomanip>

/*
 * A "Hello IAM" starter application which initializes an AWS Identity and
 * Access Management (IAM) client
```

```
* and lists the IAM policies.
*
* main function
*
* Usage: 'hello_iam'
*
*/

int main(int argc, char **argv) {
    Aws::SDKOptions options;

Add an IAM user to a group using an AWS SDK

The following code examples show how to add a user to an IAM group.

Action examples are code excerpts from larger programs and must be run in context. You can see this action in context in the following code example:

- [Create a group and add a user](#)

.NET

AWS SDK for .NET

Note

There's more on GitHub. Find the complete example and learn how to set up and run in the [AWS Code Examples Repository](#).

```
/// <summary>
/// Add an existing IAM user to an existing IAM group.
/// </summary>
/// <param name="userName">The username of the user to add.</param>
/// <param name="groupName">The name of the group to add the user to.</param>
/// <returns>A Boolean value indicating the success of the action.</returns>
public async Task<bool> AddUserToGroupAsync(string userName, string
groupName)
{
    var response = await _IAMService.AddUserToGroupAsync(new
AddUserToGroupRequest
    {
        GroupName = groupName,
        UserName = userName,
    });

    return response.HttpStatusCode == HttpStatusCode.OK;
}
```

- For API details, see [AddUserToGroup](#) in *AWS SDK for .NET API Reference*.

CLI

AWS CLI

To add a user to an IAM group

The following `add-user-to-group` command adds an IAM user named Bob to the IAM group named Admins.

```
aws iam add-user-to-group \
  --user-name Bob \
  --group-name Admins
```

This command produces no output.

For more information, see [Adding and removing users in an IAM user group](#) in the *AWS IAM User Guide*.

- For API details, see [AddUserToGroup](#) in *AWS CLI Command Reference*.

For a complete list of AWS SDK developer guides and code examples, see [Using IAM with an AWS SDK](#). This topic also includes information about getting started and details about previous SDK versions.

Attach an IAM policy to a role using an AWS SDK

The following code examples show how to attach an IAM policy to a role.

Action examples are code excerpts from larger programs and must be run in context. You can see this action in context in the following code examples:

- [Create a group and add a user](#)
- [Create a user and assume a role](#)
- [Manage roles](#)

.NET

Attach an IAM policy to a user using an AWS SDK

The following code examples show how to attach an IAM policy to a user.

Warning

To avoid security risks, don't use IAM users for authentication when developing purpose-built software or working with real data. Instead, use federation with an identity provider such as [AWS IAM Identity Center](#).

Action examples are code excerpts from larger programs and must be run in context. You can see this action in context in the following code example:

- [Create read-only and read-write users](#)

CLI

AWS CLI

To attach a managed policy to an IAM user

The following `attach-user-policy` command attaches the AWS managed policy named `AdministratorAccess` to the IAM user named `Alice`.

```
aws iam attach-user-policy \  
  --policy-arn arn:aws:iam::aws:policy/AdministratorAccess \  
  --user-name Alice
```

This command produces no output.

For more information, see [Managed policies and inline policies](#) in the *AWS IAM User Guide*.

- For API details, see [AttachUserPolicy](#) in *AWS CLI Command Reference*.

```
/// <summary>
/// Update the inline policy document embedded in a role.
/// </summary>
/// <param name="policyName">The name of the policy to embed.</param>
/// <param name="roleName">The name of the role to update.</param>
/// <param name="policyDocument">The policy document that defines the role.</
param>
/// <returns>A Boolean value indicating the success of the action.</returns>
public async Task<bool> PutRolePolicyAsync(string policyName, string
roleName, string policyDocument)
{
    var request = new PutRolePolicyRequest
    {
        PolicyName = policyName,
        RoleName = roleName,
        PolicyDocument = policyDocument
    };
};
```

```
var response = await _IAMService.PutRolePolicyAsync(request);
return response.HttpStatusCode == HttpStatusCode.OK;
}
```

- For API details, see [PutRolePolicy](#) in *AWS SDK for .NET API Reference*.

C++

SDK for C++

Note

There's more on GitHub. Find the complete example and learn how to set up and run in the [AWS Code Examples Repository](#).

```
bool AwsDoc::IAM::putRolePolicy(
    const Aws::String &roleName,
    const Aws::String &policyName,
    const Aws::String &policyDocument,
    const Aws::Client::ClientConfiguration &clientConfig) {
    Aws::IAM::IAMClient iamClient(clientConfig);
    Aws::IAM::Model::PutRolePolicyRequest request;

    request.SetRoleName(roleName);
    request.SetPolicyName(policyName);
    request.SetPolicyDocument(policyDocument);

    Aws::IAM::Model::PutRolePolicyOutcome outcome =
iamClient.PutRolePolicy(request);
    if (!outcome.IsSuccess()) {
        std::cerr << "Error putting policy on role. " <<
            outcome.GetError().GetMessage() << std::endl;
    }
    else {
        std::cout << "Successfully put the role policy." << std::endl;
    }

    return outcome.IsSuccess();
}
```

```
}
```

- For API details, see [PutRolePolicy](#) in *AWS SDK for C++ API Reference*.

CLI

AWS CLI

To attach a permissions policy to an IAM role

The following `put-role-policy` command adds a permissions policy to the role named `Test-Role`.

```
aws iam put-role-policy \  
  --role-name Test-Role \  
  --policy-name ExamplePolicy \  
  --policy-document file://AdminPolicy.json
```

This command produces no output.

The policy is defined as a JSON document in the `AdminPolicy.json` file. (The file name and extension do not have significance.)

To attach a trust policy to a role, use the `update-assume-role-policy` command.

For more information, see [Modifying a role](#) in the *AWS IAM User Guide*.

- For API details, see [PutRolePolicy](#) in *AWS CLI Command Reference*.

Create an IAM SAML provider using an AWS SDK

The following code examples show how to create an AWS Identity and Access Management (IAM) SAML provider.

CLI

AWS CLI

To create a SAML provider

This example creates a new SAML provider in IAM named `MySAMLProvider`. It is described by the SAML metadata document found in the file `SAMLMetaData.xml`.

```
aws iam create-saml-provider \  
  --saml-metadata-document file://SAMLMetaData.xml \  
  --name MySAMLProvider
```

Output:

```
{

```
/// <summary>
/// Create an IAM group.
/// </summary>
/// <param name="groupName">The name to give the IAM group.</param>
/// <returns>The IAM group that was created.</returns>
public async Task<Group> CreateGroupAsync(string groupName)
{
    var response = await _IAMService.CreateGroupAsync(new CreateGroupRequest
{ GroupName = groupName });
    return response.Group;
}
```

```
}
```

- For API details, see [CreateGroup](#) in *AWS SDK for .NET API Reference*.

CLI

AWS CLI

To create an IAM group

The following `create-group` command creates an IAM group named Admins.

```
aws iam create-group \  
  --group-name Admins
```

Output:

```
{  
  "Group": {  
    "Path": "/",  
    "CreateDate": "2015-03-09T20:30:24.940Z",  
    "GroupId": "AIDGPMS9R04H3FEXAMPLE",  
    "Arn": "arn:aws:iam::123456789012:group/Admins",  
    "GroupName": "Admins"  
  }  
}
```

For more information, see [Creating IAM user groups](#) in the *AWS IAM User Guide*.

CLI

AWS CLI

Example 1: To create a customer managed policy

The following command creates a customer managed policy named my-policy.

```
aws iam create-policy \  
  --policy-name my-policy \  
  --policy-document file://policy
```

The file policy is a JSON document in the current folder that grants read only access to the shared folder in an Amazon S3 bucket named my-bucket.

```
{  
  "Version": "2012-10-17",  
  "Statement": [  
    {  
      "Effect": "Allow",  
      "Action": [  
        "s3:Get*",  
        "s3:List*"  
      ],  
      "Resource": [  
        "arn:aws:s3:::my-bucket/shared/*"  
      ]  
    }  
  ]  
}
```

Output:

```
{  
  "Policy": {  
    "PolicyName": "my-policy",  
    "CreateDate": "2015-06-01T19:31:18.620Z",  
    "AttachmentCount": 0,  
    "IsAttachable": true,  
    "PolicyId": "ZXR6A36LTYANPAI7NJ5UV",  
    "DefaultVersionId": "v1",  
    "Path": "/",  
    "Arn": "arn:aws:iam::0123456789012:policy/my-policy",  
    "UpdateDate": "2015-06-01T19:31:18.620Z"  
  }  
}
```

For more information on using files as input for string parameters, see [Specify parameter values for the AWS CLI](#) in the *AWS CLI User Guide*.

Example 2: To create a customer managed policy with a description

The following command creates a customer managed policy named `my-policy` with an immutable description:

```
aws iam create-policy \  
  --policy-name my-policy \  
  --policy-document file://policy.json \  
  --description "This policy grants access to all Put, Get, and List actions  
for my-bucket"
```

The file `policy.json` is a JSON document in the current folder that grants access to all Put, List, and Get actions for an Amazon S3 bucket named `my-bucket`.

```
{  
  "Version": "2012-10-17",  
  "Statement": [  
    {  
      "Effect": "Allow",  
      "Action": [  
        "s3:ListBucket*",  
        "s3:PutBucket*",  
        "s3:GetBucket*"  
      ],  
      "Resource": [  
        "arn:aws:s3:::my-bucket"  
      ]  
    }  
  ]  
}
```

Output:

```
{  
  "Policy": {  
    "PolicyName": "my-policy",  
    "PolicyId": "ANPAWGSUGIDPEXAMPLE",  
    "Arn": "arn:aws:iam::123456789012:policy/my-policy",  
    "Path": "/",  
    "DefaultVersionId": "v1",  
    "AttachmentCount": 0,  
    "PermissionsBoundaryUsageCount": 0,  
  }  
}
```

```

    "IsAttachable": true,
    "CreateDate": "2023-05-24T22:38:47+00:00",
    "UpdateDate": "2023-05-24T22:38:47+00:00"
  }
}

```

For more information on Identity-based Policies, see [Identity-based policies and resource-based policies](#) in the *AWS IAM User Guide*.

Example 3: To Create a customer managed policy with tags

The following command creates a customer managed policy named `my-policy` with tags. This example uses the `--tags` parameter flag with the following JSON-formatted tags: `'{"Key": "Department", "Value": "Accounting"}'` `'{"Key": "Location", "Value": "Seattle"}'`. Alternatively, the `--tags` flag can be used with tags in the shorthand format: `'Key=Department,Value=Accounting Key=Location,Value=Seattle'`.

```

aws iam create-policy \
  --policy-name my-policy \
  --policy-document file://policy.json \
  --tags '{"Key": "Department", "Value": "Accounting"}' '{"Key": "Location",
"Value": "Seattle"}'

```

The file `policy.json` is a JSON document in the current folder that grants access to all Put, List, and Get actions for an Amazon S3 bucket named `my-bucket`.

```

{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "s3:ListBucket*",
        "s3:PutBucket*",
        "s3:GetBucket*"
      ],
      "Resource": [
        "arn:aws:s3:::my-bucket"
      ]
    }
  ]
}

```

```
]
}
```

Output:

```
{
  "Policy": {
    "PolicyName": "my-policy",
    "PolicyId": "ANPAWGSUGIDPEXAMPLE",
    "Arn": "arn:aws:iam::12345678012:policy/my-policy",
    "Path": "/",
    "DefaultVersionId": "v1",
    "AttachmentCount": 0,
    "PermissionsBoundaryUsageCount": 0,
    "IsAttachable": true,
    "CreateDate": "2023-05-24T23:16:39+00:00",
    "UpdateDate": "2023-05-24T23:16:39+00:00",
    "Tags": [
      {
        "Key": "Department",
        "Value": "Accounting"
      },
      {
        "Key": "Location",
        "Value": "Seattle"
      }
    ]
  }
}
```

For more information on Tagging policies, see [Tagging customer managed policies](#) in the *AWS IAM User Guide*.

Create an IAM policy version using an AWS SDK

The following code examples show how to create an IAM policy version.

Action examples are code excerpts from larger programs and must be run in context. You can see this action in context in the following code example:

- [Manage policies](#)

CLI

AWS CLI

To create a new version of a managed policy

This example creates a new v2 version of the IAM policy whose ARN is `arn:aws:iam::123456789012:policy/MyPolicy` and makes it the default version.

```
aws iam create-policy-version \  
  --policy-arn arn:aws:iam::123456789012:policy/MyPolicy \  
  --policy-document file://NewPolicyVersion.json \  
  --set-as-default
```

Output:

```
{  
  "PolicyVersion": {  
    "CreateDate": "2015-06-16T18:56:03.721Z",  
    "VersionId": "v2",  
    "IsDefaultVersion": true  
  }  
}
```

For more information, see [Versioning IAM policies](#) in the *AWS IAM User Guide*.

- For API details, see [CreatePolicyVersion](#) in *AWS CLI Command Reference*.

Python

C++

SDK for C++

Note

There's more on GitHub. Find the complete example and learn how to set up and run in the [AWS Code Examples Repository](#).

```
bool AwsDoc::IAM::createIamRole(
    const Aws::String &roleName,
    const Aws::String &policy,
    const Aws::Client::ClientConfiguration &clientConfig) {
    Aws::IAM::IAMClient client(clientConfig);
    Aws::IAM::Model::CreateRoleRequest request;

    request.SetRoleName(roleName);
    request.SetAssumeRolePolicyDocument(policy);

    Aws::IAM::Model::CreateRoleOutcome outcome = client.CreateRole(request);
    if (!outcome.IsSuccess()) {
        std::cerr << "Error creating role. " <<
            outcome.GetError().GetMessage() << std::endl;
    }
}
```

```
else {
    const Aws::IAM::Model::Role iamRole = outcome.GetResult().GetRole();
    std::cout << "Created role " << iamRole.GetRoleName() << "\n";
    std::cout << "ID: " << iamRole.GetRoleId() << "\n";
    std::cout << "ARN: " << iamRole.GetArn() << std::endl;
}

return outcome.IsSuccess();
}
```

- For API details, see [CreateRole](#) in *AWS SDK for C++ API Reference*.

CLI

AWS CLI

Example 1: To create an IAM role

The following `create-role` command creates a role named `Test-Role` and attaches a trust policy to it.

```
aws iam create-role \
  --role-name Test-Role \
  --assume-role-policy-document file://Test-Role-Trust-Policy.json
```

Output:

```
{
  "Role": {
    "AssumeRolePolicyDocument": "<URL-encoded-JSON>",
    "RoleId": "AKIAIOSFODNN7EXAMPLE",
    "CreateDate": "2013-06-07T20:43:32.821Z",
    "RoleName": "Test-Role",
    "Path": "/",
    "Arn": "arn:aws:iam::123456789012:role/Test-Role"
  }
}
```

The trust policy is defined as a JSON document in the *Test-Role-Trust-Policy.json* file. (The file name and extension do not have significance.) The trust policy must specify a principal.

To attach a permissions policy to a role, use the `put-role-policy` command.

For more information, see [Creating IAM roles](#) in the *AWS IAM User Guide*.

Example 2: To create an IAM role with specified maximum session duration

The following `create-role` command creates a role named `Test-Role` and sets a maximum session duration of 7200 seconds (2 hours).

```
aws iam create-role \  
  --role-name Test-Role \  
  --assume-role-policy-document file://Test-Role-Trust-Policy.json \  
  --max-session-duration 7200
```

Output:

```
{  
  "Role": {  
    "Path": "/",  
    "RoleName": "Test-Role",  
    "RoleId": "AKIAIOSFODNN7EXAMPLE",  
    "Arn": "arn:aws:iam::12345678012:role/Test-Role",  
    "CreateDate": "2023-05-24T23:50:25+00:00",  
    "AssumeRolePolicyDocument": {  
      "Version": "2012-10-17",  
      "Statement": [  
        {  
          "Sid": "Statement1",  
          "Effect": "Allow",  
          "Principal": {  
            "AWS": "arn:aws:iam::12345678012:root"  
          },  
          "Action": "sts:AssumeRole"  
        }  
      ]  
    }  
  }  
}
```

For more information, see [Modifying a role maximum session duration \(AWS API\)](#) in the *AWS IAM User Guide*.

Example 3: To create an IAM Role with tags

The following command creates an IAM Role Test-Role with tags. This example uses the `--tags` parameter flag with the following JSON-formatted tags: `'{"Key": "Department", "Value": "Accounting"}' '{"Key": "Location", "Value": "Seattle"}'`. Alternatively, the `--tags` flag can be used with tags in the shorthand format: `'Key=Department,Value=Accounting Key=Location,Value=Seattle'`.

```
aws iam create-role \  
  --role-name Test-Role \  
  --assume-role-policy-document file://Test-Role-Trust-Policy.json \  
  --tags '{"Key": "Department", "Value": "Accounting"}' '{"Key": "Location",  
  "Value": "Seattle"}'
```

Output:

```
{  
  "Role": {  
    "Path": "/",  
    "RoleName": "Test-Role",  
    "RoleId": "AKIAIOSFODNN7EXAMPLE",  
    "Arn": "arn:aws:iam::123456789012:role/Test-Role",  
    "CreateDate": "2023-05-25T23:29:41+00:00",  
    "AssumeRolePolicyDocument": {  
      "Version": "2012-10-17",  
      "Statement": [  
        {  
          "Sid": "Statement1",  
          "Effect": "Allow",  
          "Principal": {  
            "AWS": "arn:aws:iam::123456789012:root"  
          },  
          "Action": "sts:AssumeRole"  
        }  
      ]  
    },  
    "Tags": [  
      {  
        "Key": "Department",  
        "Value": "Accounting"  
      },  
      {  
        "Key": "Location",  
        "Value": "Seattle"  
      }  
    ]  
  }  
}
```

```

    }
  ]
}
}

```

For more information, see [Tagging IAM roles](#) in the *AWS IAM User Guide*.

- For API details, see [CreateRole](#) in *AWS CLI Command Reference*.

```
/// <summary>
/// Create an IAM service-linked role.
/// </summary>
/// <param name="serviceName">The name of the AWS Service.</param>
/// <param name="description">A description of the IAM service-linked role.</
param>
/// <returns>The IAM role that was created.</returns>
public async Task<Role> CreateServiceLinkedRoleAsync(string serviceName,
string description)
{
    var request = new CreateServiceLinkedRoleRequest
    {
        AWSServiceName = serviceName,
        Description = description
    };

    var response = await _IAMService.CreateServiceLinkedRoleAsync(request);
    return response.Role;
}
```

- For API details, see [CreateServiceLinkedRole](#) in *AWS SDK for .NET API Reference*.

CLI

AWS CLI

To create a service-linked role

The following `create-service-linked-role` example creates a service-linked role for the specified AWS service and attaches the specified description.

```
aws iam create-service-linked-role \  
  --aws-service-name lex.amazonaws.com \  
  --description "My service-linked role to support Lex"
```

Output:

```
{  
  "Role": {  
    "Path": "/aws-service-role/lex.amazonaws.com/",  
    "RoleName": "AWSServiceRoleForLexBots",  
    "RoleId": "AROA1234567890EXAMPLE",  
    "Arn": "arn:aws:iam::1234567890:role/aws-service-role/lex.amazonaws.com/  
AWSServiceRoleForLexBots",  
    "CreateDate": "2019-04-17T20:34:14+00:00",  
    "AssumeRolePolicyDocument": {  
      "Version": "2012-10-17",  
      "Statement": [  
        {  
          "Action": [  
            "sts:AssumeRole"  
          ],  
          "Effect": "Allow",  
          "Principal": {  
            "Service": [  
              "lex.amazonaws.com"  
            ]  
          }  
        }  
      ]  
    }  
  }  
}
```

For a complete list of AWS SDK developer guides and code examples, see [Using IAM with an AWS SDK](#). This topic also includes information about getting started and details about previous SDK versions.

Create an IAM user using an AWS SDK

The following code examples show how to create an IAM user.

Warning

To avoid security risks, don't use IAM users for authentication when developing purpose-built software or working with real data. Instead, use federation with an identity provider such as [AWS IAM Identity Center](#).

Action examples are code excerpts from larger programs and must be run in context. You can see this action in context in the following code examples:

- [Create a group and add a user](#)
- [Create a user and assume a role](#)
- [Create read-only and read-write users](#)

create_request.SetUserName(userName);

auto create_outcome = iam.CreateUser(create_request);
if (!create_outcome.IsSuccess()) {
    std::cerr << "Error creating IAM user " << userName << ":" <<
        create_outcome.GetError().GetMessage() << std::endl;
}
else {
    std::cout << "Successfully created IAM user " << userName << std::endl;
}

return create_outcome.IsSuccess();
```

- For API details, see [CreateUser](#) in *AWS SDK for C++ API Reference*.

CLI

AWS CLI

Example 1: To create an IAM user

The following `create-user` command creates an IAM user named Bob in the current account.

```
aws iam create-user \  
    --user-name Bob
```

Output:

```
{
  "User": {
    "UserName": "Bob",
    "Path": "/",
    "CreateDate": "2023-06-08T03:20:41.270Z",
    "UserId": "AIDAIOSFODNN7EXAMPLE",
    "Arn": "arn:aws:iam::123456789012:user/Bob"
  }
}
```

For more information, see [Creating an IAM user in your AWS account](#) in the *AWS IAM User Guide*.

Example 2: To create an IAM user at a specified path

The following `create-user` command creates an IAM user named Bob at the specified path.

```
aws iam create-user \
  --user-name Bob \
  --path /division_abc/subdivision_xyz/
```

Output:

```
{
  "User": {
    "Path": "/division_abc/subdivision_xyz/",
    "UserName": "Bob",
    "UserId": "AIDAIOSFODNN7EXAMPLE",
    "Arn": "arn:aws:iam::12345678012:user/division_abc/subdivision_xyz/Bob",
    "CreateDate": "2023-05-24T18:20:17+00:00"
  }
}
```

For more information, see [IAM identifiers](#) in the *AWS IAM User Guide*.

Example 3: To Create an IAM User with tags

The following `create-user` command creates an IAM user named Bob with tags. This example uses the `--tags` parameter flag with the following JSON-formatted

tags: '{"Key": "Department", "Value": "Accounting"}' '{"Key": "Location", "Value": "Seattle"}'. Alternatively, the `--tags` flag can be used with tags in the shorthand format: `'Key=Department, Value=Accounting Key=Location, Value=Seattle'`.

```
aws iam create-user \  
  --user-name Bob \  
  --tags '{"Key": "Department", "Value": "Accounting"}' '{"Key": "Location",  
  "Value": "Seattle"}'
```

Output:

```
{  
  "User": {  
    "Path": "/",  
    "UserName": "Bob",  
    "UserId": "AIDAIOSFODNN7EXAMPLE",  
    "Arn": "arn:aws:iam::12345678012:user/Bob",  
    "CreateDate": "2023-05-25T17:14:21+00:00",  
    "Tags": [  
      {  
        "Key": "Department",  
        "Value": "Accounting"  
      },  
      {  
        "Key": "Location",  
        "Value": "Seattle"  
      }  
    ]  
  }  
}
```

For more information, see [Tagging IAM users](#) in the *AWS IAM User Guide*.

Example 3: To create an IAM user with a set permissions boundary

The following `create-user` command creates an IAM user named Bob with the permissions boundary of `AmazonS3FullAccess`.

```
aws iam create-user \  
  --user-name Bob \  
  --permissions-boundary arn:aws:iam::aws:policy/AmazonS3FullAccess
```

Output:

```
{
  "User": {
    "Path": "/",
    "UserName": "Bob",
    "UserId": "AIDAIOSFODNN7EXAMPLE",
    "Arn": "arn:aws:iam::12345678012:user/Bob",
    "CreateDate": "2023-05-24T17:50:53+00:00",
    "PermissionsBoundary": {
      "PermissionsBoundaryType": "Policy",
      "PermissionsBoundaryArn": "arn:aws:iam::aws:policy/AmazonS3FullAccess"
    }
  }
}
```

For more information, see [Permissions boundaries for IAM entities](#) in the *AWS IAM User Guide*.

Create an IAM access key using an AWS SDK

The following code examples show how to create an IAM access key.

⚠ Warning

To avoid security risks, don't use IAM users for authentication when developing purpose-built software or working with real data. Instead, use federation with an identity provider such as [AWS IAM Identity Center](#).

Action examples are code excerpts from larger programs and must be run in context. You can see this action in context in the following code examples:

- [Create a group and add a user](#)
- [Create a user and assume a role](#)
- [Create read-only and read-write users](#)
- [Manage access keys](#)

```
Aws::String AwsDoc::IAM::createAccessKey(const Aws::String &userName,
                                         const Aws::Client::ClientConfiguration
&clientConfig) {
    Aws::IAM::IAMClient iam(clientConfig);

    Aws::IAM::Model::CreateAccessKeyRequest request;
    request.SetUserName(userName);

    Aws::String result;
```

```
Aws::IAM::Model::CreateAccessKeyOutcome outcome =
iam.CreateAccessKey(request);
if (!outcome.IsSuccess()) {
    std::cerr << "Error creating access key for IAM user " << userName
                << ":" << outcome.GetError().GetMessage() << std::endl;
}
else {
    const auto &accessKey = outcome.GetResult().GetAccessKey();
    std::cout << "Successfully created access key for IAM user " <<
                userName << std::endl << "  aws_access_key_id = " <<
                accessKey.GetAccessKeyId() << std::endl <<
                "  aws_secret_access_key = " << accessKey.GetSecretAccessKey()
    <<
                std::endl;
    result = accessKey.GetAccessKeyId();
}

return result;
}
```

- For API details, see [CreateAccessKey](#) in *AWS SDK for C++ API Reference*.

CLI

AWS CLI

To create an access key for an IAM user

The following `create-access-key` command creates an access key (access key ID and secret access key) for the IAM user named Bob.

```
aws iam create-access-key \
  --user-name Bob
```

Output:

```
{
  "AccessKey": {
    "UserName": "Bob",
    "Status": "Active",
    "CreateDate": "2015-03-09T18:39:23.411Z",
```

```
    "SecretAccessKey": "wJalrXUtnFEMI/K7MDENG/bPxrFiCYzEXAMPLEKEY",
    "AccessKeyId": "AKIAIOSFODNN7EXAMPLE"
  }
}
```

Store the secret access key in a secure location. If it is lost, it cannot be recovered, and you must create a new access key.

For more information, see [Managing access keys for IAM users](#) in the *AWS IAM User Guide*.

- For API details, see [CreateAccessKey](#) in *AWS CLI Command Reference*.

Create an inline IAM policy for a group using an AWS SDK

The following code examples show how to create an inline IAM policy for a group.

Action examples are code excerpts from larger programs and must be run in context. You can see this action in context in the following code example:

- [Create a group and add a user](#)

.NET

AWS SDK for .NET

Note

There's more on GitHub. Find the complete example and learn how to set up and run in the [AWS Code Examples Repository](#).

```
/// <summary>
/// Add or update an inline policy document that is embedded in an IAM group.
/// </summary>
/// <param name="groupName">The name of the IAM group.</param>
/// <param name="policyName">The name of the IAM policy.</param>
/// <param name="policyDocument">The policy document defining the IAM
policy.</param>
/// <returns>A Boolean value indicating the success of the action.</returns>
public async Task<bool> PutGroupPolicyAsync(string groupName, string
policyName, string policyDocument)
{
    var request = new PutGroupPolicyRequest
    {
        GroupName = groupName,
        PolicyName = policyName,
        PolicyDocument = policyDocument
    };

    var response = await _IAMService.PutGroupPolicyAsync(request);
    return response.HttpStatusCode == System.Net.HttpStatusCode.OK;
}
```

- For API details, see [PutGroupPolicy](#) in *AWS SDK for .NET API Reference*.

CLI

AWS CLI

To add a policy to a group

The following `put-group-policy` command adds a policy to the IAM group named `Admins`.

```
aws iam put-group-policy \  
  --group-name Admins \  
  --policy-document file://AdminPolicy.json \  
  --policy-name AdminRoot
```

This command produces no output.

The policy is defined as a JSON document in the `AdminPolicy.json` file. (The file name and extension do not have significance.)

For more information, see [Managing IAM policies](#) in the *AWS IAM User Guide*.

- For API details, see [PutGroupPolicy](#) in *AWS CLI Command Reference*.

For a complete list of AWS SDK developer guides and code examples, see [Using IAM with an AWS SDK](#). This topic also includes information about getting started and details about previous SDK versions.

Create an inline IAM policy for a user using an AWS SDK

The following code examples show how to create an inline IAM policy for a user.

Warning

To avoid security risks, don't use IAM users for authentication when developing purpose-built software or working with real data. Instead, use federation with an identity provider such as [AWS IAM Identity Center](#).

Action examples are code excerpts from larger programs and must be run in context. You can see this action in context in the following code example:

- [Create a user and assume a role](#)

CLI

AWS CLI

To attach a policy to an IAM user

The following `put-user-policy` command attaches a policy to the IAM user named Bob.

```
aws iam put-user-policy \  
  --user-name Bob \  
  --policy-name ExamplePolicy \  
  --policy-document file://AdminPolicy.json
```

This command produces no output.

The policy is defined as a JSON document in the `AdminPolicy.json` file. (The file name and extension do not have significance.)

For more information, see [Adding and removing IAM identity permissions](#) in the *AWS IAM User Guide*.

- For API details, see [PutUserPolicy](#) in *AWS CLI Command Reference*.

CLI

AWS CLI

To create an instance profile

The following `create-instance-profile` command creates an instance profile named `Webserver`.

```
aws iam create-instance-profile \  
    --instance-profile-name Webserver
```

Output:

```
{  
  "InstanceProfile": {  
    "InstanceId": "AIPAJMBC7DLSPEXAMPLE",
```

```
    "Roles": [],
    "CreateDate": "2015-03-09T20:33:19.626Z",
    "InstanceProfileName": "Webserver",
    "Path": "/",
    "Arn": "arn:aws:iam::123456789012:instance-profile/Webserver"
  }
}
```

To add a role to an instance profile, use the `add-role-to-instance-profile` command.

For more information, see [Using an IAM role to grant permissions to applications running on Amazon EC2 instances](#) in the *AWS IAM User Guide*.

- For API details, see [CreateInstanceProfile](#) in *AWS CLI Command Reference*.

Delete an IAM SAML provider using an AWS SDK

The following code examples show how to delete an AWS Identity and Access Management (IAM) SAML provider.

CLI

AWS CLI

To delete a SAML provider

This example deletes the IAM SAML 2.0 provider whose ARN is `arn:aws:iam::123456789012:saml-provider/SAMLADFSPROVIDER`.

```
aws iam delete-saml-provider \  
--saml-provider-arn arn:aws:iam::123456789012:saml-provider/SAMLADFSPROVIDER
```

This command produces no output.

For more information, see [Creating IAM SAML identity providers](#) in the *AWS IAM User Guide*.

- For API details, see [DeleteSAMLProvider](#) in *AWS CLI Command Reference*.

CLI

AWS CLI

To delete an IAM role

The following `delete-role` command removes the role named `Test-Role`.

```
aws iam delete-role \
  --role-name Test-Role
```

This command produces no output.

Before you can delete a role, you must remove the role from any instance profile (`remove-role-from-instance-profile`), detach any managed policies (`detach-role-policy`) and delete any inline policies that are attached to the role (`delete-role-policy`).

For more information, see [Creating IAM roles](#) and [Using instance profiles](#) in the *AWS IAM User Guide*.

- For API details, see [DeleteRole](#) in *AWS CLI Command Reference*.

Go

Delete an IAM service-linked role using an AWS SDK

The following code examples show how to delete an IAM service-linked role.

CLI

AWS CLI

To delete a service-linked role

The following `delete-service-linked-role` example deletes the specified service-linked role that you no longer need. The deletion happens asynchronously. You can check the status of the deletion and confirm when it is done by using the `get-service-linked-role-deletion-status` command.

```
aws iam delete-service-linked-role \
  --role-name AWSServiceRoleForLexBots
```

Output:

```
{
  "DeletionTaskId": "task/aws-service-role/lex.amazonaws.com/
  AWSServiceRoleForLexBots/1a2b3c4d-1234-abcd-7890-abcdeEXAMPLE"
}
```

For more information, see [Using service-linked roles](#) in the *AWS IAM User Guide*.

- For API details, see [DeleteServiceLinkedRole](#) in *AWS CLI Command Reference*.

CLI

AWS CLI

To delete an access key for an IAM user

The following `delete-access-key` command deletes the specified access key (access key ID and secret access key) for the IAM user named Bob.

```
aws iam delete-access-key \
  --access-key-id AKIDPMS9R04H3FEXAMPLE \
  --user-name Bob
```

This command produces no output.

To list the access keys defined for an IAM user, use the `list-access-keys` command.

For more information, see [Managing access keys for IAM users](#) in the *AWS IAM User Guide*.

- For API details, see [DeleteAccessKey](#) in *AWS CLI Command Reference*.

Delete an inline IAM policy from a user using an AWS SDK

The following code examples show how to delete an inline IAM policy from a user.

Warning

To avoid security risks, don't use IAM users for authentication when developing purpose-built software or working with real data. Instead, use federation with an identity provider such as [AWS IAM Identity Center](#).

Action examples are code excerpts from larger programs and must be run in context. You can see this action in context in the following code example:

- [Create a user and assume a role](#)

.NET

AWS SDK for .NET

Note

There's more on GitHub. Find the complete example and learn how to set up and run in the [AWS Code Examples Repository](#).

```
/// <summary>
/// Delete an IAM user policy.
/// </summary>
/// <param name="policyName">The name of the IAM policy to delete.</param>
/// <param name="userName">The username of the IAM user.</param>
/// <returns>A Boolean value indicating the success of the action.</returns>
public async Task<bool> DeleteUserPolicyAsync(string policyName, string
userName)
{
    var response = await _IAMService.DeleteUserPolicyAsync(new
DeleteUserPolicyRequest { PolicyName = policyName, UserName = userName });

    return response.HttpStatusCode == System.Net.HttpStatusCode.OK;
}
```

- For API details, see [DeleteUserPolicy](#) in *AWS SDK for .NET API Reference*.

CLI

AWS CLI

To remove a policy from an IAM user

The following `delete-user-policy` command removes the specified policy from the IAM user named Bob.

```
aws iam delete-user-policy \
  --user-name Bob \
  --policy-name ExamplePolicy
```

This command produces no output.

To get a list of policies for an IAM user, use the `list-user-policies` command.

For more information, see [Creating an IAM user in your AWS account](#) in the *AWS IAM User Guide*.

- For API details, see [DeleteUserPolicy](#) in *AWS CLI Command Reference*.

CLI

AWS CLI

To delete an instance profile

The following `delete-instance-profile` command deletes the instance profile named `ExampleInstanceProfile`.

```
aws iam delete-instance-profile \
    --instance-profile-name ExampleInstanceProfile
```

This command produces no output.

For more information, see [Using instance profiles](#) in the *AWS IAM User Guide*.

- For API details, see [DeleteInstanceProfile](#) in *AWS CLI Command Reference*.

Detach an IAM policy from a user using an AWS SDK

The following code examples show how to detach an IAM policy from a user.

Warning

To avoid security risks, don't use IAM users for authentication when developing purpose-built software or working with real data. Instead, use federation with an identity provider such as [AWS IAM Identity Center](#).

Action examples are code excerpts from larger programs and must be run in context. You can see this action in context in the following code example:

- [Create read-only and read-write users](#)

CLI

AWS CLI

To detach a policy from a user

This example removes the managed policy with the ARN `arn:aws:iam::123456789012:policy/TesterPolicy` from the user Bob.

```
aws iam detach-user-policy \  
  --user-name Bob \  
  --policy-arn arn:aws:iam::123456789012:policy/TesterPolicy
```

This command produces no output.

For more information, see [Changing permissions for an IAM user](#) in the *AWS IAM User Guide*.

- For API details, see [DetachUserPolicy](#) in *AWS CLI Command Reference*.

Generate a credential report from IAM using an AWS SDK

The following code examples show how to generate a credential report from IAM for the current account. After the report is generated, get it by using the GetCredentialReport action.

Action examples are code excerpts from larger programs and must be run in context. You can see this action in context in the following code example:

- [Manage your account](#)

CLI

AWS CLI

To generate a credential report

The following example attempts to generate a credential report for the AWS account.

```
aws iam generate-credential-report
```

Output:

```
{
  "State": "STARTED",
  "Description": "No report exists. Starting a new report generation task"
}
```

For more information, see [Getting credential reports for your AWS account](#) in the *AWS IAM User Guide*.

- For API details, see [GenerateCredentialReport](#) in *AWS CLI Command Reference*.

Python

SDK for Python (Boto3)

Note

There's more on GitHub. Find the complete example and learn how to set up and run in the [AWS Code Examples Repository](#).

```
def generate_credential_report():
    """
    Starts generation of a credentials report about the current account. After
    calling this function to generate the report, call get_credential_report
    to get the latest report. A new report can be generated a minimum of four
    hours
    after the last one was generated.
    """
    try:
```

```
response = iam.meta.client.generate_credential_report()
logger.info(
    "Generating credentials report for your account. " "Current state is
%s.",
    response["State"],
)
except ClientError:
    logger.exception("Couldn't generate a credentials report for your
account.")
    raise
else:
    return response
```

Get an IAM policy version using an AWS SDK

The following code examples show how to get an IAM policy version.

Action examples are code excerpts from larger programs and must be run in context. You can see this action in context in the following code examples:

- [Manage policies](#)
- [Work with the IAM Policy Builder API](#)

CLI

AWS CLI

To retrieve information about the specified version of the specified managed policy

This example returns the policy document for the v2 version of the policy whose ARN is `arn:aws:iam::123456789012:policy/MyManagedPolicy`.

```
aws iam get-policy-version \  
  --policy-arn arn:aws:iam::123456789012:policy/MyPolicy \  
  --version-id v2
```

Output:

```
{  
  "PolicyVersion": {  
    "Document": {  
      "Version": "2012-10-17",  
      "Statement": [  
        {  
          "Effect": "Allow",  
          "Action": "iam:*",  
          "Resource": "*" }  
      ]  
    },  
    "VersionId": "v2",  
    "IsDefaultVersion": true,  
    "CreateDate": "2023-04-11T00:22:54+00:00"  
  }  
}
```

```
}
```

For more information, see [Policies and permissions in IAM](#) in the *AWS IAM User Guide*.

- For API details, see [GetPolicyVersion](#) in *AWS CLI Command Reference*.

Python

SDK for Python (Boto3)

Note

There's more on GitHub. Find the complete example and learn how to set up and run in the [AWS Code Examples Repository](#).

```
def get_default_policy_statement(policy_arn):
    """
    Gets the statement of the default version of the specified policy.

    :param policy_arn: The ARN of the policy to look up.
    :return: The statement of the default policy version.
    """
    try:
        policy = iam.Policy(policy_arn)
        # To get an attribute of a policy, the SDK first calls get_policy.
        policy_doc = policy.default_version.document
        policy_statement = policy_doc.get("Statement", None)
        logger.info("Got default policy doc for %s.", policy.policy_name)
        logger.info(policy_doc)
    except ClientError:
        logger.exception("Couldn't get default policy statement for %s.",
            policy_arn)
        raise
    else:
        return policy_statement
```

- For API details, see [GetPolicyVersion](#) in *AWS SDK for Python (Boto3) API Reference*.

For a complete list of AWS SDK developer guides and code examples, see [Using IAM with an AWS SDK](#). This topic also includes information about getting started and details about previous SDK versions.

Get an IAM role using an AWS SDK

The following code examples show how to get an IAM role.

.NET

AWS SDK for .NET

Note

There's more on GitHub. Find the complete example and learn how to set up and run in the [AWS Code Examples Repository](#).

```
/// <summary>
/// Get information about an IAM role.
/// </summary>
/// <param name="roleName">The name of the IAM role to retrieve information
/// for.</param>
/// <returns>The IAM role that was retrieved.</returns>
public async Task<Role> GetRoleAsync(string roleName)
{
    var response = await _IAMService.GetRoleAsync(new GetRoleRequest
    {
        RoleName = roleName,
    });

    return response.Role;
}
```

- For API details, see [GetRole](#) in *AWS SDK for .NET API Reference*.

CLI

AWS CLI

To get information about an IAM role

The following `get-role` command gets information about the role named `Test-Role`.

```
aws iam get-role \  
  --role-name Test-Role
```

Output:

```
{  
  "Role": {  
    "Description": "Test Role",  
    "AssumeRolePolicyDocument": "<URL-encoded-JSON>",  
    "MaxSessionDuration": 3600,  
    "RoleId": "AROA1234567890EXAMPLE",  
    "CreateDate": "2019-11-13T16:45:56Z",  
    "RoleName": "Test-Role",  
    "Path": "/",  
    "RoleLastUsed": {  
      "Region": "us-east-1",  
      "LastUsedDate": "2019-11-13T17:14:00Z"  
    },  
    "Arn": "arn:aws:iam::123456789012:role/Test-Role"  
  }  
}
```

The command displays the trust policy attached to the role. To list the permissions policies attached to a role, use the `list-role-policies` command.

For more information, see [Creating IAM roles](#) in the *AWS IAM User Guide*.

- For API details, see [GetRole](#) in *AWS CLI Command Reference*.

Go

Get an IAM service-linked role's deletion status using an AWS SDK

The following code examples show how to get an AWS Identity and Access Management (IAM) service-linked role's deletion status.

CLI

AWS CLI

To check the status of a request to delete a service-linked role

The following `get-service-linked-role-deletion-status` example displays the status of a previously request to delete a service-linked role. The delete operation occurs asynchronously. When you make the request, you get a `DeletionTaskId` value that you provide as a parameter for this command.

```
aws iam get-service-linked-role-deletion-status \
  --deletion-task-id task/aws-service-role/lex.amazonaws.com/
  AWSServiceRoleForLexBots/1a2b3c4d-1234-abcd-7890-abcdeEXAMPLE
```

Output:

```
{
  "Status": "SUCCEEDED"
}
```

For more information, see [Using service-linked roles](#) in the *AWS IAM User Guide*.

- For API details, see [GetServiceLinkedRoleDeletionStatus](#) in *AWS CLI Command Reference*.

JavaScript

SDK for JavaScript (v3)

Note

There's more on GitHub. Find the complete example and learn how to set up and run in the [AWS Code Examples Repository](#).

```
import {
  GetServiceLinkedRoleDeletionStatusCommand,
  IAMClient,
} from "@aws-sdk/client-iam";
```

```
const client = new IAMClient({});

/**
 *
 * @param {string} deletionTaskId
 */
export const getServiceLinkedRoleDeletionStatus = (deletionTaskId) => {
  const command = new GetServiceLinkedRoleDeletionStatusCommand({
    DeletionTaskId: deletionTaskId,
  });

  return client.send(command);
};
```

- For API details, see [GetServiceLinkedRoleDeletionStatus](#) in *AWS SDK for JavaScript API Reference*.

Get a summary of account usage from IAM using an AWS SDK

The following code examples show how to get a summary of account usage from IAM.

Action examples are code excerpts from larger programs and must be run in context. You can see this action in context in the following code example:

- [Manage your account](#)

CLI

AWS CLI

To get information about IAM entity usage and IAM quotas in the current account

The following `get-account-summary` command returns information about the current IAM entity usage and current IAM entity quotas in the account.

```
aws iam get-account-summary
```

Output:

```
{
  "SummaryMap": {
    "UsersQuota": 5000,
    "GroupsQuota": 100,
    "InstanceProfiles": 6,
    "SigningCertificatesPerUserQuota": 2,
    "AccountAccessKeysPresent": 0,
    "RolesQuota": 250,
    "RolePolicySizeQuota": 10240,
    "AccountSigningCertificatesPresent": 0,
    "Users": 27,
    "ServerCertificatesQuota": 20,
    "ServerCertificates": 0,
    "AssumeRolePolicySizeQuota": 2048,
    "Groups": 7,
    "MFADevicesInUse": 1,
    "Roles": 3,
    "AccountMFAEnabled": 1,
    "MFADevices": 3,
    "GroupsPerUserQuota": 10,
    "GroupPolicySizeQuota": 5120,
    "InstanceProfilesQuota": 100,
    "AccessKeysPerUserQuota": 2,
    "Providers": 0,
    "UserPolicySizeQuota": 2048
  }
}
```

Get the IAM account password policy using an AWS SDK

The following code examples show how to get the IAM account password policy.

.NET

AWS SDK for .NET

Note

There's more on GitHub. Find the complete example and learn how to set up and run in the [AWS Code Examples Repository](#).

```
/// <summary>
/// Gets the IAM password policy for an AWS account.
/// </summary>
/// <returns>The PasswordPolicy for the AWS account.</returns>
public async Task<PasswordPolicy> GetAccountPasswordPolicyAsync()
{
    var response = await _IAMService.GetAccountPasswordPolicyAsync(new
GetAccountPasswordPolicyRequest());
    return response.PasswordPolicy;
}
```

- For API details, see [GetAccountPasswordPolicy](#) in *AWS SDK for .NET API Reference*.

CLI

AWS CLI

To see the current account password policy

The following `get-account-password-policy` command displays details about the password policy for the current account.

```
aws iam get-account-password-policy
```

Output:

```
{
  "PasswordPolicy": {
    "AllowUsersToChangePassword": false,
    "RequireLowercaseCharacters": false,
    "RequireUppercaseCharacters": false,
    "MinimumPasswordLength": 8,
    "RequireNumbers": true,
    "RequireSymbols": true
  }
}
```

If no password policy is defined for the account, the command returns a `NoSuchEntity` error.

    }
}

return true;
}
```

- For API details, see [ListAccessKeys](#) in *AWS SDK for C++ API Reference*.

CLI

AWS CLI

To list the access key IDs for an IAM user

The following `list-access-keys` command lists the access keys IDs for the IAM user named Bob.

```
aws iam list-access-keys \  
  --user-name Bob
```

Output:

```
{  
  "AccessKeyMetadata": [  
    {  
      "UserName": "Bob",  
      "Status": "Active",  
      "CreateDate": "2013-06-04T18:17:34Z",  
      "AccessKeyId": "AKIAIOSFODNN7EXAMPLE"  
    },  
    {  
      "UserName": "Bob",  
      "Status": "Inactive",  
      "CreateDate": "2013-06-06T20:42:26Z",  
      "AccessKeyId": "AKIAI44QH8DHBEXAMPLE"  
    }  
  ]  
}
```

You cannot list the secret access keys for IAM users. If the secret access keys are lost, you must create new access keys using the `create-access-keys` command.

For more information, see [Managing access keys for IAM users](#) in the *AWS IAM User Guide*.

- For API details, see [ListAccessKeys](#) in *AWS CLI Command Reference*.

List inline policies for an IAM role using an AWS SDK

The following code examples show how to list inline policies for an IAM role.

.NET

AWS SDK for .NET

Note

There's more on GitHub. Find the complete example and learn how to set up and run in the [AWS Code Examples Repository](#).

```
/// <summary>
/// List IAM role policies.
/// </summary>
/// <param name="roleName">The IAM role for which to list IAM policies.</
param>
/// <returns>A list of IAM policy names.</returns>
public async Task<List<string>> ListRolePoliciesAsync(string roleName)
{
    var listRolePoliciesPaginator =
_IAMService.Paginators.ListRolePolicies(new ListRolePoliciesRequest { RoleName =
roleName });
    var policyNames = new List<string>();

    await foreach (var response in listRolePoliciesPaginator.Responses)
    {
        policyNames.AddRange(response.PolicyNames);
    }

    return policyNames;
}
```

- For API details, see [ListRolePolicies](#) in *AWS SDK for .NET API Reference*.

CLI

AWS CLI

To list the policies attached to an IAM role

The following `list-role-policies` command lists the names of the permissions policies for the specified IAM role.

```
aws iam list-role-policies \  
  --role-name Test-Role
```

Output:

```
{  
  "PolicyNames": [  
    "ExamplePolicy"  
  ]  
}
```

To see the trust policy attached to a role, use the `get-role` command. To see the details of a permissions policy, use the `get-role-policy` command.

For more information, see [Creating IAM roles](#) in the *AWS IAM User Guide*.

- For API details, see [ListRolePolicies](#) in *AWS CLI Command Reference*.

List inline IAM policies for a user using an AWS SDK

The following code examples show how to list inline IAM policies for a user.

⚠ Warning

To avoid security risks, don't use IAM users for authentication when developing purpose-built software or working with real data. Instead, use federation with an identity provider such as [AWS IAM Identity Center](#).

CLI

AWS CLI**To list policies for an IAM user**

The following `list-user-policies` command lists the policies that are attached to the IAM user named Bob.

```
aws iam list-user-policies \  
  --user-name Bob
```

Output:

```
{  
  "PolicyNames": [  
    "ExamplePolicy",  
    "TestPolicy"  
  ]  
}
```

For more information, see [Creating an IAM user in your AWS account](#) in the *AWS IAM User Guide*.

```
/// <summary>
/// Remove a user from an IAM group.
/// </summary>
/// <param name="userName">The username of the user to remove.</param>
/// <param name="groupName">The name of the IAM group to remove the user
from.</param>
/// <returns>A Boolean value indicating the success of the action.</returns>
public async Task<bool> RemoveUserFromGroupAsync(string userName, string
groupName)
{
    // Remove the user from the group.
    var removeUserRequest = new RemoveUserFromGroupRequest()
    {
        UserName = userName,
        GroupName = groupName,
    };

    var response = await
_IAMService.RemoveUserFromGroupAsync(removeUserRequest);
    return response.HttpStatusCode == HttpStatusCode.OK;
}
```

- For API details, see [RemoveUserFromGroup](#) in *AWS SDK for .NET API Reference*.

CLI

AWS CLI

To remove a user from an IAM group

The following `remove-user-from-group` command removes the user named Bob from the IAM group named Admins.

```
aws iam remove-user-from-group \  
  --user-name Bob \  
  --group-name Admins
```

This command produces no output.

For more information, see [Adding and removing users in an IAM user group](#) in the *AWS IAM User Guide*.

- For API details, see [RemoveUserFromGroup](#) in *AWS CLI Command Reference*.

For a complete list of AWS SDK developer guides and code examples, see [Using IAM with an AWS SDK](#). This topic also includes information about getting started and details about previous SDK versions.

Update an IAM server certificate using an AWS SDK

The following code examples show how to update an IAM server certificate.

C++

SDK for C++

Note

There's more on GitHub. Find the complete example and learn how to set up and run in the [AWS Code Examples Repository](#).

```
bool AwsDoc::IAM::updateServerCertificate(const Aws::String  
  &currentCertificateName,  
                                          const Aws::String &newCertificateName,
```

```

const Aws::Client::ClientConfiguration
&clientConfig) {
    Aws::IAM::IAMClient iam(clientConfig);
    Aws::IAM::Model::UpdateServerCertificateRequest request;
    request.SetServerCertificateName(currentCertificateName);
    request.SetNewServerCertificateName(newCertificateName);

    auto outcome = iam.UpdateServerCertificate(request);
    bool result = true;
    if (outcome.IsSuccess()) {
        std::cout << "Server certificate " << currentCertificateName
                  << " successfully renamed as " << newCertificateName
                  << std::endl;
    }
    else {
        if (outcome.GetError().GetErrorType() !=
Aws::IAM::IAMErrors::NO_SUCH_ENTITY) {
            std::cerr << "Error changing name of server certificate " <<
                    currentCertificateName << " to " << newCertificateName <<
": " <<
                    outcome.GetError().GetMessage() << std::endl;
            result = false;
        }
        else {
            std::cout << "Certificate '" << currentCertificateName
                    << "' not found." << std::endl;
        }
    }

    return result;
}

```

- For API details, see [UpdateServerCertificate](#) in *AWS SDK for C++ API Reference*.

CLI

AWS CLI

To change the path or name of a server certificate in your AWS account

The following `update-server-certificate` command changes the name of the certificate from `myServerCertificate` to `myUpdatedServerCertificate`. It also

changes the path to `/cloudfront/` so that it can be accessed by the Amazon CloudFront service. This command produces no output. You can see the results of the update by running the `list-server-certificates` command.

```
aws-iam update-server-certificate \  
  --server-certificate-name myServerCertificate \  
  --new-server-certificate-name myUpdatedServerCertificate \  
  --new-path /cloudfront/
```

This command produces no output.

For more information, see [Managing server certificates in IAM](#) in the *AWS IAM User Guide*.

- For API details, see [UpdateServerCertificate](#) in *AWS CLI Command Reference*.

```

- For API details, see [UpdateUser](#) in *AWS SDK for C++ API Reference*.

CLI

AWS CLI

To change an IAM user's name

The following `update-user` command changes the name of the IAM user Bob to Robert.

```
aws iam update-user \
  --user-name Bob \
  --new-user-name Robert
```

This command produces no output.

For more information, see [Renaming an IAM user group](#) in the *AWS IAM User Guide*.

- For API details, see [UpdateUser](#) in *AWS CLI Command Reference*.

Update an IAM access key using an AWS SDK

The following code examples show how to update an IAM access key.

Warning

To avoid security risks, don't use IAM users for authentication when developing purpose-built software or working with real data. Instead, use federation with an identity provider such as [AWS IAM Identity Center](#).

Action examples are code excerpts from larger programs and must be run in context. You can see this action in context in the following code example:

- [Manage access keys](#)

C++

SDK for C++

Note

There's more on GitHub. Find the complete example and learn how to set up and run in the [AWS Code Examples Repository](#).

```
bool AwsDoc::IAM::updateAccessKey(const Aws::String &userName,
```

```
const Aws::String &accessKeyID,  
    Aws::IAM::Model::StatusType status,  
    const Aws::Client::ClientConfiguration  
&clientConfig) {  
    Aws::IAM::IAMClient iam(clientConfig);  
    Aws::IAM::Model::UpdateAccessKeyRequest request;  
    request.SetUserName(userName);  
    request.SetAccessKeyId(accessKeyID);  
    request.SetStatus(status);  
  
    auto outcome = iam.UpdateAccessKey(request);  
    if (outcome.IsSuccess()) {  
        std::cout << "Successfully updated status of access key "  
                  << accessKeyID << " for user " << userName << std::endl;  
    }  
    else {  
        std::cerr << "Error updated status of access key " << accessKeyID <<  
                  << " for user " << userName << ": " <<  
                  << outcome.GetError().GetMessage() << std::endl;  
    }  
  
    return outcome.IsSuccess();  
}
```

- For API details, see [UpdateAccessKey](#) in *AWS SDK for C++ API Reference*.

CLI

AWS CLI

To activate or deactivate an access key for an IAM user

The following `update-access-key` command deactivates the specified access key (access key ID and secret access key) for the IAM user named Bob.

```
aws iam update-access-key \  
  --access-key-id AKIAIOSFODNN7EXAMPLE \  
  --status Inactive \  
  --user-name Bob
```

This command produces no output.

Deactivating the key means that it cannot be used for programmatic access to AWS. However, the key is still available and can be reactivated.

For more information, see [Managing access keys for IAM users](#) in the *AWS IAM User Guide*.

- For API details, see [UpdateAccessKey](#) in *AWS CLI Command Reference*.

Upload an IAM server certificate using an AWS SDK

The following code examples show how to upload an AWS Identity and Access Management (IAM) server certificate.

CLI

AWS CLI

To upload a server certificate to your AWS account

The following **upload-server-certificate** command uploads a server certificate to your AWS account. In this example, the certificate is in the file `public_key_cert_file.pem`, the associated private key is in the file `my_private_key.pem`, and the the certificate chain provided by the certificate authority (CA) is in the `my_certificate_chain_file.pem` file. When the file has finished uploading, it is available under the name `myServerCertificate`. Parameters that begin with `file://` tells the command to read the contents of the file and use that as the parameter value instead of the file name itself.

```
aws iam upload-server-certificate \  
  --server-certificate-name myServerCertificate \  
  --certificate-body file://public_key_cert_file.pem \  
  --private-key file://my_private_key.pem \  
  --certificate-chain file://my_certificate_chain_file.pem
```

Output:

```
{  
  "ServerCertificateMetadata": {  
    "Path": "/",  
    "ServerCertificateName": "myServerCertificate",  
    "ServerCertificateId": "ASCAEXAMPLE123EXAMPLE",  
    "Arn": "arn:aws:iam::1234567989012:server-certificate/  
myServerCertificate",  
    "UploadDate": "2019-04-22T21:13:44+00:00",
```

```
    "Expiration": "2019-10-15T22:23:16+00:00"
  }
}
```

For more information, see [Creating, Uploading, and Deleting Server Certificates](#) in the *Using IAM* guide.

- For API details, see [UploadServerCertificate](#) in *AWS CLI Command Reference*.

Scenarios for IAM using AWS SDKs

The following code examples show you how to implement common scenarios in IAM with AWS SDKs. These scenarios show you how to accomplish specific tasks by calling multiple functions within IAM. Each scenario includes a link to GitHub, where you can find instructions on how to set up and run the code.

Examples

- [Build and manage a resilient service using an AWS SDK](#)
- [Create an IAM group and add a user to the group using an AWS SDK](#)
- [Create an IAM user and assume a role with AWS STS using an AWS SDK](#)
- [Create read-only and read-write IAM users using an AWS SDK](#)
- [Manage IAM access keys using an AWS SDK](#)
- [Manage IAM policies using an AWS SDK](#)
- [Manage IAM roles using an AWS SDK](#)
- [Manage your IAM account using an AWS SDK](#)
- [Roll back an IAM policy version using an AWS SDK](#)
- [Work with the IAM Policy Builder API using an AWS SDK](#)

Build and manage a resilient service using an AWS SDK

The following code examples show how to create a load-balanced web service that returns book, movie, and song recommendations. The example shows how the service responds to failures, and how to restructure the service for more resilience when failures occur.

- Use an Amazon EC2 Auto Scaling group to create Amazon Elastic Compute Cloud (Amazon EC2) instances based on a launch template and to keep the number of instances in a specified range.
- Handle and distribute HTTP requests with Elastic Load Balancing.
- Monitor the health of instances in an Auto Scaling group and forward requests only to healthy instances.
- Run a Python web server on each EC2 instance to handle HTTP requests. The web server responds with recommendations and health checks.
- Simulate a recommendation service with an Amazon DynamoDB table.
- Control web server response to requests and health checks by updating AWS Systems Manager parameters.

.NET

AWS SDK for .NET

Note

There's more on GitHub. Find the complete example and learn how to set up and run in the [AWS Code Examples Repository](#).

Run the interactive scenario at a command prompt.

```
static async Task Main(string[] args)
{
    _configuration = new ConfigurationBuilder()
        .SetBasePath(Directory.GetCurrentDirectory())
        .AddJsonFile("settings.json") // Load settings from .json file.
        .AddJsonFile("settings.local.json",
            true) // Optionally, load local settings.
        .Build();

    // Set up dependency injection for the AWS services.
    using var host = Host.CreateDefaultBuilder(args)
        .ConfigureLogging(logging =>
            logging.AddFilter("System", LogLevel.Debug)
                .AddFilter<DebugLoggerProvider>("Microsoft",
                    LogLevel.Information)
                .AddFilter<ConsoleLoggerProvider>("Microsoft",
                    LogLevel.Trace))
        .ConfigureServices((_, services) =>
            services.AddAWSService<IAmazonIdentityManagementService>()

Create an IAM group and add a user to the group using an AWS SDK

The following code example shows how to:

- Create a group and grant full Amazon S3 access permissions to it.
- Create a new user with no permissions to access Amazon S3.
- Add the user to the group and show that they now have permissions for Amazon S3, then clean up resources.

.NET

AWS SDK for .NET

Note

There's more on GitHub. Find the complete example and learn how to set up and run in the [AWS Code Examples Repository](#).

For a complete list of AWS SDK developer guides and code examples, see [Using IAM with an AWS SDK](#). This topic also includes information about getting started and details about previous SDK versions.

Create an IAM user and assume a role with AWS STS using an AWS SDK

The following code examples show how to create a user and assume a role.

Warning

To avoid security risks, don't use IAM users for authentication when developing purpose-built software or working with real data. Instead, use federation with an identity provider such as [AWS IAM Identity Center](#).

- Create a user with no permissions.
- Create a role that grants permission to list Amazon S3 buckets for the account.
- Add a policy to let the user assume the role.
- Assume the role and list S3 buckets using temporary credentials, then clean up resources.

.NET

AWS SDK for .NET

Note

There's more on GitHub. Find the complete example and learn how to set up and run in the [AWS Code Examples Repository](#).

Java

SDK for Java 2.x

Note

There's more on GitHub. Find the complete example and learn how to set up and run in the [AWS Code Examples Repository](#).

Create functions that wrap IAM user actions.

```
/*  
  To run this Java V2 code example, set up your development environment,  
  including your credentials.  
  
  For information, see this documentation topic:  
  
  https://docs.aws.amazon.com/sdk-for-java/latest/developer-guide/get-  
  started.html  
  
  This example performs these operations:  
  
  1. Creates a user that has no permissions.  
  2. Creates a role and policy that grants Amazon S3 permissions.  
  3. Creates a role.  
  4. Grants the user permissions.  
  5. Gets temporary credentials by assuming the role.  Creates an Amazon S3  
  Service client object with the temporary credentials.  
  6. Deletes the resources.  
*/
```

```

Create read-only and read-write IAM users using an AWS SDK

The following code example shows how to create users and attach policies to them.

⚠ Warning

To avoid security risks, don't use IAM users for authentication when developing purpose-built software or working with real data. Instead, use federation with an identity provider such as [AWS IAM Identity Center](#).

- Create two IAM users.
- Attach a policy for one user to get and put objects in an Amazon S3 bucket.
- Attach a policy for the second user to get objects from the bucket.
- Get different permissions to the bucket based on user credentials.

Manage IAM access keys using an AWS SDK

The following code example shows how to manage access keys.

Warning

To avoid security risks, don't use IAM users for authentication when developing purpose-built software or working with real data. Instead, use federation with an identity provider such as [AWS IAM Identity Center](#).

- Create and list access keys.
- Find out when and how an access key was last used.
- Update and delete access keys.

Python

SDK for Python (Boto3)

Note

There's more on GitHub. Find the complete example and learn how to set up and run in the [AWS Code Examples Repository](#).

Create functions that wrap IAM access key actions.

```
import logging

Code examples for AWS STS using AWS SDKs

The following code examples show how to use AWS STS with an AWS software development kit (SDK).

Actions are code excerpts from larger programs and must be run in context. While actions show you how to call individual service functions, you can see actions in context in their related scenarios and cross-service examples.

Scenarios are code examples that show you how to accomplish a specific task by calling multiple functions within the same service.

For a complete list of AWS SDK developer guides and code examples, see [Using IAM with an AWS SDK](#). This topic also includes information about getting started and details about previous SDK versions.

```

- For API details, see [AssumeRole](#) in *AWS SDK for C++ API Reference*.

CLI

AWS CLI

To assume a role

The following `assume-role` command retrieves a set of short-term credentials for the IAM role `s3-access-example`.

```
aws sts assume-role \
  --role-arn arn:aws:iam::123456789012:role/xaccounts3access \
  --role-session-name s3-access-example
```

Output:

```
{
  "AssumedRoleUser": {
    "AssumedRoleId": "AROA3XFRBF535PLBIFPI4:s3-access-example",
    "Arn": "arn:aws:sts::123456789012:assumed-role/xaccounts3access/s3-
access-example"
  },
  "Credentials": {
```

```

    "SecretAccessKey": "9drTJvcXLB89EXAMPLELb8923FB892xMFI",
    "SessionToken": "AQoXdzELDDY//////////
wEaoAK1wvxJY12r2IrDFT2IvAzTCn3zHoZ7YNtpiQLF0MqZye/
qwjzP2iEXAMPLEbw/m3hsj8VBTkPORGvr9jM5sgP+w9IZWZnU+LWhmg
+a5fDi2oTGUYcdg9uexQ4mtCHIHfi4citgqZTgco40Yqr4lIlo4V2b2Dyauk0eYFNebHtY1FVgAUj
+7Indz3LU0aTWk1WKIjHmMCIoTkyYp/k7kUG7moeEYKSitwQIi6Gjn+nyzM
+PtoA3685ixzv0R7i5rjQi0YE0lf1oeie3bDiNHncmzosRM6SFiPzSvp6h/32xQuZsjcypmwsPSDtTPYcs0+YN/8B
IcrxSpnWEXAMPLEXSDFTAQAM6Dl9zR0tXoybnlrZIwMLlMi1Kcgo50ytwU=",
    "Expiration": "2016-03-15T00:05:07Z",
    "AccessKeyId": "ASIAJEXAMPLEXEG2JICEA"
  }
}

```

The output of the command contains an access key, secret key, and session token that you can use to authenticate to AWS.

For AWS CLI use, you can set up a named profile associated with a role. When you use the profile, the AWS CLI will call `assume-role` and manage credentials for you. For more information, see [Use an IAM role in the AWS CLI](#) in the *AWS CLI User Guide*.

- For API details, see [AssumeRole](#) in *AWS CLI Command Reference*.

Get a session token with AWS STS using an AWS SDK

The following code examples show how to get a session token with AWS STS and use it to perform a service action that requires an MFA token.

Action examples are code excerpts from larger programs and must be run in context. You can see this action in context in the following code example:

- [Get a session token that requires an MFA token](#)

CLI

AWS CLI

To get a set of short term credentials for an IAM identity

The following `get-session-token` command retrieves a set of short-term credentials for the IAM identity making the call. The resulting credentials can be used for requests where multi-factor authentication (MFA) is required by policy. The credentials expire 15 minutes after they are generated.

```
aws sts get-session-token \  
  --duration-seconds 900 \  
  --serial-number "YourMFADeviceSerialNumber" \  
  --token-code 123456
```

Output:

```
{  
  "Credentials": {  
    "AccessKeyId": "ASIAIOSFODNN7EXAMPLE",  
    "SecretAccessKey": "wJalrXUtnFEMI/K7MDENG/bPxrFiCYzEXAMPLEKEY",  
    "SessionToken": "AQoEXAMPLEH4aoAH0gNCAPyJxz4B1CFFxWNE1OPTgk5TthT

For a complete list of AWS SDK developer guides and code examples, see [Using IAM with an AWS SDK](#). This topic also includes information about getting started and details about previous SDK versions.

Scenarios for AWS STS using AWS SDKs

The following code examples show you how to implement common scenarios in AWS STS with AWS SDKs. These scenarios show you how to accomplish specific tasks by calling multiple functions within AWS STS. Each scenario includes a link to GitHub, where you can find instructions on how to set up and run the code.

Examples

- [Assume an IAM role that requires an MFA token with AWS STS using an AWS SDK](#)
- [Construct a URL with AWS STS for federated users using an AWS SDK](#)
- [Get a session token that requires an MFA token with AWS STS using an AWS SDK](#)

Assume an IAM role that requires an MFA token with AWS STS using an AWS SDK

The following code example shows how to assume a role that requires an MFA token.

⚠ Warning

To avoid security risks, don't use IAM users for authentication when developing purpose-built software or working with real data. Instead, use federation with an identity provider such as [AWS IAM Identity Center](#).

- Create an IAM role that grants permission to list Amazon S3 buckets.
- Create an IAM user that has permission to assume the role only when MFA credentials are provided.
- Register an MFA device for the user.
- Assume the role and use temporary credentials to list S3 buckets.

Python

SDK for Python (Boto3)**📘 Note**

There's more on GitHub. Find the complete example and learn how to set up and run in the [AWS Code Examples Repository](#).

Create an IAM user, register an MFA device, and create a role that grants permission to list S3 buckets. The user has rights only to assume the role.

```
def setup(iam_resource):
    """
    Creates a new user with no permissions.
    Creates a new virtual MFA device.
    Displays the QR code to seed the device.
    Asks for two codes from the MFA device.
    Registers the MFA device for the user.
    Creates an access key pair for the user.
    Creates a role with a policy that lets the user assume the role and requires
    MFA.
    Creates a policy that allows listing Amazon S3 buckets.
    Attaches the policy to the role.
    Creates an inline policy for the user that lets the user assume the role.
```

For demonstration purposes, the user is created in the same account as the role,
but in practice the user would likely be from another account.

Any MFA device that can scan a QR code will work with this demonstration. Common choices are mobile apps like LastPass Authenticator, Microsoft Authenticator, or Google Authenticator.

```
:param iam_resource: A Boto3 AWS Identity and Access Management (IAM)
resource
    that has permissions to create users, roles, and
policies
    in the account.
:return: The newly created user, user key, virtual MFA device, and role.
"""
user = iam_resource.create_user(Username=unique_name("user"))
print(f"Created user {user.name}.")

- For API details, see [AssumeRole](#) in *AWS SDK for Python (Boto3) API Reference*.

For a complete list of AWS SDK developer guides and code examples, see [Using IAM with an AWS SDK](#). This topic also includes information about getting started and details about previous SDK versions.

Get a session token that requires an MFA token with AWS STS using an AWS SDK

The following code example shows how to get a session token that requires an MFA token.

Warning

To avoid security risks, don't use IAM users for authentication when developing purpose-built software or working with real data. Instead, use federation with an identity provider such as [AWS IAM Identity Center](#).

- Create an IAM role that grants permission to list Amazon S3 buckets.
- Create an IAM user that has permission to assume the role only when MFA credentials are provided.
- Register an MFA device for the user.
- Provide MFA credentials to get a session token and use temporary credentials to list S3 buckets.

Python

SDK for Python (Boto3)

Note

There's more on GitHub. Find the complete example and learn how to set up and run in the [AWS Code Examples Repository](#).

Create an IAM user, register an MFA device, and create a role that grants permission to let the user list S3 buckets only when MFA credentials are used.

```
def setup(iam_resource):
    """
    Creates a new user with no permissions.
    Creates a new virtual multi-factor authentication (MFA) device.
    Displays the QR code to seed the device.
    Asks for two codes from the MFA device.
    Registers the MFA device for the user.
    Creates an access key pair for the user.
    Creates an inline policy for the user that lets the user list Amazon S3
    buckets,
    but only when MFA credentials are used.

    Any MFA device that can scan a QR code will work with this demonstration.
    Common choices are mobile apps like LastPass Authenticator,
    Microsoft Authenticator, or Google Authenticator.

    :param iam_resource: A Boto3 AWS Identity and Access Management (IAM)
    resource
                        that has permissions to create users, MFA devices, and
                        policies in the account.
    :return: The newly created user, user key, and virtual MFA device.
    """
    user = iam_resource.create_user(UserName=unique_name("user"))
    print(f"Created user {user.name}.")

    virtual_mfa_device = iam_resource.create_virtual_mfa_device(
        VirtualMFADeviceName=unique_name("mfa")
    )
    print(f"Created virtual MFA device {virtual_mfa_device.serial_number}")
```

```
print(
    f"Showing the QR code for the device. Scan this in the MFA app of your "
    f"choice."

Security in IAM and AWS STS

Cloud security at AWS is the highest priority. As an AWS customer, you benefit from data centers and network architectures that are built to meet the requirements of the most security-sensitive organizations.

Security is a shared responsibility between AWS and you. The [shared responsibility model](#) describes this as security *of* the cloud and security *in* the cloud:

- **Security of the cloud** – AWS is responsible for protecting the infrastructure that runs AWS services in the AWS Cloud. AWS also provides you with services that you can use securely. Third-party auditors regularly test and verify the effectiveness of our security as part of the [AWS Compliance Programs](#). To learn about the compliance programs that apply to AWS Identity and Access Management (IAM), see [AWS Services in Scope by Compliance Program](#).
- **Security in the cloud** – Your responsibility is determined by the AWS service that you use. You are also responsible for other factors including the sensitivity of your data, your company's requirements, and applicable laws and regulations.

This documentation helps you understand how to apply the shared responsibility model when using AWS Identity and Access Management (IAM) and AWS Security Token Service (AWS STS). The following topics show you how to configure IAM and AWS STS to meet your security and compliance objectives. You also learn how to use other AWS services that help you to monitor and secure your IAM resources.

AWS security credentials

When you interact with AWS, you specify your *AWS security credentials* to verify who you are and whether you have permission to access the resources that you are requesting. AWS uses the security credentials to authenticate and authorize your requests.

For example, if you want to download a protected file from an Amazon Simple Storage Service (Amazon S3) bucket, your credentials must allow that access. If your credentials don't show you are authorized to download the file, AWS denies your request. However, your AWS security credentials aren't required for you to download a file in an Amazon S3 bucket that is publicly shared.

There are different types of users in AWS. All AWS users have security credentials. There is the account owner (root user), users in AWS IAM Identity Center, federated users, and IAM users.

Users have either long-term or temporary security credentials. Root user, IAM user, and access keys have long-term security credentials that do not expire. To protect long-term credentials have processes in place to [manage access keys](#), [change passwords](#), and [enable MFA](#).

IAM roles, users in AWS IAM Identity Center, and federated users have temporary security credentials. Temporary security credentials expire after a defined period of time or when the user ends their session. Temporary credentials work almost identically to long-term credentials, with the following differences:

- Temporary security credentials are *short-term*, as the name implies. They can be configured to last for anywhere from a few minutes to several hours. After the credentials expire, AWS no longer recognizes them or allows any kind of access from API requests made with them.
- Temporary security credentials are not stored with the user but are generated dynamically and provided to the user when requested. When (or even before) the temporary security credentials expire, the user can request new credentials, as long as the user requesting them still has permissions to do so.

As a result, temporary credentials have the following advantages over long-term credentials:

- You do not have to distribute or embed long-term AWS security credentials with an application.
- You can provide access to your AWS resources to users without having to define an AWS identity for them. Temporary credentials are the basis for [roles and identity federation](#).
- The temporary security credentials have a limited lifetime, so you do not have to update them or explicitly revoke them when they're no longer needed. After temporary security credentials

expire, they cannot be reused. You can specify how long the credentials are valid, up to a maximum limit.

Security considerations

We recommend that you consider the following information when determining the security provisions for your AWS account:

- When you create an AWS account, we create the account root user. The credentials of the root user (account owner) allow full access to all resources in the account. The first task you perform with the root user is to grant another user administrative permissions to your AWS account so that you minimize the usage of the root user.
- You can't use IAM policies to deny the root user access to resources explicitly. You can only use an AWS Organizations [service control policy \(SCP\)](#) to limit the permissions of the root user.
- If you forget or lose your root user password, you must have access to the email address associated with your account in order to reset it.
- If you lose your root user access keys, you must be able to sign in to your account as the root user to create new ones.
- Do not use the root user for your everyday tasks. Use it to perform the tasks that only the root user can perform. For the complete list of tasks that require you to sign in as the root user, see [Tasks that require root user credentials](#).
- Security credentials are account-specific. If you have access to multiple AWS accounts, you have separate credentials for each account.
- [Policies](#) determine what actions a user, role, or member of a user group can perform, on which AWS resources, and under what conditions. Using policies you can securely control access to AWS services and resources in your AWS account. If you must modify or revoke permissions in response to a security event, you delete or modify the policies instead of making changes directly to the identity.
- Be sure to save the sign-in credentials for your *Emergency Access* IAM user and any access keys you created for programmatic access in a secure location. If you lose your access keys, you must sign in to your account to create new ones.
- We strongly recommend that you use temporary credentials provided by IAM roles and federated users instead of the long-term credentials provided by IAM users and access keys.

Federated identity

Federated identities are users with external identities that are granted temporary AWS credentials that they can use to access secure AWS account resources. External identities can come from a corporate identity store (such as LDAP or Windows Active Directory) or from a third party (such as Login in with Amazon, Facebook, or Google). Federated identities do not sign in with the AWS Management Console or AWS access portal.

To enable federated identities to sign in to AWS, you must create a custom URL that includes `https://signin.aws.amazon.com/federation`. For more information, see [Enabling custom identity broker access to the AWS console](#).

For more information about federated identities, see [Identity providers and federation](#).

Multi-factor authentication (MFA)

Multi-factor authentication (MFA) provides an extra level of security for users who can access your AWS account. For additional security, we recommend that you require MFA on the AWS account root user credentials and all IAM users. For more information, see [Using multi-factor authentication \(MFA\) in AWS](#).

When you activate MFA and you sign in to your AWS account, you are prompted for your sign-in credentials, plus a response generated by an MFA device, such as a code, a touch or tap, or a biometric scan. When you add MFA, your AWS account settings and resources are more secure.

By default, MFA isn't activated. You can activate and manage MFA devices for the AWS account root user by going to the [Security credentials](#) page or the [IAM](#) dashboard in the AWS Management Console. For more information about activating MFA for IAM users, see [Enabling MFA devices for users in AWS](#).

For more information about signing in with multi-factor authentication (MFA) devices, see [Using MFA devices with your IAM sign-in page](#).

Programmatic access

You provide your AWS access keys to make programmatic calls to AWS or to use the AWS Command Line Interface or AWS Tools for PowerShell. We recommend using short-term access keys when possible.

When you create a long-term access key, you create the access key ID (for example, AKIAIOSFODNN7EXAMPLE) and secret access key (for example, wJalrXUtnFEMI/K7MDENG/

bPXRfiCYEXAMPLEKEY) as a set. The secret access key is available for download only when you create it. If you don't download your secret access key or if you lose it, you must create a new one.

In many scenarios, you don't need long-term access keys that never expire (as you have when you create access keys for an IAM user). Instead, you can create IAM roles and generate temporary security credentials. Temporary security credentials include an access key ID and a secret access key, but they also include a security token that indicates when the credentials expire. After they expire, they're no longer valid.

Access key IDs beginning with AKIA are long-term access keys for an IAM user or an AWS account root user. Access key IDs beginning with ASIA are temporary credentials access keys that you create using AWS STS operations.

Users need programmatic access if they want to interact with AWS outside of the AWS Management Console. The way to grant programmatic access depends on the type of user that's accessing AWS.

To grant users programmatic access, choose one of the following options.

Which user needs programmatic access?	To	By
Workforce identity (Users managed in IAM Identity Center)	Use temporary credentials to sign programmatic requests to the AWS CLI, AWS SDKs, or AWS APIs.	Following the instructions for the interface that you want to use. <ul style="list-style-type: none"> • For the AWS CLI, see Configuring the AWS CLI to use AWS IAM Identity Center in the <i>AWS Command Line Interface User Guide</i>. • For AWS SDKs, tools, and AWS APIs, see IAM Identity Center authentication in the <i>AWS SDKs and Tools Reference Guide</i>.

Which user needs programmatic access?	To	By
IAM	Use temporary credentials to sign programmatic requests to the AWS CLI, AWS SDKs, or AWS APIs.	Following the instructions in Using temporary credentials with AWS resources in the <i>IAM User Guide</i> .
IAM	(Not recommended) Use long-term credentials to sign programmatic requests to the AWS CLI, AWS SDKs, or AWS APIs.	Following the instructions for the interface that you want to use. <ul style="list-style-type: none"> • For the AWS CLI, see Authenticating using IAM user credentials in the <i>AWS Command Line Interface User Guide</i>. • For AWS SDKs and tools, see Authenticate using long-term credentials in the <i>AWS SDKs and Tools Reference Guide</i>. • For AWS APIs, see Managing access keys for IAM users in the <i>IAM User Guide</i>.

Alternatives to long-term access keys

For many common use cases, there are alternatives to long-term access keys. To improve your account security, consider the following.

- **Don't embed long-term access keys and secret access keys in your application code or in a code repository** – Instead, use AWS Secrets Manager, or other secrets management solution, so you don't have to hardcode keys in plaintext. The application or client can then retrieve secrets

when needed. For more information, see [What is AWS Secrets Manager?](#) in the *AWS Secrets Manager User Guide*.

- **Use IAM roles to generate temporary security credentials whenever possible** – Always use mechanisms to issue temporary security credentials when possible, rather than long-term access keys. Temporary security credentials are more secure because they are not stored with the user but are generated dynamically and provided to the user when requested. Temporary security credentials have a limited lifetime so you don't have to manage or update them. Mechanisms that provide temporary access keys include IAM roles or the authentication of an IAM Identity Center user. For machines that run outside of AWS you can use [AWS Identity and Access Management Roles Anywhere](#).
- **Use alternatives to long-term access keys for the AWS Command Line Interface (AWS CLI) or the `aws -shell`** – Alternatives include the following.
 - **AWS CloudShell** is a browser-based, pre-authenticated shell that you can launch directly from the AWS Management Console. You can run AWS CLI commands against AWS services through your preferred shell (Bash, Powershell, or Z shell). When you do this, you don't need to download or install command line tools. For more information, see [What is AWS CloudShell?](#) in the *AWS CloudShell User Guide*.
 - **AWS CLI Version 2 integration with AWS IAM Identity Center (IAM Identity Center)**. You can authenticate users and provide short-term credentials to run AWS CLI commands. To learn more, see [Integrating AWS CLI with IAM Identity Center](#) in the *AWS IAM Identity Center User Guide* and [Configuring the AWS CLI to use IAM Identity Center](#) in the *AWS Command Line Interface User Guide*.
- **Don't create long-term access keys for human users who need access to applications or AWS services** – IAM Identity Center can generate temporary access credentials for your external IdP users to access AWS services. This eliminates the need to create and manage long-term credentials in IAM. In IAM Identity Center, create an IAM Identity Center permission set that grants the external IdP users access. Then assign a group from IAM Identity Center to the permission set in the selected AWS accounts. For more information, see [What is AWS IAM Identity Center](#), [Connect to your external identity provider](#), and [Permission sets](#) in the *AWS IAM Identity Center User Guide*.
- **Don't store long-term access keys within an AWS compute service** – Instead, assign an IAM role to compute resources. This automatically supplies temporary credentials to grant access. For example, when you create an instance profile that is attached to an Amazon EC2 instance, you can assign an AWS role to the instance and make it available to all of its applications. An

instance profile contains the role and enables programs that are running on the Amazon EC2 instance to get temporary credentials. To learn more, see [Using an IAM role to grant permissions to applications running on Amazon EC2 instances](#).

Accessing AWS using your AWS credentials

AWS requires different types of security credentials, depending on how you access AWS and what type of AWS user you are. For example, you use sign-in credentials for the AWS Management Console while you use access keys to make programmatic calls to AWS. Also, each identity you use, whether it be the account root user, an AWS Identity and Access Management (IAM) user, an AWS IAM Identity Center user, or a federated identity, has unique credentials within AWS.

For step-by-step instructions on how to sign in to AWS according to your user type, see [How to sign in to AWS](#) in the *AWS Sign-In User Guide*.

AWS security audit guidelines

Periodically audit your security configuration to make sure it meets your current business needs. An audit gives you an opportunity to remove unneeded IAM users, roles, groups, and policies, and to make sure that your users and software don't have excessive permissions.

Following are guidelines for systematically reviewing and monitoring your AWS resources for security best practices.

Tip

You can monitor your usage of IAM as it relates to security best practices by using [AWS Security Hub](#). Security Hub uses security controls to evaluate resource configurations and security standards to help you comply with various compliance frameworks. For more information about using Security Hub to evaluate IAM resources, see [AWS Identity and Access Management controls](#) in the AWS Security Hub User Guide.

Contents

- [When to perform a security audit](#)
- [Guidelines for auditing](#)

- [Review your AWS account credentials](#)
- [Review your IAM users](#)
- [Review your IAM groups](#)
- [Review your IAM roles](#)
- [Review your IAM providers for SAML and OpenID Connect \(OIDC\)](#)
- [Review Your mobile apps](#)
- [Tips for reviewing IAM policies](#)

When to perform a security audit

Audit your security configuration in the following situations:

- On a periodic basis. Perform the steps described in this document at regular intervals as a best practice for security.
- If there are changes in your organization, such as people leaving.
- If you have stopped using one or more individual AWS services to verify that you have removed permissions that users in your account no longer need.
- If you've added or removed software in your accounts, such as applications on Amazon EC2 instances, AWS OpsWorks stacks, AWS CloudFormation templates, etc.
- If you suspect that an unauthorized person might have accessed your account.

Guidelines for auditing

As you review your account's security configuration, follow these guidelines:

- **Be thorough.** Look at all aspects of your security configuration, including those that are seldom used.
- **Don't assume.** If you are unfamiliar with some aspect of your security configuration (for example, the reasoning behind a particular policy or the existence of a role), investigate the business need until you understand the potential risk.
- **Keep things simple.** To make auditing (and management) easier, use IAM groups, IAM roles, consistent naming schemes, and straightforward policies.

Review your AWS account credentials

Take these steps when you audit your AWS account credentials:

1. If you have access keys for your root user that you're not using, you can remove them. We [strongly recommend](#) that you don't use root access keys for everyday work with AWS, and that instead you use users with temporary credentials, such users in AWS IAM Identity Center.
2. If you require access keys for your account, make sure you [update them when needed](#).

Review your IAM users

Take these steps when you audit your existing IAM users:

1. [List your users](#) and then [delete users](#) that aren't needed.
2. [Remove users from groups](#) that they don't require access to.
3. Review the policies attached to the groups the user is in. See [Tips for reviewing IAM policies](#).
4. Delete security credentials that the user doesn't need or that might have been exposed. For example, an IAM user used for an application doesn't need a password (which is necessary only to sign in to AWS websites). Similarly, if a user doesn't use access keys, there's no reason for the user to have one. For more information, see [Managing Passwords for IAM users](#) and [Managing Access Keys for IAM users](#).

You can generate and download a credential report that lists all IAM users in your account and the status of their various credentials, including passwords, access keys, and MFA devices. For passwords and access keys, the credential report shows the date and time when the password or access key was last used. Consider removing credentials that haven't been used recently from your account. (Don't remove your Emergency Access user.) For more information, see [Getting Credential Reports for your AWS Account](#).

5. Update passwords and access keys when needed for use cases that require long-term credentials. For more information, see [Managing Passwords for IAM Users](#) and [Managing Access Keys for IAM users](#).
6. As a best practice, require human users to use federation with an identity provider to access AWS using temporary credentials. If possible, transition from IAM users to federated users, such as users in IAM Identity Center. Retain the minimum number of IAM users needed for your applications.

Review your IAM groups

Take these steps when you audit your IAM groups:

1. [List your groups](#) and then [delete groups](#) that you aren't using.
2. [Review users](#) in each group and [remove users](#) that don't belong.
3. Review the policies attached to the group. See [Tips for reviewing IAM policies](#).

Review your IAM roles

Take these steps when you audit your IAM roles:

1. [List your roles](#) and then [delete roles](#) that you aren't using.
2. [Review](#) the role's trust policy. Make sure that you know who the principal is and that you understand why that account or user needs to be able to assume the role.
3. [Review](#) the access policy for the role to be sure that it grants suitable permissions to whoever assumes the role—see [Tips for reviewing IAM policies](#).

Review your IAM providers for SAML and OpenID Connect (OIDC)

If you have created an IAM entity for establishing trust with a [SAML or OIDC identity provider \(IdP\)](#), take these steps:

1. Delete unused providers.
2. Download and review the AWS metadata documents for each SAML IdP and make sure the documents reflect your current business needs.
3. Get the latest metadata documents from the SAML IdPs and [update the provider in IAM](#).

Review Your mobile apps

If you have created a mobile app that makes requests to AWS, take these steps:

1. Make sure that the mobile app doesn't contain embedded access keys, even if they're in encrypted storage.
2. Get temporary credentials for the app by using APIs designed for that purpose.

Note

We recommend that you use [Amazon Cognito](#) to manage user identity in your app. This service lets you authenticate users using Login with Amazon, Facebook, Google, or any OpenID Connect (OIDC)–compatible identity provider. For more information, see [Amazon Cognito identity pools](#) in the *Amazon Cognito Developer Guide*.

Tips for reviewing IAM policies

Policies are powerful and subtle, so it's important to study and understand the permissions granted by each policy. Use the following guidelines when reviewing policies:

- Attach policies to groups or roles instead of to individual users. If an individual user has a policy, make sure you understand why that user needs the policy.
- Make sure that IAM users, groups, and roles have the permissions that they need and don't have any additional permissions.
- Use the [IAM Policy Simulator](#) to test policies attached to users or groups.
- Remember that a user's permissions are the result of all applicable policies— both identity-based policies (on users, groups, or roles) and resource-based policies (on resources such as Amazon S3 buckets, Amazon SQS queues, Amazon SNS topics, and AWS KMS keys). It's important to examine all the policies that apply to a user and to understand the complete set of permissions granted to an individual user.
- Be aware that allowing a user to create an IAM user, group, role, or policy and attach a policy to the principal entity is effectively granting that user all permissions to all resources in your account. Users who can create policies and attach them to a user, group, or role can grant themselves any permissions. In general, don't grant IAM permissions to users or roles whom you don't trust with full access to the resources in your account. When conducting your security audit confirm that the following IAM permissions are granted to trusted identities:
 - iam:PutGroupPolicy
 - iam:PutRolePolicy
 - iam:PutUserPolicy
 - iam:CreatePolicy
 - iam:CreatePolicyVersion
 - iam:AttachGroupPolicy

- `iam:AttachRolePolicy`
- `iam:AttachUserPolicy`
- Make sure policies don't grant permissions for services that you don't use. For example, if you use [AWS managed policies](#), make sure the AWS managed policies that are in use in your account are for services that you actually use. To find out which AWS managed policies are in use in your account, use the IAM [GetAccountAuthorizationDetails](#) API (AWS CLI command: [aws iam get-account-authorization-details](#)).
- If the policy grants a user permission to launch an Amazon EC2 instance, it might also allow the `iam:PassRole` action, but if so it should [explicitly list the roles](#) that the user can pass to the Amazon EC2 instance.
- Examine any values for the Action or Resource element that include *. When possible, grant Allow access to the individual actions and resources that users need. However, the following are reasons that it might be suitable to use * in a policy:
 - The policy is designed to grant administrative-level permissions.
 - The wildcard character is used for a set of similar actions (for example, `Describe*`) as a convenience, and you are comfortable with the complete list of actions that are referenced in this way.
 - The wildcard character is used to indicate a class of resources or a resource path (for example, `arn:aws:iam::account-id:users/division_abc/*`), and you are comfortable granting access to all the resources in that class or path.
 - A service action doesn't support resource-level permissions, and the only choice for a resource is *.
- Examine policy names to make sure they reflect the policy's function. For example, although a policy might have a name that includes "read only," the policy might actually grant write or change permissions.

For more information about planning for your security audit, see [Best Practices for Security, Identity, and Compliance](#) in the *AWS Architecture Center*.

Data protection in AWS Identity and Access Management

The AWS [shared responsibility model](#) applies to data protection in AWS Identity and Access Management. As described in this model, AWS is responsible for protecting the global infrastructure that runs all of the AWS Cloud. You are responsible for maintaining control over your

content that is hosted on this infrastructure. You are also responsible for the security configuration and management tasks for the AWS services that you use. For more information about data privacy, see the [Data Privacy FAQ](#). For information about data protection in Europe, see the [AWS Shared Responsibility Model and GDPR](#) blog post on the *AWS Security Blog*.

For data protection purposes, we recommend that you protect AWS account credentials and set up individual users with AWS IAM Identity Center or AWS Identity and Access Management (IAM). That way, each user is given only the permissions necessary to fulfill their job duties. We also recommend that you secure your data in the following ways:

- Use multi-factor authentication (MFA) with each account.
- Use SSL/TLS to communicate with AWS resources. We require TLS 1.2 and recommend TLS 1.3.
- Set up API and user activity logging with AWS CloudTrail.
- Use AWS encryption solutions, along with all default security controls within AWS services.
- Use advanced managed security services such as Amazon Macie, which assists in discovering and securing sensitive data that is stored in Amazon S3.
- If you require FIPS 140-2 validated cryptographic modules when accessing AWS through a command line interface or an API, use a FIPS endpoint. For more information about the available FIPS endpoints, see [Federal Information Processing Standard \(FIPS\) 140-2](#).

We strongly recommend that you never put confidential or sensitive information, such as your customers' email addresses, into tags or free-form text fields such as a **Name** field. This includes when you work with IAM or other AWS services using the console, API, AWS CLI, or AWS SDKs. Any data that you enter into tags or free-form text fields used for names may be used for billing or diagnostic logs. If you provide a URL to an external server, we strongly recommend that you do not include credentials information in the URL to validate your request to that server.

Data encryption in IAM and AWS STS

Data encryption typically falls into two categories: encryption at rest and encryption in transit.

Encryption at rest

Data that is collected and stored by IAM is encrypted at rest.

- **IAM** – Data collected and stored within IAM includes IP addresses, customer account metadata, and customer identifying data that includes passwords. Customer account metadata and customer identifying data are encrypted at rest using AES 256 or is hashed using SHA 256.

- **AWS STS** – AWS STS does not collect customer content except for service logs that log successful, erroneous, and faulty requests to the service.

Encryption in transit

Customer identifying data, including passwords, is encrypted in transit using TLS 1.2 and 1.3. All AWS STS endpoints support HTTPS for encrypting data in transit. For a list of AWS STS endpoints, see [Regions and endpoints](#).

Key management in IAM and AWS STS

You can't manage encryption keys using IAM or AWS STS. For more information about encryption keys, see [What is AWS KMS?](#) in the AWS Key Management Service Developer Guide

Internet traffic privacy in IAM and AWS STS

Requests to IAM must be made using Transport Layer Security protocol (TLS). You can secure connections to the AWS STS service by using VPC endpoints. To learn more, see [Interface VPC endpoints](#).

Logging and monitoring in AWS Identity and Access Management

Monitoring is an important part of maintaining the reliability, availability, and performance of AWS Identity and Access Management (IAM), AWS Security Token Service (AWS STS) and your other AWS solutions. AWS provides several tools for monitoring your AWS resources and responding to potential incidents:

- *AWS CloudTrail* captures all API calls for IAM and AWS STS as events, including calls from the console and API calls. To learn more about using CloudTrail with IAM and AWS STS, see [Logging IAM and AWS STS API calls with AWS CloudTrail](#). For more information about CloudTrail, see the [AWS CloudTrail User Guide](#).
- *AWS Identity and Access Management Access Analyzer* helps you identify the resources in your organization and accounts, such as Amazon S3 buckets or IAM roles, that are shared with an external entity. This helps you identify unintended access to your resources and data, which is a security risk. To learn more, see [What is IAM Access Analyzer?](#)

- *Amazon CloudWatch* monitors your AWS resources and the applications that you run on AWS in real time. You can collect and track metrics, create customized dashboards, and set alarms that notify you or take actions when a specified metric reaches a threshold that you specify. For example, you can have CloudWatch track CPU usage or other metrics of your Amazon EC2 instances and automatically launch new instances when needed. For more information, see the [Amazon CloudWatch User Guide](#).
- *Amazon CloudWatch Logs* helps you monitor, store, and access your log files from Amazon EC2 instances, CloudTrail, and other sources. CloudWatch Logs can monitor information in the log files and notify you when certain thresholds are met. You can also archive your log data in highly durable storage. For more information, see the [Amazon CloudWatch Logs User Guide](#).

For additional resources and security best practices for IAM, see [Security best practices and use cases in AWS Identity and Access Management](#).

Compliance validation for AWS Identity and Access Management

Third-party auditors assess the security and compliance of AWS Identity and Access Management (IAM) as part of multiple AWS compliance programs. These include SOC, PCI, FedRAMP, ISO, and others.

To learn whether an AWS service is within the scope of specific compliance programs, see [AWS services in Scope by Compliance Program](#) and choose the compliance program that you are interested in. For general information, see [AWS Compliance Programs](#).

You can download third-party audit reports using AWS Artifact. For more information, see [Downloading Reports in AWS Artifact](#).

Your compliance responsibility when using AWS services is determined by the sensitivity of your data, your company's compliance objectives, and applicable laws and regulations. AWS provides the following resources to help with compliance:

- [Security and Compliance Quick Start Guides](#) – These deployment guides discuss architectural considerations and provide steps for deploying baseline environments on AWS that are security and compliance focused.
- [Architecting for HIPAA Security and Compliance on Amazon Web Services](#) – This whitepaper describes how companies can use AWS to create HIPAA-eligible applications.

Note

Not all AWS services are HIPAA eligible. For more information, see the [HIPAA Eligible Services Reference](#).

- [AWS Compliance Resources](#) – This collection of workbooks and guides might apply to your industry and location.
- [AWS Customer Compliance Guides](#) – Understand the shared responsibility model through the lens of compliance. The guides summarize the best practices for securing AWS services and map the guidance to security controls across multiple frameworks (including National Institute of Standards and Technology (NIST), Payment Card Industry Security Standards Council (PCI), and International Organization for Standardization (ISO)).
- [Evaluating Resources with Rules](#) in the *AWS Config Developer Guide* – The AWS Config service assesses how well your resource configurations comply with internal practices, industry guidelines, and regulations.
- [AWS Security Hub](#) – This AWS service provides a comprehensive view of your security state within AWS. Security Hub uses security controls to evaluate your AWS resources and to check your compliance against security industry standards and best practices. For a list of supported services and controls, see [Security Hub controls reference](#).
- [AWS Audit Manager](#) – This AWS service helps you continuously audit your AWS usage to simplify how you manage risk and compliance with regulations and industry standards.

Resilience in AWS Identity and Access Management

The AWS global infrastructure is built around AWS Regions and Availability Zones. AWS Regions have multiple physically separated and isolated Availability Zones, which are connected with low-latency, high-throughput, and highly redundant networking. For more information about AWS Regions and Availability Zones, see [AWS Global Infrastructure](#).

AWS Identity and Access Management (IAM) and AWS Security Token Service (AWS STS) are self-sustaining, Region-based services that are available globally.

IAM is a critical AWS service. Every operation performed in AWS must be authenticated and authorized by IAM. IAM checks each request against the identities and policies stored in IAM to determine if the request is allowed or denied. IAM was designed with a separate *control plane* and

data plane so that the service authenticates even during unexpected failures. IAM resources that are used in authorizations, such as roles and policies, are stored in the control plane. IAM customers can change the configuration of these resources by using IAM operations such as `DeletePolicy` and `AttachRolePolicy`. Those configuration change requests go to the control plane. There is one IAM control plane for all commercial AWS Regions, which is located in the US East (N. Virginia) Region. The IAM system then propagates configuration changes to the IAM data planes in every [enabled AWS Region](#). The IAM data plane is essentially a read-only replica of the IAM control plane configuration data. Each AWS Region has a completely independent instance of the IAM data plane, which performs authentication and authorization for requests from the same Region. In each Region, the IAM data plane is distributed across at least three Availability Zones, and has sufficient capacity to tolerate the loss of an Availability Zone without any customer impairment. Both the IAM control and data planes were built for *zero planned downtime*, with all software updates and scaling operations performed in a manner that is invisible to customers.

AWS STS requests always go to a single global endpoint by default. You can use a Regional AWS STS endpoint to reduce latency or provide additional redundancy for your applications. To learn more, see [Managing AWS STS in an AWS Region](#).

Certain events can interrupt communication between AWS Regions over the network. However, even when you can't communicate with the global IAM endpoint, AWS STS can still authenticate IAM principals and IAM can authorize your requests. The specific details of an event that interrupts communication will determine your ability to access AWS services. In most situations, you can continue to use IAM credentials in your AWS environment. The following conditions might apply to an event that interrupts communication.

Access keys for IAM users

You can authenticate indefinitely in a Region with long-term [access keys for IAM users](#). When you use the AWS Command Line Interface and APIs, you can provide AWS access keys so that AWS can verify your identity in programmatic requests.

Important

As a [best practice](#), we recommend that your users sign in with [temporary credentials](#) instead of long-term access keys.

Temporary credentials

You can [request new temporary credentials](#) with the AWS STS Regional [service endpoint](#) for at least 24 hours. The following API operations generate temporary credentials.

- **AssumeRole**
- **AssumeRoleWithWebIdentity**
- **AssumeRoleWithSAML**
- **GetFederationToken**
- **GetSessionToken**

Principals and permissions

- You might not be able to add, modify, or remove principals or permissions in IAM.
- Your credentials might not reflect changes to your permissions that you recently applied in IAM. For more information, see [Changes that I make are not always immediately visible](#).

AWS Management Console

- You might be able to use a Regional sign-in endpoint to sign in to the AWS Management Console as an IAM user. Regional sign-in endpoints have the following URL format.

```
https://{Account ID}.signin.aws.amazon.com/console?region={Region}
```

Example: <https://111122223333.signin.aws.amazon.com/console?region=us-west-2>

- You might not be able to complete [Universal 2nd Factor \(U2F\)](#) multi-factor authentication (MFA).

Best practices for IAM resilience

AWS has built resilience into AWS Regions and Availability Zones. When you observe the following IAM best practices in the systems that interact with your environment, you take advantage of that resilience.

1. Use an AWS STS Regional [service endpoint](#) instead of the default global endpoint.
2. Review the configuration of your environment for vital resources that routinely create or modify IAM resources, and prepare a fallback solution that uses existing IAM resources.

Infrastructure security in AWS Identity and Access Management

As a managed service, AWS Identity and Access Management is protected by AWS global network security. For information about AWS security services and how AWS protects infrastructure, see [AWS Cloud Security](#). To design your AWS environment using the best practices for infrastructure security, see [Infrastructure Protection](#) in *Security Pillar AWS Well-Architected Framework*.

You use AWS published API calls to access IAM through the network. Clients must support the following:

- Transport Layer Security (TLS). We require TLS 1.2 and recommend TLS 1.3.
- Cipher suites with perfect forward secrecy (PFS) such as DHE (Ephemeral Diffie-Hellman) or ECDHE (Elliptic Curve Ephemeral Diffie-Hellman). Most modern systems such as Java 7 and later support these modes.

Additionally, requests must be signed by using an access key ID and a secret access key that is associated with an IAM principal. Or you can use the [AWS Security Token Service](#) (AWS STS) to generate temporary security credentials to sign requests.

IAM can be accessed programmatically by using the IAM HTTPS API, which lets you issue HTTPS requests directly to the service. The Query API returns sensitive information, including security credentials. Therefore, you must use HTTPS with all API requests. When you use the HTTPS API, you must include code to digitally sign requests using your credentials.

You can call these API operations from any network location, but IAM does support resource-based access policies, which can include restrictions based on the source IP address. You can also use IAM policies to control access from specific Amazon Virtual Private Cloud (Amazon VPC) endpoints or specific VPCs. Effectively, this isolates network access to a given IAM resource from only the specific VPC within the AWS network.

Configuration and vulnerability analysis in AWS Identity and Access Management

AWS handles basic security tasks like guest operating system (OS) and database patching, firewall configuration, and disaster recovery. These procedures have been reviewed and certified by the appropriate third parties. For more details, see the following resources:

- [Shared Responsibility Model](#)

- [Amazon Web Services: Overview of Security Processes](#) (whitepaper)

The following resources also address configuration and vulnerability analysis in AWS Identity and Access Management (IAM):

- [Compliance validation for AWS Identity and Access Management](#)
- [Security best practices and use cases in AWS Identity and Access Management](#)

AWS managed policies for AWS Identity and Access Management Access Analyzer

An AWS managed policy is a standalone policy that is created and administered by AWS. AWS managed policies are designed to provide permissions for many common use cases so that you can start assigning permissions to users, groups, and roles.

Keep in mind that AWS managed policies might not grant least-privilege permissions for your specific use cases because they're available for all AWS customers to use. We recommend that you reduce permissions further by defining [customer managed policies](#) that are specific to your use cases.

You cannot change the permissions defined in AWS managed policies. If AWS updates the permissions defined in an AWS managed policy, the update affects all principal identities (users, groups, and roles) that the policy is attached to. AWS is most likely to update an AWS managed policy when a new AWS service is launched or new API operations become available for existing services.

For more information, see [AWS managed policies](#) in the *IAM User Guide*.

IAMReadOnlyAccess

Use the IAMReadOnlyAccess managed policy to allow read only access to IAM resources. This policy grants permission to get and list all IAM resources. It allows viewing details and activity reports for users, groups, roles, policies, identity providers, and MFA devices. It does not include the

ability to create or delete resources or access to IAM Access Analyzer resources. View the [policy](#) for the full list of services and actions supported by this policy.

IAMUserChangePassword

Use the IAMUserChangePassword managed policy to allow IAM users to change their password.

You configure your IAM **Account settings** and the **Password policy** to allow IAM users to change their IAM account password. When you allow this action, IAM attaches the following policy to each user:

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "iam:ChangePassword"
      ],
      "Resource": [
        "arn:aws:iam::*:user/${aws:username}"
      ]
    },
    {
      "Effect": "Allow",
      "Action": [
        "iam:GetAccountPasswordPolicy"
      ],
      "Resource": "*"
    }
  ]
}
```

IAMAccessAnalyzerFullAccess

Use the IAMAccessAnalyzerFullAccess AWS managed policy to allow your administrators to access IAM Access Analyzer.

Permissions groupings

This policy is grouped into statements based on the set of permissions provided.

- **IAM Access Analyzer** – Allows full administrative permissions to all resources in IAM Access Analyzer.
- **Create service linked role** – Allows the administrator to create a [service-linked role](#), which allows IAM Access Analyzer to analyze resources in other services on your behalf. This permission allows creating the service-linked role only for use by IAM Access Analyzer.
- **AWS Organizations** – Allows administrators to use IAM Access Analyzer for an organization in AWS Organizations. After [enabling trusted access](#) for IAM Access Analyzer in AWS Organizations, members of the management account can view findings across their organization.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "access-analyzer:*"
      ],
      "Resource": "*"
    },
    {
      "Effect": "Allow",
      "Action": "iam:CreateServiceLinkedRole",
      "Resource": "*",
      "Condition": {
        "StringEquals": {
          "iam:AWSServiceName": "access-analyzer.amazonaws.com"
        }
      }
    }
  ],
  {
    "Effect": "Allow",
    "Action": [
      "organizations:DescribeAccount",
      "organizations:DescribeOrganization",
      "organizations:DescribeOrganizationalUnit",
      "organizations:ListAccounts",
      "organizations:ListAccountsForParent",
      "organizations:ListAWSServiceAccessForOrganization",
      "organizations:ListChildren",
      "organizations:ListDelegatedAdministrators",
      "organizations:ListOrganizationalUnitsForParent",
```

```
        "organizations:ListParents",
        "organizations:ListRoots"
    ],
    "Resource": "*"
}
]
```

IAMAccessAnalyzerReadOnlyAccess

Use the `IAMAccessAnalyzerReadOnlyAccess` AWS managed policy to allow read-only access to IAM Access Analyzer.

To also allow read-only access to IAM Access Analyzer for AWS Organizations, create a customer managed policy that allows the Describe and List actions from the [IAMAccessAnalyzerFullAccess](#) AWS managed policy.

Service-level permissions

This policy provides read-only access to IAM Access Analyzer. No other service permissions are included in this policy.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "IAMAccessAnalyzerReadOnlyAccess",
      "Effect": "Allow",
      "Action": [
        "access-analyzer:CheckAccessNotGranted",
        "access-analyzer:CheckNoNewAccess",
        "access-analyzer:Get*",
        "access-analyzer:List*",
        "access-analyzer:ValidatePolicy"
      ],
      "Resource": "*"
    }
  ]
}
```

AccessAnalyzerServiceRolePolicy

You can't attach AccessAnalyzerServiceRolePolicy to your IAM entities. This policy is attached to a service-linked role that allows IAM Access Analyzer to perform actions on your behalf. For more information, see [Using service-linked roles for AWS Identity and Access Management Access Analyzer](#).

Permissions groupings

This policy allows access to IAM Access Analyzer to analyze resource metadata from multiple AWS services.

- **Amazon DynamoDB** – Allows permissions to view DynamoDB streams and tables.
- **Amazon Elastic Compute Cloud** – Allows permissions to describe IP addresses, snapshots, and VPCs.
- **Amazon Elastic Container Registry** – Allows permissions to describe image repositories and retrieve repository policies.
- **Amazon Elastic File System** – Allows permissions to view the description of an Amazon EFS file system and view the resource-level policy for an Amazon EFS file system.
- **AWS Identity and Access Management** – Allows permissions to retrieve information about a specified role and list the IAM roles that have a specified path prefix. Allows permissions to retrieve information about users, user groups, login profiles, access keys, and service last accessed data.
- **AWS Key Management Service** – Allows permissions to view detailed information about an KMS key and its key policies and grants.
- **AWS Lambda** – Allows permissions to view information about Lambda aliases, functions, layers, and aliases.
- **AWS Organizations** – Allows permissions to Organizations and allows the creation of an analyzer within the AWS organization as the zone of trust.
- **Amazon Relational Database Service** – Allows permissions to view detailed information about Amazon RDS DB snapshots and Amazon RDS DB cluster snapshots.
- **Amazon Simple Storage Service** – Allows permissions to view detailed information about Amazon S3 access points, buckets, and Amazon S3 directory buckets that use the Amazon S3 Express One storage class.
- **AWS Secrets Manager** – Allows permissions to view detailed information about secrets and resource policies attached to secrets.

- **Amazon Simple Notification Service** – Allows permissions to view detailed information about a topic.
- **Amazon Simple Queue Service** – Allows permissions to view detailed information about specified queues.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "AccessAnalyzerServiceRolePolicy",
      "Effect": "Allow",
      "Action": [
        "dynamodb:GetResourcePolicy",
        "dynamodb:ListStreams",
        "dynamodb:ListTables",
        "ec2:DescribeAddresses",
        "ec2:DescribeByoipCidrs",
        "ec2:DescribeSnapshotAttribute",
        "ec2:DescribeSnapshots",
        "ec2:DescribeVpcEndpoints",
        "ec2:DescribeVpcs",

IAM and IAM Access Analyzer updates to AWS managed policies

View details about updates to IAM and AWS managed policies since the service began tracking these changes. For automatic alerts about changes to this page, subscribe to the RSS feed on the IAM and IAM Access Analyzer Document history pages.

Change	Description	Date
AccessAnalyzerServiceRolePolicy – Added permissions	IAM Access Analyzer added support for permission to retrieve the current state of the block public access for Amazon EC2 snapshots to the service-level permissions of AccessAnalyzerServiceRolePolicy .	January 23, 2024
AccessAnalyzerServiceRolePolicy – Added permissions	IAM Access Analyzer added support for DynamoDB streams and tables to the service-level permissions of AccessAnalyzerServiceRolePolicy .	January 11, 2024
AccessAnalyzerServiceRolePolicy – Added permissions	IAM Access Analyzer added support for Amazon S3	December 1, 2023

Change	Description	Date
	<p>directory buckets to the service-level permissions of <code>AccessAnalyzerServiceRolePolicy</code> .</p>	
<p>IAMAccessAnalyzerReadOnlyAccess – Added permissions</p>	<p>IAM Access Analyzer added permissions to allow you to check whether updates to your policies grant additional access.</p> <p>This permission is required by IAM Access Analyzer to perform policy checks on your policies.</p>	<p>November 26, 2023</p>
<p>AccessAnalyzerServiceRolePolicy – Added permissions</p>	<p>IAM Access Analyzer added IAM actions to the service-level permissions of <code>AccessAnalyzerServiceRolePolicy</code> to support the following actions:</p> <ul style="list-style-type: none"> • Listing entities for a policy • Generating service last accessed details • Listing access key information 	<p>November 26, 2023</p>

Change	Description	Date
AccessAnalyzerServiceRolePolicy – Added permissions	IAM Access Analyzer added support for the following resource types to the service-level permissions of <code>AccessAnalyzerServiceRolePolicy</code> : <ul style="list-style-type: none">• Amazon EBS volume snapshots• Amazon ECR repositories• Amazon EFS file systems• Amazon RDS DB snapshots• Amazon RDS DB cluster snapshots• Amazon SNS topics	October 25, 2022
AccessAnalyzerServiceRolePolicy – Added permissions	IAM Access Analyzer added the <code>lambda:GetFunctionUrlConfig</code> action to the service-level permissions of <code>AccessAnalyzerServiceRolePolicy</code> .	April 6, 2022
AccessAnalyzerServiceRolePolicy – Added permissions	IAM Access Analyzer added new Amazon S3 actions to analyze metadata associated with multi-region access points.	September 2, 2021

Change	Description	Date
IAMAccessAnalyzerReadOnlyAccess – Added permissions	<p>IAM Access Analyzer added a new action to grant <code>ValidatePolicy</code> permissions to allow you to use the policy checks for validation.</p> <p>This permission is required by IAM Access Analyzer to perform policy checks on your policies.</p>	March 16, 2021
IAM Access Analyzer started tracking changes	IAM Access Analyzer started tracking changes for its AWS managed policies.	March 1, 2021

Using AWS Identity and Access Management Access Analyzer

AWS Identity and Access Management Access Analyzer provides the following capabilities:

- IAM Access Analyzer external access analyzers help [identify resources](#) in your organization and accounts that are shared with an external entity.
- IAM Access Analyzer unused access analyzers help [identify unused access](#) in your organization and accounts.
- IAM Access Analyzer [validates IAM policies](#) against policy grammar and AWS best practices.
- IAM Access Analyzer custom policy checks help [validate IAM policies against your specified security standards](#).
- IAM Access Analyzer [generates IAM policies](#) based on access activity in your AWS CloudTrail logs.

Identifying resources shared with an external entity

IAM Access Analyzer helps you identify the resources in your organization and accounts, such as Amazon S3 buckets or IAM roles, shared with an external entity. This lets you identify unintended access to your resources and data, which is a security risk. IAM Access Analyzer identifies resources shared with external principals by using logic-based reasoning to analyze the resource-based policies in your AWS environment. For each instance of a resource shared outside of your account, IAM Access Analyzer generates a finding. Findings include information about the access and the external principal granted to it. You can review findings to determine if the access is intended and safe or if the access is unintended and a security risk. In addition to helping you identify resources shared with an external entity, you can use IAM Access Analyzer findings to preview how your policy affects public and cross-account access to your resource before deploying resource permissions. The findings are organized in a visual summary dashboard. The dashboard highlights the split between public and cross-account access findings, and provides a breakdown of findings by resource type. To learn more about the dashboard, see [Viewing the IAM Access Analyzer findings dashboard](#).

Note

An external entity can be another AWS account, a root user, an IAM user or role, a federated user, an AWS service, an anonymous user, or other entity that you can use to create a filter. For more information, see [AWS JSON Policy Elements: Principal](#).

When you enable IAM Access Analyzer, you create an analyzer for your entire organization or your account. The organization or account you choose is known as the zone of trust for the analyzer. The analyzer monitors all of the [supported resources](#) within your zone of trust. Any access to resources by principals within your zone of trust is considered trusted. Once enabled, IAM Access Analyzer analyzes the policies applied to all of the supported resources in your zone of trust. After the first analysis, IAM Access Analyzer analyzes these policies periodically. If you add a new policy, or change an existing policy, IAM Access Analyzer analyzes the new or updated policy within about 30 minutes.

When analyzing the policies, if IAM Access Analyzer identifies one that grants access to an external principal that isn't within your zone of trust, it generates a finding. Each finding includes details about the resource, the external entity with access to it, and the permissions granted so that you can take appropriate action. You can view the details included in the finding to determine whether the resource access is intentional or a potential risk that you should resolve. When you add a policy to a resource, or update an existing policy, IAM Access Analyzer analyzes the policy. IAM Access Analyzer also analyzes all resource-based policies periodically.

On rare occasions under certain conditions, IAM Access Analyzer does not receive notification of an added or updated policy, which can cause delays in generated findings. IAM Access Analyzer can take up to 6 hours to generate or resolve findings if you create or delete a multi-region access point associated with an Amazon S3 bucket, or update the policy for the multi-region access point. Also, if there is a delivery issue with AWS CloudTrail log delivery, the policy change does not trigger a rescan of the resource reported in the finding. When this happens, IAM Access Analyzer analyzes the new or updated policy during the next periodic scan, which is within 24 hours. If you want to confirm a change you make to a policy resolves an access issue reported in a finding, you can rescan the resource reported in a finding by using the **Rescan** link in the **Findings** details page, or by using the [StartResourceScan](#) operation of the IAM Access Analyzer API. To learn more, see [Resolving findings](#).

⚠ Important

IAM Access Analyzer analyzes only policies applied to resources in the same AWS Region where it's enabled. To monitor all resources in your AWS environment, you must create an analyzer to enable IAM Access Analyzer in each Region where you're using supported AWS resources.

IAM Access Analyzer analyzes the following resource types:

- [Amazon Simple Storage Service buckets](#)
- [Amazon Simple Storage Service directory buckets](#)
- [AWS Identity and Access Management roles](#)
- [AWS Key Management Service keys](#)
- [AWS Lambda functions and layers](#)
- [Amazon Simple Queue Service queues](#)
- [AWS Secrets Manager secrets](#)
- [Amazon Simple Notification Service topics](#)
- [Amazon Elastic Block Store volume snapshots](#)
- [Amazon Relational Database Service DB snapshots](#)
- [Amazon Relational Database Service DB cluster snapshots](#)
- [Amazon Elastic Container Registry repositories](#)
- [Amazon Elastic File System file systems](#)

Identifying unused access granted to IAM users and roles

IAM Access Analyzer helps you identify and review unused access in your AWS organization and accounts. IAM Access Analyzer continuously monitors all IAM roles and users in your AWS organization and accounts and generates findings for unused access. The findings highlight unused roles, unused access keys for IAM users, and unused passwords for IAM users. For active IAM roles and users, the findings provide visibility into unused services and actions.

The findings for both external access and unused access analyzers are organized into a visual summary dashboard. The dashboard highlights your AWS accounts that have the most findings and

provides a breakdown of findings by type. For more information about the dashboard, see [Viewing the IAM Access Analyzer findings dashboard](#).

IAM Access Analyzer reviews last accessed information for all roles in your AWS organization and accounts to help you identify unused access. IAM action last accessed information helps you identify unused actions for roles in your AWS accounts. For more information, see [Refining permissions in AWS using last accessed information](#).

Validating policies against AWS best practices

You can validate your policies against IAM [policy grammar](#) and [AWS best practices](#) using the basic policy checks provided by IAM Access Analyzer policy validation. You can create or edit a policy using the AWS CLI, AWS API, or JSON policy editor in the IAM console. You can view policy validation check findings that include security warnings, errors, general warnings, and suggestions for your policy. These findings provide actionable recommendations that help you author policies that are functional and conform to AWS best practices. To learn more about validating policies using policy validation, see [IAM Access Analyzer policy validation](#).

Validating policies against your specified security standards

You can validate your policies against your specified security standards using the IAM Access Analyzer custom policy checks. You can create or edit a policy using the AWS CLI, AWS API, or JSON policy editor in the IAM console. Through the console, you can check whether your updated policy grants new access compared to the existing version. Through AWS CLI and AWS API, you can also check specific IAM actions that you consider critical are not allowed by a policy. These checks highlight a policy statement that grants new access. You can update the policy statement and re-run the checks until the policy conform to your security standard. To learn more about validating policies using custom policy checks, see [IAM Access Analyzer custom policy checks](#).

Generating policies

IAM Access Analyzer analyzes your AWS CloudTrail logs to identify actions and services that have been used by an IAM entity (user or role) within your specified date range. It then generates an IAM policy that is based on that access activity. You can use the generated policy to refine an entity's permissions by attaching it to an IAM user or role. To learn more about generating policies using IAM Access Analyzer, see [IAM Access Analyzer policy generation](#).

Pricing for IAM Access Analyzer

IAM Access Analyzer charges for unused access analysis based on the number of IAM roles and users analyzed per analyzer per month.

- You will be charged for each unused access analyzer that you create.
- Creating unused access analyzers across multiple Regions will result in you being charged for each analyzer.
- Service-linked roles aren't analyzed for unused access activity and they aren't included in the total number of IAM roles analyzed.

IAM Access Analyzer charges for custom policy checks based on the number of API requests made to IAM Access Analyzer to check for new access.

For a complete list of charges and prices for IAM Access Analyzer, see [IAM Access Analyzer pricing](#).

To see your bill, go to the **Billing and Cost Management Dashboard** in the [AWS Billing and Cost Management console](#). Your bill contains links to usage reports that provide details about your bill.

To learn more about AWS account billing, see the [AWS Billing User Guide](#)

If you have questions concerning AWS billing, accounts, and events, [contact AWS Support](#).

Findings for external and unused access

IAM Access Analyzer generates findings for external access and unused access in your AWS account or organization. For external access, IAM Access Analyzer generates a finding for each instance of a resource-based policy that grants access to a resource within your zone of trust to a principal that is not within your zone of trust. When you create an external access analyzer, you choose an organization or AWS account to analyze. Any principal in the organization or account that you choose for the analyzer is considered trusted. Because principals in the same organization or account are trusted, the resources and principals within the organization or account comprise the zone of trust for the analyzer. Any sharing that is within the zone of trust is considered safe, so IAM Access Analyzer does not generate a finding. For example, if you select an organization as the zone of trust for an analyzer, all resources and principals in the organization are within the zone of trust. If you grant permissions to an Amazon S3 bucket in one of your organization member accounts to a principal in another organization member account, IAM Access Analyzer does not generate a finding. But if you grant permission to a principal in an account that is not a member of the organization, IAM Access Analyzer generates a finding.

IAM Access Analyzer also generates findings for unused access granted in your AWS organization and accounts. When you create an unused access analyzer, IAM Access Analyzer continuously monitors all IAM roles and users in your AWS organization and accounts and generates findings for unused access. IAM Access Analyzer generates the following types of findings for unused access:

- **Unused roles** – Roles with no access activity within the specified usage window.
- **Unused IAM user access keys and passwords** – Credentials belonging to IAM users that enable them to access your AWS account.
- **Unused permissions** – Service-level and action-level permissions that weren't used by a role within the specified usage window. IAM Access Analyzer uses identity-based policies attached to roles to determine the services and actions that those roles can access. IAM Access Analyzer supports review of unused permissions for all service-level permissions. For a complete list of action-level permissions that are supported for unused access findings, see [IAM action last accessed information services and actions](#).

Note

IAM Access Analyzer offers external access findings for free and charges for unused access findings based on the number of IAM roles and users analyzed per analyzer per month. For more details about pricing, see [IAM Access Analyzer pricing](#).

How IAM Access Analyzer findings work

This topic describes the concepts and terms that are used in IAM Access Analyzer to help you become familiar with how IAM Access Analyzer monitors access to your AWS resources.

External access

For external access analyzers, AWS Identity and Access Management Access Analyzer is built on [Zelkova](#), which translates IAM policies into equivalent logical statements, and runs a suite of general-purpose and specialized logical solvers (satisfiability modulo theories) against the problem. IAM Access Analyzer applies Zelkova repeatedly to a policy with increasingly specific queries to characterize classes of behaviors the policy allows, based on the content of the policy. To learn more about satisfiability modulo theories, see [Satisfiability Modulo Theories](#).

For external access analyzers, IAM Access Analyzer does not examine access logs to determine whether an external entity accessed a resource within your zone of trust. It generates a finding when a resource-based policy allows access to a resource, even if the resource was not accessed by the external entity. IAM Access Analyzer also does not consider the state of any external accounts when making its determination. That is, if it indicates that account 111122223333 can access your Amazon S3 bucket, it knows nothing about the state of users, roles, service control policies (SCP), and other relevant configurations in that account. This is for customer privacy – IAM Access Analyzer doesn't consider who owns the other account. It is also for security – if the account is not owned by the IAM Access Analyzer customer, it is still important to know that an external entity could gain access to their resources even if there are currently no principals in the account that could access the resources.

IAM Access Analyzer considers only certain IAM condition keys that external users cannot directly influence, or that are otherwise impactful to authorization. For examples of condition keys IAM Access Analyzer considers, see [IAM Access Analyzer filter keys](#).

IAM Access Analyzer does not currently report findings from AWS service principals or internal service accounts. In rare cases where IAM Access Analyzer isn't able to fully determine whether a

policy statement grants access to an external entity, it errs on the side of declaring a false positive finding. IAM Access Analyzer is designed to provide a comprehensive view of the resource sharing in your account, and strives to minimize false negatives.

Unused access

You must create an analyzer for unused access findings for your roles even if you've already created an analyzer to generate external access findings for your resources. After creating the analyzer, IAM Access Analyzer reviews access activity to identify unused access. IAM Access Analyzer reviews last accessed information for all roles, user access keys, and user passwords in your AWS organization and accounts to help you identify unused access. For active IAM roles and users, IAM Access Analyzer uses IAM service and action last accessed information to identify unused permissions. You can use unused access analyzers to scale your review process at the AWS organization and account level. You can use action last accessed information for deeper investigation of individual roles.

Summary dashboard

For both external and unused access, IAM Access Analyzer organizes the findings in a summary dashboard. For external access, the summary dashboard highlights the split between public and cross-account access findings, and provides a breakdown of findings by resource type. For the unused access, the dashboard highlights your AWS accounts that have the most findings and provides a breakdown of findings by type. After you create an analyzer for external or unused access, IAM Access Analyzer automatically adds new findings to the dashboard focused on roles with unused permissions.

Getting started with AWS Identity and Access Management Access Analyzer findings

Use the information in this topic to learn about the requirements necessary to use and manage AWS Identity and Access Management Access Analyzer, and then how to enable IAM Access Analyzer. To learn more about the service-linked role for IAM Access Analyzer, see [Using service-linked roles for AWS Identity and Access Management Access Analyzer](#).

Permissions required to use IAM Access Analyzer

To successfully configure and use IAM Access Analyzer, the account you use must be granted the required permissions.

AWS managed policies for IAM Access Analyzer

AWS Identity and Access Management Access Analyzer provides AWS managed policies to help you get started quickly.

- [IAMAccessAnalyzerFullAccess](#) - Allows full access to IAM Access Analyzer for administrators. This policy also allows creating the service-linked roles that are required to allow IAM Access Analyzer to analyze resources in your account or AWS organization.
- [IAMAccessAnalyzerReadOnlyAccess](#) - Allows read-only access to IAM Access Analyzer. You must add additional policies to your IAM identities (users, groups of users, or roles) to allow them to view their findings.

Resources defined by IAM Access Analyzer

To view the resources defined by IAM Access Analyzer, see [Resource types defined by IAM Access Analyzer](#) in the *Service Authorization Reference*.

Required IAM Access Analyzer service permissions

IAM Access Analyzer uses a service-linked role (SLR) named `AWSServiceRoleForAccessAnalyzer`. This SLR grants the service read-only access to analyze AWS resources with resource-based policies and analyze unused access on your behalf. The service creates the role in your account in the following scenarios:

- You create an external access analyzer with your account as the zone of trust.
- You create an unused access analyzer with your account as the selected account.

For more information, see [Using service-linked roles for AWS Identity and Access Management Access Analyzer](#).

Note

IAM Access Analyzer is Regional. For external access, you must enable IAM Access Analyzer in each Region independently.

For unused access, findings for the analyzer do not change based on Region. Creating an analyzer in each Region where you have resources is not required.

In some cases, after you create an external access or unused access analyzer in IAM Access Analyzer, the **Findings** page or dashboard loads with no findings or summary. This might be due to a delay in the console for populating your findings. You might need to manually refresh the browser or check back later to view your findings or summary. If you still don't see any findings for an external access analyzer, it's because you have no supported resources in your account that can be accessed by an external entity. If a policy that grants access to an external entity is applied to a resource, IAM Access Analyzer generates a finding.

Note

For external access analyzers, it may take up to 30 minutes after a policy is modified for IAM Access Analyzer to analyze the resource and then either generate a new external access finding or update an existing finding for the access to the resource. For both external and unused access analyzers, updates for findings might not be reflected in the dashboard immediately.

Required IAM Access Analyzer permissions to view the findings dashboard

To view the [IAM Access Analyzer findings dashboard](#), the account you use must be granted access to perform the following required actions:

- [GetAnalyzer](#)
- [ListAnalyzers](#)
- `GetFindingsStatistics`

To view all of the actions defined by IAM Access Analyzer, see [Actions defined by IAM Access Analyzer](#) in the *Service Authorization Reference*.

Enabling IAM Access Analyzer

To create an external access analyzer with the AWS account as the zone of trust

To enable an external access analyzer in a Region, you must create an analyzer in that Region. You must create an external access analyzer in each Region in which you want to monitor access to your resources.

1. Open the IAM console at <https://console.aws.amazon.com/iam/>.

2. Choose **Access analyzer**.
3. Choose **Analyzer settings**.
4. Choose **Create analyzer**.
5. In the **Analysis** section, choose **External access analysis**.
6. In the **Analyzer details** section, confirm that the Region displayed is the Region where you want to enable IAM Access Analyzer.
7. Enter a name for the analyzer.
8. Choose **Current AWS account** as the zone of trust for the analyzer.

 **Note**

If your account is not the AWS Organizations management account or [delegated administrator](#) account, you can create only one analyzer with your account as the zone of trust.

9. Optional. Add any tags that you want to apply to the analyzer.
10. Choose **Submit**.

When you create an external access analyzer to enable IAM Access Analyzer, a service-linked role named `AWSServiceRoleForAccessAnalyzer` is created in your account.

To create an external access analyzer with the organization as the zone of trust

1. Open the IAM console at <https://console.aws.amazon.com/iam/>.
2. Choose **Access analyzer**.
3. Choose **Analyzer settings**.
4. Choose **Create analyzer**.
5. In the **Analysis** section, choose **External access analysis**.
6. In the **Analyzer details** section, confirm that the Region displayed is the Region where you want to enable IAM Access Analyzer.
7. Enter a name for the analyzer.
8. Choose **Current organization** as the zone of trust for the analyzer.
9. Optional. Add any tags that you want to apply to the analyzer.

10. Choose **Submit**.

When you create an external access analyzer with the organization as the zone of trust, a service-linked role named `AWSServiceRoleForAccessAnalyzer` is created in each account of your organization.

To create an unused access analyzer for the current account

Use the following procedure to create an unused access analyzer for a single AWS account. For unused access, findings for the analyzer do not change based on Region. Creating an analyzer in each Region where you have resources is not required.

IAM Access Analyzer charges for unused access analysis based on the number of IAM roles and users analyzed per month per analyzer. For more details about pricing, see [IAM Access Analyzer pricing](#).

1. Open the IAM console at <https://console.aws.amazon.com/iam/>.
2. Choose **Access analyzer**.
3. Choose **Analyzer settings**.
4. Choose **Create analyzer**.
5. In the **Analysis** section, choose **Unused access analysis**.
6. Enter a name for the analyzer.
7. For **Tracking period**, enter the number of days for which to generate findings for unused permissions. For example, if you enter 90 days, the analyzer will generate findings for IAM entities within the selected account for any permissions that haven't been used in 90 or more days since the analyzer's last scan. You can choose a value between 1 and 180 days.
8. For **Selected accounts**, choose **Current AWS account**.

Note

If your account is not the AWS Organizations management account or [delegated administrator](#) account, you can create only one analyzer with your account as the selected account.

9. Optional. Add any tags that you want to apply to the analyzer.
10. Choose **Submit**.

When you create an unused access analyzer to enable IAM Access Analyzer, a service-linked role named `AWSServiceRoleForAccessAnalyzer` is created in your account.

To create an unused access analyzer with the current organization

Use the following procedure to create an unused access analyzer for an organization to centrally review all AWS accounts in an organization. For unused access analysis, findings for the analyzer do not change based on Region. Creating an analyzer in each Region where you have resources is not required.

IAM Access Analyzer charges for unused access analysis based on the number of IAM roles and users analyzed per month per analyzer. For more details about pricing, see [IAM Access Analyzer pricing](#).

Note

If a member account is removed from the organization, the unused access analyzer will stop generating new findings and updating existing findings for that account after 24 hours. Findings associated with the member account that is removed from the organization will be removed permanently after 90 days.

1. Open the IAM console at <https://console.aws.amazon.com/iam/>.
2. Choose **Access analyzer**.
3. Choose **Analyzer settings**.
4. Choose **Create analyzer**.
5. In the **Analysis** section, choose **Unused access analysis**.
6. Enter a name for the analyzer.
7. For **Tracking period**, enter the number of days for which to generate findings for unused permissions. For example, if you enter 90 days, the analyzer will generate findings for IAM entities within the accounts of the selected organization for any permissions that haven't been used in 90 or more days since the analyzer's last scan. You can choose a value between 1 and 180 days.
8. For **Selected accounts**, choose **Current organization** as the selected accounts for the analyzer.
9. Optional. Add any tags that you want to apply to the analyzer.
10. Choose **Submit**.

When you create an unused access analyzer to enable IAM Access Analyzer, a service-linked role named `AWSServiceRoleForAccessAnalyzer` is created in your account.

IAM Access Analyzer status

To view the status of your analyzers, choose **Analyzers**. Analyzers created for an organization or account can have the following status:

Status	Description
Active	<p>For external access analyzers, the analyzer is actively monitoring resources within its zone of trust. The analyzer actively generates new findings and updates existing findings.</p> <p>For unused access analyzers, the analyzer is actively monitoring unused access within the selected organization or AWS account in the specified tracking period. The analyzer actively generates new findings and updates existing findings.</p>
Creating	<p>The creation of the analyzer is still in progress. The analyzer becomes active once creation is complete.</p>
Disabled	<p>The analyzer is disabled due to an action taken by the AWS Organizations administrator. For example, removing the analyzer's account as the delegated administrator for IAM Access Analyzer. When the analyzer is in a disabled state, it does not generate new findings or update existing findings.</p>
Failed	<p>The creation of the analyzer failed due to a configuration issue. The analyzer won't generate any findings. Delete the analyzer and create a new analyzer.</p>

Viewing the IAM Access Analyzer findings dashboard

AWS Identity and Access Management Access Analyzer organizes external access and unused access findings into a visual summary dashboard. The dashboard helps you gain visibility into the effective use of permissions at scale and identify accounts that need attention. You can use the dashboard to review findings by AWS organization, account, and finding type.

To view the summary dashboard for external access analyzers

Note

After you create or update an analyzer, it can take time for the summary dashboard to reflect updates to findings.

1. Open the IAM console at <https://console.aws.amazon.com/iam/>.
2. Choose **Access analyzer**. The **Summary** window is displayed.
3. Choose an analyzer from the **External access analyzer** dropdown. A summary of the findings for the analyzer is displayed in the **External access findings** section.

In the preceding image, the external access findings dashboard is visible from within the **Summary** page:

1. The **Active findings** section includes the number of active findings for public access and the number of active findings that provide access outside of the account or organization. Choose a number to list all of the active findings of each type.
2. The **Findings overview** section includes a breakdown of the type of active findings. Choose **View all active findings** for a complete list of active findings for the analyzer's account or organization.
3. The **Primary resource types with active findings** section includes a breakdown of the primary resource types with active findings. This information helps you prioritize findings for the primary resources first. For example, Amazon S3, DynamoDB, and AWS KMS. This is not an exhaustive list of every resource type. Your analyzer might have active findings for resource types not listed in this section.

To view the summary dashboard for unused access analyzers

IAM Access Analyzer charges for unused access analysis based on the number of IAM roles and users analyzed per month. For more details about pricing, see [IAM Access Analyzer pricing](#).

Note

After you create or update an analyzer, based on the amount of users and roles, it can take time for the summary dashboard to reflect updates to findings.

1. Open the IAM console at <https://console.aws.amazon.com/iam/>.
2. Choose **Access analyzer**. The **Summary** window is displayed.
3. Choose an analyzer from the **Unused access analyzer** dropdown. A summary of the findings for the analyzer is displayed in the **Unused access findings** section.

Finding status 3

Accounts with the most findings for unused access 4

Account	Active findings	Findings by type
Audit 11111111111111	15	Unused roles, Unused access keys, Unused passwords, Roles with unused permissions, Users with unused permissions
Log 22222222222222	10	Unused roles, Unused access keys, Unused passwords, Roles with unused permissions, Users with unused permissions
Security 33333333333333	10	Unused roles, Unused access keys, Unused passwords, Roles with unused permissions, Users with unused permissions
Production 44444444444444	10	Unused roles, Unused access keys, Unused passwords
Sandbox 55555555555555	5	Unused access keys, Roles with unused permissions, Users with unused permissions

In the preceding image, the external access findings dashboard is visible from within the **Summary** page:

1. The **Active findings** section includes the number of active findings for unused roles, unused credentials, and unused permissions in your account or organization. **Unused credentials** include both unused access key and unused password findings. **Unused permissions** include both users

and roles with unused permissions. Choose a number to list all of the active findings of each type.

2. The **Findings overview** section includes a breakdown of the type of active findings. Choose **View all active findings** for a complete list of active findings for the analyzer's account or organization.
3. The **Finding status** section includes a breakdown of the status of findings (**Active**, **Archived**, and **Resolved**) for your account or organization.
4. The **Accounts with the most findings for unused access** section is only displayed if the selected accounts of your unused access analyzer is at the organization level. It includes a breakdown of the accounts in your organization with the most active findings. This is not an exhaustive list of every account in your organization. Your analyzer might have active findings for other accounts not listed in this section.

Working with findings

External access findings

External access findings are generated only once for each instance of a resource that is shared outside of your zone of trust. Each time a resource-based policy is modified, IAM Access Analyzer analyzes the policy. If the updated policy shares a resource that is already identified in a finding, but with different permissions or conditions, a new finding is generated for that instance of the resource sharing. If the access in the first finding is removed, that finding is updated to a status of **Resolved**.

The status of all findings remains **Active** until you archive them or remove the access that generated the finding. When you remove the access, the finding status is updated to **Resolved**.

Note

It may take up to 30 minutes after a policy is modified for IAM Access Analyzer to analyze the resource and then update the external access finding.

Unused access findings

Unused access findings are generated for IAM entities within the selected account or organization based on the number of days specified while creating the analyzer. A new finding is generated the next time the analyzer scans the entities if one of the following conditions is met:

- A role is inactive for the specified number of days.
- An unused permission, unused user password, or unused user access key surpasses the specified number of days.

You should review all of the findings in your account to determine whether the external or unused access is expected and approved. If the external or unused access identified in the finding is expected, you can archive the finding. When you archive a finding, the status is changed to **Archived**, and the finding is removed from the active findings list. The finding is not deleted. You can view your archived findings at any time. Work through all of the findings in your account until you have zero active findings. After you get to zero findings, you know that any new **Active** findings that are generated are from a recent change in your environment.

Note

Unused access findings are only available using the [ListFindingsV2](#) API action.

Reviewing findings

After you [enable IAM Access Analyzer](#), the next step is to review any findings to determine whether the access identified in the finding is intentional or unintentional. You can also review findings to determine similar findings for access that is intended, and then [create an archive rule](#) to automatically archive those findings. You can also review archived and resolved findings.

To review findings

1. Open the IAM console at <https://console.aws.amazon.com/iam/>.
2. Choose **Access analyzer**.
3. The findings dashboard is displayed. Select the active findings for your external or unused access analyzer.

For more information on viewing the findings dashboard, see [Viewing the IAM Access Analyzer findings dashboard](#).

Note

Findings are displayed only if you have permission to view findings for the analyzer.

All findings are displayed for the analyzer. To view other findings generated by the analyzer, choose the appropriate finding type from the **Status** dropdown:

- Choose **Active** to view all active findings that were generated by the analyzer.
- Choose **Archived** to view only findings generated by the analyzer that have been archived. To learn more, see [Archiving findings](#).
- Choose **Resolved** to view only findings that were generated by the analyzer that have been resolved. When you remediate the issue that generated the finding, the finding status is changed to **Resolved**.

Important

Resolved findings are deleted 90 days after the last update to the finding. Active and archived findings are not deleted unless you delete the analyzer that generated them.

- Choose **All** to view all findings with any status that were generated by the analyzer.

External access findings

Choose **External access** and then choose the external access analyzer from the **View analyzer** dropdown. The **Findings** page for external access analyzers displays the following details about the shared resource and policy statement that generated the finding:

Finding ID

The unique ID assigned to the finding. Choose the finding ID to display additional details about the resource and policy statement that generated the finding.

Resource

The type and partial name of the resource that has a policy applied to it that grants access to an external entity not within your zone of trust.

Resource owner account

This column is displayed only if you are using an organization as the zone of trust. The account in the organization that owns the resource reported in the finding.

External principal

The principal, not within your zone of trust, that the analyzed policy grants access to. Valid values include:

- **AWS account** – All principals in the listed AWS account with permissions from that account's administrator can access the resource.
- **Any principal** – All principals in any AWS account that meet the conditions included in the **Conditions** column have permission to access the resource. For example, if a VPC is listed, it means that any principal in any account that has permission to access the listed VPC can access the resource.
- **Canonical user** – All principals in the AWS account with the listed canonical user ID have permission to access the resource.
- **IAM role** – The listed IAM role has permission to access the resource.
- **IAM user** – The listed IAM user has permission to access the resource.

Condition

The condition from the policy statement that grants the access. For example, if the **Condition** field includes **Source VPC**, it means that the resource is shared with a principal that has access to the VPC listed. Conditions can be global or service-specific. [Global condition keys](#) have the `aws :` prefix.

Shared through

The **Shared through** field indicates how the access that generated the finding is granted. Valid values include:

- **Bucket policy** – The bucket policy attached to the Amazon S3 bucket.
- **Access control list** – The access control list (ACL) attached to the Amazon S3 bucket.
- **Access point** – An access point or multi-region access point associated with the Amazon S3 bucket. The ARN of the access point is displayed in the **Findings** details.

Access level

The level of access granted to the external entity by the actions in the resource-based policy. View the details of the finding for more information. Access level values include the following:

- **List** – Permission to list resources within the service to determine whether an object exists. Actions with this level of access can list objects but cannot see the contents of a resource.
- **Read** – Permission to read but not edit the contents and attributes of resources in the service.
- **Write** – Permission to create, delete, or modify resources in the service.
- **Permissions** – Permission to grant or modify resource permissions in the service.
- **Tagging** – Permission to perform actions that only change the state of resource tags.

Updated

A timestamp for the most recent update to the finding status, or the time and date the finding was generated if no updates have been made.

Note

It may take up to 30 minutes after a policy is modified for IAM Access Analyzer to again analyze the resource and then update the finding.

Status

The status of the finding, one of **Active**, **Archived**, or **Resolved**.

Unused access findings

IAM Access Analyzer charges for unused access analysis based on the number of IAM roles and users analyzed per month. For more details about pricing, see [IAM Access Analyzer pricing](#).

Choose **Unused access** and then choose the unused access analyzer from the **View analyzer** dropdown. The **Findings** page for unused access analyzers displays the following details about the IAM entity that generated the finding:

Finding ID

The unique ID assigned to the finding. Choose the finding ID to display additional details about the IAM entity that generated the finding.

Finding type

The type of unused access finding: **Unused access key**, **Unused password**, **Unused permission**, or **Unused role**.

IAM entity

The IAM entity reported in the finding. This can be an IAM user or role.

AWS account ID

This column is displayed only if you set up the analyzer for all AWS accounts in the organization. The AWS account in the organization that owns the IAM entity reported in the finding.

Last updated

The last time that the IAM entity reported in the finding was updated, or when the entity was created if no updates have been made.

Status

The status of the finding (**Active**, **Archived**, or **Resolved**).

Filtering findings

The default filtering for a findings page is to display all findings. To view active findings, choose the **Active** status from the **Status** dropdown. To view archived findings, choose the **Archived** status from the **Status** dropdown. When you first start using IAM Access Analyzer, there are no archived findings.

Use filters to display only the findings that meet the specified property criteria. To create a filter, select the property to filter on, then choose whether the property equals or contains a value, then enter or choose a property value to filter on. For example, to create a filter that displays only findings for a specific AWS account, choose **AWS Account** for the property, then choose **AWS Account =**, then enter the account number for the AWS account that you want to view findings for.

For a list of filter keys that you can use to create or update an archive rule, see [IAM Access Analyzer filter keys](#).

Filtering external access findings

To filter external access findings

1. Choose **External access** and then choose the analyzer in the **View analyzer** dropdown.

2. Choose the search box to display a list of available properties.
3. Choose the property to use to filter the findings displayed.
4. Choose the value to match for the property. Only findings with that value in the finding are displayed.

For example, choose **Resource** as the property, then choose **Resource :**, then type part or all of the name of a bucket, then press Enter. Only findings for the bucket that matches the filter criteria are displayed. To create a filter that displays only findings for resources that allow public access, you can choose the **Public access** property, then choose **Public access =**, then choose **Public access = true**.

You can add additional properties to further filter the findings displayed. When you add additional properties, only findings that match all conditions in the filter are displayed. Defining a filter to display findings that match one property OR another property is not supported. Choose **Clear filters** to clear any filters you have defined and display all of the findings with the specified status for your analyzer.

Some fields are displayed only when you are viewing findings for an analyzer with an organization as its zone of trust.

The following properties are available for defining filters:

- **Public access** – To filter by findings for resources that allow public access, filter by **Public access** then choose **Public access: true**.
- **Resource** – To filter by resource, type all or part of the name of the resource.
- **Resource Type** – To filter by resource type, choose the type from the list displayed.
- **Resource Owner Account** – Use this property to filter by the account in the organization that owns the resource reported in the finding.
- **AWS Account** – Use this property to filter by AWS account that is granted access in the **Principal** section of a policy statement. To filter by AWS account, type all or part of the 12-digit AWS account ID, or all or part of the full account ARN of the external AWS user or role that has access to resources in the current account.
- **Canonical User** – To filter by canonical user, type the canonical user ID as defined for Amazon S3 buckets. To learn more, see [AWS Account Identifiers](#).
- **Federated User** – To filter by federated user, type all or part of the ARN of the federated identity. To learn more, see [Identity Providers and Federation](#).

- **Finding ID** – To filter by finding ID, type all or part of the finding ID.
- **Principal ARN** – Use this property to filter on the ARN of the principal (IAM user, role, or group) used in an `aws:PrincipalArn` condition key. To filter by Principal ARN, type all or part of the ARN of the IAM user, role, or group from an external AWS account reported in a finding.
- **Principal OrgID** – To filter by Principal OrgID, type all or part of the organization ID associated with the external principals that belong to the AWS organization specified as a condition in the finding. To learn more, see [AWS global condition context keys](#).
- **Principal OrgPaths** – To filter by Principal OrgPaths, type all or part of the ID for the AWS organization or organizational unit (OU) that allows access to all external principals that are account members of the specified organization or OU as a condition in the policy. To learn more, see [AWS global condition context keys](#).
- **Source Account** – To filter on Source Account, type all or part of the AWS account ID associated with the resources, as used in some cross-service permissions in AWS. To learn more, see [AWS global condition context keys](#).
- **Source ARN** – To filter by Source ARN, type all or part of the ARN specified as a condition in the finding. To learn more, see [AWS global condition context keys](#).
- **Source IP** – To filter by Source IP, type all or part of the IP address that allows external entities access to resources in the current account when using the specified IP address. To learn more, see [AWS global condition context keys](#).
- **Source VPC** – To filter by Source VPC, type all or part of the VPC ID that allows external entities access to resources in the current account when using the specified VPC. To learn more, see [AWS global condition context keys](#).
- **Source OrgID** – To filter by Source OrgID, type all or part of the organization ID associated with the resources, as used in some cross-service permissions in AWS. To learn more, see [AWS global condition context keys](#).
- **Source OrgPaths** – To filter by Source OrgPaths, type all or part of the organizational unit (OU) associated with the resources, as used in some cross-service permission in AWS. To learn more, see [AWS global condition context keys](#).
- **User ID** – To filter by User ID, type all or part of the user ID of the IAM user from an external AWS account who is allowed access to resource in the current account. To learn more, see [AWS global condition context keys](#).
- **KMS Key ID** – To filter by KMS key ID, type all or part of the key ID for the KMS key specified as a condition for AWS KMS-encrypted Amazon S3 object access in your current account.

- **Google Audience** – To filter by Google Audience, type all or part of the Google application ID specified as a condition for IAM role access in your current account. To learn more, see [IAM and AWS STS condition context keys](#).
- **Cognito Audience** – To filter by Amazon Cognito audience, type all or part of the Amazon Cognito identity pool ID specified as a condition for IAM role access in your current account. To learn more, see [IAM and AWS STS condition context keys](#).
- **Caller Account** – The AWS account ID of the account that owns or contains the calling entity, such as an IAM role, user, or account root user. This is used by services calling AWS KMS. To filter by caller account, type all or part of the AWS account ID.
- **Facebook App ID** – To filter by Facebook App ID, type all or part of the Facebook application ID (or site ID) specified as a condition to allow Login with Facebook federation access to an IAM role in your current account. To learn more, see the **id** section in [IAM and AWS STS condition context keys](#).
- **Amazon App ID** – To filter by Amazon App ID, type all or part of the Amazon application ID (or site ID) specified as a condition to allow Login with Amazon federation access to an IAM role in your current account. To learn more, see the **id** section in [IAM and AWS STS condition context keys](#).
- **Lambda Event Source Token** – To filter on Lambda Event Source Token passed in with Alexa integrations, type all or part of the token string.

Filtering unused access findings

To filter unused access findings

1. Choose **Unused access** and then choose the analyzer in the **View analyzer** dropdown.
2. Choose the search box to display a list of available properties.
3. Choose the property to use to filter the findings displayed.
4. Choose the value to match for the property. Only findings with that value in the finding are displayed.

For example, choose **Findings type** as the property, then choose **Findings type =**, then choose **Findings type = UnusedIAMRole**, Only findings with a type of **UnusedIAMRole** are displayed.

You can add additional properties to further filter the findings displayed. When you add additional properties, only findings that match all conditions in the filter are displayed. Defining a filter to

display findings that match one property OR another property is not supported. Choose **Clear filters** to clear any filters you have defined and display all of the findings with the specified status for your analyzer.

The following fields are displayed only when you are viewing findings for an analyzer that is monitoring unused access:

- **Findings type** – To filter by finding type, filter by **Findings type** and then choose the type of finding.
- **Resource** – To filter by resource, type all or part of the name of the resource.
- **Resource Type** – To filter by resource type, choose the type from the list displayed.
- **Resource Owner Account** – Use this property to filter by the account in the organization that owns the resource reported in the finding.
- **Finding id** – To filter by finding ID, type all or part of the finding ID.

Archiving findings

When you get a finding for access to a resource that is intentional, you can archive the findings. For example, an external access finding for an IAM role that is used by multiple users for approved workflows or an unused access finding for an access key that may still be necessary. When you archive a finding, it is cleared from active findings list. Archived findings aren't deleted. You can filter the **Findings** page to display your archived findings, and unarchive them at any time.

To archive findings from the Findings page

1. Select the check box next to one or more findings to archive.
2. Choose **Actions** and then choose **Archive**.

A confirmation is displayed at the top of the screen.

To archive findings from the Findings Details page

1. Choose the **Finding ID** for the finding to archive.
2. Choose **Archive**.

A confirmation is displayed at the top of the screen.

To unarchive findings, repeat the preceding steps, but choose **Unarchive** instead of **Archive**. When you unarchive a finding, the status is set to Active.

Resolving findings

External access findings

To resolve external access findings generated from access that you did not intend to allow, modify the policy statement to remove the permissions that allow access to the identified resource. For example, for findings on Amazon S3 buckets, use the Amazon S3 console to configure the permissions on the bucket. For IAM roles, use the IAM console to [modify the trust policy](#) for the listed IAM role. Use the console for the other supported resources to modify the policy statements that resulted in a generated finding.

After you make a change to resolve an external access finding, such as modifying a policy applied to an IAM role, IAM Access Analyzer scans the resource again. If the resource is no longer shared outside of your zone of trust, the status of the finding is changed to Resolved. The finding is no longer displayed in the active findings list, and instead is displayed in the resolved findings list.

Note

This does not apply to **Error** findings. When IAM Access Analyzer is not able to analyze a resource, it generates an error finding. If you resolve the issue that prevented IAM Access Analyzer from analyzing the resource, the error finding is removed completely rather than changing to a resolved finding.

If the changes you made resulted in the resource being shared outside of your zone of trust, but in a different way, such as with a different principal or for a different permission, IAM Access Analyzer generates a new Active finding.

Note

It may take up to 30 minutes after a policy is modified for IAM Access Analyzer to again analyze the resource and then update the finding. Resolved findings are deleted 90 days after the last update to the finding status.

Unused access findings

To resolve unused access findings, use the IAM console to remove the unused access key, password, permission, or role. For more information, see the following resources:

- For more information about deleting an access key, see [Managing access keys \(console\)](#).
- For more information about deleting an IAM user password, see [Creating, changing, or deleting an IAM user password \(console\)](#).
- For more information about changing permissions for an IAM user, see [Changing permissions for a user \(console\)](#).
- For more information about deleting an IAM role, see [Deleting an IAM role \(console\)](#).

After you make a change to resolve an unused access finding, the status of the finding is changed to **Resolved** the next time the unused access analyzer runs. The finding is no longer displayed in the active findings list, and instead is displayed in the resolved findings list. If you make a change that only partially addresses an unused access finding, the existing finding is changed to **Resolved** but a new finding is generated. For example, you remove only some of the unused permissions in a finding, but not all of them.

IAM Access Analyzer charges for unused access analysis based on the number of IAM roles and users analyzed per month. For more details about pricing, see [IAM Access Analyzer pricing](#).

IAM Access Analyzer resource types for external access

For external access analyzers, IAM Access Analyzer analyzes the resource-based policies that are applied to AWS resources in the Region where you enabled IAM Access Analyzer. It only analyzes resource-based policies. Review the information about each resource for details about how IAM Access Analyzer generates findings for each resource type.

Note

The supported resource types listed are for external access analyzers. Unused access analyzers only support IAM users and roles. For more information, see [Working with findings](#).

Supported resource types for external access:

- [Amazon Simple Storage Service buckets](#)

- [Amazon Simple Storage Service directory buckets](#)
- [AWS Identity and Access Management roles](#)
- [AWS Key Management Service keys](#)
- [AWS Lambda functions and layers](#)
- [Amazon Simple Queue Service queues](#)
- [AWS Secrets Manager secrets](#)
- [Amazon Simple Notification Service topics](#)
- [Amazon Elastic Block Store volume snapshots](#)
- [Amazon Relational Database Service DB snapshots](#)
- [Amazon Relational Database Service DB cluster snapshots](#)
- [Amazon Elastic Container Registry repositories](#)
- [Amazon Elastic File System file systems](#)

Amazon Simple Storage Service buckets

When IAM Access Analyzer analyzes Amazon S3 buckets, it generates a finding when an Amazon S3 bucket policy, ACL, or access point, including a multi-Region access point, applied to a bucket grants access to an external entity. An external entity is a principal or other entity that you can use to [create a filter](#) that isn't within your zone of trust. For example, if a bucket policy grants access to another account or allows public access, IAM Access Analyzer generates a finding. However, if you enable [Block Public Access](#) on your bucket, you can block access at the account level or the bucket level.

Note

IAM Access Analyzer doesn't analyze the access point policy attached to cross-account access points because the access point and its policy are outside the analyzer account. IAM Access Analyzer generates a public finding when a bucket delegates access to a cross-account access point and Block Public Access is not enabled on the bucket or account. When you enable Block Public Access, the public finding is resolved and IAM Access Analyzer generates a cross-account finding for the cross-account access point.

Amazon S3 *Block Public Access* settings override the bucket policies applied to the bucket. The settings also override the access point policies applied to the bucket's access points. IAM Access

Analyzer analyzes Block Public Access settings at the bucket level whenever a policy changes. However, it evaluates the Block Public Access settings at the account level only once every 6 hours. This means that IAM Access Analyzer might not generate or resolve a finding for public access to a bucket for up to 6 hours. For example, if you have a bucket policy that allows public access, IAM Access Analyzer generates a finding for that access. If you then enable Block Public Access to block all public access to the bucket at the account level, IAM Access Analyzer doesn't resolve the finding for the bucket policy for up to 6 hours, even though all public access to the bucket is blocked. Resolution of public findings for cross-account access points can also take up to 6 hours once you enable Block Public Access at the account level.

For a multi-Region access point, IAM Access Analyzer uses an established policy for generating findings. IAM Access Analyzer evaluates changes to multi-Region access points once every 6 hours. This means IAM Access Analyzer doesn't generate or resolve a finding for up to 6 hours, even if you create or delete a multi-Region access point, or update the policy for it.

Amazon Simple Storage Service directory buckets

Amazon S3 directory buckets use the Amazon S3 Express One storage class, which is recommended for performance-critical workloads or applications. For Amazon S3 directory buckets, IAM Access Analyzer analyzes the directory bucket policy, including condition statements in a policy, that allow an external entity to access a directory bucket. For more information about Amazon S3 directory buckets, see [Directory buckets](#) in the Amazon Simple Storage Service User Guide.

AWS Identity and Access Management roles

For IAM roles, IAM Access Analyzer analyzes [trust policies](#). In a role trust policy, you define the principals that you trust to assume the role. A role trust policy is a required resource-based policy that is attached to a role in IAM. IAM Access Analyzer generates findings for roles within the zone of trust that can be accessed by an external entity that is outside your zone of trust.

Note

An IAM role is a global resource. If a role trust policy grants access to an external entity, IAM Access Analyzer generates a finding in each enabled Region.

AWS Key Management Service keys

For AWS KMS keys, IAM Access Analyzer analyzes the key policies and grants applied to a key. IAM Access Analyzer generates a finding if a key policy or grant allows an external entity to access the key. For example, if you use the [kms:CallerAccount](#) condition key in a policy statement to allow access to all users in a specific AWS account, and you specify an account other than the current account (the zone of trust for the current analyzer), IAM Access Analyzer generates a finding. To learn more about AWS KMS condition keys in IAM policy statements, see [AWS KMS Condition Keys](#).

When IAM Access Analyzer analyzes a KMS key it reads key metadata, such as the key policy and list of grants. If the key policy doesn't allow the IAM Access Analyzer role to read the key metadata, an Access Denied error finding is generated. For example, if the following example policy statement is the only policy applied to a key, it results in an Access denied error finding in IAM Access Analyzer.

```
{
  "Sid": "Allow access for Key Administrators",
  "Effect": "Allow",
  "Principal": {
    "AWS": "arn:aws:iam::111122223333:role/Admin"
  },
  "Action": "kms:*",
  "Resource": "*"
}
```

Because this statement allows only the role named *Admin* from the AWS account 111122223333 to access the key, an Access Denied error finding is generated because IAM Access Analyzer isn't able to fully analyze the key. An error finding is displayed in red text in the **Findings** table. The finding looks similar to the following.

```
{
  "error": "ACCESS_DENIED",
  "id": "12345678-1234-abcd-dcba-111122223333",
  "analyzedAt": "2019-09-16T14:24:33.352Z",
  "resource": "arn:aws:kms:us-west-2:1234567890:key/1a2b3c4d-5e6f-7a8b-9c0d-1a2b3c4d5e6f7g8a",
  "resourceType": "AWS::KMS::Key",
  "status": "ACTIVE",
  "updatedAt": "2019-09-16T14:24:33.352Z"
}
```

When you create a KMS key, the permissions granted to access the key depend on how you create the key. If you receive an Access Denied error finding for a key resource, apply the following policy statement to the key resource to grant IAM Access Analyzer permission to access the key.

```
{
  "Sid": "Allow IAM Access Analyzer access to key metadata",
  "Effect": "Allow",
  "Principal": {
    "AWS": "arn:aws:iam::111122223333:role/aws-service-role/access-
  analyzer.amazonaws.com/AWSServiceRoleForAccessAnalyzer"
  },
  "Action": [
    "kms:DescribeKey",
    "kms:GetKeyPolicy",
    "kms:List*"
  ],
  "Resource": "*"
},
```

After you receive an Access Denied finding for a KMS key resource, and then resolve the finding by updating the key policy, the finding is updated to a status of Resolved. If there are policy statements or key grants that grant permission to the key to an external entity, you might see additional findings for the key resource.

AWS Lambda functions and layers

For AWS Lambda functions, IAM Access Analyzer analyzes policies, including condition statements in a policy, that grant access to the function to an external entity. IAM Access Analyzer also analyzes permissions granted when using the [AddPermission](#) operation of the AWS Lambda API with an EventSourceToken.

Amazon Simple Queue Service queues

For Amazon SQS queues, IAM Access Analyzer analyzes policies, including condition statements in a policy, that allow an external entity access to a queue.

AWS Secrets Manager secrets

For AWS Secrets Manager secrets, IAM Access Analyzer analyzes policies, including condition statements in a policy, that allow an external entity to access a secret.

Amazon Simple Notification Service topics

IAM Access Analyzer analyzes resource-based policies attached to Amazon SNS topics, including condition statements in the policies that allow external access to a topic. You can allow external accounts to perform Amazon SNS actions such as subscribing to and publishing topics through a resource-based policy. An Amazon SNS topic is externally accessible if principals from an account outside of your zone of trust can perform operations on the topic. When you choose Everyone in your policy when creating an Amazon SNS topic, you make the topic accessible to the public. AddPermission is another way to add a resource-based policy to an Amazon SNS topic that allows external access.

Amazon Elastic Block Store volume snapshots

Amazon Elastic Block Store volume snapshots do not have resource-based policies. A snapshot is shared through Amazon EBS sharing permissions. For Amazon EBS volume snapshots, IAM Access Analyzer analyzes access control lists that allow an external entity access to a snapshot. An Amazon EBS volume snapshot can be shared with external accounts when encrypted. An unencrypted volume snapshot can be shared with external accounts and grant public access. Sharing settings are in the CreateVolumePermissions attribute of the snapshot. When customers preview external access of an Amazon EBS snapshot, they can specify the encryption key as an indicator that the snapshot is encrypted, similar to how IAM Access Analyzer preview handles Secrets Manager secrets.

Amazon Relational Database Service DB snapshots

Amazon RDS DB snapshots do not have resource-based policies. A DB snapshot is shared through Amazon RDS database permissions, and only manual DB snapshots can be shared. For Amazon RDS DB snapshots, IAM Access Analyzer analyzes access control lists that allow an external entity access to a snapshot. Unencrypted DB snapshots can be public. Encrypted DB snapshots cannot be shared publicly, but they can be shared with up to 20 other accounts. For more information, see [Creating a DB snapshot](#). IAM Access Analyzer considers the ability to export a database manual snapshot (for example, to an Amazon S3 bucket) as trusted access.

Note

IAM Access Analyzer does not identify public or cross-account access configured directly on the database itself. IAM Access Analyzer only identifies findings for public or cross-account access configured on the Amazon RDS DB snapshot.

Amazon Relational Database Service DB cluster snapshots

Amazon RDS DB cluster snapshots do not have resource-based policies. A snapshot is shared through Amazon RDS DB cluster permissions. For Amazon RDS DB cluster snapshots, IAM Access Analyzer analyzes access control lists that allow an external entity access to a snapshot. Unencrypted cluster snapshots can be public. Encrypted cluster snapshots cannot be shared publicly. Both unencrypted and encrypted cluster snapshots can be shared with up to 20 other accounts. For more information, see [Creating a DB cluster snapshot](#). IAM Access Analyzer considers the ability to export a DB cluster snapshot (for example, to an Amazon S3 bucket) as trusted access.

Note

IAM Access Analyzer findings do not include monitoring of any share of Amazon RDS DB clusters and clones with another AWS account or organization using AWS Resource Access Manager. IAM Access Analyzer only identifies findings for public or cross-account access configured on the Amazon RDS DB cluster snapshot.

Amazon Elastic Container Registry repositories

For Amazon ECR repositories, IAM Access Analyzer analyzes resource-based policies, including condition statements in a policy, that allow an external entity access to a repository (similar to other resource types like Amazon SNS topics and Amazon EFS file systems). For Amazon ECR repositories, a principal must have permission to `ecr:GetAuthorizationToken` through an identity-based policy to be considered externally available.

Amazon Elastic File System file systems

For Amazon EFS file systems, IAM Access Analyzer analyzes policies, including condition statements in a policy, that allow an external entity access to a file system. An Amazon EFS file system is externally accessible if principals from an account outside of your zone of trust can perform operations on that file system. Access is defined by a file system policy that uses IAM, and by how the file system is mounted. For example, mounting your Amazon EFS file system in another account is considered externally accessible, unless that account is in your organization and you have defined the organization as your zone of trust. If you are mounting the file system from a virtual private cloud with a public subnet, the file system is externally accessible. When you use Amazon EFS with AWS Transfer Family, file system access requests received from a Transfer Family

server that is owned by a different account than the file system are blocked if the file system allows public access.

Settings for IAM Access Analyzer

If you're configuring AWS Identity and Access Management Access Analyzer in your AWS Organizations management account, you can add a member account in the organization as the delegated administrator to manage IAM Access Analyzer for your organization. The delegated administrator has permissions to create and manage analyzers within the organization. Only the management account can add a delegated administrator.

Delegated administrator for IAM Access Analyzer

The delegated administrator for IAM Access Analyzer is a member account within the organization that has permissions to create and manage analyzers that analyze access across the organization. Only the management account can add, remove, or change a delegated administrator.

If you add a delegated administrator, you can later change to a different account for the delegated administrator. When you do, the former delegated administrator account loses permission to all analyzers that were created using that account to analyze access across the organization. These analyzers move to a disabled state and no longer generate new or update existing findings. The existing findings for these analyzers are also no longer accessible. You can access them again in the future by configuring the account as the delegated administrator. If you know that you won't use the same account as a delegated administrator, consider deleting the analyzers before changing the delegated administrator. This deletes all findings generated. When the new delegated administrator creates new analyzers, new instances of the same findings are generated. You don't lose any findings, they just get generated for the new analyzer in a different account. And you can continue to access findings for the organization using the organization management account, which also has administrator permissions. The new delegated administrator must create new analyzers for IAM Access Analyzer to start monitoring resources in your organization.

If the delegated administrator leaves the AWS organization, the delegated administration privileges are removed from the account. All analyzers in the account with the organization as the zone of trust move to a disabled state. The existing findings for these analyzers are also no longer accessible.

The first time that you configure analyzers in the management account, you can choose **Add delegated administrator** on the **Analyzer settings** page in the IAM Access Analyzer console.

Note

IAM Access Analyzer charges for unused access analyzers based on the number of IAM roles and users analyzed per analyzer per month. If you create an unused access analyzer in the management account and the delegated administrator account, you will be charged for both unused access analyzers. For more details about pricing, see [IAM Access Analyzer pricing](#).

To add a delegated administrator using the console

1. Log in to the AWS console using the management account for your organization.
2. Open the IAM console at <https://console.aws.amazon.com/iam/>.
3. Under **Access Analyzer**, choose **Analyzer settings**.
4. Choose **Add delegated administrator**.
5. In the **Delegated administrator** field, enter the AWS account number of an organization member account to make the delegated administrator.

The account must be a member of your organization.

6. Choose **Save changes**.

To add a delegated administrator using the AWS CLI or the AWS SDKs

When you create an analyzer to analyze access across the organization in a delegated administrator account using the AWS CLI, AWS API (using the AWS SDKs) or AWS CloudFormation, you must use AWS Organizations APIs to enable service access for IAM Access Analyzer and register the member account as a delegated administrator.

1. Enable trusted service access for IAM Access Analyzer in AWS Organizations. See [How to Enable or Disable Trusted Access](#) in the AWS Organizations User Guide.
2. Register a valid member account of your AWS organization as a delegated administrator using the AWS Organizations [RegisterDelegatedAdministrator](#) API operation or the `register-delegated-administrator` AWS CLI command.

After you change the delegated administrator, the new administrator must create analyzers to start monitoring access to the resources in your organization.

Deleting analyzers

You can delete existing external and unused access analyzers from the **Analyzer settings** page. When you delete an analyzer, the resources specified in the analyzer are no longer monitored and no new findings are generated. All findings that were generated by the analyzer are deleted.

For findings that are deleted because the analyzer that generated them is deleted, the event is sent to EventBridge in the next two days after the analyzer was deleted. It can take up to 90 days after the analyzer was deleted for the Security Hub findings to be deleted.

To delete an analyzer

1. Open the IAM console at <https://console.aws.amazon.com/iam/>.
2. Under **Access Analyzer**, choose **Analyzer settings**.
3. Select the analyzer to delete and then choose **Delete**.
4. Type **delete** in the confirmation text box and then choose **Delete**.

Archive rules

Archive rules automatically archive new findings that meet the criteria you define when you create the rule. You can also apply archive rules retroactively to archive existing findings that meet the archive rule criteria. For example, you can create an archive rule to automatically archive any findings for a specific Amazon S3 bucket that you regularly grant access to. Or if you grant access to multiple resources to a specific principal, you can create a rule that automatically archives any new finding generated for access granted to that principal. This lets you focus only on active findings that may indicate a security risk.

When you create an archive rule, only new findings that match the rule criteria are automatically archived. Existing findings are not automatically archived. When you create a rule, you can include up to 20 values per criterion in the rule. For a list of filter keys that you can use to create or update an archive rule, see [IAM Access Analyzer filter keys](#).

Note

When you create or edit an archive rule, IAM Access Analyzer does not validate the values you include in the filter for the rule. For example, if you add a rule to match an AWS

account, IAM Access Analyzer accepts any value in the field, even if it is not a valid AWS account number.

To create an archive rule

1. Open the IAM console at <https://console.aws.amazon.com/iam/>.
2. Choose **Access analyzer**, then choose **Analyzer settings**.
3. In the **Analyzers** section, choose the analyzer for which you want to create an archive rule.
4. On the **Archive rules** tab, choose **Create archive rule**.
5. Enter a name for the rule if you want to change the default name.
6. In the **Rule** section, under **Criteria**, select a property to match for the rule.
7. Choose an condition for the property value, such as **Contains**, **Is**, or **Not Equals**.

The operators available depend on the property you choose.

8. Optionally, add additional values for the property, or add additional criteria for the rule. For external access findings, to ensure that your rule won't archive new findings for public access, you can also include the criterion **Public access** and set it to **false**.

To add another value for a criterion, choose **Add another value**. To add another criterion for the rule, choose **Add criterion**.

9. When you finish adding criteria and values, choose **Create rule** to apply the rule to new findings only. Choose **Create and archive active findings** to archive new and existing findings based on the rule criteria. In the **Results** section, you can review the list of active findings the archive rule applies to.

For example, to create a rule for external access findings that automatically archives any findings for Amazon S3 buckets: choose **Resource type**, and then choose **Is** for the condition. Next choose **S3 bucket** from the **Value** list.

To create a rule for unused access findings that automatically archives any finding for a particular account: choose **Resource Owner Account**, and then choose **Equals** for the condition. Type the AWS account ID in the **Value** text box.

Continue to define criteria to customize the rule as appropriate for your environment, and then choose **Create rule**.

If you are create a new rule and add multiple criteria, you can remove a single criterion from the rule by choosing **Remove this criterion**. You can remove a value added for a criterion by choosing **Remove value**.

To edit an archive rule

1. Choose name of the rule to edit in the **Name** column.

You can edit only one archive rule at a time.

2. Add new criteria or remove the existing criteria and values for each criterion.
3. Choose **Save changes** to apply the rule to new findings only. Choose **Save and archive active findings** to archive new and existing findings based on the rule criteria.

To delete an archive rule

1. Select the check box for the rules that you want to delete.
2. Choose **Delete**.
3. Type **delete** in the **Delete archive rule** confirmation dialog, and then choose **Delete**.

The rules are deleted only from the analyzer in the current Region. You must delete archive rules separately for each analyzer that you created in other Regions.

Monitoring AWS Identity and Access Management Access Analyzer with Amazon EventBridge

Use the information in this topic to learn how to monitor IAM Access Analyzer findings and access previews with Amazon EventBridge. EventBridge is the new version of Amazon CloudWatch Events.

Findings events

IAM Access Analyzer sends an event to EventBridge for each generated finding, for a change to the status of an existing finding, and when a finding is deleted. To receive findings and notifications about findings, you must create an event rule in Amazon EventBridge. When you create an event rule, you can also specify a target action to trigger based on the rule. For example, you could create an event rule that triggers an Amazon SNS topic when an event for a new finding is received from IAM Access Analyzer.

Access preview events

IAM Access Analyzer sends an event to EventBridge for each access preview and change to its status. This includes an event when the access preview is first created (status `Creating`), when the access preview is complete (status `Completed`), or when the access preview creation failed (status `Failed`). To receive notifications about access previews, you must create an event rule in EventBridge. When you create an event rule, you can specify a target action to trigger based on the rule. For example, you could create an event rule that triggers an Amazon SNS topic when an event for a completed access preview is received from IAM Access Analyzer.

Event notification frequency

IAM Access Analyzer sends events for new findings and findings with status updates to EventBridge within about an hour from when the event occurs in your account. IAM Access Analyzer also sends events to EventBridge when a resolved finding is deleted because the retention period has expired. For findings that are deleted because the analyzer that generated them is deleted, the event is sent to EventBridge approximately 24 hours after the analyzer was deleted. When a finding is deleted, the finding status is not changed. Instead, the `isDeleted` attribute is set to `true`. IAM Access Analyzer also sends events for newly created access previews and access preview status changes to EventBridge.

Example external access findings events

The following is an example IAM Access Analyzer external access finding event sent to EventBridge. The `id` listed is the ID for the event in EventBridge. To learn more, see [Events and Event Patterns in EventBridge](#).

In the `detail` object, the values for the `accountId` and `region` attributes refer to the account and region reported in the finding. The `isDeleted` attribute indicates whether the event was from the finding being deleted. The `id` is the finding ID. The `resources` array is a singleton with the ARN of the analyzer that generated the finding.

```
{
  "account": "111122223333",
  "detail": {
    "accountId": "111122223333",
    "action": [
      "s3:GetObject"
    ],
  },
}
```

```

    "analyzedAt": "2019-11-21T01:22:22Z",
    "condition": {},
    "createdAt": "2019-11-20T04:58:50Z",
    "id": "22222222-dcba-4444-dcba-333333333333",
    "isDeleted": false,
    "isPublic": false,
    "principal": {
      "AWS": "999988887777"
    },
    "region": "us-west-2",
    "resource": "arn:aws:s3::my-bucket",
    "resourceType": "AWS::S3::Bucket",
    "status": "ACTIVE",
    "updatedAt": "2019-11-21T01:14:07Z",
    "version": "1.0"
  },
  "detail-type": "Access Analyzer Finding",
  "id": "11111111-2222-4444-aaaa-333333333333",

  "time": "2019-11-21T01:22:33Z",
  "version": "0"
}

```

IAM Access Analyzer also sends events to EventBridge for error findings. An error finding is a finding generated when IAM Access Analyzer can't analyze the resource. Events for error findings include an error attribute as shown in the following example.

```

{
  "account": "111122223333",
  "detail": {
    "accountId": "111122223333",
    "analyzedAt": "2019-11-21T01:22:22Z",

    "time": "2019-11-21T01:22:33Z",
    "version": "0"
}

```

Example unused access findings related events

The following is an example IAM Access Analyzer unused access finding event sent to EventBridge. The `id` listed is the ID for the event in EventBridge. To learn more, see [Events and Event Patterns in EventBridge](#).

In the `detail` object, the values for the `accountId` and `region` attributes refer to the account and region reported in the finding. The `isDeleted` attribute indicates whether the event was from the finding being deleted. The `id` is the finding ID.

```

{
    "version": "0",
    "id": "dc7ce3ee-114b-3243-e249-7f10f9054b21",
    "detail-type": "Unused Access Finding for IAM entities",
    "source": "aws.access-analyzer",
    "account": "123456789012",
    "time": "2023-09-29T17:31:40Z",
    "region": "us-west-2",
    "resources": [
        "arn:aws:access-analyzer:us-west-2:123456789012:analyzer/
integTestLongLivingAnalyzer-DO-NOT-DELETE"
    ],
    "detail": {
        "findingId": "b8ae0460-5d29-4922-b92a-ba956c986277",
        "resource": "arn:aws:iam::111122223333:role/FindingIntegTestFakeRole",
        "resourceType": "AWS::IAM::Role",
        "accountId": "111122223333",
        "createdAt": "2023-09-29T17:29:18.758Z",

```

```

    "updatedAt": "2023-09-29T17:29:18.758Z",
    "analyzedAt": "2023-09-29T17:29:18.758Z",
    "previousStatus": "",
    "status": "ACTIVE",
    "version": "62160bda-8e94-46d6-ac97-9670930d8ffb",
    "isDeleted": false,
    "findingType": "UnusedPermission",
    "numberOfUnusedServices": 0,
    "numberOfUnusedActions": 1
  }
}

```

IAM Access Analyzer also sends events to EventBridge for error findings. An error finding is a finding generated when IAM Access Analyzer can't analyze the resource. Events for error findings include an error attribute as shown in the following example.

```

{
  "version": "0",
  "id": "c2e7aa1a-4df7-7652-f33e-64113b8997d4",
  "detail-type": "Unused Access Finding for IAM entities",
  "source": "aws.access-analyzer",
  "account": "111122223333",
  "time": "2023-10-31T20:26:12Z",
  "region": "us-west-2",
  "resources": [
    "arn:aws:access-analyzer:us-west-2:111122223333:analyzer/ba811f91-
de99-41a4-97c0-7481898b53f2"
  ],
  "detail": {
    "findingId": "b01a34f2-e118-46c9-aef8-0d8526b495c7",
    "resource": "arn:aws:iam::123456789012:role/TestRole",
    "resourceType": "AWS::IAM::Role",
    "accountId": "444455556666",
    "createdAt": "2023-10-31T20:26:08.647Z",
    "updatedAt": "2023-10-31T20:26:09.245Z",
    "analyzedAt": "2023-10-31T20:26:08.525Z",
    "previousStatus": "",
    "status": "ACTIVE",
    "version": "7c7a72a2-7963-4c59-ac71-f0be597010f7",
    "isDeleted": false,
    "findingType": "UnusedIAMRole",
    "error": "INTERNAL_ERROR"
  }
}

```

```
}
```

Example access preview events

The following example shows data for the first event that is sent to EventBridge when you create an access preview. The `resources` array is a singleton with the ARN of the analyzer that the access preview is associated with. In the `detail` object, the `id` refers to the access preview ID and `configuredResources` refers to the resource for which the access preview was created. The status is `Creating` and refers to the access preview status. The `previousStatus` is not specified because the access preview was just created.

```
{
  "account": "111122223333",
  "detail": {
    "accessPreviewId": "aaaabbbb-cccc-dddd-eeee-ffffaaaabbbb",
    "configuredResources": [
      "arn:aws:s3:::example-bucket"
    ],
    "createdAt": "2020-02-20T00:00:00.00Z",
    "region": "us-west-2",
    "status": "CREATING",
    "version": "1.0"
  },
  "detail-type": "Access Preview State Change",
  "id": "aaaabbbb-2222-3333-4444-555566667777",
  "region": "us-west-2",
  "resources": [
    "arn:aws:access-analyzer:us-west-2:111122223333:analyzer/MyAnalyzer"
  ],
  "source": "aws.access-analyzer",
  "time": "2020-02-20T00:00:00.00Z",
  "version": "0"
}
```

The following example shows data for an event that is sent to EventBridge for an access preview with a status change from `Creating` to `Completed`. In the `detail` object, the `id` refers to the access preview ID. The `status` and `previousStatus` refer to the access preview status, where the previous status was `Creating` and the current status is `Completed`.

```
{
  "account": "111122223333",
```

```

"detail": {
  "accessPreviewId": "aaaabbbb-cccc-dddd-eeee-ffffaaaabbbb",
  "configuredResources": [
    "arn:aws:s3:::example-bucket"
  ],
  "createdAt": "2020-02-20T00:00:00.000Z",
  "previousStatus": "CREATING",
  "region": "us-west-2",
  "status": "COMPLETED",
  "version": "1.0"
},
"detail-type": "Access Preview State Change",
"id": "11112222-3333-4444-5555-666677778888",
"region": "us-west-2",
"resources": [
  "arn:aws:access-analyzer:us-west-2:111122223333:analyzer/MyAnalyzer"
],
"source": "aws.access-analyzer",
"time": "2020-02-20T00:00:00.00Z",
"version": "0"
}

```

The following example shows data for an event that is sent to EventBridge for an access preview with a status change from Creating to Failed. In the detail object, the id refers to the access preview ID. The status and previousStatus refer to the access preview status, where the previous status was Creating and the current status is Failed. The statusReason field provides the reason code indicating that the access preview failed due to an invalid resource configuration.

```

{
  "account": "111122223333",
  "detail": {
    "accessPreviewId": "aaaabbbb-cccc-dddd-eeee-ffffaaaabbbb",
    "configuredResources": [
      "arn:aws:s3:::example-bucket"
    ],
    "createdAt": "2020-02-20T00:00:00.00Z",
    "previousStatus": "CREATING",
    "region": "us-west-2",
    "status": "FAILED",
    "statusReason": {
      "code": "INVALID_CONFIGURATION"
    }
  }
}

```

```
    },
    "version": "1.0"
  },
  "detail-type": "Access Preview State Change",
  "id": "99998888-7777-6666-5555-444433332222",
  "region": "us-west-2",
  "resources": [
    "arn:aws:access-analyzer:us-west-2:111122223333:analyzer/MyAnalyzer"
  ],
  "source": "aws.access-analyzer",
  "time": "2020-02-20T00:00:00.00Z",
  "version": "0"
}
```

Creating an event rule using the console

The following procedure describes how to create an event rule using the console.

1. Open the Amazon EventBridge console at <https://console.aws.amazon.com/events/>.
2. Using the following values, create an EventBridge rule that monitors finding events or access preview events:
 - For **Rule type**, choose **Rule with an event pattern**.
 - For **Event source**, choose **Other**.
 - For **Event pattern**, choose **Custom patterns (JSON editor)**, and paste one of the following event pattern examples into the text area:
 - To create a rule based on an external access or unused access findings event, use the following pattern example:

```
{
  "source": [
    "aws.access-analyzer"
  ],
  "detail-type": [
    "Access Analyzer Finding"
  ]
}
```

- To create a rule based only on an unused access findings event, use the following pattern example:

```
{
  "source": [
    "aws.access-analyzer"
  ],
  "detail-type": [
    "Unused Access Finding for IAM entities"
  ]
}
```

Note

You can't create a rule based only on an external access findings event.

- To create a rule based on an access preview event, use the following pattern example:

```
{
  "source": [
    "aws.access-analyzer"
  ],
  "detail-type": [
    "Access Preview State Change"
  ]
}
```

- For **Target types**, choose **AWS service**, and for **Select a target**, choose a target such as an Amazon SNS topic or AWS Lambda function. The target is triggered when an event is received that matches the event pattern defined in the rule.

To learn more about creating rules, see [Creating Amazon EventBridge rules that react to events](#) in the *Amazon EventBridge User Guide*.

Creating an event rule using the CLI

1. Use the following to create a rule for Amazon EventBridge using the AWS CLI. Replace the rule name *TestRule* with the name for your rule.

```
aws events put-rule --name TestRule --event-pattern "{\"source\": [\"aws.access-analyzer\"]}"
```

2. You can customize the rule to trigger target actions only for a subset of generated findings, such as findings with specific attributes. The following example demonstrates how to create a rule that triggers a target action only for findings with a status of Active.

```
aws events put-rule --name TestRule --event-pattern "{\"source\": [\"aws.access-analyzer\"], \"detail-type\": [\"Access Analyzer Finding\"], \"detail\": {\"status\": [\"ACTIVE\"]}}"
```

The following example demonstrates how to create a rule that triggers a target action only for access previews with a status from Creating to Completed.

```
aws events put-rule --name TestRule --event-pattern "{\"source\": [\"aws.access-analyzer\"], \"detail-type\": [\"Access Preview State Change\"], \"detail\": {\"status\": [\"COMPLETED\"]}}"
```

3. To define a Lambda function as a target for the rule you created, use the following example command. Replace the Region and the function name in the ARN as appropriate for your environment.

```
aws events put-targets --rule TestRule --targets Id=1,Arn=arn:aws:lambda:us-east-1:111122223333:function:MyFunction
```

4. Add the permissions required to invoke the rule target. The following example demonstrates how to grant permissions to a Lambda function, following the preceding examples.

```
aws lambda add-permission --function-name MyFunction --statement-id 1 --action 'lambda:InvokeFunction' --principal events.amazonaws.com
```

Integration with AWS Security Hub

[AWS Security Hub](#) provides you with a comprehensive view of your security state in AWS and helps you to check your environment against security industry standards and best practices. Security Hub collects security data from across AWS accounts, services, and supported third-party partner products and helps you to analyze your security trends and identify the highest priority security issues.

The AWS Identity and Access Management Access Analyzer integration with Security Hub enables you to send findings from IAM Access Analyzer to Security Hub. Security Hub can then include those findings in its analysis of your security posture.

Contents

- [How IAM Access Analyzer sends findings to Security Hub](#)
 - [Types of findings that IAM Access Analyzer sends](#)
 - [Latency for sending findings](#)
 - [Retrying when Security Hub is not available](#)
 - [Updating existing findings in Security Hub](#)
- [Viewing IAM Access Analyzer findings in Security Hub](#)
 - [Interpreting IAM Access Analyzer finding names in Security Hub](#)
- [Typical findings from IAM Access Analyzer](#)
- [Enabling and configuring the integration](#)
- [How to stop sending findings](#)

How IAM Access Analyzer sends findings to Security Hub

In Security Hub, security issues are tracked as findings. Some findings come from issues that are detected by other AWS services or by third-party partners. Security Hub also has a set of rules that it uses to detect security issues and generate findings.

Security Hub provides tools to manage findings from across all of these sources. You can view and filter lists of findings and view details for a finding. See [Viewing findings](#) in the *AWS Security Hub User Guide*. You can also track the status of an investigation into a finding. See [Taking action on findings](#) in the *AWS Security Hub User Guide*.

All findings in Security Hub use a standard JSON format called the AWS Security Finding Format (ASFF). The ASFF includes details about the source of the issue, the affected resources, and the current status of the finding. See [AWS Security Finding Format \(ASFF\)](#) in the *AWS Security Hub User Guide*.

AWS Identity and Access Management Access Analyzer is one of the AWS services that sends findings to Security Hub. For external access, IAM Access Analyzer generates a finding when it detects a policy statement that allows an external principal access to a [supported resource](#) in your organization or account. IAM Access Analyzer groups all of its findings for a resource and sends a

single finding to Security Hub. For unused access, IAM Access Analyzer generates a finding when it detects unused access granted to IAM users or roles. IAM Access Analyzer then sends these findings to Security Hub

Types of findings that IAM Access Analyzer sends

IAM Access Analyzer sends the findings to Security Hub using the [AWS Security Finding Format \(ASFF\)](#). In ASFF, the Types field provides the finding type. Findings from IAM Access Analyzer can have the following values for Types.

- External access findings – Effects/Data Exposure/External Access Granted
- External access findings – Software and Configuration Checks/AWS Security Best Practices/External Access Granted
- Unused access findings – Software and Configuration Checks/AWS Security Best Practices/Unused Permission
- Unused access findings – Software and Configuration Checks/AWS Security Best Practices/Unused IAM Role
- Unused access findings – Software and Configuration Checks/AWS Security Best Practices/Unused IAM User Password
- Unused access findings – Software and Configuration Checks/AWS Security Best Practices/Unused IAM User Access Key

Latency for sending findings

When IAM Access Analyzer creates a new finding, it is usually sent to Security Hub within 30 minutes. Rarely, and under certain conditions, IAM Access Analyzer is not notified that a policy was added or updated. For example, a change to Amazon S3 account-level block public access settings can take up to 12 hours. Also, if there is a delivery issue with AWS CloudTrail log delivery, the policy change does not trigger a rescan of the resource that was reported in the finding. When this happens, IAM Access Analyzer analyzes the new or updated policy during the next periodic scan.

Retrying when Security Hub is not available

If Security Hub is not available, IAM Access Analyzer retries sending the findings on a periodic basis.

Updating existing findings in Security Hub

After it sends a finding to Security Hub, AWS Identity and Access Management Access Analyzer sends updates to reflect additional observations of the finding activity to Security Hub. The updates are reflected within the same finding.

As IAM Access Analyzer groups external access findings per resource, the finding for a resource in Security Hub is active if at least one of the findings for the resource in IAM Access Analyzer is active. If all findings in IAM Access Analyzer for a resource are archived or resolved, then the Security Hub finding is archived. The Security Hub finding is updated when you change the policy access between public and cross-account access. This update can include changes to the type, title, description, and severity of the finding.

IAM Access Analyzer does not group unused access findings by resource, so if an unused access finding is resolved in IAM Access Analyzer, then the Security Hub finding is resolved. The Security Hub finding is updated when you update the IAM user or role that generated the unused access finding.

Viewing IAM Access Analyzer findings in Security Hub

To view your IAM Access Analyzer findings in Security Hub, choose **See findings** in the **AWS: IAM Access Analyzer** section of the summary page. Alternatively, you can choose **Findings** from the navigation panel. You can then filter the findings to display only AWS Identity and Access Management Access Analyzer findings by choosing the **Product name:** field with a value of **IAM Access Analyzer**.

Interpreting IAM Access Analyzer finding names in Security Hub

AWS Identity and Access Management Access Analyzer sends the findings to Security Hub using the AWS Security Finding Format (ASFF). In ASFF, the **Types** field provides the finding type. ASFF types use a different naming scheme than AWS Identity and Access Management Access Analyzer. The following table includes details about all of the ASFF types associated with AWS Identity and Access Management Access Analyzer findings as they appear in Security Hub.

ASFF finding type	Security Hub finding title	Description
Effects/Data Exposure/External Access Granted	<resource ARN> allows public access	A resource-based policy attached to the resource allows public access on

ASFF finding type	Security Hub finding title	Description
		the resource to all external principals.
Software and Configuration Checks/AWS Security Best Practices/External Access Granted	<resource ARN> allows cross-account access	A resource-based policy attached to the resource allows cross-account access to external principals outside the zone of trust for the analyzer.
Software and Configuration Checks/AWS Security Best Practices/Unused Permission	<resource ARN> contains unused permissions	A user or role contains unused service and action permissions.
Software and Configuration Checks/AWS Security Best Practices/Unused IAM Role	<resource ARN> contains unused IAM role	A user or role contains an unused IAM role.
Software and Configuration Checks/AWS Security Best Practices/Unused IAM User Password	<resource ARN> contains unused IAM user password	A user or role contains an unused IAM user password.
Software and Configuration Checks/AWS Security Best Practices/Unused IAM User Access Key	<resource ARN> contains unused IAM user access key	A user or role contains an unused IAM user access key.

Typical findings from IAM Access Analyzer

IAM Access Analyzer sends findings to Security Hub using the [AWS Security Finding Format \(ASFF\)](#).

Here is an example of a typical finding from IAM Access Analyzer for external access findings.

```
{
  "SchemaVersion": "2018-10-08",
  "Id": "arn:aws:access-analyzer:us-west-2:111122223333:analyzer/my-analyzer/arn:aws:s3:::my-bucket",
```

```
"ProductArn": "arn:aws:securityhub:us-west-2::product/aws/access-analyzer",

```

Enabling and configuring the integration

To use the integration with Security Hub, you must enable Security Hub. For information on how to enable Security Hub, see [Setting up Security Hub](#) in the *AWS Security Hub User Guide*.

When you enable both IAM Access Analyzer and Security Hub, the integration is enabled automatically. IAM Access Analyzer immediately begins to send findings to Security Hub.

How to stop sending findings

To stop sending findings to Security Hub, you can use either the Security Hub console or the API.

See [Disabling and enabling the flow of findings from an integration \(console\)](#) or [Disabling the flow of findings from an integration \(Security Hub API, AWS CLI\)](#) in the *AWS Security Hub User Guide*.

Logging IAM Access Analyzer API calls with AWS CloudTrail

IAM Access Analyzer is integrated with AWS CloudTrail, a service that provides a record of actions taken by a user, role, or an AWS service in IAM Access Analyzer. CloudTrail captures all API calls for IAM Access Analyzer as events. The calls captured include calls from the IAM Access Analyzer console and code calls to the IAM Access Analyzer API operations.

If you create a trail, you can enable continuous delivery of CloudTrail events to an Amazon S3 bucket, including events for IAM Access Analyzer. If you don't configure a trail, you can still view the most recent events in the CloudTrail console in **Event history**.

Using the information collected by CloudTrail, you can determine the request that was made to IAM Access Analyzer, the IP address from which the request was made, who made the request, when it was made, and additional details.

To learn more about CloudTrail, see the [AWS CloudTrail User Guide](#).

IAM Access Analyzer information in CloudTrail

CloudTrail is enabled on your AWS account when you create the account. When activity occurs in IAM Access Analyzer, that activity is recorded in a CloudTrail event along with other AWS service events in **Event history**. You can view, search, and download recent events in your AWS account. For more information, see [Viewing Events with CloudTrail Event History](#).

For an ongoing record of events in your AWS account, including events for IAM Access Analyzer, create a trail. A *trail* enables CloudTrail to deliver log files to an Amazon S3 bucket. By default, when you create a trail in the console, the trail applies to all AWS Regions. The trail logs events from all Regions in the AWS partition and delivers the log files to the Amazon S3 bucket that you specify. Additionally, you can configure other AWS services to further analyze and act upon the event data collected in CloudTrail logs. For more information, see the following:

- [Overview for Creating a Trail](#)
- [CloudTrail Supported Services and Integrations](#)
- [Configuring Amazon SNS Notifications for CloudTrail](#)
- [Receiving CloudTrail Log Files from Multiple Regions](#) and [Receiving CloudTrail Log Files from Multiple Accounts](#)

All IAM Access Analyzer actions are logged by CloudTrail and are documented in the [IAM Access Analyzer API Reference](#). For example, calls to the `CreateAnalyzer`, `CreateArchiveRule` and `ListFindings` actions generate entries in the CloudTrail log files.

Every event or log entry contains information about who generated the request. The identity information helps you determine the following:

- Whether the request was made with root or AWS Identity and Access Management (IAM) user credentials.
- Whether the request was made with temporary security credentials for a role or federated user.
- Whether the request was made by another AWS service.

For more information, see the [CloudTrail userIdentity Element](#).

Understanding IAM Access Analyzer log file entries

A trail is a configuration that enables delivery of events as log files to an Amazon S3 bucket that you specify. CloudTrail log files contain one or more log entries. An event represents a single request from any source and includes information about the requested action, the date and time of the action, request parameters, and so on. CloudTrail log files aren't an ordered stack trace of the public API calls, so they don't appear in any specific order.

The following example shows a CloudTrail log entry that demonstrates the `CreateAnalyzer` operation made by an assumed-role session named `Alice-tempcreds` on "June 14, 2021". The role session was issued by the role named `admin-tempcreds`.

```
{
  "eventVersion": "1.05",
  "userIdentity": {
    "type": "AssumedRole",
    "principalId": "AROAIIBKEVSQ6C2EXAMPLE:Alice-tempcreds",

IAM Access Analyzer filter keys

You can use the filter keys below to define an archive rule ([CreateArchiveRule](#)), update an archive rule ([UpdateArchiveRule](#)), retrieve a list of findings ([ListFindings](#) and [ListFindingsV2](#)), or retrieve a list of access preview findings for a resource

([ListAccessPreviewFindings](#)). There is no difference between using IAM API and AWS CloudFormation for configuring archive rules.

Criterion	Description	Type	Archive rule	List findings	List access preview findings
resource	The ARN uniquely identifying the resource that the external principal has access to. To learn more, see Amazon resource names (ARNs) .	String	 Yes	 Yes	 Yes
resourceType AWS::IAM::Role AWS::KMS::Key AWS::Lambda::Function AWS::Lambda::LayerVersion AWS::S3::Bucket AWS::S3Express::DirectoryBucket AWS::SQS::Queue	The type of resource that the external principal has access to.	String	 Yes	 Yes	 Yes

Criterion	Description	Type	Archive rule	List findings	List access preview findings
AWS::SecretsManager::Secret AWS::EFS::FileSystem AWS::EC2::Snapshot AWS::ECR::Repository AWS::RDS::DBSnapshot AWS::RDS::DBClusterSnapshot AWS::SNS::Topic					
resourceOwnerAccount	The 12 digit AWS account ID that owns the resource. To learn more, see AWS account identifiers .	String	 Yes	 Yes	 Yes
isPublic	Indicates whether the finding reports a resource that has a policy that allows public access.	Boolean	 Yes	 Yes	 Yes

Criterion	Description	Type	Archive rule	List findings	List access preview findings
findingType UnusedIAMRole UnusedIAMUserAccessKey UnusedIAMUserPassword UnusedPermission	The type of the finding. You can only filter by finding type for unused access findings.	String	 Yes	 Yes	 Yes
status ACTIVE ARCHIVED RESOLVED	The current status of the finding.	String	 No	 Yes	 Yes
error	Indicates the error reported for the finding.	String	 Yes	 Yes	 Yes

Criterion	Description	Type	Archive rule	List findings	List access preview findings
principal.AWS	The account granted access to the resource in the <code>Principal</code> field of the finding. Enter the 12-digit AWS account ID or the ARN of the external AWS user or role. To learn more, see AWS account identifiers .	String	 Yes	 Yes	 Yes
principal.Federated	The ARN of the federated identity that has access to the resource in the finding. To learn more, see Identity providers and federation	String	 Yes	 Yes	 Yes
condition.aws:PrincipalArn	The ARN of the principal (IAM user, role, or group) indicated as the condition for resource access. To learn more, see AWS global condition context keys .	String	 Yes	 Yes	 Yes
condition.aws:PrincipalOrgID	The organization identifier of the principal indicated as the condition for resource access. To learn more, see AWS global condition context keys .	String	 Yes	 Yes	 Yes

Criterion	Description	Type	Archive rule	List findings	List access preview findings
condition .aws:PrincipalOrgPaths	The organization or organizational unit (OU) ID indicated as the condition for resource access. To learn more, see AWS global condition context keys .	String	 Yes	 Yes	 Yes
condition .aws:SourceIp	The IP address that allows the principal access to the resource when using the specified IP address. To learn more, see AWS global condition context keys .	IP address	 Yes	 Yes	 Yes
condition .aws:SourceVpc	The VPC ID that allows the principal access to the resource when using the specified VPC. To learn more, see AWS global condition context keys .	String	 Yes	 Yes	 Yes
condition .aws:UserId	The user ID of the IAM user from an external account indicated as the condition for access to the resource. To learn more, see AWS global condition context keys .	String	 Yes	 Yes	 Yes

Criterion	Description	Type	Archive rule	List findings	List access preview findings
condition .cognito- identity. amazonaws .com:aud	The Amazon Cognito identity pool ID specified as a condition for IAM role access in the finding. To learn more, see IAM and AWS STS condition context keys .	String	 Yes	 Yes	 Yes
condition .graph.facebook.com: app_id	The Facebook application ID (or site ID) specified as a condition to allow Login with Facebook federation access to the IAM role in the finding. To learn more, see IAM and AWS STS condition context keys .	String	 Yes	 Yes	 Yes
condition .accounts.google.com: aud	The Google application ID specified as a condition for access to the IAM role. To learn more, see IAM and AWS STS condition context keys .	String	 Yes	 Yes	 Yes

Criterion	Description	Type	Archive rule	List findings	List access preview findings
condition.kms:CallerAccount	The AWS account ID that owns the calling entity (IAM user, role or account root user) used by services calling AWS KMS. To learn more, see Condition keys for AWS Key Management Service .	String	 Yes	 Yes	 Yes
condition.www.amazon.com:app_id	The Amazon application ID (or site ID) specified as a condition to allow Login with Amazon federation access to the role. To learn more, see	String	 Yes	 Yes	 Yes
id	The ID of the finding.	String	 No	 Yes	 Yes
changeType	Provides context on how the access preview finding compares to existing access identified in IAM Access Analyzer.	String	 No	 No	 Yes
existingFindingId	The existing ID of the finding in IAM Access Analyzer, provided only for existing findings in the access preview.	String	 No	 No	 Yes

Criterion	Description	Type	Archive rule	List findings	List access preview findings
existingFindingStatus	The existing status of the finding, provided only for existing findings in the access preview.	String	 No	 No	 Yes

Using service-linked roles for AWS Identity and Access Management Access Analyzer

AWS Identity and Access Management Access Analyzer uses an IAM [service-linked role](#). A service-linked role is a unique type of IAM role linked directly to IAM Access Analyzer. Service-linked roles are predefined by IAM Access Analyzer and include all the permissions that the feature requires to call other AWS services on your behalf.

A service-linked role makes setting up IAM Access Analyzer easier because you don't have to manually add the necessary permissions. IAM Access Analyzer defines the permissions of its service-linked roles, and unless defined otherwise, only IAM Access Analyzer can assume its roles. The defined permissions include the trust policy and the permissions policy, and that permissions policy cannot be attached to any other IAM entity.

For information about other services that support service-linked roles, see [AWS Services That Work with IAM](#) and look for the services that have **Yes** in the **Service-Linked Role** column. Choose a **Yes** with a link to view the service-linked role documentation for that service.

Service-linked role permissions for AWS Identity and Access Management Access Analyzer

AWS Identity and Access Management Access Analyzer uses the service-linked role named **AWSServiceRoleForAccessAnalyzer** – Allow Access Analyzer to analyze resource metadata for external access and to analyze activity to identify unused access.

The AWSServiceRoleForAccessAnalyzer service-linked role trusts the following services to assume the role:

- `access-analyzer.amazonaws.com`

The role permissions policy named [AccessAnalyzerServiceRolePolicy](#) allows IAM Access Analyzer to complete actions on specific resources.

You must configure permissions to allow an IAM entity (such as a user, group, or role) to create, edit, or delete a service-linked role. For more information, see [Service-Linked Role Permissions](#) in the *IAM User Guide*.

Creating a service-linked role for IAM Access Analyzer

You don't need to manually create a service-linked role. When you enable Access Analyzer in the AWS Management Console or the AWS API, IAM Access Analyzer creates the service-linked role for you. The same service-linked role is used in all Regions in which you enable IAM Access Analyzer. Both external access and unused access findings use the same service-linked role.

Note

IAM Access Analyzer is Regional. You must enable IAM Access Analyzer in each Region independently.

If you delete this service-linked role, IAM Access Analyzer recreates the role when you next create an analyzer.

You can also use the IAM console to create a service-linked role with the **Access Analyzer** use case. In the AWS CLI or the AWS API, create a service-linked role with the `access-analyzer.amazonaws.com` service name. For more information, see [Creating a Service-Linked Role](#) in the *IAM User Guide*. If you delete this service-linked role, you can use this same process to create the role again.

Editing a service-linked role for IAM Access Analyzer

IAM Access Analyzer does not allow you to edit the `AWSServiceRoleForAccessAnalyzer` service-linked role. After you create a service-linked role, you cannot change the name of the role because various entities might reference the role. However, you can edit the description of the role using IAM. For more information, see [Editing a Service-Linked Role](#) in the *IAM User Guide*.

Deleting a service-linked role for IAM Access Analyzer

If you no longer need to use a feature or service that requires a service-linked role, we recommend that you delete that role. That way you don't have an unused entity that isn't actively monitored or

maintained. However, you must clean up the resources for your service-linked role before you can manually delete it.

Note

If IAM Access Analyzer is using the role when you try to delete the resources, then the deletion might fail. If that happens, wait for a few minutes and try the operation again.

To delete IAM Access Analyzer resources used by the `AWSServiceRoleForAccessAnalyzer`

1. Open the IAM console at <https://console.aws.amazon.com/iam/>.
2. In the **Access reports** section, under **Access analyzer**, choose **Analyzers**.
3. Choose the check box on the top left above the list of analyzers in the **Analyzers** table to select all analyzers.
4. Choose **Delete**.
5. To confirm that you want to delete the analyzers, enter **delete**, and then choose **Delete**.

To manually delete the service-linked role using IAM

Use the IAM console, the AWS CLI, or the AWS API to delete the `AWSServiceRoleForAccessAnalyzer` service-linked role. For more information, see [Deleting a Service-Linked Role](#) in the *IAM User Guide*.

Supported Regions for IAM Access Analyzer service-linked roles

IAM Access Analyzer supports using service-linked roles in all of the Regions where the service is available. For more information, see [AWS Regions and Endpoints](#).

Preview access

In addition to helping you identify resources that are shared with an external entity, AWS IAM Access Analyzer also enables you to preview IAM Access Analyzer findings before deploying resource permissions so you can validate that your policy changes grant only intended public and cross-account access to your resource. This helps you start with intended external access to your resources.

You can preview and validate public and cross-account access to your Amazon S3 buckets in the [Amazon S3 console](#). You can also use IAM Access Analyzer APIs to preview public and cross-account

access for your Amazon S3 buckets, AWS KMS keys, IAM roles, Amazon SQS queues and Secrets Manager secrets by providing proposed permissions for your resource.

Topics

- [Previewing access in Amazon S3 console](#)
- [Previewing access with IAM Access Analyzer APIs](#)

Previewing access in Amazon S3 console

After you complete your bucket policy in the Amazon S3 console you have the option to preview public and cross-account access to your Amazon S3 bucket. You can validate that your policy changes grant only intended external access before you choose **Save changes**. This optional step enables you to preview AWS Identity and Access Management Access Analyzer findings for your bucket. You can validate whether the policy change introduces new findings or resolves existing findings for external access. You can skip this validation step and save your Amazon S3 bucket policy at any time.

To preview external access to your bucket, you must have an active account analyzer in your bucket's region with the account as the zone of trust. You must also have the permissions required to use IAM Access Analyzer and preview access. For more information on enabling IAM Access Analyzer and permissions required, see [Enabling IAM Access Analyzer](#).

To preview access to your Amazon S3 bucket when you create or edit your bucket policy

1. Once you finish creating or editing your bucket policy, ensure your policy is a valid Amazon S3 bucket policy. The policy ARN must match the bucket ARN and the [policy elements](#) must be valid.
2. Below the policy, under **Preview external access**, choose an active account analyzer, then choose **Preview**. A preview of IAM Access Analyzer findings is generated for your bucket. The preview analyzes the displayed Amazon S3 bucket policy, together with the existing bucket permissions. This includes the bucket and account BPA settings, bucket ACL, the Amazon S3 access points and multi-region access points attached to the bucket, and their policies and BPA settings.
3. When the access preview completes, a preview of IAM Access Analyzer findings is displayed. Each finding reports an instance of a principal outside of the account with access to your bucket after you save the policy. You can validate access to your bucket by reviewing each finding. The finding header provides a summary of the access and you can expand the finding

to review the [finding details](#). Finding badges provide context on how saving the bucket policy would change access to the bucket. For example, they help you validate whether the policy change introduces new findings or resolves existing findings for external access:

- a. **New** – indicates a finding for new external access that the policy would introduce.
 - b. **Resolved** – indicates a finding for existing external access that the policy would remove.
 - c. **Archived** – indicates a finding for new external access that would be automatically archived, based on the archive rules for the analyzer that define when findings should be marked as intended.
 - d. **Existing** – indicates an existing finding for external access that would remain unchanged.
 - e. **Public** – if a finding is for public access to the resource, it will have a **Public** badge, in addition to one of the badges above.
4. If you identify external access you do not intend to introduce or remove, you can revise the policy and then choose **Preview** again until you have achieved the external access you intend. If you have a finding labeled **Public**, we recommend you revise the policy to remove public access before you choose **Save changes**. Previewing access is an optional step and you can choose **Save changes** at any time.

Previewing access with IAM Access Analyzer APIs

You can use [IAM Access Analyzer APIs](#) to preview public and cross-account access for your Amazon S3 buckets, AWS KMS keys, IAM roles, Amazon SQS queues and Secrets Manager secrets. You can preview access by providing proposed permissions for an existing resource you own or a new resource you want to deploy.

To preview external access to your resource, you must have an active account analyzer for the account and region of the resource. You must also have the permissions required to use IAM Access Analyzer and preview access. For more information on enabling IAM Access Analyzer and permissions required, see [Enabling IAM Access Analyzer](#).

To preview access for a resource, you can use the `CreateAccessPreview` operation and provide the analyzer ARN and the access control configuration for the resource. The service returns the unique ID for the access preview, which you can use to check the status of the access preview with the `GetAccessPreview` operation. When the status is `Completed`, you can use the `ListAccessPreviewFindings` operation to retrieve the findings generated for the access

preview. The `GetAccessPreview` and `ListAccessPreviewFindings` operations will retrieve access previews and findings created within about 24 hours.

Each finding retrieved contains [finding details](#) describing the access. A preview status of the finding describing whether the finding would be `Active`, `Archived`, or `Resolved` after permissions deployment, and a `changeType`. The `changeType` provides context on how the access preview finding compares to existing access identified in IAM Access Analyzer:

- **New** – the finding is for newly introduced access.
- **Unchanged** – the preview finding is an existing finding that would remain unchanged.
- **Changed** – the preview finding is an existing finding with a change in status.

The status and the `changeType` help you understand how the resource configuration would change existing resource access. If the `changeType` is `Unchanged` or `Changed`, the finding will also contain the existing ID and status of the finding in IAM Access Analyzer. For example, a `Changed` finding with preview status `Resolved` and existing status `Active` indicates the existing `Active` finding for the resource would become `Resolved` as a result of the proposed permissions change.

You can use the `ListAccessPreviews` operation to retrieve a list of access previews for the specified analyzer. This operation will retrieve information on access preview created within about one hour.

In general, if the access preview is for an existing resource and you leave a configuration option unspecified, the access preview will use the existing resource configuration by default. If the access preview is for a new resource and you leave a configuration option unspecified, the access preview will use the default value depending on the resource type. For configuration cases for each resource type, see below.

Preview access to your Amazon S3 bucket

To create an access preview for a new Amazon S3 bucket or an existing Amazon S3 bucket that you own, you can propose a bucket configuration by specifying the Amazon S3 bucket policy, bucket ACLs, bucket BPA settings, and Amazon S3 access points, including multi-region access points, attached to the bucket.

Note

Before attempting to create an access preview for a new bucket, we recommend you call the Amazon S3 [HeadBucket](#) operation to check whether the named bucket already exists. This operation is useful to determine if a bucket exists and you have permission to access it.

Bucket policy – If the configuration is for an existing Amazon S3 bucket and you do not specify the Amazon S3 bucket policy, the access preview uses the existing policy attached to the bucket. If the access preview is for a new resource and you do not specify the Amazon S3 bucket policy, the access preview assumes a bucket without a policy. To propose deletion of an existing bucket policy, you can specify an empty string. For more information about supported bucket policy limits, see [Bucket policy examples](#).

Bucket ACL grants – You can propose up to 100 ACL grants per bucket. If the proposed grant configuration is for an existing bucket, the access preview uses the proposed list of grant configurations in place of the existing grants. Otherwise, the access preview uses the existing grants for the bucket.

Bucket access points – The analysis supports up to 100 access points, including multi-region access points, per bucket, including up to ten new access points you can propose per bucket. If the proposed Amazon S3 access point configuration is for an existing bucket, the access preview uses the proposed access point configuration in place of the existing access points. To propose an access point without a policy, you can provide an empty string as the access point policy. For more information about access point policy limits, see [Access points restrictions and limitations](#).

Block public access configuration – If the proposed configuration is for an existing Amazon S3 bucket and you do not specify the configuration, the access preview uses the existing setting. If the proposed configuration is for a new bucket and you do not specify the bucket BPA configuration, the access preview uses `false`. If the proposed configuration is for a new access point or multi-region access point, and you do not specify the access point BPA configuration, the access preview uses `true`.

Preview access to your AWS KMS key

To create an access preview for a new AWS KMS key or an existing AWS KMS key that you own, you can propose a AWS KMS key configuration by specifying the key policy and the AWS KMS grant configuration.

AWS KMS key policy – If the configuration is for an existing key and you do not specify the key policy, the access preview uses the existing policy for the key. If the access preview is for a new resource and you do not specify the key policy, then the access preview uses the default key policy. The proposed key policy cannot be an empty string.

AWS KMS grants – The analysis supports up to 100 KMS grants per configuration*. If the proposed grant configuration is for an existing key, the access preview uses the proposed list of grant configurations in place of the existing grants. Otherwise, the access preview uses the existing grants for the key.

Preview access to your IAM role

To create an access preview for a new IAM role or an existing IAM role that you own, you can propose an IAM role configuration by specifying the trust policy.

Role trust policy – If the configuration is for a new IAM role, you must specify the trust policy. If the configuration is for an existing IAM role that you own and you do not propose the trust policy, the access preview uses the existing trust policy for the role. The proposed trust policy cannot be an empty string.

Preview access to your Amazon SQS queue

To create an access preview for a new Amazon SQS queue or an existing Amazon SQS queue that you own, you can propose an Amazon SQS queue configuration by specifying the Amazon SQS policy for the queue.

Amazon SQS queue policy – If the configuration is for an existing Amazon SQS queue and you do not specify the Amazon SQS policy, the access preview uses the existing Amazon SQS policy for the queue. If the access preview is for a new resource and you do not specify the policy, the access preview assumes an Amazon SQS queue without a policy. To propose deletion of an existing Amazon SQS queue policy, you can specify an empty string for the Amazon SQS policy.

Preview access to your Secrets Manager secret

To create an access preview for a new Secrets Manager secret or an existing Secrets Manager secret that you own, you can propose a Secrets Manager secret configuration by specifying the secret policy and optional AWS KMS encryption key.

Secret policy – If the configuration is for an existing secret and you do not specify the secret policy, the access preview uses the existing policy for the secret. If the access preview is for a new resource

and you do not specify the policy, the access preview assumes a secret without a policy. To propose deletion of an existing policy, you can specify an empty string.

AWS KMS encryption key – If the proposed configuration is for a new secret and you do not specify the AWS KMS key ID, the access preview uses the default KMS key of the AWS account. If you specify an empty string for the AWS KMS key ID, the access preview uses the default KMS key of the AWS account.

Checks for validating policies

IAM Access Analyzer provides policy checks that help validate your IAM policies before you attach them to an entity. These include basic policy checks provided by policy validation to validate your policy against [policy grammar](#) and [AWS best practices](#). You can view policy validation check findings that include security warnings, errors, general warnings, and suggestions for your policy.

You can use custom policy checks to check for new access based on your security standards. A charge is associated with each check for new access. For more details about pricing, see [IAM Access Analyzer pricing](#).

Topics

- [IAM Access Analyzer policy validation](#)
- [IAM Access Analyzer custom policy checks](#)

IAM Access Analyzer policy validation

You can validate your policies using AWS Identity and Access Management Access Analyzer policy validation. You can create or edit a policy using the AWS CLI, AWS API, or JSON policy editor in the IAM console. IAM Access Analyzer validates your policy against IAM [policy grammar](#) and [AWS best practices](#). You can view policy validation check findings that include security warnings, errors, general warnings, and suggestions for your policy. These findings provide actionable recommendations that help you author policies that are functional and conform to security best practices. To view a list of the basic policy checks that are run by IAM Access Analyzer, see [Access Analyzer policy check reference](#).

Validating policies in IAM (console)

You can view findings generated by IAM Access Analyzer policy validation when you create or edit a managed policy in the IAM console. You can also view these findings for inline user or role policies. IAM Access Analyzer does not generate these findings for inline group policies.

To view findings generated by policy checks for IAM JSON policies

1. Sign in to the AWS Management Console and open the IAM console at <https://console.aws.amazon.com/iam/>.
2. Begin creating or editing a policy using one of the following methods:
 - a. To create a new managed policy, go to the **Policies** page and create a new policy. For more information, see [Creating policies using the JSON editor](#).
 - b. To view policy checks for an existing customer managed policy, go the **Policies** page, choose the name of a policy, and then choose **Edit**. For more information, see [Editing customer managed policies \(console\)](#).
 - c. To view policy checks for an inline policy on a user or role, go the **Users** or **Roles** page, choose the name of a user or role, choose the name of the policy on the **Permissions** tab and then choose **Edit**. For more information, see [Editing customer managed policies \(console\)](#).
3. In the policy editor, choose the **JSON** tab.
4. In the policy validation pane below the policy, choose one or more of the following tabs. The tab names also indicate the number of each finding type for your policy.
 - **Security** – View warnings if your policy allows access that AWS considers a security risk because the access is overly permissive.
 - **Errors** – View errors if your policy includes lines that prevent the policy from functioning.
 - **Warnings** – View warnings if your policy doesn't conform to best practices, but the issues are not security risks.
 - **Suggestions** – View suggestions if AWS recommends improvements that don't impact the permissions of the policy.
5. Review the finding details provided by the IAM Access Analyzer policy check. Each finding indicates the location of the reported issue. To learn more about what causes the issue and how to resolve it, choose the **Learn more** link next to the finding. You can also search for the policy check associated with each finding in the [Access Analyzer policy checks](#) reference page.

- Optional. If you are editing an existing policy, you can run a custom policy check to determine whether your updated policy grants new access compared to the existing version. In the policy validation pane below the policy, choose the **Check for new access** tab and then choose **Check policy**. If the modified permissions grant new access, the statement will be highlighted in the policy validation pane. If you do not intend to grant new access, update the policy statement and choose **Check policy** until no new access is detected. For more information, see [IAM Access Analyzer custom policy checks](#).

Note

A charge is associated with each check for new access. For more details on pricing, see [IAM Access Analyzer pricing](#).

- Update your policy to resolve the findings.

Important

Test new or edited policies thoroughly before implementing them in your production workflow.

- When you are finished, choose **Next**. The [Policy validator](#) reports any syntax errors that are not reported by IAM Access Analyzer.

Note

You can switch between the **Visual** and **JSON** tabs anytime. However, if you make changes or choose **Next** in the **Visual** tab, IAM might restructure your policy to optimize it for the visual editor. For more information, see [Policy restructuring](#).

- For new policies, on the **Review and create** page, enter a **Policy name** and a **Description** (optional) for the policy that you are creating. Review the **Permissions defined in this policy** to see the permissions that are granted by your policy. Then choose **Create policy** to save your work.

For existing policies, on the **Review and save** page, review the **Permissions defined in this policy** to see the permissions that are granted by your policy. Choose the **Set this new version as the default** check box to save the updated version as the default version of the policy. Then choose **Save changes** to save your work.

Validating policies using IAM Access Analyzer (AWS CLI or AWS API)

You can view findings generated by IAM Access Analyzer policy validation from the AWS Command Line Interface (AWS CLI).

To view findings generated by IAM Access Analyzer policy validation (AWS CLI or AWS API)

Use one of the following:

- AWS CLI: [aws accessanalyzer validate-policy](#)
- AWS API: [ValidatePolicy](#)

Access Analyzer policy check reference

You can validate your policies using AWS Identity and Access Management Access Analyzer policy validation. You can create or edit a policy using the AWS CLI, AWS API, or JSON policy editor in the IAM console. IAM Access Analyzer validates your policy against IAM [policy grammar](#) and [AWS best practices](#). You can view policy validation check findings that include security warnings, errors, general warnings, and suggestions for your policy. These findings provide actionable recommendations that help you author policies that are functional and conform to security best practices. The list of basic policy checks provided by IAM Access Analyzer are shared below. There is no additional charge associated with running the policy validation checks. To learn more about validating policies using policy validation, see [IAM Access Analyzer policy validation](#).

Error – ARN account not allowed

In the AWS Management Console, the finding for this check includes the following message:

```
ARN account not allowed: The service {{service}} does not support specifying an account ID in the resource ARN.
```

In programmatic calls to the AWS CLI or AWS API, the finding for this check includes the following message:

```
"findingDetails": "The service {{service}} does not support specifying an account ID in the resource ARN."
```

Resolving the error

Remove the account ID from the resource ARN. The resource ARNs for some AWS services do not support specifying an account ID.

For example, Amazon S3 does not support an account ID as a namespace in bucket ARNs. An Amazon S3 bucket name is globally unique, and the namespace is shared by all AWS accounts. To view all of the resource types available in Amazon S3, see [Resource types defined by Amazon S3](#) in the *Service Authorization Reference*.

Related terms

- [Policy resources](#)
- [Account Identifiers](#)
- [Resource ARNs](#)
- [AWS service resources with ARN formats](#)

Error – ARN Region not allowed

In the AWS Management Console, the finding for this check includes the following message:

```
ARN Region not allowed: The service {{service}} does not support specifying a Region in the resource ARN.
```

In programmatic calls to the AWS CLI or AWS API, the finding for this check includes the following message:

```
"findingDetails": "The service {{service}} does not support specifying a Region in the resource ARN."
```

Resolving the error

Remove the Region from the resource ARN. The resource ARNs for some AWS services do not support specifying a Region.

For example, IAM is a global service. The Region portion of an IAM resource ARN is always kept blank. IAM resources are global, like an AWS account is today. For example, after you sign in as an IAM user, you can access AWS services in any geographic region.

- [Policy resources](#)
- [Resource ARNs](#)

- [AWS service resources with ARN formats](#)

Error – Data type mismatch

In the AWS Management Console, the finding for this check includes the following message:

```
Data type mismatch: The text does not match the expected JSON data type {{data_type}}.
```

In programmatic calls to the AWS CLI or AWS API, the finding for this check includes the following message:

```
"findingDetails": "The text does not match the expected JSON data type {{data_type}}."
```

Resolving the error

Update the text to use the supported data type.

For example, the `Version` global condition key requires a `String` data type. If you provide a date or an integer, the data type won't match.

Related terms

- [Global condition keys](#)
- [IAM JSON policy elements: Condition operators](#)

Error – Duplicate keys with different case

In the AWS Management Console, the finding for this check includes the following message:

```
Duplicate keys with different case: The condition key {{key}} appears more than once with different capitalization in the same condition block. Remove the duplicate condition keys.
```

In programmatic calls to the AWS CLI or AWS API, the finding for this check includes the following message:

```
"findingDetails": "The condition key {{key}} appears more than once with different capitalization in the same condition block. Remove the duplicate condition keys."
```

Resolving the error

Review the similar condition keys within the same condition block and use the same capitalization for all instances.

A *condition block* is the text within the `Condition` element of a policy statement. Condition key *names* are not case-sensitive. The case-sensitivity of condition key *values* depends on the condition operator that you use. For more information about case-sensitivity in condition keys, see [IAM JSON policy elements: Condition](#).

Related terms

- [Conditions](#)
- [Condition block](#)
- [Global condition keys](#)
- [AWS service condition keys](#)

Error – Invalid action

In the AWS Management Console, the finding for this check includes the following message:

```
Invalid action: The action {{action}} does not exist. Did you mean {{valid_action}}?
```

In programmatic calls to the AWS CLI or AWS API, the finding for this check includes the following message:

```
"findingDetails": "The action {{action}} does not exist. Did you mean {{valid_action}}?"
```

Resolving the error

The action that you specified is not valid. This can happen if you mis-type the service prefix or the action name. For some common issues, the policy check returns a suggested action.

Related terms

- [Policy actions](#)
- [AWS service actions](#)

AWS managed policies with this error

[AWS managed policies](#) enable you to get started with AWS by assigning permissions based on general AWS use cases.

The following AWS managed policies include invalid actions in their policy statements. Invalid actions do not affect the permissions granted by the policy. When using an AWS managed policy as a reference to create your managed policy, AWS recommends that you remove invalid actions from your policy.

- [AmazonEMRFullAccessPolicy_v2](#)
- [CloudWatchSyntheticsFullAccess](#)

Error – Invalid ARN account

In the AWS Management Console, the finding for this check includes the following message:

```
Invalid ARN account: The resource ARN account ID {{account}} is not valid. Provide a 12-digit account ID.
```

In programmatic calls to the AWS CLI or AWS API, the finding for this check includes the following message:

```
"findingDetails": "The resource ARN account ID {{account}} is not valid. Provide a 12-digit account ID."
```

Resolving the error

Update the account ID in the resource ARN. Account IDs are 12-digit integers. To learn how to view your account ID, see [Finding your AWS account ID](#).

Related terms

- [Policy resources](#)
- [Account Identifiers](#)
- [Resource ARNs](#)
- [AWS service resources with ARN formats](#)

Error – Invalid ARN prefix

In the AWS Management Console, the finding for this check includes the following message:

```
Invalid ARN prefix: Add the required prefix (arn) to the resource ARN.
```

In programmatic calls to the AWS CLI or AWS API, the finding for this check includes the following message:

```
"findingDetails": "Add the required prefix (arn) to the resource ARN."
```

Resolving the error

AWS resource ARNs must include the required `arn: prefix`.

Related terms

- [Policy resources](#)
- [Resource ARNs](#)
- [AWS service resources with ARN formats](#)

Error – Invalid ARN Region

In the AWS Management Console, the finding for this check includes the following message:

```
Invalid ARN Region: The Region {{region}} is not valid for this resource. Update the resource ARN to include a supported Region.
```

In programmatic calls to the AWS CLI or AWS API, the finding for this check includes the following message:

```
"findingDetails": "The Region {{region}} is not valid for this resource. Update the resource ARN to include a supported Region."
```

Resolving the error

The resource type is not supported in the specified Region. For a table of AWS services supported in each Region, see the [Region table](#).

Related terms

- [Policy resources](#)
- [Resource ARNs](#)
- [Region names and codes](#)

Error – Invalid ARN resource

In the AWS Management Console, the finding for this check includes the following message:

```
Invalid ARN resource: Resource ARN does not match the expected ARN format. Update the resource portion of the ARN.
```

In programmatic calls to the AWS CLI or AWS API, the finding for this check includes the following message:

```
"findingDetails": "Resource ARN does not match the expected ARN format. Update the resource portion of the ARN."
```

Resolving the error

The resource ARN must match the specifications for known resource types. To view the expected ARN format for a service, see [Actions, resources, and condition keys for AWS services](#). Choose the name of the service to view its resource types and ARN formats.

Related terms

- [Policy resources](#)
- [Resource ARNs](#)
- [AWS service resources with ARN formats](#)

Error – Invalid ARN service case

In the AWS Management Console, the finding for this check includes the following message:

```
Invalid ARN service case: Update the service name ${service} in the resource ARN to use all lowercase letters.
```

In programmatic calls to the AWS CLI or AWS API, the finding for this check includes the following message:

```
"findingDetails": "Update the service name ${service} in the resource ARN to use all lowercase letters."
```

Resolving the error

The service in the resource ARN must match the specifications (including capitalization) for service prefixes. To view the prefix for a service, see [Actions, resources, and condition keys for AWS services](#). Choose the name of the service and locate its prefix in the first sentence.

Related terms

- [Policy resources](#)
- [Resource ARNs](#)
- [AWS service resources with ARN formats](#)

Error – Invalid condition data type

In the AWS Management Console, the finding for this check includes the following message:

```
Invalid condition data type: The condition value data types do not match. Use condition values of the same JSON data type.
```

In programmatic calls to the AWS CLI or AWS API, the finding for this check includes the following message:

```
"findingDetails": "The condition value data types do not match. Use condition values of the same JSON data type."
```

Resolving the error

The value in the condition key-value pair must match the data type of the condition key and condition operator. To view the condition key data type for a service, see [Actions, resources, and condition keys for AWS services](#). Choose the name of the service to view the condition keys for that service.

For example, the [CurrentTime](#) global condition key supports the Date condition operator. If you provide a string or an integer for the value in the condition block, the data type won't match.

Related terms

- [Conditions](#)
- [Condition block](#)
- [IAM JSON policy elements: Condition operators](#)
- [Global condition keys](#)
- [AWS service condition keys](#)

Error – Invalid condition key format

In the AWS Management Console, the finding for this check includes the following message:

```
Invalid condition key format: The condition key format is not valid. Use the format
service:keyname.
```

In programmatic calls to the AWS CLI or AWS API, the finding for this check includes the following message:

```
"findingDetails": "The condition key format is not valid. Use the format
service:keyname."
```

Resolving the error

The key in the condition key-value pair must match the specifications for the service. To view the condition keys for a service, see [Actions, resources, and condition keys for AWS services](#). Choose the name of the service to view the condition keys for that service.

Related terms

- [Conditions](#)
- [Global condition keys](#)
- [AWS service condition keys](#)

Error – Invalid condition multiple Boolean

In the AWS Management Console, the finding for this check includes the following message:

```
Invalid condition multiple Boolean: The condition key does not support multiple Boolean
values. Use a single Boolean value.
```

In programmatic calls to the AWS CLI or AWS API, the finding for this check includes the following message:

```
"findingDetails": "The condition key does not support multiple Boolean values. Use a single Boolean value."
```

Resolving the error

The key in the condition key-value pair expects a single Boolean value. When you provide multiple Boolean values, the condition match might not return the results that you expect.

To view the condition keys for a service, see [Actions, resources, and condition keys for AWS services](#). Choose the name of the service to view the condition keys for that service.

- [Conditions](#)
- [Global condition keys](#)
- [AWS service condition keys](#)

Error – Invalid condition operator

In the AWS Management Console, the finding for this check includes the following message:

```
Invalid condition operator: The condition operator {{operator}} is not valid. Use a valid condition operator.
```

In programmatic calls to the AWS CLI or AWS API, the finding for this check includes the following message:

```
"findingDetails": "The condition operator {{operator}} is not valid. Use a valid condition operator."
```

Resolving the error

Update the condition to use a supported condition operator.

Related terms

- [IAM JSON policy elements: Condition operators](#)

- [Condition element](#)
- [Overview of JSON policies](#)

Error – Invalid effect

In the AWS Management Console, the finding for this check includes the following message:

```
Invalid effect: The effect {{effect}} is not valid. Use Allow or Deny.
```

In programmatic calls to the AWS CLI or AWS API, the finding for this check includes the following message:

```
"findingDetails": "The effect {{effect}} is not valid. Use Allow or Deny."
```

Resolving the error

Update the Effect element to use a valid effect. Valid values for Effect are **Allow** and **Deny**.

Related terms

- [Effect element](#)
- [Overview of JSON policies](#)

Error – Invalid global condition key

In the AWS Management Console, the finding for this check includes the following message:

```
Invalid global condition key: The condition key {{key}} does not exist. Use a valid condition key.
```

In programmatic calls to the AWS CLI or AWS API, the finding for this check includes the following message:

```
"findingDetails": "The condition key {{key}} does not exist. Use a valid condition key."
```

Resolving the error

Update the condition key in the condition key-value pair to use a supported global condition key.

Global condition keys are condition keys with an `aws:` prefix. AWS services can support global condition keys or provide service-specific keys that include their service prefix. For example, IAM condition keys include the `iam:` prefix. For more information, see [Actions, Resources, and Condition Keys for AWS Services](#) and choose the service whose keys you want to view.

Related terms

- [Global condition keys](#)

Error – Invalid partition

In the AWS Management Console, the finding for this check includes the following message:

```
Invalid partition: The resource ARN for the service {{service}} does not support the partition {{partition}}. Use the supported values: {{partitions}}
```

In programmatic calls to the AWS CLI or AWS API, the finding for this check includes the following message:

```
"findingDetails": "The resource ARN for the service {{service}} does not support the partition {{partition}}. Use the supported values: {{partitions}}"
```

Resolving the error

Update the resource ARN to include a supported partition. If you included a supported partition, then the service or resource might not support the partition that you included.

A *partition* is a group of AWS Regions. Each AWS account is scoped to one partition. In Classic Regions, use the `aws` partition. In China Regions, use `aws-cn`.

Related terms

- [Amazon Resource Names \(ARNs\) - Partitions](#)

Error – Invalid policy element

In the AWS Management Console, the finding for this check includes the following message:

```
Invalid policy element: The policy element {{element}} is not valid.
```

In programmatic calls to the AWS CLI or AWS API, the finding for this check includes the following message:

```
"findingDetails": "The policy element {{element}} is not valid."
```

Resolving the error

Update the policy to include only supported JSON policy elements.

Related terms

- [JSON policy elements](#)

Error – Invalid principal format

In the AWS Management Console, the finding for this check includes the following message:

```
Invalid principal format: The Principal element contents are not valid. Specify a key-value pair in the Principal element.
```

In programmatic calls to the AWS CLI or AWS API, the finding for this check includes the following message:

```
"findingDetails": "The Principal element contents are not valid. Specify a key-value pair in the Principal element."
```

Resolving the error

Update the principal to use a supported key-value pair format.

You can specify a principal in a resource-based policy, but not an identity-based policy.

For example, to define access for everyone in an AWS account, use the following principal in your policy:

```
"Principal": { "AWS": "123456789012" }
```

Related terms

- [JSON policy elements: Principal](#)
- [Identity-based policies and resource-based policies](#)

Error – Invalid principal key

In the AWS Management Console, the finding for this check includes the following message:

```
Invalid principal key: The principal key {{principal-key}} is not valid.
```

In programmatic calls to the AWS CLI or AWS API, the finding for this check includes the following message:

```
"findingDetails": "The principal key {{principal-key}} is not valid."
```

Resolving the error

Update the key in the principal key-value pair to use a supported principal key. The following are supported principal keys:

- AWS
- CanonicalUser
- Federated
- Service

Related terms

- [Principal element](#)

Error – Invalid Region

In the AWS Management Console, the finding for this check includes the following message:

```
Invalid Region: The Region {{region}} is not valid. Update the condition value to a supported Region.
```

In programmatic calls to the AWS CLI or AWS API, the finding for this check includes the following message:

```
"findingDetails": "The Region {{region}} is not valid. Update the condition value to a supported Region."
```

Resolving the error

Update the value of the condition key-value pair to include a supported Region. For a table of AWS services supported in each Region, see the [Region table](#).

Related terms

- [Policy resources](#)
- [Resource ARNs](#)
- [Region names and codes](#)

Error – Invalid service

In the AWS Management Console, the finding for this check includes the following message:

```
Invalid service: The service {{service}} does not exist. Use a valid service name.
```

In programmatic calls to the AWS CLI or AWS API, the finding for this check includes the following message:

```
"findingDetails": "The service {{service}} does not exist. Use a valid service name."
```

Resolving the error

The service prefix in the action or condition key must match the specifications (including capitalization) for service prefixes. To view the prefix for a service, see [Actions, resources, and condition keys for AWS services](#). Choose the name of the service and locate its prefix in the first sentence.

Related terms

- [Known services and their actions, resources, and condition keys](#)

Error – Invalid service condition key

In the AWS Management Console, the finding for this check includes the following message:

```
Invalid service condition key: The condition key {{key}} does not exist in the service {{service}}. Use a valid condition key.
```

In programmatic calls to the AWS CLI or AWS API, the finding for this check includes the following message:

```
"findingDetails": "The condition key {{key}} does not exist in the service {{service}}. Use a valid condition key."
```

Resolving the error

Update the key in the condition key-value pair to use a known condition key for the service. Global condition key names begin with the `aws` prefix. AWS services can provide service-specific keys that include their service prefix. To view the prefix for a service, see [Actions, resources, and condition keys for AWS services](#).

Related terms

- [Global condition keys](#)
- [Known services and their actions, resources, and condition keys](#)

Error – Invalid service in action

In the AWS Management Console, the finding for this check includes the following message:

```
Invalid service in action: The service {{service}} specified in the action does not exist. Did you mean {{service2}}?
```

In programmatic calls to the AWS CLI or AWS API, the finding for this check includes the following message:

```
"findingDetails": "The service {{service}} specified in the action does not exist. Did you mean {{service2}}?"
```

Resolving the error

The service prefix in the action must match the specifications (including capitalization) for service prefixes. To view the prefix for a service, see [Actions, resources, and condition keys for AWS services](#). Choose the name of the service and locate its prefix in the first sentence.

Related terms

- [Action element](#)
- [Known services and their actions](#)

Error – Invalid variable for operator

In the AWS Management Console, the finding for this check includes the following message:

```
Invalid variable for operator: Policy variables can only be used with String and ARN operators.
```

In programmatic calls to the AWS CLI or AWS API, the finding for this check includes the following message:

```
"findingDetails": "Policy variables can only be used with String and ARN operators."
```

Resolving the error

You can use policy variables in the Resource element and in string comparisons in the Condition element. Conditions support variables when you use string operators or ARN operators. String operators include `StringEquals`, `StringLike`, and `StringNotLike`. ARN operators include `ArnEquals` and `ArnLike`. You can't use a policy variable with other operators, such as `Numeric`, `Date`, `Boolean`, `Binary`, `IP Address`, or `Null` operators.

Related terms

- [Using policy variables in the Condition element](#)
- [Condition element](#)

Error – Invalid version

In the AWS Management Console, the finding for this check includes the following message:

```
Invalid version: The version ${version} is not valid. Use one of the following versions: ${versions}
```

In programmatic calls to the AWS CLI or AWS API, the finding for this check includes the following message:

```
"findingDetails": "The version ${version} is not valid. Use one of the following versions: ${versions}"
```

Resolving the error

The `Version` policy element specifies the language syntax rules that AWS uses to process a policy. To use all of the available policy features, include the latest `Version` element before the `Statement` element in all of your policies.

```
"Version": "2012-10-17"
```

Related terms

- [Version element](#)

Error – Json syntax error

In the AWS Management Console, the finding for this check includes the following message:

```
Json syntax error: Fix the JSON syntax error at index {{index}} line {{line}} column {{column}}.
```

In programmatic calls to the AWS CLI or AWS API, the finding for this check includes the following message:

```
"findingDetails": "Fix the JSON syntax error at index {{index}} line {{line}} column {{column}}."
```

Resolving the error

Your policy includes a syntax error. Check your JSON syntax.

Related terms

- [JSON validator](#)
- [IAM JSON policy elements reference](#)
- [Overview of JSON policies](#)

Error – Json syntax error

In the AWS Management Console, the finding for this check includes the following message:

```
Json syntax error: Fix the JSON syntax error.
```

In programmatic calls to the AWS CLI or AWS API, the finding for this check includes the following message:

```
"findingDetails": "Fix the JSON syntax error."
```

Resolving the error

Your policy includes a syntax error. Check your JSON syntax.

Error – Missing action

In the AWS Management Console, the finding for this check includes the following message:

```
Missing action: Add an Action or NotAction element to the policy statement.
```

In programmatic calls to the AWS CLI or AWS API, the finding for this check includes the following message:

```
"findingDetails": "Add an Action or NotAction element to the policy statement."
```

Resolving the error

AWS JSON policies must include an Action or NotAction element.

Related terms

- [Action element](#)

Error – Missing ARN field

In the AWS Management Console, the finding for this check includes the following message:

```
Missing ARN field: Resource ARNs must include at least {{fields}} fields in the following structure: arn:partition:service:region:account:resource
```

In programmatic calls to the AWS CLI or AWS API, the finding for this check includes the following message:

```
"findingDetails": "Resource ARNs must include at least {{fields}} fields in the following structure: arn:partition:service:region:account:resource"
```

Resolving the error

All of the fields in the resource ARN must match the specifications for a known resource type. To view the expected ARN format for a service, see [Actions, resources, and condition keys for AWS services](#). Choose the name of the service to view its resource types and ARN formats.

Related terms

Error – Missing ARN Region

In the AWS Management Console, the finding for this check includes the following message:

```
Missing ARN Region: Add a Region to the {{service}} resource ARN.
```

In programmatic calls to the AWS CLI or AWS API, the finding for this check includes the following message:

```
"findingDetails": "Add a Region to the {{service}} resource ARN."
```

Resolving the error

The resource ARNs for most AWS services require that you specify a Region. For a table of AWS services supported in each Region, see the [Region table](#).

Related terms

- [Policy resources](#)
- [Resource ARNs](#)
- [Region names and codes](#)

Error – Missing effect

In the AWS Management Console, the finding for this check includes the following message:

```
Missing effect: Add an Effect element to the policy statement with a value of Allow or Deny.
```

In programmatic calls to the AWS CLI or AWS API, the finding for this check includes the following message:

```
"findingDetails": "Add an Effect element to the policy statement with a value of Allow or Deny."
```

Resolving the error

AWS JSON policies must include an Effect element with a value of **Allow** and **Deny**.

Related terms

- [Effect element](#)

Error – Missing principal

In the AWS Management Console, the finding for this check includes the following message:

```
Missing principal: Add a Principal element to the policy statement.
```

In programmatic calls to the AWS CLI or AWS API, the finding for this check includes the following message:

```
"findingDetails": "Add a Principal element to the policy statement."
```

Resolving the error

Resource-based policies must include a `Principal` element.

For example, to define access for everyone in an AWS account, use the following principal in your policy:

```
"Principal": { "AWS": "123456789012" }
```

Related terms

- [Principal element](#)
- [Identity-based policies and resource-based policies](#)

Error – Missing qualifier

In the AWS Management Console, the finding for this check includes the following message:

```
Missing qualifier: The request context key ${key} has multiple values. Use the ForAllValues or ForAnyValue condition key qualifiers in your policy.
```

In programmatic calls to the AWS CLI or AWS API, the finding for this check includes the following message:

```
"findingDetails": "The request context key ${key} has multiple values. Use the ForAllValues or ForAnyValue condition key qualifiers in your policy."
```

Resolving the error

In the `Condition` element, you build expressions in which you use condition operators like `equal` or `less than` to compare a condition in the policy against keys and values in the request context. For requests that include multiple values for a single condition key, you must enclose the conditions within brackets like an array (`"Key2":["Value2A", "Value2B"]`). You must also use

the `ForAllValues` or `ForAnyValue` set operators with the `StringLike` condition operator. These qualifiers add set-operation functionality to the condition operator so that you can test multiple request values against multiple condition values.

Related terms

- [Multivalued context keys](#)
- [Condition element](#)

AWS managed policies with this error

[AWS managed policies](#) enable you to get started with AWS by assigning permissions based on general AWS use cases.

The following AWS managed policies include a missing qualifier for condition keys in their policy statements. When using the AWS managed policy as a reference to create your customer managed policy, AWS recommends that you add the `ForAllValues` or `ForAnyValue` condition key qualifiers to your `Condition` element.

- [AWSGlueConsoleSageMakerNotebookFullAccess](#)

Error – Missing resource

In the AWS Management Console, the finding for this check includes the following message:

```
Missing resource: Add a Resource or NotResource element to the policy statement.
```

In programmatic calls to the AWS CLI or AWS API, the finding for this check includes the following message:

```
"findingDetails": "Add a Resource or NotResource element to the policy statement."
```

Resolving the error

Identity-based policies must include a `Resource` or `NotResource` element.

Related terms

- [Resource element](#)

- [NotResource element](#)
- [Identity-based policies and resource-based policies](#)
- [Overview of JSON policies](#)

Error – Missing statement

In the AWS Management Console, the finding for this check includes the following message:

```
Missing statement: Add a statement to the policy
```

In programmatic calls to the AWS CLI or AWS API, the finding for this check includes the following message:

```
"findingDetails": "Add a statement to the policy"
```

Resolving the error

A JSON policy must include a statement.

Related terms

- [JSON policy elements](#)

Error – Null with if exists

In the AWS Management Console, the finding for this check includes the following message:

```
Null with if exists: The Null condition operator cannot be used with the IfExists suffix. Update the operator or the suffix.
```

In programmatic calls to the AWS CLI or AWS API, the finding for this check includes the following message:

```
"findingDetails": "The Null condition operator cannot be used with the IfExists suffix. Update the operator or the suffix."
```

Resolving the error

You can add `IfExists` to the end of any condition operator name except the `Null` condition operator. Use a `Null` condition operator to check if a condition key is present at the time of authorization. Use `...IfExists` to say "If the policy key is present in the context of the request, process the key as specified in the policy. If the key is not present, evaluate the condition element as true."

Related terms

- [...IfExists condition operators](#)
- [Null condition operator](#)

Error – SCP syntax error action wildcard

In the AWS Management Console, the finding for this check includes the following message:

```
SCP syntax error action wildcard: SCP actions can include wildcards (*) only at the end of a string. Update {{action}}.
```

In programmatic calls to the AWS CLI or AWS API, the finding for this check includes the following message:

```
"findingDetails": "SCP actions can include wildcards (*) only at the end of a string. Update {{action}}."
```

Resolving the error

AWS Organizations service control policies (SCPs) support specifying values in the `Action` or `NotAction` elements. However, these values can include wildcards (*) only at the end of the string. This means that you can specify `iam:Get*` but not `iam:*role`.

To specify multiple actions, AWS recommends that you list them individually.

Related terms

- [SCP Action and NotAction elements](#)
- [SCP evaluation](#)
- [AWS Organizations service control policies](#)

- [IAM JSON policy elements: Action](#)

Error – SCP syntax error allow condition

In the AWS Management Console, the finding for this check includes the following message:

```
SCP syntax error allow condition: SCPs do not support the Condition element with effect Allow. Update the element Condition or the effect.
```

In programmatic calls to the AWS CLI or AWS API, the finding for this check includes the following message:

```
"findingDetails": "SCPs do not support the Condition element with effect Allow. Update the element Condition or the effect."
```

Resolving the error

AWS Organizations service control policies (SCPs) support specifying values in the Condition element only when you use "Effect": "Deny".

To allow only a single action, you can deny access to everything except the condition that you specify using the `NotEquals` version of a condition operator. This negates the comparison made by the operator.

Related terms

- [SCP Condition element](#)
- [SCP evaluation](#)
- [AWS Organizations service control policies](#)
- [Example policy: Denies access to AWS based on the requested Region](#)
- [IAM JSON policy elements: Condition operators](#)

Error – SCP syntax error allow NotAction

In the AWS Management Console, the finding for this check includes the following message:

```
SCP syntax error allow NotAction: SCPs do not support NotAction with effect Allow.  
Update the element NotAction or the effect.
```

In programmatic calls to the AWS CLI or AWS API, the finding for this check includes the following message:

```
"findingDetails": "SCPs do not support NotAction with effect Allow. Update the element  
NotAction or the effect."
```

Resolving the error

AWS Organizations service control policies (SCPs) do not support using the NotAction element with "Effect": "Allow".

You must rewrite the logic to allow a list of actions, or to deny every action that is not listed.

Related terms

- [SCP Action and NotAction elements](#)
- [SCP evaluation](#)
- [AWS Organizations service control policies](#)
- [IAM JSON policy elements: Action](#)

Error – SCP syntax error allow resource

In the AWS Management Console, the finding for this check includes the following message:

```
SCP syntax error allow resource: SCPs do not support Resource with effect Allow. Update  
the element Resource or the effect.
```

In programmatic calls to the AWS CLI or AWS API, the finding for this check includes the following message:

```
"findingDetails": "SCPs do not support Resource with effect Allow. Update the element  
Resource or the effect."
```

Resolving the error

AWS Organizations service control policies (SCPs) support specifying values in the `Resource` element only when you use `"Effect": "Deny"`.

You must rewrite the logic to allow all resources, or to deny every resource that is listed.

Related terms

- [SCP Resource element](#)
- [SCP evaluation](#)
- [AWS Organizations service control policies](#)
- [IAM JSON policy elements: Resource](#)

Error – SCP syntax error `NotResource`

In the AWS Management Console, the finding for this check includes the following message:

```
SCP syntax error NotResource: SCPs do not support the NotResource element. Update the policy to use Resource instead.
```

In programmatic calls to the AWS CLI or AWS API, the finding for this check includes the following message:

```
"findingDetails": "SCPs do not support the NotResource element. Update the policy to use Resource instead."
```

Resolving the error

AWS Organizations service control policies (SCPs) do not support the `NotResource` element.

You must rewrite the logic to allow all resources, or to deny every resource that is listed.

Related terms

- [SCP Resource element](#)
- [SCP evaluation](#)
- [AWS Organizations service control policies](#)
- [IAM JSON policy elements: Resource](#)

Error – SCP syntax error principal

In the AWS Management Console, the finding for this check includes the following message:

```
SCP syntax error principal: SCPs do not support specifying principals. Remove the Principal or NotPrincipal element.
```

In programmatic calls to the AWS CLI or AWS API, the finding for this check includes the following message:

```
"findingDetails": "SCPs do not support specifying principals. Remove the Principal or NotPrincipal element."
```

Resolving the error

AWS Organizations service control policies (SCPs) do not support the `Principal` or `NotPrincipal` elements.

You can specify the Amazon Resource Name (ARN) using the `aws:PrincipalArn` global condition key in the `Condition` element.

Related terms

- [SCP syntax](#)
- [Global condition keys for principals](#)

Error – Unique Sids required

In the AWS Management Console, the finding for this check includes the following message:

```
Unique Sids required: Duplicate statement IDs are not supported for this policy type. Update the Sid value.
```

In programmatic calls to the AWS CLI or AWS API, the finding for this check includes the following message:

```
"findingDetails": "Duplicate statement IDs are not supported for this policy type. Update the Sid value."
```

Resolving the error

For some policy types, statement IDs must be unique. The `Sid` (statement ID) element allows you to enter an optional identifier that you provide for the policy statement. You can assign a statement ID value to each statement in a statement array using the `SID` element. In services that let you specify an ID element, such as SQS and SNS, the `Sid` value is just a sub-ID of the policy document's ID. For example, in IAM, the `Sid` value must be unique within a JSON policy.

Related terms

- [IAM JSON policy elements: Sid](#)

Error – Unsupported action in policy

In the AWS Management Console, the finding for this check includes the following message:

```
Unsupported action in policy: The action {{action}} is not supported for the resource-based policy attached to the resource type {{resourceType}}.
```

In programmatic calls to the AWS CLI or AWS API, the finding for this check includes the following message:

```
"findingDetails": "The action {{action}} is not supported for the resource-based policy attached to the resource type {{resourceType}}."
```

Resolving the error

Some actions aren't supported in the `Action` element in the resource-based policy attached to a different resource type. For example, AWS Key Management Service actions aren't supported in Amazon S3 bucket policies. Specify an action that is supported by resource type attached to your resource-based policy.

Related terms

- [JSON policy elements: Action](#)

Error – Unsupported element combination

In the AWS Management Console, the finding for this check includes the following message:

Unsupported element combination: The policy elements `${element1}` and `${element2}` can not be used in the same statement. Remove one of these elements.

In programmatic calls to the AWS CLI or AWS API, the finding for this check includes the following message:

```
"findingDetails": "The policy elements ${element1} and ${element2} can not be used in the same statement. Remove one of these elements."
```

Resolving the error

Some combinations of JSON policy elements can't be used together. For example, you cannot use both `Action` and `NotAction` in the same policy statement. Other pairs that are mutually exclusive include `Principal/NotPrincipal` and `Resource/NotResource`.

Related terms

- [IAM JSON policy elements reference](#)
- [Overview of JSON policies](#)

Error – Unsupported global condition key

In the AWS Management Console, the finding for this check includes the following message:

```
Unsupported global condition key: The condition key aws:ARN is not supported. Use aws:PrincipalArn or aws:SourceArn instead.
```

In programmatic calls to the AWS CLI or AWS API, the finding for this check includes the following message:

```
"findingDetails": "The condition key aws:ARN is not supported. Use aws:PrincipalArn or aws:SourceArn instead."
```

Resolving the error

AWS does not support using the specified global condition key. Depending on your use case, you can use the `aws:PrincipalArn` or `aws:SourceArn` global condition keys. For example, instead

of `aws:ARN`, use the `aws:PrincipalArn` to compare the Amazon Resource Name (ARN) of the principal that made the request with the ARN that you specify in the policy. Alternatively, use the `aws:SourceArn` global condition key to compare the Amazon Resource Name (ARN) of the resource making a service-to-service request with the ARN that you specify in the policy.

Related terms

- [AWS global condition context keys](#)

Error – Unsupported principal

In the AWS Management Console, the finding for this check includes the following message:

```
Unsupported principal: The policy type ${policy_type} does not support the Principal element. Remove the Principal element.
```

In programmatic calls to the AWS CLI or AWS API, the finding for this check includes the following message:

```
"findingDetails": "The policy type ${policy_type} does not support the Principal element. Remove the Principal element."
```

Resolving the error

The `Principal` element specifies the principal that is allowed or denied access to a resource. You cannot use the `Principal` element in an IAM identity-based policy. You can use it in the trust policies for IAM roles and in resource-based policies. Resource-based policies are policies that you embed directly in a resource. For example, you can embed policies in an Amazon S3 bucket or an AWS KMS key.

Related terms

- [AWS JSON policy elements: Principal](#)
- [Cross account resource access in IAM](#)

Error – Unsupported resource ARN in policy

In the AWS Management Console, the finding for this check includes the following message:

```
Unsupported resource ARN in policy: The resource ARN is not supported for the resource-based policy attached to the resource type {{resourceType}}.
```

In programmatic calls to the AWS CLI or AWS API, the finding for this check includes the following message:

```
"findingDetails": "The resource ARN is not supported for the resource-based policy attached to the resource type {{resourceType}}."
```

Resolving the error

Some resource ARNs aren't supported in the Resource element of the resource-based policy when the policy is attached to a different resource type. For example, AWS KMS ARNs aren't supported in the Resource element for Amazon S3 bucket policies. Specify a resource ARN that is supported by a resource type attached to your resource-based policy.

Related terms

- [JSON policy elements: Action](#)

Error – Unsupported Sid

In the AWS Management Console, the finding for this check includes the following message:

```
Unsupported Sid: Update the characters in the Sid element to use one of the following character types: [a-z, A-Z, 0-9]
```

In programmatic calls to the AWS CLI or AWS API, the finding for this check includes the following message:

```
"findingDetails": "Update the characters in the Sid element to use one of the following character types: [a-z, A-Z, 0-9]"
```

Resolving the error

The Sid element supports uppercase letters, lowercase letters, and numbers.

Related terms

- [IAM JSON policy elements: Sid](#)

Error – Unsupported wildcard in principal

In the AWS Management Console, the finding for this check includes the following message:

```
Unsupported wildcard in principal: Wildcards (*, ?) are not supported with the principal key {{principal_key}}. Replace the wildcard with a valid principal value.
```

In programmatic calls to the AWS CLI or AWS API, the finding for this check includes the following message:

```
"findingDetails": "Wildcards (*, ?) are not supported with the principal key {{principal_key}}. Replace the wildcard with a valid principal value."
```

Resolving the error

The `Principal` element structure supports using a key-value pair. The principal value specified in the policy includes a wildcard (*). You can't include a wildcard with the principal key that you specified. For example, when you specify users in a `Principal` element, you cannot use a wildcard to mean "all users". You must name a specific user or users. Similarly, when you specify an assumed-role session, you cannot use a wildcard to mean "all sessions". You must name a specific session. You also cannot use a wildcard to match part of a name or an ARN.

To resolve this finding, remove the wildcard and provide a more specific principal.

Related terms

- [AWS JSON policy elements: Principal](#)

Error – Missing brace in variable

In the AWS Management Console, the finding for this check includes the following message:

```
Missing brace in variable: The policy variable is missing a closing curly brace. Add } after the variable text.
```

In programmatic calls to the AWS CLI or AWS API, the finding for this check includes the following message:

```
"findingDetails": "The policy variable is missing a closing curly brace. Add } after the variable text."
```

Resolving the error

Policy variable structure supports using a \$ prefix followed by a pair of curly braces ({ }). Inside the \${ } characters, include the name of the value from the request that you want to use in the policy.

To resolve this finding, add the missing brace to make sure the full opening and closing set of braces is present.

Related terms

- [IAM policy elements: Variables](#)

Error – Missing quote in variable

In the AWS Management Console, the finding for this check includes the following message:

```
Missing quote in variable: The policy variable default value must begin and end with a single quote. Add the missing quote.
```

In programmatic calls to the AWS CLI or AWS API, the finding for this check includes the following message:

```
"findingDetails": "The policy variable default value must begin and end with a single quote. Add the missing quote."
```

Resolving the error

When you add a variable to your policy, you can specify a default value for the variable. If a variable is not present, AWS uses the default text that you provide.

To add a default value to a variable, surround the default value with single quotes (' '), and separate the variable text and the default value with a comma and space (,).

For example, if a principal is tagged with team=yellow, they can access the *DOC-EXAMPLE-BUCKET* Amazon S3 bucket with the name *DOC-EXAMPLE-BUCKET*-yellow. A policy with this

resource might allow team members to access their own resources, but not those of other teams. For users without team tags, you might set a default value of company-wide. These users can access only the *DOC-EXAMPLE-BUCKET*-company-wide bucket where they can view broad information, such as instructions for joining a team.

```
"Resource": "arn:aws:s3::DOC-EXAMPLE-BUCKET-${aws:PrincipalTag/team, 'company-wide'}"
```

Related terms

- [IAM policy elements: Variables](#)

Error – Unsupported space in variable

In the AWS Management Console, the finding for this check includes the following message:

```
Unsupported space in variable: A space is not supported within the policy variable text. Remove the space.
```

In programmatic calls to the AWS CLI or AWS API, the finding for this check includes the following message:

```
"findingDetails": "A space is not supported within the policy variable text. Remove the space."
```

Resolving the error

Policy variable structure supports using a \$ prefix followed by a pair of curly braces ({ }). Inside the \${ } characters, include the name of the value from the request that you want to use in the policy. Although you can include a space when you specify a default variable, you cannot include a space in the variable name.

Related terms

- [IAM policy elements: Variables](#)

Error – Empty variable

In the AWS Management Console, the finding for this check includes the following message:

Empty variable: Empty policy variable. Remove the `${ }` variable structure or provide a variable within the structure.

In programmatic calls to the AWS CLI or AWS API, the finding for this check includes the following message:

```
"findingDetails": "Empty policy variable. Remove the ${ } variable structure or provide a variable within the structure."
```

Resolving the error

Policy variable structure supports using a `$` prefix followed by a pair of curly braces (`{ }`). Inside the `${ }` characters, include the name of the value from the request that you want to use in the policy.

Related terms

- [IAM policy elements: Variables](#)

Error – Variable unsupported in element

In the AWS Management Console, the finding for this check includes the following message:

```
Variable unsupported in element: Policy variables are supported in the Resource and Condition elements. Remove the policy variable {{variable}} from this element.
```

In programmatic calls to the AWS CLI or AWS API, the finding for this check includes the following message:

```
"findingDetails": "Policy variables are supported in the Resource and Condition elements. Remove the policy variable {{variable}} from this element."
```

Resolving the error

You can use policy variables in the Resource element and in string comparisons in the Condition element.

Related terms

- [IAM policy elements: Variables](#)

Error – Variable unsupported in version

In the AWS Management Console, the finding for this check includes the following message:

```
Variable unsupported in version: To include variables in your policy, use the policy version 2012-10-17 or later.
```

In programmatic calls to the AWS CLI or AWS API, the finding for this check includes the following message:

```
"findingDetails": "To include variables in your policy, use the policy version 2012-10-17 or later."
```

Resolving the error

To use policy variables, you must include the `Version` element and set it to a version that supports policy variables. Variables were introduced in version `2012-10-17`. Earlier versions of the policy language don't support policy variables. If you don't set the `Version` to `2012-10-17` or later, variables like `${aws:username}` are treated as literal strings in the policy.

A `Version` policy element is different from a policy version. The `Version` policy element is used within a policy and defines the version of the policy language. A policy version, is created when you change a customer managed policy in IAM. The changed policy doesn't overwrite the existing policy. Instead, IAM creates a new version of the managed policy.

Related terms

- [IAM policy elements: Variables](#)
- [IAM JSON policy elements: Version](#)

Error – Private IP address

In the AWS Management Console, the finding for this check includes the following message:

```
Private IP address: aws:SourceIp works only for public IP address ranges. The values for condition key aws:SourceIp include only private IP addresses and will not have the desired effect. Update the value to include only public IP addresses.
```

In programmatic calls to the AWS CLI or AWS API, the finding for this check includes the following message:

```
"findingDetails": "aws:SourceIp works only for public IP address ranges. The values for condition key aws:SourceIp include only private IP addresses and will not have the desired effect. Update the value to include only public IP addresses."
```

Resolving the error

The global condition key `aws:SourceIp` works only for public IP address ranges. You receive this error when your policy allows only private IP addresses. In this case, the condition would never match.

- [aws:SourceIp global condition key](#)
- [IAM JSON policy elements: Condition](#)

Error – Private NotIpAddress

In the AWS Management Console, the finding for this check includes the following message:

```
Private NotIpAddress: The values for condition key aws:SourceIp include only private IP addresses and has no effect. aws:SourceIp works only for public IP address ranges. Update the value to include only public IP addresses.
```

In programmatic calls to the AWS CLI or AWS API, the finding for this check includes the following message:

```
"findingDetails": "The values for condition key aws:SourceIp include only private IP addresses and has no effect. aws:SourceIp works only for public IP address ranges. Update the value to include only public IP addresses."
```

Resolving the error

The global condition key `aws:SourceIp` works only for public IP address ranges. You receive this error when you use the `NotIpAddress` condition operator and list only private IP addresses. In this case, the condition would always match and would be ineffective.

- [aws:SourceIp global condition key](#)
- [IAM JSON policy elements: Condition](#)

Error – Policy size exceeds SCP quota

In the AWS Management Console, the finding for this check includes the following message:

```
Policy size exceeds SCP quota: The {{policySize}} characters in the service control policy (SCP) exceed the {{policySizeQuota}} character maximum for SCPs. We recommend that you use multiple granular policies.
```

In programmatic calls to the AWS CLI or AWS API, the finding for this check includes the following message:

```
"findingDetails": "The {{policySize}} characters in the service control policy (SCP) exceed the {{policySizeQuota}} character maximum for SCPs. We recommend that you use multiple granular policies."
```

Resolving the error

AWS Organizations service control policies (SCPs) support specifying values in the Action or NotAction elements. However, these values can include wildcards (*) only at the end of the string. This means that you can specify iam:Get* but not iam:*role.

To specify multiple actions, AWS recommends that you list them individually.

Related terms

- [Quotas for AWS Organizations](#)
- [AWS Organizations service control policies](#)

Error – Invalid service principal format

In the AWS Management Console, the finding for this check includes the following message:

```
Invalid service principal format: The service principal does not match the expected format. Use the format {{expectedFormat}}.
```

In programmatic calls to the AWS CLI or AWS API, the finding for this check includes the following message:

```
"findingDetails": "The service principal does not match the expected format. Use the format {{expectedFormat}}."
```

Resolving the error

The value in the condition key-value pair must match a defined service principal format.

A *service principal* is an identifier that is used to grant permissions to a service. You can specify a service principal in the `Principal` element or as a value for some global condition keys and service-specific keys. The service principal is defined by each service.

The identifier for a service principal includes the service name, and is usually in the following format in all lowercase letters:

```
service-name.amazonaws.com
```

Some service-specific keys may use a different format for service principals. For example, the `kms:ViaService` condition key requires the following format for service principals in all lowercase letters:

```
service-name.AWS_region.amazonaws.com
```

Related terms

- [Service principals](#)
- [AWS global condition keys](#)
- [kms:ViaService condition key](#)

Error – Missing tag key in condition

In the AWS Management Console, the finding for this check includes the following message:

```
Missing tag key in condition: The condition key {{conditionKeyName}} must include a tag key to control access based on tags. Use the format {{conditionKeyName}}tag-key and specify a key name for tag-key.
```

In programmatic calls to the AWS CLI or AWS API, the finding for this check includes the following message:

```
"findingDetails": "The condition key {{conditionKeyName}} must include a tag key to control access based on tags. Use the format {{conditionKeyName}}tag-key and specify a key name for tag-key."
```

Resolving the error

To control access based on tags, you provide tag information in the [condition element](#) of a policy.

For example, to [control access to AWS resources](#), you include the `aws:ResourceTag` condition key. This key requires the format `aws:ResourceTag/tag-key`. To specify the tag key owner and the tag value JaneDoe in a condition, use the following format.

```
"Condition": {
  "StringEquals": {"aws:ResourceTag/owner": "JaneDoe"}
}
```

Related terms

- [Controlling access using tags](#)
- [Conditions](#)
- [Global condition keys](#)
- [AWS service condition keys](#)

Error – Invalid vpc format

In the AWS Management Console, the finding for this check includes the following message:

```
Invalid vpc format: The VPC identifier in the condition key value is not valid. Use the prefix 'vpc-' followed by 8 or 17 alphanumeric characters.
```

In programmatic calls to the AWS CLI or AWS API, the finding for this check includes the following message:

```
"findingDetails": "The VPC identifier in the condition key value is not valid. Use the prefix 'vpc-' followed by 8 or 17 alphanumeric characters."
```

Resolving the error

The `aws:SourceVpc` condition key must use the prefix `vpc-` followed by either 8 or 17 alphanumeric characters, for example, `vpc-11223344556677889` or `vpc-12345678`.

Related terms

- [AWS global condition keys: aws:SourceVpc](#)

Error – Invalid vpce format

In the AWS Management Console, the finding for this check includes the following message:

```
Invalid vpce format: The VPCE identifier in the condition key value is not valid. Use the prefix 'vpce-' followed by 8 or 17 alphanumeric characters.
```

In programmatic calls to the AWS CLI or AWS API, the finding for this check includes the following message:

```
"findingDetails": "The VPCE identifier in the condition key value is not valid. Use the prefix 'vpce-' followed by 8 or 17 alphanumeric characters."
```

Resolving the error

The `aws:SourceVpce` condition key must use the prefix `vpce-` followed by either 8 or 17 alphanumeric characters, for example, `vpce-11223344556677889` or `vpce-12345678`.

Error – Federated principal not supported

In the AWS Management Console, the finding for this check includes the following message:

```
Federated principal not supported: The policy type does not support a federated identity provider in the principal element. Use a supported principal.
```

In programmatic calls to the AWS CLI or AWS API, the finding for this check includes the following message:

```
"findingDetails": "The policy type does not support a federated identity provider in the principal element. Use a supported principal."
```

Resolving the error

The `Principal` element uses federated principals for trust policies attached to IAM roles to provide access through identity federation. Identity policies and other resource-based policies don't support a federated identity provider in the `Principal` element. For example, you can't use a

SAML principal in an Amazon S3 bucket policy. Change the `Principal` element to a supported principal type.

Related terms

- [Creating a role for identity federation](#)

Error – Unsupported action for condition key

In the AWS Management Console, the finding for this check includes the following message:

```
Unsupported action for condition key: The following actions: {{actions}} are not supported by the condition key {{key}}. The condition will not be evaluated for these actions. We recommend that you move these actions to a different statement without this condition key.
```

In programmatic calls to the AWS CLI or AWS API, the finding for this check includes the following message:

```
"findingDetails": "The following actions: {{actions}} are not supported by the condition key {{key}}. The condition will not be evaluated for these actions. We recommend that you move these actions to a different statement without this condition key."
```

Resolving the error

Make sure that the condition key in the `Condition` element of the policy statement applies to every action in the `Action` element. To ensure that the actions you specify are effectively allowed or denied by your policy, you should move the unsupported actions to a different statement without the condition key.

Note

If the `Action` element has actions with wildcards, IAM Access Analyzer doesn't evaluate those actions for this error.

Related terms

- [JSON policy elements: Action](#)

Error – Unsupported action in policy

In the AWS Management Console, the finding for this check includes the following message:

```
Unsupported action in policy: The action {{action}} is not supported for the resource-based policy attached to the resource type {{resourceType}}.
```

In programmatic calls to the AWS CLI or AWS API, the finding for this check includes the following message:

```
"findingDetails": "The action {{action}} is not supported for the resource-based policy attached to the resource type {{resourceType}}."
```

Resolving the error

Some actions aren't supported in the Action element in the resource-based policy attached to a different resource type. For example, AWS Key Management Service actions aren't supported in Amazon S3 bucket policies. Specify an action that is supported by resource type attached to your resource-based policy.

Related terms

- [JSON policy elements: Action](#)

Error – Unsupported resource ARN in policy

In the AWS Management Console, the finding for this check includes the following message:

```
Unsupported resource ARN in policy: The resource ARN is not supported for the resource-based policy attached to the resource type {{resourceType}}.
```

In programmatic calls to the AWS CLI or AWS API, the finding for this check includes the following message:

```
"findingDetails": "The resource ARN is not supported for the resource-based policy attached to the resource type {{resourceType}}."
```

Resolving the error

Some resource ARNs aren't supported in the `Resource` element of the resource-based policy when the policy is attached to a different resource type. For example, AWS KMS ARNs aren't supported in the `Resource` element for Amazon S3 bucket policies. Specify a resource ARN that is supported by a resource type attached to your resource-based policy.

Related terms

- [JSON policy elements: Action](#)

Error – Unsupported condition key for service principal

In the AWS Management Console, the finding for this check includes the following message:

```
Unsupported condition key for service principal: The following condition keys are not supported when used with the service principal: {{conditionKeys}}.
```

In programmatic calls to the AWS CLI or AWS API, the finding for this check includes the following message:

```
"findingDetails": "The following condition keys are not supported when used with the service principal: {{conditionKeys}}."
```

Resolving the error

You can specify AWS services in the `Principal` element of a resource-based policy using a *service principal*, which is an identifier for the service. You can't use some condition keys with certain service principals. For example, you can't use the `aws:PrincipalOrgID` condition key with the service principal `cloudfront.amazonaws.com`. You should remove condition keys that do not apply to the service principal in the `Principal` element.

Related terms

- [Service principals](#)

Error – Role trust policy syntax error notprincipal

In the AWS Management Console, the finding for this check includes the following message:

```
Role trust policy syntax error notprincipal: Role trust policies do not support NotPrincipal. Update the policy to use a Principal element instead.
```

In programmatic calls to the AWS CLI or AWS API, the finding for this check includes the following message:

```
"findingDetails": "Role trust policies do not support NotPrincipal. Update the policy to use a Principal element instead."
```

Resolving the error

A role trust policy is a resource-based policy that is attached to an IAM role. Trust policies define which principal entities (accounts, users, roles, and federated users) can assume the role. Role trust policies do not support `NotPrincipal`. Update the policy to use a `Principal` element instead.

Related terms

- [JSON policy elements: Principal](#)

Error – Role trust policy unsupported wildcard in principal

In the AWS Management Console, the finding for this check includes the following message:

```
Role trust policy unsupported wildcard in principal: "Principal:" "*" is not supported in the principal element of a role trust policy. Replace the wildcard with a valid principal value.
```

In programmatic calls to the AWS CLI or AWS API, the finding for this check includes the following message:

```
"findingDetails": "\"Principal:\" \"*\" is not supported in the principal element of a role trust policy. Replace the wildcard with a valid principal value."
```

Resolving the error

A role trust policy is a resource-based policy that is attached to an IAM role. Trust policies define which principal entities (accounts, users, roles, and federated users) can assume the role.

"Principal:" "*" is not supported in the Principal element of a role trust policy. Replace the wildcard with a valid principal value.

- [JSON policy elements: Principal](#)

Error – Role trust policy syntax error resource

In the AWS Management Console, the finding for this check includes the following message:

```
Role trust policy syntax error resource: Role trust policies apply to the role that they are attached to. You cannot specify a resource. Remove the Resource or NotResource element.
```

In programmatic calls to the AWS CLI or AWS API, the finding for this check includes the following message:

```
"findingDetails": "Role trust policies apply to the role that they are attached to. You cannot specify a resource. Remove the Resource or NotResource element."
```

Resolving the error

A role trust policy is a resource-based policy that is attached to an IAM role. Trust policies define which principal entities (accounts, users, roles, and federated users) can assume the role. Role trust policies apply to the role that they are attached to. You cannot specify a Resource or NotResource element in a role trust policy. Remove the Resource or NotResource element.

- [JSON policy elements: Resource](#)
- [JSON policy elements: NotResource](#)

Error – Type mismatch IP range

In the AWS Management Console, the finding for this check includes the following message:

```
Type mismatch IP range: The condition operator {{operator}} is used with an invalid IP range value. Specify the IP range in standard CIDR format.
```

In programmatic calls to the AWS CLI or AWS API, the finding for this check includes the following message:

```
"findingDetails": "The condition operator {{operator}} is used with an invalid IP range value. Specify the IP range in standard CIDR format."
```

Resolving the error

Update the text to use the IP address condition operator data type, in a CIDR format.

Related terms

- [IP address condition operators](#)

Error – Missing action for condition key

In the AWS Management Console, the finding for this check includes the following message:

```
Missing action for condition key: The {{actionName}} action must be in the action block to allow setting values for the condition key {{keyName}}. Add {{actionName}} to the action block.
```

In programmatic calls to the AWS CLI or AWS API, the finding for this check includes the following message:

```
"findingDetails": "The {{actionName}} action must be in the action block to allow setting values for the condition key {{keyName}}. Add {{actionName}} to the action block."
```

Resolving the error

The condition key in the `Condition` element of the policy statement is not evaluated unless the specified action is in the `Action` element. To ensure that the condition keys you specify are effectively allowed or denied by your policy, add the action to the `Action` element.

Related terms

- [JSON policy elements: Action](#)

Error – Invalid federated principal syntax in role trust policy

In the AWS Management Console, the finding for this check includes the following message:

Invalid federated principal syntax in role trust policy: The principal value specifies a federated principal that does not match the expected format. Update the federated principal to a domain name or a SAML metadata ARN.

In programmatic calls to the AWS CLI or AWS API, the finding for this check includes the following message:

```
"findingDetails": "The principal value specifies a federated principal that does not match the expected format. Update the federated principal to a domain name or a SAML metadata ARN."
```

Resolving the error

The principal value specifies a federated principal that does not match the expected format. Update the format of the federated principal to a valid domain name or a SAML metadata ARN.

Related terms

- [Federated users and roles](#)

Error – Mismatched action for principal

In the AWS Management Console, the finding for this check includes the following message:

```
Mismatched action for principal: The {{actionName}} action is invalid with the following principal(s): {{principalNames}}. Use a SAML provider principal with the sts:AssumeRoleWithSAML action or use an OIDC provider principal with the sts:AssumeRoleWithWebIdentity action. Ensure the provider is Federated if you use either of the two options.
```

In programmatic calls to the AWS CLI or AWS API, the finding for this check includes the following message:

```
"findingDetails": "The {{actionName}} action is invalid with the following principal(s): {{principalNames}}. Use a SAML provider principal with the sts:AssumeRoleWithSAML action or use an OIDC provider principal with the sts:AssumeRoleWithWebIdentity action. Ensure the provider is Federated if you use either of the two options."
```

Resolving the error

The action specified in the Action element of the policy statement is invalid with the principal specified in the Principal element. For example, you can't use a SAML provider principal with the `sts:AssumeRoleWithWebIdentity` action. You should use a SAML provider principal with the `sts:AssumeRoleWithSAML` action or use an OIDC provider principal with the `sts:AssumeRoleWithWebIdentity` action.

Related terms

- [AssumeRoleWithSAML](#)
- [AssumeRoleWithWebIdentity](#)

Error – Missing action for roles anywhere trust policy

In the AWS Management Console, the finding for this check includes the following message:

```
Missing action for roles anywhere trust policy: The rolesanywhere.amazonaws.com service principal requires the sts:AssumeRole, sts:SetSourceIdentity, and sts:TagSession permissions to assume a role. Add the missing permissions to the policy.
```

In programmatic calls to the AWS CLI or AWS API, the finding for this check includes the following message:

```
"findingDetails": "The rolesanywhere.amazonaws.com service principal requires the sts:AssumeRole, sts:SetSourceIdentity, and sts:TagSession permissions to assume a role. Add the missing permissions to the policy."
```

Resolving the error

For IAM Roles Anywhere to be able to assume a role and deliver temporary AWS credentials, the role must trust the IAM Roles Anywhere service principal. The IAM Roles Anywhere service principal requires the `sts:AssumeRole`, `sts:SetSourceIdentity`, and `sts:TagSession` permissions to assume a role. If any of the permissions are missing, you must add them to your policy.

General Warning – Create SLR with star in action and NotResource

In the AWS Management Console, the finding for this check includes the following message:

```
Create SLR with star in action and NotResource: Using an action with a wildcard(*) and NotResource can allow creation of unintended service-linked roles because it can allow iam:CreateServiceLinkedRole permissions on multiple resources. We recommend that you specify resource ARNs instead.
```

In programmatic calls to the AWS CLI or AWS API, the finding for this check includes the following message:

```
"findingDetails": "Using an action with a wildcard(*) and NotResource can allow creation of unintended service-linked roles because it can allow iam:CreateServiceLinkedRole permissions on multiple resources. We recommend that you specify resource ARNs instead."
```

Resolving the general warning

The action `iam:CreateServiceLinkedRole` grants permission to create an IAM role that allows an AWS service to perform actions on your behalf. Policies with a wildcard (*) in the `Action` and that include the `NotResource` element can allow creation of unintended service-linked roles for multiple resources. AWS recommends that you specify allowed ARNs in the `Resource` element instead.

- [CreateServiceLinkedRole operation](#)
- [IAM JSON policy elements: NotResource](#)
- [IAM JSON policy elements: Resource](#)

General Warning – Create SLR with NotAction and NotResource

In the AWS Management Console, the finding for this check includes the following message:

```
Create SLR with NotAction and NotResource: Using NotAction with NotResource can allow creation of unintended service-linked roles because it allows iam:CreateServiceLinkedRole permissions on multiple resources. We recommend that you specify resource ARNs instead.
```

In programmatic calls to the AWS CLI or AWS API, the finding for this check includes the following message:

```
"findingDetails": "Using NotAction with NotResource can allow creation of unintended service-linked roles because it allows iam:CreateServiceLinkedRole permissions on multiple resources. We recommend that you specify resource ARNs instead."
```

Resolving the general warning

The action `iam:CreateServiceLinkedRole` grants permission to create an IAM role that allows an AWS service to perform actions on your behalf. Using the `NotAction` element with the `NotResource` element can allow creating unintended service-linked roles for multiple resources. AWS recommends that you rewrite the policy to allow `iam:CreateServiceLinkedRole` on a limited list of ARNs in the `Resource` element instead. You can also add `iam:CreateServiceLinkedRole` to the `NotAction` element.

General Warning – Create SLR with star in resource

In the AWS Management Console, the finding for this check includes the following message:

```
Create SLR with star in resource: Using the iam:CreateServiceLinkedRole action with wildcards (*) in the resource can allow creation of unintended service-linked roles. We recommend that you specify resource ARNs instead.
```

In programmatic calls to the AWS CLI or AWS API, the finding for this check includes the following message:

```
"findingDetails": "Using the iam:CreateServiceLinkedRole action with wildcards (*) in the resource can allow creation of unintended service-linked roles. We recommend that you specify resource ARNs instead."
```

Resolving the general warning

The action `iam:CreateServiceLinkedRole` grants permission to create an IAM role that allows an AWS service to perform actions on your behalf. Using `iam:CreateServiceLinkedRole` in a policy with a wildcard (*) in the Resource element can allow creating unintended service-linked roles for multiple resources. AWS recommends that you specify allowed ARNs in the Resource element instead.

- [CreateServiceLinkedRole operation](#)
- [IAM JSON policy elements: Resource](#)

AWS managed policies with this general warning

[AWS managed policies](#) enable you to get started with AWS by assigning permissions based on general AWS use cases.

Some of those use cases are for power users within your account. The following AWS managed policies provide power user access and grant permissions to create [service-linked roles](#) for any

AWS service. AWS recommends that you attach the following AWS managed policies to only IAM identities that you consider power users.

- [PowerUserAccess](#)
- [AlexaForBusinessFullAccess](#)
- [AWSOrganizationsServiceTrustPolicy](#) – This AWS managed policy provides permissions for use by the AWS Organizations service-linked role. This role allows Organizations to create additional service-linked roles for other services in your AWS organization.

General Warning – Create SLR with star in action and resource

In the AWS Management Console, the finding for this check includes the following message:

```
Create SLR with star in action and resource: Using wildcards (*) in the action and the resource can allow creation of unintended service-linked roles because it allows iam:CreateServiceLinkedRole permissions on all resources. We recommend that you specify resource ARNs instead.
```

In programmatic calls to the AWS CLI or AWS API, the finding for this check includes the following message:

```
"findingDetails": "Using wildcards (*) in the action and the resource can allow creation of unintended service-linked roles because it allows iam:CreateServiceLinkedRole permissions on all resources. We recommend that you specify resource ARNs instead."
```

Resolving the general warning

The action `iam:CreateServiceLinkedRole` grants permission to create an IAM role that allows an AWS service to perform actions on your behalf. Policies with a wildcard (*) in the Action and Resource elements can allow creating unintended service-linked roles for multiple resources. This allows creating a service-linked role when you specify `"Action": "*" , "Action": "iam:*" , or "Action": "iam:Create*"`. AWS recommends that you specify allowed ARNs in the Resource element instead.

- [CreateServiceLinkedRole operation](#)
- [IAM JSON policy elements: Action](#)
- [IAM JSON policy elements: Resource](#)

AWS managed policies with this general warning

[AWS managed policies](#) enable you to get started with AWS by assigning permissions based on general AWS use cases.

Some of those use cases are for administrators within your account. The following AWS managed policies provide administrator access and grant permissions to create [service-linked roles](#) for any AWS service. AWS recommends that you attach the following AWS managed policies to only the IAM identities that you consider administrators.

- [AdministratorAccess](#)
- [IAMFullAccess](#)

General Warning – Create SLR with star in resource and NotAction

In the AWS Management Console, the finding for this check includes the following message:

```
Create SLR with star in resource and NotAction: Using a resource with wildcards (*) and NotAction can allow creation of unintended service-linked roles because it allows iam:CreateServiceLinkedRole permissions on all resources. We recommend that you specify resource ARNs instead.
```

In programmatic calls to the AWS CLI or AWS API, the finding for this check includes the following message:

```
"findingDetails": "Using a resource with wildcards (*) and NotAction can allow creation of unintended service-linked roles because it allows iam:CreateServiceLinkedRole permissions on all resources. We recommend that you specify resource ARNs instead."
```

Resolving the general warning

The action `iam:CreateServiceLinkedRole` grants permission to create an IAM role that allows an AWS service to perform actions on your behalf. Using the `NotAction` element in a policy with a wildcard (*) in the `Resource` element can allow creating unintended service-linked roles for multiple resources. AWS recommends that you specify allowed ARNs in the `Resource` element instead. You can also add `iam:CreateServiceLinkedRole` to the `NotAction` element.

- [CreateServiceLinkedRole operation](#)
- [IAM JSON policy elements: NotAction](#)

- [IAM JSON policy elements: Action](#)
- [IAM JSON policy elements: Resource](#)

General Warning – Deprecated global condition key

In the AWS Management Console, the finding for this check includes the following message:

```
Deprecated global condition key: We recommend that you update aws:ARN to use the newer condition key aws:PrincipalArn.
```

In programmatic calls to the AWS CLI or AWS API, the finding for this check includes the following message:

```
"findingDetails": "We recommend that you update aws:ARN to use the newer condition key aws:PrincipalArn."
```

Resolving the general warning

The policy includes a deprecated global condition key. Update the condition key in the condition key-value pair to use a supported global condition key.

- [Global condition keys](#)

General Warning – Invalid date value

In the AWS Management Console, the finding for this check includes the following message:

```
Invalid date value: The date {{date}} might not resolve as expected. We recommend that you use the YYYY-MM-DD format.
```

In programmatic calls to the AWS CLI or AWS API, the finding for this check includes the following message:

```
"findingDetails": "The date {{date}} might not resolve as expected. We recommend that you use the YYYY-MM-DD format."
```

Resolving the general warning

Unix Epoch time describes a point in time that has elapsed since January 1, 1970, minus leap seconds. Epoch time might not resolve to the precise time that you expect. AWS recommends that you use the W3C standard for date and time formats. For example, you could specify a complete date, such as YYYY-MM-DD (1997-07-16), or you could also append the time to the second, such as YYYY-MM-DDThh:mm:ssTZD (1997-07-16T19:20:30+01:00).

- [W3C Date and Time Formats](#)
- [IAM JSON policy elements: Version](#)
- [aws:CurrentTime global condition key](#)

General Warning – Invalid role reference

In the AWS Management Console, the finding for this check includes the following message:

```
Invalid role reference: The Principal element includes the IAM role ID {{roleid}}. We recommend that you use a role ARN instead.
```

In programmatic calls to the AWS CLI or AWS API, the finding for this check includes the following message:

```
"findingDetails": "The Principal element includes the IAM role ID {{roleid}}. We recommend that you use a role ARN instead."
```

Resolving the general warning

AWS recommends that you specify the Amazon Resource Name (ARN) for an IAM role instead of its principal ID. When IAM saves the policy, it will transform the ARN into the principal ID for the existing role. AWS includes a safety precaution. If someone deletes and recreates the role, it will have a new ID, and the policy won't match the new role's ID.

- [Specifying a principal: IAM roles](#)
- [IAM ARNs](#)
- [IAM unique IDs](#)

General Warning – Invalid user reference

In the AWS Management Console, the finding for this check includes the following message:

```
Invalid user reference: The Principal element includes the IAM user ID {{userid}}. We recommend that you use a user ARN instead.
```

In programmatic calls to the AWS CLI or AWS API, the finding for this check includes the following message:

```
"findingDetails": "The Principal element includes the IAM user ID {{userid}}. We recommend that you use a user ARN instead."
```

Resolving the general warning

AWS recommends that you specify the Amazon Resource Name (ARN) for an IAM user instead of its principal ID. When IAM saves the policy, it will transform the ARN into the principal ID for the existing user. AWS includes a safety precaution. If someone deletes and recreates the user, it will have a new ID, and the policy won't match the new user's ID.

- [Specifying a principal: IAM users](#)
- [IAM ARNs](#)
- [IAM unique IDs](#)

General Warning – Missing version

In the AWS Management Console, the finding for this check includes the following message:

```
Missing version: We recommend that you specify the Version element to help you with debugging permission issues.
```

In programmatic calls to the AWS CLI or AWS API, the finding for this check includes the following message:

```
"findingDetails": "We recommend that you specify the Version element to help you with debugging permission issues."
```

Resolving the general warning

AWS recommends that you include the optional `Version` parameter in your policy. If you do not include a `Version` element, the value defaults to `2012-10-17`, but newer features, such as policy

variables, will not work with your policy. For example, variables such as `${aws:username}` aren't recognized as variables and are instead treated as literal strings in the policy.

- [IAM JSON policy elements: Version](#)

General Warning – Unique Sids recommended

In the AWS Management Console, the finding for this check includes the following message:

```
Unique Sids recommended: We recommend that you use statement IDs that are unique to your policy. Update the Sid value.
```

In programmatic calls to the AWS CLI or AWS API, the finding for this check includes the following message:

```
"findingDetails": "We recommend that you use statement IDs that are unique to your policy. Update the Sid value."
```

Resolving the general warning

AWS recommends that you use unique statement IDs. The `Sid` (statement ID) element allows you to enter an optional identifier that you provide for the policy statement. You can assign a statement ID value to each statement in a statement array using the `SID` element.

Related terms

- [IAM JSON policy elements: Sid](#)

General Warning – Wildcard without like operator

In the AWS Management Console, the finding for this check includes the following message:

```
Wildcard without like operator: Your condition value includes a * or ? character. If you meant to use a wildcard (*, ?), update the condition operator to include Like.
```

In programmatic calls to the AWS CLI or AWS API, the finding for this check includes the following message:

```
"findingDetails": "Your condition value includes a * or ? character. If you meant to use a wildcard (*, ?), update the condition operator to include Like."
```

Resolving the general warning

The `Condition` element structure requires that you use a condition operator and a key-value pair. When you specify a condition value that uses a wildcard (*, ?), you must use the `Like` version of the condition operator. For example, instead of the `StringEquals` string condition operator, use `StringLike`.

```
"Condition": {"StringLike": {"aws:PrincipalTag/job-category": "admin-*"}}
```

- [IAM JSON policy elements: Condition operators](#)
- [IAM JSON policy elements: Condition](#)

AWS managed policies with this general warning

[AWS managed policies](#) enable you to get started with AWS by assigning permissions based on general AWS use cases.

The following AWS managed policies include wildcards in their condition value without a condition operator that includes `Like` for pattern-matching. When using the AWS managed policy as a reference to create your customer managed policy, AWS recommends that you use a condition operator that supports pattern-matching with wildcards (*, ?), such as `StringLike`.

- [AWSGlueConsoleSageMakerNotebookFullAccess](#)

General Warning – Policy size exceeds identity policy quota

In the AWS Management Console, the finding for this check includes the following message:

```
Policy size exceeds identity policy quota: The {{policySize}} characters in the identity policy, excluding whitespace, exceed the {{policySizeQuota}} character maximum for inline and managed policies. We recommend that you use multiple granular policies.
```

In programmatic calls to the AWS CLI or AWS API, the finding for this check includes the following message:

```
"findingDetails": "The {{policySize}} characters in the identity policy, excluding whitespace, exceed the {{policySizeQuota}} character maximum for inline and managed policies. We recommend that you use multiple granular policies."
```

Resolving the general warning

You can attach up to 10 managed policies to an IAM identity (user, group of users, or role). However, the size of each managed policy cannot exceed the default quota of 6,144 characters. IAM does not count white space when calculating the size of a policy against this quota. Quotas, also referred to as limits in AWS, are the maximum values for the resources, actions, and items in your AWS account.

Additionally, you can add as many inline policies as you want to an IAM identity. However, the sum size of all inline policies per identity cannot exceed the specified quota.

If your policy is larger than the quota, you can organize your policy into multiple statements and group the statements into multiple policies.

AWS managed policies with this general warning

[AWS managed policies](#) enable you to get started with AWS by assigning permissions based on general AWS use cases.

The following AWS managed policies grant permissions to actions across many AWS services and exceed the maximum policy size. When using the AWS managed policy as a reference to create your managed policy, you must split the policy into multiple policies.

- [ReadOnlyAccess](#)
- [AWSSupportServiceRolePolicy](#)

General Warning – Policy size exceeds resource policy quota

In the AWS Management Console, the finding for this check includes the following message:

Policy size exceeds resource policy quota: The `{{policySize}}` characters in the resource policy exceed the `{{policySizeQuota}}` character maximum for resource policies. We recommend that you use multiple granular policies.

In programmatic calls to the AWS CLI or AWS API, the finding for this check includes the following message:

```
"findingDetails": "The {{policySize}} characters in the resource policy exceed the {{policySizeQuota}} character maximum for resource policies. We recommend that you use multiple granular policies."
```

Resolving the general warning

Resource-based policies are JSON policy documents that you attach to a resource, such as an Amazon S3 bucket. These policies grant the specified principal permission to perform specific actions on that resource and define under what conditions this applies. The size of resource-based policies cannot exceed the quota set for that resource. Quotas, also referred to as limits in AWS, are the maximum values for the resources, actions, and items in your AWS account.

If your policy is larger than the quota, you can organize your policy into multiple statements and group the statements into multiple policies.

Related terms

General Warning – Type mismatch

In the AWS Management Console, the finding for this check includes the following message:

```
Type mismatch: Use the operator type {{allowed}} instead of operator {{operator}} for the condition key {{key}}.
```

In programmatic calls to the AWS CLI or AWS API, the finding for this check includes the following message:

```
"findingDetails": "Use the operator type {{allowed}} instead of operator {{operator}} for the condition key {{key}}."
```

Resolving the general warning

Update the text to use the supported condition operator data type.

For example, the `aws:MultiFactorAuthPresent` global condition key requires a condition operator with the Boolean data type. If you provide a date or an integer, the data type won't match.

Related terms

- [Global condition keys](#)
- [IAM JSON policy elements: Condition operators](#)

General Warning – Type mismatch Boolean

In the AWS Management Console, the finding for this check includes the following message:

```
Type mismatch Boolean: Add a valid Boolean value (true or false) for the condition operator {{operator}}.
```

In programmatic calls to the AWS CLI or AWS API, the finding for this check includes the following message:

```
"findingDetails": "Add a valid Boolean value (true or false) for the condition operator {{operator}}."
```

Resolving the general warning

Update the text to use a Boolean condition operator data type, such as `true` or `false`.

For example, the `aws:MultiFactorAuthPresent` global condition key requires a condition operator with the Boolean data type. If you provide a date or an integer, the data type won't match.

Related terms

- [Boolean condition operators](#)
- [IAM JSON policy elements: Condition operators](#)

General Warning – Type mismatch date

In the AWS Management Console, the finding for this check includes the following message:

```
Type mismatch date: The date condition operator is used with an invalid value. Specify a valid date using YYYY-MM-DD or other ISO 8601 date/time format.
```

In programmatic calls to the AWS CLI or AWS API, the finding for this check includes the following message:

```
"findingDetails": "The date condition operator is used with an invalid value. Specify a valid date using YYYY-MM-DD or other ISO 8601 date/time format."
```

Resolving the general warning

Update the text to use the date condition operator data type, in a YYYY-MM-DD or other ISO 8601 date time format.

Related terms

- [Date condition operators](#)
- [IAM JSON policy elements: Condition operators](#)

General Warning – Type mismatch number

In the AWS Management Console, the finding for this check includes the following message:

```
Type mismatch number: Add a valid numeric value for the condition operator {{operator}}.
```

In programmatic calls to the AWS CLI or AWS API, the finding for this check includes the following message:

```
"findingDetails": "Add a valid numeric value for the condition operator {{operator}}."
```

Resolving the general warning

Update the text to use the numeric condition operator data type.

Related terms

- [Numeric condition operators](#)
- [IAM JSON policy elements: Condition operators](#)

General Warning – Type mismatch string

In the AWS Management Console, the finding for this check includes the following message:

```
Type mismatch string: Add a valid base64-encoded string value for the condition operator {{operator}}.
```

In programmatic calls to the AWS CLI or AWS API, the finding for this check includes the following message:

```
"findingDetails": "Add a valid base64-encoded string value for the condition operator {{operator}}."
```

Resolving the general warning

Update the text to use the string condition operator data type.

Related terms

- [String condition operators](#)

General Warning – Specific github repo and branch recommended

In the AWS Management Console, the finding for this check includes the following message:

```
Specific github repo and branch recommended: Using a wildcard (*) in token.actions.githubusercontent.com:sub can allow requests from more sources than you intended. Specify the value of token.actions.githubusercontent.com:sub with the repository and branch name.
```

In programmatic calls to the AWS CLI or AWS API, the finding for this check includes the following message:

```
"findingDetails": "Using a wildcard (*) in token.actions.githubusercontent.com:sub can allow requests from more sources than you intended. Specify the value of token.actions.githubusercontent.com:sub with the repository and branch name."
```

Resolving the general warning

If you use GitHub as an OIDC IdP, best practice is to limit the entities that can assume the role associated with the IAM IdP. When you include a Condition statement in a role trust policy, you can limit the role to a specific GitHub organization, repository, or branch. You can use the condition key `token.actions.githubusercontent.com:sub` to limit access. We recommend that you limit the condition to a specific set of repositories or branches. If you use a wildcard (*) in `token.actions.githubusercontent.com:sub`, then GitHub Actions from organizations or repositories outside of your control are able to assume roles associated with the GitHub IAM IdP in your AWS account.

Related terms

- [Configuring a role for GitHub OIDC identity provider](#)

General Warning – Policy size exceeds role trust policy quota

In the AWS Management Console, the finding for this check includes the following message:

```
Policy size exceeds role trust policy quota: The characters in the role trust policy, excluding whitespace, exceed the character maximum. We recommend that you request a role trust policy length quota increase using Service Quotas and AWS Support Center. If the quotas have already been increased, then you can ignore this warning.
```

In programmatic calls to the AWS CLI or AWS API, the finding for this check includes the following message:

```
"findingDetails": "The characters in the role trust policy, excluding whitespace, exceed the character maximum. We recommend that you request a role trust policy length quota increase using Service Quotas and AWS Support Center. If the quotas have already been increased, then you can ignore this warning."
```

Resolving the general warning

IAM and AWS STS have quotas that limit the size of role trust policies. The characters in the role trust policy, excluding whitespace, exceed the character maximum. We recommend that you request a role trust policy length quota increase using Service Quotas and the AWS Support Center Console.

Related terms

- [IAM and AWS STS quotas, name requirements, and character limits](#)

Security Warning – Allow with NotPrincipal

In the AWS Management Console, the finding for this check includes the following message:

```
Allow with NotPrincipal: Using Allow with NotPrincipal can be overly permissive. We recommend that you use Principal instead.
```

In programmatic calls to the AWS CLI or AWS API, the finding for this check includes the following message:

```
"findingDetails": "Using Allow with NotPrincipal can be overly permissive. We recommend that you use Principal instead."
```

Resolving the security warning

Using "Effect": "Allow" with the NotPrincipal can be overly permissive. For example, this can grant permissions to anonymous principals. AWS recommends that you specify principals that need access using the Principal element. Alternatively, you can allow broad access and then add another statement that uses the NotPrincipal element with "Effect": "Deny".

- [AWS JSON policy elements: Principal](#)
- [AWS JSON policy elements: NotPrincipal](#)

Security Warning – ForAllValues with single valued key

In the AWS Management Console, the finding for this check includes the following message:

```
ForAllValues with single valued key: Using ForAllValues qualifier with the single-valued condition key {{key}} can be overly permissive. We recommend that you remove ForAllValues:.
```

In programmatic calls to the AWS CLI or AWS API, the finding for this check includes the following message:

```
"findingDetails": "Using ForAllValues qualifier with the single-valued condition key {{key}} can be overly permissive. We recommend that you remove ForAllValues:."
```

Resolving the security warning

AWS recommends that you use the `ForAllValues` only with multivalued conditions. The `ForAllValues` set operator tests whether the value of every member of the request set is a subset of the condition key set. The condition returns true if every key value in the request matches at least one value in the policy. It also returns true if there are no keys in the request, or if the key values resolve to a null data set, such as an empty string.

To learn whether a condition supports a single value or multiple values, review the [Actions, resources, and condition keys](#) page for the service. Condition keys with the `ArrayOf` data type prefix are multivalued condition keys. For example, Amazon SES supports keys with single values (`String`) and the `ArrayOfString` multivalued data type.

- [Multivalued context keys](#)

Security Warning – Pass role with `NotResource`

In the AWS Management Console, the finding for this check includes the following message:

```
Pass role with NotResource: Using the iam:PassRole action with NotResource can be overly permissive because it can allow iam:PassRole permissions on multiple resources. We recommend that you specify resource ARNs instead.
```

In programmatic calls to the AWS CLI or AWS API, the finding for this check includes the following message:

```
"findingDetails": "Using the iam:PassRole action with NotResource can be overly permissive because it can allow iam:PassRole permissions on multiple resources. We recommend that you specify resource ARNs instead."
```

Resolving the security warning

To configure many AWS services, you must pass an IAM role to the service. To allow this you must grant the `iam:PassRole` permission to an identity (user, group of users, or role). Using

`iam:PassRole` in a policy with the `NotResource` element can allow your principals to access more services or features than you intended. AWS recommends that you specify allowed ARNs in the `Resource` element instead. Additionally, you can reduce permissions to a single service by using the `iam:PassedToService` condition key.

- [Passing a role to a service](#)
- [iam:PassedToService](#)
- [IAM JSON policy elements: NotResource](#)
- [IAM JSON policy elements: Resource](#)

Security Warning – Pass role with star in action and NotResource

In the AWS Management Console, the finding for this check includes the following message:

```
Pass role with star in action and NotResource: Using an action with a wildcard (*) and NotResource can be overly permissive because it can allow iam:PassRole permissions on multiple resources. We recommend that you specify resource ARNs instead.
```

In programmatic calls to the AWS CLI or AWS API, the finding for this check includes the following message:

```
"findingDetails": "Using an action with a wildcard (*) and NotResource can be overly permissive because it can allow iam:PassRole permissions on multiple resources. We recommend that you specify resource ARNs instead."
```

Resolving the security warning

To configure many AWS services, you must pass an IAM role to the service. To allow this you must grant the `iam:PassRole` permission to an identity (user, group of users, or role). Policies with a wildcard (*) in the `Action` and that include the `NotResource` element can allow your principals to access more services or features than you intended. AWS recommends that you specify allowed ARNs in the `Resource` element instead. Additionally, you can reduce permissions to a single service by using the `iam:PassedToService` condition key.

- [Passing a role to a service](#)
- [iam:PassedToService](#)

- [IAM JSON policy elements: Resource](#)

Security Warning – Pass role with NotAction and NotResource

In the AWS Management Console, the finding for this check includes the following message:

```
Pass role with NotAction and NotResource: Using NotAction with NotResource can be overly permissive because it can allow iam:PassRole permissions on multiple resources.. We recommend that you specify resource ARNs instead.
```

In programmatic calls to the AWS CLI or AWS API, the finding for this check includes the following message:

```
"findingDetails": "Using NotAction with NotResource can be overly permissive because it can allow iam:PassRole permissions on multiple resources.. We recommend that you specify resource ARNs instead."
```

Resolving the security warning

To configure many AWS services, you must pass an IAM role to the service. To allow this you must grant the `iam:PassRole` permission to an identity (user, group of users, or role). Using the `NotAction` element and listing some resources in the `NotResource` element can allow your principals to access more services or features than you intended. AWS recommends that you specify allowed ARNs in the `Resource` element instead. Additionally, you can reduce permissions to a single service by using the `iam:PassedToService` condition key.

- [Passing a role to a service](#)
- [iam:PassedToService](#)
- [IAM JSON policy elements: NotAction](#)
- [IAM JSON policy elements: Action](#)
- [IAM JSON policy elements: NotResource](#)
- [IAM JSON policy elements: Resource](#)

Security Warning – Pass role with star in resource

In the AWS Management Console, the finding for this check includes the following message:

Pass role with star in resource: Using the `iam:PassRole` action with wildcards (*) in the resource can be overly permissive because it allows `iam:PassRole` permissions on multiple resources. We recommend that you specify resource ARNs or add the `iam:PassedToService` condition key to your statement.

In programmatic calls to the AWS CLI or AWS API, the finding for this check includes the following message:

```
"findingDetails": "Using the iam:PassRole action with wildcards (*) in the resource can be overly permissive because it allows iam:PassRole permissions on multiple resources. We recommend that you specify resource ARNs or add the iam:PassedToService condition key to your statement."
```

Resolving the security warning

To configure many AWS services, you must pass an IAM role to the service. To allow this you must grant the `iam:PassRole` permission to an identity (user, group of users, or role). Policies that allow `iam:PassRole` and that include a wildcard (*) in the Resource element can allow your principals to access more services or features than you intended. AWS recommends that you specify allowed ARNs in the Resource element instead. Additionally, you can reduce permissions to a single service by using the `iam:PassedToService` condition key.

Some AWS services include their service namespace in the name of their role. This policy check takes these conventions into account while analyzing the policy to generate findings. For example, the following resource ARN might not generate a finding:

```
arn:aws:iam::*:role/Service*
```

- [Passing a role to a service](#)
- [iam:PassedToService](#)
- [IAM JSON policy elements: Resource](#)

AWS managed policies with this security warning

[AWS managed policies](#) enable you to get started with AWS by assigning permissions based on general AWS use cases.

One of those use cases is for administrators within your account. The following AWS managed policies provide administrator access and grant permissions to pass any IAM role to any service.

AWS recommends that you attach the following AWS managed policies only to IAM identities that you consider administrators.

- [AdministratorAccess-Amplify](#)

The following AWS managed policies include permissions to `iam:PassRole` with a wildcard (*) in the resource and are on a [deprecation path](#). For each of these policies, we updated the permission guidance, such as recommending a new AWS managed policy that supports the use case. To view alternatives to these policies, see the guides for [each service](#).

- [IAM JSON policy elements: Resource](#)

Security Warning – Missing paired condition keys

In the AWS Management Console, the finding for this check includes the following message:

```
Missing paired condition keys: Using the condition key {{conditionKeyName}} can be overly permissive without also using the following condition keys: {{recommendedKeys}}. Condition keys like this one are more secure when paired with
```

a related key. We recommend that you add the related condition keys to the same condition block.

In programmatic calls to the AWS CLI or AWS API, the finding for this check includes the following message:

```
"findingDetails": "Using the condition key {{conditionKeyName}} can be overly permissive without also using the following condition keys: {{recommendedKeys}}. Condition keys like this one are more secure when paired with a related key. We recommend that you add the related condition keys to the same condition block."
```

Resolving the security warning

Some condition keys are more secure when paired with other related condition keys. AWS recommends that you include the related condition keys in the same condition block as the existing condition key. This makes the permissions granted through the policy more secure.

For example, you can use the `aws:VpcSourceIp` condition key to compare the IP address from which a request was made with the IP address that you specify in the policy. AWS recommends that you add the related `aws:SourceVPC` condition key. This checks whether the request comes from the VPC that you specify in the policy *and* the IP address that you specify.

Related terms

- [aws:VpcSourceIp global condition key](#)
- [aws:SourceVPC global condition key](#)

Security Warning – Deny with unsupported tag condition key for service

In the AWS Management Console, the finding for this check includes the following message:

```
Deny with unsupported tag condition key for service: Using the effect Deny with the tag condition key {{conditionKeyName}} and actions for services with the following prefixes can be overly permissive: {{serviceNames}}. Actions for the listed services are not denied by this statement. We recommend that you move these actions to a different statement without this condition key.
```

In programmatic calls to the AWS CLI or AWS API, the finding for this check includes the following message:

```
"findingDetails": "Using the effect Deny with the tag condition key  
{{conditionKeyName}} and actions for services with the following prefixes can be  
overly permissive: {{serviceNames}}. Actions for the listed services are not denied  
by this statement. We recommend that you move these actions to a different statement  
without this condition key."
```

Resolving the security warning

Using unsupported tag condition keys in the `Condition` element of a policy with `"Effect": "Deny"` can be overly permissive, because the condition is ignored for that service. AWS recommends that you remove the service actions that don't support the condition key and create another statement to deny access to specific resources for those actions.

If you use the `aws:ResourceTag` condition key and it's not supported by a service action, then the key is not included in the request context. In this case, the condition in the Deny statement always returns `false` and the action is never denied. This happens even if the resource is tagged correctly.

When a service supports the `aws:ResourceTag` condition key, you can use tags to control access to that service's resources. This is known as [attribute-based access control \(ABAC\)](#). Services that don't support these keys require you to control access to resources using [resource-based access control \(RBAC\)](#).

Note

Some services allow support for the `aws:ResourceTag` condition key for a subset of their resources and actions. IAM Access Analyzer returns findings for the service actions that are not supported. For example, Amazon S3 supports `aws:ResourceTag` for a subset of its resources. To view all of the resource types available in Amazon S3 that support the `aws:ResourceTag` condition key, see [Resource types defined by Amazon S3](#) in the Service Authorization Reference.

For example, assume that you want to deny access to untag delete specific resources that are tagged with the key-value pair `status=Confidential`. Also assume that AWS Lambda allows you to tag and untag resources, but doesn't support the `aws:ResourceTag` condition key.

To deny the delete actions for AWS App Mesh and AWS Backup if this tag is present, use the `aws:ResourceTag` condition key. For Lambda, use a resource naming convention that includes the "Confidential" prefix. Then include a separate statement that prevents deleting resources with that naming convention.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "DenyDeleteSupported",
      "Effect": "Deny",
      "Action": [
        "appmesh:DeleteMesh",
        "backup:DeleteBackupPlan"
      ],
      "Resource": "*",
      "Condition": {
        "StringEquals": {
          "aws:ResourceTag/status": "Confidential"
        }
      }
    },
    {
      "Sid": "DenyDeleteUnsupported",
      "Effect": "Deny",
      "Action": "lambda:DeleteFunction",
      "Resource": "arn:aws:lambda:*:123456789012:function:status-Confidential*"
    }
  ]
}
```

Warning

Do not use the [...IfExists](#) version of the condition operator as a workaround for this finding. This means "Deny the action if the key is present in the request context and the values match. Otherwise, deny the action." In the previous example, including the `lambda:DeleteFunction` action in the `DenyDeleteSupported` statement with the `StringEqualsIfExists` operator always denies the action. For that action, the key is not present in the context, and every attempt to delete that resource type is denied, regardless of whether the resource is tagged.

Related terms

Security Warning – Deny NotAction with unsupported tag condition key for service

In the AWS Management Console, the finding for this check includes the following message:

```
Deny NotAction with unsupported tag condition key for service: Using the effect Deny with NotAction and the tag condition key {{conditionKeyName}} can be overly permissive because some service actions are not denied by this statement. This is because the condition key doesn't apply to some service actions. We recommend that you use Action instead of NotAction.
```

In programmatic calls to the AWS CLI or AWS API, the finding for this check includes the following message:

```
"findingDetails": "Using the effect Deny with NotAction and the tag condition key {{conditionKeyName}} can be overly permissive because some service actions are not denied by this statement. This is because the condition key doesn't apply to some service actions. We recommend that you use Action instead of NotAction."
```

Resolving the security warning

Using tag condition keys in the Condition element of a policy with the element NotAction and "Effect": "Deny" can be overly permissive. The condition is ignored for service actions that don't support the condition key. AWS recommends that you rewrite the logic to deny a list of actions.

If you use the `aws:ResourceTag` condition key with NotAction, any new or existing service actions that don't support the key are not denied. AWS recommends that you explicitly list the actions that you want to deny. IAM Access Analyzer returns a separate finding for listed actions that don't support the `aws:ResourceTag` condition key. For more information, see [Security Warning – Deny with unsupported tag condition key for service](#).

When a service supports the `aws:ResourceTag` condition key, you can use tags to control access to that service's resources. This is known as [attribute-based access control \(ABAC\)](#). Services that don't support these keys require you to control access to resources using [resource-based access control \(RBAC\)](#).

Related terms

- [Overview of JSON policies](#)

Security Warning – Restrict access to service principal

In the AWS Management Console, the finding for this check includes the following message:

```
Restrict access to service principal: Granting access to a service principal without specifying a source is overly permissive. Use aws:SourceArn, aws:SourceAccount, aws:SourceOrgID, or aws:SourceOrgPaths condition key to grant fine-grained access.
```

In programmatic calls to the AWS CLI or AWS API, the finding for this check includes the following message:

```
"findingDetails": "Granting access to a service principal without specifying a source is overly permissive. Use aws:SourceArn, aws:SourceAccount, aws:SourceOrgID, or aws:SourceOrgPaths condition key to grant fine-grained access."
```

Resolving the security warning

You can specify AWS services in the `Principal` element of a resource-based policy using a service principal, which is an identifier for the service. When granting access to a service principal to act on your behalf, restrict access. You can prevent overly permissive policies by using the `aws:SourceArn`, `aws:SourceAccount`, `aws:SourceOrgID`, or `aws:SourceOrgPaths` condition keys to restrict access to a specific source, such as a specific resource ARN, AWS account, organization ID, or organization paths. Restricting access helps you prevent a security issue called *the confused deputy problem*.

Security Warning – Missing condition key for oidc principal

In the AWS Management Console, the finding for this check includes the following message:

```
Missing condition key for oidc principal: Using an Open ID Connect principal without a condition can be overly permissive. Add condition keys with a prefix that matches your federated OIDC principals to ensure that only the intended identity provider assumes the role.
```

In programmatic calls to the AWS CLI or AWS API, the finding for this check includes the following message:

```
"findingDetails": "Using an Open ID Connect principal without a condition can be overly permissive. Add condition keys with a prefix that matches your federated OIDC principals to ensure that only the intended identity provider assumes the role."
```

Resolving the security warning

Using an Open ID Connect principal without a condition can be overly permissive. Add condition keys with a prefix that matches your federated OIDC principals to ensure that only the intended identity provider assumes the role.

Related terms

- [Creating a role for web identity or OpenID Connect Federation \(console\)](#)

Security Warning – Missing github repo condition key

In the AWS Management Console, the finding for this check includes the following message:

Missing github repo condition key: Granting a federated GitHub principal permissions without a condition key can allow more sources to assume the role than you intended. Add the `token.actions.githubusercontent.com:sub` condition key and specify the branch and repository name in the value.

In programmatic calls to the AWS CLI or AWS API, the finding for this check includes the following message:

```
"findingDetails": "Granting a federated GitHub principal permissions without a condition key can allow more sources to assume the role than you intended. Add the token.actions.githubusercontent.com:sub condition key and specify the branch and repository name in the value."
```

Resolving the security warning

If you use GitHub as an OIDC IdP, best practice is to limit the entities that can assume the role associated with the IAM IdP. When you include a `Condition` statement in a role trust policy, you can limit the role to a specific GitHub organization, repository, or branch. You can use the condition key `token.actions.githubusercontent.com:sub` to limit access. We recommend that you limit the condition to a specific set of repositories or branches. If you do not include this condition, then GitHub Actions from organizations or repositories outside of your control are able to assume roles associated with the GitHub IAM IdP in your AWS account.

Related terms

Suggestion – Empty array action

In the AWS Management Console, the finding for this check includes the following message:

```
Empty array action: This statement includes no actions and does not affect the policy. Specify actions.
```

In programmatic calls to the AWS CLI or AWS API, the finding for this check includes the following message:

```
"findingDetails": "This statement includes no actions and does not affect the policy. Specify actions."
```

Resolving the suggestion

Statements must include either an `Action` or `NotAction` element that includes a set of actions. When the element is empty, the policy statement provides no permissions. Specify actions in the `Action` element.

- [IAM JSON policy elements: Action](#)

Suggestion – Empty array condition

In the AWS Management Console, the finding for this check includes the following message:

```
Empty array condition: There are no values for the condition key {{key}} and it does not affect the policy. Specify conditions.
```

In programmatic calls to the AWS CLI or AWS API, the finding for this check includes the following message:

```
"findingDetails": "There are no values for the condition key {{key}} and it does not affect the policy. Specify conditions."
```

Resolving the suggestion

The optional `Condition` element structure requires that you use a condition operator and a key-value pair. When the condition value is empty, the condition returns `true` and the policy statement provides no permissions. Specify a condition value.

- [IAM JSON policy elements: Condition](#)

Suggestion – Empty array condition ForAllValues

In the AWS Management Console, the finding for this check includes the following message:

```
Empty array condition ForAllValues: The ForAllValues prefix with an empty condition key matches only if the key {{key}} is missing from the request context. To determine if the request context is empty, we recommend that you use the Null condition operator with the value of true instead.
```

In programmatic calls to the AWS CLI or AWS API, the finding for this check includes the following message:

```
"findingDetails": "The ForAllValues prefix with an empty condition key matches only if the key {{key}} is missing from the request context. To determine if the request context is empty, we recommend that you use the Null condition operator with the value of true instead."
```

Resolving the suggestion

The `Condition` element structure requires that you use a condition operator and a key-value pair. The `ForAllValues` set operator tests whether the value of every member of the request set is a subset of the condition key set.

When you use `ForAllValues` with an empty condition key, the condition matches only if there are no keys in the request. AWS recommends that if you want to test whether a request context is empty, use the `Null` condition operator instead.

- [Multivalued context keys](#)
- [Null condition operator](#)
- [IAM JSON policy elements: Condition](#)

Suggestion – Empty array condition `ForAnyValue`

In the AWS Management Console, the finding for this check includes the following message:

```
Empty array condition ForAnyValue: The ForAnyValue prefix with an empty condition key {{key}} never matches the request context and it does not affect the policy. Specify conditions.
```

In programmatic calls to the AWS CLI or AWS API, the finding for this check includes the following message:

```
"findingDetails": "The ForAnyValue prefix with an empty condition key {{key}} never matches the request context and it does not affect the policy. Specify conditions."
```

Resolving the suggestion

The `Condition` element structure requires that you use a condition operator and a key-value pair. The `ForAnyValues` set operator tests whether at least one member of the set of request values matches at least one member of the set of condition key values.

When you use `ForAnyValues` with an empty condition key, the condition never matches. This means that the statement has no effect on the policy. AWS recommends that you rewrite the condition.

- [Multivalued context keys](#)
- [IAM JSON policy elements: Condition](#)

Suggestion – Empty array condition `IfExists`

In the AWS Management Console, the finding for this check includes the following message:

```
Empty array condition IfExists: The IfExists suffix with an empty condition key matches only if the key {{key}} is missing from the request context. To determine if the request context is empty, we recommend that you use the Null condition operator with the value of true instead.
```

In programmatic calls to the AWS CLI or AWS API, the finding for this check includes the following message:

```
"findingDetails": "The IfExists suffix with an empty condition key matches only if the key {{key}} is missing from the request context. To determine if the request context is empty, we recommend that you use the Null condition operator with the value of true instead."
```

Resolving the suggestion

The `...IfExists` suffix edits a condition operator. It means that if the policy key is present in the context of the request, process the key as specified in the policy. If the key is not present, evaluate the condition element as true.

When you use `...IfExists` with an empty condition key, the condition matches only if there are no keys in the request. AWS recommends that if you want to test whether a request context is empty, use the `Null` condition operator instead.

- [...IfExists condition operators](#)
- [IAM JSON policy elements: Condition](#)

Suggestion – Empty array principal

In the AWS Management Console, the finding for this check includes the following message:

```
Empty array principal: This statement includes no principals and does not affect the policy. Specify principals.
```

In programmatic calls to the AWS CLI or AWS API, the finding for this check includes the following message:

```
"findingDetails": "This statement includes no principals and does not affect the policy. Specify principals."
```

Resolving the suggestion

You must use the `Principal` or `NotPrincipal` element in the trust policies for IAM roles and in resource-based policies. Resource-based policies are policies that you embed directly in a resource.

When you provide an empty array in a statement's `Principal` element, the statement has no effect on the policy. AWS recommends that you specify the principals that should have access to the resource.

- [IAM JSON policy elements: Principal](#)
- [IAM JSON policy elements: NotPrincipal](#)

Suggestion – Empty array resource

In the AWS Management Console, the finding for this check includes the following message:

```
Empty array resource: This statement includes no resources and does not affect the policy. Specify resources.
```

In programmatic calls to the AWS CLI or AWS API, the finding for this check includes the following message:

```
"findingDetails": "This statement includes no resources and does not affect the policy. Specify resources."
```

Resolving the suggestion

Statements must include either a Resource or a NotResource element.

When you provide an empty array in a statement's resource element, the statement has no effect on the policy. AWS recommends that you specify Amazon Resource Names (ARNs) for resources.

- [IAM JSON policy elements: Resource](#)
- [IAM JSON policy elements: NotResource](#)

Suggestion – Empty object condition

In the AWS Management Console, the finding for this check includes the following message:

```
Empty object condition: This condition block is empty and it does not affect the policy. Specify conditions.
```

In programmatic calls to the AWS CLI or AWS API, the finding for this check includes the following message:

```
"findingDetails": "This condition block is empty and it does not affect the policy. Specify conditions."
```

Resolving the suggestion

The Condition element structure requires that you use a condition operator and a key-value pair.

When you provide an empty object in a statement's condition element, the statement has no effect on the policy. Remove the optional element or specify conditions.

- [IAM JSON policy elements: Condition](#)

Suggestion – Empty object principal

In the AWS Management Console, the finding for this check includes the following message:

```
Empty object principal: This statement includes no principals and does not affect the policy. Specify principals.
```

In programmatic calls to the AWS CLI or AWS API, the finding for this check includes the following message:

```
"findingDetails": "This statement includes no principals and does not affect the policy. Specify principals."
```

Resolving the suggestion

You must use the `Principal` or `NotPrincipal` element in the trust policies for IAM roles and in resource-based policies. Resource-based policies are policies that you embed directly in a resource.

When you provide an empty object in a statement's `Principal` element, the statement has no effect on the policy. AWS recommends that you specify the principals that should have access to the resource.

- [IAM JSON policy elements: Principal](#)
- [IAM JSON policy elements: NotPrincipal](#)

Suggestion – Empty Sid value

In the AWS Management Console, the finding for this check includes the following message:

```
Empty Sid value: Add a value to the empty string in the Sid element.
```

In programmatic calls to the AWS CLI or AWS API, the finding for this check includes the following message:

```
"findingDetails": "Add a value to the empty string in the Sid element."
```

Resolving the suggestion

The optional `Sid` (statement ID) element allows you to enter an identifier that you provide for the policy statement. You can assign an `Sid` value to each statement in a statement array. If you choose to use the `Sid` element, you must provide a string value.

Related terms

- [IAM JSON policy elements: Sid](#)

Suggestion – Improve IP range

In the AWS Management Console, the finding for this check includes the following message:

```
Improve IP range: The non-zero bits in the IP address after the masked bits are ignored. Replace address with {{addr}}.
```

In programmatic calls to the AWS CLI or AWS API, the finding for this check includes the following message:

```
"findingDetails": "The non-zero bits in the IP address after the masked bits are ignored. Replace address with {{addr}}."
```

Resolving the suggestion

IP address conditions must be in the standard CIDR format, such as 203.0.113.0/24 or 2001:DB8:1234:5678::/64. When you include non-zero bits after the masked bits, they are not considered for the condition. AWS recommends that you use the new address included in the message.

- [IP address condition operators](#)
- [IAM JSON policy elements: Condition](#)

Suggestion – Null with qualifier

In the AWS Management Console, the finding for this check includes the following message:

```
Null with qualifier: Avoid using the Null condition operator with the ForAllValues or ForAnyValue qualifiers because they always return a true or false respectively.
```

In programmatic calls to the AWS CLI or AWS API, the finding for this check includes the following message:

```
"findingDetails": "Avoid using the Null condition operator with the ForAllValues or ForAnyValue qualifiers because they always return a true or false respectively."
```

Resolving the suggestion

In the Condition element, you build expressions in which you use condition operators like equal or less than to compare a condition in the policy against keys and values in the request context. For requests that include multiple values for a single condition key, you must use the ForAllValues or ForAnyValue set operators.

When you use the `Null` condition operator with `ForAllValues`, the statement always returns `true`. When you use the `Null` condition operator with `ForAnyValue`, the statement always returns `false`. AWS recommends that you use the `StringLike` condition operator with these set operators.

Related terms

- [Multivalued context keys](#)
- [Null condition operator](#)
- [Condition element](#)

Suggestion – Private IP address subset

In the AWS Management Console, the finding for this check includes the following message:

```
Private IP address subset: The values for condition key aws:SourceIp include a mix of private and public IP addresses. The private addresses will not have the desired effect. aws:SourceIp works only for public IP address ranges. To define permissions for private IP ranges, use aws:VpcSourceIp.
```

In programmatic calls to the AWS CLI or AWS API, the finding for this check includes the following message:

```
"findingDetails": "The values for condition key aws:SourceIp include a mix of private and public IP addresses. The private addresses will not have the desired effect. aws:SourceIp works only for public IP address ranges. To define permissions for private IP ranges, use aws:VpcSourceIp."
```

Resolving the suggestion

The global condition key `aws:SourceIp` works only for public IP address ranges.

When your `Condition` element includes a mix of private and public IP addresses, the statement might not have the desired effect. You can specify private IP addresses using `aws:VpcSourceIP`.

Note

The global condition key `aws:VpcSourceIP` matches only if the request originates from the specified IP address and it goes through a VPC endpoint.

- [aws:SourceIp global condition key](#)
- [aws:VpcSourceIp global condition key](#)
- [IP address condition operators](#)
- [IAM JSON policy elements: Condition](#)

Suggestion – Private NotIpAddress subset

In the AWS Management Console, the finding for this check includes the following message:

```
Private NotIpAddress subset: The values for condition key aws:SourceIp include a mix of private and public IP addresses. The private addresses have no effect. aws:SourceIp works only for public IP address ranges. To define permissions for private IP ranges, use aws:VpcSourceIp.
```

In programmatic calls to the AWS CLI or AWS API, the finding for this check includes the following message:

```
"findingDetails": "The values for condition key aws:SourceIp include a mix of private and public IP addresses. The private addresses have no effect. aws:SourceIp works only for public IP address ranges. To define permissions for private IP ranges, use aws:VpcSourceIp."
```

Resolving the suggestion

The global condition key `aws:SourceIp` works only for public IP address ranges.

When your Condition element includes the `NotIpAddress` condition operator and a mix of private and public IP addresses, the statement might not have the desired effect. Every public IP addresses that is not specified in the policy will match. No private IP addresses will match. To achieve this effect, you can use `NotIpAddress` with `aws:VpcSourceIP` and specify the private IP addresses that should not match.

- [aws:SourceIp global condition key](#)
- [aws:VpcSourceIp global condition key](#)
- [IP address condition operators](#)
- [IAM JSON policy elements: Condition](#)

Suggestion – Redundant action

In the AWS Management Console, the finding for this check includes the following message:

```
Redundant action: The {{redundantActionCount}} action(s) are redundant because they provide similar permissions. Update the policy to remove the redundant action such as: {{redundantAction}}.
```

In programmatic calls to the AWS CLI or AWS API, the finding for this check includes the following message:

```
"findingDetails": "The {{redundantActionCount}} action(s) are redundant because they provide similar permissions. Update the policy to remove the redundant action such as: {{redundantAction}}."
```

Resolving the suggestion

When you use wildcards (*) in the Action element, you can include redundant permissions. AWS recommends that you review your policy and include only the permissions that you need. This can help you remove redundant actions.

For example, the following actions include the `iam:GetCredentialReport` action twice.

```
"Action": [  
    "iam:Get*",  
    "iam:List*",  
    "iam:GetCredentialReport"  
],
```

In this example, permissions are defined for every IAM action that begins with `Get` or `List`. When IAM adds additional `get` or `list` operations, this policy will allow them. You might want to allow all of these read-only actions. The `iam:GetCredentialReport` action is already included as part of `iam:Get*`. To remove the duplicate permissions, you could remove `iam:GetCredentialReport`.

You receive a finding for this policy check when all of the contents of an action are redundant. In this example, if the element included `iam:*CredentialReport`, it is not considered redundant. That includes `iam:GetCredentialReport`, which is redundant, and `iam:GenerateCredentialReport`, which is not. Removing either `iam:Get*` or `iam:*CredentialReport` would change the policy's permissions.

- [IAM JSON policy elements: Action](#)

AWS managed policies with this suggestion

[AWS managed policies](#) enable you to get started with AWS by assigning permissions based on general AWS use cases.

Redundant actions do not affect the permissions granted by the policy. When using an AWS managed policy as a reference to create your customer managed policy, AWS recommends that you remove redundant actions from your policy.

Suggestion – Redundant condition value num

In the AWS Management Console, the finding for this check includes the following message:

```
Redundant condition value num: Multiple values in {{operator}} are redundant. Replace with the {{greatest/least}} single value for {{key}}.
```

In programmatic calls to the AWS CLI or AWS API, the finding for this check includes the following message:

```
"findingDetails": "Multiple values in {{operator}} are redundant. Replace with the {{greatest/least}} single value for {{key}}."
```

Resolving the suggestion

When you use numeric condition operators for similar values in a condition key, you can create an overlap that results in redundant permissions.

For example, the following Condition element includes multiple `aws:MultiFactorAuthAge` conditions that have an age overlap of 1200 seconds.

```
"Condition": {
  "NumericLessThan": {
    "aws:MultiFactorAuthAge": [
      "2700",
      "3600"
    ]
  }
}
```

In this example, the permissions are defined if multi-factor authentication (MFA) was completed less than 3600 seconds (1 hour) ago. You could remove the redundant 2700 value.

- [Numeric condition operators](#)
- [IAM JSON policy elements: Condition](#)

Suggestion – Redundant resource

In the AWS Management Console, the finding for this check includes the following message:

```
Redundant resource: The {{redundantResourceCount}} resource ARN(s) are redundant because they reference the same resource. Review the use of wildcards (*)
```

In programmatic calls to the AWS CLI or AWS API, the finding for this check includes the following message:

```
"findingDetails": "The {{redundantResourceCount}} resource ARN(s) are redundant because they reference the same resource. Review the use of wildcards (*)"
```

Resolving the suggestion

When you use wildcards (*) in Amazon Resource Names (ARNs), you can create redundant resource permissions.

For example, the following Resource element includes multiple ARNs with redundant permissions.

```
"Resource": [  
    "arn:aws:iam::111122223333:role/jane-admin",  
    "arn:aws:iam::111122223333:role/jane-s3only",  
    "arn:aws:iam::111122223333:role/jane*"  
],
```

In this example, the permissions are defined for any role with a name starting with jane. You could remove the redundant jane-admin and jane-s3only ARNs without changing the resulting permissions. This does make the policy dynamic. It will define permissions for any future roles that begin with jane. If the intention of the policy is to allow access to a static number of roles, then remove the last ARN and list only the ARNs that should be defined.

- [IAM JSON policy elements: Resource](#)

AWS managed policies with this suggestion

[AWS managed policies](#) enable you to get started with AWS by assigning permissions based on general AWS use cases.

Redundant resources do not affect the permissions granted by the policy. When using an AWS managed policy as a reference to create your customer managed policy, AWS recommends that you remove redundant resources from your policy.

Suggestion – Redundant statement

In the AWS Management Console, the finding for this check includes the following message:

```
Redundant statement: The statements are redundant because they provide identical permissions. Update the policy to remove the redundant statement.
```

In programmatic calls to the AWS CLI or AWS API, the finding for this check includes the following message:

```
"findingDetails": "The statements are redundant because they provide identical permissions. Update the policy to remove the redundant statement."
```

Resolving the suggestion

The Statement element is the main element for a policy. This element is required. The Statement element can contain a single statement or an array of individual statements.

When you include the same statement more than once in a long policy, the statements are redundant. You can remove one of the statements without affecting the permissions granted by the policy. When someone edits a policy, they might change one of the statements without updating the duplicate. This might result in more permissions than intended.

- [IAM JSON policy elements: Statement](#)

Suggestion – Wildcard in service name

In the AWS Management Console, the finding for this check includes the following message:

```
Wildcard in service name: Avoid using wildcards (*, ?) in the service name because it might grant unintended access to other AWS services with similar names.
```

In programmatic calls to the AWS CLI or AWS API, the finding for this check includes the following message:

```
"findingDetails": "Avoid using wildcards (*, ?) in the service name because it might grant unintended access to other AWS services with similar names."
```

Resolving the suggestion

When you include the name of an AWS service in a policy, AWS recommends that you do not include wildcards (*, ?). This might add permissions for future services that you do not intend. For example, there are more than a dozen AWS services with the word `*code*` in their name.

```
"Resource": "arn:aws:*code*::111122223333:*"
```

- [IAM JSON policy elements: Resource](#)

Suggestion – Allow with unsupported tag condition key for service

In the AWS Management Console, the finding for this check includes the following message:

```
Allow with unsupported tag condition key for service: Using the effect Allow with the tag condition key {{conditionKeyName}} and actions for services with the following prefixes does not affect the policy: {{serviceNames}}. Actions for the listed service are not allowed by this statement. We recommend that you move these actions to a different statement without this condition key.
```

In programmatic calls to the AWS CLI or AWS API, the finding for this check includes the following message:

```
"findingDetails": "Using the effect Allow with the tag condition key {{conditionKeyName}} and actions for services with the following prefixes does not affect the policy: {{serviceNames}}. Actions for the listed service are not allowed by this statement. We recommend that you move these actions to a different statement without this condition key."
```

Resolving the suggestion

Using unsupported tag condition keys in the Condition element of a policy with "Effect": "Allow" does not affect the permissions granted by the policy, because the condition is ignored

for that service action. AWS recommends that you remove the actions for services that don't support the condition key and create another statement to allow access to specific resources in that service.

If you use the `aws:ResourceTag` condition key and it's not supported by a service action, then the key is not included in the request context. In this case, the condition in the `Allow` statement always returns `false` and the action is never allowed. This happens even if the resource is tagged correctly.

When a service supports the `aws:ResourceTag` condition key, you can use tags to control access to that service's resources. This is known as [attribute-based access control \(ABAC\)](#). Services that don't support these keys require you to control access to resources using [resource-based access control \(RBAC\)](#).

Note

Some services allow support for the `aws:ResourceTag` condition key for a subset of their resources and actions. IAM Access Analyzer returns findings for the service actions that are not supported. For example, Amazon S3 supports `aws:ResourceTag` for a subset of its resources. To view all of the resource types available in Amazon S3 that support the `aws:ResourceTag` condition key, see [Resource types defined by Amazon S3](#) in the Service Authorization Reference.

For example, assume that you want to allow team members to view details for specific resources that are tagged with the key-value pair `team=BumbleBee`. Also assume that AWS Lambda allows you to tag resources, but doesn't support the `aws:ResourceTag` condition key. To allow view actions for AWS App Mesh and AWS Backup if this tag is present, use the `aws:ResourceTag` condition key. For Lambda, use a resource naming convention that includes the team name as a prefix. Then include a separate statement that allows viewing resources with that naming convention.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "AllowViewSupported",
      "Effect": "Allow",
      "Action": [
```

```

        "appmesh:DescribeMesh",
        "backup:GetBackupPlan"
    ],
    "Resource": "*",
    "Condition": {
        "StringEquals": {
            "aws:ResourceTag/team": "BumbleBee"
        }
    }
},
{
    "Sid": "AllowViewUnsupported",
    "Effect": "Allow",
    "Action": "lambda:GetFunction",
    "Resource": "arn:aws:lambda:*:123456789012:function:team-BumbleBee*"
}
]
}

```

Warning

Do not use the Not [version of the condition operator](#) with "Effect": "Allow" as a workaround for this finding. These condition operators provide negated matching. This means that after the condition is evaluated, the result is negated. In the previous example, including the `lambda:GetFunction` action in the `AllowViewSupported` statement with the `StringNotEquals` operator always allows the action, regardless of whether the resource is tagged.

Do not use the [...IfExists](#) version of the condition operator as a workaround for this finding. This means "Allow the action if the key is present in the request context and the values match. Otherwise, allow the action." In the previous example, including the `lambda:GetFunction` action in the `AllowViewSupported` statement with the `StringEqualsIfExists` operator always allows the action. For that action, the key is not present in the context, and every attempt to view that resource type is allowed, regardless of whether the resource is tagged.

Suggestion – Allow NotAction with unsupported tag condition key for service

In the AWS Management Console, the finding for this check includes the following message:

```
Allow NotAction with unsupported tag condition key for service: Using the effect Allow with NotAction and the tag condition key {{conditionKeyName}} allows only service actions that support the condition key. The condition key doesn't apply to some service actions. We recommend that you use Action instead of NotAction.
```

In programmatic calls to the AWS CLI or AWS API, the finding for this check includes the following message:

```
"findingDetails": "Using the effect Allow with NotAction and the tag condition key {{conditionKeyName}} allows only service actions that support the condition key. The condition key doesn't apply to some service actions. We recommend that you use Action instead of NotAction."
```

Resolving the suggestion

Using unsupported tag condition keys in the `Condition` element of a policy with the element `NotAction` and `"Effect": "Allow"` does not affect the permissions granted by the policy. The condition is ignored for service actions that don't support the condition key. AWS recommends that you rewrite the logic to allow a list of actions.

If you use the `aws:ResourceTag` condition key with `NotAction`, any new or existing service actions that don't support the key are not allowed. AWS recommends that you explicitly list the actions that you want to allow. IAM Access Analyzer returns a separate finding for listed actions that don't support the `aws:ResourceTag` condition key. For more information, see [Suggestion – Allow with unsupported tag condition key for service](#).

When a service supports the `aws:ResourceTag` condition key, you can use tags to control access to that service's resources. This is known as [attribute-based access control \(ABAC\)](#). Services that don't support these keys require you to control access to resources using [resource-based access control \(RBAC\)](#).

Related terms

- [Global condition keys](#)

Suggestion – Recommended condition key for service principal

In the AWS Management Console, the finding for this check includes the following message:

```
Recommended condition key for service principal: To restrict access to the service principal {{servicePrincipalPrefix}} operating on your behalf, we recommend aws:SourceArn, aws:SourceAccount, aws:SourceOrgID, or aws:SourceOrgPaths instead of {{key}}.
```

In programmatic calls to the AWS CLI or AWS API, the finding for this check includes the following message:

```
"findingDetails": "To restrict access to the service principal {{servicePrincipalPrefix}} operating on your behalf, we recommend aws:SourceArn, aws:SourceAccount, aws:SourceOrgID, or aws:SourceOrgPaths instead of {{key}}."
```

Resolving the suggestion

You can specify AWS services in the `Principal` element of a resource-based policy using a *service principal*, which is an identifier for the service. You should use the `aws:SourceArn`, `aws:SourceAccount`, `aws:SourceOrgID`, or `aws:SourceOrgPaths` condition keys when granting access to service principals instead of other condition keys, such as `aws:Referer`. This helps you prevent a security issue called *the confused deputy problem*.

Related terms

- [AWS service principals](#)
- [AWS global condition keys: aws:SourceAccount](#)
- [AWS global condition keys: aws:SourceArn](#)
- [AWS global condition keys: aws:SourceOrgId](#)
- [AWS global condition keys: aws:SourceOrgPaths](#)

- [The confused deputy problem](#)

Suggestion – Irrelevant condition key in policy

In the AWS Management Console, the finding for this check includes the following message:

```
Irrelevant condition key in policy: The condition key {{condition-key}} is not relevant for the {{resource-type}} policy. Use this key in an identity-based policy to govern access to this resource.
```

In programmatic calls to the AWS CLI or AWS API, the finding for this check includes the following message:

```
"findingDetails": "The condition key {{condition-key}} is not relevant for the {{resource-type}} policy. Use this key in an identity-based policy to govern access to this resource."
```

Resolving the suggestion

Some condition keys aren't relevant for resource-based policies. For example, the `s3:ResourceAccount` condition key isn't relevant for the resource-based policy attached to an Amazon S3 bucket or Amazon S3 access point resource type.

You should use the condition key in an identity-based policy to control access to the resource.

Related terms

- [Identity-based policies and resource-based policies](#)

Suggestion – Redundant principal in role trust policy

In the AWS Management Console, the finding for this check includes the following message:

```
Redundant principal in role trust policy: The assumed-role principal {{redundant_principal}} is redundant with its parent role {{parent_role}}. Remove the assumed-role principal.
```

In programmatic calls to the AWS CLI or AWS API, the finding for this check includes the following message:

```
"findingDetails": "The assumed-role principal {{redundant_principal}} is redundant with its parent role {{parent_role}}. Remove the assumed-role principal."
```

Resolving the suggestion

If you specify both an assumed-role principal and its parent role in the `Principal` element of a policy, it does not allow or deny any different permissions. For example, it is redundant if you specify the `Principal` element using the following format:

```
"Principal": {
  "AWS": [
    "arn:aws:iam::AWS-account-ID:role/rolename",
    "arn:aws:iam::AWS-account-ID:assumed-role/rolename/roleessionname"
  ]
}
```

We recommend removing the assumed-role principal.

Related terms

- [Role session principals](#)

Suggestion – Confirm audience claim type

In the AWS Management Console, the finding for this check includes the following message:

```
Confirm audience claim type: The 'aud' (audience) claim key identifies the recipients that the JSON web token is intended for. Audience claims can be multivalued or single-valued. If the claim is multivalued, use a ForAllValues or ForAnyValue qualifier. If the claim is single-valued, do not use a qualifier.
```

In programmatic calls to the AWS CLI or AWS API, the finding for this check includes the following message:

```
"findingDetails": "The 'aud' (audience) claim key identifies the recipients that the JSON web token is intended for. Audience claims can be multivalued or single-valued. If the claim is multivalued, use a ForAllValues or ForAnyValue qualifier. If the claim is single-valued, do not use a qualifier."
```

Resolving the suggestion

The `aud` (audience) claim key is a unique identifier for your app that is issued to you when you register your app with the IdP and identifies the recipients that the JSON web token is intended for. Audience claims can be multivalued or single-valued. If the claim is multivalued, use a `ForAllValues` or `ForAnyValue` condition set operator. If the claim is single-valued, do not use a condition set operator.

IAM Access Analyzer custom policy checks

You can validate your policies against your specified security standards using AWS Identity and Access Management Access Analyzer custom policy checks. There are two kinds of custom policy checks that you can run:

- **Check against a reference policy:** When editing a policy, you can check whether the updated policy grants new access compared to a reference policy, such as an existing version of the policy. You can run this check when you edit a policy using the AWS Command Line Interface (AWS CLI), IAM Access Analyzer API (API), or JSON policy editor in the IAM console.
- **Check against a list of IAM actions:** You can check to ensure that specific IAM actions are not allowed by your policy. You can run this check when you create or edit a policy using the AWS CLI or the API.

A charge is associated with each custom policy check. For more details about pricing, see [IAM Access Analyzer pricing](#).

How custom policy checks work

You can run custom policy checks on identity and resource-based policies. Custom policy checks don't rely on pattern-matching techniques or examining access logs to determine whether new or a specified access is allowed by a policy. Similar to external access findings, custom policy checks are built on [Zelkova](#). Zelkova translates IAM policies into equivalent logical statements, and runs a suite of general-purpose and specialized logical solvers (satisfiability modulo theories) against the problem. To check for new or specified access, IAM Access Analyzer applies Zelkova repeatedly

to a policy. Queries become increasingly specific to characterize classes of behaviors that the policy allows based on the content of the policy. For more information about satisfiability modulo theories, see [Satisfiability Modulo Theories](#).

In rare cases, IAM Access Analyzer isn't able to fully determine whether a policy statement grants new or specified access. In those cases, it errs on the side of declaring a false positive by failing the custom policy check. IAM Access Analyzer is designed to provide a comprehensive policy evaluation and strives to minimize false negatives. This approach means that IAM Access Analyzer provides a high degree of assurance that a passed check means access wasn't granted by the policy. You can inspect failed checks manually by reviewing the policy statement that's reported in the response from IAM Access Analyzer.

Reference policy examples to check for new access

You can find examples for reference policies and learn how to set up and run a custom policy check for new access in the [IAM Access Analyzer custom policy checks samples](#) repository on GitHub.

Before using these examples

Before you use these sample reference policies, do the following:

- Carefully review and customize the reference policies for your unique requirements.
- Thoroughly test the reference policies in your environment with the AWS services that you use.

The reference policies demonstrate the implementation and use of custom policy checks. They're **not** intended to be interpreted as official AWS recommendations or best practices to be implemented exactly as shown. It is your responsibility to carefully test reference policies for their suitability to solve the security requirements for your environment.

- Custom policy checks are environment-agnostic in their analysis. Their analysis only considers information contained within the input policies. For example, custom policy checks can't check whether an account is a member of a specific AWS organization. Therefore, the custom policy checks can't compare new access based on condition key values for the [aws:PrincipalOrgId](#) and [aws:PrincipalAccount](#) condition keys.

Inspecting failed custom policy checks

When a custom policy check fails, the response from IAM Access Analyzer includes the [statement ID \(Sid\)](#) of the policy statement that caused the check to fail. Although the statement ID is an optional policy element, we recommend that you add a statement ID for every policy statement. The custom policy check also returns a statement index to help identify the reason for the check failure. The statement index follows zero-based numbering, where the first statement is referenced as 0. When there are multiple statements that cause a check to fail, the check returns only one statement ID at a time. We recommend that you fix the statement highlighted in the reason and rerun the check until it passes.

Validating policies with custom policy checks (console)

As an optional step, you can run a custom policy check when editing a policy in the JSON policy editor in the IAM console. You can check whether the updated policy grants new access compared to the existing version.

To check for new access when editing IAM JSON policies

1. Sign in to the AWS Management Console and open the IAM console at <https://console.aws.amazon.com/iam/>.
2. In the navigation pane on the left, choose **Policies**.
3. In the list of policies, choose the policy name of the policy that you want to edit. You can use the search box to filter the list of policies.
4. Choose the **Permissions** tab, and then choose **Edit**.
5. Choose the **JSON** option and make updates to your policy.
6. In the policy validation pane below the policy, choose the **Check for new access** tab and then choose **Check policy**. If the modified permissions grant new access, the statement will be highlighted in the policy validation pane.
7. If you don't intend to grant new access, update the policy statement and choose **Check policy** until no new access is detected.

Note

A charge is associated with each check for new access. For more details about pricing, see [IAM Access Analyzer pricing](#).

8. Choose **Next**.
9. On the **Review and save** page, review **Permissions defined in this policy** and then choose **Save changes**.

Validating policies with custom policy checks (AWS CLI or API)

You can run IAM Access Analyzer custom policy checks from the AWS CLI or the IAM Access Analyzer API.

To run IAM Access Analyzer custom policy checks (AWS CLI)

- To check whether new access is allowed for an updated policy when compared to the existing policy, run the following command: [check-no-new-access](#)
- To check whether the specified access isn't allowed by a policy, run the following command: [check-access-not-granted](#)

To run IAM Access Analyzer custom policy checks (API)

- To check whether new access is allowed for an updated policy when compared to the existing policy, use the [CheckNoNewAccess](#) API operation.
- To check whether the specified access isn't allowed by a policy, use the [CheckAccessNotGranted](#) API operation.

IAM Access Analyzer policy generation

As an administrator or developer, you might grant permissions to IAM entities (users or roles) beyond what they require. IAM provides several options to help you refine the permissions that you grant. One option is to generate an IAM policy that is based on access activity for an entity. IAM Access Analyzer reviews your AWS CloudTrail logs and generates a policy template that contains the permissions that the entity used in your specified date range. You can use the template to create a policy with fine-grained permissions that grant only the permissions that are required to support your specific use case.

How policy generation works

IAM Access Analyzer analyzes your CloudTrail events to identify actions and services that have been used by an IAM entity (user or role). It then generates an IAM policy that is based on that activity. You can refine an entity's permissions when you replace a broad permissions policy attached to the entity with the generated policy. The following is a high-level overview of the policy generation process.

- **Set up for policy template generation** – You specify a time period of up to 90 days for IAM Access Analyzer to analyze your historical AWS CloudTrail events. You must specify an existing service role or create a new one. The service role gives IAM Access Analyzer access to your CloudTrail trail and service last accessed information to identify the services and actions that were used. You must specify the CloudTrail trail that is logging events for the account before you can generate a policy. For more information about IAM Access Analyzer quotas for CloudTrail data, see [IAM Access Analyzer quotas](#).
- **Generate policy** – IAM Access Analyzer generates a policy based on the access activity in your CloudTrail events.
- **Review and customize policy** – After the policy is generated, you can review the services and actions that were used by the entity during the specified date range. You can further customize the policy by adding or removing permissions, specifying resources, and adding conditions to the policy template.
- **Create and attach policy** – You have the option to save the generated policy by creating a managed policy. You can attach the policy that you create to the user or role whose activity was used to generate the policy.

Service and action-level information

When IAM Access Analyzer generates an IAM policy, information is returned to help you to further customize the policy. Two categories of information can be returned when a policy is generated:

- **Policy with action-level information** – For some AWS services, such as Amazon EC2, IAM Access Analyzer can identify the actions found in your CloudTrail events and lists the actions used in the policy it generates. For a list of supported services, see [IAM Access Analyzer policy generation services](#). For some services, IAM Access Analyzer prompts you to add actions for the services to the generated policy.
- **Policy with service-level information** – IAM Access Analyzer uses [last accessed](#) information to create a policy template with all of the recently used services. When using the AWS Management Console, we prompt you to review the services and add actions to complete the policy.

For a list of actions in each service, see [Actions, Resources, and Condition Keys for AWS Services](#) in the Service Authorization Reference.

Things to know about generating policies

Before you generate a policy, review the following important details.

- **Enable a CloudTrail trail** – You must have a CloudTrail trail enabled for your account to generate a policy based on access activity. When you create a CloudTrail trail, CloudTrail sends events related to your trail to an Amazon S3 bucket that you specify. To learn how to create a CloudTrail trail, see [Creating a trail for your AWS account](#) in the *AWS CloudTrail User Guide*.
- **Data events not available** – IAM Access Analyzer does not identify action-level activity for data events, such as Amazon S3 data events, in generated policies.
- **PassRole** – The `iam:PassRole` action is not tracked by CloudTrail and is not included in generated policies.
- **Reduce policy generation time** – To generate a policy faster, reduce the date range that you specify during setup for policy generation.
- **Use CloudTrail for auditing** – Do not use policy generation for auditing purposes; use CloudTrail instead. For more information about using CloudTrail, see [Logging IAM and AWS STS API calls with AWS CloudTrail](#).
- **Denied actions** – Policy generation reviews all CloudTrail events, including denied actions.
- **One policy IAM console** – You can have one generated policy at a time in the IAM console.

- **Generated policy availability IAM console** – You can review a generated policy in the IAM console for up to 7 days after it is generated. After 7 days, you must generate a new policy.
- **Policy generation quotas** – For additional information about IAM Access Analyzer policy generation quotas, see [IAM Access Analyzer quotas](#).
- **Amazon S3 standard rates apply** – When you use the policy generation feature, IAM Access Analyzer reviews CloudTrail logs in your S3 bucket. There are no additional storage charges to access your CloudTrail logs for policy generation. AWS charges standard Amazon S3 rates for requests and data transfer of CloudTrail logs stored in your S3 bucket.
- **AWS Control Tower support** – Policy generation does not support AWS Control Tower for generating policies.

Permissions required to generate a policy

The permissions that you need to generate a policy for the first time differ from those that you need to generate a policy for subsequent uses.

First-time setup

When you generate a policy for the first time, you must choose a suitable existing [service role](#) in your account or create a new service role. The service role gives IAM Access Analyzer access to CloudTrail and service last accessed information in your account. Only administrators should have the permissions necessary to create and configure roles. Therefore, we recommend that an administrator creates the service role during the first-time setup. To learn more about the permissions required to create service roles, see [Creating a role to delegate permissions to an AWS service](#).

Permissions required for service role

When you create a service role, you configure two policies for the role. You attach an IAM *permissions policy* to the role that specifies what the role can do. You also attach a *role trust policy* to the role that specifies the principal who can use the role.

The first example policy shows the permissions policy for the service role that is required to generate a policy. The second example policy shows the role trust policy that is required for the service role. You can use these policies to help you create a service role when you use the AWS API or AWS CLI to generate a policy. When you use the IAM console to create a service role as part of the policy generation process, we generate these policies for you.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": "cloudtrail:GetTrail",
      "Resource": "*"
    },
    {
      "Effect": "Allow",
      "Action": [
        "iam:GetServiceLastAccessedDetails",
        "iam:GenerateServiceLastAccessedDetails"
      ],
      "Resource": "*"
    },
    {
      "Effect": "Allow",
      "Action": [
        "s3:GetObject",
        "s3:ListBucket"
      ],
      "Resource": [
        "arn:aws:s3:::DOC-EXAMPLE-BUCKET",
        "arn:aws:s3:::DOC-EXAMPLE-BUCKET/*"
      ]
    }
  ]
}
```

The following example policy shows the role trust policy with the permissions that allows IAM Access Analyzer to assume the role.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Principal": {
        "Service": "access-analyzer.amazonaws.com"
      },
      "Action": "sts:AssumeRole"
    }
  ]
}
```

```
]
}
```

Subsequent uses

To generate policies in the AWS Management Console, an IAM user must have a permissions policy that allows them to pass the service role that is used for policy generation to IAM Access Analyzer. `iam:PassRole` is usually accompanied by `iam:GetRole` so that the user can get the details of the role to be passed. In this example, the user can pass only roles that exist in the specified account with names that begin with `AccessAnalyzerMonitorServiceRole*`. To learn more about passing IAM roles to AWS services, see [Granting a user permissions to pass a role to an AWS service](#).

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "AllowUserToPassRole",
      "Effect": "Allow",
      "Action": [
        "iam:GetRole",
        "iam:PassRole"
      ],
      "Resource": "arn:aws:iam::123456789012:role/service-role/
AccessAnalyzerMonitorServiceRole*"
    }
  ]
}
```

You must also have the following IAM Access Analyzer permissions to generate policies in the AWS Management Console, AWS API, or AWS CLI as shown in the following policy statement.

```
{
  "Sid": "AllowUserToGeneratePolicy",
  "Effect": "Allow",
  "Action": [
    "access-analyzer:CancelPolicyGeneration",
    "access-analyzer:GetGeneratedPolicy",
    "access-analyzer:ListPolicyGenerations",
    "access-analyzer:StartPolicyGeneration"
  ],
  "Resource": "*"
}
```

```
}
```

For both first-time and subsequent uses

When you use the AWS Management Console to generate a policy, you must have `cloudtrail:ListTrails` permission to list the CloudTrail trails in your account as shown in the following policy statement.

```
{
  "Sid": "AllowUserToListTrails",
  "Effect": "Allow",
  "Action": [
    "CloudTrail:ListTrails"
  ],
  "Resource": "*"
}
```

Generate a policy based on CloudTrail activity (console)

You can generate a policy for an IAM user or role.

Step 1: Generate a policy based on CloudTrail activity

The following procedure explains how to generate a policy for a role using the AWS Management Console.

Generate a policy for an IAM role

1. Sign in to the AWS Management Console and open the IAM console at <https://console.aws.amazon.com/iam/>.
2. In the navigation pane on the left, choose **Roles**.

Note

The steps to generate a policy based on activity for an IAM user are almost identical. To do this, choose **Users** instead of **Roles**.

3. In the list of roles in your account, choose the name of the role whose activity you want to use to generate a policy.

4. On the **Permissions** tab, in the **Generate policy based on CloudTrail events** section, choose **Generate policy**.
5. On the **Generate policy** page, specify the time period that you want IAM Access Analyzer to analyze your CloudTrail events for actions taken with the role. You can choose a range of up to 90 days. We recommend that you choose the shortest time period possible to reduce the policy generation time.
6. In the **CloudTrail access** section, choose a suitable existing role or create a new role if a suitable role does not exist. The role gives IAM Access Analyzer permissions to access your CloudTrail data on your behalf to review access activity to identify the services and actions that have been used. To learn more about the permissions required for this role, see [Permissions required to generate a policy](#).
7. In the **CloudTrail trail to be analyzed** section, specify the CloudTrail trail that logs events for the account.

If you choose a CloudTrail trail that stores logs in a different account, an information box about cross-account access is displayed. Cross-account access requires additional set up. To learn more, see [Choose a role for cross-account access](#) later in this topic.

8. Choose **Generate policy**.
9. While policy generation is in progress, you are returned to the **Roles Summary** page on the **Permissions** tab. Wait until the status in the **Policy request details** section displays **Success**, and then choose **View generated policy**. You can view the generated policy for up to seven days. If you generate another policy, the existing policy is replaced with the new one that you generate.

Step 2: Review permissions and add actions for services used

Review the services and actions that IAM Access Analyzer identified that the role used. You can add actions for any services that were used to the generated policy template.

1. Review the following sections:
 - On the **Review permissions** page, review the list of **Actions included in the generated policy**. The list displays the services *and* actions that IAM Access Analyzer identified were used by the role in the specified date range.
 - The **Services used** section displays additional services that IAM Access Analyzer identified that were used by the role in the specified date range. Information about which actions were

used might not be available for the services listed in this section. Use the menus for each service listed to manually choose the actions that you want to include in the policy.

- When you are done adding actions, choose **Next**.

Step 3: Further customize the generated policy

You can further customize the policy by adding or removing permissions or specifying resources.

To customize the generated policy

- Update the policy template. The policy template contains resource ARN placeholders for actions that support resource-level permissions, as shown in the following image. *Resource-level permissions* refers to the ability to specify which resources users are allowed to perform actions on. We recommend that you use [ARNs](#) to specify your individual resources in the policy for actions that support resource-level permissions. You can replace the placeholder resource ARNs with valid resource ARNs for your use case.

If an action does not support resource-level permissions, you must use a wildcard (*) to specify that all resources can be affected by the action. To learn which AWS services support resource-level permissions, see [AWS services that work with IAM](#). For a list of actions in each service, and to learn which actions support resource-level permissions, see [Actions, Resources, and Condition Keys for AWS Services](#).

Generated policy

1 2 3

Customize permissions

Review the following policy template. You must specify resources for actions that support resource-level permissions to continue creating the policy.

```

1 - {
2   "Version": "2012-10-17",
3   "Statement": [
4     {
5       "Effect": "Allow",
6       "Action": [
7         "access-analyzer:ValidatePolicy",
8         "iam:GetAccountPasswordPolicy",
9         "iam:GetAccountSummary",
10        "iam:ListAccountAliases",
11        "iam:ListGroups",
12        "iam:ListPolicies",
13        "iam:ListRoles",
14        "iam:ListUsers"
15      ],
16      "Resource": "*"
17    },
18    {
19      "Effect": "Allow",
20      "Action": [
21        "iam:GetRole",
22        "iam:ListAttachedRolePolicies",
23        "iam:ListInstanceProfilesForRole",
24        "iam:ListRolePolicies",
25        "iam:ListRoleTags"
26      ],
27      "Resource": "arn:aws:iam:${Account}:role/${RoleNameWithPath}"
28    },
29    {
30      "Effect": "Allow",
31      "Action": [
32        "iam:GetUser",
33        "iam:ListAccessKeys",
34        "iam:ListAttachedUserPolicies",
35        "iam:ListGroupsForUser",
36        "iam:ListUserTags"
37      ],
38      "Resource": "arn:aws:iam:${Account}:user/${UserNameWithPath}"
39    }
40  ]
41 }

```

2. (Optional) Add, modify, or remove JSON policy statements in the template. To learn more about writing JSON policies, see [Creating IAM policies \(console\)](#).
3. When you are done customizing the policy template, you have the following options:
 - (Optional) You can copy the JSON in the template to use separately outside of the **Generated policy** page. For example, if you want to use the JSON to create a policy in a different account. If the policy in your template exceeds the 6,144 character limit for JSON policies, the policy is split into multiple policies.
 - Choose **Next** to review and create a managed policy in the same account.

Step 4: Review and create a managed policy

If you have permissions to create and attach IAM policies, you can create a managed policy from the policy that was generated. You can then attach the policy to a user or role in your account.

To review and create a policy

1. On the **Review and create managed policy** page, enter a **Name** and **Description** (optional) for the policy that you are creating.
2. (Optional) In the **Summary** section, you can review the permissions that will be included in the policy.
3. (Optional) Add metadata to the policy by attaching tags as key-value pairs. For more information about using tags in IAM, see [Tagging IAM resources](#).
4. When you are finished, do one of the following:
 - You can attach the new policy directly to the role that was used to generate the policy. To do this, near the bottom of the page, select the check box next to the **Attach policy to *YourRoLeName***. Then choose **Create and attach policy**.
 - Otherwise, choose **Create policy**. You can find the policy that you created in the list of policies in the **Policies** navigation pane of the IAM console.
5. You can attach the policy that you created to an entity in your account. After you attach the policy, you can remove any other overly broad policies that might be attached to the entity. To learn how to attach a managed policy, see [Adding IAM identity permissions \(console\)](#).

Generate a policy using AWS CloudTrail data in another account

You might create CloudTrail trails that store data in central accounts to streamline governing activities. For example, you can use AWS Organizations to create a trail that logs all events for all of the AWS accounts in that organization. The trail belongs to a central account. If you want to generate a policy for a user or role in an account that is different from the account where your CloudTrail log data is stored, you must grant cross-account access. To do this, you need both a role and a bucket policy that grant IAM Access Analyzer permissions to your CloudTrail logs. For more information about creating Organizations trails, see [Creating a trail for an organization](#).

In this example, assume that you want to generate a policy for a user or role in account A. The CloudTrail trail in account A stores CloudTrail logs in a bucket in account B. Before you can generate a policy, you must make the following updates:

1. Choose an existing role, or create a new service role that grants IAM Access Analyzer access to the bucket in account B (where your CloudTrail logs are stored).
2. Verify your Amazon S3 bucket object ownership and bucket permissions policy in account B so that IAM Access Analyzer can access objects in the bucket.

Step 1: Choose or create a role for cross-account access

- On the **Generate policy** screen, the option to **Use an existing role** is pre-selected for you if a role with the required permissions exists in your account. Otherwise, choose **Create and use a new service role**. The new role is used to grant IAM Access Analyzer access to your CloudTrail logs in account B.

Step 2: Verify or update your Amazon S3 bucket configuration in account B

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the **Buckets** list, choose the name of the bucket where your CloudTrail trail logs are stored.
3. Choose the **Permissions** tab and go to the **Object Ownership** section.

Use Amazon S3 Object Ownership bucket settings to control ownership of objects that you upload to your buckets. By default, when other AWS accounts upload objects to your bucket, the uploading account owns the objects. To generate a policy, the bucket owner must own all of the objects in the bucket. Depending on your ACL use case, you might need to change

the **Object Ownership** setting for your bucket. Set **Object Ownership** to one of the following options.

- **Bucket owner enforced** (recommended)
- **Bucket owner preferred**

⚠ Important

To successfully generate a policy, the objects in the bucket must be owned by the bucket owner. If you choose to use **Bucket owner preferred**, you can only generate a policy for the time period after the object ownership change was made.

To learn more about object ownership in Amazon S3, see [Controlling ownership of objects and disabling ACLs for your bucket](#) in the *Amazon S3 User Guide*.

4. Add permissions to your Amazon S3 bucket policy in account B to allow access for the role in account A.

The following example policy allows ListBucket and GetObject for the bucket named *DOC-EXAMPLE-BUCKET*. It allows access if the role accessing the bucket belongs to an account in your organization and has a name that starts with AccessAnalyzerMonitorServiceRole. Using [aws:PrincipalArn](#) as a Condition in the Resource element ensures that the role can only access activity for the account if it belongs to account A. You can replace *DOC-EXAMPLE-BUCKET* with your bucket name, optional-prefix with an optional prefix for the bucket, and organization-id with your organization ID.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "PolicyGenerationBucketPolicy",
      "Effect": "Allow",
      "Principal": {
        "AWS": "*"
      },
      "Action": [
        "s3:GetObject",
```

```

    "s3:ListBucket"
  ],
  "Resource": [
    "arn:aws:s3:::DOC-EXAMPLE-BUCKET",
    "arn:aws:s3:::DOC-EXAMPLE-BUCKET/optional-prefix/AWSLogs/organization-id/
    ${aws:PrincipalAccount}/*"
  ],
  "Condition": {
    "StringEquals": {
      "aws:PrincipalOrgID": "organization-id"
    },
    "StringLike": {
      "aws:PrincipalArn": "arn:aws:iam::${aws:PrincipalAccount}:role/service-
      role/AccessAnalyzerMonitorServiceRole*"
    }
  }
}
]
}

```

5. If you encrypt your logs using AWS KMS, update your AWS KMS key policy in the account where you store the CloudTrail logs to grant IAM Access Analyzer access to use your key, as shown in the following policy example. Replace `CROSS_ACCOUNT_ORG_TRAIL_FULL_ARN` with the ARN for your trail and `organization-id` with your organization ID.

```

{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Principal": {
        "AWS": "*"
      },
      "Action": "kms:Decrypt",
      "Resource": "*",
      "Condition": {
        "StringEquals": {
          "kms:EncryptionContext:aws:cloudtrail:arn":
          "CROSS_ACCOUNT_ORG_TRAIL_FULL_ARN",
          "aws:PrincipalOrgID": "organization-id"
        },
        "StringLike": {
          "kms:ViaService": [

```

```
        "access-analyzer.*.amazonaws.com",
        "s3.*.amazonaws.com"
    ]
    "aws:PrincipalArn": "arn:aws:iam:${aws:PrincipalAccount}:role/service-
role/AccessAnalyzerMonitorServiceRole*"
}
}
}
]
```

Generate a policy based on CloudTrail activity (AWS CLI)

You can use the following commands to generate a policy using the AWS CLI.

To generate a policy

- [aws accessanalyzer start-policy-generation](#)

To view a generated policy

- [aws accessanalyzer get-generated-policy](#)

To cancel a policy generation request

- [aws accessanalyzer cancel-policy-generation](#)

To view a list of policy generation requests

- [aws accessanalyzer list-policy-generations](#)

Generate a policy based on CloudTrail activity (AWS API)

You can use the following operations to generate a policy using the AWS API.

To generate a policy

- [StartPolicyGeneration](#)

To view a generated policy

- [GetGeneratedPolicy](#)

To cancel a policy generation request

- [CancelPolicyGeneration](#)

To view a list of policy generation requests

- [ListPolicyGenerations](#)

IAM Access Analyzer policy generation services

The following table lists the AWS services for which [IAM Access Analyzer](#) generates policies with action-level information. For a list of actions in each service, see [Actions, resources, and condition keys for AWS services](#) in the Service Authorization Reference.

Service	Service prefix
AWS Identity and Access Management Access Analyzer	access-analyzer
AWS Account Management	account
AWS Certificate Manager	acm
Amazon Managed Workflows for Apache Airflow	airflow
AWS Amplify	amplify
AWS Amplify UI Builder	amplifyuibuilder
Amazon AppIntegrations	app-integrations
AWS AppConfig	appconfig
Amazon AppFlow	appflow

Service	Service prefix
AWS Application Cost Profiler	application-cost-profiler
Amazon CloudWatch Application Insights	applicationinsights
AWS App Mesh	appmesh
Amazon AppStream 2.0	appstream
AWS AppSync	appsync
Amazon Managed Service for Prometheus	aps
Amazon Athena	athena
AWS Audit Manager	auditmanager
AWS Auto Scaling	autoscaling
AWS Marketplace	aws-marketplace
AWS Backup	backup
AWS Batch	batch
Amazon Braket	braket
AWS Budgets	budgets
AWS Cloud9	cloud9
AWS CloudFormation	cloudformation
Amazon CloudFront	cloudfront
AWS CloudHSM	cloudhsm
Amazon CloudSearch	cloudsearch
AWS CloudTrail	cloudtrail

Service	Service prefix
Amazon CloudWatch	cloudwatch
AWS CodeArtifact	codeartifact
AWS CodeDeploy	codedeploy
Amazon CodeGuru Profiler	codeguru-profiler
Amazon CodeGuru Reviewer	codeguru-reviewer
AWS CodePipeline	codepipeline
AWS CodeStar	codestar
AWS CodeStar Notifications	codestar-notifications
Amazon Cognito Identity	cognito-identity
Amazon Cognito user pools	cognito-idp
Amazon Cognito Sync	cognito-sync
Amazon Comprehend Medical	comprehendmedical
AWS Compute Optimizer	compute-optimizer
AWS Config	config
Amazon Connect	connect
AWS Cost and Usage Report	cur
AWS Glue DataBrew	databrew
AWS Data Exchange	dataexchange
AWS Data Pipeline	datapipeline

Service	Service prefix
DynamoDB Accelerator	dax
AWS Device Farm	devicefarm
Amazon DevOps Guru	devops-guru
AWS Direct Connect	directconnect
Amazon Data Lifecycle Manager	dlm
AWS Database Migration Service	dms
Amazon DocumentDB Elastic Clusters	docdb-elastic
AWS Directory Service	ds
Amazon DynamoDB	dynamodb
Amazon Elastic Block Store	ebs
Amazon Elastic Compute Cloud	ec2
Amazon Elastic Container Registry	ecr
Amazon Elastic Container Registry Public	ecr-public
Amazon Elastic Container Service	ecs

IAM Access Analyzer quotas

IAM Access Analyzer has the following quotas:

Resource	Default quota	Maximum quota
Maximum account-level analyzers per analyzer type per AWS account per Region	1	1
Maximum organization-level analyzers per analyzer type per AWS account per Region	5	20 ¹
Maximum archive rules per analyzer	100 Each archive rule can have up to 20 values per criterion.	1,000 ¹
Maximum number of access previews per analyzer per hour	1,000	1,000
AWS CloudTrail log files processed per policy generations	100,000	100,000
Concurrent policy generations	1	1
Policy generation AWS CloudTrail data size	25 GB	25 GB
Policy generation AWS CloudTrail time range	90 days	90 days

Resource	Default quota	Maximum quota
Policy generations per day	Africa (Cape Town): 5 Asia Pacific (Hong Kong): 5 Europe (Milan): 5 Middle East (Bahrain): 5 All other supported regions: 50	Africa (Cape Town): 5 Asia Pacific (Hong Kong): 5 Europe (Milan): 5 Middle East (Bahrain): 5 All other supported regions: 50

 **Note**

Canceled policy generation requests apply to the daily quota.

¹Some quotas are customer-configurable using [Service Quotas](#).

Troubleshooting IAM

If you encounter access-denied issues or similar difficulties when working with AWS Identity and Access Management (IAM), consult the topics in this section.

Topics

- [Troubleshooting general IAM issues](#)
- [Troubleshooting access denied error messages](#)
- [Troubleshooting IAM policies](#)
- [Troubleshooting FIDO security keys](#)
- [Troubleshooting IAM roles](#)
- [Troubleshooting IAM and Amazon EC2](#)
- [Troubleshooting IAM and Amazon S3](#)
- [Troubleshooting SAML 2.0 federation with AWS](#)

Troubleshooting general IAM issues

Use the information here to help you diagnose and fix common issues when you work with AWS Identity and Access Management (IAM).

Issues

- [I can't sign in to my AWS account](#)
- [I lost my access keys](#)
- [Policy variables aren't working](#)
- [Changes that I make are not always immediately visible](#)
- [I am not authorized to perform: iam:DeleteVirtualMFADevice](#)
- [How do I securely create IAM users?](#)
- [Additional resources](#)

I can't sign in to my AWS account

Verify that you have the correct credentials and that you are using the correct method to sign in. For more information, see [Troubleshooting sign-in issues](#) in the *AWS Sign-In User Guide*.

I lost my access keys

Access keys consist of two parts:

- **The access key identifier.** This is not a secret, and can be seen in the IAM console wherever access keys are listed, such as on the user summary page.
- **The secret access key.** This is provided when you initially create the access key pair. Just like a password, it *cannot be retrieved later*. If you lost your secret access key, then you must create a new access key pair. If you already have the [maximum number of access keys](#), you must delete an existing pair before you can create another.

For more information, see [Resetting lost or forgotten passwords or access keys for AWS](#).

Policy variables aren't working

- Verify that all policies that include variables include the following version number in the policy: "Version": "2012-10-17". Without the correct version number, the variables are not replaced during evaluation. Instead, the variables are evaluated literally. Any policies that don't include variables will still work if you include the latest version number.

A `Version` policy element is different from a policy version. The `Version` policy element is used within a policy and defines the version of the policy language. A policy version, on the other hand, is created when you make changes to a customer managed policy in IAM. The changed policy doesn't overwrite the existing policy. Instead, IAM creates a new version of the managed policy. To learn more about the `Version` policy element see [IAM JSON policy elements: Version](#). To learn more about policy versions, see [the section called "Versioning IAM policies"](#).

- Verify that your policy variables are in the right case. For details, see [IAM policy elements: Variables and tags](#).

Changes that I make are not always immediately visible

As a service that is accessed through computers in data centers around the world, IAM uses a distributed computing model called [eventual consistency](#). Any change that you make in IAM (or other AWS services), including tags used in [attribute-based access control \(ABAC\)](#), takes time to become visible from all possible endpoints. Some of the delay results from the time it takes to send the data from server to server, from replication zone to replication zone, and from Region to

Region around the world. IAM also uses caching to improve performance, but in some cases this can add time. The change might not be visible until the previously cached data times out.

You must design your global applications to account for these potential delays. Ensure that they work as expected, even when a change made in one location is not instantly visible at another. Such changes include creating or updating users, groups, roles, or policies. We recommend that you do not include such IAM changes in the critical, high-availability code paths of your application. Instead, make IAM changes in a separate initialization or setup routine that you run less frequently. Also, be sure to verify that the changes have been propagated before production workflows depend on them.

For more information about how some other AWS services are affected by this, consult the following resources:

- **Amazon DynamoDB:** [What is the consistency model of Amazon DynamoDB?](#) in the *DynamoDB FAQ*, and [Read Consistency](#) in the *Amazon DynamoDB Developer Guide*.
- **Amazon EC2:** [EC2 Eventual Consistency](#) in the *Amazon EC2 API Reference*.
- **Amazon EMR:** [Ensuring Consistency When Using Amazon S3 and Amazon Elastic MapReduce for ETL Workflows](#) in the *AWS Big Data Blog*
- **Amazon Redshift:** [Managing Data Consistency](#) in the *Amazon Redshift Database Developer Guide*
- **Amazon S3:** [Amazon S3 Data Consistency Model](#) in the *Amazon Simple Storage Service User Guide*

I am not authorized to perform: iam:DeleteVirtualMFADevice

You might receive the following error when you attempt to assign or remove a virtual MFA device for yourself or others:

```
User: arn:aws:iam::123456789012:user/Diego is not authorized to perform:
iam:DeleteVirtualMFADevice on resource: arn:aws:iam::123456789012:mfa/Diego with an
explicit deny
```

This could happen if someone previously began assigning a virtual MFA device to a user in the IAM console and then cancelled the process. This creates a virtual MFA device for the user in IAM but never assigns it to the user. You must delete the existing virtual MFA device before you can create a new virtual MFA device with the same device name.

To fix this issue, an administrator should **not** edit policy permissions. Instead, the administrator must use the AWS CLI or AWS API to delete the existing but unassigned virtual MFA device.

To delete an existing but unassigned virtual MFA device

1. View the virtual MFA devices in your account.
 - AWS CLI: [aws iam list-virtual-mfa-devices](#)
 - AWS API: [ListVirtualMFADevices](#)
2. In the response, locate the ARN of the virtual MFA device for the user you are trying to fix.
3. Delete the virtual MFA device.
 - AWS CLI: [aws iam delete-virtual-mfa-device](#)
 - AWS API: [DeleteVirtualMFADevice](#)

How do I securely create IAM users?

If you have employees that require access to AWS, you might choose to create IAM users or [use IAM Identity Center for authentication](#). If you use IAM, AWS recommends that you create an IAM user and securely communicate the credentials to the employee. If you are not physically located next to your employee, use a secure workflow to communicate credentials to employees.

Use the following workflow to securely create a new user in IAM:

1. [Create a new user](#) using the AWS Management Console. Choose to grant AWS Management Console access with an auto-generated password. If necessary, select the **Users must create a new password at next sign-in** check box. Do not add a permissions policy to the user until after they have changed their password.
2. After the user is added, copy the sign-in URL, user name, and password for the new user. To view the password, choose **Show**.
3. Send the password to your employee using a secure communications method in your company, such as email, chat, or a ticketing system. Separately, provide your users with the IAM user console link and their user name. Tell the employee to confirm that they can sign in successfully before you will grant them permissions.
4. After the employee confirms, add the permissions that they need. As a security best practice, add a policy that requires the user to authenticate using MFA to manage their credentials.

For an example policy, see [AWS: Allows MFA-authenticated IAM users to manage their own credentials on the Security credentials page](#).

Additional resources

The following resources can help you troubleshoot as you work with AWS.

- [AWS CloudTrail User Guide](#) – Use AWS CloudTrail to track a history of API calls made to AWS and store that information in log files. This helps you determine which users and accounts accessed resources in your account, when the calls were made, what actions were requested, and more. For more information, see [Logging IAM and AWS STS API calls with AWS CloudTrail](#).
- [AWS Knowledge Center](#) – Find FAQs and links to other resources to help you troubleshoot issues.
- [AWS Support Center](#) – Get technical support.
- [AWS Premium Support Center](#) – Get premium technical support.

Troubleshooting access denied error messages

Access denied errors appear when AWS explicitly or implicitly denies an authorization request. An *explicit denial* occurs when a policy contains a Deny statement for the specific AWS action. An *implicit denial* occurs when there is no applicable Deny statement and also no applicable Allow statement. Because an IAM policy denies an IAM principal by default, the policy must explicitly allow the principal to perform an action. Otherwise, the policy implicitly denies access. For more information, see [The difference between explicit and implicit denies](#).

If multiple policies of the same policy type deny an authorization request, then AWS doesn't specify the number of policies in the access denied error message. If multiple policy types deny an authorization request, AWS includes only one of those policy types in the error message.

I get "access denied" when I make a request to an AWS service

- Check if the error message includes the type of policy responsible for denying access. For example, if the error mentions that access is denied due to a Service Control Policy (SCP), then you can focus on troubleshooting SCP issues. When you know the policy type, you can also check for a deny statement or a missing allow on the specific action in policies of that policy type. If the error message doesn't mention the policy type responsible for denying access, use the rest of the guidelines in this section to troubleshoot further.

- Verify that you have the identity-based policy permission to call the action and resource that you have requested. If any conditions are set, you must also meet those conditions when you send the request. For information about viewing or modifying policies for an IAM user, group, or role, see [Managing IAM policies](#).
- If the AWS Management Console returns a message stating that you're not authorized to perform an action, then you must contact your administrator for assistance. Your administrator provided you with your sign-in credentials or sign-in link.

The following example error occurs when the `mateojackson` IAM user attempts to use the console to view details about a fictional `my-example-widget` resource but does not have the fictional `widgets:GetWidget` permissions.

```
User: arn:aws:iam::123456789012:user/mateojackson is not authorized to perform:
widgets:GetWidget on resource: my-example-widget
```

In this case, Mateo must ask his administrator to update his policies to allow access to the `my-example-widget` resource using the `widgets:GetWidget` action.

- Are you trying to access a service that supports [resource-based policies](#), such as Amazon S3, Amazon SNS, or Amazon SQS? If so, verify that the policy specifies you as a principal and grants you access. If you make a request to a service within your account, either your identity-based policies or the resource-based policies can grant you permission. If you make a request to a service in a different account, then both your identity-based policies and the resource-based policies must grant you permission. To view the services that support resource-based policies, see [AWS services that work with IAM](#).
- If your policy includes a condition with a key–value pair, review it carefully. Examples include the `aws:RequestTag/tag-key` global condition key, the AWS KMS `kms:EncryptionContext:encryption_context_key`, and the `ResourceTag/tag-key` condition key supported by multiple services. Make sure that the key name does not match multiple results. Because condition key names are not case sensitive, a condition that checks for a key named `foo` matches `foo`, `Foo`, or `F00`. If your request includes multiple key–value pairs with key names that differ only by case, then your access might be unexpectedly denied. For more information, see [IAM JSON policy elements: Condition](#).
- If you have a [permissions boundary](#), verify that the policy that is used for the permissions boundary allows your request. If your identity-based policies allow the request, but your permissions boundary does not, then the request is denied. A permissions boundary controls the maximum permissions that an IAM principal (user or role) can have. Resource-based policies

are not limited by permissions boundaries. Permissions boundaries are not common. For more information about how AWS evaluates policies, see [Policy evaluation logic](#).

- If you are signing requests manually (without using the [AWS SDKs](#)), verify that you have correctly [signed the request](#).

I get "access denied" when I make a request with temporary security credentials

- First, make sure that you are not denied access for a reason that is unrelated to your temporary credentials. For more information, see [I get "access denied" when I make a request to an AWS service](#).
- Verify that the service accepts temporary security credentials, see [AWS services that work with IAM](#).
- Verify that your requests are being signed correctly and that the request is well-formed. For details, see your [toolkit](#) documentation or [Using temporary credentials with AWS resources](#).
- Verify that your temporary security credentials haven't expired. For more information, see [Temporary security credentials in IAM](#).
- Verify that the IAM user or role has the correct permissions. Permissions for temporary security credentials are derived from an IAM user or role. As a result, the permissions are limited to those that are granted to the role whose temporary credentials you have assumed. For more information about how permissions for temporary security credentials are determined, see [Controlling permissions for temporary security credentials](#).
- If you assumed a role, your role session might be limited by session policies. When you [request temporary security credentials](#) programmatically using AWS STS, you can optionally pass inline or managed [session policies](#). Session policies are advanced policies that you pass as a parameter when you programmatically create a temporary credential session for a role. You can pass a single JSON inline session policy document using the `Policy` parameter. You can use the `PolicyArns` parameter to specify up to 10 managed session policies. The resulting session's permissions are the intersection of the role's identity-based policies and the session policies. Alternatively, if your administrator or a custom program provides you with temporary credentials, they might have included a session policy to limit your access.
- If you are a federated user, your session might be limited by session policies. You become a federated user by signing in to AWS as an IAM user and then requesting a federation token. For more information about federated users, see [GetFederationToken—federation through a](#)

[custom identity broker](#). If you or your identity broker passed session policies while requesting a federation token, then your session is limited by those policies. The resulting session's permissions are the intersection of your IAM user identity-based policies and the session policies. For more information about session policies, see [Session policies](#).

- If you are accessing a resource that has a resource-based policy by using a role, verify that the policy grants permissions to the role. For example, the following policy allows MyRole from account 111122223333 to access MyBucket.

```
{
  "Version": "2012-10-17",
  "Statement": [{
    "Sid": "S3BucketPolicy",
    "Effect": "Allow",
    "Principal": {"AWS": ["arn:aws:iam::111122223333:role/MyRole"]},
    "Action": ["s3:PutObject"],
    "Resource": ["arn:aws:s3:::MyBucket/*"]
  }]
}
```

Access denied error message examples

Most access denied error messages appear in the format User *user* is not authorized to perform *action* on *resource* because *context*. In this example, *user* is the [Amazon Resource Name \(ARN\)](#) that doesn't receive access, *action* is the service action that the policy denies, and *resource* is the ARN of the resource on which the policy acts. The *context* field represents additional context about the policy type that explains why the policy denied access.

When a policy explicitly denies access because the policy contains a Deny statement, then AWS includes the phrase with an explicit deny in a *type* policy in the access denied error message. When the policy implicitly denies access, then AWS includes the phrase because no *type* policy allows the *action* action in the access denied error message.

Note

Some AWS services do not support this access denied error message format. The content of access denied error messages can vary depending on the service making the authorization request.

The following examples show the format for different types of access denied error messages.

Access denied due to a Service Control Policy – implicit denial

1. Check for a missing Allow statement for the action in your Service Control Policies (SCPs). For the following example, the action is `codecommit:ListRepositories`.
2. Update your SCP by adding the Allow statement. For more information, see [Updating an SCP](#) in the *AWS IAM Identity Center User Guide*.

```
User: arn:aws:iam::777788889999:user/JohnDoe is not authorized to perform:
codecommit:ListRepositories because no service control policy allows the
codecommit:ListRespositories action
```

Access denied due to a Service Control Policy – explicit denial

1. Check for a Deny statement for the action in your Service Control Policies (SCPs). For the following example, the action is `codecommit:ListRepositories`.
2. Update your SCP by removing the Deny statement. For more information, see [Updating an SCP](#) in the *AWS IAM Identity Center User Guide*.

```
User: arn:aws:iam::777788889999:user/JohnDoe is not authorized to perform:
codecommit:ListRepositories with an explicit deny in a service control policy
```

Access denied due to a VPC endpoint policy – implicit denial

1. Check for a missing Allow statement for the action in your Virtual Private Cloud (VPC) endpoint policies. For the following example, the action is `codecommit:ListRepositories`.
2. Update your VPC endpoint policy by adding the Allow statement. For more information, see [Update a VPC endpoint policy](#) in the *AWS PrivateLink Guide*.

```
User: arn:aws:iam::123456789012:user/JohnDoe is not authorized to perform:
codecommit:ListRepositories because no VPC endpoint policy allows the
codecommit:ListRepositories action
```

Access denied due to a VPC endpoint policy – explicit denial

1. Check for an explicit Deny statement for the action in your Virtual Private Cloud (VPC) endpoint policies. For the following example, the action is `codedeploy:ListDeployments`.
2. Update your VPC endpoint policy by removing the Deny statement. For more information, see [Update a VPC endpoint policy](#) in the *AWS PrivateLink Guide*.

```
User: arn:aws:iam::123456789012:user/JohnDoe is not authorized to perform:
codedeploy:ListDeployments on resource: arn:aws:codedeploy:us-
east-1:123456789012:deploymentgroup:* with an explicit deny in a VPC endpoint policy
```

Access denied due to a permissions boundary – implicit denial

1. Check for a missing Allow statement for the action in your permissions boundary. For the following example, the action is `codedeploy:ListDeployments`.
2. Update your permissions boundary by adding the Allow statement to your IAM policy. For more information, see [Permissions boundaries for IAM entities](#) and [Editing IAM policies](#).

```
User: arn:aws:iam::123456789012:user/JohnDoe is not authorized to perform:
codedeploy:ListDeployments on resource: arn:aws:codedeploy:us-
east-1:123456789012:deploymentgroup:* because no permissions boundary allows the
codedeploy:ListDeployments action
```

Access denied due to a permissions boundary – explicit denial

1. Check for an explicit Deny statement for the action in your permissions boundary. For the following example, the action is `sagemaker:ListModels`.
2. Update your permissions boundary by removing the Deny statement from your IAM policy. For more information, see [Permissions boundaries for IAM entities](#) and [Editing IAM policies](#).

```
User: arn:aws:iam::777788889999:user/JohnDoe is not authorized to perform:
sagemaker:ListModels with an explicit deny in a permissions boundary
```

Access denied due to session policies – implicit denial

1. Check for a missing Allow statement for the action in your session policies. For the following example, the action is `codecommit:ListRepositories`.
2. Update your session policy by adding the Allow statement. For more information, see [Session policies](#) and [Editing IAM policies](#).

```
User: arn:aws:iam::123456789012:user/JohnDoe is not authorized to perform:
codecommit:ListRepositories because no session policy allows the
codecommit:ListRepositories action
```

Access denied due to session policies – explicit denial

1. Check for an explicit Deny statement for the action in your session policies. For the following example, the action is `codedeploy:ListDeployments`.
2. Update your session policy by removing the Deny statement. For more information, see [Session policies](#) and [Editing IAM policies](#).

```
User: arn:aws:iam::123456789012:user/JohnDoe is not authorized to perform:
codedeploy:ListDeployments on resource: arn:aws:codedeploy:us-
east-1:123456789012:deploymentgroup:* with an explicit deny in a sessions policy
```

Access denied due to resource-based policies – implicit denial

1. Check for a missing Allow statement for the action in your resource-based policy. For the following example, the action is `secretsmanager:GetSecretValue`.
2. Update your policy by adding the Allow statement. For more information, see [Resource-based policies](#) and [Editing IAM policies](#).

```
User: arn:aws:iam::123456789012:user/JohnDoe is not authorized to perform:
secretsmanager:GetSecretValue because no resource-based policy allows the
secretsmanager:GetSecretValue action
```

Access denied due to resource-based policies – explicit denial

1. Check for an explicit Deny statement for the action in your resource-based policy. For the following example, the action is `secretsmanager:GetSecretValue`.
2. Update your policy by removing the Deny statement. For more information, see [Resource-based policies](#) and [Editing IAM policies](#).

```
User: arn:aws:iam::123456789012:user/JohnDoe is not authorized to perform:
secretsmanager:GetSecretValue on resource: arn:aws:secretsmanager:us-
east-1:123456789012:secret:* with an explicit deny in a resource-based policy
```

Access denied due to role trust policies – implicit denial

1. Check for a missing Allow statement for the action in your role trust policy. For the following example, the action is `sts:AssumeRole`.
2. Update your policy by adding the Allow statement. For more information, see [Resource-based policies](#) and [Editing IAM policies](#).

```
User: arn:aws:iam::123456789012:user/JohnDoe is not authorized to perform:
sts:AssumeRole because no role trust policy allows the sts:AssumeRole action
```

Access denied due to role trust policies – explicit denial

1. Check for an explicit Deny statement for the action in your role trust policy. For the following example, the action is `sts:AssumeRole`.
2. Update your policy by removing the Deny statement. For more information, see [Resource-based policies](#) and [Editing IAM policies](#).

```
User: arn:aws:iam::777788889999:user/JohnDoe is not authorized to perform:
sts:AssumeRole with an explicit deny in the role trust policy
```

Access denied due to identity-based policies – implicit denial

1. Check for a missing Allow statement for the action in identity-based policies attached to the identity. For the following example, the action is `codecommit:ListRepositories` attached to user `JohnDoe`.
2. Update your policy by adding the Allow statement. For more information, see [Identity-based policies](#) and [Editing IAM policies](#).

```
User: arn:aws:iam::123456789012:user/JohnDoe is not authorized to perform:
codecommit:ListRepositories because no identity-based policy allows the
codecommit:ListRepositories action
```

Access denied due to identity-based policies – explicit denial

1. Check for an explicit Deny statement for the action in identity-based policies attached to the identity. For the following example, the action is `codedeploy:ListDeployments` attached to user `JohnDoe`.
2. Update your policy by removing the Deny statement. For more information, see [Identity-based policies](#) and [Editing IAM policies](#).

```
User: arn:aws:iam::123456789012:user/JohnDoe is not authorized to perform:
codedeploy:ListDeployments on resource: arn:aws:codedeploy:us-
east-1:123456789012:deploymentgroup:* with an explicit deny in an identity-based policy
```

Access denied when a VPC request fails due to another policy

1. Check for an explicit Deny statement for the action in your Service Control Policies (SCPs). For the following example, the action is `SNS:Publish`.
2. Update your SCP by removing the Deny statement. For more information, see [Updating an SCP](#) in the *AWS IAM Identity Center User Guide*.

```
User: arn:aws:sts::111122223333:assumed-role/role-name/role-session-name is not
authorized to perform:
SNS:Publish on resource: arn:aws:sns:us-east-1:444455556666:role-name-2
```

with an explicit deny in a VPC endpoint policy transitively through a service control policy

Troubleshooting IAM policies

A [policy](#) is an entity in AWS that, when attached to an identity or resource, defines their permissions. AWS evaluates these policies when a principal, such as a user, makes a request. Permissions in the policies determine whether the request is allowed or denied. Policies are stored in AWS as JSON documents that are attached to principals as *identity-based policies* or to resources as *resource-based policies*. You can attach an identity-based policy to a principal (or identity), such as an IAM group, user, or role. Identity-based policies include AWS managed policies, customer managed policies, and inline policies. You can create and edit customer managed policies in the AWS Management Console using both **Visual** and **JSON** editor options. When you view a policy in the AWS Management Console, you can see a summary of the permissions that are granted by that policy. You can use the visual editor and policy summaries to help you diagnose and fix common errors encountered while managing IAM policies.

Keep in mind that all IAM policies are stored using syntax that begins with the rules of [JavaScript Object Notation](#) (JSON). You do not have to understand this syntax to create or manage your policies. You can create and edit a policy using the visual editor in the AWS Management Console. To learn more about JSON syntax in IAM policies, see [Grammar of the IAM JSON policy language](#).

Troubleshoot using the visual editor

When you create or edit a customer managed policy, you can use information in the **Visual** editor to help you troubleshoot errors in your policy. To view an example of using the visual editor to create a policy, see [the section called “Controlling access to identities”](#).

Policy restructuring

When you create a policy, AWS validates, processes, and transforms the policy before storing it. When AWS returns the policy in response to a user query or displays it in the console, AWS transforms the policy back into a human-readable format without changing the permissions granted by the policy. This can result in differences in what you see in the policy visual editor or **JSON** tab: Visual editor permission blocks can be added, removed, or reordered, and content within a block can be optimized. In the **JSON** tab, insignificant white space can be removed, and elements within JSON maps can be reordered. In addition, AWS account IDs within the principal elements can be replaced by the ARN of the AWS account root user. Because of these possible changes, you should not compare JSON policy documents as strings.

When you create a customer managed policy in the AWS Management Console, you can choose to work entirely in the **JSON** editor. If you never make any changes in the **Visual** editor and choose **Next** from the **JSON** editor, the policy is less likely to be restructured. However, if you create a policy and use the **Visual** editor to make any modifications, or if you choose **Next** from the **Visual** editor option, then IAM might restructure the policy to optimize its appearance in the visual editor.

This restructuring exists only in your editing session and is not saved automatically.

If your policy is restructured in your editing session, IAM determines whether to save the restructuring based on the following situations:

Using this editor option	If you edit your policy	And then choose <i>Next</i> from this tab	When you choose <i>Save changes</i>
Visual	Edited	Visual	The policy is restructured
Visual	Edited	JSON	The policy is restructured
Visual	Not Edited	Visual	The policy is restructured
JSON	Edited	Visual	The policy is restructured
JSON	Edited	JSON	The policy structure is not changed
JSON	Not Edited	JSON	The policy structure is not changed

IAM might restructure complex policies or policies that have permission blocks or statements that allow multiple services, resource types, or condition keys.

Choosing a resource ARN in the visual editor

When you create or edit a policy using the visual editor, you must first choose a service, and then choose actions from that service. If the service and actions that you selected support choosing [specific resources](#), then the visual editor lists the supported resource types. You can then choose **Add ARN** to provide the details about your resource. You can choose from the following options for adding an ARN for a resource type.

- **Use the ARN builder** – Based on the resource type, you might see different fields to build your ARN. You can also choose **Any** to provide permissions for any value for the specified setting. For example, if you selected the Amazon EC2 **Read** access level group, then the actions in your policy support the `instance` resource type. You must provide the **Region**, **Account**, and **InstanceID**

values for your resource. If you provide your account ID but choose **Any** for the Region and instance ID, then the policy grants permissions to any instance in your account.

- **Type or paste the ARN** – You can specify resources by their [Amazon Resource Name \(ARN\)](#). You can include a wildcard character (*) in any field of the ARN (between each pair of colons). For more information, see [IAM JSON policy elements: Resource](#).

Denying permissions in the visual editor

By default, the policy that you create using the visual editor allows the actions that you choose. To deny the chosen actions instead, choose **Switch to deny permissions**. Because requests are *denied by default*, we recommend as a security best practice that you allow permissions to only those actions and resources that a user needs. You should create a statement to deny permissions only if you want to override a permission separately that is allowed by another statement or policy. We recommend that you limit the number of deny permissions to a minimum because they can increase the difficulty of troubleshooting permissions. For more information about how IAM evaluates policy logic, see [Policy evaluation logic](#).

Note

By default, only the AWS account root user has access to all the resources in that account. So if you are not signed in as the root user, you must have permissions granted by a policy.

Specifying multiple services in the visual editor

When you use the visual editor to construct a policy, you can select only one service at a time. This is a best practice because the visual editor then allows you to choose from the actions for that one service. You then choose from the resources supported by that service and the selected actions. This makes it easier to create and troubleshoot your policy.

If you are familiar with the JSON syntax, you can also use a wildcard character (*) to manually specify multiple services. For example, type **Code*** to provide permissions for all services beginning with Code, such as CodeBuild and CodeCommit. However, you must then type the actions and resource ARNs to complete your policy. Additionally, when you save your policy, it might be [restructured](#) to include each service in a separate permission block.

Alternatively, to use JSON syntax (such as wildcards) for services, create, edit, and save your policy using the **JSON** editor option.

Reducing the size of your policy in the visual editor

When you use the visual editor to create a policy, IAM creates a JSON document to store your policy. You can view this document by switching to the **JSON** editor option. If this JSON document exceeds the size limit of a policy, the visual editor displays an error message and does not allow you to review and save your policy. To view the IAM limitation on the size of a managed policy, see [IAM and STS character limits](#).

To reduce the size of your policy in the visual editor, edit your policy or move permission blocks to another policy. The error message includes the number of characters that your policy document contains, and you can use this information to help you reduce the size of your policy.

Fixing unrecognized services, actions, or resource types in the visual editor

When you create or edit a policy in the visual editor, you might see a warning that your policy includes an unrecognized service, action, or resource type.

Note

IAM reviews service names, actions, and resource types for services that support policy summaries. However, your policy summary might include a resource value or condition that does not exist. Always test your policies with the [policy simulator](#).

If your policy includes unrecognized services, actions or resource types, one of the following errors has occurred:

- **Preview service** – Services that are in preview do not support the visual editor. If you are participating in the preview, you can ignore the warning and continue, though you must manually type the actions and resource ARNs to complete your policy. Alternatively, you can choose the **JSON** editor option to type or paste a JSON policy document.
- **Custom service** – Custom services do not support the visual editor. If you are using a custom service, you can ignore the warning and continue, though you must manually type the actions and resource ARNs to complete your policy. Alternatively, you can choose the **JSON** editor option to type or paste a JSON policy document.
- **Service does not support the visual editor** – If your policy includes a generally available (GA) service that does not support the visual editor, you can ignore the warning and continue, though you must manually type the actions and resource ARNs to complete your policy. Alternatively, you can choose the **JSON** editor option to type or paste a JSON policy document.

Generally available services are services that are released publicly and are not preview or custom services. If an unrecognized service is generally available and the name is spelled correctly, then the service does not support the visual editor. To learn how to request visual editor or policy summary support for a GA service, see [Service does not support IAM policy summaries](#).

- **Action does not support the visual editor** – If your policy includes a supported service with an unsupported action, you can ignore the warning and continue, though you must manually type the resource ARNs to complete your policy. Alternatively, you can choose the **JSON** editor option to type or paste a JSON policy document.

If your policy includes a supported service with an unsupported action, then the service does not fully support the visual editor. To learn how to request visual editor or policy summary support for a GA service, see [Service does not support IAM policy summaries](#).

- **Resource type does not support the visual editor** – If your policy includes a supported action with an unsupported resource type, you can ignore the warning and continue. However, IAM cannot confirm that you have included resources for all of your selected actions, and you might see additional warnings.
- **Typo** – When you manually type a service, action, or resource in the visual editor, you can create a policy that includes a typo. To avoid this, we recommend that you use the visual editor by selecting from the list of services and actions, and then complete the resource section according to the prompts. However, if a service does not fully support the visual editor, you might have to manually type parts of your policy.

If you are certain that your policy contains none of the errors above, then your policy might include a typo. Check for misspelled service, action, and resource type names. For example, you might use `s2` instead of `s3` and `ListMyBuckets` instead of `ListAllMyBuckets`. Another common action typo is the inclusion of unnecessary text in ARNs, such as `arn:aws:s3: : :*`, or missing colons in actions, such as `iam.CreateUser`. You can evaluate a policy that might include typos by choosing **Next** to review the policy summary and confirm whether the policy provides the permissions you intended.

Troubleshoot using policy summaries

You can diagnose and resolve issues related to policy summaries.

Missing policy summary

The IAM console includes *policy summary* tables that describe the access level, resources, and conditions that are allowed or denied for each service in a policy. Policies are summarized in three tables: the [policy summary](#), the [service summary](#), and the [action summary](#). The *policy summary* table includes a list of services and summaries of the permissions that are defined by the chosen policy. You can view the [policy summary](#) for any policies that are attached to an entity on the **Policy details** page for that policy. You can view the policy summary for managed policies on the **Policies** page. If AWS is unable to render a summary for a policy, then you see the JSON policy document instead of the summary, and receive the following error:

A summary for this policy cannot be generated. You can still view or edit the JSON policy document.

If your policy does not include a summary, one of the following errors has occurred:

- **Unsupported policy element** – IAM does not support generating policy summaries for policies that include one of the following [policy elements](#):
 - Principal
 - NotPrincipal
 - NotResource
- **No policy permissions** – If a policy does not provide any effective permissions, then the policy summary cannot be generated. For example, if a policy includes a single statement with the element "NotAction": "*", then it grants access to all actions except "all actions" (*). This means it grants Deny or Allow access to nothing.

Note

You must be careful when using these policy elements such as NotPrincipal, NotAction, and NotResource. For information about using policy elements, see [IAM JSON policy elements reference](#).

You can create a policy that does not provide effective permissions if you provide mismatched services and resources. This can occur if you specify actions in one service and resources from another service. In this case, the policy summary does appear. The only indication that there is a problem is that the resource column in the summary can include a resource from a different

service. If this column includes a mismatched resource, then you should review your policy for errors. To better understand your policies, always test them with the [policy simulator](#).

Policy summary includes unrecognized services, actions, or resource types

In the IAM console, if a [policy summary](#) includes a warning symbol

then the policy might include an unrecognized service, action or resource type. To learn about warnings within a policy summary, see [Policy summary \(list of services\)](#).

Note

IAM reviews service names, actions, and resource types for services that support policy summaries. However, your policy summary might include a resource value or condition that does not exist. Always test your policies with the [policy simulator](#).

If your policy includes unrecognized services, actions or resource types, one of the following errors has occurred:

- **Preview service** – Services that are in preview do not support policy summaries.
- **Custom service** – Custom services do not support policy summaries.
- **Service does not support summaries** – If your policy includes a generally available (GA) service that does not support policy summaries, then the service is included in the **Unrecognized services** section of the policy summary table. Generally available services are services that are released publicly and are not preview or custom services. If an unrecognized service is generally available and the name is spelled correctly, then the service does not support IAM policy summaries. To learn how to request policy summary support for a GA service, see [Service does not support IAM policy summaries](#).
- **Action does not support summaries** – If your policy includes a supported service with an unsupported action, then the action is included in the **Unrecognized actions** section of the service summary table. To learn about warnings within a service summary, see [Service summary \(list of actions\)](#).
- **Resource type does not support summaries** – If your policy includes a supported action with an unsupported resource type, then the resource is included in the **Unrecognized resource types**

section of the service summary table. To learn about warnings within a service summary, see [Service summary \(list of actions\)](#).

- **Typo** – AWS checks that the JSON is syntactically correct, and that the policy does not include typos or other errors as part of [policy validation](#).

Note

As a [best practice](#), we recommend that you use IAM Access Analyzer to validate your IAM policies to ensure secure and functional permissions. We recommend that you open your existing policies and review and resolve any policy validation recommendations.

Service does not support IAM policy summaries

When a generally available (GA) service or action is not recognized by IAM policy summaries or the visual editor, it is possible that the service does not support these features. Generally available services are services that are released publicly and are not previewed or custom services. If an unrecognized service is generally available and the name is spelled correctly, then the service does not support these features. If your policy includes a supported service with an unsupported action, then the service does not fully support IAM policy summaries.

To request that a service add IAM policy summary or visual editor support

1. Sign in to the AWS Management Console and open the IAM console at <https://console.aws.amazon.com/iam/>.
2. Locate the policy that includes the unsupported service:
 - If the policy is a managed policy, choose **Policies** in the navigation pane. In the list of policies, choose the name of the policy that you want to view.
 - If the policy is an inline policy attached to the user, choose **Users** in the navigation pane. In the list of users, choose the name of the user whose policy you want to view. In the table of policies for the user, expand the header for the policy summary that you want to view.
3. In the left side on the AWS Management Console footer, choose **Feedback**. In the **Feedback for IAM** box, type **I request that the <ServiceName> service add support for IAM policy summaries and the visual editor**. If you want more than one service to support summaries, type **I request that the <ServiceName1>, <ServiceName2>**,

and <ServiceName3> services add support for IAM policy summaries and the visual editor.

To request that a service add IAM policy summary support for a missing action

1. Sign in to the AWS Management Console and open the IAM console at <https://console.aws.amazon.com/iam/>.
2. Locate the policy that includes the unsupported service:
 - If the policy is a managed policy, choose **Policies** in the navigation pane. In the list of policies, choose the name of the policy that you want to view.
 - If the policy is an inline policy attached to the user, choose **Users** in the navigation pane. In the list of users, choose the name of the user whose policy you want to view. In the table of policies for the user, choose the name of the policy that you want to view to expand the policy summary.
3. In the policy summary, choose the name of the service that includes an unsupported action.
4. In the left side on the AWS Management Console footer, choose **Feedback**. In the **Feedback for IAM** box, type **I request that the <ServiceName> service add IAM policy summary and the visual editor support for the <ActionName> action.** If you want to report more than one unsupported action, type **I request that the <ServiceName> service add IAM policy summary and the visual editor support for the <ActionName1>, <ActionName2>, and <ActionName3> actions.**

To request that a different service includes missing actions, repeat the last three steps.

My policy does not grant the expected permissions

To assign permissions to a user, group, role, or resource, you create a *policy*, which is a document that defines permissions. The policy document includes the following elements:

- **Effect** – whether the policy allows or denies access
- **Action** – the list of actions that are allowed or denied by the policy
- **Resource** – the list of resources on which the actions can occur
- **Condition** (Optional) – the circumstances under which the policy grants permission

To learn about these and other policy elements, see [IAM JSON policy elements reference](#).

To grant access, your policy must define an action with a supported resource. If your policy also includes a condition, that condition must include a [global condition key](#) or must apply to the action. To learn which resources are supported by an action, see the [AWS documentation](#) for your service. To learn which conditions are supported by an action, see [Actions, Resources, and Condition Keys for AWS Services](#).

To learn whether your policy defines an action, resource, or condition that does not grant permissions, you can view the [policy summary](#) for your policy using the IAM console at <https://console.aws.amazon.com/iam/>. You can use policy summaries to identify and correct problems in your policy.

There are several reasons why an element might not grant permissions despite being defined in the IAM policy:

- [An action is defined without an applicable resource](#)
- [A resource is defined without an applicable action](#)
- [A condition is defined without an applicable action](#)

To view examples of policy summaries that include warnings, see [the section called "Policy summary \(list of services\)"](#).

An action is defined without an applicable resource

The policy below defines all `ec2:Describe*` actions and defines a specific resource. None of the `ec2:Describe` actions are granted because none of these actions support resource-level permissions. Resource-level permissions mean that the action supports resources using [ARNs](#) in the policy's [Resource](#) element. If an action does not support resource-level permissions, then that statement in the policy must use a wildcard (*) in the Resource element. To learn which services support resource-level permissions, see [AWS services that work with IAM](#).

```
{
  "Version": "2012-10-17",
  "Statement": [{
    "Effect": "Allow",
    "Action": "ec2:Describe*",
    "Resource": "arn:aws:ec2:us-east-2:ACCOUNT-ID:instance/*"
  }]
}
```

This policy does not provide any permissions, and the policy summary includes the following error:

This policy does not grant any permissions. To grant access, policies must have an action that has an applicable resource or condition.

To fix this policy, you must use `*` in the Resource element.

```
{
  "Version": "2012-10-17",
  "Statement": [{
    "Effect": "Allow",
    "Action": "ec2:Describe*",
    "Resource": "*"
  }]
}
```

A resource is defined without an applicable action

The policy below defines an Amazon S3 bucket resource but does not include an S3 action that can be performed on that resource. This policy also grants full access to all Amazon CloudFront actions.

```
{
  "Version": "2012-10-17",
  "Statement": [{
    "Effect": "Allow",
    "Action": "cloudfront:*",
    "Resource": [
      "arn:aws:cloudfront:*",
      "arn:aws:s3:::examplebucket"
    ]
  }]
}
```

This policy provides permissions for all CloudFront actions. But because the policy defines the S3 `examplebucket` resource without defining any S3 actions, the policy summary includes the following warning:

This policy defines some actions, resources, or conditions that do not provide permissions. To grant access, policies must have an action that has an applicable resource or condition.

To fix this policy to provide S3 bucket permissions, you must define S3 actions that can be performed on a bucket resource.

```
{
  "Version": "2012-10-17",
  "Statement": [{
    "Effect": "Allow",
    "Action": [
      "cloudfront:*",
      "s3:CreateBucket",
      "s3:ListBucket*",
      "s3:PutBucket*",
      "s3:GetBucket*"
    ],
    "Resource": [
      "arn:aws:cloudfront:*",
      "arn:aws:s3:::examplebucket"
    ]
  }]
}
```

Alternately, to fix this policy to provide only CloudFront permissions, remove the S3 resource.

A condition is defined without an applicable action

The policy below defines two Amazon S3 actions for all S3 resources, if the S3 prefix equals custom and the version ID equals 1234. However, the `s3:VersionId` condition key is used for object version tagging and is not supported by the defined bucket actions. To learn which conditions are supported by an action, see [Actions, Resources, and Condition Keys for AWS Services](#) and follow the link to the service documentation for condition keys.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "s3:ListBucketVersions",
        "s3:ListBucket"
      ],
      "Resource": "*",
      "Condition": {
```

```

        "StringEquals": {
            "s3:prefix": [
                "custom"
            ],
            "s3:VersionId": [
                "1234"
            ]
        }
    ]
}

```

This policy provides permissions for the `s3:ListBucketVersions` action and the `s3:ListBucket` action if the bucket name includes the custom prefix. But because the `s3:VersionId` condition is not supported by any of the defined actions, the policy summary includes the following error:

This policy does not grant any permissions. To grant access, policies must have an action that has an applicable resource or condition.

To fix this policy to use S3 object version tagging, you must define an S3 action that supports the `s3:VersionId` condition key.

```

{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "s3:ListBucketVersions",
        "s3:ListBucket",
        "s3:GetObjectVersion"
      ],
      "Resource": "*",
      "Condition": {
        "StringEquals": {
          "s3:prefix": [
            "custom"
          ],
          "s3:VersionId": [
            "1234"
          ]
        }
      }
    }
  ]
}

```

```

    ]
  }
}
]
}

```

This policy provides permissions for every action and condition in the policy. However, the policy still does not provide any permissions because there is no case where a single action matches both conditions. Instead, you must create two separate statements that each include only actions with the conditions to which they apply.

To fix this policy, create two statements. The first statement includes the actions that support the `s3:prefix` condition, and the second statement includes the actions that support the `s3:VersionId` condition.

```

{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "s3:ListBucketVersions",
        "s3:ListBucket"
      ],
      "Resource": "*",
      "Condition": {
        "StringEquals": {
          "s3:prefix": "custom"
        }
      }
    },
    {
      "Effect": "Allow",
      "Action": "s3:GetObjectVersion",
      "Resource": "*",
      "Condition": {
        "StringEquals": {
          "s3:VersionId": "1234"
        }
      }
    }
  ]
}

```

}

Troubleshoot policy management

You can diagnose and resolve issues relating to policy management.

Attaching or detaching a policy in an IAM account

Some AWS managed policies are linked to a service. These policies are used only with a [service-linked role](#) for that service. In the IAM console, when you view the **Policy details** page for a policy, the page includes a banner to indicate that the policy is linked to a service. You cannot attach this policy to a user, group, or role within IAM. When you create a service-linked role for the service, this policy is automatically attached to your new role. Because the policy is required, you cannot detach the policy from the service-linked role.

Changing policies for your IAM identities based on their activity

You can update policies for your IAM identities (users, groups, and roles) based on their activity. To do this, view your account's events in CloudTrail **Event history**. CloudTrail event logs include detailed event information that you can use to change the policy's permissions. You might find that a user or role is attempting to perform an action in AWS and that request is denied. In that case, you can consider whether the user or role should have permission to perform the action. If so, you can add the action and even the ARN of the resource that they attempted to access to their policy. Alternatively, if the user or role has permissions that they are not using, you might consider removing those permissions from their policy. Make sure that your policies grant the [least privilege](#) that is needed to perform only the necessary actions. For more information about using CloudTrail, see [Viewing CloudTrail Events in the CloudTrail Console](#) in the *AWS CloudTrail User Guide*.

Troubleshoot JSON policy documents

You can diagnose and resolve issues relating to JSON policy documents.

Validate your policies

When you create or edit a JSON policy, IAM can perform policy validation to help you create an effective policy. IAM identifies JSON syntax errors, while IAM Access Analyzer provides additional policy checks with recommendations to help you further refine your policies. To learn more about policy validation, see [Validating IAM policies](#). To learn more about IAM Access Analyzer policy checks and actionable recommendations, see [IAM Access Analyzer policy validation](#).

I don't have permissions for policy validation in the JSON editor

In the AWS Management Console, you might receive the following error if you do not have permissions to view IAM Access Analyzer policy validation results:

You need permissions. You do not have the permissions required to perform this operation. Ask your administrator to add permissions.

To fix this error, ask your administrator to add the `access-analyzer:ValidatePolicy` permission for you.

More than one JSON policy object

An IAM policy must consist of one and only one JSON object. You denote an object by placing `{ }` braces around it. Although you can nest other objects within a JSON object by embedding additional `{ }` braces within the outer pair, a policy can contain only one outermost pair of `{ }` braces. The following example is incorrect because it contains two objects at the top level (called out in *red*):

```
{
  "Version": "2012-10-17",
  "Statement":
  {
    "Effect": "Allow",
    "Action": "ec2:Describe*",
    "Resource": "*"
  }
}
{
  "Statement": {
    "Effect": "Allow",
    "Action": "s3:*",
    "Resource": "arn:aws:s3:::my-bucket/*"
  }
}
```

You can, however, meet the intention of the previous example with the use of correct policy grammar. Instead of including two complete policy objects each with its own `Statement` element, you can combine the two blocks into a single `Statement` element. The `Statement` element has an array of two objects as its value, as shown in the following example (called out in **bold**):

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": "ec2:Describe*",
      "Resource": "*"
    },
    {
      "Effect": "Allow",
      "Action": "s3:*",
      "Resource": "arn:aws:s3:::my-bucket/*"
    }
  ]
}
```

More than one JSON statement element

This error might at first appear to be a variation on the previous section. However, syntactically it is a different type of error. The following example has only one policy object as denoted by a single pair of { } braces at the top level. However, that object contains two Statement elements within it.

An IAM policy must contain only one Statement element, consisting of the name (Statement) appearing to the left of a colon, followed by its value on the right. The value of a Statement element must be an object, denoted by { } braces, containing one Effect element, one Action element, and one Resource element. The following example is incorrect because it contains two Statement elements in the policy object (called out in *red*):

```
{
  "Version": "2012-10-17",
  "Statement": {
    "Effect": "Allow",
    "Action": "ec2:Describe*",
    "Resource": "*"
  },
  "Statement": {
    "Effect": "Allow",
    "Action": "s3:*",
    "Resource": "arn:aws:s3:::my-bucket/*"
  }
}
```

A value object can be an array of multiple value objects. To solve this problem, combine the two Statement elements into one element with an object array, as shown in the following example (called out in **bold**):

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": "ec2:Describe*",
      "Resource": "*"
    },
    {
      "Effect": "Allow",
      "Action": "s3:*",
      "Resource": "arn:aws:s3:::my-bucket/*"
    }
  ]
}
```

The value of the Statement element is an object array. The array in this example consists of two objects, each of which is by itself a correct value for a Statement element. Each object in the array is separated by commas.

More than one effect, action, or resource element in a JSON statement element

On the value side of the Statement name/value pair, the object must consist of only one Effect element, one Action element, and one Resource element. The following policy is incorrect because it has two Effect elements in the value object of the Statement:

```
{
  "Version": "2012-10-17",
  "Statement": {
    "Effect": "Deny",
    "Effect": "Allow",
    "Action": "ec2:* ",
    "Resource": "*"
  }
}
```

Note

The policy engine does not allow such errors in new or edited policies. However, the policy engine continues to permit policies that were saved before the engine was updated. The behavior of existing policies with the error is as follows:

- **Multiple Effect elements:** only the last Effect element is observed. The others are ignored.
- **Multiple Action elements:** all Action elements are combined internally and treated as if they were a single list.
- **Multiple Resource elements:** all Resource elements are combined internally and treated as if they were a single list.

The policy engine does not allow you to save any policy with syntax errors. You must correct the errors in the policy before you can save it. We recommend that you review any correct any [policy validation](#) recommendations for your policies.

In each case, the solution is to remove the incorrect extra element. For Effect elements, this is straightforward: if you want the previous example to *deny* permissions to Amazon EC2 instances, then you must remove the line "Effect": "Allow" , from the policy, as follows:

```
{
  "Version": "2012-10-17",
  "Statement": {
    "Effect": "Deny",
    "Action": "ec2:* ",
    "Resource": "*"
  }
}
```

However, if the duplicate element is Action or Resource, then the resolution can be more complicated. You might have multiple actions that you want to allow (or deny) permission to, or you might want to control access to multiple resources. For example, the following example is incorrect because it has multiple Resource elements (called out in *red*):

```
{
  "Version": "2012-10-17",
```

```
"Statement": {
  "Effect": "Allow",
  "Action": "s3:*",
  "Resource": "arn:aws:s3::my-bucket",
  "Resource": "arn:aws:s3::my-bucket/*"
}
```

Each of the required elements in a Statement element's value object can be present only once. The solution is to place each value in an array. The following example illustrates this by making the two separate resource elements into one Resource element with an array as the value object (called out in **bold**):

```
{
  "Version": "2012-10-17",
  "Statement": {
    "Effect": "Allow",
    "Action": "s3:*",
    "Resource": [
      "arn:aws:s3::my-bucket",
      "arn:aws:s3::my-bucket/*"
    ]
  }
}
```

Missing JSON version element

A `Version` policy element is different from a policy version. The `Version` policy element is used within a policy and defines the version of the policy language. A policy version, on the other hand, is created when you make changes to a customer managed policy in IAM. The changed policy doesn't overwrite the existing policy. Instead, IAM creates a new version of the managed policy. To learn more about the `Version` policy element see [IAM JSON policy elements: Version](#). To learn more about policy versions, see [the section called "Versioning IAM policies"](#).

As AWS features evolve, new capabilities are added to IAM policies to support those features. Sometimes, an update to the policy syntax includes a new version number. If you use newer features of the policy grammar in your policy, then you must tell the policy parsing engine which version you are using. The default policy version is "2008-10-17." If you want to use any policy feature that was introduced later, then you must specify the version number that supports the feature you want. We recommend that you *always* include the latest policy syntax version number,

which is currently "Version": "2012-10-17". For example, the following policy is incorrect because it uses a policy variable `${...}` in the ARN for a resource. But it fails to specify a policy syntax version that supports policy variables (called out in *red*):

```
{
  "Statement":
  {
    "Action": "iam:*AccessKey*",
    "Effect": "Allow",
    "Resource": "arn:aws:iam::123456789012:user/${aws:username}"
  }
}
```

Adding a `Version` element at the top of the policy with the value `2012-10-17`, the first IAM API version that supports policy variables, solves this problem (called out in **bold**):

```
{
  "Version": "2012-10-17",
  "Statement":
  {
    "Action": "iam:*AccessKey*",
    "Effect": "Allow",
    "Resource": "arn:aws:iam::123456789012:user/${aws:username}"
  }
}
```

Troubleshooting FIDO security keys

Use the information here to help you diagnose common issues that you might encounter when working with FIDO2 security keys.

Topics

- [I can't enable my FIDO security key](#)
- [I can't sign in using my FIDO security key](#)
- [I lost or broke my FIDO security key](#)
- [Other issues](#)

I can't enable my FIDO security key

Consult the following solutions depending on your status as an IAM user or system administrator

IAM users

If you can't enable your FIDO security key, check the following:

- Are you using a supported configuration?

For information on devices and browsers you can use with WebAuthn and AWS, see [Supported configurations for using FIDO security keys](#).

- Are you using Mozilla Firefox?

Current Firefox versions support WebAuthn by default. To enable support for WebAuthn in Firefox, do the following:

1. From the Firefox address bar, type **about:config**.
2. In the Search bar of the screen that opens, type **webauthn**.
3. Choose **security.webauth.webauthn** and change its value to **true**.

- Are you using any browser plugins?

AWS does not support the use of plugins to add WebAuthn browser support. Instead, use a browser that offers native support of the WebAuthn standard.

Even if you're using a supported browser, you may have a plugin that is incompatible with WebAuthn. An incompatible plugin may prevent you from enabling and using your FIDO-compliant security key. You should disable any plugins that might be incompatible and restart your browser. Then retry enabling the FIDO security key.

- Do you have the appropriate permissions?

If you don't have any of the above compatibility issues, you may not have the appropriate permissions. Contact your system administrator.

System administrators

If you're an administrator and your IAM users can't enable their FIDO security keys despite using a supported configuration, make sure they have the appropriate permissions. For a detailed example, see [IAM tutorial: Permit users to manage their credentials and MFA settings](#).

I can't sign in using my FIDO security key

If you're an IAM user and you can't sign in to the AWS Management Console using your FIDO security key, first see [Supported configurations for using FIDO security keys](#). If you're using a supported configuration but cannot sign in, contact your system administrator for assistance.

I lost or broke my FIDO security key

Up to **eight** MFA devices of any combination of the [currently supported MFA types](#) can be assigned to a user. With multiple MFA devices, you only need one MFA device to sign in to the AWS Management Console. Replacing a FIDO security key is similar to replacing a hardware TOTP token. For information on what to do if you lose or break any type of MFA device, see [What if an MFA device is lost or stops working?](#).

Other issues

If you have an issue with FIDO security keys that is not covered here, do one of the following:

- IAM users: Contact your system administrator.
- AWS account root users: Contact [AWS Support](#).

Troubleshooting IAM roles

Use the information here to help you diagnose and fix common issues that you might encounter when working with IAM roles.

Topics

- [I can't assume a role](#)
- [A new role appeared in my AWS account](#)
- [I can't edit or delete a role in my AWS account](#)
- [I'm not authorized to perform: iam:PassRole](#)
- [Why can't I assume a role with a 12-hour session? \(AWS CLI, AWS API\)](#)
- [I receive an error when I try to switch roles in the IAM console](#)
- [My role has a policy that allows me to perform an action, but I get "access denied"](#)
- [The service did not create the role's default policy version](#)
- [There is no use case for a service role in the console](#)

I can't assume a role

Check the following:

- To allow users to assume the current role again within a role session, specify the role ARN or AWS account ARN as a principal in the role trust policy. AWS services that provide compute resources such as Amazon EC2, Amazon ECS, Amazon EKS, and Lambda provide temporary credentials and automatically update these credentials. This ensures that you always have a valid set of credentials. For these services, it's not necessary to assume the current role again to obtain temporary credentials. However, if you intend to pass [session tags](#) or a [session policy](#), you need to assume the current role again. To learn how to modify a role trust policy to add the principal role ARN or AWS account ARN, see [Modifying a role trust policy \(console\)](#).
- When you assume a role using the AWS Management Console, make sure to use the exact name of your role. Role names are case sensitive when you assume a role.
- When you assume a role using AWS STS API or AWS CLI, make sure to use the exact name of your role in the ARN. Role names are case sensitive when you assume a role.
- Verify that your IAM policy grants you permission to call `sts:AssumeRole` for the role that you want to assume. The `Action` element of your IAM policy must allow you to call the `AssumeRole` action. In addition, the `Resource` element of your IAM policy must specify the role that you want to assume. For example, the `Resource` element can specify a role by its Amazon Resource Name (ARN) or by a wildcard (*). For example, at least one policy applicable to you must grant permissions similar to the following:

```
"Effect": "Allow",  
"Action": "sts:AssumeRole",  
"Resource": "arn:aws:iam::account_id_number:role/role-name-you-want-to-assume"
```

- Verify that your IAM identity is tagged with any tags that the IAM policy requires. For example, in the following policy permissions, the `Condition` element requires that you, as the principal requesting to assume the role, must have a specific tag. You must be tagged with `department = HR` or `department = CS`. Otherwise, you cannot assume the role. To learn about tagging IAM users and roles, see [the section called "Tagging IAM resources"](#).

```
"Effect": "Allow",  
"Action": "sts:AssumeRole",  
"Resource": "*",  
"Condition": {"StringEquals": {"aws:PrincipalTag/department": [  
    "HR",
```

```
"CS"
  ]}}
```

- Verify that you meet all the conditions that are specified in the role's trust policy. A `Condition` can specify an expiration date, an external ID, or that a request must come only from specific IP addresses. Consider the following example: If the current date is any time after the specified date, then the policy never matches and cannot grant you the permission to assume the role.

```
"Effect": "Allow",
"Action": "sts:AssumeRole",
"Resource": "arn:aws:iam::account_id_number:role/role-name-you-want-to-assume"
"Condition": {
  "DateLessThan" : {
    "aws:CurrentTime" : "2016-05-01T12:00:00Z"
  }
}
```

- Verify that the AWS account from which you are calling `AssumeRole` is a trusted entity for the role that you are assuming. Trusted entities are defined as a `Principal` in a role's trust policy. The following example is a trust policy that is attached to the role that you want to assume. In this example, the account ID with the IAM user that you signed in with must be 123456789012. If your account number is not listed in the `Principal` element of the role's trust policy, then you cannot assume the role. It does not matter what permissions are granted to you in access policies. Note that the example policy limits permissions to actions that occur between July 1, 2017 and December 31, 2017 (UTC), inclusive. If you log in before or after those dates, then the policy does not match, and you cannot assume the role.

```
"Effect": "Allow",
"Principal": { "AWS": "arn:aws:iam::123456789012:root" },
"Action": "sts:AssumeRole",
"Condition": {
  "DateGreaterThan": {"aws:CurrentTime": "2017-07-01T00:00:00Z"},
  "DateLessThan": {"aws:CurrentTime": "2017-12-31T23:59:59Z"}
}
```

- **Source Identity** – Administrators can configure roles to require identities to pass a custom string that identifies the person or application that is performing actions in AWS, called *source identity*. Verify whether the role being assumed requires that a source identity is set. For more information about source identity, see [Monitor and control actions taken with assumed roles](#).

A new role appeared in my AWS account

Some AWS services require that you use a unique type of service role that is linked directly to the service. This [service-linked role](#) is predefined by the service and includes all the permissions that the service requires. This makes setting up a service easier because you don't have to manually add the necessary permissions. For general information about service-linked roles, see [Using service-linked roles](#).

You might already be using a service when it begins supporting service-linked roles. If so, you might receive an email telling you about a new role in your account. This role includes all the permissions that the service needs to perform actions on your behalf. You don't need to take any action to support this role. However, you should not delete the role from your account. Doing so could remove permissions that the service needs to access AWS resources. You can view the service-linked roles in your account by going to the IAM **Roles** page of the IAM console. Service-linked roles appear with **(Service-linked role)** in the **Trusted entities** column of the table.

For information about which services support service-linked roles, see [AWS services that work with IAM](#) and look for the services that have **Yes** in the **Service-Linked Role** column. For information about using the service-linked role for a service, choose the **Yes** link.

I can't edit or delete a role in my AWS account

You cannot delete or edit the permissions for a [service-linked role](#) in IAM. These roles include predefined trusts and permissions that are required by the service in order to perform actions on your behalf. You can use the IAM console, AWS CLI, or API to edit only the description of a service-linked role. You can view the service-linked roles in your account by going to the IAM **Roles** page in the console. Service-linked roles appear with **(Service-linked role)** in the **Trusted entities** column of the table. A banner on the role's **Summary** page also indicates that the role is a service-linked role. You can manage and delete these roles only through the linked service, if that service supports the action. Be careful when modifying or deleting a service-linked role because doing so could remove permissions that the service needs to access AWS resources.

For information about which services support service-linked roles, see [AWS services that work with IAM](#) and look for the services that have **Yes** in the **Service-Linked Role** column.

I'm not authorized to perform: iam:PassRole

When you create a service-linked role, you must have permission to pass that role to the service. Some services automatically create a service-linked role in your account when

you perform an action in that service. For example, Amazon EC2 Auto Scaling creates the `AWSServiceRoleForAutoScaling` service-linked role for you the first time that you create an Auto Scaling group. If you try to create an Auto Scaling group without the `PassRole` permission, you receive the following error:

```
ClientError: An error occurred (AccessDenied) when calling the
PutLifecycleHook operation: User: arn:aws:sts::111122223333:assumed-role/
Testrole/Diego is not authorized to perform: iam:PassRole on resource:
arn:aws:iam::111122223333:role/aws-service-role/autoscaling.amazonaws.com/
AWSServiceRoleForAutoScaling
```

To fix this error, ask your administrator to add the `iam:PassRole` permission for you.

To learn which services support service-linked roles, see [AWS services that work with IAM](#). To learn whether a service automatically creates a service-linked role for you, choose the **Yes** link to view the service-linked role documentation for the service.

Why can't I assume a role with a 12-hour session? (AWS CLI, AWS API)

When you use the AWS STS `AssumeRole*` API or `assume-role*` CLI operations to assume a role, you can specify a value for the `DurationSeconds` parameter. You can specify a value from 900 seconds (15 minutes) up to the **Maximum session duration** setting for the role. If you specify a value higher than this setting, the operation fails. This setting can have a maximum value of 12 hours. For example, if you specify a session duration of 12 hours, but your administrator set the maximum session duration to 6 hours, your operation fails. To learn how to view the maximum value for your role, see [View the maximum session duration setting for a role](#).

If you use [role chaining](#) (using a role to assume a second role), your session is limited to a maximum of one hour. If you then use the `DurationSeconds` parameter to provide a value greater than one hour, the operation fails.

I receive an error when I try to switch roles in the IAM console

The information you enter on the **Switch Role** page must match the information for the role. Otherwise, the operation fails and you receive the following error:

```
Invalid information in one or more fields. Check your information or
contact your administrator.
```

If you receive this error, confirm that the following information is correct:

- **Account ID or alias** – The AWS account ID is a 12-digit number. Your account might have an alias, which is a friendly identifier such as your company name that can be used instead of your AWS account ID. You can use either the account ID or the alias in this field.
- **Role name** – Role names are case sensitive. The account ID and role name must match what is configured for the role.

If you continue to receive an error message, contact your administrator to verify the previous information. The role trust policy or the IAM user policy might limit your access. Your administrator can verify the permissions for these policies.

My role has a policy that allows me to perform an action, but I get "access denied"

Your role session might be limited by session policies. When you [request temporary security credentials](#) programmatically using AWS STS, you can optionally pass inline or managed [session policies](#). Session policies are advanced policies that you pass as a parameter when you programmatically create a temporary credential session for a role. You can pass a single JSON inline session policy document using the `Policy` parameter. You can use the `PolicyArns` parameter to specify up to 10 managed session policies. The resulting session's permissions are the intersection of the role's identity-based policies and the session policies. Alternatively, if your administrator or a custom program provides you with temporary credentials, they might have included a session policy to limit your access.

The service did not create the role's default policy version

A service role is a role that a service assumes to perform actions in your account on your behalf. When you set up some AWS service environments, you must define a role for the service to assume. In some cases, the service creates the service role and its policy in IAM for you. Although you can modify or delete the service role and its policy from within IAM, AWS does not recommend this. The role and policy are intended for use only by that service. If you edit the policy and set up another environment, when the service tries to use the same role and policy, the operation can fail.

For example, when you use AWS CodeBuild for the first time, the service creates a role named `codebuild-RWBCore-service-role`. That service role uses the policy named `codebuild-RWBCore-managed-policy`. If you edit the policy, it creates a new version and saves that version

as the default version. If you perform a subsequent operation in AWS CodeBuild, the service might try to update the policy. If it does, you receive the following error:

```
codebuild.amazonaws.com did not create the default version (V2) of the
codebuild-RWBCore-managed-policy policy that is attached to the codebuild-
RWBCore-service-role role. To continue, detach the policy from any other
identities and then delete the policy and the role.
```

If you receive this error, you must make changes in IAM before you can continue with your service operation. First, set the default policy version to V1 and try the operation again. If V1 was previously deleted, or if choosing V1 doesn't work, then clean up and delete the existing policy and role.

For more information on editing managed policies, see [Editing customer managed policies \(console\)](#). For more information about policy versions, see [Versioning IAM policies](#).

To delete a service role and its policy

1. Sign in to the AWS Management Console and open the IAM console at <https://console.aws.amazon.com/iam/>.
2. In the navigation pane, choose **Policies**.
3. In the list of policies, choose the name of the policy that you want to delete.
4. Choose the **Entities attached** tab to view which IAM users, groups, or roles use this policy. If any of these identities use the policy, complete the following tasks:
 - a. Create a new managed policy with the necessary permissions. To ensure that the identities have the same permissions before and after your actions, copy the JSON policy document from the existing policy. Then create the new managed policy and paste the JSON document as described in [Creating Policies using the JSON editor](#).
 - b. For each affected identity, attach the new policy and then detach the old one. For more information, see [Adding and removing IAM identity permissions](#).
5. In the navigation pane, choose **Roles**.
6. In the list of roles, choose the name of the role that you want to delete.
7. Choose the **Trust relationships** tab to view which entities can assume the role. If any entity other than the service is listed, complete the following tasks:
 - a. [Create a new role](#) that trusts those entities.

- b. The policy that you created in the previous step. If you skipped that step, create the new managed policy now.
 - c. Notify anyone who was assuming the role that they can no longer do so. Provide them with information about how to assume the new role and have the same permissions.
8. [Delete the policy.](#)
9. [Delete the role.](#)

There is no use case for a service role in the console

Some services require that you manually create a service role to grant the service permissions to perform actions on your behalf. If the service is not listed in the IAM console, you must manually list the service as the trusted principal. If the documentation for the service or feature that you are using does not include instructions for listing the service as the trusted principal, provide feedback for the page.

To manually create a service role, you must know the [service principal](#) for the service that will assume the role. A service principal is an identifier that is used to grant permissions to a service. The service principal is defined by the service.

You can find the service principal for some services by checking the following:

1. Open [AWS services that work with IAM](#).
2. Check whether the service has **Yes** in the **Service-linked roles** column.
3. Choose the **Yes** link to view the service-linked role documentation for that service.
4. Find the Service-linked role permissions section for that service to view the [service principal](#).

You can manually create a service role using [AWS CLI commands](#) or [AWS API operations](#). To manually create a service role using the IAM console, complete the following tasks:

1. Create an IAM role using your account ID. Do not attach a policy or grant any permissions. For details, see [Creating a role to delegate permissions to an IAM user](#).
2. Open the role and edit the trust relationship. Instead of trusting the account, the role must trust the service. For example, update the following `Principal` element:

```
"Principal": { "AWS": "arn:aws:iam::123456789012:root" }
```

Change the principal to the value for your service, such as IAM.

```
"Principal": { "Service": "iam.amazonaws.com" }
```

3. Add the permissions that the service requires by attaching permissions policies to the role.
4. Return to the service that requires the permissions and use the documented method to notify the service about the new service role.

Troubleshooting IAM and Amazon EC2

Use the information here to help you troubleshoot and fix access denied or other issues that you might encounter when working with Amazon EC2 and IAM.

Topics

- [When attempting to launch an instance, I don't see the role I expected to see in the Amazon EC2 console IAM Role list](#)
- [The credentials on my instance are for the wrong role](#)
- [When I attempt to call the AddRoleToInstanceProfile, I get an AccessDenied error](#)
- [Amazon EC2: When I attempt to launch an instance with a role, I get an AccessDenied error](#)
- [I can't access the temporary security credentials on my EC2 instance](#)
- [What do the errors from the info document in the IAM subtree mean?](#)

When attempting to launch an instance, I don't see the role I expected to see in the Amazon EC2 console IAM Role list

Check the following:

- If you are signed in as an IAM user, verify that you have permission to call `ListInstanceProfiles`. For information about the permissions necessary to work with roles, see "Permissions Required for Using Roles with Amazon EC2" in [Using an IAM role to grant permissions to applications running on Amazon EC2 instances](#). For information about adding permissions to a user, see [Managing IAM policies](#).

If you cannot modify your own permissions, you must contact an administrator who can work with IAM in order to update your permissions.

- If you created a role by using the IAM CLI or API, verify that you created an instance profile and added the role to that instance profile. Also, if you name your role and instance profile differently, you won't see the correct role name in the list of IAM roles in the Amazon EC2 console. The **IAM Role** list in the Amazon EC2 console lists the names of instance profiles, not the names of roles. You will have to select the name of the instance profile that contains the role you want. For details about instance profiles, see [Using instance profiles](#).

Note

If you use the IAM console to create roles, you don't need to work with instance profiles. For each role that you create in the IAM console, an instance profile is created with the same name as the role, and the role is automatically added to that instance profile. An instance profile can contain only one IAM role, and that limit cannot be increased.

The credentials on my instance are for the wrong role

The role in the instance profile might have been replaced recently. If so, your application will need to wait for the next automatically scheduled credential rotation before credentials for your role become available.

To force the change, you must [disassociate the instance profile](#) and then [associate the instance profile](#), or you can stop your instance and then restart it.

When I attempt to call the `AddRoleToInstanceProfile`, I get an `AccessDenied` error

If you are making requests as an IAM user, verify that you have the following permissions:

- `iam:AddRoleToInstanceProfile` with the resource matching the instance profile ARN (for example, `arn:aws:iam::999999999999:instance-profile/ExampleInstanceProfile`).

For more information about the permissions necessary to work with roles, see "How Do I Get Started?" in [Using an IAM role to grant permissions to applications running on Amazon EC2 instances](#). For information about adding permissions to a user, see [Managing IAM policies](#).

Amazon EC2: When I attempt to launch an instance with a role, I get an AccessDenied error

Check the following:

- Launch an instance without an instance profile. This will help ensure that the problem is limited to IAM roles for Amazon EC2 instances.
- If you are making requests as an IAM user, verify that you have the following permissions:
 - `ec2:RunInstances` with a wildcard resource ("`*`")
 - `iam:PassRole` with the resource matching the role ARN (for example, `arn:aws:iam::999999999999:role/ExampleRoleName`)
- Call the IAM `GetInstanceProfile` action to ensure that you are using a valid instance profile name or a valid instance profile ARN. For more information, see [Using IAM roles with Amazon EC2 instances](#).
- Call the IAM `GetInstanceProfile` action to ensure that the instance profile has a role. Empty instance profiles will fail with an `AccessDenied` error. For more information about creating a role, see [Creating IAM roles](#).

For more information about the permissions necessary to work with roles, see "How Do I Get Started?" in [Using an IAM role to grant permissions to applications running on Amazon EC2 instances](#). For information about adding permissions to a user, see [Managing IAM policies](#).

I can't access the temporary security credentials on my EC2 instance

To access temporary security credentials on your EC2 instance, you must first use the IAM console to create a role. Then you launch an EC2 instance that uses that role and examine the running instance. For more information, see **How Do I Get Started?** in [Using an IAM role to grant permissions to applications running on Amazon EC2 instances](#).

If you still can't access your temporary security credentials on your EC2 instance, check the following:

- Can you access another part of the Instance Metadata Service (IMDS)? If not, check that you have no firewall rules blocking access to requests to the IMDS.

```
[ec2-user@domU-12-31-39-0A-8D-DE ~]$ GET http://169.254.169.254/latest/meta-data/  
hostname; echo
```

- Does the `iam` subtree of the IMDS exist? If not, verify that your instance has an IAM instance profile associated with it by calling the EC2 DescribeInstances API operation or using the `aws ec2 describe-instances` CLI command.

```
[ec2-user@domU-12-31-39-0A-8D-DE ~]$ GET http://169.254.169.254/latest/meta-data/iam;  
echo
```

- Check the `info` document in the IAM subtree for an error. If you have an error, see [What do the errors from the info document in the IAM subtree mean?](#) for more information.

```
[ec2-user@domU-12-31-39-0A-8D-DE ~]$ GET http://169.254.169.254/latest/meta-data/iam/  
info; echo
```

What do the errors from the `info` document in the IAM subtree mean?

The `iam/info` document indicates "Code": "InstanceProfileNotFound"

Your IAM instance profile has been deleted and Amazon EC2 can no longer provide credentials to your instance. You must attach a valid instance profile to your Amazon EC2 instance.

If an instance profile with that name exists, check that the instance profile wasn't deleted and another was created with the same name:

1. Call the IAM `GetInstanceProfile` operation to get the `InstanceProfileId`.
2. Call the Amazon EC2 `DescribeInstances` operation to get the `IamInstanceProfileId` for the instance.
3. Verify that the `InstanceProfileId` from the IAM operation matches the `IamInstanceProfileId` from the Amazon EC2 operation.

If the IDs are different, then the instance profile attached to your instances is no longer valid. You must attach a valid instance profile to the instance.

The `iam/info` document indicates a success but indicates `"Message": "Instance Profile does not contain a role..."`

The role has been removed from the instance profile by the IAM `RemoveRoleFromInstanceProfile` action. You can use the IAM `AddRoleToInstanceProfile` action to attach a role to the instance profile. Your application will need to wait until the next scheduled refresh to access the credentials for the role.

To force the change, you must [disassociate the instance profile](#) and then [associate the instance profile](#), or you can stop your instance and then restart it.

The `iam/security-credentials/[role-name]` document indicates `"Code": "AssumeRoleUnauthorizedAccess"`

Amazon EC2 does not have permission to assume the role. Permission to assume the role is controlled by the trust policy attached to the role, like the example that follows. Use the IAM `UpdateAssumeRolePolicy` API to update the trust policy.

```
{"Version": "2012-10-17", "Statement": [{"Effect": "Allow", "Principal": {"Service": ["ec2.amazonaws.com"]}, "Action": ["sts:AssumeRole"]}]}
```

Your application will need to wait until the next automatically scheduled refresh to access the credentials for the role.

To force the change, you must [disassociate the instance profile](#) and then [associate the instance profile](#), or you can stop your instance and then restart it.

Troubleshooting IAM and Amazon S3

Use the information here to help you troubleshoot and fix issues that you might encounter when working with Amazon S3 and IAM.

How do I grant anonymous access to an Amazon S3 bucket?

You use an Amazon S3 bucket policy that specifies a wildcard (*) in the `principal` element, which means anyone can access the bucket. With anonymous access, anyone (including users without an AWS account) will be able to access the bucket. For a sample policy, see [Example Cases for Amazon S3 Bucket Policies](#) in the *Amazon Simple Storage Service User Guide*.

I'm signed in as an AWS account root user; why can't I access an Amazon S3 bucket under my account?

In some cases, you might have an IAM user with full access to IAM and Amazon S3. If the IAM user assigns a bucket policy to an Amazon S3 bucket and doesn't specify the AWS account root user as a principal, the root user is denied access to that bucket. However, as the root user, you can still access the bucket. To do that, modify the bucket policy to allow root user access from the Amazon S3 console or the AWS CLI. Use the following principal, replacing `123456789012` with the ID of the AWS account.

```
"Principal": { "AWS": "arn:aws:iam::123456789012:root" }
```

Troubleshooting SAML 2.0 federation with AWS

Use the information here to help you diagnose and fix issues that you might encounter when working with SAML 2.0 and federation with IAM.

Topics

- [Error: Source Identity must match \[a-zA-Z_0-9+ =, .@-\]{2,64} and not begin with "aws:" \(service: AWSSecurityTokenService; status code: 400; error code: InvalidIdentityToken\)](#)
- [Error: Response signature invalid \(service: AWSSecurityTokenService; status code: 400; error code: InvalidIdentityToken\)](#)
- [Error: Failed to assume role: Issuer not present in specified provider \(service: AWSOpenIdDiscoveryService; status code: 400; error code: AuthSamlInvalidSamlResponseException\)](#)
- [Error: Could not parse metadata.](#)
- [Error: Specified provider doesn't exist.](#)

- [Error: Requested DurationSeconds exceeds MaxSessionDuration set for this role.](#)
- [Error: Response does not contain the required audience.](#)
- [How to view a SAML response in your browser for troubleshooting](#)

Error: Your request included an invalid SAML response. To logout, click here.

This error can occur when the SAML response from the identity provider does not include an attribute with the Name set to `https://aws.amazon.com/SAML/Attributes/Role`. The attribute must contain one or more `AttributeValue` elements, each containing a comma-separated pair of strings:

- The ARN of a role that the user can be mapped to
- The ARN of the SAML provider

For more information, see [Configuring SAML assertions for the authentication response](#). To view the SAML response in your browser, follow the steps listed in [How to view a SAML response in your browser for troubleshooting](#).

Error: RoleSessionName is required in AuthnResponse (service: AWSSecurityTokenService; status code: 400; error code: InvalidIdentityToken)

This error can occur when the SAML response from the identity provider does not include an attribute with the Name set to `https://aws.amazon.com/SAML/Attributes/RoleSessionName`. The attribute value is an identifier for the user and is typically a user ID or an email address.

For more information, see [Configuring SAML assertions for the authentication response](#). To view the SAML response in your browser, follow the steps listed in [How to view a SAML response in your browser for troubleshooting](#).

Error: Not authorized to perform sts:AssumeRoleWithSAML (service: AWSSecurityTokenService; status code: 403; error code: AccessDenied)

This error can occur if the IAM role specified in the SAML response is misspelled or does not exist. Make sure to use the exact name of your role, because role names are case sensitive. Correct the name of the role in the SAML service provider configuration.

You are allowed access only if your role trust policy includes the `sts:AssumeRoleWithSAML` action. If your SAML assertion is configured to use the [PrincipalTag attribute](#), your trust policy must also include the `sts:TagSession` action. For more information about session tags, see [Passing session tags in AWS STS](#).

This error can occur if you do not have `sts:SetSourceIdentity` permissions in your role trust policy. If your SAML assertion is configured to use the [SourceIdentity](#) attribute, then your trust policy must also include the `sts:SetSourceIdentity` action. For more information about source identity, see [Monitor and control actions taken with assumed roles](#).

This error can also occur if the federated users do not have permissions to assume the role. The role must have a trust policy that specifies the ARN of the IAM SAML identity provider as the `Principal`. The role also contains conditions that control which users can assume the role. Ensure that your users meet the requirements of the conditions.

This error can also occur if the SAML response does not include a `Subject` containing a `NameID`.

For more information, see [Establish Permissions in AWS for Federated Users](#) and [Configuring SAML assertions for the authentication response](#). To view the SAML response in your browser, follow the steps listed in [How to view a SAML response in your browser for troubleshooting](#).

Error: RoleSessionName in AuthnResponse must match [a-zA-Z_0-9+ =, . @ -] { 2, 64 } (service: AWSSecurityTokenService; status code: 400; error code: InvalidIdentityToken)

This error can occur if the `RoleSessionName` attribute value is too long or contains invalid characters. The maximum valid length is 64 characters.

For more information, see [Configuring SAML assertions for the authentication response](#). To view the SAML response in your browser, follow the steps listed in [How to view a SAML response in your browser for troubleshooting](#).

Error: Source Identity must match [a-zA-Z_0-9+ =, .@-]{2,64} and not begin with "aws :" (service: AWSSecurityTokenService; status code: 400; error code: InvalidIdentityToken)

This error can occur if the `sourceIdentity` attribute value is too long or contains invalid characters. The maximum valid length is 64 characters. For more information about source identity, see [Monitor and control actions taken with assumed roles](#).

For more information about creating SAML assertions, see [Configuring SAML assertions for the authentication response](#). To view the SAML response in your browser, follow the steps listed in [How to view a SAML response in your browser for troubleshooting](#).

Error: Response signature invalid (service: AWSSecurityTokenService; status code: 400; error code: InvalidIdentityToken)

This error can occur when federation metadata of the identity provider does not match the metadata of the IAM identity provider. For example, the metadata file for the identity service provider might have changed to update an expired certificate. Download the updated SAML metadata file from your identity service provider. Then update it in the AWS identity provider entity that you define in IAM with the `aws iam update-saml-provider` cross-platform CLI command or the `Update-IAMSAMLProvider` PowerShell cmdlet.

Error: Failed to assume role: Issuer not present in specified provider (service: AWSOpenIdDiscoveryService; status code: 400; error code: AuthSamlInvalidSamlResponseException)

This error can occur if the issuer in the SAML response does not match the issuer declared in the federation metadata file. The metadata file was uploaded to AWS when you created the identity provider in IAM.

Error: Could not parse metadata.

This error can occur if you do not format your metadata file properly.

When you [create or manage a SAML identity provider](#) in the AWS Management Console, you must retrieve the SAML metadata document from your identity provider.

This metadata file includes the issuer name, expiration information, and keys that can be used to validate the SAML authentication response (assertions) received from the IdP. The metadata file must be encoded in UTF-8 format without a byte order mark (BOM). To remove the BOM, you can encode the file as UTF-8 using a text editing tool, such as Notepad++.

The x.509 certificate included as part of the SAML metadata document must use a key size of at least 1024 bits. Also, the x.509 certificate must also be free of any repeated extensions. You can use extensions, but the extensions can only appear once in the certificate. If the x.509 certificate does not meet either condition, IdP creation fails and returns an "Unable to parse metadata" error.

As defined by the [SAML V2.0 Metadata Interoperability Profile Version 1.0](#), IAM neither evaluates nor takes action regarding the expiration of the metadata document's X.509 certificate.

Error: Specified provider doesn't exist.

This error can occur if the name of the provider that you specify in the SAML assertion does not match the name of the provider configured in IAM. For more information about viewing the provider name, see [Creating IAM SAML identity providers](#).

Error: Requested DurationSeconds exceeds MaxSessionDuration set for this role.

This error can occur if you assume a role from the AWS CLI or API.

When you use the [assume-role-with-saml](#) CLI or [AssumeRoleWithSAML](#) API operations to assume a role, you can specify a value for the `DurationSeconds` parameter. You can specify a value from 900 seconds (15 minutes) up to the maximum session duration setting for the role. If you specify a value higher than this setting, the operation fails. For example, if you specify a session duration of 12 hours, but your administrator set the maximum session duration to 6 hours, your operation fails. To learn how to view the maximum value for your role, see [View the maximum session duration setting for a role](#).

Error: Response does not contain the required audience.

This error can occur if there is a mismatch between the audience URL and the identity provider in the SAML configuration. Make sure that your identity provider (IdP) relying party identifier exactly matches the audience URL (entity ID) provided in the SAML configuration.

How to view a SAML response in your browser for troubleshooting

The following procedures describe how to view the SAML response from your service provider from in your browser when troubleshooting a SAML 2.0–related issue.

For all browsers, go to the page where you can reproduce the issue. Then follow the steps for the appropriate browser:

Topics

- [Google Chrome](#)
- [Mozilla Firefox](#)
- [Apple Safari](#)
- [What to do with the Base64-encoded SAML response](#)

Google Chrome

To view a SAML response in Chrome

These steps were tested using version 106.0.5249.103 (Official Build) (arm64) of Google Chrome. If you use another version, you might need to adapt the steps accordingly.

1. Press **F12** to start the **Developer Tools** console.
2. Select the **Network** tab, and then select **Preserve log** in the upper left of the **Developer Tools** window.
3. Reproduce the issue.
4. (Optional) If the **Method** column is not visible in the **Developer Tools Network** log pane, right-click on any column label and choose **Method** to add the column.
5. Look for a **SAML Post** in the **Developer Tools Network** log pane. Select that row, and then view the **Payload** tab at the top. Look for the **SAMLResponse** element that contains the encoded request. The associated value is the Base64-encoded response.

Mozilla Firefox

To view a SAML response in Firefox

This procedure was tested on version 105.0.3 (64-bit) of Mozilla Firefox. If you use another version, you might need to adapt the steps accordingly.

1. Press **F12** to start the **Web Developer Tools** console.
2. Select the **Network** tab.
3. In the upper right of the **Web Developer Tools** window, choose options (the small gear icon). Select **Persist logs**.
4. Reproduce the issue.
5. (Optional) If the **Method** column is not visible in the **Web Developer Tools Network** log pane, right-click on any column label and choose **Method** to add the column.
6. Look for a **POST SAML** in the table. Select that row, and then view the **Request** tab and find the **SAMLResponse** element. The associated value is the Base64-encoded response.

Apple Safari

To view a SAML response in Safari

These steps were tested using version 16.0 (17614.1.25.9.10, 17614) of Apple Safari. If you use another version, you might need to adapt the steps accordingly.

1. Enable Web Inspector in Safari. Open the **Preferences** window, select the **Advanced** tab, and then select **Show Develop menu in the menu bar**.
2. Now you can open Web Inspector. Choose **Develop** in the menu bar, then select **Show Web Inspector**.
3. Select the **Network** tab.
4. In the upper left of the **Web Inspector** window, choose options (the small circle icon containing three horizontal lines). Select **Preserve Log**.
5. (Optional) If the **Method** column is not visible in the **Web Inspector Network** log pane, right-click on any column label and choose **Method** to add the column.
6. Reproduce the issue.
7. Look for a **POST SAML** in the table. Select that row, and then view the Headers tab.
8. Look for the **SAMLResponse** element that contains the encoded request. Scroll down to find Request Data with the name SAMLResponse. The associated value is the Base64-encoded response.

What to do with the Base64-encoded SAML response

Once you find the Base64-encoded SAML response element in your browser, copy it and use your favorite Base-64 decoding tool to extract the XML tagged response.

Security tip

Because the SAML response data that you are viewing might contain sensitive security data, we recommend that you do not use an *online* base64 decoder. Instead use a tool installed on your local computer that does not send your SAML data over the network.

Built-in option for Windows systems (PowerShell):

```
PS C:
\> [System.Text.Encoding]::UTF8.GetString([System.Convert]::FromBase64String("base64encodedtext"))
```

Built-in option for MacOS and Linux systems:

```
$ echo "base64encodedtext" | base64 --decode
```

Reference information for AWS Identity and Access Management

Use the topics in this section to find detailed reference material for various aspects of IAM and AWS STS.

Topics

- [Amazon Resource Names \(ARNs\)](#)
- [IAM identifiers](#)
- [IAM and AWS STS quotas](#)
- [Interface VPC endpoints](#)
- [AWS services that work with IAM](#)
- [Signing AWS API requests](#)
- [IAM JSON policy reference](#)

Amazon Resource Names (ARNs)

Amazon Resource Names (ARNs) uniquely identify AWS resources. We require an ARN when you need to specify a resource unambiguously across all of AWS, such as in IAM policies, Amazon Relational Database Service (Amazon RDS) tags, and API calls.

ARN format

The following are the general formats for ARNs. The specific formats depend on the resource. To use an ARN, replace the *italicized* text with the resource-specific information. Be aware that the ARNs for some resources omit the Region, the account ID, or both the Region and the account ID.

```
arn:partition:service:region:account-id:resource-id
arn:partition:service:region:account-id:resource-type/resource-id
arn:partition:service:region:account-id:resource-type:resource-id
```

partition

The partition in which the resource is located. A *partition* is a group of AWS Regions. Each AWS account is scoped to one partition.

The following are the supported partitions:

- `aws` - AWS Regions
- `aws-cn` - China Regions
- `aws-us-gov` - AWS GovCloud (US) Regions

service

The service namespace that identifies the AWS product.

region

The Region code. For example, `us-east-2` for US East (Ohio). For the list of Region codes, see [Regional endpoints](#) in the *AWS General Reference*.

account-id

The ID of the AWS account that owns the resource, without the hyphens. For example, `123456789012`.

resource-type

The resource type. For example, `vpc` for a virtual private cloud (VPC).

resource-id

The resource identifier. This is the name of the resource, the ID of the resource, or a [resource path](#). Some resource identifiers include a parent resource (`sub-resource-type/parent-resource/sub-resource`) or a qualifier such as a version (`resource-type:resource-name:qualifier`).

Examples

IAM user

```
arn:aws:iam::123456789012:user/johndoe
```

SNS topic

```
arn:aws:sns:us-east-1:123456789012:example-sns-topic-name
```

VPC

```
arn:aws:ec2:us-east-1:123456789012:vpc/vpc-0e9801d129EXAMPLE
```

Look up the ARN format for a resource

The exact format of an ARN depends on the service and resource type. Some resource ARNs can include a path, a variable, or a wildcard. To look up the ARN format for a specific AWS resource, open the [Service Authorization Reference](#), open the page for the service, and navigate to the resource types table.

Paths in ARNs

Resource ARNs can include a path. For example, in Amazon S3, the resource identifier is an object name that can include forward slashes (/) to form a path. Similarly, IAM user names and group names can include paths. Only alphanumeric characters and the following characters are allowed in IAM paths: forward slash (/), plus (+), equals (=), comma (,), period (.), at (@), underscore (_), and hyphen (-).

Using wildcards in paths

Paths can include a wildcard character, namely an asterisk (*). For example, if you are writing an IAM policy, you can specify all IAM users that have the path `product_1234` using a wildcard as follows:

```
arn:aws:iam::123456789012:user/Development/product_1234/*
```

Similarly, you can specify `user/*` to mean all users or `group/*` to mean all groups, as in the following examples:

```
"Resource": "arn:aws:iam::123456789012:user/*"  
"Resource": "arn:aws:iam::123456789012:group/*"
```

The following example shows ARNs for an Amazon S3 bucket in which the resource name includes a path:

```
arn:aws:s3::my_corporate_bucket/*  
arn:aws:s3::my_corporate_bucket/Development/*
```

Incorrect wildcard usage

You cannot use a wildcard in the portion of the ARN that specifies the resource type, such as the term `user` in an IAM ARN. For example, the following is not allowed.

```
arn:aws:iam::123456789012:u* <== not allowed
```

IAM identifiers

IAM uses a few different identifiers for users, user groups, roles, policies, and server certificates. This section describes the identifiers and when you use each.

Topics

- [Friendly names and paths](#)
- [IAM ARNs](#)
- [Unique identifiers](#)

Friendly names and paths

When you create a user, a role, a user group, or a policy, or when you upload a server certificate, you give it a friendly name. Examples include Bob, TestApp1, Developers, ManageCredentialsPermissions, or ProdServerCert.

If you use the IAM API or AWS Command Line Interface (AWS CLI) to create IAM resources, you can add an optional path. You can use a single path, or nest multiple paths as a folder structure. For example, you could use the nested path `/division_abc/subdivision_xyz/product_1234/engineering/` to match your company organizational structure. You could then create a policy to allow all users in that path to access the policy simulator API. To view this policy, see [IAM: Access the policy simulator API based on user path](#). For information about how a friendly name can be specified, see [the User API documentation](#). For additional examples of how you might use paths, see [IAM ARNs](#).

When you use AWS CloudFormation to create resources, you can specify a path for users, user groups, and roles, and customer managed policies.

If you have a user and user group in the same path, IAM doesn't automatically put the user in that user group. For example, you might create a Developers user group and specify the path as `/division_abc/subdivision_xyz/product_1234/engineering/`. If you create a user

named Bob and add the same path to him, this doesn't automatically put Bob in the Developers user group. IAM doesn't enforce any boundaries between users or user groups based on their paths. Users with different paths can use the same resources if they've been granted permission to those resources. The number and size of IAM resources in an AWS account are limited. For more information, see [IAM and AWS STS quotas](#).

IAM ARNs

Most resources have a friendly name for example, a user named Bob or a user group named Developers. However, the permissions policy language requires you to specify the resource or resources using the following *Amazon Resource Name (ARN)* format.

```
arn:partition:service:region:account:resource
```

Where:

- *partition* identifies the partition for the resource. For standard AWS Regions, the partition is `aws`. If you have resources in other partitions, the partition is `aws-partitionname`. For example, the partition for resources in the China (Beijing) Region is `aws-cn`. You cannot [delegate access](#) between accounts in different partitions.
- *service* identifies the AWS product. IAM resources always use `iam`.
- *region* identifies the Region of the resource. For IAM resources, this is always kept blank.
- *account* specifies the AWS account ID with no hyphens.
- *resource* identifies the specific resource by name.

You can specify IAM and AWS STS ARNs using the following syntax. The Region portion of the ARN is blank because IAM resources are global.

Syntax:

```
arn:aws:iam::account:root
arn:aws:iam::account:user/user-name-with-path
arn:aws:iam::account:group/group-name-with-path
arn:aws:iam::account:role/role-name-with-path
arn:aws:iam::account:policy/policy-name-with-path
arn:aws:iam::account:instance-profile/instance-profile-name-with-path
arn:aws:sts::account:federated-user/user-name
arn:aws:sts::account:assumed-role/role-name/role-session-name
```

```
arn:aws:iam::account:mfa/virtual-device-name-with-path
arn:aws:iam::account:u2f/u2f-token-id
arn:aws:iam::account:server-certificate/certificate-name-with-path
arn:aws:iam::account:saml-provider/provider-name
arn:aws:iam::account:oidc-provider/provider-name
```

Many of the following examples include paths in the resource part of the ARN. Paths cannot be created or manipulated in the AWS Management Console. To use paths, you must work with the resource by using the AWS API, the AWS CLI, or the Tools for Windows PowerShell.

Examples:

```
arn:aws:iam::123456789012:root
arn:aws:iam::123456789012:user/JohnDoe
arn:aws:iam::123456789012:user/division_abc/subdivision_xyz/JaneDoe
arn:aws:iam::123456789012:group/Developers
arn:aws:iam::123456789012:group/division_abc/subdivision_xyz/product_A/Developers
arn:aws:iam::123456789012:role/S3Access
arn:aws:iam::123456789012:role/application_abc/component_xyz/RDSAccess
arn:aws:iam::123456789012:role/aws-service-role/access-analyzer.amazonaws.com/
AWSServiceRoleForAccessAnalyzer
arn:aws:iam::123456789012:role/service-role/QuickSightAction
arn:aws:iam::123456789012:policy/UsersManageOwnCredentials
arn:aws:iam::123456789012:policy/division_abc/subdivision_xyz/UsersManageOwnCredentials
arn:aws:iam::123456789012:instance-profile/Webserver
arn:aws:sts::123456789012:federated-user/JohnDoe
arn:aws:sts::123456789012:assumed-role/Accounting-Role/JaneDoe
arn:aws:iam::123456789012:mfa/JaneDoeMFA
arn:aws:iam::123456789012:u2f/user/JohnDoe/default (U2F security key)
arn:aws:iam::123456789012:server-certificate/ProdServerCert
arn:aws:iam::123456789012:server-certificate/division_abc/subdivision_xyz/
ProdServerCert
arn:aws:iam::123456789012:saml-provider/ADFSPProvider
arn:aws:iam::123456789012:oidc-provider/GoogleProvider
arn:aws:iam::123456789012:oidc-provider/oidc.eks.us-west-2.amazonaws.com/id/
a1b2c3d4567890abcdefEXAMPLE11111
arn:aws:iam::123456789012:oidc-provider/server.example.org
```

The following examples provide more detail to help you understand the ARN format for different types of IAM and AWS STS resources.

- An IAM user in the account:

Note

Each IAM user name is unique. The user name is case-insensitive for the user, such as during the sign in process, but is case-sensitive when you use it in a policy or as part of an ARN.

```
arn:aws:iam::123456789012:user/JohnDoe
```

- Another user with a path reflecting an organization chart:

```
arn:aws:iam::123456789012:user/division_abc/subdivision_xyz/JaneDoe
```

- An IAM user group:

```
arn:aws:iam::123456789012:group/Developers
```

- An IAM user group with a path:

```
arn:aws:iam::123456789012:group/division_abc/subdivision_xyz/product_A/Developers
```

- An IAM role:

```
arn:aws:iam::123456789012:role/S3Access
```

- A [service-linked role](#):

```
arn:aws:iam::123456789012:role/aws-service-role/access-analyzer.amazonaws.com/  
AWSServiceRoleForAccessAnalyzer
```

- A [service role](#):

```
arn:aws:iam::123456789012:role/service-role/QuickSightAction
```

- A managed policy:

```
arn:aws:iam::123456789012:policy/ManageCredentialsPermissions
```

- An instance profile that can be associated with an Amazon EC2 instance:

```
arn:aws:iam::123456789012:instance-profile/Webserver
```

- A federated user identified in IAM as "Paulo":

```
arn:aws:sts::123456789012:federated-user/Paulo
```

- The active session of someone assuming the role of "Accounting-Role", with a role session name of "Mary":

```
arn:aws:sts::123456789012:assumed-role/Accounting-Role/Mary
```

- The multi-factor authentication device assigned to the user named Jorge:

```
arn:aws:iam::123456789012:mfa/Jorge
```

- A server certificate:

```
arn:aws:iam::123456789012:server-certificate/ProdServerCert
```

- A server certificate with a path that reflects an organization chart:

```
arn:aws:iam::123456789012:server-certificate/division_abc/subdivision_xyz/  
ProdServerCert
```

- Identity providers (SAML and OIDC):

```
arn:aws:iam::123456789012:saml-provider/ADFSPProvider  
arn:aws:iam::123456789012:oidc-provider/GoogleProvider  
arn:aws:iam::123456789012:oidc-provider/server.example.org
```

- OIDC identity provider with a path that reflects an Amazon EKS OIDC identity provider URL:

```
arn:aws:iam::123456789012:oidc-provider/oidc.eks.us-west-2.amazonaws.com/id/  
a1b2c3d4567890abcdefEXAMPLE11111
```

Another important ARN is the root user ARN. Although this is not an IAM resource, you should be familiar with the format of this ARN. It is often used in the [Principal element](#) of a resource-based policy.

- The AWS account displays the following:

```
arn:aws:iam::123456789012:root
```

The following example shows a policy you could assign to Richard to allow him to manage his access keys. Notice that the resource is the IAM user Richard.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "ManageRichardAccessKeys",
      "Effect": "Allow",
      "Action": [
        "iam:*AccessKey*",
        "iam:GetUser"
      ],
      "Resource": "arn:aws:iam::*:user/division_abc/subdivision_xyz/Richard"
    },
    {
      "Sid": "ListForConsole",
      "Effect": "Allow",
      "Action": "iam:ListUsers",
      "Resource": "*"
    }
  ]
}
```

Note

When you use ARNs to identify resources in an IAM policy, you can include *policy variables*. Policy variables can include placeholders for runtime information (such as the user's name) as part of the ARN. For more information, see [IAM policy elements: Variables and tags](#)

Using wildcards and paths in ARNs

You can use wildcards in the *resource* portion of the ARN to specify multiple users or user groups or policies. For example, to specify all users working on product_1234, you use:

```
arn:aws:iam::123456789012:user/division_abc/subdivision_xyz/product_1234/*
```

If you have users whose names start with the string `app_`, you could refer to them all with the following ARN.

```
arn:aws:iam::123456789012:user/division_abc/subdivision_xyz/product_1234/app_*
```

To specify all users, user groups, or policies in your AWS account, use a wildcard after the `user/`, `group/`, or `policy/` part of the ARN, respectively.

```
arn:aws:iam::123456789012:user/*
arn:aws:iam::123456789012:group/*
arn:aws:iam::123456789012:policy/*
```

If you specify the following ARN for a user `arn:aws:iam::111122223333:user/*` it matches both of the following examples.

```
arn:aws:iam::111122223333:user/JohnDoe
arn:aws:iam::111122223333:user/division_abc/subdivision_xyz/JaneDoe
```

But, if you specify the following ARN for a user `arn:aws:iam::111122223333:user/division_abc*` it matches the second example, but not the first.

```
arn:aws:iam::111122223333:user/JohnDoe
arn:aws:iam::111122223333:user/division_abc/subdivision_xyz/JaneDoe
```

Don't use a wildcard in the `user/`, `group/`, or `policy/` part of the ARN. For example, IAM does not allow the following:

```
arn:aws:iam::123456789012:u*
```

Example Example use of paths and ARNs for a project-based user group

Paths cannot be created or manipulated in the AWS Management Console. To use paths you must work with the resource by using the AWS API, the AWS CLI, or the Tools for Windows PowerShell.

In this example, Jules in the `Marketing_Admin` user group creates a project-based user group within the `/marketing/` path. Jules assigns users from different parts of the company to the user group. This example illustrates that a user's path isn't related to the user groups the user is in.

The marketing group has a new product they'll be launching, so Jules creates a new user group in the `/marketing/` path called `Widget_Launch`. Jules then assigns the following policy to the user group, which gives the user group access to objects in the part of the `example_bucket` that is designated to this particular launch.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": "s3:*",
      "Resource": "arn:aws:s3:::example_bucket/marketing/newproductlaunch/widget/*"
    },
    {
      "Effect": "Allow",
      "Action": "s3:ListBucket*",
      "Resource": "arn:aws:s3:::example_bucket",
      "Condition": {"StringLike": {"s3:prefix": "marketing/newproductlaunch/widget/*"}}
    }
  ]
}
```

Jules then assigns the users who are working on this launch to the user group. This includes Patricia and Eli from the `/marketing/` path. It also includes Chris and Chloe from the `/sales/` path, and Alice and Jim from the `/legal/` path.

Unique identifiers

When IAM creates a user, user group, role, policy, instance profile, or server certificate, it assigns a unique ID to each resource. The unique ID looks like this:

```
AIDAJQABLZS4A3QDU576Q
```

For the most part, you use friendly names and [ARNs](#) when you work with IAM resources. That way you don't need to know the unique ID for a specific resource. However, the unique ID can sometimes be useful when it isn't practical to use friendly names.

One example reuses friendly names in your AWS account. Within your account, a friendly name for a user, user group, role, or policy must be unique. For example, you might create an IAM user named John. Your company uses Amazon S3 and has a bucket with folders for each employee. IAM user John is a member of an IAM user group named `User1-S3-Access` with permissions

that allows users access only to their own folders in the bucket. For an example of how you might create an identity-based policy that allows IAM users to access their own bucket object in S3 using the friendly name of users, see [Amazon S3: Allows IAM users access to their S3 home directory, programmatically and in the console](#).

Suppose that the employee named John leaves your company and you delete the corresponding IAM user named John. But later another employee named John starts, and you create a new IAM user named John. You add the new IAM user named John to the existing IAM user group User-S3-Access. If the policy associated to the user group specifies the friendly IAM user name John, the policy allows the new John to access information that was left by the former John.

In general, we recommend that you specify the ARN for the resource in your policies instead of its unique ID. However, every IAM user has a unique ID, even if you create a new IAM user that reuses a friendly name you deleted before. In the example, the old IAM user John and the new IAM user John have different unique IDs. You can create resource-based policies that grant access by unique ID and not just by user name. Doing so reduces the chance that you could inadvertently grant access to information that an employee should not have.

The following example shows how you might specify unique IDs in the [Principal element](#) of a resource-based policy.

```
"Principal": {
  "AWS": [
    "arn:aws:iam::111122223333:role/role-name",
    "AIDACKCEVSQ6C2EXAMPLE",
    "AROADBQP57FF2AEXAMPLE"
  ]
}
```

The following example shows how you might specify unique IDs in the [Condition element](#) of a policy using global condition key [aws:userid](#).

```
"Condition": {
  "StringLike": {
    "aws:userId": [
      "AIDACKCEVSQ6C2EXAMPLE",
      "AROADBQP57FF2AEXAMPLE:role-session-name",
      "AROAI234567890EXAMPLE:*",
      "111122223333"
    ]
  }
}
```

}

Another example where user IDs can be useful is if you maintain your own database (or other store) of IAM user or role information. The unique ID can provide a unique identifier for each IAM user or role you create. This is the case when you have IAM users or roles that reuse a name, as in the previous example.

Understanding unique ID prefixes

IAM uses the following prefixes to indicate what type of resource each unique ID applies to. Prefixes may vary based on when they were created.

Prefix	Resource type
ABIA	AWS STS service bearer token
ACCA	Context-specific credential
AGPA	User group
AIDA	IAM user
AIPA	Amazon EC2 instance profile
AKIA	Access key
ANPA	Managed policy
ANVA	Version in a managed policy
APKA	Public key
AROA	Role
ASCA	Certificate
ASIA	Temporary (AWS STS) access key IDs use this prefix, but are unique only in combination with the secret access key and the session token.

Getting the unique identifier

The unique ID for an IAM resource is not available in the IAM console. To get the unique ID, you can use the following AWS CLI commands or IAM API calls.

AWS CLI:

- [get-caller-identity](#)
- [get-group](#)
- [get-role](#)
- [get-user](#)
- [get-policy](#)
- [get-instance-profile](#)
- [get-server-certificate](#)

IAM API:

- [GetCallerIdentity](#)
- [GetGroup](#)
- [GetRole](#)
- [GetUser](#)
- [GetPolicy](#)
- [GetInstanceProfile](#)
- [GetServerCertificate](#)

IAM and AWS STS quotas

AWS Identity and Access Management (IAM) and AWS Security Token Service (STS) have quotas that limit the size of objects. This affects how you name an object, the number of objects you can create, and the number of characters you can use when you pass an object.

Note

To get account-level information about IAM usage and quotas, use the [GetAccountSummary](#) API operation or the [get-account-summary](#) AWS CLI command.

IAM name requirements

IAM names have the following requirements and restrictions:

- Policy documents can contain only the following Unicode characters: horizontal tab (U+0009), linefeed (U+000A), carriage return (U+000D), and characters in the range U+0020 to U+00FF.
- Names of users, groups, roles, policies, instance profiles, server certificates, and paths must be alphanumeric, including the following common characters: plus (+), equals (=), comma (,), period (.), at (@), underscore (_), and hyphen (-). Path names must begin and end with a forward slash (/).
- Names of users, groups, roles, and instance profiles must be unique within the account. They aren't distinguished by case, for example, you can't create groups named both **ADMINS** and **admins**.
- The external ID value that a third party uses to assume a role must have a minimum of 2 characters and a maximum of 1,224 characters. The value must be alphanumeric without white space. It can also include the following symbols: plus (+), equal (=), comma (,), period (.), at (@), colon (:), forward slash (/), and hyphen (-). For more information about the external ID, see [How to use an external ID when granting access to your AWS resources to a third party](#).
- Policy names for [inline policies](#) must be unique to the user, group, or role they're embedded in. The names can contain any Basic Latin (ASCII) characters except for the following reserved characters: backward slash (\), forward slash (/), asterisk (*), question mark (?), and white space. These characters are reserved according to [RFC 3986, section 2.2](#).
- User passwords (login profiles) can contain any Basic Latin (ASCII) characters.
- AWS account ID aliases must be unique across AWS products, and must be alphanumeric following DNS naming conventions. An alias must be lowercase, it must not start or end with a hyphen, it can't contain two consecutive hyphens, and it can't be a 12-digit number.

For a list of Basic Latin (ASCII) characters, go to the [Library of Congress Basic Latin \(ASCII\) Code Table](#).

IAM object quotas

Quotas, also referred to as limits in AWS, are the maximum values for the resources, actions, and items in your AWS account. Use Service Quotas to manage your IAM quotas.

For the list of IAM service endpoints and service quotas, see [AWS Identity and Access Management endpoints and quotas](#) in the *AWS General Reference*.

To request a quota increase

1. Follow the sign-in procedure appropriate to your user type as described in the topic [How to sign in to AWS](#) in the *AWS Sign-In User Guide* to sign in to the AWS Management Console.
2. Open the Service Quotas console.
3. In the navigation pane, choose **AWS services**.
4. On the navigation bar, choose the **US East (N. Virginia)** Region. Then search for **IAM**.
5. Choose **AWS Identity and Access Management (IAM)**, choose a quota, and follow the directions to request a quota increase.

For more information, see [Requesting a Quota Increase](#) in the *Service Quotas User Guide*.

To see an example of how to request an IAM quota increase using the Service Quotas console, watch the following video.

[Request an IAM quota increase using the Service Quotas console.](#)

You can request an increase to default quotas for adjustable IAM quotas. Requests up to the [maximum quota](#) are automatically approved and completed within a few minutes.

The following table lists the resources for which quota increases area can be automatically approved.

Adjustable quotas for IAM resources

Resource	Default quota	Maximum quota
Customer managed policies per account	1500	5000
Groups per account	300	500
Instance profiles per account	1000	5000
Managed policies per role	10	20
Managed policies per user	10	20

Resource	Default quota	Maximum quota
Role trust policy length	2048 characters	4096 characters
Roles per account	1000	5000
Server certificates per account	20	1000

IAM Access Analyzer quotas

For the list of IAM Access Analyzer service endpoints and service quotas, see [IAM Access Analyzer endpoints and quotas](#) in the *AWS General Reference*.

IAM Roles Anywhere quotas

For the list of IAM Roles Anywhere service endpoints and service quotas, see [AWS Identity and Access Management Roles Anywhere endpoints and quotas](#) in the *AWS General Reference*.

IAM and STS character limits

The following are the maximum character counts and size limits for IAM and AWS STS. You can't request an increase for the following limits.

Description	Limit
Alias for an AWS account ID	3–63 characters
For inline policies	<p>You can add as many inline policies as you want to an IAM user, role, or group. But the total aggregate policy size (the sum size of all inline policies) per entity can't exceed the following limits:</p> <ul style="list-style-type: none"> User policy size can't exceed 2,048 characters. Role policy size can't exceed 10,240 characters.

Description	Limit
	<ul style="list-style-type: none"> Group policy size can't exceed 5,120 characters. <div data-bbox="829 367 1507 636" style="border: 1px solid #add8e6; border-radius: 10px; padding: 10px; background-color: #e6f2ff;"> <p>Note</p> <p>IAM doesn't count white space when calculating the size of a policy against these limits.</p> </div>
<p>For managed policies</p>	<ul style="list-style-type: none"> The size of each managed policy can't exceed 6,144 characters. <div data-bbox="829 829 1507 1098" style="border: 1px solid #add8e6; border-radius: 10px; padding: 10px; background-color: #e6f2ff;"> <p>Note</p> <p>IAM doesn't count white space when calculating the size of a policy against this limit.</p> </div>
Group name	128 characters
Instance profile name	128 characters
Password for a login profile	1–128 characters
Path	512 characters
Policy name	128 characters

Description	Limit
Role name	64 characters <div data-bbox="829 302 1508 667"><p> Important</p><p>If you intend to use a role with the Switch Role feature in the AWS Management Console, then the combined Path and RoleName can't exceed 64 characters.</p></div>
Role session duration	12 hours <p>When you assume a role from the AWS CLI or API, you can use the <code>duration-seconds</code> CLI parameter or the <code>DurationSeconds</code> API parameter to request a longer role session. You can specify a value from 900 seconds (15 minutes) up to the maximum session duration setting for the role, which can range 1–12 hours. If you don't specify a value for the <code>DurationSeconds</code> parameter, your security credentials are valid for one hour. IAM users who switch roles in the console are granted the maximum session duration, or the remaining time in the user's session, whichever is less. The maximum session duration setting doesn't limit sessions assumed by AWS services. To learn how to view the maximum value for your role, see View the maximum session duration setting for a role.</p>
Role session name	64 characters

Description	Limit
Role session policies	<ul style="list-style-type: none">• The size of the passed JSON policy document and all passed managed policy ARN characters combined can't exceed 2,048 characters.• You can pass a maximum of 10 managed policy ARNs when you create a session.• You can pass only one JSON policy document when you programmatically create a temporary session for a role or federated user.• Additionally, an AWS conversion compresses the passed session policies and session tags into a packed binary format that has a separate limit. The <code>PackedPolicySize</code> response element indicates by percentage how close the policies and tags for your request are to the upper size limit.• We recommend that you pass session policies using the AWS CLI or AWS API. The AWS Management Console might add additional console session information to the packed policy.

Description	Limit
Role session tags	<ul style="list-style-type: none"> • Session tags must meet the tag key limit of 128 characters and the tag value limit of 256 characters. • You can pass up to 50 session tags. • An AWS conversion compresses the passed session policies and session tags into a packed binary format that has a separate limit. You can pass session tags using the AWS CLI or AWS API. The <code>PackedPolicySize</code> response element indicates by percentage how close the policies and tags for your request are to the upper size limit.
SAML authentication response base64 encoded	<p>100,000 characters</p> <p>This character limit applies to assume-role-with-saml CLI or AssumeRoleWithSAML API operation.</p>
Tag key	<p>128 characters</p> <p>This character limit applies to tags on IAM resources and session tags.</p>
Tag value	<p>256 characters</p> <p>This character limit applies to tags on IAM resources and session tags.</p> <p>Tag values can be empty which means tag values can have a length of 0 characters.</p>

Description	Limit
Unique IDs created by IAM	128 characters. For example: <ul style="list-style-type: none"> • User IDs that begin with AIDA • Group IDs that begin with AGPA • Role IDs that begin with AROA • Managed policy IDs that begin with ANPA • Server certificate IDs that begin with ASCA <div data-bbox="829 646 1511 961" style="border: 1px solid #add8e6; border-radius: 10px; padding: 10px; margin-top: 10px;"> <p> Note</p> <p>This isn't intended to be an exhaustive list, nor is it a guarantee that IDs of a certain type begin only with the specified letter combination.</p> </div>
User name	64 characters

Interface VPC endpoints

If you use Amazon Virtual Private Cloud (Amazon VPC) to host your AWS resources, you can establish a private connection between your VPC and AWS Security Token Service (AWS STS). You can use this connection to enable AWS STS to communicate with your resources in your VPC without going through the public internet.

Amazon VPC is an AWS service that you can use to launch AWS resources in a virtual network that you define. With a VPC, you have control over your network settings, such as the IP address range, subnets, route tables, and network gateways. To connect your VPC to AWS STS, you define an *interface VPC endpoint* for AWS STS. The endpoint provides reliable, scalable connectivity to AWS STS without requiring an internet gateway, network address translation (NAT) instance, or VPN connection. For more information, see [What Is Amazon VPC?](#) in the *Amazon VPC User Guide*.

Interface VPC endpoints are powered by AWS PrivateLink, an AWS technology that enables private communication between AWS services using an elastic network interface with private IP addresses. For more information, see [AWS PrivateLink for AWS Services](#).

The following information is for users of Amazon VPC. For more information, see [Getting Started with Amazon VPC](#) in the *Amazon VPC User Guide*.

Availability

AWS STS currently supports VPC endpoints in the following Regions:

- US East (Ohio)
- US East (N. Virginia)
- US West (N. California)
- US West (Oregon)
- Africa (Cape Town)
- Asia Pacific (Hong Kong)
- Asia Pacific (Mumbai)
- Asia Pacific (Osaka)
- Asia Pacific (Seoul)
- Asia Pacific (Singapore)
- Asia Pacific (Sydney)
- Asia Pacific (Tokyo)
- Canada (Central)
- China (Beijing)
- China (Ningxia)
- Europe (Frankfurt)
- Europe (Ireland)
- Europe (London)
- Europe (Milan)
- Europe (Paris)
- Europe (Stockholm)

- Middle East (Bahrain)
- South America (São Paulo)
- AWS GovCloud (US-East)
- AWS GovCloud (US-West)

Create a VPC endpoint for AWS STS

To start using AWS STS with your VPC, create an interface VPC endpoint for AWS STS. For more information, see [Access an AWS service using an interface VPC endpoint](#) in the *Amazon VPC User Guide*.

After you create the VPC endpoint, you must use the matching regional endpoint to send your AWS STS requests. AWS STS recommends that you use both the `setRegion` and `setEndpoint` methods to make calls to a Regional endpoint. You can use the `setRegion` method alone for manually enabled Regions, such as Asia Pacific (Hong Kong). In this case, the calls are directed to the STS Regional endpoint. To learn how to manually enable a Region, see [Managing AWS Regions](#) in the *AWS General Reference*. If you use the `setRegion` method alone for Regions enabled by default, the calls are directed to the global endpoint of <https://sts.amazonaws.com>.

When you use regional endpoints, AWS STS calls other AWS services using either public endpoints or private interface VPC endpoints, whichever are in use. For example, assume that you have created an interface VPC endpoint for AWS STS and have already requested temporary credentials from AWS STS from resources that are located in your VPC. In that case, these credentials begin flowing through the interface VPC endpoint by default. For more information about making Regional requests using AWS STS, see [Managing AWS STS in an AWS Region](#).

AWS services that work with IAM

The AWS services listed below are grouped alphabetically and include information about what IAM features they support:

- **Service** – You can choose the name of a service to view the AWS documentation about IAM authorization and access for that service.
- **Actions** – You can specify individual actions in a policy. If the service does not support this feature, then **All actions** is selected in the [visual editor](#). In a JSON policy document, you must use `*` in the `Action` element. For a list of actions in each service, see [Actions, Resources, and Condition Keys for AWS Services](#).

- **Resource-level permissions** – You can use [ARNs](#) to specify individual resources in the policy. If the service does not support this feature, then **All resources** is chosen in the [policy visual editor](#). In a JSON policy document, you must use * in the Resource element. Some actions, such as List* actions, do not support specifying an ARN because they are designed to return multiple resources. If a service supports this feature for some resources but not others, it is indicated by **Partial** in the table. See the documentation for that service for more information.
- **Resource-based policies** – You can attach resource-based policies to a resource within the service. Resource-based policies include a Principal element to specify which IAM identities can access that resource. For more information, see [Identity-based policies and resource-based policies](#).
- **ABAC (authorization based on tags)** – To control access based on tags, you provide tag information in the [condition element](#) of a policy using the `aws:ResourceTag/key-name`, `aws:RequestTag/key-name`, or `aws:TagKeys` condition keys. If a service supports all three condition keys for every resource type, then the value is **Yes** for the service. If a service supports all three condition keys for only some resource types, then the value is **Partial**. For more information about defining permissions based on attributes such as tags, see [What is ABAC for AWS?](#). To view a tutorial with steps for setting up ABAC, see [Use attribute-based access control \(ABAC\)](#).
- **Temporary credentials** – You can use short-term credentials that you obtain when you sign in using IAM Identity Center, switch roles in the console, or that you generate using AWS STS in the AWS CLI or AWS API. You can access services with a **No** value only while using your long-term IAM user credentials. This includes a user name and password or your user access keys. For more information, see [Temporary security credentials in IAM](#).
- **Service-linked roles** – A [service-linked role](#) is a special type of service role that gives the service permission to access resources in other services on your behalf. Choose the **Yes** or **Partial** link to see the documentation for services that support these roles. This column does not indicate if the service uses standard service roles. For more information, see [Using service-linked roles](#).
- **More information** – If a service doesn't fully support a feature, you can review the footnotes for an entry to view the limitations and links to related information.

Services that work with IAM

Service	Actions	Resource-level permissions	Resource-based policies	ABAC	Temporary credentials	Service-linked roles
AWS Account Management	 Yes	 Yes	 No	 No	 Yes	 No
AWS Activate Console	 Yes	 No	 No	 No	 Yes	 No
AWS Amplify Admin	 Yes	 Yes	 No	 No	 Yes	 No
AWS Amplify	 Yes	 Yes	 No	 Partial	 Yes	 No
AWS Amplify UI Builder	 Yes	 Yes	 No	 Yes	 Yes	 No
Apache Kafka APIs for Amazon MSK clusters	 Yes	 Yes	 No	 No	 Yes	 No

Service	Actions	Resource-level permissions	Resource-based policies	ABAC	Temporary credentials	Service-linked roles
Amazon API Gateway	 Yes	 Yes	 Yes	 No	 Yes	 Yes
Amazon API Gateway Management	 Yes	 Yes	 No	 Yes	 Yes	 No
Amazon API Gateway Management V2	 Yes	 Yes	 No	 Yes	 Yes	 No

More information

Amazon CloudFront

CloudFront doesn't have service-linked roles, but Lambda@Edge does. For more information, see [Service-Linked Roles for Lambda@Edge](#) in the Amazon CloudFront Developer Guide.

AWS CloudTrail

CloudTrail supports resource-based policies only on CloudTrail channels used for [CloudTrail Lake integrations with event sources outside of AWS](#).

CloudTrail supports tag-based access control for CloudTrail Lake event data stores and channels. CloudTrail doesn't support tag-based access controls for trails.

Amazon CloudWatch

CloudWatch service-linked roles cannot be created using the AWS Management Console, and support only the [Alarm Actions](#) feature.

AWS CodeBuild

CodeBuild supports cross-account resource sharing using AWS RAM.

CodeBuild supports ABAC for project-based actions.

AWS Config

AWS Config supports resource-level permissions for multi-account multi-Region data aggregation and AWS Config Rules. For a list of supported resources, see the **Multi-Account Multi-Region Data Aggregation** section and **AWS Config Rules** section of the [AWS Config API Guide](#).

AWS Database Migration Service

You can create and modify policies that are attached to AWS KMS encryption keys you create to encrypt data migrated to supported target endpoints. The supported target endpoints include Amazon Redshift and Amazon S3. For more information, see [Creating and Using AWS KMS Keys to Encrypt Amazon Redshift Target Data](#) and [Creating AWS KMS Keys to Encrypt Amazon S3 Target Objects](#) in the *AWS Database Migration Service User Guide*.

Amazon Elastic Compute Cloud

Amazon EC2 service-linked roles can be used only for the following features: [Spot Instance Requests](#), [Spot Fleet Requests](#), [Amazon EC2 Fleets](#), and [Fast launching for Windows instances](#).

Amazon Elastic Container Service

Only some Amazon ECS actions [support resource-level permissions](#).

AWS Elemental MediaPackage

MediaPackage supports service-linked roles for publishing customer access logs to CloudWatch but not for other API actions.

AWS Identity and Access Management

IAM supports only one type of resource-based policy called a role *trust policy*, which is attached to an IAM role. For more information, see [Granting a user permissions to switch roles](#).

IAM supports tag-based access control for most IAM resources. For more information, see [Tagging IAM resources](#).

Only some of the API actions for IAM can be called with temporary credentials. For more information, see [Comparing your API options](#).

AWS IoT

Devices connected to AWS IoT are authenticated by using X.509 certificates or using Amazon Cognito Identities. You can attach AWS IoT policies to an X.509 certificate or Amazon Cognito Identity to control what the device is authorized to do. For more information, see [Security and Identity for AWS IoT](#) in the *AWS IoT Developer Guide*.

AWS Lambda

Lambda supports attribute-based access control (ABAC) for API actions that use a Lambda function as the required resource. Layers, event source mappings, and code signing config resources are not supported.

Lambda doesn't have service-linked roles, but Lambda@Edge does. For more information, see [Service-Linked Roles for Lambda@Edge](#) in the *Amazon CloudFront Developer Guide*.

Amazon Lightsail

Lightsail partially supports resource-level permissions and ABAC. For more information, see [Actions, resources, and condition keys for Amazon Lightsail](#).

AWS Network Manager

AWS Cloud WAN also supports service-linked roles. For more information, see [AWS Cloud WAN service-linked roles](#) in the *Amazon VPC AWS Cloud WAN Guide*.

Amazon Relational Database Service

Amazon Aurora is a fully managed relational database engine that's compatible with MySQL and PostgreSQL. You can choose the Aurora MySQL or Aurora PostgreSQL as the DB engine option when setting up new database servers through Amazon RDS. For more information, see [Identity and access management for Amazon Aurora](#) in the *Amazon Aurora User Guide*.

Amazon Rekognition

Resource-based policies are only supported for copying Amazon Rekognition Custom Labels models.

AWS Resource Groups

Users can assume a role with a policy that allows Resource Groups operations.

Amazon SageMaker

Service-linked roles are currently available for SageMaker Studio and SageMaker training jobs.

AWS Security Token Service

AWS STS does not have "resources," but does allow restricting access in a similar way to users. For more information, see [Denying Access to Temporary Security Credentials by Name](#).

Only some of the API operations for AWS STS support calling with temporary credentials. For more information, see [Comparing your API options](#).

Amazon Simple Email Service

You can only use resource-level permissions in policy statements that refer to actions related to sending email, such as `ses:SendEmail` or `ses:SendRawEmail`. For policy statements that refer to any other actions, the Resource element can only contain `*`.

Only the Amazon SES API supports temporary security credentials. The Amazon SES SMTP interface does not support SMTP credentials that are derived from temporary security credentials.

Amazon Simple Storage Service

Amazon S3 supports tag-based authorization for only object resources.

Amazon S3 supports service-linked roles for Amazon S3 Storage Lens.

AWS Trusted Advisor

API access to Trusted Advisor is through the AWS Support API and is controlled by AWS Support IAM policies.

Amazon Virtual Private Cloud

In an IAM user policy, you cannot restrict permissions to a specific Amazon VPC endpoint. Any Action element that includes the `ec2:*VpcEndpoint*` or `ec2:DescribePrefixLists` API actions must specify `"Resource": "*" "`. For more information, see [Identity and access management for VPC endpoints and VPC endpoint services](#) in the *AWS PrivateLink Guide*.

Amazon VPC supports attaching a single resource policy to a VPC endpoint to restrict what can be accessed through that endpoint. For more information about using resource-based policies to control access to resources from specific Amazon VPC endpoints, see [Control access to services using endpoint policies](#) in the *AWS PrivateLink Guide*.

Amazon VPC doesn't have service-linked roles, but AWS Transit Gateway does. For more information, see [Use service-linked roles for transit gateway](#) in the *Amazon VPC AWS Transit Gateway Guide*.

AWS X-Ray

X-Ray does not support resource-level permissions for all actions.

X-Ray supports tag-based access control for groups and sampling rules.

Signing AWS API requests

Important

If you use an AWS SDKs (see [Sample Code and Libraries](#)) or AWS command line (CLI) tool to send API requests to AWS, you can skip this section because the SDK and CLI clients authenticate your requests by using the access keys that you provide. Unless you have a good reason not to, we recommend that you always use an SDK or the CLI.

In Regions that support multiple signature versions, manually signing requests mean you must specify which signature version is used. When you supply requests to Multi-Region

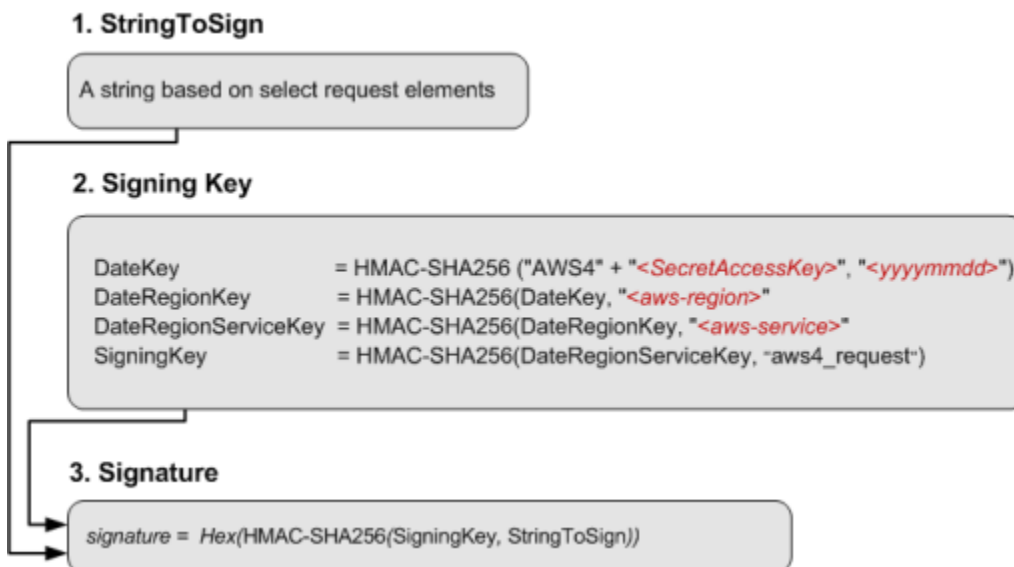

Access Points, SDKs and the CLI automatically switch to using Signature Version 4A without additional configuration.

Authentication information that you send in a request must include a signature. To calculate a signature, you first concatenate select request elements to form a string, referred to as the string to sign. You then use a signing key to calculate the hash-based message authentication code (HMAC) of the *string to sign*.

In AWS Signature Version 4, you don't use your secret access key to sign the request. Instead, you first use your secret access key to derive a signing key. The derived signing key is specific to the date, service, and Region. For more information about how to derive a signing key in different programming languages, see [Request signature examples](#).

Signature Version 4 is the AWS signing protocol. AWS also supports an extension, Signature Version 4A, which supports signatures for multi-Region API requests. For more information, see the [sigv4a-signing-examples](#) project on GitHub.

The following diagram illustrates the general process of computing a signature.

- The **string to sign** depends on the request type. For example, when you use the HTTP Authorization header or the query parameters for authentication, you use a varying combination of request elements to create the string to sign. For an HTTP POST request, the POST policy in the request is the string you sign.
- For **signing key**, the diagram shows series of calculations, where result of each step you feed into the next step. The final step is the signing key.

- When an AWS service receives an authenticated request, it recreates the **signature** using the authentication information contained in the request. If the signatures match, the service processes the request. Otherwise, it rejects the request.

Contents

- [When to sign requests](#)
- [Why requests are signed](#)
- [Elements of an AWS API request signature](#)
- [Authentication methods](#)
- [Create a signed AWS API request](#)
- [Request signature examples](#)
- [Troubleshoot signed requests for AWS APIs](#)

When to sign requests

When you write custom code that sends API requests to AWS, you must include code that signs the requests. You might write custom code because:

- You are working with a programming language for which there is no AWS SDK.
- You need complete control over how requests are sent to AWS.

Why requests are signed

The signing process helps secure requests in the following ways:

- **Verify the identity of the requester**

Authenticated requests require a signature that you create by using your access keys (access key ID, secret access key). If you are using temporary security credentials, the signature calculations also require a security token. For more information, see [AWS security credentials programmatic access](#).

- **Protect data in transit**

To prevent tampering with a request while it's in transit, some of the request elements are used to calculate a hash (digest) of the request, and the resulting hash value is included as part of the

request. When an AWS service receives the request, it uses the same information to calculate a hash and matches it against the hash value in your request. If the values don't match, AWS denies the request.

- **Protect against potential replay attacks**

In most cases, a request must reach AWS within five minutes of the time stamp in the request. Otherwise, AWS denies the request.

Elements of an AWS API request signature

Important

Unless you are using the AWS SDKs or CLI, you must write code to calculate signatures that provide authentication information in your requests. Signature calculation in AWS Signature Version 4 can be a complex undertaking, and we recommend that you use the AWS SDKs or CLI whenever possible.

Each HTTP/HTTPS request that uses Signature Version 4 signing must contain these elements.

Elements

- [Endpoint specification](#)
- [Action](#)
- [Action parameters](#)
- [Date](#)
- [Authentication information](#)

Endpoint specification

Specifies the DNS name of the endpoint to which you send the request. This name usually contains the service code and the Region. For example, the endpoint for Amazon DynamoDB in the us-east-1 Region is `dynamodb.us-east-1.amazonaws.com`.

For HTTP/1.1 requests, you must include the Host header. For HTTP/2 requests, you can include the `:authority` header or the Host header. Use only the `:authority` header for compliance with the HTTP/2 specification. Not all services support HTTP/2 requests.

For the endpoints supported by each service, see [Service endpoints and quotas](#) in the *AWS General Reference*.

Action

Specifies an API action for the service. For example, the DynamoDB `CreateTable` action or the Amazon EC2 `DescribeInstances` action.

For the actions supported by each service, see the [Service Authorization Reference](#).

Action parameters

Specifies the parameters for the action specified in the request. Each AWS API action has a set of required and optional parameters. The API version is usually a required parameter.

For the parameters supported by an API action, see the [API Reference](#) for the service.

Date

Specifies the date and time of the request. Including the date and time in a request helps prevent third parties from intercepting your request and resubmitting it later. The date that you specify in the credential scope must match the date of your request.

The time stamp must be in UTC and use the following ISO 8601 format: `YYYYMMDDTHHMMSSZ`. For example, `20220830T123600Z`. Do not include milliseconds in the time stamp.

You can use a date or an `x-amz-date` header, or include `x-amz-date` as a query parameter. If we can't find an `x-amz-date` header, then we look for a date header.

Authentication information

Each request that you send must include the following information. AWS uses this information to ensure the validity and authenticity of the request.

- **Algorithm** – Use `AWS4-HMAC-SHA256` to specify Signature Version 4 with the HMAC-SHA256 hash algorithm.
- **Credential** – A string that consists of your access key ID, the date in `YYYYMMDD` format, the Region code, the service code, and the `aws4_request` termination string, separated by slashes (/). The Region code, service code, and termination string must use lowercase characters.

```
AKIAIOSFODNN7EXAMPLE/YYYYMMDD/region/service/aws4_request
```

- Signed headers – The HTTP headers to include in the signature, separated by semicolons (;). For example, `host;x-amz-date`.
- Signature – A hexadecimal-encoded string that represents the calculated signature. You must calculate the signature using the algorithm that you specified in the `Algorithm` parameter.

Authentication methods

Important

Unless you are using the AWS SDKs or CLI, you must write code to calculate signatures that provide authentication information in your requests. Signature calculation in AWS Signature Version 4 can be a complex undertaking, and we recommend that you use the AWS SDKs or CLI whenever possible.

You can express authentication information by using one of the following methods.

HTTP authorization header

The HTTP `Authorization` header is the most common method of authenticating a request. All REST API operations (except for browser-based uploads using POST requests) require this header. For more information about the authorization header value, and how to calculate signature and related options, see [Authenticating Requests: Using the Authorization Header \(AWS Signature Version 4\)](#) in the *Amazon S3 API Reference*.

The following is an example of the `Authorization` header value. Line breaks are added to this example for readability. In your code, the header must be a continuous string. There is no comma between the algorithm and `Credential`, but the other elements must be separated by commas.

```
Authorization: AWS4-HMAC-SHA256
Credential=AKIAIOSFODNN7EXAMPLE/20130524/us-east-1/s3/aws4_request,
SignedHeaders=host;range;x-amz-date,
Signature=fe5f80f77d5fa3beca038a248ff027d0445342fe2855ddc963176630326f1024
```

The following table describes the various components of the `Authorization` header value in the preceding example:

Component	Description
Authorization	<p>The algorithm that was used to calculate the signature. You must provide this value when you use AWS Signature Version 4 for authentication. The string specifies AWS Signature Version 4 (AWS4) and the signing algorithm (HMAC-SHA256).</p>
Credential	<p>Your access key ID and the scope information, which includes the date, Region, and service that were used to calculate the signature.</p> <p>This string has the following form:</p> <pre data-bbox="829 827 1365 957"><your-access-key-id>/<date>/ <aws-region>/<aws-service>/ aws4_request</pre> <p>Where: <date> value is specified using YYYYMMDD format. <aws-service> value is s3 when sending request to Amazon S3.</p>
SignedHeaders	<p>A semicolon-separated list of request headers that you used to compute Signature . The list includes header names only, and the header names must be in lowercase. For example: host;range;x-amz-date</p>
Signature	<p>The 256-bit signature expressed as 64 lowercase hexadecimal characters. For example: fe5f80f77d5fa3beca038a248ff027d0445342fe2855ddc963176630326f1024</p> <p>Note that the signature calculations vary depending on the option you choose to transfer the payload.</p>

Query string parameters

You can use a query string to express a request entirely in a URL. In this case, you use query parameters to provide request information, including the authentication information. Because the request signature is part of the URL, this type of URL is often referred to as a presigned URL. You can use presigned URLs to embed clickable links in HTML, which can be valid for up to seven days. For more information, see [Authenticating Requests: Using Query Parameters \(AWS Signature Version 4\)](#) in the *Amazon S3 API Reference*.

The following is an example presigned URL. Line breaks are added to this example for readability:

```
https://s3.amazonaws.com/examplebucket/test.txt ?
X-Amz-Algorithm=AWS4-HMAC-SHA256 &
X-Amz-Credential=<your-access-key-id>/20130721/us-east-1/s3/aws4_request &
X-Amz-Date=20130721T201207Z &
X-Amz-Expires=86400 &
X-Amz-SignedHeaders=host &X-Amz-Signature=<signature-value>
```

Note

The `X-Amz-Credential` value in the URL shows the "/" character only for readability. In practice, it should be encoded as `%2F`. For example:

```
&X-Amz-Credential=<your-access-key-id>%2F20130721%2Fus-east-1%2Fs3%2Faws4_request
```

The following table describes the query parameters in the URL that provide authentication information.

Query string parameter name	Description
X-Amz-Algorithm	Identifies the version of AWS Signature and the algorithm that you used to calculate the signature. For AWS Signature Version 4, you set this parameter value to <code>AWS4-HMAC-SHA256</code> . This string identifies AWS Signature Version 4 (AWS4) and the HMAC-SHA256 algorithm (HMAC-SHA256).

Query string parameter name	Description
X-Amz-Credential	<p>In addition to your access key ID, this parameter also provides scope (AWS Region and service) for which the signature is valid. This value must match the scope you use in signature calculations, discussed in the following section.</p> <p>The general form for this parameter value is as follows:</p> <pre><your-access-key-id>/<date>/ <AWS Region>/<AWS-service>/aws4_ request</pre> <p>For example: AKIAIOSFODNN7EXAMP LE/20130721/us-east-1/s3/aw s4_request</p> <p>For a list of AWS regional strings, see Regional Endpoints in the <i>AWS General Reference</i>.</p>
X-Amz-Date	<p>The date and time format must follow the ISO 8601 standard, and must be formatted with the yyyyMMddTHHmmsZ format. For example if the date and time was "08/01/2016 15:32:41.982-700" then it must first be converted to UTC (Coordinated Universal Time) and then submitted as "20160801T223241Z".</p>

Query string parameter name	Description
X-Amz-Expires	<p>Provides the time period, in seconds, for which the generated presigned URL is valid. For example, 86400 (24 hours). This value is an integer. The minimum value you can set is 1, and the maximum is 604800 (seven days). A presigned URL can be valid for a maximum of seven days because the signing key you use in signature calculation is valid for up to seven days.</p>
X-Amz-SignedHeaders	<p>Lists the headers that you used to calculate the signature. The following headers are required in the signature calculations:</p> <ul style="list-style-type: none">• The HTTP host header.• Any x-amz-* headers that you plan to add to the request. <p>For added security, you should sign all the request headers that you plan to include in your request.</p>
X-Amz-Signature	<p>Provides the signature to authenticate your request. This signature must match the signature the service calculates; otherwise, the service denies the request. For example,</p> <pre>733255ef022bec3f2a8701cd61d 4b371f3f28c9f193a1f02279211 d48d5193d7</pre> <p>Signature calculations are described in the following section.</p>
X-Amz-Security-Token	<p>Optional credential parameter if using credentials sourced from the STS service.</p>

Create a signed AWS API request

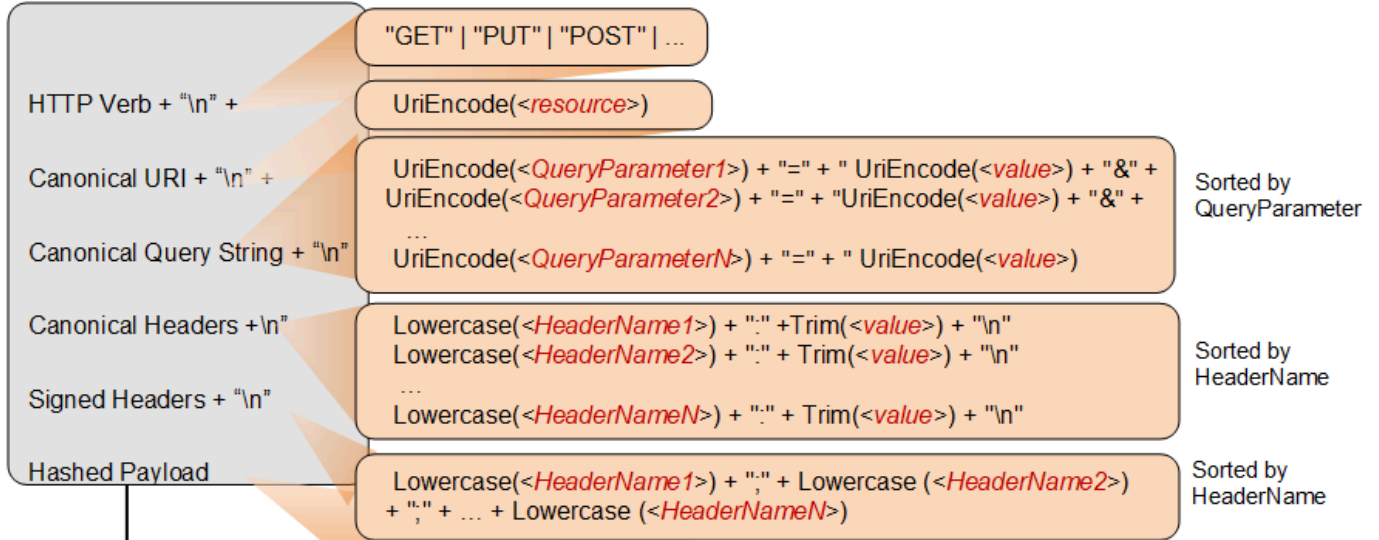

Important

If you use an AWS SDKs (see [Sample Code and Libraries](#)) or AWS command line (CLI) tool to send API requests to AWS, you can skip this section because the SDK and CLI clients authenticate your requests by using the access keys that you provide. Unless you have a good reason not to, we recommend that you always use an SDK or the CLI.

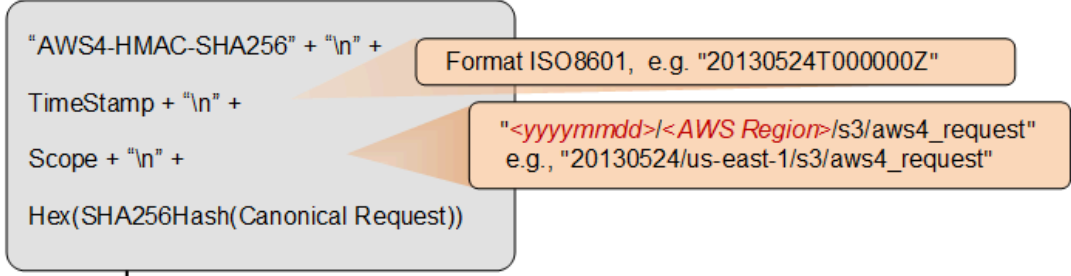

In Regions that support multiple signature versions, manually signing requests mean you must specify which signature version is used. When you supply requests to Multi-Region Access Points, SDKs and the CLI automatically switch to using Signature Version 4A without additional configuration.

The following is an overview of the process to create a signed request. To calculate a signature, you first need a string to sign. You then calculate a HMAC-SHA256 hash of the string to sign by using a signing key. The following diagram illustrates the process, including the various components of the string that you create for signing.

1. Canonical Request

2. StringToSign

3. Signing Key

4. Signature

The following table describes the functions that are shown in the diagram. You need to implement code for these functions. For more information, see the [code examples in the AWS SDKs](#).

Function	Description
<code>Lowercase()</code>	Convert the string to lowercase.
<code>Hex()</code>	Lowercase base 16 encoding.
<code>SHA256Hash()</code>	Secure Hash Algorithm (SHA) cryptographic hash function.
<code>HMAC-SHA256()</code>	Computes HMAC by using the SHA256 algorithm with the signing key provided. This is the final signature.
<code>Trim()</code>	Remove any leading or trailing whitespace.
<code>UriEncode()</code>	<p>URI encode every byte. <code>UriEncode()</code> must enforce the following rules:</p> <ul style="list-style-type: none">• URI encode every byte except the unreserved characters: 'A'-'Z', 'a'-'z', '0'-'9', '-', '.', '_', and '~'.• The space character is a reserved character and must be encoded as "%20" (and not as "+").• Each URI encoded byte is formed by a '%' and the two-digit hexadecimal value of the byte.• Letters in the hexadecimal value must be uppercase, for example "%1A".• Encode the forward slash character, '/', everywhere except in the object key name. For example, if the object key name is <code>photos/Jan/sample.jpg</code>, the forward slash in the key name is not encoded.

Function	Description
	<p>⚠ Important</p> <p>The standard UriEncode functions provided by your development platform may not work because of differences in implementation and related ambiguity in the underlying RFCs. We recommend that you write your own custom UriEncode function to ensure that your encoding will work.</p> <p>To see an example of a UriEncode function in Java, see Java Utilities on the GitHub website.</p>

Note

When signing your requests, you can use either AWS Signature Version 4 or AWS Signature Version 4A. The key difference between the two is determined by how the signature is calculated. With AWS Signature Version 4A, the signature does not include Region-specific information and is calculated using the AWS4-ECDSA-P256-SHA256 algorithm.

Temporary security credentials

Instead of using long-term credentials to sign a request, you can use temporary security credentials provided by AWS Security Token Service (AWS STS).

When you use temporary security credentials, you must add `X-Amz-Security-Token` to the Authorization header or the query string to hold the session token. Some services require that you add `X-Amz-Security-Token` to the canonical request. Other services require only that you add `X-Amz-Security-Token` at the end, after you calculate the signature. Check the documentation for each AWS service for details.

Summary of signing steps

Step 1: Create a canonical request

Arrange the contents of your request (host, action, headers, etc.) into a standard canonical format. The canonical request is one of the inputs used to create a string to sign. For details, see [Elements of an AWS API request signature](#).

Step 2: Create a hash of the canonical request

Derive a signing key by performing a succession of keyed hash operations (HMAC operations) on the request date, Region, and service, with your AWS secret access key as the key for the initial hashing operation.

Step 3: Create a String to Sign

Create a string to sign with the canonical request and extra information such as the algorithm, request date, credential scope, and the digest (hash) of the canonical request.

Step 4: Calculate the signature

After you derive the signing key, you then calculate the signature by performing a keyed hash operation on the string to sign. Use the derived signing key as the hash key for this operation.

Step 5: Add the signature to the request

After you calculate the signature, add it to an HTTP header or to the query string of the request.

Step 1: Create a canonical request

Create a canonical request by concatenating the following strings, separated by newline characters. This helps ensure that the signature that you calculate and the signature that AWS calculates can match.

```
<HTTPMethod>\n<CanonicalURI>\n<CanonicalQueryString>\n<CanonicalHeaders>\n<SignedHeaders>\n<HashedPayload>
```

- *HTTPMethod* – The HTTP method, such as GET, PUT, HEAD, and DELETE.

- **CanonicalUri** – The URI-encoded version of the absolute path component URI, starting with the "/" that follows the domain name and up to the end of the string or to the question mark character (?) if you have query string parameters. If the absolute path is empty, use a forward slash character (/). The URI in the following example, /examplebucket/myphoto.jpg, is the absolute path and you don't encode the "/" in the absolute path:

```
http://s3.amazonaws.com/examplebucket/myphoto.jpg
```

- **CanonicalQueryString** – The URI-encoded query string parameters. You URI-encode each name and values individually. You must also sort the parameters in the canonical query string alphabetically by key name. The sorting occurs after encoding. The query string in the following URI example is:

```
http://s3.amazonaws.com/examplebucket?prefix=somePrefix&marker=someMarker&max-keys=2
```

The canonical query string is as follows (line breaks are added to this example for readability):

```
UriEncode("marker")+"="+UriEncode("someMarker")+"&"+  
UriEncode("max-keys")+"="+UriEncode("20") + "&" +  
UriEncode("prefix")+"="+UriEncode("somePrefix")
```

When a request targets a subresource, the corresponding query parameter value will be an empty string (""). For example, the following URI identifies the ACL subresource on the examplebucket bucket:

```
http://s3.amazonaws.com/examplebucket?acl
```

The CanonicalQueryString in this case is as follows:

```
UriEncode("acl") + "=" + ""
```

If the URI does not include a '?', there is no query string in the request, and you set the canonical query string to an empty string (""). You will still need to include the "\n".

- **CanonicalHeaders** – A list of request headers with their values. Individual header name and value pairs are separated by the newline character ("\n"). The following is an example of a **canonicalheader**:

```
Lowercase(<HeaderName1>)+": "+Trim(<value>)+"\n"  
Lowercase(<HeaderName2>)+": "+Trim(<value>)+"\n"  
...  
Lowercase(<HeaderNameN>)+": "+Trim(<value>)+"\n"
```

CanonicalHeaders list must include the following:

- HTTP host header.
- If the Content-Type header is present in the request, you must add it to the *CanonicalHeaders* list.
- Any x-amz-* headers that you plan to include in your request must also be added. For example, if you are using temporary security credentials, you need to include x-amz-security-token in your request. You must add this header in the list of *CanonicalHeaders*.

 **Note**

The x-amz-content-sha256 header is required for Amazon S3 AWS requests. It provides a hash of the request payload. If there is no payload, you must provide the hash of an empty string.

Each header name must:

- use lowercase characters.
- appear in alphabetical order.
- be followed by a colon (:).

For values, you must:

- trim any leading or trailing spaces.
- convert sequential spaces to a single space.
- separate the values for a multi-value header using commas.
- You must include the host header (HTTP/1.1) or the :authority header (HTTP/2), and any x-amz-* headers in the signature. You can optionally include other standard headers in the signature, such as content-type.

The `Lowercase()` and `Trim()` functions used in this example are described in the preceding section.

The following is an example `CanonicalHeaders` string. The header names are in lowercase and sorted.

```
host:s3.amazonaws.com
x-amz-content-sha256:e3b0c44298fc1c149afbf4c8996fb92427ae41e4649b934ca495991b7852b855
x-amz-date:20130708T220855Z
```

Note

For the purpose of calculating an authorization signature, only the host and any `x-amz-*` headers are required; however, in order to prevent data tampering, you should consider including all the headers in the signature calculation.

- ***SignedHeaders*** – An alphabetically sorted, semicolon-separated list of lowercase request header names. The request headers in the list are the same headers that you included in the `CanonicalHeaders` string. For example, for the previous example, the value of ***SignedHeaders*** would be as follows:

```
host;x-amz-content-sha256;x-amz-date
```

- ***HashedPayload*** – A string created using the payload in the body of the HTTP request as input to a hash function. This string uses lowercase hexadecimal characters.

```
Hex(SHA256Hash(<payload>))
```

If there is no payload in the request, you compute a hash of the empty string as follows:

```
Hex(SHA256Hash(""))
```

The hash returns the following value:

```
e3b0c44298fc1c149afb4c8996fb92427ae41e4649b934ca495991b7852b855
```

For example, when you upload an object by using a PUT request, you provide object data in the body. When you retrieve an object by using a GET request, you compute the empty string hash.

Step 2: Create a hash of the canonical request

Create a hash (digest) of the canonical request using the same algorithm that you used to create the hash of the payload. The hash of the canonical request is a string of lowercase hexadecimal characters.

Step 3: Create a string to sign

Create a string by concatenating the following strings, separated by newline characters. Do not end this string with a newline character.

```
Algorithm \n
RequestDateTime \n
CredentialScope \n
HashedCanonicalRequest
```

- *Algorithm* – The algorithm used to create the hash of the canonical request. For SHA-256, the algorithm is AWS4-HMAC-SHA256.
- *RequestDateTime* – The date and time used in the credential scope. This value is the current UTC time in ISO 8601 format (for example, 20130524T000000Z).
- *CredentialScope* – The credential scope. This restricts the resulting signature to the specified Region and service. The string has the following format: *YYYYMMDD/region/service/aws4_request*.
- *HashedCanonicalRequest* – The hash of the canonical request. This value is calculated in Step 2.

The following is an example string to sign.

```
"AWS4-HMAC-SHA256" + "\n" +
timeStampISO8601Format + "\n" +
<Scope> + "\n" +
```

```
Hex(SHA256Hash(<CanonicalRequest>))
```

Step 4: Calculate the signature

In AWS Signature Version 4, instead of using your AWS access keys to sign a request, you create a signing key that is scoped to a specific Region and service as the authentication information you'll add to your request.

```
DateKey = HMAC-SHA256("AWS4"+"<SecretAccessKey>", "<YYYYMMDD>")
DateRegionKey = HMAC-SHA256(<DateKey>, "<aws-region>")
DateRegionServiceKey = HMAC-SHA256(<DateRegionKey>, "<aws-service>")
SigningKey = HMAC-SHA256(<DateRegionServiceKey>, "aws4_request")
```

For a list of Region strings, see [Regional Endpoints](#) in the *AWS General Reference*.

For each step, call the hash function with the required key and data. The result of each call to the hash function becomes the input for the next call to the hash function.

Required input

- A string, *Key*, that contains your secret access key
- A string, *Date*, that contains the date used in the credential scope, in the format *YYYYMMDD*
- A string, *Region*, that contains the Region code (for example, *us-east-1*)
- A string, *Service*, that contains the service code (for example, *ec2*)
- The string to sign that you created in the previous step.

To calculate the signature

1. Concatenate "AWS4" and the secret access key. Call the hash function with the concatenated string as the key and the date string as the data.

```
kDate = hash("AWS4" + Key, Date)
```

2. Call the hash function with the result of the previous call as the key and the Region string as the data.

```
kRegion = hash(kDate, Region)
```

3. Call the hash function with the result of the previous call as the key and the service string as the data.

```
kService = hash(kRegion, Service)
```

4. Call the hash function with the result of the previous call as the key and "aws4_request" as the data.

```
kSigning = hash(kService, "aws4_request")
```

5. Call the hash function with the result of the previous call as the key and the string to sign as the data. The result is the signature as a binary value.

```
signature = hash(kSigning, string-to-sign)
```

6. Convert the signature from binary to hexadecimal representation, in lowercase characters.

Step 5: Add the signature to the request

Example Example: Authorization header

The following example shows an Authorization header for the DescribeInstances action. For readability, this example is formatted with line breaks. In your code, this must be a continuous string. There is no comma between the algorithm and Credential. However, the other elements must be separated by commas.

```
Authorization: AWS4-HMAC-SHA256  
Credential=AKIAIOSFODNN7EXAMPLE/20220830/us-east-1/ec2/aws4_request,  
SignedHeaders=host;x-amz-date,  
Signature=calculated-signature
```

Example Example: Request with authentication parameters in the query string

The following example shows a query for the DescribeInstances action that includes the authentication information. For readability, this example is formatted with line breaks and is not URL encoded. In your code, the query string must be a continuous string that is URL encoded.

```
https://ec2.amazonaws.com/?  
Action=DescribeInstances&  
Version=2016-11-15&
```

```
X-Amz-Algorithm=AWS4-HMAC-SHA256&
X-Amz-Credential=AKIAIOSFODNN7EXAMPLE/20220830/us-east-1/ec2/aws4_request&
X-Amz-Date=20220830T123600Z&
X-Amz-SignedHeaders=host;x-amz-date&
X-Amz-Signature=calculated-signature
```

Source code in the AWS SDKs

The AWS SDKs include source code on GitHub for signing AWS API requests. For code samples, see [Example projects in AWS samples repository](#)

- AWS SDK for .NET – [AWS4Signer.cs](#)
- AWS SDK for C++ – [AWSAuthV4Signer.cpp](#)
- AWS SDK for Go – [v4.go](#)
- AWS SDK for Java – [BaseAws4Signer.java](#)
- AWS SDK for JavaScript – [v4.js](#)
- AWS SDK for PHP – [SignatureV4.php](#)
- AWS SDK for Python (Boto) – [signers.py](#)
- AWS SDK for Ruby – [signer.rb](#)

Request signature examples

The following examples of AWS signing requests show you how you can use SigV4 to sign requests sent without the AWS SDK or AWS command line tool.

Browser based Amazon S3 upload using HTTP POST

[Authenticating Requests: Browser-Based Uploads](#) describes the signature and relevant information that Amazon S3 uses to calculate the signature upon receiving the request.

[Example: Browser-Based Upload using HTTP POST \(Using AWS Signature Version 4\)](#) provides more information with a sample POST policy and a form that you can use to upload a file. The example policy and fictitious credentials show you the workflow and resulting signature and policy hash.

VPC Lattice authenticated requests

[Examples for Signature Version 4 \(SigV4\) authenticated requests](#) provides Python and Java examples showing how you can perform request signing with and without custom interceptors.

Using Signature Version 4 with Amazon Translate

[Using Signature Version 4 with Amazon Translate](#) shows how to use a Python program to add authentication information to Amazon Translate requests. The example makes a POST request, creates a JSON structure that contains the text to be translated in the body (payload) of the request, and passes authentication information in an Authorization header.

Using Signature Version 4 with Neptune

[Example: Connecting to Neptune Using Python with Signature Version 4 Signing](#) shows how to make signed requests to Neptune using Python. This example includes variations for using an access key or temporary credentials.

Signing HTTP requests to S3 Glacier

[Example Signature Calculation for Streaming API](#) walks you through the details of creating a signature for Upload Archive (POST archive), one of the two streaming APIs in S3 Glacier.

Making HTTP Requests to Amazon SWF

[Making HTTP Requests to Amazon SWF](#) shows the header contents for a JSON request to Amazon SWF.

Signature calculation for streaming APIs in Amazon OpenSearch Service

[Signing an Amazon OpenSearch Service search request with AWS SDK for PHP Version 3](#) includes an example of how to send signed HTTP requests to Amazon OpenSearch Service.

Example projects in AWS samples repository

The following example projects show how to sign requests to make Rest API requests to AWS services with common languages such as Python, Node.js, Java, C#, Go and Rust.

Signature Version 4a projects

The [sigv4a-signing-examples](#) project provides examples of how to sign requests with SigV4A to make Rest API requests to AWS services with common languages such as Python, Node.js, Java, C#, Go and Rust.

[Making requests using a Multi-Region Access Point \(MRAP\)](#) uses Signature Version 4a to access data in Amazon S3 using Python boto 3.

Publish to AWS IoT Core

[Python code to publish to AWS IoT Core using HTTPs protocol](#) provides guidance on how to publish messages to AWS IoT Core using Https protocol and AWS SigV4 authentication. It has two reference implementations - one in Python and other in NodeJs.

[.Net Framework application to publish to AWS IoT Core using HTTPs protocol](#) provides guidance on how to publish messages to AWS IoT Core using Https protocol and AWS SigV4 authentication. This project also includes a .NET core equivalent implementation.

Troubleshoot signed requests for AWS APIs

Important

Unless you are using the AWS SDKs or CLI, you must write code to calculate signatures that provide authentication information in your requests. SigV4 signature calculation can be a complex undertaking, and we recommend that you use the AWS SDKs or CLI whenever possible.

When you develop code that creates a signed request, you might receive HTTP 403 SignatureDoesNotMatch from AWS services. These errors mean that the signature value in your HTTP request to AWS did not match the signature that the AWS service calculated. HTTP 401 Unauthorized errors return when permissions do not allow the caller to make the request.

API requests might return an error if:

- The API request isn't signed and the API request uses IAM authentication.
- The IAM credentials used to sign the request are incorrect or don't have permissions to invoke the API.
- The signature of the signed API request doesn't match the signature that the AWS service calculated.
- The API request header is incorrect.

Note

Update your signing protocol from AWS Signature version 2 (SigV2) to AWS Signature version 4 (SigV4) before exploring other error solutions. Services, such as Amazon S3, and Regions no longer support SigV2 signing.

Possible causes

- [Credential errors](#)
- [Canonical request and signing string errors](#)
- [Credential scope errors](#)
- [Key signing errors](#)

Credential errors

Make sure that the API request is signed with SigV4. If the API request isn't signed, then you might receive the error: Missing Authentication Token. [Add the missing signature](#) and resend the request.

Verify that the authentication credentials for the access key and secret key are correct. If the access key is incorrect, then you might receive the error: Unauthorized. Make sure the entity used to sign the request is authorized to make the request. For details, see [Troubleshooting access denied error messages](#).

Canonical request and signing string errors

If you incorrectly calculated the canonical request in [Step 2: Create a hash of the canonical request](#) or [Step 3: Create a string to sign](#), the signature verification step performed by the service fails with the error message:

```
The request signature we calculated does not match the signature you provided
```

When the AWS service receives a signed request, it recalculates the signature. If there are differences in the values, then the signatures don't match. Compare the canonical request and string to your signed request with the value in the error message. Modify the signing process if there are any differences.

Note

You can also verify that you didn't send the request through a proxy that modifies the headers or the request.

Example Example canonical request

```

GET ----- HTTP method
/ ----- Path. For API stage
  endpoint, it should be /{stage-name}/{resource-path}
value pair. Leave it blank if the request doesn't have a query string.
content-type:application/json ----- Query string key-
  pair. One header per line. ----- Header key-value
host:0123456789.execute-api.us-east-1.amazonaws.com ----- Host and x-amz-date
  are required headers for all signed requests.
x-amz-date:20220806T024003Z
content-type;host;x-amz-date ----- A list of signed
  headers
d167e99c53f15b0c105101d468ae35a3dc9187839ca081095e340f3649a04501 ----- Hash
  of the payload

```

To verify that the secret key matches the access key ID, you can test them with a known working implementation. For example, use an AWS SDK or the AWS CLI to make a request to AWS.

API request header

Make sure that the SigV4 authorization header you added in [Step 4: Calculate the signature](#) includes the correct credential key similar to the following:

```

Authorization: AWS4-HMAC-SHA256
Credential=AKIAIOSFODNN7EXAMPLE/20130524/us-east-1/s3/aws4_request,
SignedHeaders=host;range;x-amz-date,
Signature=example-generated-signature

```

If the credential key is missing or incorrect, you might receive the error: Authorization header requires 'Credential' parameter. Authorization header requires 'Signature' parameter. Make sure that the SigV4 authorization request also includes the request date using either HTTP Date or the x-amz-date header.

Credential scope errors

The credential scope you created in [Step 3: Create a string to sign](#) restricts a signature to a specific date, Region, and service. This string has the following format:

```
YYYYMMDD/region/service/aws4_request
```

Note

If you are using SigV4a, the Region is not included in credential scope.

Date

If the credential scope does not specify the same date as the x-amz-date header, the signature verification step fails with the following error message:

```
Date in Credential scope does not match YYYYMMDD from ISO-8601 version of date from HTTP
```

If the request specifies a time in the future, the signature verification step fails with the following error message:

```
Signature not yet current: date is still later than date
```

If the request has expired, the signature verification step fails with the following error message:

```
Signature expired: date is now earlier than date
```

Region

If the credential scope does not specify the same Region as the request, the signature verification step fails with the following error message:

```
Credential should be scoped to a valid Region, not region-code
```

Service

If the credential scope does not specify the same service as the host header, the signature verification step fails with the following error message:

```
Credential should be scoped to correct service: 'service'
```

Termination string

If the credential scope does not end with `aws4_request`, the signature verification step fails with the following error message:

```
Credential should be scoped with a valid terminator: 'aws4_request'
```

Key signing errors

Errors that are caused by incorrect derivation of the signing key or improper use of cryptography are more difficult to troubleshoot. After you verify that the canonical string and the string to sign are correct, you can also check for one of the following issues:

- The secret access key does not match the access key ID that you specified.
- There is a problem with your key derivation code.

To verify that the secret key matches the access key ID, you can test them with a known working implementation. For example, use an AWS SDK or the AWS CLI to make a request to AWS. For examples, see [Request signature examples](#)

IAM JSON policy reference

This section presents detailed syntax, descriptions, and examples of the elements, variables, and evaluation logic of JSON policies in IAM. For more general information, see [Overview of JSON policies](#).

This reference includes the following sections.

- [IAM JSON policy elements reference](#) — Learn more about the elements that you can use when you create a policy. View additional policy examples and learn about conditions, supported data types, and how they are used in various services.
- [Policy evaluation logic](#) — This section describes AWS requests, how they are authenticated, and how AWS uses policies to determine access to resources.

- [Grammar of the IAM JSON policy language](#) — This section presents a formal grammar for the language that is used to create policies in IAM.
- [AWS managed policies for job functions](#) — This section lists all the AWS managed policies that directly map to common job functions in the IT industry. Use these policies to grant the permissions that are needed to carry out the tasks expected of someone in a specific job function. These policies consolidate permissions for many services into a single policy.
- [AWS global condition context keys](#) — This section includes a list of all the AWS global condition keys that you can use to limit permissions in an IAM policy.
- [IAM and AWS STS condition context keys](#) — This section includes a list of all the IAM and AWS STS condition keys that you can use to limit permissions in an IAM policy.
- [Actions, Resources, and Condition Keys for AWS Services](#) — This section presents a list of all the AWS API operations that you can use as permissions in an IAM policy. It also includes the service-specific condition keys that can be used to further refine the request.

IAM JSON policy elements reference

JSON policy documents are made up of elements. The elements are listed here in the general order you use them in a policy. The order of the elements doesn't matter—for example, the `Resource` element can come before the `Action` element. You're not required to specify any `Condition` elements in the policy. To learn more about the general structure and purpose of a JSON policy document, see [Overview of JSON policies](#).

Some JSON policy elements are mutually exclusive. This means that you cannot create a policy that uses both. For example, you cannot use both `Action` and `NotAction` in the same policy statement. Other pairs that are mutually exclusive include `Principal/NotPrincipal` and `Resource/NotResource`.

The details of what goes into a policy vary for each service, depending on what actions the service makes available, what types of resources it contains, and so on. When you're writing policies for a specific service, it's helpful to see examples of policies for that service. For a list of all the services that support IAM, and for links to the documentation in those services that discusses IAM and policies, see [AWS services that work with IAM](#).

When you create or edit a JSON policy, IAM can perform policy validation to help you create an effective policy. IAM identifies JSON syntax errors, while IAM Access Analyzer provides additional policy checks with recommendations to help you further refine your policies. To learn more about

policy validation, see [Validating IAM policies](#). To learn more about IAM Access Analyzer policy checks and actionable recommendations, see [IAM Access Analyzer policy validation](#).

IAM JSON policy elements: Version

Disambiguation note

This `Version` JSON policy element is different from a *policy version*. The `Version` policy element is used within a policy and defines the version of the policy language. A policy version, on the other hand, is created when you make changes to a customer managed policy in IAM. The changed policy doesn't overwrite the existing policy. Instead, IAM creates a new version of the managed policy. If you were searching for information about the multiple version support available for managed policies, see [the section called "Versioning IAM policies"](#).

The `Version` policy element specifies the language syntax rules that are to be used to process a policy. To use all of the available policy features, include the following `Version` element **outside** the `Statement` element in all of your policies.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": "s3:ListAllMyBuckets",
      "Resource": "*"
    }
  ]
}
```

IAM supports the following `Version` element values:

- `2012-10-17`. This is the current version of the policy language, and you should always include a `Version` element and set it to `2012-10-17`. Otherwise, you cannot use features such as [policy variables](#) that were introduced with this version.
- `2008-10-17`. This was an earlier version of the policy language. You might see this version on older existing policies. Do not use this version for any new policies or when you update any existing policies. Newer features, such as policy variables, will not work with your policy. For example, variables such as `${aws:username}` aren't recognized as variables and are instead treated as literal strings in the policy.

IAM JSON policy elements: `Id`

The `Id` element specifies an optional identifier for the policy. The ID is used differently in different services. ID is allowed in resource-based policies, but not in identity-based policies.

For services that let you set an ID element, we recommend you use a UUID (GUID) for the value, or incorporate a UUID as part of the ID to ensure uniqueness.

```
{
  "Version": "2012-10-17",
  "Id": "cd3ad3d9-2776-4ef1-a904-4c229d1642ee",
  "Statement": [
    {
```

```
    "Effect": "Allow",
    "Action": "s3:ListAllMyBuckets",
    "Resource": "*"
  }
]
```

Note

Some AWS services (for example, Amazon SQS or Amazon SNS) might require this element and have uniqueness requirements for it. For service-specific information about writing policies, refer to the documentation for the service you're working with.

IAM JSON policy elements: Statement

The Statement element is the main element for a policy. This element is required. The Statement element can contain a single statement or an array of individual statements. Each individual statement block must be enclosed in curly braces { }. For multiple statements, the array must be enclosed in square brackets [].

```
"Statement": [{...},{...},{...}]
```

The following example shows a policy that contains an array of three statements inside a single Statement element. (The policy allows you to access your own "home folder" in the Amazon S3 console.) The policy includes the `aws:username` variable, which is replaced during policy evaluation with the user name from the request. For more information, see [Introduction](#).

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "s3:ListAllMyBuckets",
        "s3:GetBucketLocation"
      ],
      "Resource": "arn:aws:s3:::*"
    },
    {
```

```

    "Effect": "Allow",
    "Action": "s3:ListBucket",
    "Resource": "arn:aws:s3:::BUCKET-NAME",
    "Condition": {"StringLike": {"s3:prefix": [
        "",
        "home/",
        "home/${aws:username}/"
    ]}}
  },
  {
    "Effect": "Allow",
    "Action": "s3:*",
    "Resource": [
      "arn:aws:s3:::BUCKET-NAME/home/${aws:username}",
      "arn:aws:s3:::BUCKET-NAME/home/${aws:username}/*"
    ]
  }
]
}

```

IAM JSON policy elements: Sid

You can provide a `Sid` (statement ID) as an optional identifier for the policy statement. You can assign a `Sid` value to each statement in a statement array. You can use the `Sid` value as a description for the policy statement. In services that let you specify an ID element, such as SQS and SNS, the `Sid` value is just a sub-ID of the policy document ID. In IAM, the `Sid` value must be unique within a JSON policy.

```

{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "ExampleStatementID",
      "Effect": "Allow",
      "Action": "s3:ListAllMyBuckets",
      "Resource": "*"
    }
  ]
}

```

The `Sid` element supports ASCII uppercase letters (A-Z), lowercase letters (a-z), and numbers (0-9).

IAM does not expose the `Sid` in the IAM API. You can't retrieve a particular statement based on this ID.

Note

Some AWS services (for example, Amazon SQS or Amazon SNS) might require this element and have uniqueness requirements for it. For service-specific information about writing policies, refer to the documentation for the service you work with.

IAM JSON policy elements: Effect

The `Effect` element is required and specifies whether the statement results in an allow or an explicit deny. Valid values for `Effect` are `Allow` and `Deny`. The `Effect` value is case sensitive.

```
"Effect": "Allow"
```

By default, access to resources is denied. To allow access to a resource, you must set the `Effect` element to `Allow`. To override an allow (for example, to override an allow that is otherwise in force), you set the `Effect` element to `Deny`. For more information, see [Policy evaluation logic](#).

AWS JSON policy elements: Principal

Use the `Principal` element in a resource-based JSON policy to specify the principal that is allowed or denied access to a resource.

You must use the `Principal` element in [resource-based policies](#). Several services support resource-based policies, including IAM. The IAM resource-based policy type is a role trust policy. In IAM roles, use the `Principal` element in the role trust policy to specify who can assume the role. For cross-account access, you must specify the 12-digit identifier of the trusted account. To learn whether principals in accounts outside of your zone of trust (trusted organization or account) have access to assume your roles, see [What is IAM Access Analyzer?](#)

Note

After you create the role, you can change the account to `"*"` to allow everyone to assume the role. If you do this, we strongly recommend that you limit who can access the role through other means, such as a `Condition` element that limits access to only certain IP addresses. Do not leave your role accessible to everyone!

Other examples of resources that support resource-based policies include an Amazon S3 bucket or an AWS KMS key.

You cannot use the `Principal` element in an identity-based policy. Identity-based policies are permissions policies that you attach to IAM identities (users, groups, or roles). In those cases, the principal is implicitly the identity where the policy is attached.

Topics

- [Specifying a principal](#)
- [AWS account principals](#)
- [IAM role principals](#)
- [Role session principals](#)
- [IAM user principals](#)
- [IAM Identity Center principals](#)
- [AWS STS federated user session principals](#)
- [AWS service principals](#)
- [AWS service principals in opt-in Regions](#)
- [All principals](#)
- [More information](#)

Specifying a principal

You specify a principal in the `Principal` element of a resource-based policy or in condition keys that support principals.

You can specify any of the following principals in a policy:

- AWS account and root user
- IAM roles
- Role sessions
- IAM users
- Federated user sessions
- AWS services
- All principals

You cannot identify a user group as a principal in a policy (such as a resource-based policy) because groups relate to permissions, not authentication, and principals are authenticated IAM entities.

You can specify more than one principal for each of the principal types in following sections using an array. Arrays can take one or more values. When you specify more than one principal in an element, you grant permissions to each principal. This is a logical OR and not a logical AND, because you authenticate as one principal at a time. If you include more than one value, use square brackets ([and]) and comma-delimit each entry for the array. The following example policy defines permissions for the 123456789012 account or the 555555555555 account.

```
"Principal" : {
  "AWS": [
    "123456789012",
    "555555555555"
  ]
}
```

Note

You cannot use a wildcard to match part of a principal name or ARN.

AWS account principals

You can specify AWS account identifiers in the `Principal` element of a resource-based policy or in condition keys that support principals. This delegates authority to the account. When you allow access to a different account, an administrator in that account must then grant access to an identity (IAM user or role) in that account. When you specify an AWS account, you can use the account ARN (`arn:aws:iam::account-ID:root`), or a shortened form that consists of the `"AWS":` prefix followed by the account ID.

For example, given an account ID of 123456789012, you can use either of the following methods to specify that account in the `Principal` element:

```
"Principal": { "AWS": "arn:aws:iam::123456789012:root" }
```

```
"Principal": { "AWS": "123456789012" }
```

The account ARN and the shortened account ID behave the same way. Both delegate permissions to the account. Using the account ARN in the `Principal` element does not limit permissions to only the root user of the account.

Note

When you save a resource-based policy that includes the shortened account ID, the service might convert it to the principal ARN. This does not change the functionality of the policy.

Some AWS services support additional options for specifying an account principal. For example, Amazon S3 lets you specify a [canonical user ID](#) using the following format:

```
"Principal": { "CanonicalUser":  
  "79a59df900b949e55d96a1e698fbacedfd6e09d98eacf8f8d5218e7cd47ef2be" }
```

You can also specify more than one AWS account, (or canonical user ID) as a principal using an array. For example, you can specify a principal in a bucket policy using all three methods.

```
"Principal": {  
  "AWS": [  
    "arn:aws:iam::123456789012:root",  
    "999999999999"  
  ],  
  "CanonicalUser": "79a59df900b949e55d96a1e698fbacedfd6e09d98eacf8f8d5218e7cd47ef2be"  
}
```

IAM role principals

You can specify IAM role principal ARNs in the `Principal` element of a resource-based policy or in condition keys that support principals. IAM roles are identities. In IAM, identities are resources to which you can assign permissions. Roles trust another authenticated identity to assume that role. This includes a principal in AWS or a user from an external identity provider (IdP). When a principal or identity assumes a role, they receive temporary security credentials with the assumed role's permissions. When they use those session credentials to perform operations in AWS, they become a *role session principal*.

IAM roles are identities that exist in IAM. Roles trust another authenticated identity, such as a principal in AWS or a user from an external identity provider. When a principal or identity assumes

a role, they receive temporary security credentials. They can then use those credentials as a role session principal to perform operations in AWS.

When you specify a role principal in a resource-based policy, the effective permissions for the principal are limited by any policy types that limit permissions for the role. This includes session policies and permissions boundaries. For more information about how the effective permissions for a role session are evaluated, see [Policy evaluation logic](#).

To specify the role ARN in the `Principal` element, use the following format:

```
"Principal": { "AWS": "arn:aws:iam::AWS-account-ID:role/role-name" }
```

Important

If your `Principal` element in a role trust policy contains an ARN that points to a specific IAM role, then that ARN transforms to the role unique principal ID when you save the policy. This helps mitigate the risk of someone escalating their privileges by removing and recreating the role. You don't normally see this ID in the console, because IAM uses a reverse transformation back to the role ARN when the trust policy is displayed. However, if you delete the role, then you break the relationship. The policy no longer applies, even if you recreate the role because the new role has a new principal ID that does not match the ID stored in the trust policy. When this happens, the principal ID appears in resource-based policies because AWS can no longer map it back to a valid ARN. The end result is that if you delete and recreate a role referenced in a trust policy's `Principal` element, you must edit the role in the policy to replace the principal ID with the correct ARN. The ARN once again transforms into the role's new principal ID when you save the policy.

Alternatively, you can specify the role principal as the principal in a resource-based policy or [create a broad-permission policy](#) that uses the `aws:PrincipalArn` condition key. When you use this key, the role session principal is granted the permissions based on the ARN of role that was assumed, and not the ARN of the resulting session. Because AWS does not convert condition key ARNs to IDs, permissions granted to the role ARN persist if you delete the role and then create a new role with the same name. Identity-based policy types, such as permissions boundaries or session policies, do not limit permissions granted using the `aws:PrincipalArn` condition key with a wildcard(*) in the `Principal` element, unless the identity-based policies contain an explicit deny.

Role session principals

You can specify role sessions in the `Principal` element of a resource-based policy or in condition keys that support principals. When a principal or identity assumes a role, they receive temporary security credentials with the assumed role's permissions. When they use those session credentials to perform operations in AWS, they become a *role session principal*.

The format that you use for a role session principal depends on the AWS STS operation that was used to assume the role.

Additionally, administrators can design a process to control how role sessions are issued. For example, they can provide a one-click solution for their users that creates a predictable session name. If your administrator does this, you can use role session principals in your policies or condition keys. Otherwise, you can specify the role ARN as a principal in the `aws:PrincipalArn` condition key. How you specify the role as a principal can change the effective permissions for the resulting session. For more information, see [IAM role principals](#).

Assumed-role session principals

An *assumed-role session principal* is a session principal that results from using the AWS STS `AssumeRole` operation. For more information about which principals can assume a role using this operation, see [Comparing the AWS STS API operations](#).

To specify the assumed-role session ARN in the `Principal` element, use the following format:

```
"Principal": { "AWS": "arn:aws:sts::AWS-account-ID:assumed-role/role-name/role-session-name" }
```

When you specify an assumed-role session in a `Principal` element, you cannot use a wildcard "*" to mean all sessions. Principals must always name a specific session.

Web identity session principals

A *web identity session principal* is a session principal that results from using the AWS STS `AssumeRoleWithWebIdentity` operation. You can use an external web identity provider (IdP) to sign in, and then assume an IAM role using this operation. This leverages identity federation and issues a role session. For more information about which principals can assume a role using this operation, see [Comparing the AWS STS API operations](#).

When you issue a role from a web identity provider, you get this special type of session principal that includes information about the web identity provider.

Use this principal type in your policy to allow or deny access based on the trusted web identity provider. To specify the web identity role session ARN in the `Principal` element of a role trust policy, use the following format:

```
"Principal": { "Federated": "cognito-identity.amazonaws.com" }
```

```
"Principal": { "Federated": "www.amazon.com" }
```

```
"Principal": { "Federated": "graph.facebook.com" }
```

```
"Principal": { "Federated": "accounts.google.com" }
```

SAML session principals

A *SAML session principal* is a session principal that results from using the AWS STS `AssumeRoleWithSAML` operation. You can use an external SAML identity provider (IdP) to sign in, and then assume an IAM role using this operation. This leverages identity federation and issues a role session. For more information about which principals can assume a role using this operation, see [Comparing the AWS STS API operations](#).

When you issue a role from a SAML identity provider, you get this special type of session principal that includes information about the SAML identity provider.

Use this principal type in your policy to allow or deny access based on the trusted SAML identity provider. To specify the SAML identity role session ARN in the `Principal` element of a role trust policy, use the following format:

```
"Principal": { "Federated": "arn:aws:iam::AWS-account-ID:saml-provider/provider-name" }
```

IAM user principals

You can specify IAM users in the `Principal` element of a resource-based policy or in condition keys that support principals.

Note

In a `Principal` element, the user name part of the [Amazon Resource Name \(ARN\)](#) is case sensitive.

```
"Principal": { "AWS": "arn:aws:iam::AWS-account-ID:user/user-name" }
```

```
"Principal": {  
  "AWS": [  
    "arn:aws:iam::AWS-account-ID:user/user-name-1",  
    "arn:aws:iam::AWS-account-ID:user/user-name-2"  
  ]  
}
```

When you specify users in a `Principal` element, you cannot use a wildcard (*) to mean "all users". Principals must always name specific users.

Important

If your `Principal` element in a role trust policy contains an ARN that points to a specific IAM user, then IAM transforms the ARN to the user's unique principal ID when you save the policy. This helps mitigate the risk of someone escalating their privileges by removing and recreating the user. You don't normally see this ID in the console, because there is also a reverse transformation back to the user's ARN when the trust policy is displayed. However, if you delete the user, then you break the relationship. The policy no longer applies, even if you recreate the user. That's because the new user has a new principal ID that does not match the ID stored in the trust policy. When this happens, the principal ID appears in resource-based policies because AWS can no longer map it back to a valid ARN. The result is that if you delete and recreate a user referenced in a trust policy `Principal` element, you must edit the role to replace the now incorrect principal ID with the correct ARN. IAM once again transforms ARN into the user's new principal ID when you save the policy.

IAM Identity Center principals

In IAM Identity Center, the principal in a resource-based policy must be defined as the AWS account principal. To specify access, reference the role ARN of the permission set in the condition block. For details, see [Referencing permission sets in resource policies, Amazon EKS, and AWS KMS](#) in the *IAM Identity Center User Guide*.

AWS STS federated user session principals

You can specify *federated user sessions* in the `Principal` element of a resource-based policy or in condition keys that support principals.

⚠ Important

AWS recommends that you use AWS STS federated user sessions only when necessary, such as when [root user access is required](#). Instead, [use roles to delegate permissions](#).

An *AWS STS federated user session principal* is a session principal that results from using the AWS STS `GetFederationToken` operation. In this case, AWS STS uses [identity federation](#) as the method to obtain temporary access tokens instead of using IAM roles.

In AWS, IAM users or an AWS account root user can authenticate using long-term access keys. For more information about which principals can federate using this operation, see [Comparing the AWS STS API operations](#).

- **IAM federated user** – An IAM user federates using the `GetFederationToken` operation that results in a federated user session principal for that IAM user.
- **Federated root user** – A root user federates using the `GetFederationToken` operation that results in a federated user session principal for that root user.

When an IAM user or root user requests temporary credentials from AWS STS using this operation, they begin a temporary federated user session. This session's ARN is based on the original identity that was federated.

To specify the federated user session ARN in the `Principal` element, use the following format:

```
"Principal": { "AWS": "arn:aws:sts::AWS-account-ID:federated-user/user-name" }
```

AWS service principals

You can specify AWS services in the `Principal` element of a resource-based policy or in condition keys that support principals. A *service principal* is an identifier for a service.

IAM roles that can be assumed by an AWS service are called [service roles](#). Service roles must include a trust policy. *Trust policies* are resource-based policies attached to a role that defines which principals can assume the role. Some service roles have predefined trust policies. However, in some cases, you must specify the service principal in the trust policy. The service principal in an IAM policy can't be `"Service": "*"` .

The identifier for a service principal includes the service name, and is usually in the following format:

service-name.amazonaws.com

The service principal is defined by the service. You can find the service principal for some services by opening [AWS services that work with IAM](#), checking whether the service has **Yes** in the **Service-linked role** column, and opening the **Yes** link to view the service-linked role documentation for that service. Find the **Service-Linked Role Permissions** section for that service to view the service principal.

The following example shows a policy that can be attached to a service role. The policy enables two services, Amazon ECS and Elastic Load Balancing, to assume the role. The services can then perform any tasks granted by the permissions policy assigned to the role (not shown). To specify multiple service principals, you do not specify two `Service` elements; you can have only one. Instead, you use an array of multiple service principals as the value of a single `Service` element.

```
"Principal": {
  "Service": [
    "ecs.amazonaws.com",
    "elasticloadbalancing.amazonaws.com"
  ]
}
```

AWS service principals in opt-in Regions

You can launch resources in several AWS Regions and some of those Regions you must opt in to. For a complete list of Regions you must opt in to, see [Managing AWS Regions](#) in the *AWS General Reference* guide.

When an AWS service in an opt-in Region makes a request within the same Region, the service principal name format is identified as the non-regionalized version of their service principal name:

service-name.amazonaws.com

When an AWS service in an opt-in Region makes a cross-region request to another Region, the service principal name format is identified as the regionalized version of their service principal name:

service-name.{*region*}.amazonaws.com

For example, you have an Amazon SNS topic located in Region `ap-southeast-1` and an Amazon S3 bucket located in opt-in Region `ap-east-1`. You want to configure S3 bucket notifications to publish messages to the SNS topic. To allow the S3 service to post messages to the SNS topic you must grant the S3 service principal `sns:Publish` permission via the resource-based access policy of the topic.

If you specify the non-regionalized version of the S3 service principal, `s3.amazonaws.com`, in the topic access policy, the `sns:Publish` request from the bucket to the topic will fail. The following example specifies the non-regionalized S3 service principal in the `Principal` policy element of the SNS topic access policy.

```
"Principal": { "Service": "s3.amazonaws.com" }
```

Since the bucket is located in an opt-in Region and the request is made outside of that same Region, the S3 service principal appears as the regionalized service principal name, `s3.ap-east-1.amazonaws.com`. You must use the regionalized service principal name when an AWS service in an opt-in Region makes a request to another Region. After you specify the regionalized service principal name, if the bucket makes an `sns:Publish` request to the SNS topic located in another Region, the request will be successful. The following example specifies the regionalized S3 service principal in the `Principal` policy element of the SNS topic access policy.

```
"Principal": { "Service": "s3.ap-east-1.amazonaws.com" }
```

Resource policies or service principal-based allow-lists for cross-Region requests from an opt-in Region to another Region will only be successful if you specify the regionalized service principal name.

Note

For IAM role trust policies, we recommend using the non-regionalized service principal name. IAM resources are global and therefore the same role can be used in any Region.

All principals

You can use a wildcard (*) to specify all principals in the `Principal` element of a resource-based policy or in condition keys that support principals. [Resource-based policies](#) grant permissions and [condition keys](#) are used to limit the conditions of a policy statement.

⚠ Important

We strongly recommend that you do not use a wildcard (*) in the `Principal` element of a resource-based policy with an `Allow` effect unless you intend to grant public or anonymous access. Otherwise, specify intended principals, services, or AWS accounts in the `Principal` element and then further restrict access in the `Condition` element. This is especially true for IAM role trust policies, because they allow other principals to become a principal in your account.

For resource-based policies, using a wildcard (*) with an `Allow` effect grants access to all users, including anonymous users (public access). For IAM users and role principals within your account, no other permissions are required. For principals in other accounts, they must also have identity-based permissions in their account that allow them to access your resource. This is called [cross-account access](#).

For anonymous users, the following elements are equivalent:

```
"Principal": "*"
```

```
"Principal" : { "AWS" : "*" }
```

You cannot use a wildcard to match part of a principal name or ARN.

The following example shows a resource-based policy that can be used instead of [Specifying NotPrincipal with Deny](#) to explicitly deny all principals *except* for the ones specified in the `Condition` element.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "UsePrincipalArnInsteadOfNotPrincipalWithDeny",
      "Effect": "Deny",
      "Action": "s3:*",
      "Principal": "*",
      "Resource": [
        "arn:aws:s3:::BUCKETNAME/*",
        "arn:aws:s3:::BUCKETNAME"
      ]
    }
  ]
}
```

```
    ],
    "Condition": {
      "ArnNotEquals": {
        "aws:PrincipalArn": "arn:aws:iam::444455556666:user/user-name"
      }
    }
  }
]
```

More information

- [Amazon SQS policy examples](#) in the *Amazon Simple Queue Service Developer Guide*
- [Key policies](#) in the *AWS Key Management Service Developer Guide*
- [Account identifiers](#) in the *AWS General Reference*
- [About web identity federation](#)

AWS JSON policy elements: NotPrincipal

You can use the `NotPrincipal` element to deny access to all principals *except* the IAM user, federated user, IAM role, AWS account, AWS service, or other principal specified in the `NotPrincipal` element.

You can use it in resource-based policies for some AWS services, including VPC endpoints. Resource-based policies are policies that you embed directly in a resource. You cannot use the `NotPrincipal` element in an IAM identity-based policy nor in an IAM role trust policy.

`NotPrincipal` must be used with `"Effect": "Deny"`. Using it with `"Effect": "Allow"` is not supported.

Important

Very few scenarios require the use of `NotPrincipal`. We recommend that you explore other authorization options before you decide to use `NotPrincipal`. When you use

`NotPrincipal`, troubleshooting the effects of multiple policy types can be difficult. We recommend using the `aws:PrincipalArn` context key with ARN condition operators instead. For more information, see [All principals](#).

Specifying `NotPrincipal` with Deny

When you use `NotPrincipal` with Deny, you must also specify the account ARN of the not-denied principal. Otherwise, the policy might deny access to the entire account containing the principal. Depending on the service that you include in your policy, AWS might validate the account first and then the user. If an assumed-role user (someone who is using a role) is being evaluated, AWS might validate the account first, then the role, and then the assumed-role user. The assumed-role user is identified by the role session name that is specified when they assumed the role. Therefore, we strongly recommend that you explicitly include the ARN for a user's account, or include both the ARN for a role and the ARN for the account containing that role.

Important

Don't use resource-based policy statements that include a `NotPrincipal` policy element with a Deny effect for IAM users or roles that have a permissions boundary policy attached. The `NotPrincipal` element with a Deny effect will always deny any IAM principal that has a permissions boundary policy attached, regardless of the values specified in the `NotPrincipal` element. This causes some IAM users or roles that would otherwise have access to the resource to lose access. We recommend changing your resource-based policy statements to use the condition operator [ArnNotEquals](#) with the [aws:PrincipalArn](#) context key to limit access instead of the `NotPrincipal` element. For information about permissions boundaries, see [Permissions boundaries for IAM entities](#).

Note

As a best practice, you should include the ARNs for the account in your policy. Some services require the account ARN, although this is not required in all cases. Any existing policies without the required ARN will continue to work, but new policies that include these services must meet this requirement. IAM does not track these services, and therefore recommends that you always include the account ARN.

The following examples show how to use `NotPrincipal` and `"Effect": "Deny"` in the same policy statement effectively.

Example Example IAM user in the same or a different account

In the following example, all principals *except* the user named Bob in AWS account 444455556666 are explicitly denied access to a resource. Note that as a best practice, the `NotPrincipal` element contains the ARN of both the user Bob and the AWS account that Bob belongs to (`arn:aws:iam::444455556666:root`). If the `NotPrincipal` element contained only Bob's ARN, the effect of the policy might be to explicitly deny access to the AWS account that contains the user Bob. In some cases, a user cannot have more permissions than its parent account, so if Bob's account is explicitly denied access then Bob might be unable to access the resource.

This example works as intended when it is part of a policy statement in a resource-based policy that is attached to a resource in either the same or a different AWS account (not 444455556666). This example by itself does not grant access to Bob, it only omits Bob from the list of principals that are explicitly denied. To allow Bob access to the resource, another policy statement must explicitly allow access using `"Effect": "Allow"`.

```
{
  "Version": "2012-10-17",
  "Statement": [{
    "Effect": "Deny",
    "NotPrincipal": {"AWS": [
      "arn:aws:iam::444455556666:user/Bob",
      "arn:aws:iam::444455556666:root"
    ]},
    "Action": "s3:*",
    "Resource": [
      "arn:aws:s3:::BUCKETNAME",
      "arn:aws:s3:::BUCKETNAME/*"
    ]
  }]
}
```

Example Example IAM role in the same or different account

In the following example, all principals *except* the assumed-role user named `cross-account-audit-app` in AWS account 444455556666 are explicitly denied access to a resource. As a best practice, the `NotPrincipal` element contains the ARN of the assumed-role user (`cross-account-audit-app`), the role (`cross-account-read-only-role`), and the AWS account that the role belongs to

(444455556666). If the `NotPrincipal` element was missing the ARN of the role, the effect of the policy might be to explicitly deny access to the role. Similarly, if the `NotPrincipal` element was missing the ARN of the AWS account that the role belongs to, the effect of the policy might be to explicitly deny access to the AWS account and all entities in that account. In some cases, assumed-role users cannot have more permissions than their parent role, and roles cannot have more permissions than their parent AWS account, so when the role or the account is explicitly denied access, the assumed role user might be unable to access the resource.

This example works as intended when it is part of a policy statement in a resource-based policy that is attached to a resource in a different AWS account (not 444455556666). This example by itself does not allow access to the assumed-role user `cross-account-audit-app`, it only omits `cross-account-audit-app` from the list of principals that are explicitly denied. To give `cross-account-audit-app` access to the resource, another policy statement must explicitly allow access using `"Effect": "Allow"`.

```
{
  "Version": "2012-10-17",
  "Statement": [{
    "Effect": "Deny",
    "NotPrincipal": {"AWS": [
      "arn:aws:sts::444455556666:assumed-role/cross-account-read-only-role/cross-account-audit-app",
      "arn:aws:iam::444455556666:role/cross-account-read-only-role",
      "arn:aws:iam::444455556666:root"
    ]},
    "Action": "s3:*",
    "Resource": [
      "arn:aws:s3:::Bucket_AccountAudit",
      "arn:aws:s3:::Bucket_AccountAudit/*"
    ]
  }]
}
```

When you specify an assumed-role session in a `NotPrincipal` element, you cannot use a wildcard (*) to mean "all sessions". Principals must always name a specific session.

IAM JSON policy elements: Action

The `Action` element describes the specific action or actions that will be allowed or denied. Statements must include either an `Action` or `NotAction` element. Each AWS service has its own

set of actions that describe tasks that you can perform with that service. For example, the list of actions for Amazon S3 can be found at [Specifying Permissions in a Policy](#) in the *Amazon Simple Storage Service User Guide*, the list of actions for Amazon EC2 can be found in the [Amazon EC2 API Reference](#), and the list of actions for AWS Identity and Access Management can be found in the [IAM API Reference](#). To find the list of actions for other services, consult the API reference [documentation](#) for the service.

You specify a value using a service namespace as an action prefix (`iam`, `ec2`, `sqs`, `sns`, `s3`, etc.) followed by the name of the action to allow or deny. The name must match an action that is supported by the service. The prefix and the action name are case insensitive. For example, `iam:ListAccessKeys` is the same as `IAM:listaccesskeys`. The following examples show Action elements for different services.

Amazon SQS action

```
"Action": "sqs:SendMessage"
```

Amazon EC2 action

```
"Action": "ec2:StartInstances"
```

IAM action

```
"Action": "iam:ChangePassword"
```

Amazon S3 action

```
"Action": "s3:GetObject"
```

You can specify multiple values for the Action element.

```
"Action": [ "sqs:SendMessage", "sqs:ReceiveMessage", "ec2:StartInstances",  
            "iam:ChangePassword", "s3:GetObject" ]
```

You can use a wildcard (*) to give access to all the actions the specific AWS product offers. For example, the following Action element applies to all S3 actions.

```
"Action": "s3:*"
```

You can also use wildcards (*) as part of the action name. For example, the following Action element applies to all IAM actions that include the string AccessKey, including CreateAccessKey, DeleteAccessKey, ListAccessKeys, and UpdateAccessKey.

```
"Action": "iam:*AccessKey*"
```

Some services let you limit the actions that are available. For example, Amazon SQS lets you make available just a subset of all the possible Amazon SQS actions. In that case, the * wildcard doesn't allow complete control of the queue; it allows only the subset of actions that you've shared. For more information, see [Understanding Permissions](#) in the *Amazon Simple Queue Service Developer Guide*.

IAM JSON policy elements: NotAction

NotAction is an advanced policy element that explicitly matches everything *except* the specified list of actions. Using NotAction can result in a shorter policy by listing only a few actions that should not match, rather than including a long list of actions that will match. Actions specified in NotAction are not impacted by the Allow or Deny effect in a policy statement. This, in turn, means that all of the applicable actions or services that are not listed are allowed if you use the Allow effect. In addition, such unlisted actions or services are denied if you use the Deny effect. When you use NotAction with the Resource element, you provide scope for the policy. This is how AWS determines which actions or services are applicable. For more information, see the following example policy.

NotAction with Allow

You can use the NotAction element in a statement with "Effect": "Allow" to provide access to all of the actions in an AWS service, except for the actions specified in NotAction. You can use it with the Resource element to provide scope for the policy, limiting the allowed actions to the actions that can be performed on the specified resource.

The following example allows users to access all of the Amazon S3 actions that can be performed on any S3 resource *except* for deleting a bucket. This does not allow users to use the ListAllMyBuckets S3 API operation, because that action requires the "*" resource. This policy also does not allow actions in other services, because other service actions are not applicable to the S3 resources.

```
"Effect": "Allow",  
"NotAction": "s3:DeleteBucket",
```

```
"Resource": "arn:aws:s3:::*",
```

Sometimes, you might want to allow access to a large number of actions. By using the `NotAction` element you effectively reverse the statement, resulting in a shorter list of actions. For example, because AWS has so many services, you might want to create a policy that allows the user to do everything except access IAM actions.

The following example allows users to access every action in every AWS service except for IAM.

```
"Effect": "Allow",  
"NotAction": "iam:*",  
"Resource": "*"
```

Be careful using the `NotAction` element and `"Effect": "Allow"` in the same statement or in a different statement within a policy. `NotAction` matches all services and actions that are not explicitly listed or applicable to the specified resource, and could result in granting users more permissions than you intended.

NotAction with Deny

You can use the `NotAction` element in a statement with `"Effect": "Deny"` to deny access to all of the listed resources except for the actions specified in the `NotAction` element. This combination does not allow the listed items, but instead explicitly denies the actions not listed. You must still allow actions that you want to allow.

The following conditional example denies access to non-IAM actions if the user is not signed in using MFA. If the user is signed in with MFA, then the `"Condition"` test fails and the final `"Deny"` statement has no effect. Note, however, that this would not grant the user access to any actions; it would only explicitly deny all other actions except IAM actions.

```
{  
  "Version": "2012-10-17",  
  "Statement": [{  
    "Sid": "DenyAllUsersNotUsingMFA",  
    "Effect": "Deny",  
    "NotAction": "iam:*",  
    "Resource": "*",  
    "Condition": {"BoolIfExists": {"aws:MultiFactorAuthPresent": "false"}}  
  ]  
}
```

For an example policy that denies access to actions outside of specific Regions, except for actions from specific services, see [AWS: Denies access to AWS based on the requested Region](#).

IAM JSON policy elements: Resource

The `Resource` element specifies the object or objects that the statement covers. Statements must include either a `Resource` or a `NotResource` element. You specify a resource using an ARN. For more information about the format of ARNs, see [IAM ARNs](#).

Each service has its own set of resources. Although you always use an ARN to specify a resource, the details of the ARN for a resource depend on the service and the resource. For information about how to specify a resource, refer to the documentation for the service you want to write a statement.

Note

Some services do not let you specify actions for individual resources; instead, any actions that you list in the `Action` or `NotAction` element apply to all resources in that service. In these cases, you use the wildcard `*` in the `Resource` element.

The following example refers to a specific Amazon SQS queue.

```
"Resource": "arn:aws:sqs:us-east-2:account-ID-without-hyphens:queue1"
```

The following example refers to the IAM user named Bob in an AWS account.

Note

In the `Resource` element, the IAM user name is case sensitive.

```
"Resource": "arn:aws:iam::account-ID-without-hyphens:user/Bob"
```

Using wildcards in resource ARNs

You can use wildcards as part of the resource ARN. You can use wildcard characters (`*` and `?`) within ARN segments (the parts separated by colons) to represent any combination of characters with an asterisk (`*`) and any single character with a question mark (`?`). You can use multiple `*` or `?`

characters in each segment. If the wildcard (*) is the last character of a resource ARN segment, it can expand to match beyond colon boundaries. We recommend you use wildcards (* and ?) within ARN segments separated by a colon.

Note

You can't use a wildcard in the service segment that identifies the AWS product. For more information about ARN segments, see [Amazon Resource Names \(ARNs\)](#)

The following example refers to all IAM users whose path is /accounting.

```
"Resource": "arn:aws:iam::account-ID-without-hyphens:user/accounting/*"
```

The following example refers to all items within a specific Amazon S3 bucket.

```
"Resource": "arn:aws:s3:::DOC-EXAMPLE-BUCKET/*"
```

The asterisk (*) character can expand to replace everything within a segment, including characters like a forward slash (/) that may otherwise appear to be a delimiter within a given service namespace. For example, consider the following Amazon S3 ARN as the same wildcard expansion logic applies to all services.

```
"Resource": "arn:aws:s3:::DOC-EXAMPLE-BUCKET/*/test/*"
```

The wildcards in the ARN apply to all of the following objects in the bucket, not only the first object listed.

```
DOC-EXAMPLE-BUCKET/1/test/object.jpg  
DOC-EXAMPLE-BUCKET/1/2/test/object.jpg  
DOC-EXAMPLE-BUCKET/1/2/test/3/object.jpg  
DOC-EXAMPLE-BUCKET/1/2/3/test/4/object.jpg  
DOC-EXAMPLE-BUCKET/1///test///object.jpg  
DOC-EXAMPLE-BUCKET/1/test/.jpg  
DOC-EXAMPLE-BUCKET//test/object.jpg  
DOC-EXAMPLE-BUCKET/1/test/
```

Consider the last two objects in the previous list. An Amazon S3 object name can validly begin or end with the conventional delimiter forward slash (/) character. While "/" works as a delimiter,

there is no specific significance when this character is used within a resource ARN. It is treated the same as any other valid character. The ARN would not match the following objects:

```
DOC-EXAMPLE-BUCKET/1-test/object.jpg  
DOC-EXAMPLE-BUCKET/test/object.jpg  
DOC-EXAMPLE-BUCKET/1/2/test.jpg
```

Specifying multiple resources

You can specify multiple resources. The following example refers to two DynamoDB tables.

```
"Resource": [  
  "arn:aws:dynamodb:us-east-2:account-ID-without-hyphens:table/books_table",  
  "arn:aws:dynamodb:us-east-2:account-ID-without-hyphens:table/magazines_table"  
]
```

Using policy variables in resource ARNs

In the Resource element, you can use JSON [policy variables](#) in the part of the ARN that identifies the specific resource (that is, in the trailing part of the ARN). For example, you can use the key `{aws:username}` as part of a resource ARN to indicate that the current user's name should be included as part of the resource's name. The following example shows how you can use the `{aws:username}` key in a Resource element. The policy allows access to a Amazon DynamoDB table that matches the current user's name.

```
{  
  "Version": "2012-10-17",  
  "Statement": {  
    "Effect": "Allow",  
    "Action": "dynamodb:*",  
    "Resource": "arn:aws:dynamodb:us-east-2:account-id:table/${aws:username}"  
  }  
}
```

For more information about JSON policy variables, see [IAM policy elements: Variables and tags](#).

IAM JSON policy elements: NotResource

NotResource is an advanced policy element that explicitly matches every resource except those specified. Using NotResource can result in a shorter policy by listing only a few resources that

should not match, rather than including a long list of resources that will match. This is particularly useful for policies that apply within a single AWS service.

For example, imagine you have a group named `HRPayroll`. Members of `HRPayroll` should not be allowed to access any Amazon S3 resources except the `Payroll` folder in the `HRBucket` bucket. The following policy explicitly denies access to all Amazon S3 resources other than the listed resources. Note, however, that this policy does not grant the user access to any resources.

```
{
  "Version": "2012-10-17",
  "Statement": {
    "Effect": "Deny",
    "Action": "s3:*",
    "NotResource": [
      "arn:aws:s3:::HRBucket/Payroll",
      "arn:aws:s3:::HRBucket/Payroll/*"
    ]
  }
}
```

Normally, to explicitly deny access to a resource you would write a policy that uses `"Effect": "Deny"` and that includes a `Resource` element that lists each folder individually. However, in that case, each time you add a folder to `HRBucket`, or add a resource to Amazon S3 that should not be accessed, you must add its name to the list in `Resource`. If you use a `NotResource` element instead, users are automatically denied access to new folders unless you add the folder names to the `NotResource` element.

When using `NotResource`, you should keep in mind that resources specified in this element are the *only* resources that are not limited. This, in turn, limits all of the resources that would apply to the action. In the example above, the policy affects only Amazon S3 actions, and therefore only Amazon S3 resources. If the action also included Amazon EC2 actions, then the policy would not deny access to any EC2 resources. To learn which actions in a service allow specifying the ARN of a resource, see [Actions, Resources, and Condition Keys for AWS Services](#).

NotResource with other elements

You should **never** use the `"Effect": "Allow"`, `"Action": "*"` , and `"NotResource": "arn:aws:s3:::HRBucket"` elements together. This statement is very dangerous, because it allows all actions in AWS on all resources except the `HRBucket` S3 bucket. This would even allow the user to add a policy to themselves that allows them to access `HRBucket`. Do not do this.

Be careful using the `NotResource` element and `"Effect": "Allow"` in the same statement or in a different statement within a policy. `NotResource` allows all services and resources that are not explicitly listed, and could result in granting users more permissions than you intended. Using the `NotResource` element and `"Effect": "Deny"` in the same statement denies services and resources that are not explicitly listed.

IAM JSON policy elements: Condition

The `Condition` element (or `Condition block`) lets you specify conditions for when a policy is in effect. The `Condition` element is optional. In the `Condition` element, you build expressions in which you use [condition operators](#) (equal, less than, and others) to match the context keys and values in the policy against keys and values in the request context. To learn more about the request context, see [Request](#).

```
"Condition" : { "{condition-operator}" : { "{condition-key}" : "{condition-value}" }}
```

The context key that you specify in a policy condition can be a [global condition context key](#) or a service-specific context key. Global condition context keys have the `aws:` prefix. Service-specific context keys have the service's prefix. For example, Amazon EC2 lets you write a condition using the `ec2:InstanceType` context key, which is unique to that service. To view service-specific IAM context keys with the `iam:` prefix, see [IAM and AWS STS condition context keys](#).

Context key *names* are not case-sensitive. For example, including the `aws:SourceIP` context key is equivalent to testing for `AWS:SourceIp`. Case-sensitivity of context key *values* depends on the [condition operator](#) that you use. For example, the following condition includes the `StringEquals` operator to make sure that only requests made by `johndoe` match. Users named `JohnDoe` are denied access.

```
"Condition" : { "StringEquals" : { "aws:username" : "johndoe" } }
```

The following condition uses the [StringEqualsIgnoreCase](#) operator to match users named `johndoe` or `JohnDoe`.

```
"Condition" : { "StringEqualsIgnoreCase" : { "aws:username" : "johndoe" } }
```

Some context keys support key-value pairs that allow you to specify part of the key name. Examples include the [aws:RequestTag/tag-key](#) context key, the AWS KMS

[kms:EncryptionContext:encryption_context_key](#), and the [ResourceTag/tag-key](#) context key supported by multiple services.

- If you use the [ResourceTag/tag-key](#) context key for a service such as [Amazon EC2](#), then you must specify a key name for the tag-key.
- **Key names are not case-sensitive.** This means that if you specify "aws:ResourceTag/TagKey1": "Value1" in the condition element of your policy, then the condition matches a resource tag key named either TagKey1 or tagkey1, but not both.
- AWS services that support these attributes might allow you to create multiple key names that differ only by case. For example, you might tag an Amazon EC2 instance with ec2=test1 and EC2=test2. When you use a condition such as "aws:ResourceTag/EC2": "test1" to allow access to that resource, the key name matches both tags, but only one value matches. This can result in unexpected condition failures.

Important

As a best practice, make sure that members of your account follow a consistent naming convention when naming key-value pair attributes. Examples include tags or AWS KMS encryption contexts. You can enforce this using the [aws:TagKeys](#) context key for tagging, or the [kms:EncryptionContextKeys](#) for the AWS KMS encryption context.

- For a list of all of the condition operators and a description of how they work, see [Condition operators](#).
- Unless otherwise specified, all context keys can have multiple values. For a description of how to handle context keys that have multiple values, see [Multivalued context keys](#).
- For a list of all of the globally available context keys, see [AWS global condition context keys](#).
- For condition context keys that are defined by each service, see [Actions, Resources, and Condition Keys for AWS Services](#).

The request context

When a [principal](#) makes a [request](#) to AWS, AWS gathers the request information into a request context. The information is used to evaluate and authorize the request. You can use the `Condition` element of a JSON policy to test specific context keys against the request context.

For example, you can create a policy that uses the [aws:CurrentTime](#) context key to [allow a user to perform actions within only a specific range of dates](#).

When a request is submitted, AWS evaluates each context key in the policy and returns a value of *true*, *false*, *not present*, and occasionally *null* (an empty data string). A context key that is not present in the request is considered a mismatch. For example, the following policy allows removing your own multi-factor authentication (MFA) device, but only if you have signed in using MFA in the last hour (3,600 seconds).

```
{
  "Version": "2012-10-17",
  "Statement": {
    "Sid": "AllowRemoveMfaOnlyIfRecentMfa",
    "Effect": "Allow",
    "Action": [
      "iam:DeactivateMFADevice"
    ],
    "Resource": "arn:aws:iam::*:user/${aws:username}",
    "Condition": {
      "NumericLessThanEquals": {"aws:MultiFactorAuthAge": "3600"}
    }
  }
}
```

The request context can return the following values:

- **True** – If the requester signed in using MFA in the last one hour or less, then the condition returns *true*.
- **False** – If the requester signed in using MFA more than one hour ago, then the condition returns *false*.
- **Not present** – If the requester made a request using their IAM user access keys in the AWS CLI or AWS API, the key is not present. In this case, the key is not present, and it won't match.
- **Null** – For context keys that are defined by the user, such as passing tags in a request, it is possible to include an empty string. In this case, the value in the request context is *null*. A null value might return true in some cases. For example, if you use the multivalued [ForAllValues](#) condition operator with the [aws:TagKeys](#) context key, you can experience unexpected results if the request context returns *null*. For more information, see [aws:TagKeys](#) and [Multivalued context keys](#).

The condition block

The following example shows the basic format of a Condition element:

```
"Condition": {"StringLike": {"s3:prefix": ["janedoe/*"]}}
```

A value from the request is represented by a context key, in this case `s3:prefix`. The context key value is compared to a value that you specify as a literal value, such as `janedoe/*`. The type of comparison to make is specified by the [condition operator](#) (here, `StringLike`). You can create conditions that compare strings, dates, numbers, and more using typical Boolean comparisons such as equals, greater than, and less than. When you use [string operators](#) or [ARN operators](#), you can also use a [policy variable](#) in the context key value. The following example includes the `aws:username` variable.

```
"Condition": {"StringLike": {"s3:prefix": ["${aws:username}/*"]}}
```

Under some circumstances, context keys can contain multiple values. For example, a request to Amazon DynamoDB might ask to return or update multiple attributes from a table. A policy for access to DynamoDB tables can include the `dynamodb:Attributes` context key, which contains all the attributes listed in the request. You can test the multiple attributes in the request against a list of allowed attributes in a policy by using set operators in the Condition element. For more information, see [Multivalued context keys](#).

When the policy is evaluated during a request, AWS replaces the key with the corresponding value from the request. (In this example, AWS would use the date and time of the request.) The condition is evaluated to return true or false, which is then factored into whether the policy as a whole allows or denies the request.

Multiple values in a condition

A Condition element can contain multiple condition operators, and each condition operator can contain multiple context key-value pairs. The following figure illustrates this.

For more information, see [Multivalued context keys](#).

IAM JSON policy elements: Condition operators

Use condition operators in the `Condition` element to match the condition key and value in the policy against values in the request context. For more information about the `Condition` element, see [IAM JSON policy elements: Condition](#).

The condition operator that you can use in a policy depends on the condition key you choose. You can choose a global condition key or a service-specific condition key. To learn which condition operator you can use for a global condition key, see [AWS global condition context keys](#). To learn which condition operator you can use for a service-specific condition key, see [Actions, Resources, and Condition Keys for AWS Services](#) and choose the service that you want to view.

Important

If the key that you specify in a policy condition is not present in the request context, the values do not match and the condition is *false*. If the policy condition requires that the key is *not* matched, such as `StringNotLike` or `ArnNotLike`, and the right key is not present, the condition is *true*. This logic applies to all condition operators except [...IfExists](#) and [Null check](#). These operators test whether the key is present (exists) in the request context.

The condition operators can be grouped into the following categories:

- [String](#)
- [Numeric](#)

- [Date and time](#)
- [Boolean](#)
- [Binary](#)
- [IP address](#)
- [Amazon Resource Name \(ARN\)](#) (available for only some services.)
- [...IfExists](#) (checks if the key value exists as part of another check)
- [Null check](#) (checks if the key value exists as a standalone check)

String condition operators

String condition operators let you construct `Condition` elements that restrict access based on comparing a key to a string value.

Condition operator	Description
<code>StringEquals</code>	Exact matching, case sensitive
<code>StringNotEquals</code>	Negated matching
<code>StringEqualsIgnoreCase</code>	Exact matching, ignoring case
<code>StringNotEqualsIgnoreCase</code>	Negated matching, ignoring case
<code>StringLike</code>	Case-sensitive matching. The values can include multi-character match wildcards (*) and single-character match wildcards (?) anywhere in the string. You must specify wildcards to achieve partial string matches.

Note

If a key contains multiple values, `StringLike` can be qualified with set operators—`ForAllValues:StringLike` and `ForAnyValue:StringLike`. For more information, see [Multivalued context keys](#).

Condition operator	Description
StringNotLike	Negated case-sensitive matching. The values can include multi-character match wildcards (*) or single-character match wildcards (?) anywhere in the string.

For example, the following statement contains a `Condition` element that uses [aws:PrincipalTag](#) key to specify that the principal making the request must be tagged with the `iamuser-admin` job category.

```
{
  "Version": "2012-10-17",
  "Statement": {
    "Effect": "Allow",
    "Action": "iam:*AccessKey*",
    "Resource": "arn:aws:iam::account-id:user/*",
    "Condition": {"StringEquals": {"aws:PrincipalTag/job-category": "iamuser-admin"}}
  }
}
```

If the key that you specify in a policy condition is not present in the request context, the values do not match. In this example, the `aws:PrincipalTag/job-category` key is present in the request context if the principal is using an IAM user with attached tags. It is also included for a principal using an IAM role with attached tags or session tags. If a user without the tag attempts to view or edit an access key, the condition returns `false` and the request is implicitly denied by this statement.

You can use a [policy variable](#) with the `String` condition operator.

The following example uses the `StringLike` condition operator to perform string matching with a [policy variable](#) to create a policy that lets an IAM user use the Amazon S3 console to manage his or her own "home directory" in an Amazon S3 bucket. The policy allows the specified actions on an S3 bucket as long as the `s3:prefix` matches any one of the specified patterns.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
```

```

    "Action": [
      "s3:ListAllMyBuckets",
      "s3:GetBucketLocation"
    ],
    "Resource": "arn:aws:s3:::*"
  },
  {
    "Effect": "Allow",
    "Action": "s3:ListBucket",
    "Resource": "arn:aws:s3:::BUCKET-NAME",
    "Condition": {"StringLike": {"s3:prefix": [
      "",
      "home/",
      "home/${aws:username}/"
    ]}}
  },
  {
    "Effect": "Allow",
    "Action": "s3:*",
    "Resource": [
      "arn:aws:s3:::BUCKET-NAME/home/${aws:username}",
      "arn:aws:s3:::BUCKET-NAME/home/${aws:username}/*"
    ]
  }
]
}

```

For an example of a policy that shows how to use the `Condition` element to restrict access to resources based on an application ID and a user ID for web identity federation, see [Amazon S3: Allows Amazon Cognito users to access objects in their bucket](#).

Wildcard matching

String condition operators perform a patternless matching that does not enforce a predefined format. ARN and Date condition operators are a subset of string operators that enforce a structure on the condition key value. When you use `StringLike` or `StringNotLike` operators for partial string matches of an ARN or date, the matching ignores which portion of the structure is wildcarded.

For example, the following conditions search for a partial match of an ARN using different condition operators.

When ArnLike is used, the partition, service, account-id, resource-type, and partial resource-id portions of the ARN must have exact matching to the ARN in the request context. Only the region and resource path allow partial matching.

```
"Condition": {"ArnLike": {"aws:SourceArn": "arn:aws:cloudtrail:*:111122223333:trail/*"}}
```

When StringLike is used instead of ArnLike, matching ignores the ARN structure and allows partial matching, regardless of the portion that was wildcarded.

```
"Condition": {"StringLike": {"aws:SourceArn": "arn:aws:cloudtrail:*:111122223333:trail/*"}}
```

ARN	ArnLike	StringLike
arn:aws:cloudtrail:us-west-2:111122223333:trail/finance	Match	Match
arn:aws:cloudtrail:us-east-2:111122223333:trail/finance/archive	Match	Match
arn:aws:cloudtrail:us-east-2:444455556666:user/111122223333:trail/finance	No match	Match

Numeric condition operators

Numeric condition operators let you construct Condition elements that restrict access based on comparing a key to an integer or decimal value.

Condition operator	Description
NumericEquals	Matching

Condition operator	Description
NumericNotEquals	Negated matching
NumericLessThan	"Less than" matching
NumericLessThanEquals	"Less than or equals" matching
NumericGreaterThan	"Greater than" matching
NumericGreaterThanEquals	"Greater than or equals" matching

For example, the following statement contains a `Condition` element that uses the `NumericLessThanEquals` condition operator with the `s3:max-keys` key to specify that the requester can list *up to* 10 objects in `example_bucket` at a time.

```
{
  "Version": "2012-10-17",
  "Statement": {
    "Effect": "Allow",
    "Action": "s3:ListBucket",
    "Resource": "arn:aws:s3:::example_bucket",
    "Condition": {"NumericLessThanEquals": {"s3:max-keys": "10"}}
  }
}
```

If the key that you specify in a policy condition is not present in the request context, the values do not match. In this example, the `s3:max-keys` key is always present in the request when you perform the `ListBucket` operation. If this policy allowed all Amazon S3 operations, then only the operations that include the `max-keys` context key with a value of less than or equal to 10 would be allowed.

You can not use a [policy variable](#) with the `Numeric` condition operator.

Date condition operators

Date condition operators let you construct `Condition` elements that restrict access based on comparing a key to a date/time value. You use these condition operators with [aws:CurrentTime](#)

key or [aws:EpochTime](#) key. You must specify date/time values with one of the [W3C implementations of the ISO 8601 date formats](#) or in epoch (UNIX) time.

Note

Wildcards are not permitted for date condition operators.

Condition operator	Description
DateEquals	Matching a specific date
DateNotEquals	Negated matching
DateLessThan	Matching before a specific date and time
DateLessThanEquals	Matching at or before a specific date and time
DateGreaterThan	Matching after a specific a date and time
DateGreaterThanEquals	Matching at or after a specific date and time

For example, the following statement contains a Condition element that uses the DateGreaterThan condition operator with the [aws:TokenIssueTime](#) key. This condition specifies that the temporary security credentials used to make the request were issued in 2020. This policy can be updated programmatically every day to ensure that account members use fresh credentials.

```
{
  "Version": "2012-10-17",
  "Statement": {
    "Effect": "Allow",
    "Action": "iam:*AccessKey*",
    "Resource": "arn:aws:iam::account-id:user/*",
    "Condition": {"DateGreaterThan": {"aws:TokenIssueTime": "2020-01-01T00:00:01Z"}}
  }
}
```

If the key that you specify in a policy condition is not present in the request context, the values do not match. The `aws:TokenIssueTime` key is present in the request context only when the principal uses temporary credentials to make the request. The key is not present in AWS CLI, AWS API, or AWS SDK requests that are made using access keys. In this example, if an IAM user attempts to view or edit an access key, the request is denied.

You can not use a [policy variable](#) with the Date condition operator.

Boolean condition operators

Boolean conditions let you construct `Condition` elements that restrict access based on comparing a key to "true" or "false."

Condition operator	Description
Bool	Boolean matching

For example, this identity-based policy uses the `Bool` condition operator with the [aws:SecureTransport](#) key to denies replicating objects and object tags to the destination bucket and its contents if the request is not over SSL.

Important

This policy does not allow any actions. Use this policy in combination with other policies that allow specific actions.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "BooleanExample",
      "Action": "s3:ReplicateObject",
      "Effect": "Deny",
      "Resource": [
        "arn:aws:s3:::DOC-EXAMPLE-BUCKET",
        "arn:aws:s3:::DOC-EXAMPLE-BUCKET/*"
      ],
      "Condition": {
```

```
    "Bool": {
      "aws:SecureTransport": "false"
    }
  }
}
]
```

If the key that you specify in a policy condition is not present in the request context, the values do not match. The `aws:SecureTransport` request context returns true or false.

You can use a [policy variable](#) with the Boolean condition operator.

Binary condition operators

The `BinaryEquals` condition operator let you construct `Condition` elements that test key values that are in binary format. It compares the value of the specified key byte for byte against a [base-64](#) encoded representation of the binary value in the policy.

```
"Condition" : {
  "BinaryEquals": {
    "key" : "Qm1uYXJ5VmFsdWVJbkJhc2U2NA=="
  }
}
```

If the key that you specify in a policy condition is not present in the request context, the values do not match.

You can not use a [policy variable](#) with the Binary condition operator.

IP address condition operators

IP address condition operators let you construct `Condition` elements that restrict access based on comparing a key to an IPv4 or IPv6 address or range of IP addresses. You use these with the [aws:SourceIp](#) key. The value must be in the standard CIDR format (for example, `203.0.113.0/24` or `2001:DB8:1234:5678::/64`). If you specify an IP address without the associated routing prefix, IAM uses the default prefix value of `/32`.

Some AWS services support IPv6, using `::` to represent a range of 0s. To learn whether a service supports IPv6, see the documentation for that service.

Condition operator	Description
IpAddress	The specified IP address or range
NotIpAddress	All IP addresses except the specified IP address or range

For example, the following statement uses the `IpAddress` condition operator with the `aws:SourceIp` key to specify that the request must come from the IP range 203.0.113.0 to 203.0.113.255.

```
{
  "Version": "2012-10-17",
  "Statement": {
    "Effect": "Allow",
    "Action": "iam:*AccessKey*",
    "Resource": "arn:aws:iam::account-id:user/*",
    "Condition": {"IpAddress": {"aws:SourceIp": "203.0.113.0/24"}}
  }
}
```

The `aws:SourceIp` condition key resolves to the IP address that the request originates from. If the requests originates from an Amazon EC2 instance, `aws:SourceIp` evaluates to the instance's public IP address.

If the key that you specify in a policy condition is not present in the request context, the values do not match. The `aws:SourceIp` key is always present in the request context, except when the requester uses a VPC endpoint to make the request. In this case, the condition returns `false` and the request is implicitly denied by this statement.

You can not use a [policy variable](#) with the `IpAddress` condition operator.

The following example shows how to mix IPv4 and IPv6 addresses to cover all of your organization's valid IP addresses. We recommend that you update your organization's policies with your IPv6 address ranges in addition to IPv4 ranges you already have to ensure the policies continue to work as you make the transition to IPv6.

```
{
  "Version": "2012-10-17",
  "Statement": {
```

```

"Effect": "Allow",
"Action": "someservice:*",
"Resource": "*",
"Condition": {
  "IpAddress": {
    "aws:SourceIp": [
      "203.0.113.0/24",
      "2001:DB8:1234:5678::/64"
    ]
  }
}
}
}
}

```

The `aws:SourceIp` condition key works only in a JSON policy if you are calling the tested API directly as a user. If you instead use a service to call the target service on your behalf, the target service sees the IP address of the calling service rather than the IP address of the originating user. This can happen, for example, if you use AWS CloudFormation to call Amazon EC2 to construct instances for you. There is currently no way to pass the originating IP address through a calling service to the target service for evaluation in a JSON policy. For these types of service API calls, do not use the `aws:SourceIp` condition key.

Amazon Resource Name (ARN) condition operators

Amazon Resource Name (ARN) condition operators let you construct `Condition` elements that restrict access based on comparing a key to an ARN. The ARN is considered a string.

Condition operator	Description
<code>ArnEquals</code> , <code>ArnLike</code>	Case-sensitive matching of the ARN. Each of the six colon-delimited components of the ARN is checked separately and each can include multi-character match wildcards (*) or single-character match wildcards (?). The <code>ArnEquals</code> and <code>ArnLike</code> condition operators behave identically.
<code>ArnNotEquals</code> , <code>ArnNotLike</code>	Negated matching for ARN. The <code>ArnNotEquals</code> and <code>ArnNotLike</code> condition operators behave identically.

You can use a [policy variable](#) with the ARN condition operator.

The following resource-based policy example shows a policy attached to an Amazon SQS queue to which you want to send SNS messages. It gives Amazon SNS permission to send messages to the queue (or queues) of your choice, but only if the service is sending the messages on behalf of a particular Amazon SNS topic (or topics). You specify the queue in the `Resource` field, and the Amazon SNS topic as the value for the `SourceArn` key.

```
{
  "Version": "2012-10-17",
  "Statement": {
    "Effect": "Allow",
    "Principal": {"AWS": "123456789012"},
    "Action": "SQS:SendMessage",
    "Resource": "arn:aws:sqs:REGION:123456789012:QUEUE-ID",
    "Condition": {"ArnEquals": {"aws:SourceArn":
"arn:aws:sns:REGION:123456789012:TOPIC-ID"}}
  }
}
```

If the key that you specify in a policy condition is not present in the request context, the values do not match. The [aws:SourceArn](#) key is present in the request context only if a resource triggers a service to call another service on behalf of the resource owner. If an IAM user attempts to perform this operation directly, the condition returns `false` and the request is implicitly denied by this statement.

...IfExists condition operators

You can add `IfExists` to the end of any condition operator name except the `Null` condition—for example, `StringLikeIfExists`. You do this to say "If the policy key is present in the context of the request, process the key as specified in the policy. If the key is not present, evaluate the condition element as true." Other condition elements in the statement can still result in a nonmatch, but not a missing key when checked with `...IfExists`. If you are using an `"Effect": "Deny"` element with a negated condition operator like `StringNotEqualsIfExists`, the request is still denied even if the tag is missing.

Example using IfExists

Many condition keys describe information about a certain type of resource and only exist when accessing that type of resource. These condition keys are not present on other types of resources. This doesn't cause an issue when the policy statement applies to only one type of resource. However, there are cases where a single statement can apply to multiple types of resources, such as

when the policy statement references actions from multiple services or when a given action within a service accesses several different resource types within the same service. In such cases, including a condition key that applies to only one of the resources in the policy statement can cause the Condition element in the policy statement to fail such that the statement's "Effect" does not apply.

For example, consider the following policy example:

```
{
  "Version": "2012-10-17",
  "Statement": {
    "Sid": "THISPOLICYDOESNOTWORK",
    "Effect": "Allow",
    "Action": "ec2:RunInstances",
    "Resource": "*",
    "Condition": {"StringLike": {"ec2:InstanceType": [
      "t1.*",
      "t2.*",
      "m3.*"
    ]}}
  }
}
```

The *intent* of the preceding policy is to enable the user to launch any instance that is type t1, t2 or m3. However, launching an instance requires accessing many resources in addition to the instance itself; for example, images, key pairs, security groups, and more. The entire statement is evaluated against every resource that is required to launch the instance. These additional resources do not have the `ec2:InstanceType` condition key, so the `StringLike` check fails, and the user is not granted the ability to launch *any* instance type.

To address this, use the `StringLikeIfExists` condition operator instead. This way, the test only happens if the condition key exists. You could read the following policy as: "If the resource being checked has an `ec2:InstanceType` condition key, then allow the action only if the key value begins with t1., t2., or m3.. If the resource being checked does not have that condition key, then don't worry about it." The asterisk (*) in the condition key values, when used with the `StringLikeIfExists` condition operator, is interpreted as a wildcard to achieve partial string matches. The `DescribeActions` statement includes the actions required to view the instance in the console.

```
{
```

```
"Version": "2012-10-17",
"Statement": [
  {
    "Sid": "RunInstance",
    "Effect": "Allow",
    "Action": "ec2:RunInstances",
    "Resource": "*",
    "Condition": {
      "StringLikeIfExists": {
        "ec2:InstanceType": [
          "t1.*",

    "Resource": "*"
  }
]
```

Condition operator to check existence of condition keys

Use a `Null` condition operator to check if a condition key is absent at the time of authorization. In the policy statement, use either `true` (the key doesn't exist — it is null) or `false` (the key exists and its value is not null).

You can not use a [policy variable](#) with the `Null` condition operator.

For example, you can use this condition operator to determine whether a user is using their own credentials for the operation or temporary credentials. If the user is using temporary credentials, then the key `aws:TokenIssueTime` exists and has a value. The following example shows a condition that states that the user must not be using temporary credentials (the key must not exist) for the user to use the Amazon EC2 API.

```
{
  "Version": "2012-10-17",
  "Statement":{
    "Action":"ec2:*",
    "Effect":"Allow",
    "Resource":"*",
    "Condition":{"Null":{"aws:TokenIssueTime":"true"}}
  }
}
```

Conditions with multiple context keys or values

You can use the `Condition` element of a policy to test multiple context keys or multiple values for a single context key in a request. When you make a request to AWS, either programmatically or through the AWS Management Console, your request includes information about your principal, operation, tags, and more. You can use context keys to test the values of the matching context keys in the request, with the context keys specified in the policy condition. To learn about information and data included in a request, see [The request context](#).

Topics

- [Evaluation logic for multiple context keys or values](#)
- [Evaluation logic for negated matching condition operators](#)

Evaluation logic for multiple context keys or values

A `Condition` element can contain multiple condition operators, and each condition operator can contain multiple context key-value pairs. Most context keys support using multiple values, unless otherwise specified.

- If your policy statement has multiple [condition operators](#), the condition operators are evaluated using a logical AND.
- If your policy statement has multiple context keys attached to a single condition operator, the context keys are evaluated using a logical AND.
- If a single condition operator includes multiple values for a context key, those values are evaluated using a logical OR.
- If a single negated matching condition operator includes multiple values for a context key, those values are evaluated using a logical NOR.

All context keys in a condition element block must resolve to true to invoke the desired Allow or Deny effect. The following figure illustrates the evaluation logic for a condition with multiple condition operators and context key-value pairs.

For example, the following S3 bucket policy illustrates how the previous figure is represented in a policy. The condition block includes condition operators `StringEquals` and `ArnLike`, and context keys `aws:PrincipalTag` and `aws:PrincipalArn`. To invoke the desired Allow or Deny effect, all context keys in the condition block must resolve to true. The user making the request must have both principal tag keys, *department* and *role*, that include one of the tag key values specified in the policy. Also, the principal ARN of the user making the request must match one of the `aws:PrincipalArn` values specified in the policy to be evaluated as true.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "ExamplePolicy",
      "Effect": "Allow",
      "Principal": {
        "AWS": "arn:aws:iam::222222222222:root"
      },
      "Action": "s3:ListBucket",
      "Resource": "arn:aws:s3:::DOC-EXAMPLE-BUCKET",
      "Condition": {
        "StringEquals": {
          "aws:PrincipalTag/department": [
```

```
        "finance",
        "hr",
        "legal"
    ],
    "aws:PrincipalTag/role": [
        "audit",
        "security"
    ]
},
"ArnLike": {
    "aws:PrincipalArn": [
        "arn:aws:iam::222222222222:user/Ana",
        "arn:aws:iam::222222222222:user/Mary"
    ]
}
}
}
]
```

Evaluation logic for negated matching condition operators

Some [condition operators](#), such as `StringNotEquals` or `ArnNotLike`, use negated matching to compare the context key-value pairs in your policy against the context key-value pairs in a request. When multiple values are specified for a single context key in a policy with negated matching condition operators, the effective permissions work like a logical NOR. In negated matching, a logical NOR or NOT OR returns true only if all values evaluate to false.

The following figure illustrates the evaluation logic for a condition with multiple condition operators and context key-value pairs. The figure includes a negated matching condition operator for context key 3.

For example, the following S3 bucket policy illustrates how the previous figure is represented in a policy. The condition block includes condition operators `StringEquals` and `ArnNotLike`, and context keys `aws:PrincipalTag` and `aws:PrincipalArn`. To invoke the desired Allow or Deny effect, all context keys in the condition block must resolve to true. The user making the request must have both principal tag keys, *department* and *role*, that include one of the tag key values specified in the policy. Since the `ArnNotLike` condition operator uses negated matching, the principal ARN of the user making the request must not match any of the `aws:PrincipalArn` values specified in the policy to be evaluated as true.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "ExamplePolicy",
      "Effect": "Allow",
      "Principal": {
        "AWS": "arn:aws:iam::222222222222:root"
      },
      "Action": "s3:ListBucket",
      "Resource": "arn:aws:s3:::DOC-EXAMPLE-BUCKET",
      "Condition": {
        "StringEquals": {
          "aws:PrincipalTag/department": [
            "finance",

```

```
        "hr",
        "legal"
    ],
    "aws:PrincipalTag/role": [
        "audit",
        "security"
    ]
},
"ArnNotLike": {
    "aws:PrincipalArn": [
        "arn:aws:iam::222222222222:user/Ana",
        "arn:aws:iam::222222222222:user/Mary"
    ]
}
}
}
]
```

Single-valued vs. multivalued context keys

The difference between single-valued and multivalued context keys depends on the number of values in the [request context](#), not the number of values in the policy condition.

- *Single-valued* condition context keys have at most one value in the request context. For example, you can tag resources in AWS. Resource tags are stored as tag key-value pairs. A resource tag key can have a single tag value. Therefore, [the section called "ResourceTag"](#) is a single-valued context key. Do not use a condition set operator with a single-valued context key.
- *Multivalued* condition context keys can have multiple values in the request context. For example, you can tag resources in AWS and include multiple tag key-value pairs in a request. Therefore, [the section called "TagKeys"](#) is a multivalued context key. Multivalued context keys require a condition set operator.

Important

Multivalued context keys require a condition set operator. Do not use condition set operators `ForAllValues` or `ForAnyValue` with single-valued context keys. To learn more about condition set operators, see [Multivalued context keys](#).

The *Single-valued* and *Multivalued* classifications are included in the description of each condition context key as *Value type* in the [AWS global condition context keys](#) topic. The [Service Authorization Reference](#) uses a different value type classification for multivalued context keys in the following format: an `ArrayOf` prefix followed by the condition operator category type. For example, `ArrayOfString` or `ArrayOfARN`.

For example, a request can originate from at most one VPC endpoint, so [the section called "SourceVpce"](#) is a single-valued context key. Since a service can have more than one service principal name that belongs to the service, [aws:PrincipalServiceNamesList](#) is a multivalued context key.

You can use any available single-valued context key as a policy variable. You cannot use a multivalued context key as a policy variable. For more information about policy variables, see [IAM policy elements: Variables and tags](#).

Multivalued context keys require condition set operators `ForAllValues` or `ForAnyValue`. Context keys that include key-value pairs such as [the section called "RequestTag"](#) and [the section called "ResourceTag"](#) can cause confusion because there can be multiple *tag-key* values. But since each *tag-key* can have only one value, `aws:RequestTag` and `aws:ResourceTag` are both single-valued context keys. Using condition set operators with single-valued context keys can lead to overly permissive policies.

Multivalued context keys

To compare your condition context key against a [request context](#) key with multiple values, you must use the `ForAllValues` or `ForAnyValue` set operators. These set operators are used to compare two sets of values, such as the set of tags in a request and the set of tags in a policy condition.

The `ForAllValues` and `ForAnyValue` qualifiers add set-operation functionality to the condition operator so that you can test request context keys with multiple values against multiple context key values in a policy condition. Additionally, if you include a multivalued string context key in your policy with a wildcard or a variable, you must also use the `StringLike` [condition operator](#). Multiple condition key values must be enclosed in brackets like an [array](#). For example, "Key2": `["Value2A", "Value2B"]`.

- `ForAllValues` – This qualifier tests whether the value of every member of the request set is a subset of the condition context key set. The condition returns true if every context key value in the request matches at least one context key value in the policy. It also returns true if there are

no context keys in the request, or if the context key value resolves to a null dataset, such as an empty string. To prevent missing context keys or context keys with empty values from evaluating to true, you can include the `Null` condition operator in your policy with a false value to check if the context key exists and its value is not null.

Important

Use caution if you use `ForAllValues` with an `Allow` effect because it can be overly permissive if the presence of missing context keys or context keys with empty values in the request context is unexpected. You can include the `Null` condition operator in your policy with a false value to check if the context key exists and its value is not null. For an example, see [Controlling access based on tag keys](#).

- `ForAnyValue` – This qualifier tests whether at least one member of the set of request context key values matches at least one member of the set of context key values in your policy condition. The context key returns true if any one of the context key values in the request matches any one of the context key values in the policy. For no matching context key or a null dataset, the condition returns false.

Note

The difference between single-valued and multivalued context keys depends on the number of values in the request context, not the number of values in the policy condition.

Condition policy examples

In IAM policies, you can specify multiple values for both single-valued and multivalued context keys for comparison against the request context. The following set of policy examples demonstrates policy conditions with multiple context keys and values.

Note

If you would like to submit a policy to be included in this reference guide, use the **Feedback** button at the bottom of this page. For IAM identity-based policy examples, see [Example IAM identity-based policies](#).

Condition policy examples: Single-valued context keys

- Multiple condition blocks with single-valued context keys. ([View this example.](#))
- One condition block with multiple single-valued context keys and values. ([View this example.](#))

Condition policy examples: Multivalued context keys

- Deny policy with condition set operator `ForAllValues`. ([View this example.](#))
- Deny policy with condition set operator `ForAnyValue`. ([View this example.](#))

Multivalued context key examples

The following set of policy examples demonstrate how to create policy conditions with multivalued context keys.

Example: Deny policy with condition set operator `ForAllValues`

The following example identity-based policy denies the use of IAM tagging actions when specific tag key prefixes are included in the request. Each value for context key `aws:TagKeys` includes a wildcard (*) for partial string matching. The policy includes the `ForAllValues` set operator with context key `aws:TagKeys` because the request context key can include multiple values. In order for context key `aws:TagKeys` to return true, every value in the request must match at least one value in the policy.

The `ForAllValues` set operator also returns true if there are no context keys in the request, or if the context key value resolves to a null dataset, such as an empty string. To prevent missing context keys or context keys with empty values from evaluating to true, include the `Null` condition operator in your policy with a value of `false` to check if the context key in the request exists and its value is not null.

Important

This policy does not allow any actions. Use this policy in combination with other policies that allow specific actions.

```
{
```

```
"Version": "2012-10-17",
"Statement": [
  {
    "Sid": "DenyRestrictedTags",
    "Effect": "Deny",
    "Action": [
      "iam:Tag*",
      "iam:Untag*"
    ],
    "Resource": [
      "*"
    ],
    "Condition": {
      "Null": {
        "aws:TagKeys": "false"
      },
      "ForAllValues:StringLike": {
        "aws:TagKeys": [
          "key1*",
          "key2*",
          "key3*"
        ]
      }
    }
  }
]
```

Example: Deny policy with condition set operator ForAnyValue

The following identity-based policy example denies creating snapshots of EC2 instance volumes if any snapshots are tagged with one of the tag keys specified in the policy, `environment` or `webserver`. The policy includes the `ForAnyValue` set operator with context key `aws:TagKeys` because the request context key can include multiple values. If your tagging request includes any one of the tag key values specified in the policy, the `aws:TagKeys` context key returns true invoking the deny policy effect.

Important

This policy does not allow any actions. Use this policy in combination with other policies that allow specific actions.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Deny",
      "Action": [
        "ec2:CreateSnapshot",
        "ec2:CreateSnapshots"
      ],
      "Resource": "arn:aws:ec2:us-west-2::snapshot/*",
      "Condition": {
        "ForAnyValue:StringEquals": {
          "aws:TagKeys": ["environment", "webserver"]
        }
      }
    }
  ]
}
```

Single-valued context key policy examples

The following set of policy examples demonstrate how to create policy conditions with single-valued context keys.

Example: Multiple condition blocks with single-valued context keys

When a condition block has multiple conditions, each with a single context key, all context keys must resolve to true for the desired Allow or Deny effect to be invoked. When you use negated matching condition operators, the evaluation logic of the condition value is reversed.

The following example lets users create EC2 volumes and apply tags to the volumes during volume creation. The request context must include a value for context key `aws:RequestTag/project`, and the value for context key `aws:ResourceTag/environment` can be anything except `production`.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": "ec2:CreateVolume",
```

```

    "Resource": "*"
  },
  {
    "Effect": "Allow",
    "Action": "ec2:CreateTags",
    "Resource": "arn:aws:ec2::volume/*",
    "Condition": {
      "StringLike": {
        "aws:RequestTag/project": "*"
      }
    }
  },
  {
    "Effect": "Allow",
    "Action": "ec2:CreateTags",
    "Resource": "arn:aws:ec2:region:account:*/*",
    "Condition": {
      "StringNotEquals": {
        "aws:ResourceTag/environment": "production"
      }
    }
  }
]
}

```

The request context must include a project tag-value and cannot be created for a production resource to invoke the Allow effect. The following EC2 volume is successfully created because the project name is Feature3 with a QA resource tag.

```

aws ec2 create-volume \
  --availability-zone us-east-1a \
  --volume-type gp2 \
  --size 80 \
  --tag-specifications 'ResourceType=volume,Tags=[{Key=project,Value=Feature3},
{Key=environment,Value=QA}]'

```

Example: One condition block with multiple single-valued context keys and values

When a condition block contains multiple context keys and each context key has multiple values, each context key must resolve to true for at least one key value for the desired Allow or Deny effect to be invoked. When you use negated matching condition operators, the evaluation logic of the context key value is reversed.

The following example allows users to start and run tasks on Amazon Elastic Container Service clusters.

- The request context must include production **OR** pre-prod for the `aws:RequestTag/environment` context key **AND**.
- The `ecs:cluster` context key makes sure that tasks are run on either the `default1` **OR** `default2` ARN ECS clusters.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "ecs:RunTask",
        "ecs:StartTask"
      ],
      "Resource": [
        "*"
      ],
      "Condition": {
        "StringEquals": {
          "aws:RequestTag/environment": [
            "production",
            "prod-backup"
          ]
        },
        "ArnEquals": {
          "ecs:cluster": [
            "arn:aws:ecs:us-east-1:111122223333:cluster/default1",
            "arn:aws:ecs:us-east-1:111122223333:cluster/default2"
          ]
        }
      }
    }
  ]
}
```

IAM policy elements: Variables and tags

Use AWS Identity and Access Management (IAM) policy variables as placeholders when you don't know the exact value of a resource or condition key when you write the policy.

Note

If AWS cannot resolve a variable this might cause the entire statement to be invalid. For example, if you use the `aws:TokenIssueTime` variable, the variable resolves to a value only when the requester authenticated using temporary credentials (an IAM role). To prevent variables from causing invalid statements, use the [...IfExists condition operator](#).

Topics

- [Introduction](#)
- [Using variables in policies](#)
- [Tags as policy variables](#)
- [Where you can use policy variables](#)
- [Policy variables with no value](#)
- [Request information that you can use for policy variables](#)
- [Specifying default values](#)
- [For more information](#)

Introduction

In IAM policies, many actions allow you to provide a name for the specific resources that you want to control access to. For example, the following policy allows users to list, read, and write objects in the S3 bucket `DOC-EXAMPLE-BUCKET` for marketing projects.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": ["s3:ListBucket"],
      "Resource": ["arn:aws:s3:::DOC-EXAMPLE-BUCKET"],
      "Condition": {"StringLike": {"s3:prefix": ["marketing/*"]}}
```

```
    },
    {
      "Effect": "Allow",
      "Action": [
        "s3:GetObject",
        "s3:PutObject"
      ],
      "Resource": ["arn:aws:s3:::DOC-EXAMPLE-BUCKET/marketing/*"]
    }
  ]
}
```

In some cases, you might not know the exact name of the resource when you write the policy. You might want to generalize the policy so it works for many users without having to make a unique copy of the policy for each user. Instead of creating a separate policy for each user, we recommend you create a single group policy that works for any user in that group.

Using variables in policies

You can define dynamic values inside policies by using *policy variables* that set placeholders in a policy.

Variables are marked using a `$` prefix followed by a pair of curly braces (`{ }`) that include the variable name of the value from the request.

When the policy is evaluated, the policy variables are replaced with values that come from the conditional context keys passed in the request. Variables can be used in [identity-based policies](#), [resource policies](#), [service control policies](#), [session policies](#), and [VPC endpoint policies](#). Identity-based policies used as permissions boundaries also support policy variables.

Global condition context keys can be used as variables in requests across AWS services. Service specific condition keys can also be used as variables when interacting with AWS resources, but are only available when requests are made against resources which support them. For a list of context keys available for each AWS service and resource, see the [Service Authorization Reference](#). Under certain circumstances, you can't populate global condition context keys with a value. To learn more about each key, see [AWS global condition context keys](#).

Important

- Key names are case-insensitive. For example, `aws:CurrentTime` is equivalent to `AWS:currenttime`.

- You can use any single-valued condition key as a variable. You can't use a multivalued condition key as a variable.

The following example shows a policy for an IAM role or user that replaces a specific resource name with a policy variable. You can reuse this policy by taking advantage of the `aws:PrincipalTag` condition key. When this policy is evaluated, `${aws:PrincipalTag/team}` allows the actions only if the bucket name ends with a team name from the `team` principal tag.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": ["s3:ListBucket"],
      "Resource": ["arn:aws:s3:::DOC-EXAMPLE-BUCKET"],
      "Condition": {"StringLike": {"s3:prefix": ["${aws:PrincipalTag/team}/*"]}}
    },
    {
      "Effect": "Allow",
      "Action": [
        "s3:GetObject",
        "s3:PutObject"
      ],
      "Resource": ["arn:aws:s3:::DOC-EXAMPLE-BUCKET/${aws:PrincipalTag/team}/*"]
    }
  ]
}
```

The variable is marked using a `$` prefix followed by a pair of curly braces (`{ }`). Inside the `${ }` characters, you can include the name of the value from the request that you want to use in the policy. The values you can use are discussed later on this page.

For details about this global condition key, see [aws:PrincipalTag/tag-key](#) in the list of global condition keys.

Note

In order to use policy variables, you must include the `Version` element in a statement, and the version must be set to a version that supports policy variables. Variables were introduced in version `2012-10-17`. Earlier versions of the policy language don't support

policy variables. If you don't include the `Version` element and set it to an appropriate version date, variables like `${aws:username}` are treated as literal strings in the policy. A `Version` policy element is different from a policy version. The `Version` policy element is used within a policy and defines the version of the policy language. A policy version, on the other hand, is created when you change a customer managed policy in IAM. The changed policy doesn't overwrite the existing policy. Instead, IAM creates a new version of the managed policy. To learn more about the `Version` policy element see [the section called "Version"](#). To learn more about policy versions, see [the section called "Versioning IAM policies"](#).

A policy that allows a principal to get objects from the `/David` path of an S3 bucket looks like this:

```
{
  "Version": "2012-10-17",
  "Statement": [{
    "Effect": "Allow",
    "Action": ["s3:GetObject"],
    "Resource": ["arn:aws:s3::DOC-EXAMPLE-BUCKET/David/*"]
  }]
}
```

If this policy is attached to user `David`, that user get objects from his own S3 bucket, but you would have to create a separate policy for each user that includes the user's name. You would then attach each policy to the individual users.

By using a policy variable, you can create policies that can be reused. The following policy allows a user to get objects from an Amazon S3 bucket if the tag-key value for `aws:PrincipalTag` matches the tag-key `owner` value passed in the request.

```
{
  "Version": "2012-10-17",
  "Statement": [{
    "Sid": "AllowUnlessOwnedBySomeoneElse",
    "Effect": "Allow",
    "Action": ["s3:GetObject"],
    "Resource": ["*"],
    "Condition": {
      "StringEquals": {
        "${s3:ExistingObjectTag/owner}": "${aws:PrincipalTag/owner}"
      }
    }
  }]
}
```

```
    }
  }
}
]
```

When you use a policy variable in place of a user like this, you don't have to have a separate policy for each individual user. In the following example, the policy is attached to an IAM role that is assumed by Product Managers using temporary security credentials. When a user makes a request to add an Amazon S3 object, IAM substitutes the dept tag value from the current request for the `${aws:PrincipalTag}` variable and evaluates the policy.

```
{
  "Version": "2012-10-17",
  "Statement": [{
    "Sid": "AllowOnlyDeptS3Prefix",
    "Effect": "Allow",
    "Action": ["s3:GetObject"],
    "Resource": ["arn:aws:s3:::DOC-EXAMPLE-BUCKET/${aws:PrincipalTag}/dept/*"],
  }
]
```

Tags as policy variables

In some AWS services you can attach your own custom attributes to resources that are created by those services. For example, you can apply tags to Amazon S3 buckets or to IAM users. These tags are key-value pairs. You define the tag key name and the value that is associated with that key name. For example, you might create a tag with a **department** key and a **Human Resources** value. For more information about tagging IAM entities, see [Tagging IAM resources](#). For information about tagging resources created by other AWS services, see the documentation for that service. For information about using Tag Editor, see [Working with Tag Editor](#) in the *AWS Management Console User Guide*.

You can tag IAM resources to simplify discovering, organizing, and tracking your IAM resources. You can also tag IAM identities to control access to resources or to tagging itself. To learn more about using tags to control access, see [Controlling access to and for IAM users and roles using tags](#).

Where you can use policy variables

You can use policy variables in the Resource element and in string comparisons in the Condition element.

Resource element

You can use a policy variable in the Resource element, but only in the resource portion of the ARN. This portion of the ARN appears after the fifth colon (:). You can't use a variable to replace parts of the ARN before the fifth colon, such as the service or account. For more information about the ARN format, see [IAM ARNs](#).

To replace part of an ARN with a tag value, surround the prefix and key name with `${ }`. For example, the following Resource element refers to only a bucket that is named the same as the value in the requesting user's department tag.

```
"Resource": ["arn:aws::s3::bucket/${aws:PrincipalTag/department"}"]
```

Many AWS resources use ARNs that contain a user-created name. The following IAM policy ensures that only intended users with matching access-project, access-application, and access-environment tag values can modify their resources. In addition, using [* wildcard matches](#), they are able to allow for custom resource name suffixes.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "AllowAccessBasedOnArnMatching",
      "Effect": "Allow",
      "Action": [
        "sns:CreateTopic",
        "sns>DeleteTopic",
        "Resource": ["arn:aws:sns:*:*:${aws:PrincipalTag/access-project}-
${aws:PrincipalTag/access-application}-${aws:PrincipalTag/access-environment}-*"
      ]
    }
  ]
}
```

Condition element

You can use a policy variable for Condition values in any condition that involves the string operators or the ARN operators. String operators include `StringEquals`, `StringLike`, and `StringNotLike`. ARN operators include `ArnEquals` and `ArnLike`. You can't use a policy variable with other operators, such as `Numeric`, `Date`, `Boolean`, `Binary`, `IP Address`, or `Null` operators. For more information about condition operators, see [IAM JSON policy elements: Condition operators](#).

When referencing a tag in a Condition element expression, use the relevant prefix and key name as the condition key. Then use the value that you want to test in the condition value.

For example, the following policy example allows full access to users, but only if the tag `costCenter` is attached to the user. The tag must also have a value of either `12345` or `67890`. If the tag has no value, or has any other value, then the request fails.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "iam:*user*"
      ],
      "Resource": "*",
      "Condition": {
        "StringLike": {
          "iam:ResourceTag/costCenter": [ "12345", "67890" ]
        }
      }
    }
  ]
}
```

Policy variables with no value

When policy variables reference a condition context key that has no value or is not present in an authorization context for a request, the value is effectively null. There is no equal or like value. Condition context keys may not be present in the authorization context when:

- You are using service specific condition context keys in requests to resources that do not support that condition key.

- Tags on IAM principals, sessions, resources, or requests are not present.
- Other circumstances as listed for each global condition context key in [AWS global condition context keys](#).

When you use a variable with no value in the condition element of an IAM policy, [IAM JSON policy elements: Condition operators](#) like `StringEquals` or `StringLike` do not match, and the policy statement does not take effect.

Inverted condition operators like `StringNotEquals` or `StringNotLike` do match against a null value, as the value of the condition key they are testing against is not equal to or like the effectively null value.

In the following example, `aws:principaltag/Team` must be equal to `s3:ExistingObjectTag/Team` to allow access. Access is explicitly denied when `aws:principaltag/Team` is not set. If a variable that has no value in the authorization context is used as part of the `Resource` or `NotResource` element of a policy, the resource that includes a policy variable with no value will not match any resource.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Deny",
      "Action": "s3:GetObject",
      "Resource": "arn:aws:s3:::/example-bucket/*",
      "Condition": {
        "StringNotEquals": {
          "s3:ExistingObjectTag/Team": "${aws:PrincipalTag/Team}"
        }
      }
    }
  ]
}
```

Request information that you can use for policy variables

You can use the `Condition` element of a JSON policy to compare keys in the [request context](#) with key values that you specify in your policy. When you use a policy variable, AWS substitutes a value from the request context key in place of the variable in your policy.

Principal key values

The values for `aws:username`, `aws:userid`, and `aws:PrincipalType` depend on what type of principal initiated the request. For example, the request could be made using the credentials of an IAM user, an IAM role, or the AWS account root user. The following list shows values for these keys for different types of principals.

- **AWS account root user**
 - `aws:username`: (not present)
 - `aws:userid`: AWS account ID
 - `aws:PrincipalType`: Account
- **IAM user**
 - `aws:username`: *IAM-user-name*
 - `aws:userid`: [unique ID](#)
 - `aws:PrincipalType`: User
- **Federated user**
 - `aws:username`: (not present)
 - `aws:userid`: *account:caller-specified-name*
 - `aws:PrincipalType`: FederatedUser
- **Web federated user and SAML federated user**

Note

For information about policy keys that are available when you use web identity federation, see [Identifying users with web identity federation](#).

- `aws:username`: (not present)
- `aws:userid`: (not present)
- `aws:PrincipalType`: AssumedRole
- **Assumed role**
 - `aws:username`: (not present)
 - `aws:userid`: *role-id:caller-specified-role-name*
 - `aws:PrincipalType`: Assumed role

- **Role assigned to Amazon EC2 instance**
 - `aws:username`: (not present)
 - `aws:userid`: *role-id:ec2-instance-id*
 - `aws:PrincipalType`: Assumed role
- **Anonymous caller** (Amazon SQS Amazon SNS and Amazon S3 only)
 - `aws:username`: (not present)
 - `aws:userid`: (not present)
 - `aws:PrincipalType`: Anonymous

For the items in this list, note the following:

- *not present* means that the value is not in the current request information, and any attempt to match it fails and causes the statement to be invalid.
- *role-id* is a unique identifier assigned to each role at creation. You can display the role ID with the AWS CLI command: `aws iam get-role --role-name rolename`
- *caller-specified-name* and *caller-specified-role-name* are names that are passed by the calling process (such as an application or service) when it makes a call to get temporary credentials.
- *ec2-instance-id* is a value assigned to the instance when it is launched and appears on the **Instances** page of the Amazon EC2 console. You can also display the instance ID by running the AWS CLI command: `aws ec2 describe-instances`

Information available in requests for federated users

Federated users are users who are authenticated using a system other than IAM. For example, a company might have an application for use in-house that makes calls to AWS. It might be impractical to give an IAM identity to every corporate user who uses the application. Instead, the company might use a proxy (middle-tier) application that has a single IAM identity, or the company might use a SAML identity provider (IdP). The proxy application or SAML IdP authenticates individual users using the corporate network. A proxy application can then use its IAM identity to get temporary security credentials for individual users. A SAML IdP can in effect exchange identity information for AWS temporary security credentials. The temporary credentials can then be used to access AWS resources.

Similarly, you might create an app for a mobile device in which the app needs to access AWS resources. In that case, you might use *web identity federation*, where the app authenticates the user using a well-known identity provider like Login with Amazon, Amazon Cognito, Facebook, or Google. The app can then use the user's authentication information from these providers to get temporary security credentials for accessing AWS resources.

The recommended way to use web identity federation is by taking advantage of Amazon Cognito and the AWS mobile SDKs. For more information, see the following:

- [Amazon Cognito User Guide](#)
- [Common scenarios for temporary credentials](#)

Special characters

There are a few special predefined policy variables that have fixed values that enable you to represent characters that otherwise have special meaning. If these special characters are part of the string, you are trying to match and you inserted them literally they would be misinterpreted. For example, inserting an * asterisk in the string would be interpreted as a wildcard, matching any characters, instead of as a literal *. In these cases, you can use the following predefined policy variables:

- `${*}` - use where you need an * (asterisk) character.
- `${?}` - use where you need a ? (question mark) character.
- `${$}` - use where you need a \$ (dollar sign) character.

These predefined policy variables can be used in any string where you can use regular policy variables.

Specifying default values

To add a default value to a variable, surround the default value with single quotes (' '), and separate the variable text and the default value with a comma and space (,).

For example, if a principal is tagged with `team=yellow`, they can access ExampleCorp's Amazon S3 bucket named `DOC-EXAMPLE-BUCKET-yellow`. A policy with this resource allows team members to access their team bucket, but not those of other teams. For users without team tags, it sets a default value of company-wide for the bucket name. These users can access only the

DOC-EXAMPLE-BUCKET - company-wide bucket where they can view broad information, such as instructions for joining a team.

```
"Resource": "arn:aws:s3:::DOC-EXAMPLE-BUCKET-${aws:PrincipalTag/team, 'company-wide'}"
```

For more information

For more information about policies, see the following:

- [Policies and permissions in IAM](#)
- [Example IAM identity-based policies](#)
- [IAM JSON policy elements reference](#)
- [Policy evaluation logic](#)
- [About web identity federation](#)

IAM JSON policy elements: Supported data types

This section lists the data types that are supported when you specify values in JSON policies. The policy language doesn't support all types for each policy element; for information about each element, see the preceding sections.

- Strings
- Numbers (Ints and Floats)
- Boolean
- Null
- Lists
- Maps
- Structs (which are just nested Maps)

The following table maps each data type to the serialization. Note that all policies must be in UTF-8. For information about the JSON data types, go to [RFC 4627](#).

Type	JSON
String	String

Type	JSON
Integer	Number
Float	Number
Boolean	true false
Null	null
Date	String adhering to the W3C Profile of ISO 8601
IpAddress	String adhering to RFC 4632
List	Array
Object	Object

Policy evaluation logic

When a principal tries to use the AWS Management Console, the AWS API, or the AWS CLI, that principal sends a *request* to AWS. When an AWS service receives the request, AWS completes several steps to determine whether to allow or deny the request.

1. **Authentication** – AWS first authenticates the principal that makes the request, if necessary. This step is not necessary for a few services, such as Amazon S3, that allow some requests from anonymous users.
2. **[Processing the request context](#)** – AWS processes the information gathered in the request to determine which policies apply to the request.
3. **[Evaluating policies within a single account](#)** – AWS evaluates all of the policy types, which affect the order in which the policies are evaluated.
4. **[Determining whether a request is allowed or denied within an account](#)** – AWS then processes the policies against the request context to determine whether the request is allowed or denied.

Processing the request context

AWS processes the request to gather the following information into a *request context*:

- **Actions (or operations)** – The actions or operations that the principal wants to perform.
- **Resources** – The AWS resource object upon which the actions or operations are performed.
- **Principal** – The user, role, federated user, or application that sent the request. Information about the principal includes the policies that are associated with that principal.
- **Environment data** – Information about the IP address, user agent, SSL enabled status, or the time of day.
- **Resource data** – Data related to the resource that is being requested. This can include information such as a DynamoDB table name or a tag on an Amazon EC2 instance.

AWS then uses this information to find policies that apply to the request context.

Evaluating policies within a single account

How AWS evaluates policies depends on the types of policies that apply to the request context. The following policy types, listed in order of frequency, are available for use within a single AWS account. For more information about these policy types, see [Policies and permissions in IAM](#). To learn how AWS evaluates policies for cross-account access, see [Cross-account policy evaluation logic](#).

1. **Identity-based policies** – Identity-based policies are attached to an IAM identity (user, group of users, or role) and grant permissions to IAM entities (users and roles). If only identity-based policies apply to a request, then AWS checks all of those policies for at least one `Allow`.
2. **Resource-based policies** – Resource-based policies grant permissions to the principal (account, user, role, and session principals such as role sessions and IAM federated users) specified as the principal. The permissions define what the principal can do with the resource to which the policy is attached. If resource-based policies and identity-based policies both apply to a request, then AWS checks all the policies for at least one `Allow`. When resource-based policies are evaluated, the principal ARN that is specified in the policy determines whether implicit denies in other policy types are applicable to the final decision.
3. **IAM permissions boundaries** – Permissions boundaries are an advanced feature that sets the maximum permissions that an identity-based policy can grant to an IAM entity (user or role). When you set a permissions boundary for an entity, the entity can perform only the actions that are allowed by both its identity-based policies and its permissions boundaries. In some cases, an implicit deny in a permissions boundary can limit the permissions granted by a resource-based policy. To learn more, see [Determining whether a request is allowed or denied within an account](#) later in this topic.

- 4. AWS Organizations service control policies (SCPs)** – Organizations SCPs specify the maximum permissions for an organization or organizational unit (OU). The SCP maximum applies to principals in member accounts, including each AWS account root user. If an SCP is present, identity-based and resource-based policies grant permissions to principals in member accounts only if those policies and the SCP allow the action. If both a permissions boundary and an SCP are present, then the boundary, the SCP, and the identity-based policy must all allow the action.
- 5. Session policies** – Session policies are advanced policies that you pass as parameters when you programmatically create a temporary session for a role or federated user. To create a role session programmatically, use one of the `AssumeRole*` API operations. When you do this and pass session policies, the resulting session's permissions are the intersection of the IAM entity's identity-based policy and the session policies. To create a federated user session, you use the IAM user access keys to programmatically call the `GetFederationToken` API operation. A resource-based policy has a different effect on the evaluation of session policy permissions. The difference depends on whether the user or role's ARN or the session's ARN is listed as the principal in the resource-based policy. For more information, see [Session policies](#).

Remember, an explicit deny in any of these policies overrides the allow.

Evaluating identity-based policies with resource-based policies

Identity-based policies and resource-based policies grant permissions to the identities or resources to which they are attached. When an IAM entity (user or role) requests access to a resource within the same account, AWS evaluates all the permissions granted by the identity-based and resource-based policies. The resulting permissions are the total permissions of the two types. If an action is allowed by an identity-based policy, a resource-based policy, or both, then AWS allows the action. An explicit deny in either of these policies overrides the allow.

Evaluating identity-based policies with permissions boundaries

When AWS evaluates the identity-based policies and permissions boundary for a user, the resulting permissions are the intersection of the two categories. That means that when you add a permissions boundary to a user with existing identity-based policies, you might reduce the actions that the user can perform. Alternatively, when you remove a permissions boundary from a user, you might increase the actions they can perform. An explicit deny in either of these policies overrides the allow. To view information about how other policy types are evaluated with permissions boundaries, see [Evaluating effective permissions with boundaries](#).

Evaluating identity-based policies with Organizations SCPs

When a user belongs to an account that is a member of an organization, the resulting permissions are the intersection of the user's policies and the SCP. This means that an action must be allowed by both the identity-based policy and the SCP. An explicit deny in either of these policies overrides the allow.

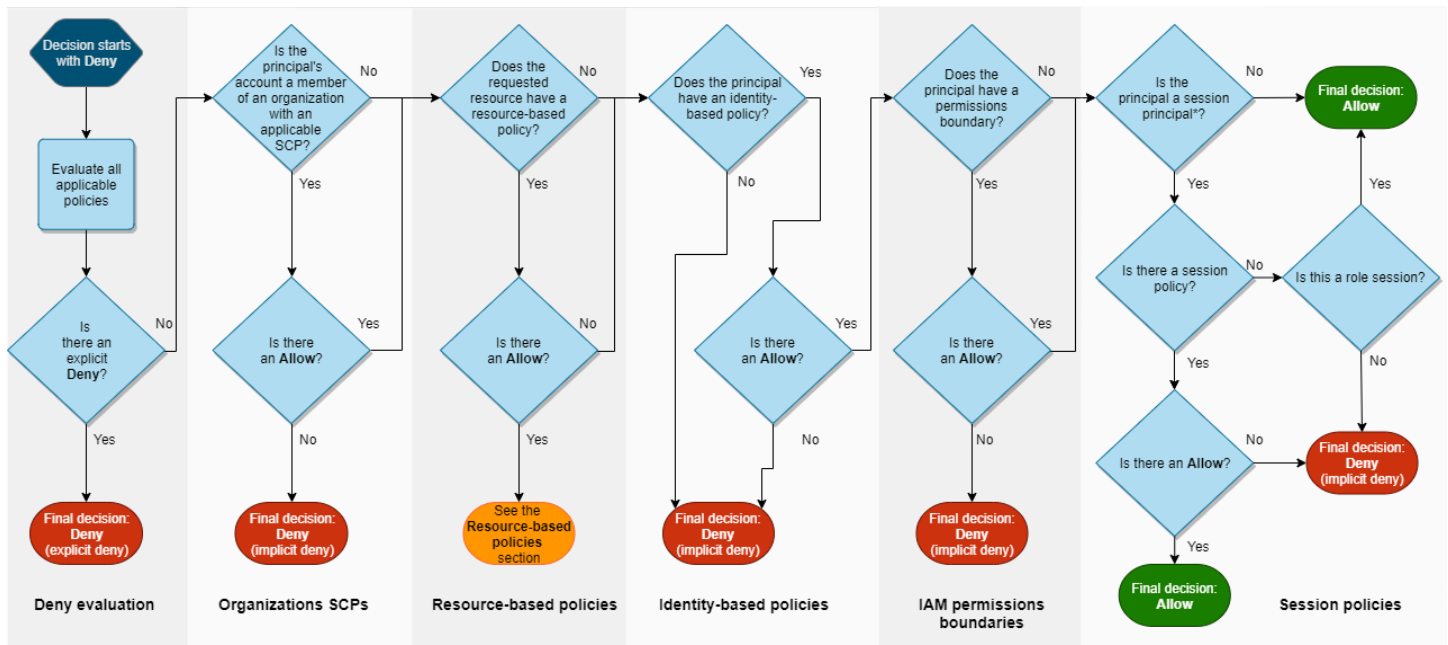

You can learn [whether your account is a member of an organization](#) in AWS Organizations. Organization members might be affected by an SCP. To view this data using the AWS CLI command or AWS API operation, you must have permissions for the `organizations:DescribeOrganization` action for your Organizations entity. You must have additional permissions to perform the operation in the Organizations console. To learn whether an SCP is denying access to a specific request, or to change your effective permissions, contact your AWS Organizations administrator.

Determining whether a request is allowed or denied within an account

Assume that a principal sends a request to AWS to access a resource in the same account as the principal's entity. The AWS enforcement code decides whether the request should be allowed or denied. AWS evaluates all policies that are applicable to the request context. The following is a summary of the AWS evaluation logic for policies within a single account.

- By default, all requests are implicitly denied with the exception of the AWS account root user, which has full access.
- An explicit allow in an identity-based or resource-based policy overrides this default.
- If a permissions boundary, Organizations SCP, or session policy is present, it might override the allow with an implicit deny.
- An explicit deny in any policy overrides any allows.

The following flow chart provides details about how the decision is made. This flow chart does not cover the impact of resource-based policies and implicit denies in other types of policies.

- 1. Deny evaluation** – By default, all requests are denied. This is called an [implicit deny](#). The AWS enforcement code evaluates all policies within the account that apply to the request. These include AWS Organizations SCPs, resource-based policies, identity-based policies, IAM permissions boundaries, and session policies. In all those policies, the enforcement code looks for a Deny statement that applies to the request. This is called an [explicit deny](#). If the enforcement code finds even one explicit deny that applies, the code returns a final decision of **Deny**. If there is no explicit deny, the enforcement code evaluation continues.
- 2. Organizations SCPs** – Then the enforcement code evaluates AWS Organizations service control policies (SCPs) that apply to the request. SCPs apply to principals of the account where the SCPs are attached. If the enforcement code does not find any applicable Allow statements in the SCPs, the request is explicitly denied, even if the denial is implicit. The enforcement code returns a final decision of **Deny**. If there is no SCP, or if the SCP allows the requested action, the enforcement code evaluation continues.
- 3. Resource-based policies** – Within the same account, resource-based policies impact policy evaluation differently depending on the type of principal accessing the resource, and the principal that is allowed in the resource-based policy. Depending on the type of principal, an Allow in a resource-based policy can result in a final decision of Allow, even if an implicit deny in an identity-based policy, permissions boundary, or session policy is present.

For most resources, you only need an explicit allow for the principal in either an identity-based policy or a resource-based policy to grant access. [IAM role trust policies](#) and [KMS key policies](#) are exceptions to this logic, because they must explicitly allow access for [principals](#).

Resource-based policy logic differs from other policy types if the specified principal is an IAM user, an IAM role, or a session principal. Session principals include IAM [role sessions](#) or an [IAM federated user session](#). If a resource-based policy grants permission directly to the IAM user or the session principal that is making the request, then an implicit deny in an identity-based policy, a permissions boundary, or a session policy does not impact the final decision.

The following table helps you understand the impact of resource-based policies for different principal types when implicit denials are present in identity-based policies, permissions boundaries, and session policies.

Resource-based policies and implicit denials in other policy types (same account)

Principal making the request	Resource-based policy	Identity-based policy	Permissions boundary	Session Policy	Result	Reason
IAM role	Not applicable	Not applicable	Not applicable	Not applicable	Not applicable	A role itself cannot make a request. Requests are made with the role session after a role is assumed.

Principal making the request	Resource-based policy	Identity-based policy	Permissions boundary	Session Policy	Result	Reason
IAM role session	Allows role ARN	Implicit deny	Implicit deny	Implicit deny	DENY	Permissions boundary and session policy are evaluated as part of the final decision. An implicit deny in either policy results in a DENY decision.
IAM role session	Allows role session ARN	Implicit deny	Implicit deny	Implicit deny	ALLOW	Permissions are granted directly to the session. Other policy types do not affect the decision.

Principal making the request	Resource-based policy	Identity-based policy	Permissions boundary	Session Policy	Result	Reason
IAM user	Allows IAM user ARN	Implicit deny	Implicit deny	Not applicable	ALLOW	Permissions are granted directly to the user. Other policy types do not affect the decision.
IAM federated user (GetFederationToken)	Allows IAM user ARN	Implicit deny	Implicit deny	Implicit deny	DENY	An implicit deny in either the permissions boundary or session policy results in a DENY.

Principal making the request	Resource-based policy	Identity-based policy	Permissions boundary	Session Policy	Result	Reason
IAM federated user (GetFederationToken)	Allows IAM federated user session ARN	Implicit deny	Implicit deny	Implicit deny	ALLOW	Permissions are granted directly to the session. Other policy types do not affect the decision.

Principal making the request	Resource-based policy	Identity-based policy	Permissions boundary	Session Policy	Result	Reason
root user	Allows root user ARN	Not applicable	Not applicable	Not applicable	ALLOW	The root user has complete, unrestricted access to all resources in your AWS account. To learn how to control access to the root user for accounts in AWS Organizations, see Service control policies (SCPs) in the <i>Organizations User Guide</i> .

Principal making the request	Resource-based policy	Identity-based policy	Permissions boundary	Session Policy	Result	Reason
AWS service principal	Allows an AWS service principal	Not applicable	Not applicable	Not applicable	ALLOW	When a resource-based policy grants permissions directly to an AWS service principal , other policy types do not affect the decision.

- **IAM role** – Resource-based policies that grant permissions to an IAM role ARN are limited by an implicit deny in a permissions boundary or session policy.

Example role ARN

```
arn:aws:iam::111122223333:role/examplerole
```

- **IAM role session** – Within the same account, resource-based policies that grant permissions to an IAM role session ARN grant permissions directly to the assumed role session. Permissions granted directly to a session are not limited by an implicit deny in an identity-based policy, a permissions boundary, or session policy. When you assume a role and make a request, the principal making the request is the IAM role session ARN and not the ARN of the role itself.

Example role session ARN

```
arn:aws:sts::111122223333:assumed-role/examplerole/examplerolesessionname
```

- **IAM user** – Within the same account, resource-based policies that grant permissions to an IAM user ARN (that is not a federated user session) are not limited by an implicit deny in an identity-based policy or permissions boundary.

Example IAM user ARN

```
arn:aws:iam::111122223333:user/exampleuser
```

- **IAM federated user sessions** – An IAM federated user session is a session created by calling [GetFederationToken](#). When a federated user makes a request, the principal making the request is the federated user ARN and not the ARN of the IAM user who federated. Within the same account, resource-based policies that grant permissions to a federated user ARN grant permissions directly to the session. Permissions granted directly to a session are not limited by an implicit deny in an identity-based policy, a permissions boundary, or session policy.

However, if a resource-based policy grants permission to the ARN of the IAM user who federated, then requests made by the federated user during the session are limited by an implicit deny in a permission boundary or session policy.

Example IAM federated user session ARN

```
arn:aws:sts::111122223333:federated-user/exampleuser
```

4. **Identity-based policies** – The code then checks the identity-based policies for the principal. For an IAM user, these include user policies and policies from groups to which the user belongs. If there are no identity-based policies or no statements in identity-based policies that allow the requested action, then the request is implicitly denied and the code returns a final decision of **Deny**. If any statement in any applicable identity-based policies allows the requested action, the code continues.
5. **IAM permissions boundaries** – The code then checks whether the IAM entity that is used by the principal has a permissions boundary. If the policy that is used to set the permissions boundary does not allow the requested action, then the request is implicitly denied. The code returns a final decision of **Deny**. If there is no permissions boundary, or if the permissions boundary allows the requested action, the code continues.

6. **Session policies** – The code then checks whether the principal is a session principal. Session principals include an IAM role session or an IAM federated user session. If the principal is not a session principal, the enforcement code returns a final decision of **Allow**.

For session principals, the code checks whether a session policy was passed in the request. You can pass a session policy while using the AWS CLI or AWS API to get temporary credentials for a role or an IAM federated user.

- If a session policy is present and does not allow the requested action, then the request is implicitly denied. The code returns a final decision of **Deny**.
- If there is no session policy, the code checks whether the principal is a role session. If the principal is a role session, then the request is **Allowed**. Otherwise, the request is implicitly denied and the code returns a final decision of **Deny**.
- If a session policy is present and allows the requested action, then the enforcement code returns a final decision of **Allow**.

7. **Errors** – If the AWS enforcement code encounters an error at any point during the evaluation, then it generates an exception and closes.

Example identity-based and resource-based policy evaluation

The most common types of policies are identity-based policies and resource-based policies. When access to a resource is requested, AWS evaluates all the permissions granted by the policies for **at least one Allow** within the same account. An explicit deny in any of the policies overrides the allow.

Important

If either the identity-based policy or the resource-based policy within the same account allows the request and the other doesn't, the request is still allowed.

Assume that Carlos has the user name `carloossalazar` and he tries to save a file to the `carloossalazar-logs` Amazon S3 bucket.

Also assume that the following policy is attached to the `carloossalazar` IAM user.

```
{
  "Version": "2012-10-17",
  "Statement": [
```

```
{
  "Sid": "AllowS3ListRead",
  "Effect": "Allow",
  "Action": [
    "s3:GetBucketLocation",
    "s3:GetAccountPublicAccessBlock",
    "s3:ListAccessPoints",
    "s3:ListAllMyBuckets"
  ],
  "Resource": "arn:aws:s3:::*"
},
{
  "Sid": "AllowS3Self",
  "Effect": "Allow",
  "Action": "s3:*",
  "Resource": [
    "arn:aws:s3:::carloossalazar/*",
    "arn:aws:s3:::carloossalazar"
  ]
},
{
  "Sid": "DenyS3Logs",
  "Effect": "Deny",
  "Action": "s3:*",
  "Resource": "arn:aws:s3:::*log*"
}
]
```

The `AllowS3ListRead` statement in this policy allows Carlos to view a list of all of the buckets in the account. The `AllowS3Self` statement allows Carlos full access to the bucket with the same name as his user name. The `DenyS3Logs` statement denies Carlos access to any S3 bucket with `log` in its name.

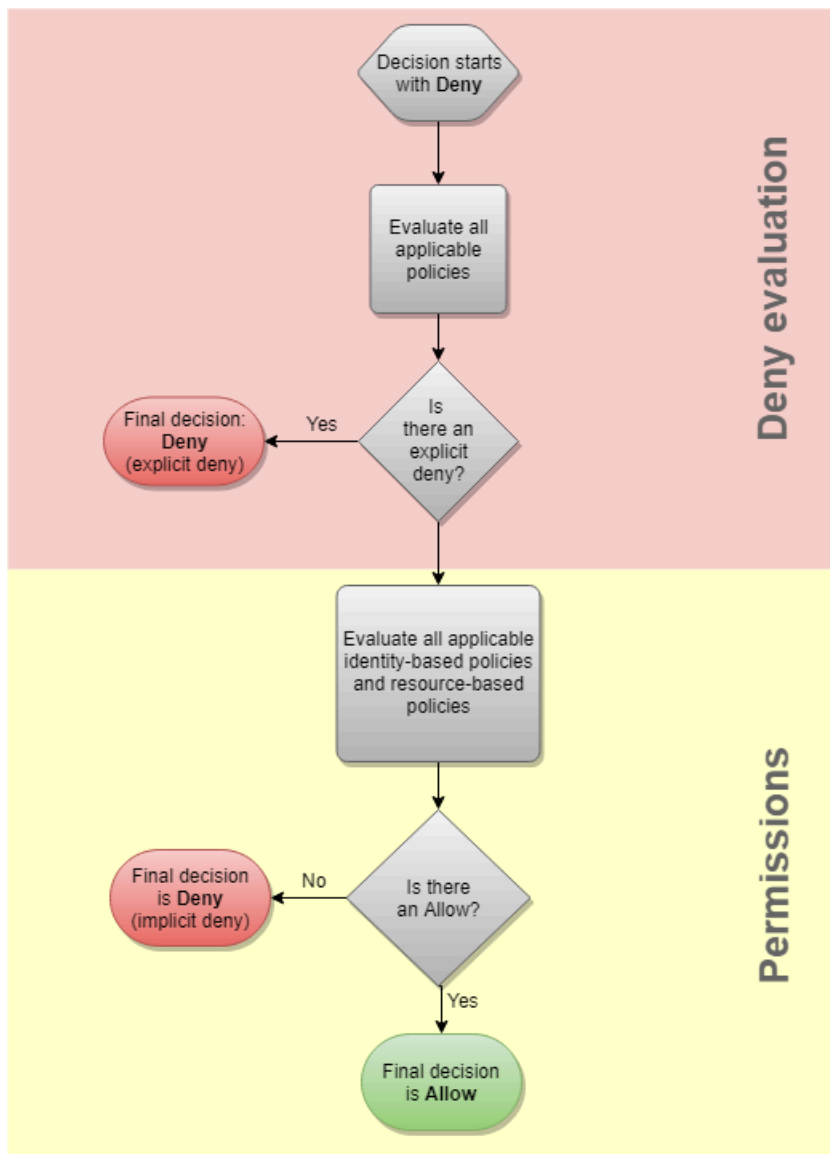

Additionally, the following resource-based policy (called a bucket policy) is attached to the `carloossalazar` bucket.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Principal": {
```

```
        "AWS": "arn:aws:iam::123456789012:user/carlossalazar"
    },
    "Action": "s3:*",
    "Resource": [
        "arn:aws:s3:::carlossalazar/*",
        "arn:aws:s3:::carlossalazar"
    ]
}
]
```

This policy specifies that only the `carlossalazar` user can access the `carlossalazar` bucket.

When Carlos makes his request to save a file to the `carlossalazar-logs` bucket, AWS determines what policies apply to the request. In this case, only the identity-based policy and the resource-based policy apply. These are both permissions policies. Because no permissions boundaries apply, the evaluation logic is reduced to the following logic.

AWS first checks for a Deny statement that applies to the context of the request. It finds one, because the identity-based policy explicitly denies Carlos access to any S3 buckets used for logging. Carlos is denied access.

Assume that he then realizes his mistake and tries to save the file to the `carloossalazar` bucket. AWS checks for a Deny statement and does not find one. It then checks the permissions policies. Both the identity-based policy and the resource-based policy allow the request. Therefore, AWS allows the request. If either of them explicitly denied the statement, the request would have been denied. If one of the policy types allows the request and the other doesn't, the request is still allowed.

The difference between explicit and implicit denies

A request results in an explicit deny if an applicable policy includes a Deny statement. If policies that apply to a request include an Allow statement and a Deny statement, the Deny statement trumps the Allow statement. The request is explicitly denied.

An implicit denial occurs when there is no applicable Deny statement but also no applicable Allow statement. Because an IAM principal is denied access by default, they must be explicitly allowed to perform an action. Otherwise, they are implicitly denied access.

When you design your authorization strategy, you must create policies with Allow statements to allow your principals to successfully make requests. However, you can choose any combination of explicit and implicit denies.

For example, you can create the following policy that includes allowed actions, implicitly denied actions, and explicitly denied actions. The AllowGetList statement **allows** read-only access to IAM actions that begin with the prefixes Get and List. All other actions in IAM, such as iam:CreatePolicy are **implicitly denied**. The DenyReports statement **explicitly denies** access to IAM reports by denying access to actions that include the Report suffix, such as iam:GetOrganizationsAccessReport. If someone adds another policy to this principal to grant them access to IAM reports, such as iam:GenerateCredentialReport, report-related requests are still denied because of this explicit deny.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "AllowGetList",
      "Effect": "Allow",
      "Action": [
        "iam:Get*",
        "iam:List*"
      ],
      "Resource": "*"
    },
    {
      "Sid": "DenyReports",
      "Effect": "Deny",
      "Action": "iam:*Report",
      "Resource": "*"
    }
  ]
}
```

```
]
}
```

Cross-account policy evaluation logic

You can allow a principal in one account to access resources in a second account. This is called cross-account access. When you allow cross-account access, the account where the principal exists is called the *trusted* account. The account where the resource exists is the *trusting* account.

To allow cross-account access, you attach a resource-based policy to the resource that you want to share. You must also attach an identity-based policy to the identity that acts as the principal in the request. The resource-based policy in the trusting account must specify the principal of the trusted account that will have access to the resource. You can specify the entire account or its IAM users, federated users, IAM roles, or assumed-role sessions. You can also specify an AWS service as a principal. For more information, see [Specifying a principal](#).

The principal's identity-based policy must allow the requested access to the resource in the trusting service. You can do this by specifying the ARN of the resource or by allowing access to all resources (*).

In IAM, you can attach a resource-based policy to an IAM role to allow principals in other accounts to assume that role. The role's resource-based policy is called a role trust policy. After assuming that role, the allowed principals can use the resulting temporary credentials to access multiple resources in your account. This access is defined in the role's identity-based permissions policy. To learn how allowing cross-account access using roles is different from allowing cross-account access using other resource-based policies, see [Cross account resource access in IAM](#).

Important

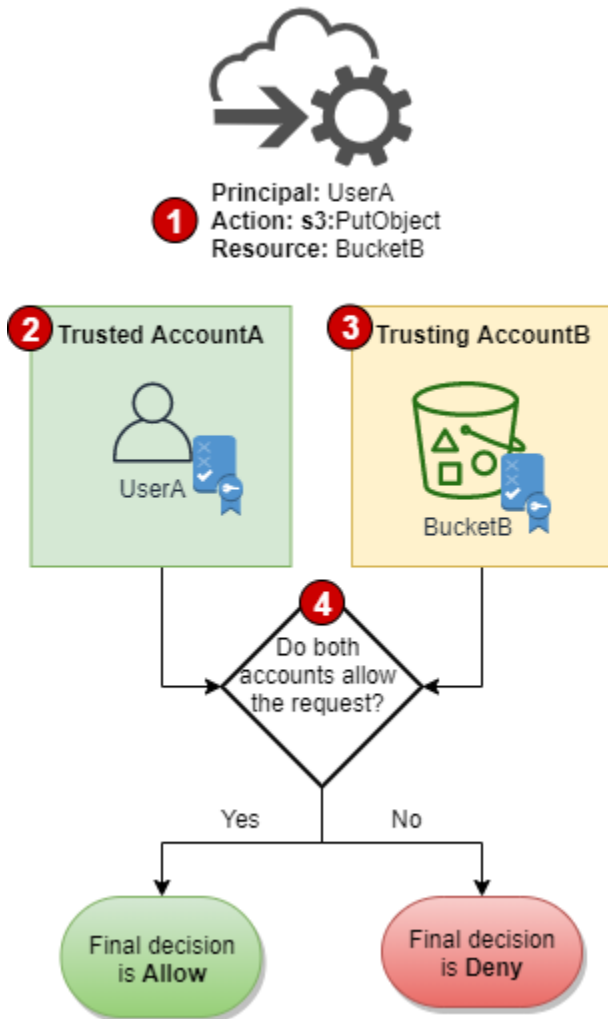

Other services can affect the policy evaluation logic. For example, AWS Organizations supports [service control policies](#) that can be applied to principals one or more accounts. AWS Resource Access Manager supports [policy fragments](#) that control which actions that principals are allowed to perform on resources that are shared with them.

Determining whether a cross-account request is allowed

For cross-account requests, the requester in the trusted AccountA must have an identity-based policy. That policy must allow them to make a request to the resource in the trusting AccountB.

Additionally, the resource-based policy in AccountB must allow the requester in AccountA to access the resource.

When you make a cross-account request, AWS performs two evaluations. AWS evaluates the request in the trusting account and the trusted account. For more information about how a request is evaluated within a single account, see [Determining whether a request is allowed or denied within an account](#). The request is allowed only if both evaluations return a decision of Allow.

1. When a principal in one account makes a request to access a resource in another account, this is a cross-account request.
2. The requesting principal exists in the trusted account (AccountA). When AWS evaluates this account, it checks the identity-based policy and any policies that can limit an identity-based policy. For more information, see [Evaluating policies within a single account](#).
3. The requested resource exists in the trusting account (AccountB). When AWS evaluates this account, it checks the resource-based policy that is attached to the requested resource and any

policies that can limit a resource-based policy. For more information, see [Evaluating policies within a single account](#).

4. AWS allows the request only if both account policy evaluations allow the request.

Example cross-account policy evaluation

The following example demonstrates a scenario where a user in one account is granted permissions by a resource-based policy in a second account.

Assume that Carlos is a developer with an IAM user named `carlossalazar` in account `111111111111`. He wants to save a file to the `Production-logs` Amazon S3 bucket in account `222222222222`.

Also assume that the following policy is attached to the `carlossalazar` IAM user.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "AllowS3ListRead",
      "Effect": "Allow",
      "Action": "s3:ListAllMyBuckets",
      "Resource": "*"
    },
    {
      "Sid": "AllowS3ProductionObjectActions",
      "Effect": "Allow",
      "Action": "s3:*Object*",
      "Resource": "arn:aws:s3:::Production/*"
    },
    {
      "Sid": "DenyS3Logs",
      "Effect": "Deny",
      "Action": "s3:*",
      "Resource": [
        "arn:aws:s3:::*log*",
        "arn:aws:s3:::*log*/*"
      ]
    }
  ]
}
```

The `AllowS3ListRead` statement in this policy allows Carlos to view a list of all of the buckets in Amazon S3. The `AllowS3ProductionObjectActions` statement allows Carlos full access to objects in the `Production` bucket. The `DenyS3Logs` statement denies Carlos access to any S3 bucket with `log` in its name. It also denies access to all objects in those buckets.

Additionally, the following resource-based policy (called a bucket policy) is attached to the `Production` bucket in account `222222222222`.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "s3:GetObject*",
        "s3:PutObject*",
        "s3:ReplicateObject",
        "s3:RestoreObject"
      ],
      "Principal": { "AWS": "arn:aws:iam::111111111111:user/carlossalazar" },
      "Resource": "arn:aws:s3:::Production/*"
    }
  ]
}
```

This policy allows the `carlossalazar` user to access objects in the `Production` bucket. He can create and edit, but not delete the objects in the bucket. He can't manage the bucket itself.

When Carlos makes his request to save a file to the `Production-logs` bucket, AWS determines what policies apply to the request. In this case, the identity-based policy attached to the `carlossalazar` user is the only policy that applies in account `111111111111`. In account `222222222222`, there is no resource-based policy attached to the `Production-logs` bucket. When AWS evaluates account `111111111111`, it returns a decision of `Deny`. This is because the `DenyS3Logs` statement in the identity-based policy explicitly denies access to any log buckets. For more information about how a request is evaluated within a single account, see [Determining whether a request is allowed or denied within an account](#).

Because the request is explicitly denied within one of the accounts, the final decision is to deny the request.

Principal: carlossalazar
Action: s3:PutObject
Resource: Production-logs

Assume that Carlos then realizes his mistake and tries to save the file to the `Production` bucket. AWS first checks account `11111111111111` to determine if the request is allowed. Only the identity-based policy applies, and it allows the request. AWS then checks account `222222222222`. Only the resource-based policy attached to the `Production` bucket applies, and it allows the request. Because both accounts allow the request, the final decision is to allow the request.

Principal: carlossalazar
 Action: s3:PutObject
 Resource: Production

Grammar of the IAM JSON policy language

This page presents a formal grammar for the language used to create JSON policies in IAM. We present this grammar so that you can understand how to construct and validate policies.

For examples of policies, see the following topics:

- [Policies and permissions in IAM](#)
- [Example IAM identity-based policies](#)
- [Example Policies for Working in the Amazon EC2 Console](#) and [Example Policies for Working With the AWS CLI, the Amazon EC2 CLI, or an AWS SDK](#) in the *Amazon EC2 User Guide for Linux Instances*.
- [Bucket Policy Examples](#) and [User Policy Examples](#) in the *Amazon Simple Storage Service User Guide*.

For examples of policies used in other AWS services, go to the documentation for those services.

Topics

- [The policy language and JSON](#)
- [Conventions used in this grammar](#)
- [Grammar](#)
- [Policy grammar notes](#)

The policy language and JSON

Policies are expressed in JSON. When you create or edit a JSON policy, IAM can perform policy validation to help you create an effective policy. IAM identifies JSON syntax errors, while IAM Access Analyzer provides additional policy checks with recommendations to help you further refine your policies. To learn more about policy validation, see [Validating IAM policies](#). To learn more about IAM Access Analyzer policy checks and actionable recommendations, see [IAM Access Analyzer policy validation](#).

In this document, we do not provide a complete description of what constitutes valid JSON. However, here are some basic JSON rules:

- White space between individual entities is allowed.
- Values are enclosed in quotation marks. Quotation marks are optional for numeric and Boolean values.
- Many elements (for example, `action_string_list` and `resource_string_list`) can take a JSON array as a value. Arrays can take one or more values. If more than one value is included, the array is in square brackets ([and]) and comma-delimited, as in the following example:

```
"Action" : ["ec2:Describe*", "ec2:List*"]
```

- Basic JSON data types (Boolean, number, and string) are defined in [RFC 7159](#).

Conventions used in this grammar

The following conventions are used in this grammar:

- The following characters are JSON tokens and *are* included in policies:

```
{ } [ ] " , :
```

- The following characters are special characters in the grammar and are *not* included in policies:

```
= < > ( ) |
```

- If an element allows multiple values, it is indicated using repeated values, a comma delimiter, and an ellipsis (...). Examples:

```
[<action_string>, <action_string>, ...]
```

```
<principal_map> = { <principal_map_entry>, <principal_map_entry>, ... }
```

If multiple values are allowed, it is also valid to include only one value. For only one value, the trailing comma must be omitted. If the element takes an array (marked with [and]) but only one value is included, the brackets are optional. Examples:

```
"Action": [<action_string>]
```

```
"Action": <action_string>
```

- A question mark (?) following an element indicates that the element is optional. Example:

```
<version_block?>
```

However, be sure to refer to the notes that follow the grammar listing for details about optional elements.

- A vertical line (|) between elements indicates alternatives. In the grammar, parentheses define the scope of the alternatives. Example:

```
("Principal" | "NotPrincipal")
```

- Elements that must be literal strings are enclosed in double quotation marks ("). Example:

```
<version_block> = "Version" : ("2008-10-17" | "2012-10-17")
```

For additional notes, see [Policy grammar notes](#) following the grammar listing.

Grammar

The following listing describes the policy language grammar. For conventions used in the listing, see the preceding section. For additional information, see the notes that follow.

Note

This grammar describes policies marked with a version of 2008-10-17 and 2012-10-17. A `Version` policy element is different from a policy version. The `Version` policy element is used within a policy and defines the version of the policy language. A policy version, on the other hand, is created when you make changes to a customer managed policy in IAM. The changed policy doesn't overwrite the existing policy. Instead, IAM creates a new version of the managed policy. To learn more about the `Version` policy element see [IAM JSON policy elements: Version](#). To learn more about policy versions, see [the section called "Versioning IAM policies"](#).

```

policy = {
  <version_block?>
  <id_block?>
  <statement_block>
}

<version_block> = "Version" : ("2008-10-17" | "2012-10-17")

<id_block> = "Id" : <policy_id_string>

<statement_block> = "Statement" : [ <statement>, <statement>, ... ]

<statement> = {
  <sid_block?>,
  <principal_block?>,
  <effect_block>,
  <action_block>,
  <resource_block>,
  <condition_block?>
}

<sid_block> = "Sid" : <sid_string>

<effect_block> = "Effect" : ("Allow" | "Deny")

<principal_block> = ("Principal" | "NotPrincipal") : ("*" | <principal_map>)

<principal_map> = { <principal_map_entry>, <principal_map_entry>, ... }

```

```

<principal_map_entry> = ("AWS" | "Federated" | "Service" | "CanonicalUser") :
    [<principal_id_string>, <principal_id_string>, ...]

<action_block> = ("Action" | "NotAction") :
    ("*" | [<action_string>, <action_string>, ...])

<resource_block> = ("Resource" | "NotResource") :
    : ("*" | <resource_string> | [<resource_string>, <resource_string>, ...])

<condition_block> = "Condition" : { <condition_map> }
<condition_map> = {
    <condition_type_string> : { <condition_key_string> : <condition_value_list> },
    <condition_type_string> : { <condition_key_string> : <condition_value_list> }, ...
}
<condition_value_list> = [<condition_value>, <condition_value>, ...]
<condition_value> = (<condition_value_string> | <condition_value_string> |
    <condition_value_string>)

```

Policy grammar notes

- A single policy can contain an array of statements.
- Policies have a maximum size between 2048 characters and 10,240 characters, depending on what entity the policy is attached to. For more information, see [IAM and AWS STS quotas](#). Policy size calculations do not include white space characters.
- Individual elements must not contain multiple instances of the same key. For example, you cannot include the Effect block twice in the same statement.
- Blocks can appear in any order. For example, `version_block` can follow `id_block` in a policy. Similarly, `effect_block`, `principal_block`, `action_block` can appear in any order within a statement.
- The `id_block` is optional in resource-based policies. It must *not* be included in identity-based policies.
- The `principal_block` element is required in resource-based policies (for example, in Amazon S3 bucket policies) and in trust policies for IAM roles. It must *not* be included in identity-based policies.
- The `principal_map` element in Amazon S3 bucket policies can include the `CanonicalUser` ID. Most resource-based policies do not support this mapping. To learn more about using the canonical user ID in a bucket policy, see [Specifying a Principal in a Policy](#) in the *Amazon Simple Storage Service User Guide*.

- Each string value (`policy_id_string`, `sid_string`, `principal_id_string`, `action_string`, `resource_string`, `condition_type_string`, `condition_key_string`, and the string version of `condition_value`) can have its own minimum and maximum length restrictions, specific allowed values, or required internal format.

Notes about string values

This section provides additional information about string values that are used in different elements in a policy.

`action_string`

Consists of a service namespace, a colon, and the name of an action. Action names can include wildcards. Examples:

```
"Action": "ec2:StartInstances"
```

```
"Action": [
  "ec2:StartInstances",
  "ec2:StopInstances"
]
```

```
"Action": "cloudformation:*"
```

```
"Action": "*"
```

```
"Action": [
  "s3:Get*",
  "s3:List*"
]
```

`policy_id_string`

Provides a way to include information about the policy as a whole. Some services, such as Amazon SQS and Amazon SNS, use the `Id` element in reserved ways. Unless otherwise restricted by an individual service, `policy_id_string` can include spaces. Some services require this value to be unique within an AWS account.

Note

The `id_block` is allowed in resource-based policies, but not in identity-based policies.

There is no limit to the length, although this string contributes to the overall length of the policy, which is limited.

```
"Id": "Admin_Policy"
```

```
"Id": "cd3ad3d9-2776-4ef1-a904-4c229d1642ee"
```

sid_string

Provides a way to include information about an individual statement. For IAM policies, basic alphanumeric characters (A-Z,a-z,0-9) are the only allowed characters in the `Sid` value. Other AWS services that support resource policies may have other requirements for the `Sid` value. For example, some services require this value to be unique within an AWS account, and some services allow additional characters such as spaces in the `Sid` value.

```
"Sid": "1"
```

```
"Sid": "ThisStatementProvidesPermissionsForConsoleAccess"
```

principal_id_string

Provides a way to specify a principal using the [Amazon Resource Name \(ARN\)](#) of the AWS account, IAM user, IAM role, federated user, or assumed-role user. For an AWS account, you can also use the short form `AWS:accountnumber` instead of the full ARN. For all of the options including AWS services, assumed roles, and so on, see [Specifying a principal](#).

Note that you can use `*` only to specify "everyone/anonymous." You cannot use it to specify part of a name or ARN.

resource_string

In most cases, consists of an [Amazon Resource Name \(ARN\)](#).

```
"Resource": "arn:aws:iam::123456789012:user/Bob"
```

```
"Resource": "arn:aws:s3:::examplebucket/*"
```

condition_type_string

Identifies the type of condition being tested, such as `StringEquals`, `StringLike`, `NumericLessThan`, `DateGreaterThanEquals`, `Bool`, `BinaryEquals`, `IpAddress`, `ArnEquals`, etc. For a complete list of condition types, see [IAM JSON policy elements: Condition operators](#).

```
"Condition": {
  "NumericLessThanEquals": {
    "s3:max-keys": "10"
  }
}

"Condition": {
  "Bool": {
    "aws:SecureTransport": "true"
  }
}

"Condition": {
  "StringEquals": {
    "s3:x-amz-server-side-encryption": "AES256"
  }
}
```

condition_key_string

Identifies the condition key whose value will be tested to determine whether the condition is met. AWS defines a set of condition keys that are available in all AWS services, including `aws:PrincipalType`, `aws:SecureTransport`, and `aws:user-id`.

For a list of AWS condition keys, see [AWS global condition context keys](#). For condition keys that are specific to a service, see the documentation for that service such as the following:

- [Specifying Conditions in a Policy](#) in the *Amazon Simple Storage Service User Guide*
- [IAM Policies for Amazon EC2](#) in the *Amazon EC2 User Guide for Linux Instances*.

```
"Condition": {
  "Bool": {
```

```
    "aws:SecureTransport": "true"
  }
}

"Condition": {
  "StringNotEquals": {
    "s3:x-amz-server-side-encryption": "AES256"
  }
}

"Condition": {
  "StringEquals": {
    "aws:ResourceTag/purpose": "test"
  }
}
```

condition_value_string

Identifies the value of the `condition_key_string` that determines whether the condition is met. For a complete list of valid values for a condition type, see [IAM JSON policy elements: Condition operators](#).

```
"Condition":{
  "ForAnyValue:StringEquals": {
    "dynamodb:Attributes": [
      "ID",
      "PostDateTime"
    ]
  }
}
```

AWS managed policies for job functions

We recommend using policies that [grant least privilege](#), or granting only the permissions required to perform a task. The most secure way to grant least privilege is to write a custom policy with only the permissions needed by your team. You must create a process to allow your team to request more permissions when necessary. It takes time and expertise to [create IAM customer managed policies](#) that provide your team with only the permissions they need.

To get started adding permissions to your IAM identities (users, groups of users, and roles), you can use [AWS managed policies](#). AWS managed policies cover common use cases and are available

in your AWS account. AWS managed policies don't grant least privilege permissions. You must consider the security risk of granting your principals more permissions than they need to do their job.

You can attach AWS managed policies, including job functions, to any IAM identity. To switch to least privilege permissions, you can run AWS Identity and Access Management Access Analyzer to monitor principals with AWS managed policies. After learning which permissions they are using, then you can write a custom policy or generate a policy with only the required permissions for your team. This is less secure, but provides more flexibility as you learn how your team is using AWS.

AWS managed policies for job functions are designed to closely align to common job functions in the IT industry. You can use these policies to grant the permissions needed to carry out the tasks expected of someone in a specific job function. These policies consolidate permissions for many services into a single policy that's easier to work with than having permissions scattered across many policies.

Use Roles to Combine Services

Some of the policies use IAM service roles to help you take advantage of features found in other AWS services. These policies grant access to `iam:passrole`, which allows a user with the policy to pass a role to an AWS service. This role delegates IAM permissions to the AWS service to carry out actions on your behalf.

You must create the roles according to your needs. For example, the Network Administrator policy allows a user with the policy to pass a role named "flow-logs-vpc" to the Amazon CloudWatch service. CloudWatch uses that role to log and capture IP traffic for VPCs created by the user.

To follow security best practices, the policies for job functions include filters that limit the names of valid roles that can be passed. This helps avoid granting unnecessary permissions. If your users do require the optional service roles, you must create a role that follows the naming convention specified in the policy. You then grant permissions to the role. Once that is done, the user can configure the service to use the role, granting it whatever permissions the role provides.

In the following sections, each policy's name is a link to the policy details page in the AWS Management Console. There you can see the policy document and review the permissions it grants.

Administrator job function

AWS managed policy name: [AdministratorAccess](#)

Use case: This user has full access and can delegate permissions to every service and resource in AWS.

Policy updates: AWS maintains and updates this policy. For a history of changes for this policy, view the policy in the IAM console and then choose the **Policy versions** tab. For more information about job function policy updates, see [Updates to AWS managed policies for job functions](#).

Policy description: This policy grants all actions for all AWS services and for all resources in the account.

Note

Before an IAM user or role can access the AWS Billing and Cost Management console with the permissions in this policy, you must first activate IAM user and role access. To do this, follow the instructions in [Step 1 of the tutorial about delegating access to the billing console](#).

Billing job function

AWS managed policy name: [Billing](#)

Use case: This user needs to view billing information, set up payments, and authorize payments. The user can monitor the costs accumulated for the entire AWS service.

Policy updates: AWS maintains and updates this policy. For a history of changes for this policy, view the policy in the IAM console and then choose the **Policy versions** tab. For more information about job function policy updates, see [Updates to AWS managed policies for job functions](#).

Policy description: This policy grants full permissions for managing billing, costs, payment methods, budgets, and reports. For additional cost management policy examples, see [AWS Billing policy examples](#) in the *AWS Billing and Cost Management User Guide*

Note

Before an IAM user or role can access the AWS Billing and Cost Management console with the permissions in this policy, you must first activate IAM user and role access. To do this, follow the instructions in [Step 1 of the tutorial about delegating access to the billing console](#).

Database administrator job function

AWS managed policy name: [DatabaseAdministrator](#)

Use case: This user sets up, configures, and maintains databases in the AWS Cloud.

Policy updates: AWS maintains and updates this policy. For a history of changes for this policy, view the policy in the IAM console and then choose the **Policy versions** tab. For more information about job function policy updates, see [Updates to AWS managed policies for job functions](#).

Policy description: This policy grants permissions to create, configure, and maintain databases. It includes access to AWS database services, such as Amazon DynamoDB, Amazon Relational Database Service (RDS), and Amazon Redshift. View the policy for the full list of database services that this policy supports.

This job function policy supports the ability to pass roles to AWS services. The policy allows the `iam:PassRole` action for only those roles named in the following table. For more information, see [Creating roles and attaching policies \(console\)](#) later in this topic.

Optional IAM service roles for the database administrator job function

Use case	Role name (* is a wildcard)	Service role type to select	Select this AWS managed policy
Allow the user to monitor RDS databases	rds-monitoring-role	Amazon RDS Role for Enhanced Monitoring	AmazonRDSEnhancedMonitoringRole
Allow AWS Lambda to monitor your database and access external databases	rdbms-lambda-access	Amazon EC2	AWSLambda_FullAccess
Allow Lambda to upload files to Amazon S3 and to Amazon Redshift clusters with DynamoDB	lambda_exec_role	AWS Lambda	Create a new managed policy as defined in the AWS Big Data Blog

Use case	Role name (* is a wildcard)	Service role type to select	Select this AWS managed policy
Allow Lambda functions to act as triggers for your DynamoDB tables	lambda-dynamodb-*	AWS Lambda	AWSLambdaDynamoDBExecutionRole
Allow Lambda functions to access Amazon RDS in a VPC	lambda-vpc-execution-role	Create a role with a trust policy as defined in the AWS Lambda Developer Guide	AWSLambdaVPCAccessExecutionRole
Allow AWS Data Pipeline to access your AWS resources	DataPipelineDefaultRole	Create a role with a trust policy as defined in the AWS Data Pipeline Developer Guide	The AWS Data Pipeline documentation lists the required permissions for this use case. See IAM roles for AWS Data Pipeline
Allow your applications running on Amazon EC2 instances to access your AWS resources	DataPipelineDefaultResourceRole	Create a role with a trust policy as defined in the AWS Data Pipeline Developer Guide	AmazonEC2RoleforDataPipelineRole

Data scientist job function

AWS managed policy name: [DataScientist](#)

Use case: This user runs Hadoop jobs and queries. The user also accesses and analyzes information for data analytics and business intelligence.

Policy updates: AWS maintains and updates this policy. For a history of changes for this policy, view the policy in the IAM console and then choose the **Policy versions** tab. For more information about job function policy updates, see [Updates to AWS managed policies for job functions](#).

Policy description: This policy grants permissions to create, manage, and run queries on an Amazon EMR cluster and perform data analytics with tools such as Amazon QuickSight. The policy includes access to additional data scientist services, such as AWS Data Pipeline, Amazon EC2, Amazon Kinesis, Amazon Machine Learning, and SageMaker. View the policy for the full list of data scientist services that this policy supports.

This job function policy supports the ability to pass roles to AWS services. One statement allows passing any role to SageMaker. Another statement allows the `iam:PassRole` action for only those roles named in the following table. For more information, see [Creating roles and attaching policies \(console\)](#) later in this topic.

Optional IAM service roles for the data scientist job function

Use case	Role name (* is a wildcard)	Service role type to select	AWS managed policy to select
Allow Amazon EC2 instances access to services and resources suitable for clusters	EMR-EC2_DefaultRole	Amazon EMR for EC2	AmazonElasticMapReduceforEC2Role
Allow Amazon EMR access to access the Amazon EC2 service and resources for clusters	EMR_DefaultRole	Amazon EMR	AmazonEMRServicePolicy_v2
Allow Kinesis Managed Service for Apache Flink to access streaming data sources	kinesis-*	Create a role with a trust policy as defined in the AWS Big Data Blog .	See the AWS Big Data Blog , which outlines four possible options depending on your use case
Allow AWS Data Pipeline to access your AWS resources	DataPipelineDefaultRole	Create a role with a trust policy as defined in the AWS Data Pipeline Developer Guide	The AWS Data Pipeline documentation lists the required permissions for this use case. See IAM

Use case	Role name (* is a wildcard)	Service role type to select	AWS managed policy to select
			roles for AWS Data Pipeline
Allow your applications running on Amazon EC2 instances to access your AWS resources	DataPipelineDefaultResourceRole	Create a role with a trust policy as defined in the AWS Data Pipeline Developer Guide	AmazonEC2RoleforDataPipelineRole

Developer power user job function

AWS managed policy name: [PowerUserAccess](#)

Use case: This user performs application development tasks and can create and configure resources and services that support AWS aware application development.

Policy updates: AWS maintains and updates this policy. For a history of changes for this policy, view the policy in the IAM console and then choose the **Policy versions** tab. For more information about job function policy updates, see [Updates to AWS managed policies for job functions](#).

Policy description: The first statement of this policy uses the [NotAction](#) element to allow all actions for all AWS services and for all resources except AWS Identity and Access Management, AWS Organizations, and AWS Account Management. The second statement grants IAM permissions to create a service-linked role. This is required by some services that must access resources in another service, such as an Amazon S3 bucket. It also grants Organizations permissions to view information about the user's organization, including the management account email and organization limitations. Although this policy limits IAM, Organizations, it allows the user to perform all IAM Identity Center actions if IAM Identity Center is enabled. It also grants Account Management permissions to view which AWS Regions are enabled or disabled for the account.

Network administrator job function

AWS managed policy name: [NetworkAdministrator](#)

Use case: This user is tasked with setting up and maintaining AWS network resources.

Policy updates: AWS maintains and updates this policy. For a history of changes for this policy, view the policy in the IAM console and then choose the **Policy versions** tab. For more information about job function policy updates, see [Updates to AWS managed policies for job functions](#).

Policy description: This policy grants permissions to create and maintain network resources in Auto Scaling, Amazon EC2, AWS Direct Connect, Route 53, Amazon CloudFront, Elastic Load Balancing, AWS Elastic Beanstalk, Amazon SNS, CloudWatch, CloudWatch Logs, Amazon S3, IAM, and Amazon Virtual Private Cloud.

This job function requires the ability to pass roles to AWS services. The policy grants `iam:GetRole` and `iam:PassRole` for only those roles named in the following table. For more information, see [Creating roles and attaching policies \(console\)](#) later in this topic.

Optional IAM service roles for the network administrator job function

Use case	Role name (* is a wildcard)	Service role type to select	AWS managed policy to select
Allows Amazon VPC to create and manage logs in CloudWatch Logs on the user's behalf to monitor IP traffic going in and out of your VPC	flow-logs-*	Create a role with a trust policy as defined in the Amazon VPC User Guide	This use case does not have an existing AWS managed policy, but the documentation lists the required permissions. See Amazon VPC User Guide .

Read-only access

AWS managed policy name: [ReadOnlyAccess](#)

Use case: This user requires read-only access to every resource in an AWS account.

Policy updates: AWS maintains and updates this policy. For a history of changes for this policy, view the policy in the IAM console and then choose the **Policy versions** tab. For more information about job function policy updates, see [Updates to AWS managed policies for job functions](#).

Policy description: This policy grants permissions to list, get, describe, and otherwise view resources and their attributes. It does not include mutating functions like create or delete. This

policy does include read-only access to security-related AWS services, such as AWS Identity and Access Management and AWS Billing and Cost Management. View the policy for the full list of services and actions that this policy supports.

Security auditor job function

AWS managed policy name: [SecurityAudit](#)

Use case: This user monitors accounts for compliance with security requirements. This user can access logs and events to investigate potential security breaches or potential malicious activity.

Policy updates: AWS maintains and updates this policy. For a history of changes for this policy, view the policy in the IAM console and then choose the **Policy versions** tab. For more information about job function policy updates, see [Updates to AWS managed policies for job functions](#).

Policy description: This policy grants permissions to view configuration data for many AWS services and to review their logs.

Support user job function

AWS managed policy name: [SupportUser](#)

Use case: This user contacts AWS Support, creates support cases, and views the status of existing cases.

Policy updates: AWS maintains and updates this policy. For a history of changes for this policy, view the policy in the IAM console and then choose the **Policy versions** tab. For more information about job function policy updates, see [Updates to AWS managed policies for job functions](#).

Policy description: This policy grants permissions to create and update AWS Support cases.

System administrator job function

AWS managed policy name: [SystemAdministrator](#)

Use case: This user sets up and maintains resources for development operations.

Policy updates: AWS maintains and updates this policy. For a history of changes for this policy, view the policy in the IAM console and then choose the **Policy versions** tab. For more information about job function policy updates, see [Updates to AWS managed policies for job functions](#).

Policy description: This policy grants permissions to create and maintain resources across a large variety of AWS services, including AWS CloudTrail, Amazon CloudWatch, AWS CodeCommit,

AWS CodeDeploy, AWS Config, AWS Directory Service, Amazon EC2, AWS Identity and Access Management, AWS Key Management Service, AWS Lambda, Amazon RDS, Route 53, Amazon S3, Amazon SES, Amazon SQS, AWS Trusted Advisor, and Amazon VPC.

This job function requires the ability to pass roles to AWS services. The policy grants `iam:GetRole` and `iam:PassRole` for only those roles named in the following table. For more information, see [Creating roles and attaching policies \(console\)](#) later in this topic.

Optional IAM service roles for the system administrator job function

Use case	Role name (* is a wildcard)	Service role type to select	AWS managed policy to select
Allow apps running in EC2 instances in an Amazon ECS cluster to access Amazon ECS	ecr-sysadmin-*	Amazon EC2 Role for EC2 Container Service	AmazonEC2ContainerServiceforEC2Role
Allow a user to monitor databases	rds-monitoring-role	Amazon RDS Role for Enhanced Monitoring	AmazonRDSEnhancedMonitoringRole
Allow apps running in EC2 instances to access AWS resources.	ec2-sysadmin-*	Amazon EC2	Sample policy for role that grants access to an S3 bucket as shown in the Amazon EC2 User Guide for Linux Instances ; customize as needed
Allow Lambda to read DynamoDB streams and write to CloudWatch Logs	lambda-sysadmin-*	AWS Lambda	AWSLambdaDynamoDBExecutionRole

View-only user job function

AWS managed policy name: [ViewOnlyAccess](#)

Use case: This user can view a list of AWS resources and basic metadata in the account across services. The user cannot read resource content or metadata that goes beyond the quota and list information for resources.

Policy updates: AWS maintains and updates this policy. For a history of changes for this policy, view the policy in the IAM console and then choose the **Policy versions** tab. For more information about job function policy updates, see [Updates to AWS managed policies for job functions](#).

Policy description: This policy grants List*, Describe*, Get*, View*, and Lookup* access to resources for AWS services. To see what actions this policy includes for each service, see [ViewOnlyAccess](#).

Updates to AWS managed policies for job functions

These policies are all maintained by AWS and are kept up to date to include support for new services and new capabilities as they are added by AWS services. These policies cannot be modified by customers. You can make a copy of the policy and then modify the copy, but that copy is not automatically updated as AWS introduces new services and API operations.

For a job function policy, you can view the version history and the time and date of each update in the IAM console. To do this, use the links on this page to view the policy details. Then choose the **Policy versions** tab to view the versions. This page shows the last 25 versions of a policy. To view all of the versions for a policy, call the [get-policy-version](#) AWS CLI command or the [GetPolicyVersion](#) API operation.

Note

You can have up to five versions of a customer managed policy, but AWS retains the full version history of AWS managed policies.

Creating roles and attaching policies (console)

Several of the previously listed policies grant the ability to configure AWS services with roles that enable those services to perform operations on your behalf. The job function policies either specify exact role names that you must use or at least include a prefix that specifies the first part of the name that can be used. To create one of these roles, perform the steps in the following procedure.

To create a role for an AWS service (IAM console)

1. Sign in to the AWS Management Console and open the IAM console at <https://console.aws.amazon.com/iam/>.
2. In the navigation pane of the IAM console, choose **Roles**, and then choose **Create role**.
3. For **Trusted entity type**, choose **AWS service**.
4. For **Service or use case**, choose a service, and then choose the use case. Use cases are defined by the service to include the trust policy that the service requires.
5. Choose **Next**.
6. For **Permissions policies**, the options depend on the use case that you selected:
 - If the service defines the permissions for the role, you can't select permissions policies.
 - Select from a limited set of permission polices.
 - Select from all permission policies.
 - Select no permissions policies, create the policies after the role is create, and then attach the policies to the role.
7. (Optional) Set a [permissions boundary](#). This is an advanced feature that is available for service roles, but not service-linked roles.
 - a. Open the **Set permissions boundary** section, and then choose **Use a permissions boundary to control the maximum role permissions**.

IAM includes a list of the AWS managed and customer-managed policies in your account.
 - b. Select the policy to use for the permissions boundary.
8. Choose **Next**.
9. For **Role name**, the options depend on the service:
 - If the service defines the role name, you can't edit the role name.
 - If the service defines a prefix for the role name, you can enter an optional suffix.
 - If the service doesn't define the role name, you can name the role.

Important

When you name a role, note the following:

- Role names must be unique within your AWS account, and can't be made unique by case.

For example, don't create roles named both **PRODRole** and **prodrole**. When a role name is used in a policy or as part of an ARN, the role name is case sensitive, however when a role name appears to customers in the console, such as during the sign-in process, the role name is case insensitive.

- You can't edit the name of the role after it's created because other entities might reference the role.

10. (Optional) For **Description**, enter a description for the role.
11. (Optional) To edit the use cases and permissions for the role, in the **Step 1: Select trusted entities** or **Step 2: Add permissions** sections, choose **Edit**.
12. (Optional) To help identify, organize, or search for the role, add tags as key-value pairs. For more information about using tags in IAM, see [Tagging IAM resources](#) in the *IAM User Guide*.
13. Review the role, and then choose **Create role**.

Example 1: Configuring a user as a database administrator (console)

This example shows the steps required to configure Alice, an IAM user, as a [Database Administrator](#). You use the information in first row of the table in that section and allow the user to enable Amazon RDS monitoring. You attach the [DatabaseAdministrator](#) policy to Alice's IAM user so that they can manage the Amazon database services. That policy also allows Alice to pass a role called `rds-monitoring-role` to the Amazon RDS service that allows the service to monitor the Amazon RDS databases on their behalf.

1. Sign in to the AWS Management Console and open the IAM console at <https://console.aws.amazon.com/iam/>.
2. Choose **Policies**, type **database** in the search box, and then press enter.
3. Select the radio button for the **DatabaseAdministrator** policy, choose **Actions**, and then choose **Attach**.
4. In the list of entities, select **Alice** and then choose **Attach policy**. Alice now can administer AWS databases. However, to allow Alice to monitor those databases, you must configure the service role.
5. In the navigation pane of the IAM console, choose **Roles**, and then choose **Create role**.
6. Choose the **AWS Service** role type, and then choose **Amazon RDS**.
7. Choose the **Amazon RDS Role for Enhanced Monitoring** use case.

8. Amazon RDS defines the permissions for your role. Choose **Next: Review** to continue.
9. The role name must be one of those specified by the DatabaseAdministrator policy that Alice now has. One of those is **rds-monitoring-role**. Enter that for the **Role name**.
10. (Optional) For **Role description**, enter a description for the new role.
11. After you review the details, choose **Create role**.
12. Alice can now enable **RDS Enhanced Monitoring** in the **Monitoring** section of the Amazon RDS console. For example, they might do this when they create a DB instance, create a read replica, or modify a DB instance. They must enter the role name they created (rds-monitoring-role) in the **Monitoring Role** box when they set **Enable Enhanced Monitoring** to **Yes**.

Example 2: Configuring a user as a network administrator (console)

This example shows the steps required to configure Jorge, an IAM user, as a [Network Administrator](#). It uses the information in the table in that section to allow Jorge to monitor IP traffic going to and from a VPC. It also allows Jorge to capture that information in the logs in CloudWatch Logs. You attach the [NetworkAdministrator](#) policy to Jorge's IAM user so that they can configure AWS network resources. That policy also allows Jorge to pass a role whose name begins with `flow-logs*` to Amazon EC2 when you create a flow log. In this scenario, unlike Example 1, there isn't a predefined service role type, so you must perform a few steps differently.

1. Sign in to the AWS Management Console and open the IAM console at <https://console.aws.amazon.com/iam/>.
2. In the navigation pane, choose **Policies** and then enter **network** in the search box, and then press enter.
3. Select the radio button next to **NetworkAdministrator** policy, choose **Actions**, and then choose **Attach**.
4. In the list of users, select the check box next to **Jorge** and then choose **Attach policy**. Jorge can now administer AWS network resources. However, to enable monitoring of IP traffic in your VPC, you must configure the service role.
5. Because the service role you need to create doesn't have a predefined managed policy, you must first create it. In the navigation pane, choose **Policies**, then choose **Create policy**.
6. In the **Policy editor** section, choose the **JSON** option and copy the text from the following JSON policy document. Paste this text into the **JSON** text box.

```
{
```

```
"Version": "2012-10-17",
"Statement": [
  {
    "Action": [
      "logs:CreateLogGroup",
      "logs:CreateLogStream",
      "logs:PutLogEvents",
      "logs:DescribeLogGroups",
      "logs:DescribeLogStreams"
    ],
    "Effect": "Allow",
    "Resource": "*"
  }
]
```

7. Resolve any security warnings, errors, or general warnings generated during [policy validation](#), and then choose **Next**.

 **Note**

You can switch between the **Visual** and **JSON** editor options any time. However, if you make changes or choose **Next** in the **Visual** editor, IAM might restructure your policy to optimize it for the visual editor. For more information, see [Policy restructuring](#).

8. On the **Review and create** page, type **vpc-flow-logs-policy-for-service-role** for the policy name. Review the **Permissions defined in this policy** to see the permissions granted by your policy, and then choose **Create policy** to save your work.

The new policy appears in the list of managed policies and is ready to attach.

9. In the navigation pane of the IAM console, choose **Roles**, and then choose **Create role**.
10. Choose the **AWS Service** role type, and then choose **Amazon EC2**.
11. Choose the **Amazon EC2** use case.
12. On the **Attach permissions policies** page, choose the policy you created earlier, **vpc-flow-logs-policy-for-service-role**, and then choose **Next: Review**.
13. The role name must be permitted by the NetworkAdministrator policy that Jorge now has. Any name that begins with `flow-logs-` is allowed. For this example, enter **flow-logs-for-jorge** for the **Role name**.
14. (Optional) For **Role description**, enter a description for the new role.

15. After you review the details, choose **Create role**.
16. Now you can configure the trust policy required for this scenario. On the **Roles** page, choose the **flow-logs-for-jorge** role (the name, not the check box). On the details page for your new role, choose the **Trust relationships** tab, and then choose **Edit trust relationship**.
17. Change the "Service" line to read as follows, replacing the entry for `ec2.amazonaws.com`:

```
"Service": "vpc-flow-logs.amazonaws.com"
```

18. Jorge can now create flow logs for a VPC or subnet in the Amazon EC2 console. When you create the flow log, specify the **flow-logs-for-jorge** role. That role has the permissions to create the log and write data to it.

AWS global condition context keys

When a [principal](#) makes a [request](#) to AWS, AWS gathers the request information into a [request context](#). You can use the `Condition` element of a JSON policy to compare keys in the request context with key values that you specify in your policy. Request information is provided by different sources, including the principal making the request, the resource the request is made against, and the metadata about the request itself.

Global condition keys can be used across all AWS services. While these condition keys can be used in all policies, the key is not available in every request context. For example, the `aws:SourceAccount` condition key is only available when the call to your resource is made directly by an [AWS service principal](#). To learn more about the circumstances under which a global key is included in the request context, see the **Availability** information for each key.

Some individual services create their own condition keys that are available in the request context for other services. **Cross-service condition keys** are a type of global condition key that include a prefix matching the name of the service, such as `ec2:` or `lambda:`, but are available across other services.

Service-specific condition keys are defined for use with an individual AWS service. For example, Amazon S3 lets you write a policy with the `s3:VersionId` condition key to limit access to a specific version of an Amazon S3 object. This condition key is unique to the service, meaning it only works with requests to the Amazon S3 service. For condition keys that are service-specific, see [Actions, Resources, and Condition Keys for AWS Services](#) and choose the service whose keys you want to view.

Note

If you use condition keys that are available only in some circumstances, you can use the [IfExists](#) versions of the condition operators. If the condition keys are missing from a request context, the policy can fail the evaluation. For example, use the following condition block with `IfExists` operators to match when a request comes from a specific IP range or from a specific VPC. If either or both keys are not included in the request context, the condition still returns `true`. The values are only checked if the specified key is included in the request context.

```
"Condition": {
  "IpAddressIfExists": {"aws:SourceIp" : ["xxx"] },
  "StringEqualsIfExists" : {"aws:SourceVpc" : ["yyy"]}
}
```

Important

To compare your condition against a request context with multiple key values, you must use the `ForAllValues` or `ForAnyValue` set operators. Use set operators only with multivalued condition keys. Do not use set operators with single-valued condition keys. For more information, see [Multivalued context keys](#).

Properties of the principal	Properties of a role session	Properties of the network	Properties of the resource	Properties of the request
aws:PrincipalArn	aws:FederatedProvider	aws:SourceIp	aws:ResourceAccount	aws:CalledVia
aws:PrincipalAccount	aws:TokenIssueTime	aws:SourceVpc	aws:ResourceOrgPaths	aws:CalledViaFirst
aws:PrincipalOrgPaths	aws:MultiFactorAuthAge	aws:VpcSourceIp	aws:ResourceOrgID	aws:CalledViaLast
aws:PrincipalOrgID			aws:ResourceOrgID	aws:ViaAWSService
			aws:ResourceTag/tag-key	

Properties of the principal	Properties of a role session	Properties of the network	Properties of the resource	Properties of the request
aws:PrincipalTag/tag-key	aws:MultiFactorAuthPresent			aws:CurrentTime
aws:PrincipalIsAWSService	aws:Ec2InstanceSourceVpc			aws:EpochTime
aws:PrincipalServiceName	aws:Ec2InstanceSourcePrivateIpv4			aws:referrer
aws:PrincipalServiceNamesList	aws:SourceIdentity			aws:RequestedRegion
aws:PrincipalType	ec2:RoleDelivery			aws:RequestedTag/tag-key
aws:userid	ec2:SourceInstanceArn			aws:TagKeys
aws:username	glue:RoleAssumedBy			aws:SecureTransport
	glue:CredentialssuingService			aws:SourceArn
	lambda:SourceFunctionArn			aws:SourceAccount
	ssm:SourceInstanceArn			aws:SourceOrgPaths
	identitystore:UserId			aws:SourceOrgID
				aws:UserAgent

Properties of the principal

Use the following condition keys to compare details about the principal making the request with the principal properties that you specify in the policy. For a list of principals that can make requests, see [Specifying a principal](#).

Contents

- [aws:PrincipalArn](#)
- [aws:PrincipalAccount](#)
- [aws:PrincipalOrgPaths](#)
- [aws:PrincipalOrgID](#)
- [aws:PrincipalTag/tag-key](#)
- [aws:PrincipalsAWSService](#)
- [aws:PrincipalServiceName](#)
- [aws:PrincipalServiceNamesList](#)
- [aws:PrincipalType](#)
- [aws:userid](#)
- [aws:username](#)

aws:PrincipalArn

Use this key to compare the [Amazon Resource Name](#) (ARN) of the principal that made the request with the ARN that you specify in the policy. For IAM roles, the request context returns the ARN of the role, not the ARN of the user that assumed the role.

- **Availability** – This key is included in the request context for all signed requests. Anonymous requests do not include this key. You can specify the following types of principals in this condition key:
 - IAM role
 - IAM user
 - AWS STS federated user session
 - AWS account root user
- **Data type** – ARN, String

AWS recommends that you use [ARN operators](#) instead of [string operators](#) when comparing ARNs.

- **Value type** – Single-valued
- **Example values** The following list shows the request context value returned for different types of principals that you can specify in the `aws:PrincipalArn` condition key:
 - **IAM role** – The request context contains the following value for condition key `aws:PrincipalArn`. Do not specify the assumed role session ARN as a value for this condition key. For more information about the assumed role session principal, see [Role session principals](#).

```
arn:aws:iam::123456789012:role/role-name
```

- **IAM user** – The request context contains the following value for condition key `aws:PrincipalArn`.

```
arn:aws:iam::123456789012:user/user-name
```

- **AWS STS federated user sessions** – The request context contains the following value for condition key `aws:PrincipalArn`.

```
arn:aws:sts::123456789012:federated-user/user-name
```

- **AWS account root user** – The request context contains the following value for condition key `aws:PrincipalArn`. When you specify the root user ARN as the value for the `aws:PrincipalArn` condition key, it limits permissions only for the root user of the AWS account. This is different from specifying the root user ARN in the principal element of a resource-based policy, which delegates authority to the AWS account. For more information about specifying the root user ARN in the principal element of a resource-based policy, see [AWS account principals](#).

```
arn:aws:iam::123456789012:root
```

You can specify the root user ARN as a value for condition key `aws:PrincipalArn` in AWS Organizations service control policies (SCPs). SCPs are a type of organization policy used to manage permissions in your organization and affect only member accounts in the organization. An SCP restricts permissions for IAM users and roles in member accounts, including the member

account's root user. For more information about the effect of SCPs on permissions, see [SCP effects on permissions](#) in the *Organizations User Guide*.

aws:PrincipalAccount

Use this key to compare the account to which the requesting principal belongs with the account identifier that you specify in the policy. For anonymous requests, the request context returns anonymous.

- **Availability** – This key is included in the request context for all requests, including anonymous requests.
- **Data type** – [String](#)
- **Value type** – Single-valued

In the following example, access is denied except to principals with the account number 123456789012.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "DenyAccessFromPrincipalNotInSpecificAccount",
      "Action": "service:*",
      "Effect": "Deny",
      "Resource": [
        "arn:aws:service:region:accountID:resource"
      ],
      "Condition": {
        "StringNotEquals": {
          "aws:PrincipalAccount": [
            "123456789012"
          ]
        }
      }
    }
  ]
}
```

aws:PrincipalOrgPaths

Use this key to compare the AWS Organizations path for the principal who is making the request to the path in the policy. That principal can be an IAM user, IAM role, federated user, or AWS account root user. In a policy, this condition key ensures that the requester is an account member within the specified organization root or organizational units (OUs) in AWS Organizations. An AWS Organizations path is a text representation of the structure of an Organizations entity. For more information about using and understanding paths, see [Understand the AWS Organizations entity path](#).

- **Availability** – This key is included in the request context only if the principal is a member of an organization. Anonymous requests do not include this key.
- **Data type** – [String](#) (list)
- **Value type** – Multivalued

Note

Organization IDs are globally unique but OU IDs and root IDs are unique only within an organization. This means that no two organizations share the same organization ID. However, another organization might have an OU or root with the same ID as yours. We recommend that you always include the organization ID when you specify an OU or root.

For example, the following condition returns `true` for principals in accounts that are attached directly to the `ou-ab12-22222222` OU, but not in its child OUs.

```
"Condition" : { "ForAnyValue:StringEquals" : {  
    "aws:PrincipalOrgPaths":["o-a1b2c3d4e5/r-ab12/ou-ab12-11111111/ou-ab12-22222222/"]  
  }  
}}
```

The following condition returns `true` for principals in an account that is attached directly to the OU or any of its child OUs. When you include a wildcard, you must use the `StringLike` condition operator.

```
"Condition" : { "ForAnyValue:StringLike" : {  
    "aws:PrincipalOrgPaths":["o-a1b2c3d4e5/r-ab12/ou-ab12-11111111/ou-ab12-22222222/  
*"]  
  }  
}}
```

The following condition returns `true` for principals in an account that is attached directly to any of the child OUs, but not directly to the parent OU. The previous condition is for the OU or any children. The following condition is for only the children (and any children of those children).

```
"Condition" : { "ForAnyValue:StringLike" : {
  "aws:PrincipalOrgPaths":["o-a1b2c3d4e5/r-ab12/ou-ab12-11111111/ou-ab12-22222222/ou-*"]
}}
```

The following condition allows access for every principal in the `o-a1b2c3d4e5` organization, regardless of their parent OU.

```
"Condition" : { "ForAnyValue:StringLike" : {
  "aws:PrincipalOrgPaths":["o-a1b2c3d4e5/*"]
}}
```

`aws:PrincipalOrgPaths` is a multivalued condition key. Multivalued keys can have multiple values in the request context. When you use multiple values with the `ForAnyValue` condition operator, the principal's path must match one of the paths listed in the policy. For more information about multivalued condition keys, see [Multivalued context keys](#).

```
"Condition": {
  "ForAnyValue:StringLike": {
    "aws:PrincipalOrgPaths": [
      "o-a1b2c3d4e5/r-ab12/ou-ab12-33333333/*",
      "o-a1b2c3d4e5/r-ab12/ou-ab12-22222222/*"
    ]
  }
}
```

`aws:PrincipalOrgID`

Use this key to compare the identifier of the organization in AWS Organizations to which the requesting principal belongs with the identifier specified in the policy.

- **Availability** – This key is included in the request context only if the principal is a member of an organization. Anonymous requests do not include this key.
- **Data type** – [String](#)
- **Value type** – Single-valued

This global key provides an alternative to listing all the account IDs for all AWS accounts in an organization. You can use this condition key to simplify specifying the `Principal` element in a [resource-based policy](#). You can specify the [organization ID](#) in the condition element. When you add and remove accounts, policies that include the `aws:PrincipalOrgID` key automatically include the correct accounts and don't require manual updating.

For example, the following Amazon S3 bucket policy allows members of any account in the o-xxxxxxxxxxx organization to add an object into the `policy-ninja-dev` bucket.

```
{
  "Version": "2012-10-17",
  "Statement": {
    "Sid": "AllowPutObject",
    "Effect": "Allow",
    "Principal": "*",
    "Action": "s3:PutObject",
    "Resource": "arn:aws:s3:::policy-ninja-dev/*",
    "Condition": {"StringEquals":
      {"aws:PrincipalOrgID": "o-xxxxxxxxxxx"}
    }
  }
}
```

Note

This global condition also applies to the management account of an AWS organization. This policy prevents all principals outside of the specified organization from accessing the Amazon S3 bucket. This includes any AWS services that interact with your internal resources, such as AWS CloudTrail sending log data to your Amazon S3 buckets. To learn how you can safely grant access for AWS services, see [aws:PrincipalsAWSService](#).

For more information about AWS Organizations, see [What Is AWS Organizations?](#) in the *AWS Organizations User Guide*.

aws:PrincipalTag/tag-key

Use this key to compare the tag attached to the principal making the request with the tag that you specify in the policy. If the principal has more than one tag attached, the request context includes one `aws:PrincipalTag` key for each attached tag key.

- **Availability** – This key is included in the request context if the principal is using an IAM user with attached tags. It is included for a principal using an IAM role with attached tags or [session tags](#). Anonymous requests do not include this key.
- **Data type** – [String](#)
- **Value type** – Single-valued

You can add custom attributes to a user or role in the form of a key-value pair. For more information about IAM tags, see [Tagging IAM resources](#). You can use `aws:PrincipalTag` to [control access](#) for AWS principals.

This example shows how you might create an identity-based policy that allows users with the **department=hr** tag to manage IAM users, groups, or roles. To use this policy, replace the *italicized placeholder text* in the example policy with your own information. Then, follow the directions in [create a policy](#) or [edit a policy](#).

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": "iam:*",
      "Resource": "*",
      "Condition": {
        "StringEquals": {
          "aws:PrincipalTag/department": "hr"
        }
      }
    }
  ]
}
```

aws:PrincipalsAWSService

Use this key to check whether the call to your resource is being made directly by an AWS [service principal](#). For example, AWS CloudTrail uses the service principal `cloudtrail.amazonaws.com` to write logs to your Amazon S3 bucket. The request context key is set to true when a service uses a service principal to perform a direct action on your resources. The context key is set to false if the service uses the credentials of an IAM principal to make a request on the principal's behalf. It is also

set to false if the service uses a [service role](#) or [service-linked role](#) to make a call on the principal's behalf.

- **Availability** – This key is present in the request context for all signed API requests that use AWS credentials. Anonymous requests do not include this key.
- **Data type** – [Boolean](#)
- **Value type** – Single-valued

You can use this condition key to limit access to your trusted identities and expected network locations while safely granting access to AWS services.

In the following Amazon S3 bucket policy example, access to the bucket is restricted unless the request originates from vpc-111bbb22 or is from a service principal, such as CloudTrail.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "Expected-network+service-principal",
      "Effect": "Deny",
      "Principal": "*",
      "Action": "s3:PutObject",
      "Resource": "arn:aws:s3:::DOC-EXAMPLE-BUCKET1/AWSLogs/AccountNumber/*",
      "Condition": {
        "StringNotEqualsIfExists": {
          "aws:SourceVpc": "vpc-111bbb22"
        },
        "BoolIfExists": {
          "aws:PrincipalIsAWSService": "false"
        }
      }
    }
  ]
}
```

In the following video, learn more about how you might use the `aws:PrincipalIsAWSService` condition key in a policy.

[Safely grant access to your authorized users, expected network locations, and AWS services together.](#)

aws:PrincipalServiceName

Use this key to compare the [service principal](#) name in the policy with the service principal that is making requests to your resources. You can use this key to check whether this call is made by a specific service principal. When a service principal makes a direct request to your resource, the `aws:PrincipalServiceName` key contains the name of the service principal. For example, the AWS CloudTrail service principal name is `cloudtrail.amazonaws.com`.

- **Availability** – This key is present in the request when the call is made by an AWS service principal. This key is not present in any other situation, including the following:
 - If the service uses a [service role](#) or [service-linked role](#) to make a call on the principal's behalf.
 - If the service uses the credentials of an IAM principal to make a request on the principal's behalf.
 - If the call is made directly by an IAM principal.
 - If the call is made by an anonymous requester.
- **Data type** – [String](#)
- **Value type** – Single-valued

You can use this condition key to limit access to your trusted identities and expected network locations while safely granting access to an AWS service.

In the following Amazon S3 bucket policy example, access to the bucket is restricted unless the request originates from `vpc-111bbb22` or is from a service principal, such as CloudTrail.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "expected-network+service-principal",
      "Effect": "Deny",
      "Principal": "*",
      "Action": "s3:PutObject",
      "Resource": "arn:aws:s3:::DOC-EXAMPLE-BUCKET1/AWSLogs/AccountNumber/*",
      "Condition": {
        "StringNotEqualsIfExists": {
          "aws:SourceVpc": "vpc-111bbb22",
          "aws:PrincipalServiceName": "cloudtrail.amazonaws.com"
        }
      }
    }
  ]
}
```

```
    }  
  ]  
}
```

aws:PrincipalServiceNamesList

This key provides a list of all [service principal](#) names that belong to the service. This is an advanced condition key. You can use it to restrict the service from accessing your resource from a specific Region only. Some services may create Regional service principals to indicate a particular instance of the service within a specific Region. You can limit access to a resource to a particular instance of the service. When a service principal makes a direct request to your resource, the `aws:PrincipalServiceNamesList` contains an unordered list of all service principal names associated with the Regional instance of the service.

- **Availability** – This key is present in the request when the call is made by an AWS service principal. This key is not present in any other situation, including the following:
 - If the service uses a [service role](#) or [service-linked role](#) to make a call on the principal's behalf.
 - If the service uses the credentials of an IAM principal to make a request on the principal's behalf.
 - If the call is made directly by an IAM principal.
 - If the call is made by an anonymous requester.
- **Data type** – [String](#) (list)
- **Value type** – Multivalued

`aws:PrincipalServiceNamesList` is a multivalued condition key. Multivalued keys can have multiple values in the request context. You must use the `ForAnyValue` or `ForAllValues` set operators with [string condition operators](#) for this key. For more information about multivalued condition keys, see [Multivalued context keys](#).

aws:PrincipalType

Use this key to compare the type of principal making the request with the principal type that you specify in the policy. For more information, see [Specifying a principal](#). For specific examples of `principal` key values, see [Principal key values](#).

- **Availability** – This key is included in the request context for all requests, including anonymous requests.

- **Data type** – [String](#)
- **Value type** – Single-valued

aws:userid

Use this key to compare the requester's principal identifier with the ID that you specify in the policy. For IAM users, the request context value is the user ID. For IAM roles, this value format can vary. For details about how the information appears for different principals, see [Specifying a principal](#). For specific examples of `principal` key values, see [Principal key values](#).

- **Availability** – This key is included in the request context for all requests, including anonymous requests.
- **Data type** – [String](#)
- **Value type** – Single-valued

aws:username

Use this key to compare the requester's user name with the user name that you specify in the policy. For details about how the information appears for different principals, see [Specifying a principal](#). For specific examples of `principal` key values, see [Principal key values](#).

- **Availability** – This key is always included in the request context for IAM users. Anonymous requests and requests that are made using the AWS account root user or IAM roles do not include this key. Requests made using IAM Identity Center credentials do not include this key in the context.
- **Data type** – [String](#)
- **Value type** – Single-valued

Properties of a role session

Use the following condition keys to compare properties of the role session at the time the session was generated. These condition keys are only available when a request is made by a principal with role session or federated user credentials. The values for these condition keys are embedded in the role's session token.

A [role](#) is a type of principal. You can also use the condition keys from the [Properties of the principal](#) section to evaluate the properties of a role when a role is making a request.

Contents

- [aws:FederatedProvider](#)
- [aws:TokenIssueTime](#)
- [aws:MultiFactorAuthAge](#)
- [aws:MultiFactorAuthPresent](#)
- [aws:Ec2InstanceSourceVpc](#)
- [aws:Ec2InstanceSourcePrivateIPv4](#)
- [aws:SourceIdentity](#)
- [ec2:RoleDelivery](#)
- [ec2:SourceInstanceArn](#)
- [glue:RoleAssumedBy](#)
- [glue:CredentialIssuingService](#)
- [lambda:SourceFunctionArn](#)
- [ssm:SourceInstanceArn](#)
- [identitystore:UserId](#)

aws:FederatedProvider

Use this key to compare the principal's issuing identity provider (IdP) with the IdP that you specify in the policy. This means that an IAM role was assumed using the `AssumeRoleWithWebIdentity` AWS STS operation. When the resulting role session's temporary credentials are used to make a request, the request context identifies the IdP that authenticated the original federated identity.

- **Availability** – This key is present when the principal is a role session principal and that session was issued when a role was assumed with `AssumeRoleWithWebIdentity`.
- **Data type** – [String](#)
- **Value type** – Single-valued

For example, if the user was authenticated through Amazon Cognito, the request context includes the value `cognito-identity.amazonaws.com`. Similarly, if the user was authenticated through Login with Amazon, the request context includes the value `www.amazon.com`.

You can use any single-valued condition key as a [variable](#). The following example resource-based policy uses the `aws:FederatedProvider` key as a policy variable in the ARN of a resource. This

policy allows any principal who authenticated using an IdP to get objects out of an Amazon S3 bucket with a path that's specific to the issuing identity provider.

aws:TokenIssueTime

Use this key to compare the date and time that temporary security credentials were issued with the date and time that you specify in the policy.

- **Availability** – This key is included in the request context only when the principal uses temporary credentials to make the request. The key is not present in AWS CLI, AWS API, or AWS SDK requests that are made using access keys.
- **Data type** – [Date](#)
- **Value type** – Single-valued

To learn which services support using temporary credentials, see [AWS services that work with IAM](#).

aws:MultiFactorAuthAge

Use this key to compare the number of seconds since the requesting principal was authorized using MFA with the number that you specify in the policy. For more information about MFA, see [Using multi-factor authentication \(MFA\) in AWS](#).

- **Availability** – This key is included in the request context only if the principal making the call was authenticated using MFA. If MFA was not used, this key is not present.
- **Data type** – [Numeric](#)
- **Value type** – Single-valued

aws:MultiFactorAuthPresent

Use this key to check whether multi-factor authentication (MFA) was used to validate the temporary security credentials that made the request.

- **Availability** – This key is included in the request context only when the principal uses temporary credentials to make the request. The key is not present in AWS CLI, AWS API, or AWS SDK requests that are made using long-term credentials.
- **Data type** – [Boolean](#)
- **Value type** – Single-valued

Temporary credentials are used to authenticate IAM roles, federated users, IAM users with temporary tokens from `sts:GetSessionToken`, and users of the AWS Management Console. IAM user access keys are long-term credentials, but in some cases, AWS creates temporary credentials on behalf of IAM users to perform operations. In these cases, the `aws:MultiFactorAuthPresent` key is present in the request and set to a value of `false`. There are two common cases where this can happen:

- IAM users in the AWS Management Console unknowingly use temporary credentials. Users sign into the console using their user name and password, which are long-term credentials. However, in the background, the console generates temporary credentials on behalf of the user.
- If an IAM user makes a call to an AWS service, the service re-uses the user's credentials to make another request to a different service. For example, when calling Athena to access an Amazon S3 bucket, or when using AWS CloudFormation to create an Amazon EC2 instance. For the subsequent request, AWS uses temporary credentials.

To learn which services support using temporary credentials, see [AWS services that work with IAM](#).

The `aws:MultiFactorAuthPresent` key is not present when an API or CLI command is called with long-term credentials, such as user access key pairs. Therefore we recommend that when you check for this key that you use the [...IfExists](#) versions of the condition operators.

It is important to understand that the following Condition element is **not** a reliable way to check whether a request is authenticated using MFA.

```
##### WARNING: NOT RECOMMENDED #####
"Effect" : "Deny",
"Condition" : { "Bool" : { "aws:MultiFactorAuthPresent" : "false" } }
```

This combination of the Deny effect, Bool element, and false value denies requests that can be authenticated using MFA, but were not. This applies only to temporary credentials that support using MFA. This statement does not deny access to requests that are made using long-term credentials, or to requests that are authenticated using MFA. Use this example with caution because its logic is complicated and it does not test whether MFA-authentication was actually used.

Also do not use the combination of the Deny effect, Null element, and true because it behaves the same way and the logic is even more complicated.

Recommended Combination

We recommend that you use the [BoolIfExists](#) operator to check whether a request is authenticated using MFA.

```
"Effect" : "Deny",  
"Condition" : { "BoolIfExists" : { "aws:MultiFactorAuthPresent" : "false" } }
```

This combination of Deny, BoolIfExists, and false denies requests that are not authenticated using MFA. Specifically, it denies requests from temporary credentials that do not include MFA. It also denies requests that are made using long-term credentials, such as AWS CLI or AWS API operations made using access keys. The *IfExists operator checks for the presence of the `aws:MultiFactorAuthPresent` key and whether or not it could be present, as indicated by its existence. Use this when you want to deny any request that is not authenticated using MFA. This is more secure, but can break any code or scripts that use access keys to access the AWS CLI or AWS API.

Alternative Combinations

You can also use the [BoolIfExists](#) operator to allow MFA-authenticated requests and AWS CLI or AWS API requests that are made using long-term credentials.

```
"Effect" : "Allow",  
"Condition" : { "BoolIfExists" : { "aws:MultiFactorAuthPresent" : "true" } }
```

This condition matches either if the key exists and is present **or** if the key does not exist. This combination of Allow, BoolIfExists, and true allows requests that are authenticated using MFA, or requests that cannot be authenticated using MFA. This means that AWS CLI, AWS API, and AWS SDK operations are allowed when the requester uses their long-term access keys. This combination does not allow requests from temporary credentials that could, but do not include MFA.

When you create a policy using the IAM console visual editor and choose **MFA required**, this combination is applied. This setting requires MFA for console access, but allows programmatic access with no MFA.

Alternatively, you can use the Bool operator to allow programmatic and console requests only when authenticated using MFA.

```
"Effect" : "Allow",
```

```
"Condition" : { "Bool" : { "aws:MultiFactorAuthPresent" : "true" } }
```

This combination of the `Allow`, `Bool`, and `true` allows only MFA-authenticated requests. This applies only to temporary credentials that support using MFA. This statement does not allow access to requests that were made using long-term access keys, or to requests made using temporary credentials without MFA.

Do not use a policy construct similar to the following to check whether the MFA key is present:

```
##### WARNING: USE WITH CAUTION #####

"Effect" : "Allow",
"Condition" : { "Null" : { "aws:MultiFactorAuthPresent" : "false" } }
```

This combination of the `Allow` effect, `Null` element, and `false` value allows only requests that can be authenticated using MFA, regardless of whether the request is actually authenticated. This allows all requests that are made using temporary credentials, and denies access for long-term credentials. Use this example with caution because it does not test whether MFA-authentication was actually used.

aws:Ec2InstanceSourceVpc

This key identifies the VPC to which Amazon EC2 IAM role credentials were delivered to. You can use this key in a policy with the [aws:SourceVPC](#) global key to check if a call is made from a VPC (`aws:SourceVPC`) that matches the VPC where a credential was delivered to (`aws:Ec2InstanceSourceVpc`).

- **Availability** – This key is included in the request context whenever the requester is signing requests with an Amazon EC2 role credential. It can be used in IAM policies, service control policies, VPC endpoint policies, and resource policies.
- **Data type** – [String](#)
- **Value type** – Single-valued

This key can be used with VPC identifier values, but is most useful when used as a variable combined with the `aws:SourceVpc` context key. The `aws:SourceVpc` context key is included in the request context only if the requester uses a VPC endpoint to make the request. Using `aws:Ec2InstanceSourceVpc` with `aws:SourceVpc` allows you to use

`aws:Ec2InstanceSourceVpc` more broadly since it compares values that typically change together.

 **Note**

This condition key is not available in EC2-Classic.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "RequireSameVPC",
      "Effect": "Deny",
      "Action": "*",
      "Resource": "*",
      "Condition": {
        "StringNotEquals": {
          "aws:SourceVpc": "${aws:Ec2InstanceSourceVpc}"
        },
        "Null": {
          "ec2:SourceInstanceARN": "false"
        },
        "BoolIfExists": {
          "aws:ViaAWSService": "false"
        }
      }
    }
  ]
}
```

In the example above, access is denied if the `aws:SourceVpc` value isn't equal to the `aws:Ec2InstanceSourceVpc` value. The policy statement is limited to only roles used as Amazon EC2 instance roles by testing for the existence of the `ec2:SourceInstanceARN` condition key.

The policy uses `aws:ViaAWSService` to allow AWS to authorize requests when requests are made on behalf of your Amazon EC2 instance roles. For example, when you make a request from an Amazon EC2 instance to an encrypted Amazon S3 bucket, Amazon S3 makes a call to AWS KMS on your behalf. Some of the keys are not present when the request is made to AWS KMS.

aws:Ec2InstanceSourcePrivateIPv4

This key identifies the private IPv4 address of the primary elastic network interface to which Amazon EC2 IAM role credentials were delivered. You must use this condition key with its companion key `aws:Ec2InstanceSourceVpc` to ensure that you have a globally unique combination of VPC ID and source private IP. Use this key with `aws:Ec2InstanceSourceVpc` to ensure that a request was made from the same private IP address that the credentials were delivered to.

- **Availability** – This key is included in the request context whenever the requester is signing requests with an Amazon EC2 role credential. It can be used in IAM policies, service control policies, VPC endpoint policies, and resource policies.
- **Data type** – [IP address](#)
- **Value type** – Single-valued

Important

This key should not be used alone in an Allow statement. Private IP addresses are by definition not globally unique. You should use the `aws:Ec2InstanceSourceVpc` key every time you use the `aws:Ec2InstanceSourcePrivateIPv4` key to specify the VPC your Amazon EC2 instance credentials can be used from.

Note

This condition key is not available in EC2-Classic.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Deny",
      "Action": "*",
      "Resource": "*",
      "Condition": {
        "StringNotEquals": {
          "aws:Ec2InstanceSourceVpc": "${aws:SourceVpc}"
        }
      }
    }
  ]
}
```

```

        },
        "Null": {
            "ec2:SourceInstanceARN": "false"
        },
        "BoolIfExists": {
            "aws:ViaAWSService": "false"
        }
    }
},
{
    "Effect": "Deny",
    "Action": "*",
    "Resource": "*",
    "Condition": {
        "StringNotEquals": {
            "aws:Ec2InstanceSourcePrivateIPv4": "${aws:VpcSourceIp}"
        },
        "Null": {
            "ec2:SourceInstanceARN": "false"
        },
        "BoolIfExists": {
            "aws:ViaAWSService": "false"
        }
    }
}
]
}

```

aws:SourceIdentity

Use this key to compare the source identity that was set by the principal with the source identity that you specify in the policy.

- **Availability** – This key is included in the request context after a source identity has been set when a role is assumed using any AWS STS assume-role CLI command, or AWS STS AssumeRole API operation.
- **Data type** – [String](#)
- **Value type** – Single-valued

You can use this key in a policy to allow actions in AWS by principals that have set a source identity when assuming a role. Activity for the role's specified source identity appears in [AWS CloudTrail](#).

This makes it easier for administrators to determine who or what performed actions with a role in AWS.

Unlike [sts:RoleSessionName](#), after the source identity is set, the value cannot be changed. It is present in the request context for all actions taken by the role. The value persists into subsequent role sessions when you use the session credentials to assume another role. Assuming one role from another is called [role chaining](#).

The [sts:SourceIdentity](#) key is present in the request when the principal initially sets a source identity while assuming a role using any AWS STS assume-role CLI command, or AWS STS AssumeRole API operation. The `aws:SourceIdentity` key is present in the request for any actions that are taken with a role session that has a source identity set.

The following role trust policy for `CriticalRole` in account `111122223333` contains a condition for `aws:SourceIdentity` that prevents a principal without a source identity that is set to `Saanvi` or `Diego` from assuming the role.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "AssumeRoleIfSourceIdentity",
      "Effect": "Allow",
      "Principal": {"AWS": "arn:aws:iam::123456789012:role/CriticalRole"},
      "Action": [
        "sts:AssumeRole",
        "sts:SetSourceIdentity"
      ],
      "Condition": {
        "StringLike": {
          "aws:SourceIdentity": ["Saanvi","Diego"]
        }
      }
    }
  ]
}
```

To learn more about using source identity information, see [Monitor and control actions taken with assumed roles](#).

ec2:RoleDelivery

Use this key to compare the version of the instance metadata service in the signed request with the IAM role credentials for Amazon EC2. The instance metadata service distinguishes between IMDSv1 and IMDSv2 requests based on whether, for any given request, either the PUT or GET headers, which are unique to IMDSv2, are present in that request.

- **Availability** – This key is included in the request context whenever the role session is created by an Amazon EC2 instance.
- **Data type** – [Numeric](#)
- **Value type** – Single-valued
- **Example values** – 1.0, 2.0

You can configure the Instance Metadata Service (IMDS) on each instance so that local code or users must use IMDSv2. When you specify that IMDSv2 must be used, IMDSv1 no longer works.

- Instance Metadata Service Version 1 (IMDSv1) – A request/response method
- Instance Metadata Service Version 2 (IMDSv2) – a session-oriented method

For information about how to configure your instance to use IMDSv2, see [Configure the instance metadata options](#).

In the following example, access is denied if the `ec2:RoleDelivery` value in the request context is 1.0 (IMDSv1). This policy statement can be applied generally because, if the request is not signed by Amazon EC2 role credentials, it has no effect.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "RequireAllEc2RolesToUseV2",
      "Effect": "Deny",
      "Action": "*",
      "Resource": "*",
      "Condition": {
        "NumericLessThan": {
          "ec2:RoleDelivery": "2.0"
        }
      }
    }
  ]
}
```

```
    }  
  ]  
}
```

For more information, see [Example policies for working with instance metadata](#).

ec2:SourceInstanceArn

Use this key to compare the ARN of the instance from which the role's session was generated.

- **Availability** – This key is included in the request context whenever the role session is created by an Amazon EC2 instance.
- **Data type** – [ARN](#)
- **Value type** – Single-valued
- **Example value** – `arn:aws:ec2:us-west-2:111111111111:instance/instance-id`

For policy examples, see [Allow a specific instance to view resources in other AWS services](#).

glue:RoleAssumedBy

The AWS Glue service sets this condition key for each AWS API request where AWS Glue makes a request using a service role on the customer's behalf (not by a job or developer endpoint, but directly by the AWS Glue service). Use this key to verify whether a call to an AWS resource came from the AWS Glue service.

- **Availability** – This key is included in the request context when AWS Glue makes a request using a service role on the customer's behalf.
- **Data type** – [String](#)
- **Value type** – Single-valued
- **Example value** – This key is always set to `glue.amazonaws.com`.

The following example adds a condition to allow the AWS Glue service to get an object from an Amazon S3 bucket.

```
{  
  "Effect": "Allow",  
  "Action": "s3:GetObject",
```

```
"Resource": "arn:aws:s3:::confidential-bucket/*",
"Condition": {
  "StringEquals": {
    "glue:RoleAssumedBy": "glue.amazonaws.com"
  }
}
```

glue:CredentialIssuingService

The AWS Glue service sets this key for each AWS API request using a service role that comes from a job or developer endpoint. Use this key to verify whether a call to an AWS resource came from an AWS Glue job or developer endpoint.

- **Availability** – This key is included in the request context when AWS Glue makes a request that comes from a job or developer endpoint.
- **Data type** – [String](#)
- **Value type** – Single-valued
- **Example value** – This key is always set to `glue.amazonaws.com`.

The following example adds a condition that is attached to an IAM role that is used by an AWS Glue job. This ensures certain actions are allowed/denied based on whether the role session is used for an AWS Glue job runtime environment.

```
{
  "Effect": "Allow",
  "Action": "s3:GetObject",
  "Resource": "arn:aws:s3:::confidential-bucket/*",
  "Condition": {
    "StringEquals": {
      "glue:CredentialIssuingService": "glue.amazonaws.com"
    }
  }
}
```

lambda:SourceFunctionArn

Use this key to identify the Lambda function ARN that IAM role credentials were delivered to. The Lambda service sets this key for each AWS API request that comes from your function's execution

environment. Use this key to verify whether a call to an AWS resource came from a specific Lambda function's code. Lambda also sets this key for some requests that come from outside the execution environment, such as writing logs to CloudWatch and sending traces to X-Ray.

- **Availability** – This key is included in the request context whenever Lambda function code is invoked.
- **Data type** – [ARN](#)
- **Value type** – Single-valued
- **Example value** – `arn:aws:lambda:us-east-1:123456789012:function:TestFunction`

The following example allows one specific Lambda function to have `s3:PutObject` access the specified bucket.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "ExampleSourceFunctionArn",
      "Effect": "Allow",
      "Action": "s3:PutObject",
      "Resource": "arn:aws:s3:::DOC-EXAMPLE-BUCKET/*",
      "Condition": {
        "ArnEquals": {
          "lambda:SourceFunctionArn": "arn:aws:lambda:us-east-1:123456789012:function:source_lambda"
        }
      }
    }
  ]
}
```

For more information, see [Working with Lambda execution environment credentials](#) in the *AWS Lambda Developer Guide*.

ssm:SourceInstanceArn

Use this key to identify the AWS Systems Manager managed instance ARN that IAM role credentials were delivered to. This condition key is not present when the request comes from a managed instance with an IAM role associated with an Amazon EC2 instance profile.

- **Availability** – This key is included in the request context whenever role credentials are delivered to an AWS Systems Manager managed instance.
- **Data type** – [ARN](#)
- **Value type** – Single-valued
- **Example value** – arn:aws:ec2:us-west-2:111111111111:instance/instance-id

identitystore:UserId

Use this key to compare IAM Identity Center workforce identity in the signed request with the identity specified in the policy.

- **Availability** – This key is included when the caller of the request is a user in IAM Identity Center.
- **Data type** – [String](#)
- **Value type** – Single-valued
- **Example value** – 94482488-3041-7026-18f3-be45837cd0e4

You can find the UserId of a user in IAM Identity Center by making a request to the [GetUserId](#) API using the AWS CLI, AWS API, or AWS SDK.

Properties of the network

Use the following condition keys to compare details about the network that the request originated from or passed through with the network properties that you specify in the policy.

Contents

- [aws:SourceIp](#)
- [aws:SourceVpc](#)
- [aws:SourceVpce](#)
- [aws:VpcSourceIp](#)

aws:SourceIp

Use this key to compare the requester's IP address with the IP address that you specify in the policy. The `aws:SourceIp` condition key can only be used for public IP address ranges.

- **Availability** – This key is included in the request context, except when the requester uses a VPC endpoint to make the request.
- **Data type** – [IP address](#)
- **Value type** – Single-valued

The `aws:SourceIp` condition key can be used in a policy to allow principals to make requests only from within a specified IP range.

 **Note**

`aws:SourceIp` supports both IPv4 and IPv6 address or range of IP addresses. For a list of AWS services that support IPv6, see [AWS services that support IPv6](#) in the *Amazon VPC User Guide*.

For example, you can attach the following identity-based policy to an IAM role. This policy allows the user to put objects into the `DOC-EXAMPLE-BUCKET3` Amazon S3 bucket if they make the call from the specified IPv4 address range. This policy also allows an AWS service that uses [Forward access sessions](#) to perform this operation on your behalf.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "PrincipalPutObjectIfIpAddress",
      "Effect": "Allow",
      "Action": "s3:PutObject",
      "Resource": "arn:aws:s3:::DOC-EXAMPLE-BUCKET3/*",
      "Condition": {
        "IpAddress": {
          "aws:SourceIp": "203.0.113.0/24"
        }
      }
    }
  ]
}
```

If you need to restrict access from networks that support both IPv4 and IPv6 addressing, you can include the IPv4 and IPv6 address or ranges of IP addresses in the IAM policy condition. The

following identity-based policy will allow the user to put objects into the *DOC-EXAMPLE-BUCKET3* Amazon S3 bucket if the user makes the call from either specified IPv4 or IPv6 address ranges. Before you include IPv6 address ranges in your IAM policy, verify that the AWS service you are working with supports IPv6. For a list of AWS services that support IPv6, see [AWS services that support IPv6](#) in the *Amazon VPC User Guide*.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "PrincipalPutObjectIfIpAddress",
      "Effect": "Allow",
      "Action": "s3:PutObject",
      "Resource": "arn:aws:s3:::DOC-EXAMPLE-BUCKET3/*",
      "Condition": {
        "IpAddress": {
          "aws:SourceIp": [
            "203.0.113.0/24",
            "2001:DB8:1234:5678::/64"
          ]
        }
      }
    }
  ]
}
```

If the request comes from a host that uses an Amazon VPC endpoint, then the `aws:SourceIp` key is not available. You should instead use a VPC-specific key such as [aws:VpcSourceIp](#). For more information about using VPC endpoints, see [Identity and access management for VPC endpoints and VPC endpoint services](#) in the *AWS PrivateLink Guide*.

aws:SourceVpc

Use this key to check whether the request travels through the VPC that the VPC endpoint is attached to. In a policy, you can use this key to allow access to only a specific VPC. For more information, see [Restricting Access to a Specific VPC](#) in the *Amazon Simple Storage Service User Guide*.

- **Availability** – This key is included in the request context only if the requester uses a VPC endpoint to make the request.
- **Data type** – [String](#)

- **Value type** – Single-valued

aws:SourceVpce

Use this key to compare the VPC endpoint identifier of the request with the endpoint ID that you specify in the policy. In a policy, you can use this key to restrict access to a specific VPC endpoint. For more information, see [Restricting Access to a Specific VPC Endpoint](#) in the *Amazon Simple Storage Service User Guide*.

- **Availability** – This key is included in the request context only if the requester uses a VPC endpoint to make the request.
- **Data type** – [String](#)
- **Value type** – Single-valued

aws:VpcSourceIp

Use this key to compare the IP address from which a request was made with the IP address that you specify in the policy. In a policy, the key matches only if the request originates from the specified IP address and it goes through a VPC endpoint.

- **Availability** – This key is included in the request context only if the request is made using a VPC endpoint.
- **Data type** – [IP address](#)
- **Value type** – Single-valued

For more information, see [Controlling Access to Services with VPC Endpoints](#) in the *Amazon VPC User Guide*.

Note

aws:VpcSourceIp supports both IPv4 and IPv6 address or range of IP addresses. For a list of AWS services that support IPv6, see [AWS services that support IPv6](#) in the *Amazon VPC User Guide*.

Properties of the resource

Use the following condition keys to compare details about the resource that is the target of the request with the resource properties that you specify in the policy.

Contents

- [aws:ResourceAccount](#)
- [aws:ResourceOrgPaths](#)
- [aws:ResourceOrgID](#)
- [aws:ResourceTag/tag-key](#)

aws:ResourceAccount

Use this key to compare the requested resource owner's [AWS account ID](#) with the resource account in the policy. You can then allow or deny access to that resource based on the account that owns the resource.

- **Availability** – This key is always included in the request context for most service actions. The following actions don't support this key:
 - AWS Audit Manager
 - `auditmanager:UpdateAssessmentFrameworkShare`
 - Amazon Elastic Block Store – All actions
 - Amazon EC2
 - `ec2:AcceptTransitGatewayPeeringAttachment`
 - `ec2:AcceptVpcEndpointConnections`
 - `ec2:AcceptVpcPeeringConnection`
 - `ec2:CopyFpgaImage`
 - `ec2:CopyImage`
 - `ec2:CopySnapshot`
 - `ec2:CreateTransitGatewayPeeringAttachment`
 - `ec2:CreateVolume`
 - `ec2:CreateVpcEndpoint`
 - `ec2:CreateVpcPeeringConnection`
 - `ec2>DeleteTransitGatewayPeeringAttachment`

- `ec2:DeleteVpcPeeringConnection`
- `ec2:RejectTransitGatewayPeeringAttachment`
- `ec2:RejectVpcEndpointConnections`
- `ec2:RejectVpcPeeringConnection`
- Amazon EventBridge
 - `events:PutEvents` – EventBridge `PutEvents` calls on an event bus in another account, if that event bus was configured as a cross-account EventBridge target before March 2, 2023. For more information, see [Grant permissions to allow events from other AWS accounts](#) in the *Amazon EventBridge User Guide*.
- Amazon GuardDuty
 - `guardduty:AcceptAdministratorInvitation`
- Amazon Macie
 - `macie2:AcceptInvitation`
- Amazon Route 53
 - `route53:AssociateVpcWithHostedZone`
 - `route53:CreateVPCAssociationAuthorization`
 - `route53>DeleteVPCAssociationAuthorization`
 - `route53:DisassociateVPCFromHostedZone`
 - `route53:ListHostedZonesByVPC`
- AWS Security Hub
 - `securityhub:AcceptAdministratorInvitation`
- Amazon WorkSpaces
 - `workspaces:DescribeWorkspaceImages`
- **Data type** – [String](#)
- **Value type** – Single-valued

Note

For additional considerations for the above unsupported actions, see the [Data Perimeter Policy Examples](#) repository.

This key is equal to the AWS account ID for the account with the resources evaluated in the request.

For most resources in your account, the [ARN](#) contains the owner account ID for that resource. For certain resources, such as Amazon S3 buckets, the resource ARN does not include the account ID. The following two examples show the difference between a resource with an account ID in the ARN, and an Amazon S3 ARN without an account ID:

- `arn:aws:iam::123456789012:role/AWSExampleRole` – IAM role created and owned within the account 123456789012.
- `arn:aws:s3:::DOC-EXAMPLE-BUCKET2` – Amazon S3 bucket created and owned within the account 111122223333, not displayed in the ARN.

Use the AWS console, or API, or CLI, to find all of your resources and corresponding ARNs.

You write a policy that denies permissions to resources based on the resource owner's account ID. For example, the following identity-based policy denies access to the *specified resource* if the resource does not belong to the *specified account*.

To use this policy, replace the *italicized placeholder text* with your account information.

Important

This policy does not allow any actions. Instead, it uses the Deny effect which explicitly denies access to all of the resources listed in the statement that do not belong to the listed account. Use this policy in combination with other policies that allow access to specific resources.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "DenyInteractionWithResourcesNotInSpecificAccount",
      "Action": "service:*",
      "Effect": "Deny",
      "Resource": [
        "arn:aws:service:region:account:*"
      ],
      "Condition": {
```

```
    "StringNotEquals": {
      "aws:ResourceAccount": [
        "account"
      ]
    }
  }
}
```

This policy denies access to all resources for a specific AWS service unless the specified AWS account owns the resource.

Note

Some AWS services require access to AWS owned resources that are hosted in another AWS account. Using `aws:ResourceAccount` in your identity-based policies might impact your identity's ability to access these resources.

Certain AWS services, such as AWS Data Exchange, rely on access to resources outside of your AWS accounts for normal operations. If you use the element `aws:ResourceAccount` in your policies, include additional statements to create exemptions for those services. The example policy [AWS: Deny access to Amazon S3 resources outside your account except AWS Data Exchange](#) demonstrates how to deny access based on the resource account while defining exceptions for service-owned resources.

Use this policy example as a template for creating your own custom policies. Refer to your service [documentation](#) for more information.

aws:ResourceOrgPaths

Use this key to compare the AWS Organizations path for the accessed resource to the path in the policy. In a policy, this condition key ensures that the resource belongs to an account member within the specified organization root or organizational units (OUs) in AWS Organizations. An AWS Organizations path is a text representation of the structure of an Organizations entity. For more information about using and understanding paths, see [Understand the AWS Organizations entity path](#)

- **Availability** – This key is included in the request context only if the account that owns the resource is a member of an organization. This global condition key does not support the following actions:
 - AWS Audit Manager
 - `auditmanager:UpdateAssessmentFrameworkShare`
 - Amazon Elastic Block Store – All actions
 - Amazon EC2
 - `ec2:AcceptTransitGatewayPeeringAttachment`
 - `ec2:AcceptVpcEndpointConnections`
 - `ec2:AcceptVpcPeeringConnection`
 - `ec2:CopyFpgaImage`
 - `ec2:CopyImage`
 - `ec2:CopySnapshot`
 - `ec2:CreateTransitGatewayPeeringAttachment`
 - `ec2:CreateVolume`
 - `ec2:CreateVpcEndpoint`
 - `ec2:CreateVpcPeeringConnection`
 - `ec2>DeleteTransitGatewayPeeringAttachment`
 - `ec2>DeleteVpcPeeringConnection`
 - `ec2:RejectTransitGatewayPeeringAttachment`
 - `ec2:RejectVpcEndpointConnections`
 - `ec2:RejectVpcPeeringConnection`
 - Amazon EventBridge
 - `events:PutEvents` – EventBridge `PutEvents` calls on an event bus in another account, if that event bus was configured as a cross-account EventBridge target before March 2, 2023. For more information, see [Grant permissions to allow events from other AWS accounts](#) in the *Amazon EventBridge User Guide*.
 - Amazon GuardDuty
 - `guardduty:AcceptAdministratorInvitation`
 - Amazon Macie
 - `macie2:AcceptInvitation`

- Amazon Route 53
 - `route53:AssociateVpcWithHostedZone`
 - `route53:CreateVPCAssociationAuthorization`
 - `route53>DeleteVPCAssociationAuthorization`
 - `route53:DisassociateVPCFromHostedZone`
 - `route53:ListHostedZonesByVPC`
- AWS Security Hub
 - `securityhub:AcceptAdministratorInvitation`
- Amazon WorkSpaces
 - `workspaces:DescribeWorkspaceImages`
- **Data type** – [String](#) (list)
- **Value type** – Multivalued

 **Note**

For additional considerations for the above unsupported actions, see the [Data Perimeter Policy Examples](#) repository.

`aws:ResourceOrgPaths` is a multivalued condition key. Multivalued keys can have multiple values in the request context. You must use the `ForAnyValue` or `ForAllValues` set operators with [string condition operators](#) for this key. For more information about multivalued condition keys, see [Multivalued context keys](#).

For example, the following condition returns `True` for resources that belong to the organization `o-a1b2c3d4e5`. When you include a wildcard, you must use the [StringLike](#) condition operator.

```
"Condition": {
  "ForAnyValue:StringLike": {
    "aws:ResourceOrgPaths":["o-a1b2c3d4e5/*"]
  }
}
```

The following condition returns `True` for resources with the OU ID `ou-ab12-11111111`. It will match resources owned by accounts attached to the OU `ou-ab12-11111111` or any of the child OUs.

```
"Condition": { "ForAnyValue:StringLike" : {  
    "aws:ResourceOrgPaths":["o-a1b2c3d4e5/r-ab12/ou-ab12-11111111/*"]  
  }  
}}
```

The following condition returns `True` for resources owned by accounts attached directly to the OU ID `ou-ab12-22222222`, but not the child OUs. The following example uses the [StringEquals](#) condition operator to specify the exact match requirement for the OU ID and not a wildcard match.

```
"Condition": { "ForAnyValue:StringEquals" : {  
    "aws:ResourceOrgPaths":["o-a1b2c3d4e5/r-ab12/ou-ab12-11111111/ou-ab12-22222222/*"]  
  }  
}}
```

Note

Some AWS services require access to AWS owned resources that are hosted in another AWS account. Using `aws:ResourceOrgPaths` in your identity-based policies might impact your identity's ability to access these resources.

Certain AWS services, such as AWS Data Exchange, rely on access to resources outside of your AWS accounts for normal operations. If you use the `aws:ResourceOrgPaths` key in your policies, include additional statements to create exemptions for those services. The example policy [AWS: Deny access to Amazon S3 resources outside your account except AWS Data Exchange](#) demonstrates how to deny access based on the resource account while defining exceptions for service-owned resources. You can create a similar policy to restrict access to resources within an organizational unit (OU) using the `aws:ResourceOrgPaths` key, while accounting for service-owned resources.

Use this policy example as a template for creating your own custom policies. Refer to your service [documentation](#) for more information.

aws:ResourceOrgID

Use this key to compare the identifier of the organization in AWS Organizations to which the requested resource belongs with the identifier specified in the policy.

- **Availability** – This key is included in the request context only if the account that owns the resource is a member of an organization. This global condition key does not support the following actions:
 - AWS Audit Manager
 - `auditmanager:UpdateAssessmentFrameworkShare`
 - Amazon Elastic Block Store – All actions
 - Amazon EC2
 - `ec2:AcceptTransitGatewayPeeringAttachment`
 - `ec2:AcceptVpcEndpointConnections`
 - `ec2:AcceptVpcPeeringConnection`
 - `ec2:CopyFpgaImage`
 - `ec2:CopyImage`
 - `ec2:CopySnapshot`
 - `ec2>CreateTransitGatewayPeeringAttachment`
 - `ec2>CreateVolume`
 - `ec2>CreateVpcEndpoint`
 - `ec2>CreateVpcPeeringConnection`
 - `ec2>DeleteTransitGatewayPeeringAttachment`
 - `ec2>DeleteVpcPeeringConnection`
 - `ec2:RejectTransitGatewayPeeringAttachment`
 - `ec2:RejectVpcEndpointConnections`
 - `ec2:RejectVpcPeeringConnection`
 - Amazon EventBridge
 - `events:PutEvents` – EventBridge `PutEvents` calls on an event bus in another account, if that event bus was configured as a cross-account EventBridge target before March 2, 2023. For more information, see [Grant permissions to allow events from other AWS accounts](#) in the *Amazon EventBridge User Guide*.
 - Amazon GuardDuty
 - `guardduty:AcceptAdministratorInvitation`
 - Amazon Macie
 - `macie2:AcceptInvitation`

- Amazon Route 53
 - `route53:AssociateVpcWithHostedZone`
 - `route53:CreateVPCAssociationAuthorization`
 - `route53>DeleteVPCAssociationAuthorization`
 - `route53:DisassociateVPCFromHostedZone`
 - `route53:ListHostedZonesByVPC`
- AWS Security Hub
 - `securityhub:AcceptAdministratorInvitation`
- Amazon WorkSpaces
 - `workspaces:DescribeWorkspaceImages`
- **Data type** – [String](#)
- **Value type** – Single-valued

 **Note**

For additional considerations for the above unsupported actions, see the [Data Perimeter Policy Examples](#) repository.

This global key returns the resource organization ID for a given request. It allows you to create rules that apply to all resources in an organization that are specified in the Resource element of an [identity-based policy](#). You can specify the [organization ID](#) in the condition element. When you add and remove accounts, policies that include the `aws:ResourceOrgID` key automatically include the correct accounts and you don't have to manually update it.

For example, the following policy prevents the principal from adding objects to the `policy-genius-dev` resource unless the Amazon S3 resource belongs to the same organization as the principal making the request.

 **Important**

This policy does not allow any actions. Instead, it uses the Deny effect which explicitly denies access to all of the resources listed in the statement that do not belong to the listed

account. Use this policy in combination with other policies that allow access to specific resources.

```
{
  "Version": "2012-10-17",
  "Statement": {
    "Sid": "DenyPutObjectToS3ResourcesOutsideMyOrganization",
    "Effect": "Deny",
    "Action": "s3:PutObject",
    "Resource": "arn:partition:s3::policy-genius-dev/*",
    "Condition": {
      "StringNotEquals": {
        "aws:ResourceOrgID": "${aws:PrincipalOrgID}"
      }
    }
  }
}
```

Note

Some AWS services require access to AWS owned resources that are hosted in another AWS account. Using `aws:ResourceOrgID` in your identity-based policies might impact your identity's ability to access these resources.

Certain AWS services, such as AWS Data Exchange, rely on access to resources outside of your AWS accounts for normal operations. If you use the `aws:ResourceOrgID` key in your policies, include additional statements to create exemptions for those services. The example policy [AWS: Deny access to Amazon S3 resources outside your account except AWS Data Exchange](#) demonstrates how to deny access based on the resource account while defining exceptions for service-owned resources. You can create a similar policy to restrict access to resources within your organization using the `aws:ResourceOrgID` key, while accounting for service-owned resources.

Use this policy example as a template for creating your own custom policies. Refer to your service [documentation](#) for more information.

In the following video, learn more about how you might use the `aws:ResourceOrgID` condition key in a policy.

Ensure identities and networks can only be used to access trusted resources.

aws:ResourceTag/tag-key

Use this key to compare the tag key-value pair that you specify in the policy with the key-value pair attached to the resource. For example, you could require that access to a resource is allowed only if the resource has the attached tag key "Dept" with the value "Marketing". For more information, see [Controlling access to AWS resources](#).

- **Availability** – This key is included in the request context when the requested resource already has attached tags or in requests that create a resource with an attached tag. This key is returned only for resources that [support authorization based on tags](#). There is one context key for each tag key-value pair.
- **Data type** – [String](#)
- **Value type** – Single-valued

This context key is formatted "aws:ResourceTag/*tag-key*": "*tag-value*" where *tag-key* and *tag-value* are a tag key and value pair. Tag keys and values are not case-sensitive. This means that if you specify "aws:ResourceTag/TagKey1": "Value1" in the condition element of your policy, then the condition matches a resource tag key named either TagKey1 or tagkey1, but not both.

For examples of using the aws:ResourceTag key to control access to IAM resources, see [Controlling access to AWS resources](#).

For examples of using the aws:ResourceTag key to control access to other AWS resources, see [Controlling access to AWS resources using tags](#).

For a tutorial on using the aws:ResourceTag condition key for attribute based access control (ABAC), see [IAM tutorial: Define permissions to access AWS resources based on tags](#).

Properties of the request

Use the following condition keys to compare details about the request itself and the contents of the request with the request properties that you specify in the policy.

Contents

- [aws:CalledVia](#)

- [aws:CalledViaFirst](#)
- [aws:CalledViaLast](#)
- [aws:ViaAWSService](#)
- [aws:CurrentTime](#)
- [aws:EpochTime](#)
- [aws:referer](#)
- [aws:RequestedRegion](#)
- [aws:RequestTag/tag-key](#)
- [aws:TagKeys](#)
- [aws:SecureTransport](#)
- [aws:SourceArn](#)
- [aws:SourceAccount](#)
- [aws:SourceOrgPaths](#)
- [aws:SourceOrgID](#)
- [aws:UserAgent](#)

aws:CalledVia

Use this key to compare the services in the policy with the services that made requests on behalf of the IAM principal (user or role). When a principal makes a request to an AWS service, that service might use the principal's credentials to make subsequent requests to other services. The `aws:CalledVia` key contains an ordered list of each service in the chain that made requests on the principal's behalf.

For example, you can use AWS CloudFormation to read and write from an Amazon DynamoDB table. DynamoDB then uses encryption supplied by AWS Key Management Service (AWS KMS).

- **Availability** – This key is present in the request when a service that supports `aws:CalledVia` uses the credentials of an IAM principal to make a request to another service. This key is not present if the service uses a [service role](#) or [service-linked role](#) to make a call on the principal's behalf. This key is also not present when the principal makes the call directly.
- **Data type** – [String](#) (list)
- **Value type** – Multivalued

To use the `aws:CalledVia` condition key in a policy, you must provide the service principals to allow or deny AWS service requests. AWS supports using the following service principals with `aws:CalledVia`.

Service principal`aoss.amazonaws.com``athena.amazonaws.com``backup.amazonaws.com``cloud9.amazonaws.com``cloudformation.amazonaws.com``databrew.amazonaws.com``dataexchange.amazonaws.com``dynamodb.amazonaws.com``imagebuilder.amazonaws.com``kms.amazonaws.com``mgn.amazonaws.com``nimble.amazonaws.com``omics.amazonaws.com``ram.amazonaws.com``robomaker.amazonaws.com``servicecatalog-appregistry.amazonaws.com``sqlworkbench.amazonaws.com`

To allow or deny access when *any* service makes a request using the principal's credentials, use the [aws:ViaAWSService](#) condition key. That condition key supports AWS services.

The `aws:CalledVia` key is a [multivalued key](#). However, you can't enforce order using this key in a condition. Using the example above, **User 1** makes a request to AWS CloudFormation, which calls DynamoDB, which calls AWS KMS. These are three separate requests. The final call to AWS KMS is performed by User 1 *via* AWS CloudFormation and then DynamoDB.

In this case, the `aws:CalledVia` key in the request context includes `cloudformation.amazonaws.com` and `dynamodb.amazonaws.com`, in that order. If you care only that the call was made via DynamoDB somewhere in the chain of requests, you can use this condition key in your policy.

For example, the following policy allows managing the AWS KMS key named `my-example-key`, but only if DynamoDB is one of the requesting services. The [ForAnyValue:StringEquals](#) condition operator ensures that DynamoDB is one of the calling services. If the principal makes the call to AWS KMS directly, the condition returns `false` and the request is not allowed by this policy.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "KmsActionsIfCalledViaDynamodb",
      "Effect": "Allow",
      "Action": [
        "kms:Encrypt",
        "kms:Decrypt",
        "kms:ReEncrypt*",
        "kms:GenerateDataKey",
        "kms:DescribeKey"
      ],
      "Resource": "arn:aws:kms:region:111122223333:key/my-example-key",
      "Condition": {
        "ForAnyValue:StringEquals": {
          "aws:CalledVia": ["dynamodb.amazonaws.com"]
        }
      }
    }
  ]
}
```

If you want to enforce which service makes the first or last call in the chain, you can use the [aws:CalledViaFirst](#) and [aws:CalledViaLast](#) keys. For example, the following policy allows managing the key named `my-example-key` in AWS KMS. These AWS KMS operations are allowed only if multiple requests were included in the chain. The first request must be made via AWS CloudFormation and the last via DynamoDB. If other services make requests in the middle of the chain, the operation is still allowed.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "KmsActionsIfCalledViaChain",
      "Effect": "Allow",
      "Action": [
        "kms:Encrypt",
        "kms:Decrypt",
        "kms:ReEncrypt*",
        "kms:GenerateDataKey",
        "kms:DescribeKey"
      ],
      "Resource": "arn:aws:kms:region:111122223333:key/my-example-key",
      "Condition": {
        "StringEquals": {
          "aws:CalledViaFirst": "cloudformation.amazonaws.com",
          "aws:CalledViaLast": "dynamodb.amazonaws.com"
        }
      }
    }
  ]
}
```

The [aws:CalledViaFirst](#) and [aws:CalledViaLast](#) keys are present in the request when a service uses an IAM principal's credentials to call another service. They indicate the first and last services that made calls in the chain of requests. For example, assume that AWS CloudFormation calls another service named X Service, which calls DynamoDB, which then calls AWS KMS. The final call to AWS KMS is performed by User 1 via AWS CloudFormation, then X Service, and then DynamoDB. It was first called via AWS CloudFormation and last called via DynamoDB.

aws:CalledViaFirst

Use this key to compare the services in the policy with the *first service* that made a request on behalf of the IAM principal (user or role). For more information, see [aws:CalledVia](#).

- **Availability** – This key is present in the request when a service uses the credentials of an IAM principal to make at least one other request to a different service. This key is not present if the service uses a [service role](#) or [service-linked role](#) to make a call on the principal's behalf. This key is also not present when the principal makes the call directly.
- **Data type** – [String](#)
- **Value type** – Single-valued

aws:CalledViaLast

Use this key to compare the services in the policy with the *last service* that made a request on behalf of the IAM principal (user or role). For more information, see [aws:CalledVia](#).

- **Availability** – This key is present in the request when a service uses the credentials of an IAM principal to make at least one other request to a different service. This key is not present if the service uses a [service role](#) or [service-linked role](#) to make a call on the principal's behalf. This key is also not present when the principal makes the call directly.
- **Data type** – [String](#)
- **Value type** – Single-valued

aws:ViaAWSService

Use this key to check whether an AWS service makes a request to another service on your behalf.

The request context key returns `true` when a service uses the credentials of an IAM principal to make a request on behalf of the principal. The context key returns `false` if the service uses a [service role](#) or [service-linked role](#) to make a call on the principal's behalf. The request context key also returns `false` when the principal makes the call directly.

- **Availability** – This key is always included in the request context.
- **Data type** – [Boolean](#)
- **Value type** – Single-valued

You can use this condition key to allow or deny access based on whether a request was made by a service.

aws:CurrentTime

Use this key to compare the date and time of the request with the date and time that you specify in the policy. To view an example policy that uses this condition key, see [AWS: Allows access based on date and time](#).

- **Availability** – This key is always included in the request context.
- **Data type** – [Date](#)
- **Value type** – Single-valued

aws:EpochTime

Use this key to compare the date and time of the request in epoch or Unix time with the value that you specify in the policy. This key also accepts the number of seconds since January 1, 1970.

- **Availability** – This key is always included in the request context.
- **Data type** – [Date](#), [Numeric](#)
- **Value type** – Single-valued

aws:referrer

Use this key to compare who referred the request in the client browser with the referer that you specify in the policy. The `aws:referrer` request context value is provided by the caller in an HTTP header. The `Referer` header is included in a web browser request when you select a link on a web page. The `Referer` header contains the URL of the web page where the link was selected.

- **Availability** – This key is included in the request context only if the request to the AWS resource was invoked by linking from a web page URL in the browser. This key is not included for programmatic requests because it doesn't use a browser link to access the AWS resource.
- **Data type** – [String](#)
- **Value type** – Single-valued

For example, you can access an Amazon S3 object directly using a URL or using direct API invocation. For more information, see [Amazon S3 API operations directly using a web browser](#).

When you access an Amazon S3 object from a URL that exists in a webpage, the URL of the source web page is used in `aws:referrer`. When you access an Amazon S3 object by typing the URL into your browser, `aws:referrer` is not present. When you invoke the API directly, `aws:referrer` is also not present. You can use the `aws:referrer` condition key in a policy to allow requests made from a specific referer, such as a link on a web page in your company's domain.

Warning

This key should be used carefully. It is dangerous to include a publicly known referer header value. Unauthorized parties can use modified or custom browsers to provide any `aws:referrer` value that they choose. As a result, `aws:referrer` should not be used to prevent unauthorized parties from making direct AWS requests. It is offered only to allow customers to protect their digital content, such as content stored in Amazon S3, from being referenced on unauthorized third-party sites.

aws:RequestedRegion

Use this key to compare the AWS Region that was called in the request with the Region that you specify in the policy. You can use this global condition key to control which Regions can be requested. To view the AWS Regions for each service, see [Service endpoints and quotas](#) in the *Amazon Web Services General Reference*.

- **Availability** – This key is always included in the request context.
- **Data type** – [String](#)
- **Value type** – Single-valued

Some global services, such as IAM, have a single endpoint. Because this endpoint is physically located in the US East (N. Virginia) Region, IAM calls are always made to the us-east-1 Region. For example, if you create a policy that denies access to all services if the requested Region is not us-west-2, then IAM calls always fail. To view an example of how to work around this, see [NotAction with Deny](#).

Note

The `aws:RequestedRegion` condition key allows you to control which endpoint of a service is invoked but does not control the impact of the operation. Some services have cross-Region impacts.

For example, Amazon S3 has API operations that extend across regions.

- You can invoke `s3:PutBucketReplication` in one Region (which is affected by the `aws:RequestedRegion` condition key), but other Regions are affected based on the replications configuration settings.
- You can invoke `s3:CreateBucket` to create a bucket in another region, and use the `s3:LocationConstraint` condition key to control the applicable regions.

You can use this context key to limit access to AWS services within a given set of Regions. For example, the following policy allows a user to view all of the Amazon EC2 instances in the AWS Management Console. However it only allows them to make changes to instances in Ireland (eu-west-1), London (eu-west-2), or Paris (eu-west-3).

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "InstanceConsoleReadOnly",
      "Effect": "Allow",
      "Action": [
        "ec2:Describe*",
        "ec2:Export*",
        "ec2:Get*",
        "ec2:Search*"
      ],
      "Resource": "*"
    },
    {
      "Sid": "InstanceWriteRegionRestricted",
      "Effect": "Allow",
      "Action": [
        "ec2:Associate*",
        "ec2:Import*",
        "ec2:Modify*",
        "ec2:Monitor*",
        "ec2:Reset*",
        "ec2:Run*",
        "ec2:Start*",
        "ec2:Stop*",
        "ec2:Terminate*"
      ]
    }
  ]
}
```

```

    ],
    "Resource": "*",
    "Condition": {
      "StringEquals": {
        "aws:RequestedRegion": [
          "eu-west-1",
          "eu-west-2",
          "eu-west-3"
        ]
      }
    }
  }
]
}

```

aws:RequestTag/*tag-key*

Use this key to compare the tag key-value pair that was passed in the request with the tag pair that you specify in the policy. For example, you could check whether the request includes the tag key "Dept" and that it has the value "Accounting". For more information, see [Controlling access during AWS requests](#).

- **Availability** – This key is included in the request context when tag key-value pairs are passed in the request. When multiple tags are passed in the request, there is one context key for each tag key-value pair.
- **Data type** – [String](#)
- **Value type** – Single-valued

This context key is formatted "aws:RequestTag/*tag-key*": "*tag-value*" where *tag-key* and *tag-value* are a tag key and value pair. Tag keys and values are not case-sensitive. This means that if you specify "aws:RequestTag/TagKey1": "Value1" in the condition element of your policy, then the condition matches a request tag key named either TagKey1 or tagkey1, but not both.

This example shows that while the key is single-valued, you can still use multiple key-value pairs in a request if the keys are different.

```

{
  "Version": "2012-10-17",

```

```
"Statement": {
  "Effect": "Allow",
  "Action": "ec2:CreateTags",
  "Resource": "arn:aws:ec2:::instance/*",
  "Condition": {
    "StringEquals": {
      "aws:RequestTag/environment": [
        "preprod",
        "production"
      ],
      "aws:RequestTag/team": [
        "engineering"
      ]
    }
  }
}
```

aws:TagKeys

Use this key to compare the tag keys in a request with the keys that you specify in the policy. We recommend that when you use policies to control access using tags, use the `aws:TagKeys` condition key to define what tag keys are allowed. For example policies and more information, see [the section called “Controlling access based on tag keys”](#).

- **Availability** – This key is included in the request context if the operation supports passing tags in the request.
- **Data type** – [String](#) (list)
- **Value type** – Multivalued

This context key is formatted `"aws:TagKeys": "tag-key"` where *tag-key* is a list of tag keys without values (for example, `["Dept", "Cost-Center"]`).

Because you can include multiple tag key-value pairs in a request, the request content could be a [multivalued](#) request. In this case, you must use the `ForAllValues` or `ForAnyValue` set operators. For more information, see [Multivalued context keys](#).

Some services support tagging with resource operations, such as creating, modifying, or deleting a resource. To allow tagging and operations as a single call, you must create a policy that includes both the tagging action and the resource-modifying action. You can then use the `aws:TagKeys`

condition key to enforce using specific tag keys in the request. For example, to limit tags when someone creates an Amazon EC2 snapshot, you must include the `ec2:CreateSnapshot` creation action **and** the `ec2:CreateTags` tagging action in the policy. To view a policy for this scenario that uses `aws:TagKeys`, see [Creating a Snapshot with Tags](#) in the *Amazon EC2 User Guide for Linux Instances*.

`aws:SecureTransport`

Use this key to check whether the request was sent using SSL. The request context returns `true` or `false`. In a policy, you can allow specific actions only if the request is sent using SSL.

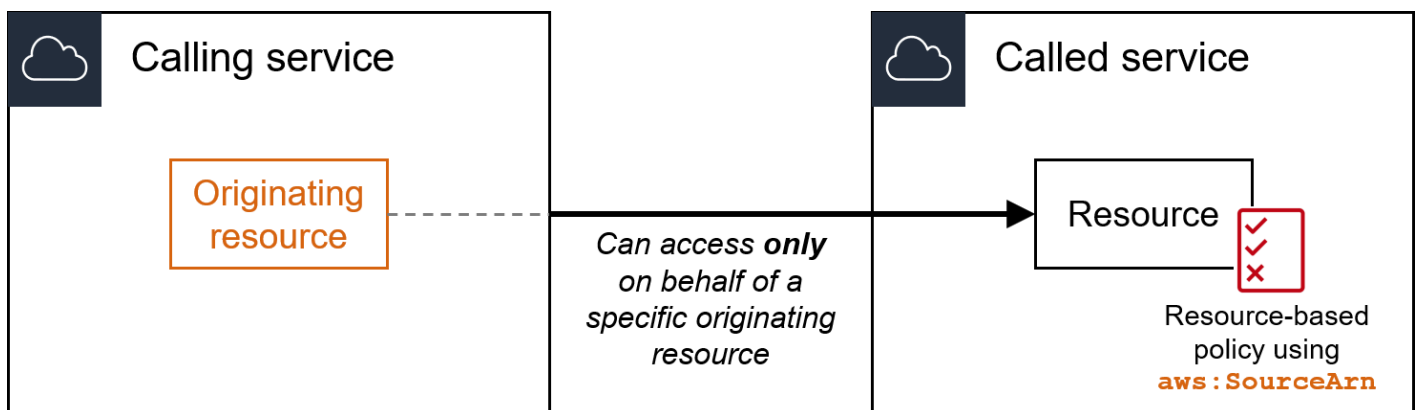

- **Availability** – This key is always included in the request context.
- **Data type** – [Boolean](#)
- **Value type** – Single-valued

`aws:SourceArn`

Use this key to compare the [Amazon Resource Name \(ARN\)](#) of the resource making a service-to-service request with the ARN that you specify in the policy, but only when the request is made by an AWS service principal. When the source's ARN includes the account ID, it is not necessary to use `aws:SourceAccount` with `aws:SourceArn`.

This key does not work with the ARN of the principal making the request. Instead, use [aws:PrincipalArn](#).

- **Availability** – This key is included in the request context only when the call to your resource is being made directly by an [AWS service principal](#) on behalf of a resource for which the configuration triggered the service-to-service request. The calling service passes the ARN of the original resource to the called service.

The following service integrations don't support this global condition key:

Calling service (service principal)	Called service (resource-based policy)	Description
logdelivery.elb.amazonaws.com	Amazon S3 bucket	Enable Elastic Load Balancing access logging in Amazon S3 bucket
logdelivery.elasticloadbalancing.amazonaws.com	Amazon S3 bucket	Enable Elastic Load Balancing access logging in Amazon S3 bucket

Note

Not all service integrations with AWS Security Token Service (AWS STS) and AWS Key Management Service (AWS KMS) are supported. See the documentation of the calling service for more information. Usage of `aws:SourceArn` in KMS key policies for keys used by AWS services via KMS key grants may result in unexpected behavior.

- **Data type** – ARN, String

AWS recommends that you use [ARN operators](#) instead of [string operators](#) when comparing ARNs.

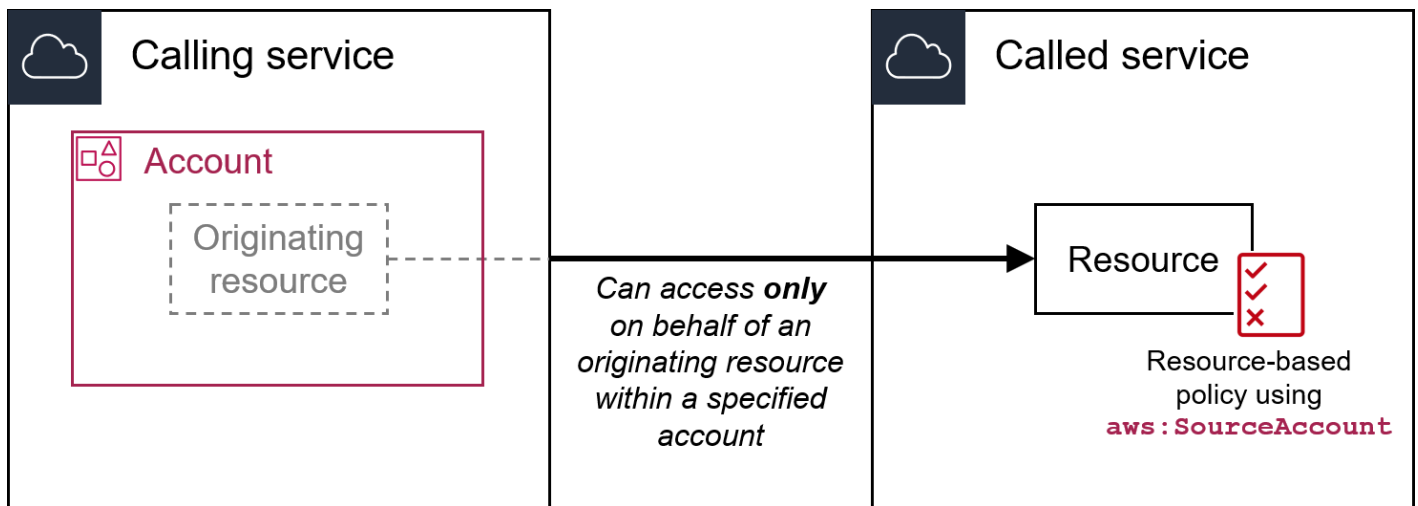

- **Value type** – Single-valued

You can use this condition key to prevent an AWS service from being used as a [confused deputy](#) during transactions between services. Use this key only in resource-based policies where the `Principal` is an AWS service principal. Set the value of this condition key to the ARN of the resource in the request. For example, when an Amazon S3 bucket update triggers an Amazon SNS topic publish, the Amazon S3 service invokes the `sns:Publish` API operation. In the topic policy that allows the `sns:Publish` operation, set the value of the condition key to the ARN of the Amazon S3 bucket. For information about how and when this condition key is recommended, see the documentation for the AWS services you are using.

aws:SourceAccount

Use this key to compare the account ID of the resource making a service-to-service request with the account ID that you specify in the policy, but only when the request is made by an AWS service principal.

- **Availability** – This key is included in the request context only when the call to your resource is being made directly by an [AWS service principal](#) on behalf of a resource for which the configuration triggered the service-to-service request. The calling service passes the account ID of the original resource to the called service.

The following service integrations don't support this global condition key:

Calling service (service principal)	Called service (resource-based policy)	Description
logdelivery.elb.amazonaws.com	Amazon S3 bucket	Enable Elastic Load Balancing access logging in Amazon S3 bucket
logdelivery.elasticloadbalancing.amazonaws.com	Amazon S3 bucket	Enable Elastic Load Balancing access logging in Amazon S3 bucket

Note

Not all service integrations with AWS Security Token Service (AWS STS) and AWS Key Management Service (AWS KMS) are supported. See the documentation of the calling service for more information. Usage of `aws:SourceAccount` in KMS key policies for keys used by AWS services via KMS key grants may result in unexpected behavior.

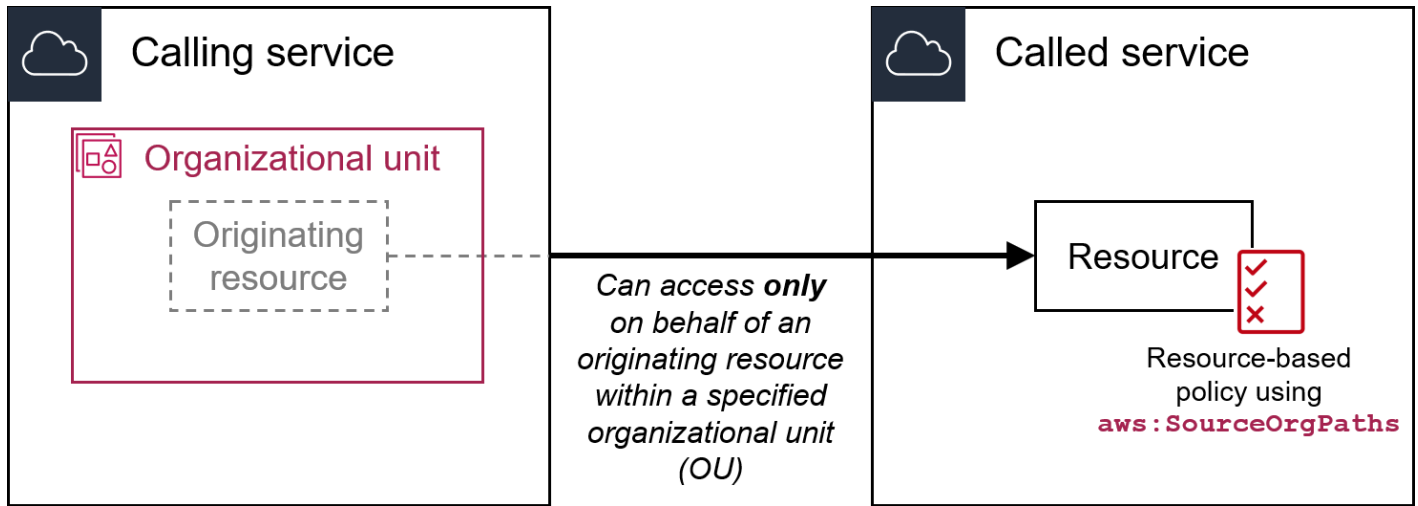

- **Data type** – [String](#)
- **Value type** – Single-valued

You can use this condition key to prevent an AWS service from being used as a [confused deputy](#) during transactions between services. Use this key only in resource-based policies where the `Principal` is an AWS service principal. Set the value of this condition key to the account ID of the resource in the request. For example, when an Amazon S3 bucket update triggers an Amazon SNS topic publish, the Amazon S3 service invokes the `sns:Publish` API operation. In the topic policy that allows the `sns:Publish` operation, set the value of the condition key to the account ID of the Amazon S3 bucket. For information about how and when this condition keys is recommended, see the documentation for the AWS services you are using.

aws:SourceOrgPaths

Use this key to compare the AWS Organizations path of the resource making a service-to-service request with the organizations path that you specify in the policy, but only when the request is made by an AWS service principal. An Organizations path is a text representation of the structure of an Organizations entity. For more information about using and understanding paths, see [Understand the AWS Organizations entity path](#).

- **Availability** – This key is included in the request context only when the call to your resource is being made directly by an [AWS service principal](#) on behalf of a resource owned by an account which is a member of an organization. The calling service passes the organization path of the original resource to the called service.

The following service integrations don't support this global condition key:

Calling service (service principal)	Called service (resource-based policy)	Description
logdelivery.elb.amazonaws.com	Amazon S3 bucket	Enable Elastic Load Balancing access logging in Amazon S3 bucket
logdelivery.elasticloadbalancing.amazonaws.com	Amazon S3 bucket	Enable Elastic Load Balancing access logging in Amazon S3 bucket
All service principals	Amazon Lex bot	Allow AWS services to use Amazon Lex bot

Note

Not all service integrations with AWS Security Token Service (AWS STS) and AWS Key Management Service (AWS KMS) are supported. See the documentation of the calling service for more information. Usage of `aws:SourceOrgPaths` in KMS key policies for keys used by AWS services via KMS key grants may result in unexpected behavior.

- **Data type** – [String](#) (list)
- **Value type** – Multivalued

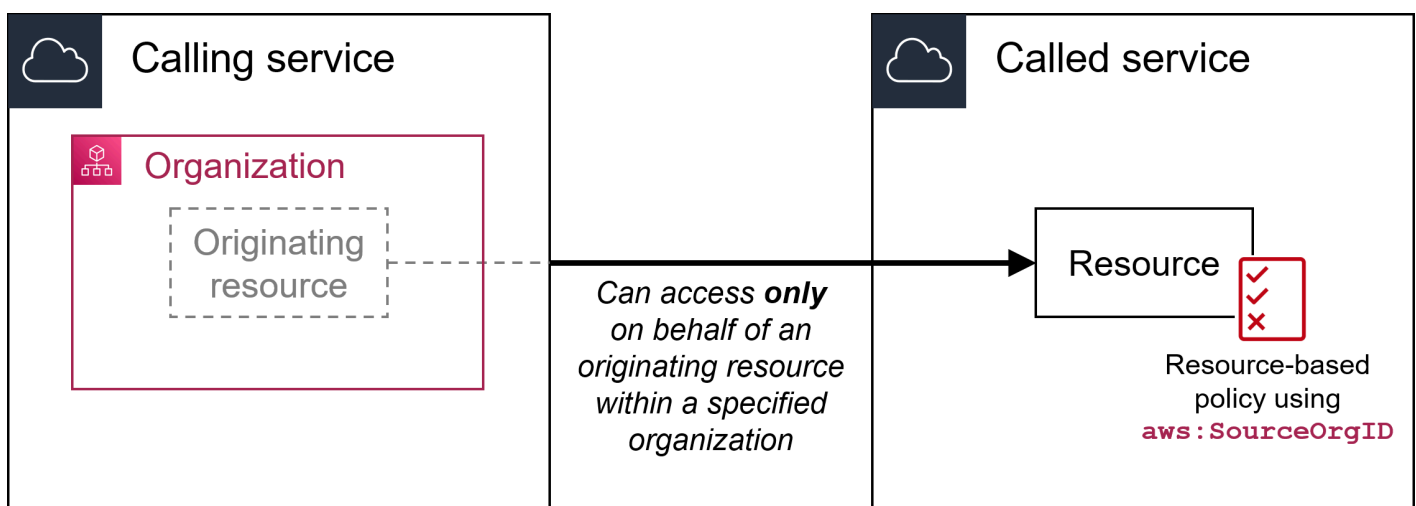

You can use this condition key to prevent an AWS service from being used as a [confused deputy](#) during transactions between services. Use this key only in resource-based policies where the `Principal` is an AWS service principal. Set the value of this condition key to the organization path of the resource in the request. For example, when an Amazon S3 bucket update triggers an Amazon SNS topic publish, the Amazon S3 service invokes the `sns:Publish` API operation. In the topic policy that allows the `sns:Publish` operation, set the value of the condition key to the organization path of the Amazon S3 bucket. For information about how and when this condition key is recommended, see the documentation for the AWS services you are using.

`aws:SourceOrgPaths` is a multivalued condition key. Multivalued keys can have multiple values in the request context. You must use the `ForAnyValue` or `ForAllValues` set operators with [string condition operators](#) for this key. For more information about multivalued condition keys, see [Multivalued context keys](#).

aws:SourceOrgID

Use this key to compare the [organization ID](#) of the resource making a service-to-service request with the organization ID that you specify in the policy, but only when the request is made by an AWS service principal. When you add and remove accounts to an organization in AWS Organizations, policies that include the `aws:SourceOrgID` key automatically include the correct accounts and you don't have to manually update the policies.

- **Availability** – This key is included in the request context only when the call to your resource is being made directly by an [AWS service principal](#) on behalf of a resource owned by an account which is a member of an organization. The calling service passes the organization ID of the original resource to the called service.

The following service integrations don't support this global condition key:

Calling service (service principal)	Called service (resource-based policy)	Description
logdelivery.elb.amazonaws.com	Amazon S3 bucket	Enable Elastic Load Balancing access logging in Amazon S3 bucket
logdelivery.elasticloadbalancing.amazonaws.com	Amazon S3 bucket	Enable Elastic Load Balancing access logging in Amazon S3 bucket
All service principals	Amazon Lex bot	Allow AWS services to use Amazon Lex bot

Note

Not all service integrations with AWS Security Token Service (AWS STS) and AWS Key Management Service (AWS KMS) are supported. See the documentation of the calling service for more information. Usage of `aws:SourceOrgID` in KMS key policies for keys used by AWS services via KMS key grants may result in unexpected behavior.

- **Data type** – [String](#)
- **Value type** – Single-valued

You can use this condition key to prevent an AWS service from being used as a [confused deputy](#) during transactions between services. Use this key only in resource-based policies where the `Principal` is an AWS service principal. Set the value of this condition key to the organization ID of the resource in the request. For example, when an Amazon S3 bucket update triggers an Amazon SNS topic publish, the Amazon S3 service invokes the `sns:Publish` API operation. In the topic policy that allows the `sns:Publish` operation, set the value of the condition key to the organization ID of the Amazon S3 bucket. For information about how and when this condition key is recommended, see the documentation for the AWS services that you are using.

aws:UserAgent

Use this key to compare the requester's client application with the application that you specify in the policy.

- **Availability** – This key is always included in the request context.
- **Data type** – [String](#)
- **Value type** – Single-valued

Warning

This key should be used carefully. Since the `aws:UserAgent` value is provided by the caller in an HTTP header, unauthorized parties can use modified or custom browsers to provide any `aws:UserAgent` value that they choose. As a result, `aws:UserAgent` should not be used to prevent unauthorized parties from making direct AWS requests. You can use it to allow only specific client applications, and only after testing your policy.

Other cross-service condition keys

AWS STS supports [SAML-based federation condition keys](#) and cross-service condition keys for [web identity federation](#). These keys are available when a user who was federated using SAML performs AWS operations in other services.

IAM and AWS STS condition context keys

You can use the `Condition` element in a JSON policy to test the value of keys that are included in the request context of all AWS requests. These keys provide information about the request itself or the resources that the request references. You can check that keys have specified values before allowing the action requested by the user. This gives you granular control over when your JSON policy statements match or don't match an incoming request. For information about how to use the `Condition` element in a JSON policy, see [IAM JSON policy elements: Condition](#).

This topic describes the keys defined and provided by the IAM service (with an `iam:` prefix) and the AWS Security Token Service (AWS STS) service (with an `sts:` prefix). Several other AWS services also provide service-specific keys that are relevant to the actions and resources defined by that service. For more information, see [Actions, Resources, and Condition Keys for AWS Services](#). The documentation for a service that supports condition keys often has additional information. For

example, for information about keys that you can use in policies for Amazon S3 resources, see [Amazon S3 Policy Keys](#) in the *Amazon Simple Storage Service User Guide*.

Topics

- [Available keys for IAM](#)
- [Available keys for AWS web identity federation](#)
- [Cross-service AWS web identity federation context keys](#)
- [Available keys for SAML-based AWS STS federation](#)
- [Cross-service SAML-based AWS STS federation context keys](#)
- [Available keys for AWS STS](#)

Available keys for IAM

You can use the following condition keys in policies that control access to IAM resources:

iam:AssociatedResourceArn

Works with [ARN operators](#).

Specifies the ARN of the resource to which this role will be associated at the destination service. The resource usually belongs to the service to which the principal is passing the role. Sometimes, the resource might belong to a third service. For example, you might pass a role to Amazon EC2 Auto Scaling that they use on an Amazon EC2 instance. In this case, the condition would match the ARN of the Amazon EC2 instance.

This condition key applies to only the [PassRole](#) action in a policy. It can't be used to limit any other action.

Use this condition key in a policy to allow an entity to pass a role, but only if that role is associated with the specified resource. You can use wildcards (*) to allow operations performed on a specific type of resource without restricting the Region or resource ID. For example, you can allow an IAM user or role to pass any role to the Amazon EC2 service to be used with instances in the Region `us-east-1` or `us-west-1`. The IAM user or role would not be allowed to pass roles to other services. In addition, it doesn't allow Amazon EC2 to use the role with instances in other Regions.

```
{
```

```
"Effect": "Allow",
"Action": "iam:PassRole",
"Resource": "*",
"Condition": {
  "StringEquals": {"iam:PassedToService": "ec2.amazonaws.com"},
  "ArnLike": {
    "iam:AssociatedResourceARN": [
      "arn:aws:ec2:us-east-1:111122223333:instance/*",
      "arn:aws:ec2:us-west-1:111122223333:instance/*"
    ]
  }
}
```

Note

AWS services that support [iam:PassedToService](#) also support this condition key.

iam:AWSServiceName

Works with [string operators](#).

Specifies the AWS service to which this role is attached.

In this example, you allow an entity to create a service-linked role if the service name is *access-analyzer.amazonaws.com*.

```
{
  "Version": "2012-10-17",
  "Statement": [{
    "Effect": "Allow",
    "Action": "iam:CreateServiceLinkedRole",
    "Resource": "*",
    "Condition": {
      "StringLike": {
        "iam:AWSServiceName": "access-analyzer.amazonaws.com"
      }
    }
  }]
}
```

iam:FIDO-certification

Works with [string operators](#).

Checks the MFA device FIDO certification level at the time of registration of a FIDO security key. The device certification is retrieved from the [FIDO Alliance Metadata Service \(MDS\)](#). If the certification status or level of your FIDO security key changes, it will not be updated unless the device is unregistered and registered again to fetch the updated certification information.

Possible values of L1, L1plus, L2, L2plus, L3, L3plus

In this example, you register a security key and retrieve the FIDO Level 1 plus certification for your device.

```
{
  "Version": "2012-10-17",
  "Statement": [{
    "Effect": "Allow",
    "Action": "iam:EnableMFADevice",
    "Resource": "*",
    "Condition": {
      "StringEquals": {
        "iam:RegisterSecurityKey" : "Create"
      }
    }
  },
  {
    "Effect": "Allow",
    "Action": "iam:EnableMFADevice",
    "Resource": "*",
    "Condition": {
      "StringEquals": {
        "iam:RegisterSecurityKey" : "Activate",
        "iam:FIDO-certification": "L1plus"
      }
    }
  }
]
}
```

iam:FIDO-FIPS-140-2-certification

Works with [string operators](#).

Checks the MFA device FIPS-140-2 validation certification level at the time of registration of a FIDO security key. The device certification is retrieved from the [FIDO Alliance Metadata Service \(MDS\)](#). If the certification status or level of your FIDO security key changes, it will not be updated unless the device is unregistered and registered again to fetch the updated certification information.

Possible values of L1, L2, L3, L4

In this example, you register a security key and retrieve the FIPS-140-2 Level 2 certification for your device.

```
{
  "Version": "2012-10-17",
  "Statement": [{
    "Effect": "Allow",
    "Action": "iam:EnableMFADevice",
    "Resource": "*",
    "Condition": {
      "StringEquals": {
        "iam:RegisterSecurityKey" : "Create"
      }
    }
  },
  {
    "Effect": "Allow",
    "Action": "iam:EnableMFADevice",
    "Resource": "*",
    "Condition": {
      "StringEquals": {
        "iam:RegisterSecurityKey" : "Activate",
        "iam:FIDO-FIPS-140-2-certification": "L2"
      }
    }
  }
]
}
```

iam:FIDO-FIPS-140-3-certification

Works with [string operators](#).

Checks the MFA device FIPS-140-3 validation certification level at the time of registration of a FIDO security key. The device certification is retrieved from the [FIDO Alliance Metadata Service \(MDS\)](#). If the certification status or level of your FIDO security key changes, it will not be updated unless the device is unregistered and registered again to fetch the updated certification information.

Possible values of L1, L2, L3, L4

In this example, you register a security key and retrieve the FIPS-140-3 Level 3 certification for your device.

```
{
  "Version": "2012-10-17",
  "Statement": [{
    "Effect": "Allow",
    "Action": "iam:EnableMFADevice",
    "Resource": "*",
    "Condition": {
      "StringEquals": {
        "iam:RegisterSecurityKey" : "Create"
      }
    }
  },
  {
    "Effect": "Allow",
    "Action": "iam:EnableMFADevice",
    "Resource": "*",
    "Condition": {
      "StringEquals": {
        "iam:RegisterSecurityKey" : "Activate",
        "iam:FIDO-FIPS-140-3-certification": "L3"
      }
    }
  }
]
}
```

iam:RegisterSecurityKey

Works with [string operators](#).

Checks the current state of MFA device enablement.

Possible values of Create or Activate.

In this example, you register a security key and retrieve the FIPS-140-3 Level 1 certification for your device.

```
{
  "Version": "2012-10-17",
  "Statement": [{
    "Effect": "Allow",
    "Action": "iam:EnableMFADevice",
    "Resource": "*",
    "Condition": {
      "StringEquals": {
        "iam:RegisterSecurityKey" : "Create"
      }
    }
  },
  {
    "Effect": "Allow",
    "Action": "iam:EnableMFADevice",
    "Resource": "*",
    "Condition": {
      "StringEquals": {
        "iam:RegisterSecurityKey" : "Activate",
        "iam:FIDO-FIPS-140-3-certification": "L1"
      }
    }
  }
]
}
```

iam:OrganizationsPolicyId

Works with [string operators](#).

Checks that the policy with the specified AWS Organizations ID matches the policy used in the request. To view an example IAM policy that uses this condition key, see [IAM: View service last accessed information for an Organizations policy](#).

iam:PassedToService

Works with [string operators](#).

Specifies the service principal of the service to which a role can be passed. This condition key applies to only the [PassRole](#) action in a policy. It can't be used to limit any other action.

When you use this condition key in a policy, specify the service using a service principal. A service principal is the name of a service that can be specified in the `Principal` element of a policy. This is the usual format: `SERVICE_NAME_URL.amazonaws.com`.

You can use `iam:PassedToService` to restrict your users so that they can pass roles only to specific services. For example, a user might create a [service role](#) that trusts CloudWatch to write log data to an Amazon S3 bucket on their behalf. Then the user must attach a permissions policy and a trust policy to the new service role. In this case, the trust policy must specify `cloudwatch.amazonaws.com` in the `Principal` element. To view a policy that allows the user to pass the role to CloudWatch, see [IAM: Pass an IAM role to a specific AWS service](#).

By using this condition key, you can ensure that users create service roles only for the services that you specify. For example, if a user with the preceding policy attempts to create a service role for Amazon EC2, the operation will fail. The failure occurs because the user does not have permission to pass the role to Amazon EC2.

Sometimes you pass a role to a service that then passes the role to a different service. `iam:PassedToService` includes only the final service that assumes the role, not the intermediate service that passes the role.

Note

Some services do not support this condition key.

iam:PermissionsBoundary

Works with [ARN operators](#).

Checks that the specified policy is attached as permissions boundary on the IAM principal resource. For more information, see [Permissions boundaries for IAM entities](#)

iam:PolicyARN

Works with [ARN operators](#).

Checks the Amazon Resource Name (ARN) of a managed policy in requests that involve a managed policy. For more information, see [Controlling access to policies](#).

iam:ResourceTag/*key-name*

Works with [string operators](#).

Checks that the tag attached to the identity resource (user or role) matches the specified key name and value.

Note

IAM and AWS STS support both the `iam:ResourceTag` IAM condition key and the `aws:ResourceTag` global condition key.

You can add custom attributes to IAM resources in the form of a key-value pair. For more information about tags for IAM resources, see [the section called “Tagging IAM resources”](#). You can use `ResourceTag` to [control access](#) to AWS resources, including IAM resources. However, because IAM does not support tags for groups, you cannot use tags to control access to groups.

This example shows how you might create an identity-based policy that allows deleting users with the `status=terminated` tag. To use this policy, replace the *italicized placeholder text* in the example policy with your own information. Then, follow the directions in [create a policy](#) or [edit a policy](#).

```
{
  "Version": "2012-10-17",
  "Statement": [{
    "Effect": "Allow",
    "Action": "iam:DeleteUser",
    "Resource": "*",
    "Condition": {"StringEquals": {"iam:ResourceTag/status": "terminated"}}
  ]
}
```

Available keys for AWS web identity federation

You can use web identity federation to give temporary security credentials to users who have been authenticated through an OpenID Connect compliant OpenID Provider (OP) to an IAM OpenID Connect (OIDC) identity provider in your AWS account. Examples of such providers include Login with Amazon, Amazon Cognito, Google, or Facebook. Identity tokens (`id_tokens`) from your own OpenID OP may be used, as well as `id_tokens` issued to service accounts of Amazon Elastic Kubernetes Service clusters. In that case, additional condition keys are available when the temporary security credentials are used to make a request. You can use these keys to write policies that limit the access of federated users to resources that are associated with a specific provider, app, or user. These keys are typically used in the trust policy for a role. Define condition keys using the name of the OIDC provider followed by the claim (`:aud`, `:azp`, `:amr`, `:sub`). For roles used by Amazon Cognito, keys are defined using `cognito-identity.amazonaws.com` followed by the claim.

amr

Works with [string operators](#).

Example: `cognito-identity.amazonaws.com:amr`

If you are using Amazon Cognito for web identity federation, the `cognito-identity.amazonaws.com:amr` key (Authentication Methods Reference) includes login information about the user. The key is multivalued, meaning that you test it in a policy using [condition set operators](#). The key can contain the following values:

- If the user is unauthenticated, the key contains only `unauthenticated`.
- If the user is authenticated, the key contains the value `authenticated` and the name of the login provider used in the call (`graph.facebook.com`, `accounts.google.com`, or `www.amazon.com`).

As an example, the following condition in the trust policy for an Amazon Cognito role tests whether the user is unauthenticated:

```
"Condition": {
  "StringEquals":
    { "cognito-identity.amazonaws.com:aud": "us-east-2:identity-pool-id" },
  "ForAnyValue:StringLike":
    { "cognito-identity.amazonaws.com:amr": "unauthenticated" }
}
```

aud

Works with [string operators](#).

Use the `aud` condition key to verify that the Google client ID or Amazon Cognito identity pool ID matches the one that you specify in the policy. You can use the `aud` key with the `sub` key for the same identity provider.

Examples:

- `graph.facebook.com:app_id`
- `accounts.google.com:aud`
- `cognito-identity.amazonaws.com:aud`

The `graph.facebook.com:app_id` field supplies the audience context that matches the `aud` field used by other identity providers.

The `accounts.google.com:aud` condition key matches the following Google ID Token fields.

- `aud` for OAuth 2.0 Google client IDs of your application, when the `azp` field is not set. When the `azp` field is set, the `aud` field matches the [accounts.google.com:oauth](#) condition key.
- `azp` when the `azp` field is set. This can happen for hybrid apps where a web application and Android app have a different OAuth 2.0 Google client ID but share the same Google APIs project.

For more information about Google `aud` and `azp` fields, see the [Google Identity Platform OpenID Connect](#) Guide.

When you write a policy using the `accounts.google.com:aud` condition key, you must know whether the app is a hybrid app that sets the `azp` field.

azp Field Not Set

The following example policy works for non-hybrid apps that do not set the `azp` field. In this case the Google ID Token `aud` field value matches both the `accounts.google.com:aud` and the `accounts.google.com:oauth` condition key values.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
```

```

    "Effect": "Allow",
    "Principal": {"Federated": "accounts.google.com"},
    "Action": "sts:AssumeRoleWithWebIdentity",
    "Condition": {
      "StringEquals": {
        "accounts.google.com:aud": "aud-value",
        "accounts.google.com:oauth": "aud-value",
        "accounts.google.com:sub": "sub-value"
      }
    }
  }
]
}

```

azp Field Set

The following example policy works for hybrid apps that do set the azp field. In this case, the Google ID Token aud field value matches only the `accounts.google.com:oauth` condition key value. The azp field value matches the `accounts.google.com:aud` condition key value.

```

{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Principal": {"Federated": "accounts.google.com"},
      "Action": "sts:AssumeRoleWithWebIdentity",
      "Condition": {
        "StringEquals": {
          "accounts.google.com:aud": "azp-value",
          "accounts.google.com:oauth": "aud-value",
          "accounts.google.com:sub": "sub-value"
        }
      }
    }
  ]
}

```

id

Works with [string operators](#).

Examples:

- `graph.facebook.com:id`
- `www.amazon.com:app_id`
- `www.amazon.com:user_id`

Use these keys to verify that the application (or site) ID or user ID matches the one that you specify in the policy. This works for Facebook or Login with Amazon. You can use the `app_id` key with the `id` key for the same identity provider.

oaud

Works with [string operators](#).

Example: `accounts.google.com:oaud`

If you use Google for web identity federation, this key specifies the Google audience (aud) that this ID token is intended for. It must be one of the OAuth 2.0 client IDs of your application.

sub

Works with [string operators](#).

Examples:

- `accounts.google.com:sub`
- `cognito-identity.amazonaws.com:sub`

Use these keys to verify that the user ID matches the one that you specify in the policy. You can use the `sub` key with the `aud` key for the same identity provider.

```
{
  "Version": "2012-10-17",
  "Statement": [
    "Condition": {
      "StringEquals": {
        "oidc.eks.us-east-1.amazonaws.com/id/111122223333:aud":
"sts.amazonaws.com",
        "oidc.eks.us-east-1.amazonaws.com/id/111122223333:sub":
"system:serviceaccount:default:assumer"
      }
    }
  ]
}
```

More information about web identity federation

For more information about web identity federation, see the following:

- [Amazon Cognito User Guide](#).
- [About web identity federation](#)

Cross-service AWS web identity federation context keys

Some web identity federation condition keys can be used in role trust policies to define what users are allowed to access in other AWS services. These are the following condition keys that can be used in role trust policies when federated principals assume another role, and in resource policies from other AWS services to authorize resource access by federated principals. If you are using Amazon Cognito for web identity federation, then these keys are available when the user is authenticated.

Select a condition key to see the description.

- [amr](#)
- [aud](#)
- [id](#)
- [sub](#)

Note

No other web identity based federation condition keys are available for use after the external identity provider (IdP) authentication and authorization for the initial AssumeRoleWithWebIdentity operation.

Available keys for SAML-based AWS STS federation

If you are working with [SAML-based federation](#) using AWS Security Token Service (AWS STS), you can include additional condition keys in the policy.

SAML role trust policies

In the trust policy of a role, you can include the following keys, which help you establish whether the caller is allowed to assume the role. Except for `saml:doc`, all the values are derived from the

SAML assertion. All items in the list are available in the IAM console visual editor when you create or edit a policy with conditions. Items marked with `[]` *can* have a value that is a list of the specified type.

saml:aud

Works with [string operators](#).

An endpoint URL to which SAML assertions are presented. The value for this key comes from the SAML Recipient field in the assertion, *not* the Audience field.

saml:commonName[]

Works with [string operators](#).

This is a commonName attribute.

saml:cn[]

Works with [string operators](#).

This is an eduOrg attribute.

saml:doc

Works with [string operators](#).

This represents the principal that was used to assume the role. The format is *account-ID/provider-friendly-name*, such as 123456789012/SAMLProviderName. The *account-ID* value refers to the account that owns the [SAML provider](#).

saml:edupersonaffiliation[]

Works with [string operators](#).

This is an eduPerson attribute.

saml:edupersonassurance[]

Works with [string operators](#).

This is an eduPerson attribute.

saml:edupersonentitlement[]

Works with [string operators](#).

This is an eduPerson attribute.

saml:edupersonnickname[]

Works with [string operators](#).

This is an eduPerson attribute.

saml:edupersonorgdn

Works with [string operators](#).

This is an eduPerson attribute.

saml:edupersonorgunitdn[]

Works with [string operators](#).

This is an eduPerson attribute.

saml:edupersonprimaryaffiliation

Works with [string operators](#).

This is an eduPerson attribute.

saml:edupersonprimaryorgunitdn

Works with [string operators](#).

This is an eduPerson attribute.

saml:edupersonprincipalname

Works with [string operators](#).

This is an eduPerson attribute.

saml:edupersonscopedaffiliation[]

Works with [string operators](#).

This is an eduPerson attribute.

saml:edupersontargetedid[]

Works with [string operators](#).

This is an eduPerson attribute.

saml:eduorghomepageuri[]

Works with [string operators](#).

This is an eduOrg attribute.

saml:eduorgidentityauthnpolicyuri[]

Works with [string operators](#).

This is an eduOrg attribute.

saml:eduorglegalname[]

Works with [string operators](#).

This is an eduOrg attribute.

saml:eduorgsuperioruri[]

Works with [string operators](#).

This is an eduOrg attribute.

saml:eduorgwhitepagesuri[]

Works with [string operators](#).

This is an eduOrg attribute.

saml:givenName[]

Works with [string operators](#).

This is a givenName attribute.

saml:iss

Works with [string operators](#).

The issuer, which is represented by a URN.

saml:mail[]

Works with [string operators](#).

This is a mail attribute.

saml:name[]

Works with [string operators](#).

This is a name attribute.

saml:namequalifier

Works with [string operators](#).

A hash value based on the friendly name of the SAML provider. The value is the concatenation of the following values, in order and separated by a '/' character:

1. The Issuer response value (`saml:iss`)
2. The AWS account ID
3. The friendly name (the last part of the ARN) of the SAML provider in IAM

The concatenation of the account ID and friendly name of the SAML provider is available to IAM policies as the key `saml:doc`. For more information, see [Uniquely identifying users in SAML-based federation](#).

saml:organizationStatus[]

Works with [string operators](#).

This is an `organizationStatus` attribute.

saml:primaryGroupSID[]

Works with [string operators](#).

This is a `primaryGroupSID` attribute.

saml:sub

Works with [string operators](#).

This is the subject of the claim, which includes a value that uniquely identifies an individual user within an organization (for example, `_cbb88bf52c2510eabe00c1642d4643f41430fe25e3`).

saml:sub_type

Works with [string operators](#).

This key can have the value `persistent`, `transient`, or consist of the full Format URI from the `Subject` and `NameID` elements used in your SAML assertion. A value of `persistent` indicates that the value in `saml:sub` is the same for a user between sessions. If the value is `transient`, the user has a different `saml:sub` value for each session. For information about the `NameID` element's `Format` attribute, see [Configuring SAML assertions for the authentication response](#).

saml:surname[]

Works with [string operators](#).

This is a surnameuid attribute.

saml:uid[]

Works with [string operators](#).

This is a uid attribute.

saml:x500UniqueIdentifier[]

Works with [string operators](#).

This is an x500UniqueIdentifier attribute.

For general information about eduPerson and eduOrg attributes, see the [REFEDS Wiki website](#). For a list of eduPerson attributes, see [eduPerson Object Class Specification \(201602\)](#).

Condition keys whose type is a list can include multiple values. To create conditions in the policy for list values, you can use [set operators](#) (ForAllValues, ForAnyValue). For example, to allow any user whose affiliation is "faculty" or "staff" (but not "student"), you might use a condition like the following:

```
"Condition": {
  "ForAllValues:StringLike": {
    "saml:edupersonaffiliation":[ "faculty", "staff"]
  }
}
```

Cross-service SAML-based AWS STS federation context keys

Some SAML-based federation condition keys can be used in subsequent requests to authorize AWS operations in other services and AssumeRole calls. These are the following condition keys that can be used in role trust policies when federated principals assume another role, and in resource policies from other AWS services to authorize resource access by federated principals. For more information about using these keys, see [About SAML 2.0-based federation](#).

Select a condition key to see the description.

- [saml:namequalifier](#)

- [saml:sub](#)
- [saml:sub_type](#)

Note

No other SAML-based federation condition keys are available for use after the initial external identity provider (IdP) authentication response.

Available keys for AWS STS

You can use the following condition keys in IAM role trust policies for roles that are assumed using AWS Security Token Service (AWS STS) operations.

saml:sub

Works with [string operators](#).

This is the subject of the claim, which includes a value that uniquely identifies an individual user within an organization (for example, `_cbb88bf52c2510eabe00c1642d4643f41430fe25e3`).

sts:AWSServiceName

Works with [string operators](#).

Use this key to specify a service where a bearer token can be used. When you use this condition key in a policy, specify the service using a service principal. A service principal is the name of a service that can be specified in the `Principal` element of a policy. For example, `codeartifact.amazonaws.com` is the AWS CodeArtifact service principal.

Some AWS services require that you have permission to get an AWS STS service bearer token before you can access their resources programmatically. For example, AWS CodeArtifact requires principals to use bearer tokens to perform some operations. The `aws codeartifact get-authorization-token` command returns a bearer token. You can then use the bearer token to perform AWS CodeArtifact operations. For more information about bearer tokens, see [Using bearer tokens](#).

Availability – This key is present in requests that get a bearer token. You cannot make a direct call to AWS STS to get a bearer token. When you perform some operations in other services, the service requests the bearer token on your behalf.

You can use this condition key to allow principals to get a bearer token for use with a specific service.

sts:DurationSeconds

Works with [numeric operators](#).

Use this key to specify the duration (in seconds) that a principal can use when getting an AWS STS bearer token.

Some AWS services require that you have permission to get an AWS STS service bearer token before you can access their resources programmatically. For example, AWS CodeArtifact requires principals to use bearer tokens to perform some operations. The `aws codeartifact get-authorization-token` command returns a bearer token. You can then use the bearer token to perform AWS CodeArtifact operations. For more information about bearer tokens, see [Using bearer tokens](#).

Availability – This key is present in requests that get a bearer token. You cannot make a direct call to AWS STS to get a bearer token. When you perform some operations in other services, the service requests the bearer token on your behalf. The key is not present for AWS STS assume-role operations.

sts:ExternalId

Works with [string operators](#).

Use this key to require that a principal provide a specific identifier when assuming an IAM role.

Availability – This key is present in the request when the principal provides an external ID while assuming a role using the AWS CLI or AWS API.

A unique identifier that might be required when you assume a role in another account. If the administrator of the account to which the role belongs provided you with an external ID, then provide that value in the `ExternalId` parameter. This value can be any string, such as a passphrase or account number. The primary function of the external ID is to address and prevent the confused deputy problem. For more information about the external ID and the confused deputy problem, see [How to use an external ID when granting access to your AWS resources to a third party](#).

The `ExternalId` value must have a minimum of 2 characters and a maximum of 1,224 characters. The value must be alphanumeric without white space. It can also include the

following symbols: plus (+), equal (=), comma (,), period (.), at (@), colon (:), forward slash (/), and hyphen (-).

sts:RequestContext/context-key

Works with [string operators](#).

Use this key to compare the session context key-value pairs that are embedded in the trusted token issuer signed context assertion passed in the request with the context key-values specified in the role trust policy.

Availability – This key is present in the request when a context assertion is provided in the `ProvidedContexts` request parameter while assuming a role using the AWS STS `AssumeRole` API operation.

This context key is formatted as `"sts:RequestContext/context-key": "context-value"` where `context-key` and `context-value` are a context key-value pair. When multiple context keys are embedded in the signed context assertion passed in the request, there is one context key for each key-value pair. You must grant permission for the `sts:SetContext` action in the role trust policy to allow a principal to set context keys within the resulting session token.

You can use this key in a role trust policy to enforce fine-grained access control based on the user or their attributes when they assume a role. For example, you can configure Amazon Redshift as an IAM Identity Center application to access Amazon S3 resources on behalf of your workforce or federated identities.

The following role trust policy allows the Amazon Redshift service principal to assume a role in account 111122223333. It also grants permission to the Amazon Redshift service principal to set context keys in the request, as long as the `identitystore:UserId` context-key value set is 1111-22-3333-44-5555. After the role is assumed, activity appears in the AWS CloudTrail logs within the `AdditionalEventData` element, containing the session context key-value pairs that were set by the context provider in the assume role request. This makes it easier for administrators to differentiate between role sessions when a role is used by different principals. The key-value pairs are set by the specified context provider, not by AWS CloudTrail or AWS STS. This gives the context provider control over what context is included in the CloudTrail logs and session information.

```
{
  "Version": "2012-10-17",
  "Statement": [
```

```

    {
      "Effect": "Allow",
      "Principal": {
        "Service": "redshift.amazonaws.com"
      },
      "Action": [
        "sts:AssumeRole",
        "sts:SetContext"
      ],
      "Condition": {
        "ForAllValues:ArnEquals": {
          "sts:RequestContextProviders": [
            "arn:aws:iam::aws:contextProvider/IdentityCenter"
          ]
        },
        "StringEquals": {
          "aws:SourceAccount": "111122223333",
          "sts:RequestContext/identitystore:UserId":
"1111-22-3333-44-5555"
        }
      }
    }
  ]
}

```

sts:RequestContextProviders

Works with [ARN operators](#).

Use this key to compare the context provider ARN in the request with the context provider ARN specified in the role trust policy.

Availability – This key is present in the request when a context assertion is provided in the `ProvidedContexts` request parameter while assuming a role using the AWS STS `AssumeRole` API operation.

The following example condition checks that the context provider ARN passed in the request matches the ARN specified in the role trust policy condition.

```

"Condition": {
  "ForAllValues:ArnEquals": {
    "sts:RequestContextProviders": [
      "arn:aws:iam::aws:contextProvider/IdentityCenter"
    ]
  }
}

```

```
    ]  
  }  
}
```

sts:RoleSessionName

Works with [string operators](#).

Use this key to compare the session name that a principal specifies when assuming a role with the value that is specified in the policy.

Availability – This key is present in the request when the principal assumes the role using the AWS Management Console, any assume-role CLI command, or any AWS STS AssumeRole API operation.

You can use this key in a role trust policy to require that your users provide a specific session name when they assume a role. For example, you can require that IAM users specify their own user name as their session name. After the IAM user assumes the role, activity appears in [AWS CloudTrail logs](#) with the session name that matches their user name. This makes it easier for administrators to differentiate between role sessions when a role is used by different principals.

The following role trust policy requires that IAM users in account 111122223333 provide their IAM user name as the session name when they assume the role. This requirement is enforced using the `aws:username` [condition variable](#) in the condition key. This policy allows IAM users to assume the role to which the policy is attached. This policy does not allow anyone using temporary credentials to assume the role because the `username` variable is present for only IAM users.

Important

You can use any single-valued condition key as a [variable](#). You can't use a multivalued condition key as a variable.

```
{  
  "Version": "2012-10-17",  
  "Statement": [  
    {  
      "Sid": "RoleTrustPolicyRequireUsernameForSessionName",  
      "Effect": "Allow",
```

```

    "Action": "sts:AssumeRole",
    "Principal": {"AWS": "arn:aws:iam::111122223333:root"},
    "Condition": {
      "StringLike": {"sts:RoleSessionName": "${aws:username}"}
    }
  }
]
}

```

When an administrator views the AWS CloudTrail log for an action, they can compare the session name to the user names in their account. In the following example, the user named `matjac` performed the operation using the role named `MateoRole`. The administrator can then contact Mateo Jackson, who has the user named `matjac`.

```

"assumedRoleUser": {
  "assumedRoleId": "AROACQRSTUVWRAOEXAMPLE:matjac",
  "arn": "arn:aws:sts::111122223333:assumed-role/MateoRole/matjac"
}

```

If you allow [cross-account access using roles](#), then users in one account can assume a role in another account. The ARN of the assumed role user listed in CloudTrail includes the account *where the role exists*. It does not include the account of the user that assumed the role. Users are unique only within an account. Therefore, we recommend that you use this method for checking CloudTrail logs only for roles that are assumed by users in accounts that you administer. Your users might use the same user name in multiple accounts.

sts:SourceIdentity

Works with [string operators](#).

Use this key to compare the source identity that a principal specifies when assuming a role with the value that is specified in the policy.

Availability – This key is present in the request when the principal provides a source identity while assuming a role using any AWS STS assume-role CLI command, or AWS STS AssumeRole API operation.

You can use this key in a role trust policy to require that your users set a specific source identity when they assume a role. For example, you can require your workforce or federated identities to specify a value for source identity. You can configure your identity provider (IdP) to use one of the attributes that are associated with your users, like a user name or email as the source

identity. The IdP then passes the source identity as an attribute in the assertions or claims that it sends to AWS. The value of the source identity attribute identifies the user or application who is assuming the role.

After the user assumes the role, activity appears in [AWS CloudTrail logs](#) with the source identity value that was set. This makes it easier for administrators to determine who or what performed actions with a role in AWS. You must grant permissions for the `sts:SetSourceIdentity` action to allow an identity to set a source identity.

Unlike [sts:RoleSessionName](#), after the source identity is set, the value cannot be changed. It is present in the request context for all actions taken with the role by the source identity. The value persists into subsequent role sessions when you use the session credentials to assume another role. Assuming one role from another is called [role chaining](#).

You can use the [aws:SourceIdentity](#) global condition key to further control access to AWS resources based on the value of source identity in subsequent requests.

The following role trust policy allows the IAM user AdminUser to assume a role in account 111122223333. It also grants permission to the AdminUser to set a source identity, as long as the source identity set is DiegoRamirez.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "AllowAdminUserAssumeRole",
      "Effect": "Allow",
      "Principal": {"AWS": "arn:aws:iam::111122223333:user/AdminUser"},
      "Action": [
        "sts:AssumeRole",
        "sts:SetSourceIdentity"
      ],
      "Condition": {
        "StringEquals": {"sts:SourceIdentity": "DiegoRamirez"}
      }
    }
  ]
}
```

To learn more about using source identity information, see [Monitor and control actions taken with assumed roles](#).

sts:TransitiveTagKeys

Works with [string operators](#).

Use this key to compare the transitive session tag keys in the request with those specified in the policy.

Availability – This key is present in the request when you make a request using temporary security credentials. These include credentials created using any assume-role operation, or the `GetFederationToken` operation.

When you make a request using temporary security credentials, the [request context](#) includes the `aws:PrincipalTag` context key. This key includes a list of [session tags](#), [transitive session tags](#), and role tags. Transitive session tags are tags that persist into all subsequent sessions when you use the session credentials to assume another role. Assuming one role from another is called [role chaining](#).

You can use this condition key in a policy to require setting specific session tags as transitive when assuming a role or federating a user.

Actions, resources, and condition keys for AWS services

Each AWS service can define actions, resources, and condition context keys for use in IAM policies. For a list of AWS services and their actions, resources, and condition context keys, see [Actions, resources, and condition keys](#) in the *Service Authorization Reference*.

Resources to learn more about IAM

IAM is a rich product, and you'll find many resources to help you learn more about how IAM can help you secure your AWS account and resources.

Topics

- [Identities](#)
- [Credentials \(passwords, access keys, and MFA devices\)](#)
- [Permissions and policies](#)
- [Federation and delegation](#)
- [IAM and other AWS products](#)
- [General security practices](#)
- [General resources](#)

Identities

Consult these resources for creating, managing, and using identities.

- [Manage identities in IAM Identity Center](#) – Procedural information about creating users and group in IAM Identity Center.
- [IAM Identities \(users, user groups, and roles\)](#) – An in-depth discussion of users, groups, and roles.

Credentials (passwords, access keys, and MFA devices)

Review the following guides to manage passwords, access keys, and MFA devices for your AWS account and for IAM users.

- [Managing user passwords in AWS](#) – Describes options for managing passwords for IAM users in your account.
- [Managing access keys for IAM users](#) – Describes how *access keys* work and how you can use them to make programmatic calls to AWS. There are other more secure alternatives to access keys that we recommend you consider first. For more information, see [Considerations and alternatives for long-term access keys](#) in the *AWS General Reference guide*.

- [Using multi-factor authentication \(MFA\) in AWS](#) – Describes how to configure your account and IAM users to require both a password and a one-time use code that is generated on a device before sign-in is allowed. (This is sometimes called two-factor authentication.)

For general information about the types of credentials you use to access Amazon Web Services, see [AWS Security Credentials](#) in the *AWS General Reference guide*.

Permissions and policies

Learn the inner workings of IAM policies and find tips on the best ways to confer permissions:

- [Policies and permissions in IAM](#) – Introduces the policy language that is used to define permissions. Describes how permissions can be attached to users or groups or, for some AWS products, to resources themselves.
- [IAM JSON policy elements reference](#) – Provides descriptions and examples of each policy language element.
- [Validating IAM policies](#) – Find resources for JSON policy validation.
- [Example IAM identity-based policies](#) – Shows examples of policies for common tasks in various AWS products.
- [AWS Policy Generator](#) – Create custom policies by choosing products and actions from a list.
- [IAM Policy Simulator](#) – Test whether a policy would allow or deny a specific request to AWS.

Federation and delegation

You can grant access to resources in your AWS account for users who are authenticated (signed in) elsewhere. These can be IAM users in another AWS account (known as *delegation*), users who are authenticated with your organization's sign-in process, or users from an Internet identity provider like Login with Amazon, Facebook, Google, or any other OpenID Connect (OIDC) compatible identity provider. In these cases, the users get temporary security credentials to access AWS resources.

- [IAM tutorial: Delegate access across AWS accounts using IAM roles](#) – Guides you through granting cross-account access to an IAM user in another AWS account.
- [Common scenarios for temporary credentials](#) – Describes ways in which users can be federated into AWS after being authenticated outside of AWS.

- [Web Identity Federation Playground](#) – Lets you experiment with Login with Amazon, Google, or Facebook to authenticate and then make a call to Amazon S3.

IAM and other AWS products

Most AWS products are integrated with IAM so that you can use IAM features to help protect access to the resources in those products. The following resources discuss IAM and security for some of the most popular AWS products. For a complete list of products that work with IAM, including links to more information on each, see [AWS services that work with IAM](#).

Using IAM with Amazon EC2

- [Controlling Access to Amazon EC2 Resources](#) – Describes how to use IAM features to permit users to administer Amazon EC2 instances, volumes, and more.
- [Using instance profiles](#) – Describes how to use IAM roles to securely provide credentials for applications that run on Amazon EC2 instances and that need access to other AWS products.

Using IAM with Amazon S3

- [Managing Access Permissions to Your Amazon S3 Resources](#) – Discusses the Amazon S3 security model for buckets and objects, which includes IAM policies.
- [Writing IAM Policies: Grant Access to User-Specific Folders in an Amazon S3 Bucket](#) – Discusses how to let users protect their own folders in Amazon S3. (For more posts about Amazon S3 and IAM, choose the **S3** tag below the title of the blog post.)

Using IAM with Amazon RDS

- [Using AWS Identity and Access Management \(IAM\) to Manage Access to Amazon RDS Resources](#) – Describes how to use IAM to control access to database instances, database snapshots, and more.
- [A Primer on RDS Resource-Level Permissions](#) – Describes how to use IAM to control access to specific Amazon RDS instances.

Using IAM with Amazon DynamoDB

- [Using IAM to Control Access to DynamoDB Resources](#) – Describes how to use IAM to permit users to administer DynamoDB tables and indexes.
- The following video (8:55) explains how to provide access control for individual DynamoDB database items or attributes (or both).

[Getting Started with Fine-Grained Access Control for DynamoDB](#)

General security practices

Find expert tips and guidance on the best ways to secure your AWS account and resources:

- [Best Practices for Security, Identity, & Compliance](#) – Find resources for how to manage security across AWS accounts and products, including suggestions for security architecture, use of IAM, encryption and data security, and more.
- [Identity and Access Management](#) – The AWS Well-Architected Framework helps you understand key concepts, design principles, and architectural best practices for designing and running workloads in the cloud.
- [Security best practices in IAM](#) – Offers recommendations for ways to use IAM to help secure your AWS account and resources.
- [AWS CloudTrail User Guide](#) – Use AWS CloudTrail to track a history of API calls made to AWS and store that information in log files. This helps you determine which users and accounts accessed resources in your account, when the calls were made, what actions were requested, and more.

General resources

Explore the following resources to learn more about IAM and AWS.

- [Product Information for IAM](#) – General information about the AWS Identity and Access Management product.
- [AWS re:Post for AWS Identity and Access Management](#) – Visit AWS re:Post to discuss technical questions related to IAM with the AWS community.

- [Classes & Workshops](#) – Links to role-based and specialty courses, in addition to self-paced labs to help sharpen your AWS skills and gain practical experience.
- [AWS Developer Center](#) – Explore tutorials, download tools, and learn about AWS developer events.
- [AWS Developer Tools](#) – Links to developer tools, SDKs, IDE toolkits, and command line tools for developing and managing AWS applications.
- [Getting Started Resource Center](#) – Learn how to set up your AWS account, join the AWS community, and launch your first application.
- [Hands-On Tutorials](#) – Follow step-by-step tutorials to launch your first application on AWS.
- [AWS Whitepapers](#) – Links to a comprehensive list of technical AWS whitepapers, covering topics such as architecture, security, and economics and authored by AWS Solutions Architects or other technical experts.
- [AWS Support Center](#) – The hub for creating and managing your AWS Support cases. Also includes links to other helpful resources, such as forums, technical FAQs, service health status, and AWS Trusted Advisor.
- [AWS Support](#) – The primary webpage for information about AWS Support, a one-on-one, fast-response support channel to help you build and run applications in the cloud.
- [Contact Us](#) – A central contact point for inquiries concerning AWS billing, account, events, abuse, and other issues.
- [AWS Site Terms](#) – Detailed information about our copyright and trademark; your account, license, and site access; and other topics.

Calling the IAM API using HTTP query requests

Contents

- [Endpoints](#)
- [HTTPS required](#)
- [Signing IAM API requests](#)

You can access the IAM and AWS STS services programmatically using the Query API. Query API requests are HTTPS requests that must contain an `Action` parameter to indicate the action to be performed. IAM and AWS STS support GET and POST requests for all actions. That is, the API does not require you to use GET for some actions and POST for others. However, GET requests are subject to the limitation size of a URL; although this limit is browser dependent, a typical limit is 2048 bytes. Therefore, for Query API requests that require larger sizes, you must use a POST request.

The response is an XML document. For details about the response, see the individual action pages in the [IAM API Reference](#) or the [AWS Security Token Service API Reference](#).

Tip

Instead of making direct calls to the IAM or AWS STS API operations, you can use one of the AWS SDKs. The AWS SDKs consist of libraries and sample code for various programming languages and platforms (Java, Ruby, .NET, iOS, Android, etc.). The SDKs provide a convenient way to create programmatic access to IAM and AWS. For example, the SDKs take care of tasks such as cryptographically signing requests (see below), managing errors, and retrying requests automatically. For information about the AWS SDKs, including how to download and install them, see the [Tools for Amazon Web Services](#) page.

For details about the API actions and errors, see the [IAM API Reference](#) or the [AWS Security Token Service API Reference](#).

Endpoints

IAM and AWS STS each have a single global endpoint:

- (IAM) <https://iam.amazonaws.com>
- (AWS STS) <https://sts.amazonaws.com>

Note

AWS STS also supports sending requests to regional endpoints in addition to the global endpoint. Before you can use AWS STS in a Region, you must first activate STS in that Region for your AWS account. For more information about activating additional Regions for AWS STS, see [Managing AWS STS in an AWS Region](#).

For more information about AWS endpoints and Regions for all services, see [Service endpoints and quotas](#) in the *AWS General Reference*.

HTTPS required

Because the Query API returns sensitive information such as security credentials, you must use HTTPS with all API requests.

Signing IAM API requests

Requests must be signed using an access key ID and a secret access key. We strongly recommend that you do not use your AWS account root user credentials for everyday work with IAM. You can use the credentials for an IAM user or you can use AWS STS to generate temporary security credentials.

To sign your API requests, we recommend using AWS Signature Version 4. For information about using Signature Version 4, go to [Signature Version 4 Signing Process](#) in the *AWS General Reference*.

If you need to use Signature Version 2, information about using Signature Version 2 is available in the [AWS General Reference](#).

For more information, see the following:

- [AWS Security Credentials](#). Provides general information about the types of credentials used for accessing AWS.
- [Security best practices in IAM](#). Presents a list of suggestions for using IAM service to help secure your AWS resources.

- [Temporary security credentials in IAM](#). Describes how to create and use temporary security credentials.

Document history for IAM

The following table describes major documentation updates for IAM.

Change	Description	Date
AccessAnalyzerServiceRolePolicy – Added permissions	IAM Access Analyzer added support for permission to retrieve the current state of the block public access for Amazon EC2 snapshots to the service-level permissions of AccessAnalyzerServiceRolePolicy .	January 23, 2024
AccessAnalyzerServiceRolePolicy – Added permissions	IAM Access Analyzer added DynamoDB streams and tables to the service-level permissions of AccessAnalyzerServiceRolePolicy .	January 11, 2024
AccessAnalyzerServiceRolePolicy – Added permissions	IAM Access Analyzer added Amazon S3 directory buckets to the service-level permissions of AccessAnalyzerServiceRolePolicy .	December 1, 2023
IAMAccessAnalyzerReadOnlyAccess – Added permissions	IAM Access Analyzer added permissions to IAMAccessAnalyzerReadOnlyAccess to allow you to check whether updates to your policies grant additional access. This permission is required by IAM Access Analyzer to	November 26, 2023

perform policy checks on your policies.

[IAM Access Analyzer added unused access analyzers](#)

IAM Access Analyzer simplifies inspecting unused access to guide you toward least privilege. IAM Access Analyzer continuously analyzes your accounts to identify unused access and creates a centralized dashboard with findings.

November 26, 2023

[IAM Access Analyzer added custom policy checks](#)

IAM Access Analyzer now provides custom policy checks to validate that IAM policies adhere to your security standards ahead of deployments.

November 26, 2023

[AccessAnalyzerServiceRolePolicy – Added permissions](#)

IAM Access Analyzer added IAM actions to the service-level permissions of [AccessAnalyzerServiceRolePolicy](#) to support the following actions:

November 26, 2023

- Listing entities for a policy
- Generating service last accessed details
- Listing access key information

[Action last accessed information and policy generation support for over 60 additional services and actions](#)

IAM now supports action last accessed information and [generates policies with action-level information](#) for over 60 additional services, along with a list of the actions for which action last accessed information is available.

November 1, 2023

[Action last accessed information support for over 140 services](#)

IAM now provides action last accessed information for more than 140 services, along with a list of the actions for which action last accessed information is available.

September 14, 2023

[Support for multiple multi-factor authentication \(MFA\) devices for root users and IAM users](#)

Now you can add up to eight MFA devices per user, including FIDO security keys, software time-based one-time password (TOTP) with virtual authenticator applications, or hardware TOTP tokens.

November 16, 2022

IAM Access Analyzer support for new resource types	<p>IAM Access Analyzer added support for the following resource types:</p> <ul style="list-style-type: none">• Amazon EBS volume snapshots• Amazon ECR repositories• Amazon EFS file systems• Amazon RDS DB snapshots• Amazon RDS DB cluster snapshots• Amazon SNS topics	October 25, 2022
U2F deprecation and WebAuthn/FIDO update	<p>Removed mentions of U2F as an MFA option and added information about WebAuthn, FIDO2, and FIDO security keys.</p>	May 31, 2022
Updates to resilience in IAM	<p>Added information about maintaining access to IAM credentials when an event disrupts communication between AWS Regions.</p>	May 16, 2022
New global condition keys for resources	<p>You can now control access to resources based on the account, Organizational Unit (OU), or organization in AWS Organizations that contains your resources. You can use the <code>aws:ResourceAccount</code>, <code>aws:ResourceOrgID</code>, and <code>aws:ResourceOrgPaths</code> global condition keys in an IAM policy.</p>	April 27, 2022

[Code examples for IAM using AWS SDKs](#)

Added code examples that show how to use IAM with an AWS software development kit (SDK). The examples are divided into code excerpts that show you how to call individual service functions and examples that show you how to accomplish a specific task by calling multiple functions within the same service.

April 7, 2022

[Updates to policy evaluation logic flow chart](#)

Updates to the policy evaluation logic flow chart and related text in the [Determining whether a request is allowed or denied within an account](#) section.

November 17, 2021

[Updates to security best practices](#)

Added information about creating administrative users instead of using root user credentials, removed the best practice of using user groups to assign permissions to IAM users, and clarified when to use managed policies instead of inline policies.

October 5, 2021

[Updates to policy evaluation logic topic for resource-based policies](#)

Added information about the impact of resource-based policies and different principal types in the same account.

October 5, 2021

Updates to single-valued and multivalued condition keys	The differences between single-valued and multivalued condition keys are now explained in more detail. The value type was added to each AWS global condition context key .	September 30, 2021
IAM Access Analyzer supports Amazon S3 Multi-Region Access Points	IAM Access Analyzer identifies Amazon S3 buckets that allow public and cross-account access, including those that use Amazon S3 Multi-Region Access Points .	September 2, 2021
AWS managed policy updates - Update to an existing policy	IAM Access Analyzer updated an existing AWS managed policy.	September 2, 2021
More services supported for action-level policy generation	IAM Access Analyzer can generate IAM policies with action-level access activity information for additional AWS services.	August 24, 2021
Generate IAM policies for cross-account trails	You can now use IAM Access Analyzer to generate fine-grained policies based on your access activity using a AWS CloudTrail trail in a different account, for example, a centralized AWS Organizations trail.	August 18, 2021

[Additional IAM Access Analyzer policy checks](#)

IAM Access Analyzer extended policy validation by adding new policy checks that validate conditions included in IAM policies. These checks analyze the condition block in your policy statement and report security warnings, errors, and suggestions along with actionable recommendations.

June 29, 2021

IAM Access Analyzer added the following policy checks:

- [Error – Invalid service principal format](#)
- [Error – Missing tag key in condition](#)
- [Security Warning – Deny NotAction with unsupported tag condition key for service](#)
- [Security Warning – Deny with unsupported tag condition key for service](#)
- [Security Warning – Missing paired condition keys](#)
- [Suggestion – Allow NotAction with unsupported tag condition key for service](#)
- [Suggestion – Allow with unsupported tag condition key for service](#)

[Action last accessed support for more services](#)

You can now view action last accessed information in the IAM console about the last time an IAM principal used an action for the following services: Amazon EC2, IAM, Lambda, and Amazon S3 management actions. You can also use the AWS CLI or AWS API to retrieve a data report. You can use this information to identify unnecessary permissions so that you can refine your IAM policies to better adhere to the principle of least privilege.

April 19, 2021

[Monitor and control actions taken with assumed roles](#)

Administrators can configure IAM roles to require that identities pass a source identity, which is logged in AWS CloudTrail. Reviewing source identity information helps administrators determine who or what performed actions with assumed role sessions.

April 13, 2021

[Generate IAM policies based on access activity](#)

You can now use IAM Access Analyzer to generate fine-grained policies based on your access activity found in your AWS CloudTrail.

April 7, 2021

IAM Access Analyzer policy checks	IAM Access Analyzer now provides over 100 policy checks with actionable recommendations during policy authoring.	March 16, 2021
Expanded policy validation options	Expanded policy validation available in the IAM console, AWS API, and AWS CLI using policy checks in IAM Access Analyzer to help you author secure and functional JSON policies.	March 15, 2021
Tagging IAM resources	You can now tag additional IAM resources using a tag key-value pair.	February 11, 2021
Default password policy for IAM users	If you do not set a custom password policy for your AWS account, IAM user passwords must now meet the default AWS password policy.	November 18, 2020
The actions, resources, and condition keys pages for AWS services have moved	Each AWS service can define actions, resources, and condition context keys for use in IAM policies. You can now find the list of AWS services and their actions, resources , and condition context keys in the <i>Service Authorization Reference</i> .	November 16, 2020

[IAM users longer role session duration](#)

IAM users can now have a longer role session duration when switching roles in the AWS Management Console, reducing interruptions due to session expiration. Users are granted the maximum session duration set for the role, or the remaining time in the IAM user's session, whichever is less.

July 24, 2020

[Use Service Quotas to request quick increases for IAM entities](#)

You can request quota increases for adjustable IAM quotas using the Service Quotas console. Now, some increases are automatically approved in Service Quotas and available in your account within a few minutes. Larger requests are submitted to AWS Support.

June 25, 2020

[Last accessed information in IAM now includes Amazon S3 management actions](#)

In addition to service last accessed information, you can now view information in the IAM console about the last time an IAM principal used an Amazon S3 action. You can also use the AWS CLI or AWS API to retrieve the data report. The report includes information about the allowed services and actions that principals last attempted to access and when. You can use this information to identify unnecessary permissions so that you can refine your IAM policies to better adhere to the principle of least privilege.

June 3, 2020

[Security chapter addition](#)

The security chapter helps you understand how to configure IAM and AWS STS to meet your security and compliance objectives. You also learn how to use other AWS services that help you to monitor and secure your IAM resources.

April 29, 2020

[sts:RoleSessionName](#)

You can now write a policy that grants permissions based on the session name that a principal specifies when assuming a role.

April 21, 2020

[AWS sign-in page update](#)

When you sign in on the main AWS sign-in page, you can no longer choose to sign in as the AWS account root user or an IAM user. When you do, the label on the page indicates whether you should provide your root user email address or your IAM user information. This documentation includes updated screen captures to help you understand the AWS sign-in pages.

March 4, 2020

[aws:ViaAWSService and aws:CalledVia condition keys](#)

You can now write a policy to limit whether services can make requests on behalf of an IAM principal (user or role). When a principal makes a request to an AWS service, that service might use the principal's credentials to make subsequent requests to other services. Use the `aws:ViaAWSService` condition key to match if any service makes a request using a principal's credentials. Use the `aws:CalledVia` condition keys to match if specific services make a request using a principal's credentials.

February 20, 2020

[Policy simulator adds support for permissions boundaries](#)

You can now test the effect of permissions boundaries on IAM entities with the IAM policy simulator.

January 23, 2020

[Cross-account policy evaluation](#)

You can now learn how AWS evaluates policies for cross-account access. This occurs when a resource in a trusting account includes a resource-based policy that allows a principal in another account to access the resource. The request must be allowed in both accounts.

January 2, 2020

[Session tags](#)

You can now include tags when you assume a role or federate a user in AWS STS. When you perform the `AssumeRole` or `GetFederationToken` operation, you can pass the session tags as attributes. When you perform the `AssumeRoleWithSAML` or `AssumeRoleWithWebIdentity` operations, you can pass attributes from your corporate identities to AWS.

November 22, 2019

[Control access for groups of AWS accounts in AWS Organizations](#)

You can now reference organizational units (OUs) from AWS Organizations in IAM policies. If you use Organizations to organize your accounts into OUs, you can require that principals belong to a specific OU before granting access to your resources. Principals include AWS account root user, IAM users and IAM roles. To do this, specify the OU path in the `aws:PrincipalOrgPaths` condition key in your policies.

November 20, 2019

[Role last used](#)

You can now view the date, time, and Region where a role was last used. This information also helps you identify unused roles in your account. You can use the AWS Management Console, AWS CLI and AWS API to view information about when a role was last used.

November 19, 2019

[Update to the global condition context keys page](#)

You can now learn when each of the global condition keys is included in the context of a request. You can also navigate to each key more easily using the page table of contents (TOC). The information on the page helps you to write more accurate policies. For example, if your employees use federation with IAM roles, you should use the `aws:userId` key and not the `aws:userName` key. The `aws:userName` key applies only to IAM users and not roles.

October 6, 2019

[ABAC in AWS](#)

Learn how attribute-based access control (ABAC) works in AWS using tags, and how it compares to the traditional AWS authorization model. Use the ABAC tutorial to learn how to create and test a policy that allows IAM roles with principal tags to access resources with matching tags. This strategy allows individuals to view or edit only the AWS resources required for their jobs.

October 3, 2019

[AWS STS GetAccessKeyInfo operation](#)

You can review the AWS access keys in your code to determine whether the keys are from an account that you own. You can pass an access key ID using the [aws sts get-access-key-info](#) AWS CLI command or the [GetAccessKeyInfo](#) AWS API operation.

July 24, 2019

[Viewing Organizations service last accessed information in IAM](#)

You can now view service last accessed information for an AWS Organizations entity or policy in the **AWS Organizations** section of the IAM console. You can also use the AWS CLI or AWS API to retrieve the data report. This data includes information about the allowed services that principals in an Organizations account last attempted to access and when. You can use this information to identify unnecessary permissions so that you can refine your Organizations policies to better adhere to the principle of least privilege.

June 20, 2019

[Using a managed policy as a session policy](#)

You can now pass up to 10 managed policy ARNs when you assume a role. This allows you to limit the permissions of the role's temporary credentials.

May 7, 2019

[AWS STS Region compatibility of session tokens for the global endpoint](#)

You can now choose whether to use version 1 or version 2 global endpoint tokens. Version 1 tokens are valid only in AWS Regions that are available by default. These tokens will not work in manually enabled Regions, such as Asia Pacific (Hong Kong). Version 2 tokens are valid in all Regions. However, version 2 tokens are longer and might affect systems where you temporarily store tokens.

April 26, 2019

[Allow enabling and disabling AWS regions](#)

You can now create a policy that allows an administrator to enable and disable the Asia Pacific (Hong Kong) Region (ap-east-1).

April 24, 2019

[IAM user my security credentials page](#)

IAM users can now manage all of their own credentials on the **My Security Credentials** page. This AWS Management Console page displays account information such as the account ID and canonical user ID. Users can also view and edit their own passwords, access keys, X.509 certificates, SSH keys, and Git credentials.

January 24, 2019

[Access advisor API](#)

You can now use the AWS CLI and AWS API to view service last accessed information.

December 7, 2018

[Tagging IAM users and roles](#)

You can now use IAM tags to add custom attributes to an identity (IAM user or role) using a tag key-value pair. You can also use tags to control an identity's access to resources or to control what tags can be attached to an identity.

November 14, 2018

[U2F security keys](#)

You can now use U2F security keys as a multi-factor authentication (MFA) option when signing in to the AWS Management Console.

September 25, 2018

[Support for Amazon VPC endpoints](#)

You can now establish a private connection between your VPC and AWS STS in the US West (Oregon) Region.

July 31, 2018

Permissions boundaries	New feature makes it easier to grant trusted employees the ability to manage IAM permissions without also granting full IAM administrative access.	July 12, 2018
aws:PrincipalOrgID	New condition key provides an easier way to control access to AWS resources by specifying the AWS organization of IAM principals.	May 17, 2018
aws:RequestedRegion	New condition key provides an easier way to use IAM policies to control access to AWS Regions.	April 25, 2018
Increased session duration for IAM roles	An IAM role can now have a session duration of 12 hours.	March 28, 2018
Updated role-creation workflow	New workflow improves the process of creating trust relationships and attaching permissions to roles.	September 8, 2017
AWS account sign-in process	Updated AWS sign-in experience allows both the root user and IAM users to use the Sign In to the Console link on the AWS Management Console's home page.	August 25, 2017
Example IAM policies	Documentation update features more than 30 example policies.	August 2, 2017

IAM best practices	Information added to the Users section of the IAM console makes it easier to follow IAM best practices.	July 5, 2017
Auto Scaling resources	Resource-level permissions can control access to and permissions for Auto Scaling resources.	May 16, 2017
Amazon RDS for MySQL and Amazon Aurora databases	Database administrators can associate database users with IAM users and roles and thus manage user access to all AWS resources from a single location.	April 24, 2017
Service-linked roles	Service-linked roles provide an easier and more secure way to delegate permissions to AWS services.	April 19, 2017
Policy summaries	New policy summaries make it easier to understand permissions in IAM policies.	March 23, 2017
