What is IAM?

 [Follow us on Twitter](#)

AWS Identity and Access Management (IAM) is a web service that helps you securely control access to AWS resources. With IAM, you can centrally manage permissions that control which AWS resources users can access. You use IAM to control who is authenticated (signed in) and authorized (has permissions) to use resources.

When you create an AWS account, you begin with one sign-in identity that has complete access to all AWS services and resources in the account. This identity is called the AWS account *root user* and is accessed by signing in with the email address and password that you used to create the account. We strongly recommend that you don't use the root user for your everyday tasks. Safeguard your root user credentials and use them to perform the tasks that only the root user can perform. For the complete list of tasks that require you to sign in as the root user, see [Tasks that require root user credentials](#).

Video introduction to IAM

AWS Training and Certification provides a 10-minute video introduction to IAM:

[Introduction to AWS Identity and Access Management](#)

IAM features

IAM gives you the following features:

Shared access to your AWS account

You can grant other people permission to administer and use resources in your AWS account without having to share your password or access key.

Granular permissions

You can grant different permissions to different people for different resources. For example, you might allow some users complete access to Amazon Elastic Compute Cloud (Amazon EC2), Amazon Simple Storage Service (Amazon S3), Amazon DynamoDB, Amazon Redshift, and other AWS services. For other users, you can allow read-only access to just some S3 buckets, or permission to administer just some EC2 instances, or to access your billing information but nothing else.

Secure access to AWS resources for applications that run on Amazon EC2

You can use IAM features to securely provide credentials for applications that run on EC2 instances. These credentials provide permissions for your application to access other AWS resources. Examples include S3 buckets and DynamoDB tables.

Multi-factor authentication (MFA)

You can add two-factor authentication to your account and to individual users for extra security. With MFA you or your users must provide not only a password or access key to work with your account, but also a code from a specially configured device. If you already use a FIDO security key with other services, and it has an AWS supported configuration, you can use WebAuthn for MFA security. For more information, see [Supported configurations for using FIDO security keys](#).

Identity federation

You can allow users who already have passwords elsewhere—for example, in your corporate network or with an internet identity provider—to get temporary access to your AWS account.

Identity information for assurance

If you use [AWS CloudTrail](#), you receive log records that include information about those who made requests for resources in your account. That information is based on IAM identities.

PCI DSS Compliance

IAM supports the processing, storage, and transmission of credit card data by a merchant or service provider, and has been validated as being compliant with Payment Card Industry (PCI) Data Security Standard (DSS). For more information about PCI DSS, including how to request a copy of the AWS PCI Compliance Package, see [PCI DSS Level 1](#).

Integrated with many AWS services

For a list of AWS services that work with IAM, see [AWS services that work with IAM](#).

Eventually Consistent

IAM, like many other AWS services, is [eventually consistent](#). IAM achieves high availability by replicating data across multiple servers within Amazon's data centers around the world. If a request to change some data is successful, the change is committed and safely stored. However, the change must be replicated across IAM, which can take some time. Such changes include creating or updating users, groups, roles, or policies. We recommend that you do not include such IAM changes in the critical, high-availability code paths of your application. Instead, make IAM changes in a separate initialization or setup routine that you run less frequently. Also, be sure to verify that the changes have been propagated before production workflows depend on them. For more information, see [Changes that I make are not always immediately visible](#).

Free to use

AWS Identity and Access Management (IAM) and AWS Security Token Service (AWS STS) are features of your AWS account offered at no additional charge. You are charged only when you access other AWS services using your IAM users or AWS STS temporary security credentials. For information about the pricing of other AWS products, see the [Amazon Web Services pricing page](#).

Accessing IAM

You can work with AWS Identity and Access Management in any of the following ways.

AWS Management Console

The console is a browser-based interface to manage IAM and AWS resources. For more information about accessing IAM through the console, see [How to sign in to AWS](#) in the *AWS Sign-In User Guide*.

AWS Command Line Tools

You can use the AWS command line tools to issue commands at your system's command line to perform IAM and AWS tasks. Using the command line can be faster and more convenient than the console. The command line tools are also useful if you want to build scripts that perform AWS tasks.

AWS provides two sets of command line tools: the [AWS Command Line Interface](#) (AWS CLI) and the [AWS Tools for Windows PowerShell](#). For information about installing and using the AWS CLI, see the [AWS Command Line Interface User Guide](#). For information about installing and using the Tools for Windows PowerShell, see the [AWS Tools for Windows PowerShell User Guide](#).

After signing in to the console, you can use AWS CloudShell from your browser to run CLI or SDK commands. The permissions for accessing AWS resources are based on the credentials you used to sign-in to the console. Depending on your experience, you may find the CLI to be a more efficient method of managing your AWS account. For more information, see [Using AWS CloudShell to work with AWS Identity and Access Management](#)

AWS SDKs

AWS provides SDKs (software development kits) that consist of libraries and sample code for various programming languages and platforms (Java, Python, Ruby, .NET, iOS, Android, etc.). The SDKs provide a convenient way to create programmatic access to IAM and AWS. For example, the SDKs take care of tasks such as cryptographically signing requests, managing errors, and retrying requests automatically. For information about the AWS SDKs, including how to download and install them, see the [Tools for Amazon Web Services](#) page.

IAM Query API

You can access IAM and AWS programmatically by using the IAM Query API, which lets you issue HTTPS requests directly to the service. When you use the Query API, you must include code to digitally sign requests using your credentials. For more information, see [Calling the IAM API using HTTP query requests](#) and the [IAM API Reference](#).

When do I use IAM?

When you are performing different job functions

AWS Identity and Access Management is a core infrastructure service that provides the foundation for access control based on identities within AWS. You use IAM every time you access your AWS account.

How you use IAM differs, depending on the work that you do in AWS.

- **Service user** – If you use an AWS service to do your job, then your administrator provides you with the credentials and permissions that you need. As you use more advanced features to do your work, you might need additional permissions. Understanding how access is managed can help you request the right permissions from your administrator.
- **Service administrator** – If you're in charge of an AWS resource at your company, you probably have full access to IAM. It's your job to determine which IAM features and resources your service users should access. You must then submit requests to your IAM administrator to change the permissions of your service users. Review the information on this page to understand the basic concepts of IAM.
- **IAM administrator** – If you're an IAM administrator, you manage IAM identities and write policies to manage access to IAM.

When you are authorized to access AWS resources

Authentication is how you sign in to AWS using your identity credentials. You must be *authenticated* (signed in to AWS) as the AWS account root user, as an IAM user, or by assuming an IAM role.

You can sign in to AWS as a federated identity by using credentials provided through an identity source. AWS IAM Identity Center (IAM Identity Center) users, your company's single sign-on authentication, and your Google or Facebook credentials are examples of federated identities. When you sign in as a federated identity, your administrator previously set up identity federation using IAM roles. When you access AWS by using federation, you are indirectly assuming a role.

Depending on the type of user you are, you can sign in to the AWS Management Console or the AWS access portal. For more information about signing in to AWS, see [How to sign in to your AWS account](#) in the *AWS Sign-In User Guide*.

If you access AWS programmatically, AWS provides a software development kit (SDK) and a command line interface (CLI) to cryptographically sign your requests by using your credentials. If you don't use AWS tools, you must sign requests yourself. For more information about using the recommended method to sign requests yourself, see [Signing AWS API requests](#) in the *IAM User Guide*.

Regardless of the authentication method that you use, you might be required to provide additional security information. For example, AWS recommends that you use multi-factor authentication (MFA) to increase the security of your account. To learn more, see [Multi-factor authentication](#) in the *AWS IAM Identity Center User Guide* and [Using multi-factor authentication \(MFA\) in AWS](#) in the *IAM User Guide*.

When you sign-in as an IAM user

An [IAM user](#) is an identity within your AWS account that has specific permissions for a single person or application. Where possible, we recommend relying on temporary credentials instead of creating IAM users who have long-term credentials such as passwords and access keys. However, if you have specific use cases that require long-term credentials with IAM users, we recommend that you rotate access keys. For more information, see [Rotate access keys regularly for use cases that require long-term credentials](#) in the *IAM User Guide*.

An [IAM group](#) is an identity that specifies a collection of IAM users. You can't sign in as a group. You can use groups to specify permissions for multiple users at a time. Groups make permissions easier to manage for large sets of users. For example, you could have a group named *IAMAdmins* and give that group permissions to administer IAM resources.

Users are different from roles. A user is uniquely associated with one person or application, but a role is intended to be assumable by anyone who needs it. Users have permanent long-term credentials, but roles provide temporary credentials. To learn more, see [When to create an IAM user \(instead of a role\)](#) in the *IAM User Guide*.

When you assume an IAM role

An [IAM role](#) is an identity within your AWS account that has specific permissions. It is similar to an IAM user, but is not associated with a specific person. You can temporarily assume an IAM role in the AWS Management Console by [switching roles](#). You can assume a role by calling an AWS CLI or AWS API operation or by using a custom URL. For more information about methods for using roles, see [Using IAM roles](#) in the *IAM User Guide*.

IAM roles with temporary credentials are useful in the following situations:

- **Federated user access** – To assign permissions to a federated identity, you create a role and define permissions for the role. When a federated identity authenticates, the identity is associated with the role and is granted the permissions that are defined by the role. For information about roles for federation, see [Creating a role for a third-party Identity Provider](#) in the *IAM User Guide*. If you use IAM Identity Center, you configure a permission set. To control what your identities can access after they authenticate, IAM Identity Center correlates the permission set to a role in IAM. For information about permission sets, see [Permission sets](#) in the *AWS IAM Identity Center User Guide*.
- **Temporary IAM user permissions** – An IAM user or role can assume an IAM role to temporarily take on different permissions for a specific task.
- **Cross-account access** – You can use an IAM role to allow someone (a trusted principal) in a different account to access resources in your account. Roles are the primary way to grant cross-account access. However, with some AWS services, you can attach a policy directly to a resource (instead of using a role as a proxy). To learn the difference between roles and resource-based policies for cross-account access, see [How IAM roles differ from resource-based policies](#) in the *IAM User Guide*.
- **Cross-service access** – Some AWS services use features in other AWS services. For example, when you make a call in a service, it's common for that service to run applications in Amazon EC2 or store objects in Amazon S3. A service might do this using the calling principal's permissions, using a service role, or using a service-linked role.
 - **Forward access sessions (FAS)** – When you use an IAM user or role to perform actions in AWS, you are considered a principal. When you use some services, you might perform an action that then initiates another action in a different service. FAS uses the permissions of the principal calling an AWS service, combined with the requesting AWS service to make requests to downstream services. FAS requests are only made when a service receives a request that requires interactions with other AWS services or resources to complete. In this case, you must have permissions to perform both actions. For policy details when making FAS requests, see [Forward access sessions](#).
- **Service role** – A service role is an [IAM role](#) that a service assumes to perform actions on your behalf. An IAM administrator can create, modify, and delete a service role from within IAM. For more information, see [Creating a role to delegate permissions to an AWS service](#) in the *IAM User Guide*.
- **Service-linked role** – A service-linked role is a type of service role that is linked to an AWS service. The service can assume the role to perform an action on your behalf. Service-linked

roles appear in your AWS account and are owned by the service. An IAM administrator can view, but not edit the permissions for service-linked roles.

- **Applications running on Amazon EC2** – You can use an IAM role to manage temporary credentials for applications that are running on an EC2 instance and making AWS CLI or AWS API requests. This is preferable to storing access keys within the EC2 instance. To assign an AWS role to an EC2 instance and make it available to all of its applications, you create an instance profile that is attached to the instance. An instance profile contains the role and enables programs that are running on the EC2 instance to get temporary credentials. For more information, see [Using an IAM role to grant permissions to applications running on Amazon EC2 instances](#) in the *IAM User Guide*.

To learn whether to use IAM roles or IAM users, see [When to create an IAM role \(instead of a user\)](#) in the *IAM User Guide*.

When you create policies and permissions

You grant permissions to a user by creating a policy, which is a document that lists the actions that a user can perform and the resources those actions can affect. Any actions or resources that are not explicitly allowed are denied by default. Policies can be created and attached to principals (users, groups of users, roles assumed by users, and resources).

These policies are used with an IAM role:

- **Trust policy** – Defines which [principals](#) can assume the role, and under which conditions. A trust policy is a specific type of resource-based policy for IAM roles. A role can have only one trust policy.
- **Identity-based policies (inline and managed)** – These policies define the permissions that the user of the role is able to perform (or is denied from performing), and on which resources.

Use the [Example IAM identity-based policies](#) to help you define permissions for your IAM identities. After you find the policy that you need, choose view the policy to view the JSON for the policy. You can use the JSON policy document as a template for your own policies.

Note

If you are using IAM Identity Center to manage your users, you assign permission sets in IAM Identity Center instead of attaching a permissions policy to a principal. When you

assign a permission set to a group or user in AWS IAM Identity Center, IAM Identity Center creates corresponding IAM roles in each account, and attaches the policies specified in the permission set to those roles. IAM Identity Center manages the role, and allows the authorized users you've defined to assume the role. If you modify the permission set, IAM Identity Center ensures that the corresponding IAM policies and roles are updated accordingly.

For more information about IAM Identity Center, see [What is IAM Identity Center?](#) in the *AWS IAM Identity Center User Guide*.

How IAM works

IAM provides the infrastructure necessary to control authentication and authorization for your AWS account. The IAM infrastructure is illustrated by the following diagram:

First, a human user or an application uses their sign-in credentials to authenticate with AWS. Authentication is provided by matching the sign-in credentials to a principal (an IAM user, federated user, IAM role, or application) trusted by the AWS account.

Next, a request is made to grant the principal access to resources. Access is granted in response to an authorization request. For example, when you first sign in to the console and are on the console Home page, you are not accessing a specific service. When you select a service, the request for authorization is sent to that service and it looks to see if your identity is on the list of authorized users, what policies are being enforced to control the level of access granted, and any other policies that might be in effect. Authorization requests can be made by principals within your AWS account or from another AWS account that you trust.

Once authorized, the principal can take action or perform operations on resources in your AWS account. For example, the principal could launch a new Amazon Elastic Compute Cloud instance, modify IAM group membership, or delete Amazon Simple Storage Service buckets.

Basic concepts

- [Terms](#)
- [Principal](#)
- [Request](#)
- [Authentication](#)
- [Authorization](#)
- [Actions or operations](#)
- [Resources](#)

Terms

These IAM terms are commonly used when working with AWS:

IAM Resource

IAM resources are stored in IAM. You can add, edit, and remove them from IAM.

- user
- group
- role
- policy
- identity-provider object

IAM Entity

IAM resources that AWS uses for authentication. Entities can be specified as a Principal in a resource-based policy.

- user
- role

IAM Identity

An IAM resource that can be authorized in policies to perform actions and to access resources. Identities include users, groups, and roles.

Principals

A person or application that uses the AWS account root user, an IAM user, or an IAM role to sign in and make requests to AWS. Principals include federated users and assumed roles.

Human users

Also known as *human identities*; the people, administrators, developers, operators, and consumers of your applications.

Workload

A collection of resources and code that delivers business value, such as an application or backend process. Can include applications, operational tools, and components.

Principal

A *principal* is a human user or workload that can make a request for an action or operation on an AWS resource. After authentication, the principal can be granted either permanent or temporary credentials to make requests to AWS, depending on the principal type. IAM users and root user are granted permanent credentials, while roles are granted temporary credentials. As a [best practice](#), we recommend that you require human users and workloads to access AWS resources using temporary credentials.

Request

When a principal tries to use the AWS Management Console, the AWS API, or the AWS CLI, that principal sends a *request* to AWS. The request includes the following information:

- **Actions or operations** – The actions or operations that the principal wants to perform. This can be an action in the AWS Management Console, or an operation in the AWS CLI or AWS API.
- **Resources** – The AWS resource object upon which the actions or operations are performed.
- **Principal** – The person or application that used an entity (user or role) to send the request. Information about the principal includes the policies that are associated with the entity that the principal used to sign in.
- **Environment data** – Information about the IP address, user agent, SSL enabled status, or the time of day.
- **Resource data** – Data related to the resource that is being requested. This can include information such as a DynamoDB table name or a tag on an Amazon EC2 instance.

AWS gathers the request information into a *request context*, which is used to evaluate and authorize the request.

Authentication

A principal must be authenticated (signed in to AWS) using their credentials to send a request to AWS. Some services, such as Amazon S3 and AWS STS, allow a few requests from anonymous users. However, they are the exception to the rule.

To authenticate from the console as a root user, you must sign in with your email address and password. As a federated user, you are authenticated by your identity provider and granted access to AWS resources by assuming IAM roles. As an IAM user, provide your account ID or alias, and then your user name and password. To authenticate workloads from the API or AWS CLI, you might use temporary credentials through being assigned a role or you might use long-term credentials by providing your access key and secret key. You might also be required to provide additional security information. As a best practice, AWS recommends that you use multi-factor authentication (MFA) and temporary credentials to increase the security of your account. To learn more about the IAM entities that AWS can authenticate, see [IAM users](#) and [IAM roles](#).

Authorization

You must also be authorized (allowed) to complete your request. During authorization, AWS uses values from the request context to check for policies that apply to the request. It then uses the policies to determine whether to allow or deny the request. Most policies are stored in AWS as [JSON documents](#) and specify the permissions for principal entities. There are [several types of policies](#) that can affect whether a request is authorized. To provide your users with permissions to access the AWS resources in their own account, you need only identity-based policies. Resource-based policies are popular for granting [cross-account access](#). The other policy types are advanced features and should be used carefully.

AWS checks each policy that applies to the context of your request. If a single permissions policy includes a denied action, AWS denies the entire request and stops evaluating. This is called an *explicit deny*. Because requests are *denied by default*, AWS authorizes your request only if every part of your request is allowed by the applicable permissions policies. The evaluation logic for a request within a single account follows these general rules:

- By default, all requests are denied. (In general, requests made using the AWS account root user credentials for resources in the account are always allowed.)
- An explicit allow in any permissions policy (identity-based or resource-based) overrides this default.
- The existence of an Organizations SCP, IAM permissions boundary, or a session policy overrides the allow. If one or more of these policy types exists, they must all allow the request. Otherwise, it is implicitly denied.
- An explicit deny in any policy overrides any allows.

To learn more about how all types of policies are evaluated, see [Policy evaluation logic](#). If you need to make a request in a different account, a policy in the other account must allow you to access the resource *and* the IAM entity that you use to make the request must have an identity-based policy that allows the request.

Actions or operations

After your request has been authenticated and authorized, AWS approves the actions or operations in your request. Operations are defined by a service, and include things that you can do to a resource, such as viewing, creating, editing, and deleting that resource. For example, IAM supports approximately 40 actions for a user resource, including the following actions:

- CreateUser
- DeleteUser
- GetUser
- UpdateUser

To allow a principal to perform an operation, you must include the necessary actions in a policy that applies to the principal or the affected resource. To see a list of actions, resource types, and condition keys supported by each service, see [Actions, Resources, and Condition Keys for AWS Services](#).

Resources

After AWS approves the operations in your request, they can be performed on the related resources within your account. A resource is an object that exists within a service. Examples include an Amazon EC2 instance, an IAM user, and an Amazon S3 bucket. The service defines a set of actions that can be performed on each resource. If you create a request to perform an unrelated action on a resource, that request is denied. For example, if you request to delete an IAM role but provide an IAM group resource, the request fails. To see AWS service tables that identify which resources are affected by an action, see [Actions, Resources, and Condition Keys for AWS Services](#).

Overview of AWS identity management: Users

You can give access to your AWS account to specific users and provide them specific permissions to access resources in your AWS account. You can use both IAM and AWS IAM Identity Center to create new users or federate existing users into AWS. The main difference between the two is that IAM users are granted long-term credentials to your AWS resources while users in IAM Identity Center have temporary credentials that are established each time the user signs-in to AWS. As a [best practice](#), require human users to use federation with an identity provider to access AWS using temporary credentials instead of as an IAM user. A primary use for IAM users is to give workloads that cannot use IAM roles the ability to make programmatic requests to AWS services using the API or CLI.

Topics

- [First-time access only: Your root user credentials](#)
- [IAM users and users in IAM Identity Center](#)

- [Federating existing users](#)
- [Access control methods](#)

First-time access only: Your root user credentials

When you create an AWS account, you begin with one sign-in identity that has complete access to all AWS services and resources in the account. This identity is called the AWS account *root user* and is accessed by signing in with the email address and password that you used to create the account. We strongly recommend that you don't use the root user for your everyday tasks. Safeguard your root user credentials and use them to perform the tasks that only the root user can perform. For the complete list of tasks that require you to sign in as the root user, see [Tasks that require root user credentials](#) in the *IAM User Guide*. Only service control policies (SCPs) in organizations can restrict the permissions that are granted to the root user.

IAM users and users in IAM Identity Center

IAM users are not separate accounts; they are users within your account. Each user can have its own password for access to the AWS Management Console. You can also create an individual access key for each user so that the user can make programmatic requests to work with resources in your account.

IAM users are granted long-term credentials to your AWS resources. As a best practice, do not create IAM users with long-term credentials for your human users. Instead, require your human users to use temporary credentials when accessing AWS.

Note

For scenarios in which you need IAM users with programmatic access and long-term credentials, we recommend that you update access keys when needed. For more information, see [Updating access keys](#).

In contrast, users in AWS IAM Identity Center are granted short-term credentials to your AWS resources. For centralized access management, we recommend that you use [AWS IAM Identity Center \(IAM Identity Center\)](#) to manage access to your accounts and permissions within those accounts. IAM Identity Center is automatically configured with an Identity Center directory as your default identity source where you can create users and groups, and assign their level of access to

your AWS resources. For more information, see [What is AWS IAM Identity Center](#) in the *AWS IAM Identity Center User Guide*.

Federating existing users

If the users in your organization already have a way to be authenticated, such as by signing in to your corporate network, you don't have to create separate IAM users or users in IAM Identity Center for them. Instead, you can *federate* those user identities into AWS using either IAM or AWS IAM Identity Center.

The following diagram shows how a user can get temporary AWS security credentials to access resources in your AWS account.

Federation is particularly useful in these cases:

- **Your users already exist in a corporate directory.**

If your corporate directory is compatible with Security Assertion Markup Language 2.0 (SAML 2.0), you can configure your corporate directory to provide single-sign on (SSO) access to the AWS Management Console for your users. For more information, see [Common scenarios for temporary credentials](#).

If your corporate directory is not compatible with SAML 2.0, you can create an identity broker application to provide single-sign on (SSO) access to the AWS Management Console for your users. For more information, see [Enabling custom identity broker access to the AWS console](#).

If your corporate directory is Microsoft Active Directory, you can use AWS IAM Identity Center to connect a self-managed directory in Active Directory or a directory in [AWS Directory Service](#) to establish trust between your corporate directory and your AWS account.

If you are using an external identity provider (IdP) such as Okta or Microsoft Entra to manage users, you can use AWS IAM Identity Center to establish trust between your IdP and your AWS account. For more information, see [Connect to an external identity provider](#) in the *AWS IAM Identity Center User Guide*.

- **Your users already have Internet identities.**

If you are creating a mobile app or web-based app that can let users identify themselves through an Internet identity provider like Login with Amazon, Facebook, Google, or any OpenID Connect (OIDC) compatible identity provider, the app can use federation to access AWS. For more information, see [About web identity federation](#).

Tip

To use identity federation with Internet identity providers, we recommend you use [Amazon Cognito](#).

Access control methods

Here are the ways you can control access to your AWS resources.

Type of user access	Why would I use it?	Where can I get more information?
Single sign-on access for human users, such as your workforce users, to AWS resources using IAM Identity Center	<p>IAM Identity Center provides a central place that brings together administration of users and their access to AWS accounts and cloud applications.</p> <p>You can set up an identity store within IAM Identity Center or you can configure federation with an existing identity provider (IdP). Granting your human users</p>	<p>For more information about setting up IAM Identity Center, see Getting Started in the <i>AWS IAM Identity Center User Guide</i></p> <p>For more information about using MFA in IAM Identity Center, see Multi-factor authentication in the <i>AWS IAM Identity Center User Guide</i></p>

Type of user access	Why would I use it?	Where can I get more information?
	<p>limited credentials to AWS resources as needed is recommended as a security best practice.</p> <p>Users have an easier sign-in experience and you maintain control over their access to resources from a single system. IAM Identity Center supports multi-factor authentication (MFA) for additional account security.</p>	
Federated access for human users, such as your workforce users, to AWS services using IAM identity providers	IAM supports IdPs that are compatible with OpenID Connect (OIDC) or SAML 2.0 (Security Assertion Markup Language 2.0). After you create an IAM identity provider, you must create one or more IAM roles that can be dynamically assigned to a federated user.	For more information about IAM identity providers and federation, see Identity providers and federation .

Type of user access	Why would I use it?	Where can I get more information?
Cross-account access between AWS accounts	<p>You want to share access to certain AWS resources with users in other AWS accounts.</p> <p>Roles are the primary way to grant cross-account access. However, some AWS services allow you to attach a policy directly to a resource (instead of using a role as a proxy). These are called resource-based policies.</p>	<p>For more information about IAM roles, see IAM roles.</p> <p>For more information about service-linked roles, see Using service-linked roles.</p> <p>For information about which services support using service-linked roles, see AWS services that work with IAM. Look for the services that have Yes in the Service-Linked Role column. To view the service-linked role documentation for that service select the link associated with the Yes in that column.</p>

Type of user access	Why would I use it?	Where can I get more information?
Long-term credentials for designated IAM users in your AWS account	<p>You might have specific use cases that require long-term credentials with IAM users in AWS. You can use IAM to create these IAM users in your AWS account, and use IAM to manage their permissions. Some of the use cases include the following:</p> <ul style="list-style-type: none">• Workloads that cannot use IAM roles• Third-party AWS clients that require programmatic access through access keys• Service-specific credentials for AWS CodeCommit or Amazon Keyspaces• AWS IAM Identity Center is not available for your account and you have no other identity provider <p>As a best practice in scenarios in which you need IAM users with programmatic access and long-term credentials, we recommend that you update access keys when needed. For more information, see Updating access keys.</p>	<p>For more information about setting up an IAM user, see Creating an IAM user in your AWS account.</p> <p>For more information about IAM user access keys, see Managing access keys for IAM users.</p> <p>For more information about service-specific credentials for AWS CodeCommit or Amazon Keyspaces, see Using IAM with CodeCommit: Git credentials, SSH keys, and AWS access keys and Using IAM with Amazon Keyspaces (for Apache Cassandra).</p>

Overview of access management: Permissions and policies

The access management portion of AWS Identity and Access Management (IAM) helps you define what a principal entity is allowed to do in an account. A principal entity is a person or application that is authenticated using an IAM entity (user or role). Access management is often referred to as *authorization*. You manage access in AWS by creating policies and attaching them to IAM identities (users, groups of users, or roles) or AWS resources. A policy is an object in AWS that, when associated with an identity or resource, defines their permissions. AWS evaluates these policies when a principal uses an IAM entity (user or role) to make a request. Permissions in the policies determine whether the request is allowed or denied. Most policies are stored in AWS as JSON documents. For more information about policy types and uses, see [Policies and permissions in IAM](#).

Policies and accounts

If you manage a single account in AWS, then you define the permissions within that account using policies. If you manage permissions across multiple accounts, it is more difficult to manage permissions for your users. You can use IAM roles, resource-based policies, or access control lists (ACLs) for cross-account permissions. However, if you own multiple accounts, we instead recommend using the AWS Organizations service to help you manage those permissions. For more information, see [What is AWS Organizations?](#) in the *Organizations User Guide*.

Policies and users

IAM users are identities in the service. When you create an IAM user, they can't access anything in your account until you give them permission. You give permissions to a user by creating an identity-based policy, which is a policy that is attached to the user or a group to which the user belongs. The following example shows a JSON policy that allows the user to perform all Amazon DynamoDB actions (`dynamodb:*`) on the Books table in the 123456789012 account within the `us-east-2` Region.

```
{
  "Version": "2012-10-17",
  "Statement": {
    "Effect": "Allow",
    "Action": "dynamodb:*",
    "Resource": "arn:aws:dynamodb:us-east-2:123456789012:table/Books"
  }
}
```

After you attach this policy to your IAM user, the user only has those DynamoDB permissions. Most users have multiple policies that together represent the permissions for that user.

Actions or resources that are not explicitly allowed are denied by default. For example, if the preceding policy is the only policy that is attached to a user, then that user is allowed to only perform DynamoDB actions on the Books table. Actions on all other tables are prohibited. Similarly, the user is not allowed to perform any actions in Amazon EC2, Amazon S3, or in any other AWS service. The reason is that permissions to work with those services are not included in the policy.

Policies and groups

You can organize IAM users into *IAM groups* and attach a policy to a group. In that case, individual users still have their own credentials, but all the users in a group have the permissions that are attached to the group. Use groups for easier permissions management, and to follow our [Security best practices in IAM](#).

Users or groups can have multiple policies attached to them that grant different permissions. In that case, the permissions for the users are calculated based on the combination of policies. But the basic principle still applies: If the user has not been granted an explicit permission for an action and a resource, the user does not have those permissions.

Federated users and roles

Federated users don't have permanent identities in your AWS account the way that IAM users do. To assign permissions to federated users, you can create an entity referred to as a *role* and define permissions for the role. When a federated user signs in to AWS, the user is associated with the role

and is granted the permissions that are defined in the role. For more information, see [Creating a role for a third-party Identity Provider \(federation\)](#).

Identity-based and resource-based policies

Identity-based policies are permissions policies that you attach to an IAM identity, such as an IAM user, group, or role. Resource-based policies are permissions policies that you attach to a resource such as an Amazon S3 bucket or an IAM role trust policy.

Identity-based policies control what actions the identity can perform, on which resources, and under what conditions. Identity-based policies can be further categorized:

- **Managed policies** – Standalone identity-based policies that you can attach to multiple users, groups, and roles in your AWS account. You can use two types of managed policies:
 - **AWS managed policies** – Managed policies that are created and managed by AWS. If you are new to using policies, we recommend that you start by using AWS managed policies.
 - **Customer managed policies** – Managed policies that you create and manage in your AWS account. Customer managed policies provide more precise control over your policies than AWS managed policies. You can create, edit, and validate an IAM policy in the visual editor or by creating the JSON policy document directly. For more information, see [Creating IAM policies](#) and [Editing IAM policies](#).
- **Inline policies** – Policies that you create and manage and that are embedded directly into a single user, group, or role. In most cases, we don't recommend using inline policies.

Resource-based policies control what actions a specified principal can perform on that resource and under what conditions. Resource-based policies are inline policies, and there are no managed resource-based policies. To enable cross-account access, you can specify an entire account or IAM entities in another account as the principal in a resource-based policy.

The IAM service supports only one type of resource-based policy called a role *trust policy*, which is attached to an IAM role. Because an IAM role is both an identity and a resource that supports resource-based policies, you must attach both a trust policy and an identity-based policy to an IAM role. Trust policies define which principal entities (accounts, users, roles, and federated users) can assume the role. To learn how IAM roles are different from other resource-based policies, see [Cross account resource access in IAM](#).

To see which services support resource-based policies, see [AWS services that work with IAM](#). To learn more about resource-based policies, see [Identity-based policies and resource-based policies](#).

What is ABAC for AWS?

Attribute-based access control (ABAC) is an authorization strategy that defines permissions based on attributes. In AWS, these attributes are called *tags*. You can attach tags to IAM resources, including IAM entities (users or roles) and to AWS resources. You can create a single ABAC policy or small set of policies for your IAM principals. These ABAC policies can be designed to allow operations when the principal's tag matches the resource tag. ABAC is helpful in environments that are growing rapidly and helps with situations where policy management becomes cumbersome.

For example, you can create three roles with the `access-project` tag key. Set the tag value of the first role to `Heart`, the second to `Star`, and the third to `Lightning`. You can then use a single policy that allows access when the role and the resource are tagged with the same value for `access-project`. For a detailed tutorial that demonstrates how to use ABAC in AWS, see [IAM tutorial: Define permissions to access AWS resources based on tags](#). To learn about services that support ABAC, see [AWS services that work with IAM](#).

Comparing ABAC to the traditional RBAC model

The traditional authorization model used in IAM is called role-based access control (RBAC). RBAC defines permissions based on a person's job function, known outside of AWS as a *role*. Within AWS a role usually refers to an IAM role, which is an identity in IAM that you can assume. IAM does include [managed policies for job functions](#) that align permissions to a job function in an RBAC model.

In IAM, you implement RBAC by creating different policies for different job functions. You then attach the policies to identities (IAM users, groups of users, or IAM roles). As a [best practice](#), you grant the minimum permissions necessary for the job function. This is known as [granting least privilege](#). Do this by listing the specific resources that the job function can access. The disadvantage to using the traditional RBAC model is that when employees add new resources, you must update policies to allow access to those resources.

For example, assume that you have three projects, named `Heart`, `Star`, and `Lightning`, on which your employees work. You create an IAM role for each project. You then attach policies to each IAM role to define the resources that anyone allowed to assume the role can access. If an employee changes jobs within your company, you assign them to a different IAM role. People or programs can be assigned to more than one role. However, the `Star` project might require additional resources, such as a new Amazon EC2 container. In that case, you must update the policy attached to the

Star role to specify the new container resource. Otherwise, Star project members aren't allowed to access the new container.

ABAC provides the following advantages over the traditional RBAC model:

- **ABAC permissions scale with innovation.** It's no longer necessary for an administrator to update existing policies to allow access to new resources. For example, assume that you designed your ABAC strategy with the `access-project` tag. A developer uses the role with the `access-project = Heart` tag. When people on the Heart project need additional Amazon EC2 resources, the developer can create new Amazon EC2 instances with the `access-project = Heart` tag. Then anyone on the Heart project can start and stop those instances because their tag values match.
- **ABAC requires fewer policies.** Because you don't have to create different policies for different job functions, you create fewer policies. Those policies are easier to manage.
- **Using ABAC, teams can change and grow quickly.** This is because permissions for new resources are automatically granted based on attributes. For example, if your company already supports the Heart and Star projects using ABAC, it's easy to add a new Lightning project. An IAM administrator creates a new role with the `access-project = Lightning` tag. It's not necessary to change the policy to support a new project. Anyone that has permissions to assume the role can create and view instances tagged with `access-project = Lightning`. Additionally, a team member might move from the Heart project to the Lightning project. The IAM administrator assigns the user to a different IAM role. It's not necessary to change the permissions policies.
- **Granular permissions are possible using ABAC.** When you create policies, it's a best practice to [grant least privilege](#). Using traditional RBAC, you must write a policy that allows access to only specific resources. However, when you use ABAC, you can allow actions on all resources, but only if the resource tag matches the principal's tag.
- **Use employee attributes from your corporate directory with ABAC.** You can configure your SAML-based or web identity provider to pass session tags to AWS. When your employees federate into AWS, their attributes are applied to their resulting principal in AWS. You can then use ABAC to allow or deny permissions based on those attributes.

For a detailed tutorial that demonstrates how to use ABAC in AWS, see [IAM tutorial: Define permissions to access AWS resources based on tags](#).

Security features outside IAM

You use IAM to control access to tasks that are performed using the AWS Management Console, the [AWS Command Line Tools](#), or service API operations using the [AWS SDKs](#). Some AWS products have other ways to secure their resources as well. The following list provides some examples, though it is not exhaustive.

Amazon EC2

In Amazon Elastic Compute Cloud you log into an instance with a key pair (for Linux instances) or using a user name and password (for Microsoft Windows instances).

For more information, see the following documentation:

- [Getting Started with Amazon EC2 Linux Instances](#) in the *Amazon EC2 User Guide for Linux Instances*
- [Getting Started with Amazon EC2 Windows Instances](#) in the *Amazon EC2 User Guide for Windows Instances*

Amazon RDS

In Amazon Relational Database Service you log into the database engine with a user name and password that are tied to that database.

For more information, see [Getting Started with Amazon RDS](#) in the *Amazon RDS User Guide*.

Amazon EC2 and Amazon RDS

In Amazon EC2 and Amazon RDS you use security groups to control traffic to an instance or database.

For more information, see the following documentation:

- [Amazon EC2 Security Groups for Linux Instances](#) in the *Amazon EC2 User Guide for Linux Instances*
- [Amazon EC2 Security Groups for Windows Instances](#) in the *Amazon EC2 User Guide for Windows Instances*
- [Amazon RDS Security Groups](#) in the *Amazon RDS User Guide*

WorkSpaces

In Amazon WorkSpaces, users sign in to a desktop with a user name and password.

For more information, see [Getting Started with WorkSpaces](#) in the *Amazon WorkSpaces Administration Guide*.

Amazon WorkDocs

In Amazon WorkDocs, users get access to shared documents by signing in with a user name and password.

For more information, see [Getting Started with Amazon WorkDocs](#) in the *Amazon WorkDocs Administration Guide*.

These access control methods are not part of IAM. IAM lets you control how these AWS products are administered—creating or terminating an Amazon EC2 instance, setting up new WorkSpaces desktops, and so on. That is, IAM helps you control the tasks that are performed by making requests to Amazon Web Services, and it helps you control access to the AWS Management Console. However, IAM does not help you manage security for tasks like signing in to an operating system (Amazon EC2), database (Amazon RDS), desktop (Amazon WorkSpaces), or collaboration site (Amazon WorkDocs).

When you work with a specific AWS product, be sure to read the documentation to learn the security options for all the resources that belong to that product.

Quick links to common tasks

Use the following links to get help with common tasks associated with IAM.

Sign in for different user types

Sign in to the [IAM console](#) by choosing **IAM user** and entering your AWS account ID or account alias. On the next page, enter your IAM user name and your password.

To sign in with your IAM Identity Center user, use the sign-in URL that was sent to your email address when you created the IAM Identity Center user.

For help signing in using an IAM Identity Center user, see [Signing in to the AWS access portal](#) in the *AWS Sign-In User Guide*.

Sign in to the [AWS Management Console](#) as the account owner by choosing **Root user** and entering your AWS account email address. On the next page, enter your password.

See [What is AWS Sign-In](#) in the *AWS Sign-In User Guide* for help determining your user type and sign-in page.

Manage passwords for users

You need a password in order to access the AWS Management Console, including access to billing information.

For your AWS account root user, see [Change the password for the AWS account root user](#) in the *AWS Account Management Reference Guide*

For an IAM user, see [Managing passwords for IAM users](#).

Manage permissions for users

You use policies to grant permissions to the IAM users in your AWS account. IAM users have no permissions when they are created, so you must add permissions to allow them to use AWS resources.

To provide access, add permissions to your users, groups, or roles:

- Users and groups in AWS IAM Identity Center:

Create a permission set. Follow the instructions in [Create a permission set](#) in the *AWS IAM Identity Center User Guide*.

- Users managed in IAM through an identity provider:

Create a role for identity federation. Follow the instructions in [Creating a role for a third-party identity provider \(federation\)](#) in the *IAM User Guide*.

- IAM users:

- Create a role that your user can assume. Follow the instructions in [Creating a role for an IAM user](#) in the *IAM User Guide*.
- (Not recommended) Attach a policy directly to a user or add a user to a user group. Follow the instructions in [Adding permissions to a user \(console\)](#) in the *IAM User Guide*.

For more information, see [Managing IAM policies](#).

List the users in your AWS account and get information about their credentials

See [Getting credential reports for your AWS account](#).

Add multi-factor authentication (MFA)

To add a virtual MFA device, see one of the following:

- [Enable a virtual MFA device for your AWS account root user \(console\)](#)
- [Enable a virtual MFA device for an IAM user \(console\)](#)

To add a FIDO security key, see one of the following:

- [Enable a FIDO security key for the AWS account root user \(console\)](#)
- [Enable a FIDO security key for another IAM user \(console\)](#)

To add a hardware MFA device, see one of the following:

- [Enable a hardware TOTP token for the AWS account root user \(console\)](#).
- [Enable a hardware TOTP token for another IAM user \(console\)](#)

Get an access key

You can use an access key to make AWS requests using the [AWS SDKs](#), the [AWS Command Line Tools](#), or the API operations.

Important

As a [best practice](#), use temporary security credentials (such as IAM roles) instead of creating long-term credentials like access keys. Before creating access keys, review the [alternatives to long-term access keys](#).

For guidance to help you protect your access keys, see [Securing access keys](#).

To learn about managing access keys for an IAM user, see [Managing access keys for IAM users](#).

For more information about the security credentials available for your AWS account, see [AWS security credentials](#).

Tag IAM resources

You can tag the following IAM resources:

- IAM users
- IAM roles
- Customer managed policies
- Identity providers
- Server certificates
- Virtual MFA devices

To learn about tags in IAM, see [Tagging IAM resources](#).

To learn about using tags to control access to AWS resources, see [Controlling access to AWS resources using tags](#).

View the actions, resources, and condition keys for all services

This set of reference documentation can help you write detailed IAM policies. Each AWS service defines the actions, resources, and condition context keys that you use in IAM policies. To learn more, see [Actions, Resources, and Condition Keys for AWS Services](#).

Get started with all of AWS

This set of documentation deals primarily with the IAM service. To learn about getting started with AWS and using multiple services to solve a problem such as building and launching your first project, see the [Getting Started Resource Center](#).

IAM console search

Use the IAM console search page as a faster option for finding IAM resources. You can use the console search to locate access keys related to your account, IAM entities (such as users, groups, roles, identity providers), policies by name, and more.

The IAM console search feature can locate any of the following:

- IAM entity names that match your search keywords (for users, groups, roles, identity providers, and policies)
- Tasks that match your search keywords

The IAM console search feature does not return information about IAM Access Analyzer.

Every line in the search result is an active link. For example, you can choose the user name in the search result, which takes you to that user's detail page. Or you can choose an action link, for example **Create user**, to go to the **Create User** page.

Note

Access key search requires you to type the full access key ID in the search box. The search result shows the user associated with that key. From there you can navigate directly to that user's page, where you can manage the access key.

Using IAM console search

Use the **Search** page in the IAM console to find items related to that account.

To search for items in the IAM console

1. Follow the sign-in procedure appropriate to your user type as described in the topic [How to sign in to AWS](#) in the *AWS Sign-In User Guide*.
2. On the **Console Home** page, select the IAM service.
3. In the navigation pane, choose **Search**.
4. In the **Search** box, type your search keywords.
5. Choose a link in the search results list to navigate to the corresponding part of the console.

Icons in the IAM console search results

The following icons identify the types of items that are found by a search:

Icon	Description
	IAM users
	IAM groups
	IAM roles
	IAM policies
	Tasks such as "create user" or "attach policy"
	Results from the keyword delete

Sample search phrases

You can use the following phrases in the IAM search. Replace terms in italics with the names of the actual IAM users, groups, roles, access keys, policies, or identity providers that you want to locate.

- *user_name* or *group_name* or *role_name* or *policy_name* or *identity_provider_name*
- *access_key*
- add user *user_name* to groups or add users to group *group_name*
- remove user *user_name* from groups
- delete *user_name* or delete *group_name* or delete *role_name*, or delete *policy_name*, or delete *identity_provider_name*
- manage access keys *user_name*
- manage signing certificates *user_name*
- users
- manage MFA for *user_name*
- manage password for *user_name*
- create role
- password policy
- edit trust policy for role *role_name*
- show policy document for role *role_name*
- attach policy to *role_name*
- create managed policy
- create user
- create group
- attach policy to *group_name*
- attach entities to *policy_name*
- detach entities from *policy_name*

Creating AWS Identity and Access Management resources with AWS CloudFormation

AWS Identity and Access Management is integrated with AWS CloudFormation, a service that helps you to model and set up your AWS resources so that you can spend less time creating and managing your resources and infrastructure. You create a template that describes all the AWS resources that you want (such as access keys, groups, group policies, instance profiles, managed policies, OIDC providers, inline policies, roles, role policies, SAML providers, server certificates, service-linked roles, users (and adding users to groups), user policies, and virtual MFA devices), and AWS CloudFormation provisions and configures those resources for you.

When you use AWS CloudFormation, you can reuse your template to set up your IAM resources consistently and repeatedly. Describe your resources once, and then provision the same resources over and over in multiple AWS accounts and Regions.

IAM and AWS CloudFormation templates

To provision and configure resources for IAM and related services, you must understand [AWS CloudFormation templates](#). Templates are formatted text files in JSON or YAML. These templates describe the resources that you want to provision in your AWS CloudFormation stacks. If you're unfamiliar with JSON or YAML, you can use AWS CloudFormation Designer to help you get started with AWS CloudFormation templates. For more information, see [What is AWS CloudFormation Designer?](#) in the *AWS CloudFormation User Guide*.

IAM supports creating access keys, groups, group policies, instance profiles, managed policies, OIDC providers, inline policies, roles, role policies, SAML providers, server certificates, service-linked roles, users (and adding users to groups), user policies, and virtual MFA devices in AWS CloudFormation. For more information, including examples of JSON and YAML templates for IAM resources, see the [AWS Identity and Access Management resource type reference](#) in the *AWS CloudFormation User Guide*.

You can also create templates that create related resources, such as roles and managed policies.

Learn more about AWS CloudFormation

To learn more about AWS CloudFormation, see the following resources:

- [AWS CloudFormation](#)

- [AWS CloudFormation User Guide](#)
- [AWS CloudFormation API Reference](#)
- [AWS CloudFormation Command Line Interface User Guide](#)

Using AWS CloudShell to work with AWS Identity and Access Management

AWS CloudShell is a browser-based, pre-authenticated shell that you can launch directly from the AWS Management Console. You can run AWS CLI commands against AWS services (including AWS Identity and Access Management) using your preferred shell (Bash, PowerShell or Z shell). And you can do this without needing to download or install command line tools.

You [launch AWS CloudShell from the AWS Management Console](#), and the AWS credentials you used to sign in to the console are automatically available in a new shell session. This pre-authentication of AWS CloudShell users allows you to skip configuring credentials when interacting with AWS services such as IAM using AWS CLI version 2 (pre-installed on the shell's compute environment).

Obtaining IAM permissions for AWS CloudShell

Using the access management resources provided by AWS Identity and Access Management, administrators can grant permissions to IAM users so they can access AWS CloudShell and use the environment's features.

The quickest way for an administrator to grant access to users is through an AWS managed policy. An [AWS managed policy](#) is a standalone policy that's created and administered by AWS. The following AWS managed policy for CloudShell can be attached to IAM identities:

- `AWSCloudShellFullAccess`: Grants permission to use AWS CloudShell with full access to all features.

If you want to limit the scope of actions that an IAM user can perform with AWS CloudShell, you can create a custom policy that uses the `AWSCloudShellFullAccess` managed policy as a template. For more information about limiting the actions that are available to users in CloudShell, see [Managing AWS CloudShell access and usage with IAM policies](#) in the *AWS CloudShell User Guide*.

Interacting with IAM using AWS CloudShell

After you launch AWS CloudShell from the AWS Management Console, you can immediately start to interact with IAM using the command line interface.

Note

When using AWS CLI in AWS CloudShell, you don't need to download or install any additional resources. Moreover, because you're already authenticated within the shell, you don't need to configure credentials before making calls.

Create an IAM group and add an IAM user to the group using AWS CloudShell

The following example uses CloudShell to create an IAM group, add an IAM user to the group, and then verify that the command succeeded.

1. From the AWS Management Console, you can launch CloudShell by choosing the following options available on the navigation bar:
 - Choose the CloudShell icon.
 - Start typing "cloudshell" in Search box and then choose the CloudShell option.
2. To create an IAM group, enter the following command in the CloudShell command line. In this example we named the group *east_coast*:

```
aws iam create-group --group-name east_coast
```

If the call is successful, the command line displays a response from the service similar to the following output:

```
{
  "Group": {
    "Path": "/",
    "GroupName": "east_coast",
    "GroupId": "AGPAYBDBW4JBY3EXAMPLE",
    "Arn": "arn:aws:iam::111122223333:group/east_coast",
    "CreateDate": "2023-09-11T21:02:21+00:00"
  }
}
```

```
}
```

3. To add a user to the group that you created, use the following command, specifying the group name and username. In this example we named the group *east_coast* and the user *johndoe*:

```
aws iam add-user-to-group --group-name east_coast --user-name johndoe
```

4. To verify that the user is in the group, use the following command, specifying the group name. In this example we continue using the group *east_coast* :

```
aws iam get-group --group-name east_coast
```

If the call is successful, the command line displays a response from the service similar to the following output:

```
{
  "Users": [
    {
      "Path": "/",
      "UserName": "johndoe",
      "UserId": "AIDAYBDBW4JBXGEXAMPLE",
      "Arn": "arn:aws:iam::552108220995:user/johndoe",
      "CreateDate": "2023-09-11T20:43:14+00:00",
      "PasswordLastUsed": "2023-09-11T20:59:14+00:00"
    }
  ],
  "Group": {
    "Path": "/",
    "GroupName": "east_coast",
    "GroupId": "AGPAYBDBW4JBY3EXAMPLE",
    "Arn": "arn:aws:iam::111122223333:group/east_coast",
    "CreateDate": "2023-09-11T21:02:21+00:00"
  }
}
```

Using IAM with an AWS SDK

AWS software development kits (SDKs) are available for many popular programming languages. Each SDK provides an API, code examples, and documentation that make it easier for developers to build applications in their preferred language.

SDK documentation	Code examples
AWS SDK for C++	AWS SDK for C++ code examples
AWS SDK for Go	AWS SDK for Go code examples
AWS SDK for Java	AWS SDK for Java code examples
AWS SDK for JavaScript	AWS SDK for JavaScript code examples
AWS SDK for Kotlin	AWS SDK for Kotlin code examples
AWS SDK for .NET	AWS SDK for .NET code examples
AWS SDK for PHP	AWS SDK for PHP code examples
AWS SDK for Python (Boto3)	AWS SDK for Python (Boto3) code examples
AWS SDK for Ruby	AWS SDK for Ruby code examples
AWS SDK for Rust	AWS SDK for Rust code examples
AWS SDK for SAP ABAP	AWS SDK for SAP ABAP code examples
AWS SDK for Swift	AWS SDK for Swift code examples

For examples specific to IAM, see [Code examples for IAM using AWS SDKs](#).

Example availability

Can't find what you need? Request a code example by using the **Provide feedback** link at the bottom of this page.

Getting set up with IAM

Important

IAM [best practices](#) recommend that you require human users to use federation with an identity provider to access AWS using temporary credentials instead of using IAM users with long-term credentials.

AWS Identity and Access Management (IAM) helps you securely control access to Amazon Web Services (AWS) and your account resources. IAM can also keep your sign-in credentials private. You don't specifically sign up to use IAM. There is no charge to use IAM.

Use IAM to give identities, such as users and roles, access to resources in your account. For example, you can use IAM with existing users in your corporate directory that you manage external to AWS or you can create users in AWS using AWS IAM Identity Center. Federated identities assume defined IAM roles to access the resources they need. For more information about IAM Identity Center, see [What is IAM Identity Center?](#) in the *AWS IAM Identity Center User Guide*.

Note

IAM is integrated with several AWS products. For a list of services that support IAM, see [AWS services that work with IAM](#).

Topics

- [Sign up for an AWS account](#)
- [Create an administrative user](#)
- [Prepare for least-privilege permissions](#)
- [IAM management methods](#)
- [Your AWS account ID and its alias](#)

Sign up for an AWS account

If you do not have an AWS account, complete the following steps to create one.

To sign up for an AWS account

1. Open <https://portal.aws.amazon.com/billing/signup>.
2. Follow the online instructions.

Part of the sign-up procedure involves receiving a phone call and entering a verification code on the phone keypad.

When you sign up for an AWS account, an *AWS account root user* is created. The root user has access to all AWS services and resources in the account. As a security best practice, [assign administrative access to an administrative user](#), and use only the root user to perform [tasks that require root user access](#).

AWS sends you a confirmation email after the sign-up process is complete. At any time, you can view your current account activity and manage your account by going to <https://aws.amazon.com/> and choosing **My Account**.

Create an administrative user

After you sign up for an AWS account, secure your AWS account root user, enable AWS IAM Identity Center, and create an administrative user so that you don't use the root user for everyday tasks.

Secure your AWS account root user

1. Sign in to the [AWS Management Console](#) as the account owner by choosing **Root user** and entering your AWS account email address. On the next page, enter your password.

For help signing in by using root user, see [Signing in as the root user](#) in the *AWS Sign-In User Guide*.

2. Turn on multi-factor authentication (MFA) for your root user.

For instructions, see [Enable a virtual MFA device for your AWS account root user \(console\)](#) in the *IAM User Guide*.

Create an administrative user

1. Enable IAM Identity Center.

For instructions, see [Enabling AWS IAM Identity Center](#) in the *AWS IAM Identity Center User Guide*.

2. In IAM Identity Center, grant administrative access to an administrative user.

For a tutorial about using the IAM Identity Center directory as your identity source, see [Configure user access with the default IAM Identity Center directory](#) in the *AWS IAM Identity Center User Guide*.

Sign in as the administrative user

- To sign in with your IAM Identity Center user, use the sign-in URL that was sent to your email address when you created the IAM Identity Center user.

For help signing in using an IAM Identity Center user, see [Signing in to the AWS access portal](#) in the *AWS Sign-In User Guide*.

Prepare for least-privilege permissions

Using *least-privilege permissions* is an IAM best practice recommendation. The concept of least-privilege permissions is to grant users the permissions required to perform a task and no additional permissions. As you get set up, consider how you are going to support least-privilege permissions. Both the root user and the administrator user have powerful permissions that aren't required for everyday tasks. While you are learning about AWS and testing out different services we recommend that you create at least one additional user in IAM Identity Center with lesser permissions that you can use in different scenarios. You can use IAM policies to define the actions that can be taken on specific resources under specific conditions and then connect to those resources with your lesser privileged account.

If you are using IAM Identity Center, consider using IAM Identity Center permissions sets to get started. To learn more, see [Create a permission set](#) in the *IAM Identity Center User Guide*.

If you aren't using IAM Identity Center, use IAM roles to define the permissions for different IAM entities. To learn more, see [Creating IAM roles](#).

Both IAM roles and IAM Identity Center permissions sets can use AWS managed policies based on job functions. For details on the permissions granted by these policies, see [AWS managed policies for job functions](#).

Important

Keep in mind that AWS managed policies might not grant least-privilege permissions for your specific use cases because they're available for use by all AWS customers. After getting set up, we recommend that you use IAM Access Analyzer to generate least-privilege policies based on your access activity that's logged in AWS CloudTrail. For more information about policy generation, see [IAM Access Analyzer policy generation](#).

IAM management methods

You can manage IAM using either the AWS console, the AWS command-line interface, or through the application interfaces (APIs) in the associated SDKs. As you are getting set up, consider which methods you want to support and how you plan to support different users.

Topics

- [AWS Console](#)
- [AWS Command Line Interface \(CLI\) and Software Development Kits \(SDKs\)](#)

AWS Console

The AWS Management Console is a web application that comprises and refers to a broad collection of service consoles for managing AWS resources. When you first sign in, you see the console home page. The home page provides access to each service console and offers a single place to access the information for performing your AWS related tasks. Which services and applications are available to you after signing in to the console depend on which AWS resources you have permission to access. You can be granted permissions to resources either through assuming a role, being a member of a group that has been granted permissions, or being explicitly granted permission. For a stand-alone AWS account, the root user or IAM administrator configures access to resources. For AWS Organizations, the management account or delegated administrator configures access to resources.

If you plan to have people using the AWS Management Console to manage AWS resources, we recommend configuring users with temporary credentials as a security [best practice](#). IAM users that have assumed a role, federated users, and users in IAM Identity Center have temporary credentials, while the IAM user and root user have long-term credentials. Root user credentials provide full

access to the AWS account, while other users have credentials that provide access to the resources granted them by IAM policies.

The sign-in experience is different for the different types of AWS Management Console users.

- IAM users and the root user sign-in from the main AWS sign-in URL (<https://signin.aws.amazon.com>). Once they sign in they have access to the resources in the account to which they have been granted permission.

To sign in as the root user you must have the root user email address and password.

To sign in as an IAM user you must have the AWS account number or alias, the IAM user name, and the IAM user password.

We recommend that you restrict IAM users in your account to specific situations that require long-term credentials, such as for emergency access, and that you use the root user only for [tasks that require root user credentials](#).

For convenience, the AWS sign-in page uses a browser cookie to remember the IAM user name and account information. The next time the user goes to any page in the AWS Management Console, the console uses the cookie to redirect the user to the account sign-in page.

Sign out of the console when you finish your session to prevent reuse of your previous sign in.

- IAM Identity Center users sign in using a specific AWS access portal that's unique to their organization. Once they sign in they can choose which account or application to access. If they choose to access an account, they choose which permission set they want to use for the management session.
- Federated users managed in an external identity provider linked to an AWS account sign-in using a custom enterprise access portal. The AWS resources available to federated users are dependent upon the policies selected by their organization.

Note

To provide an additional level of security, root user, IAM users, and users in IAM Identity Center can have multi-factor authentication (MFA) verified by AWS before granting access to AWS resources. When MFA is enabled, you must also have access to the MFA device to sign in.

To learn more about how different users sign-in to the management console, see [Sign in to the AWS Management Console](#) in the *AWS Sign-In User Guide*.

AWS Command Line Interface (CLI) and Software Development Kits (SDKs)

IAM Identity Center and IAM users use different methods to authenticate their credentials when they authenticate through the CLI or the application interfaces (APIs) in the associated SDKs.

Credentials and configuration settings are located in multiple places, such as the system or user environment variables, local AWS configuration files, or explicitly declared on the command line as a parameter. Certain locations take precedence over others.

Both IAM Identity Center and IAM provide access keys that can be used with the CLI or SDK. IAM Identity Center access keys are temporary credentials that can be automatically refreshed and are recommended over the long-term access keys associated with IAM users.

To manage your AWS account using the CLI or SDK you can use AWS CloudShell from your browser. If you use CloudShell to run CLI or SDK commands you must first sign-in to the console. The permissions for accessing AWS resources are based on the credentials you used to sign-in to the console. Depending on your experience, you may find the CLI to be a more efficient method of managing your AWS account.

For application development, you can download the CLI or SDK to your computer and sign-in from the command prompt or a Docker window. In this scenario, you configure authentication and access credentials as part of the CLI script or SDK application. You can configure programmatic access to resources in different ways, depending on the environment and the access available to you.

- Recommended options for authenticating local code with AWS service are IAM Identity Center and IAM Roles Anywhere
- Recommended options for authenticating code running within an AWS environment are to use IAM roles or use IAM Identity Center credentials.

If you are using IAM Identity Center you can get short-term credentials from the start page of the AWS access portal where you choose your permission set. These credentials have a defined duration and don't automatically refresh. If you want to use these credentials, after signing in to the AWS portal, choose the AWS account and then choose the permissions set. Select

Command line or programmatic access to view the options you can use to access AWS resources programmatically or from the CLI. For more information about these methods, see [Getting and refreshing temporary credentials](#) in the *IAM Identity Center User Guide*. These credentials are often used during application development to quickly test code.

We recommend using IAM Identity Center credentials that automatically refresh when automating access to your AWS resources. If you have configured users and permission sets in IAM Identity Center you use the `aws configure sso` command to use a command-line wizard that will help you identify the credentials available to you and store them in a profile. For more information about configuring your profile, see [Configure your profile with the `aws configure sso` wizard](#) in the *AWS Command Line Interface User Guide for Version 2*.

Note

Many sample applications use long-term access keys associated with IAM users or root user. You should only use long-term credentials within a sandbox environment as part of a learning exercise. Review the [alternatives to long-term access keys](#) and plan to transition your code to use alternative credentials, such as IAM Identity Center credentials or IAM roles, as soon as possible. After transitioning your code, delete the access keys.

To learn more about configuring the CLI, see [Install or update the latest version of the AWS CLI](#) in the *AWS Command Line Interface User Guide for Version 2* and [Authentication and access credentials](#) in the *AWS Command Line Interface User Guide*

To learn more about configuring the SDK, see [IAM Identity Center authentication](#) in the *AWS SDKs and Tools Reference Guide* and [IAM Roles Anywhere](#) in the *AWS SDKs and Tools Reference Guide*.

Your AWS account ID and its alias

IAM users in the account sign in using a web URL that includes either the account alias or an account ID. If you don't have the URL, the AWS sign-in page requires that you provide either the AWS account alias or account ID.

If you don't know your account ID or alias:

- Check your browser history. If you have signed in previously, it could be stored in your recent web sites.

- If you have configured the AWS CLI or an AWS SDK with your account credentials, you can obtain your account ID from your configuration files.
- Ask your local administrator or account owner, AWS cannot provide account IDs to users.

Tip

To create a bookmark for your account sign-in page in your web browser, you should manually type the sign-in URL in the bookmark entry. Don't use your web browser's "bookmark this page" feature because that captures information specific to your current browser session that interfere with future visits to the sign-in page.

Topics

- [View your AWS account ID](#)
- [About account aliases](#)
- [Creating, deleting, and listing an AWS account alias](#)

View your AWS account ID

You can view the account ID for your AWS account using the following methods.

View Your Account ID using the console

There are different ways to view your account ID in the console depending on your user type. If you have assumed a role, **Security credentials** is not available.

User type	Procedure
Root user	In the navigation bar at the upper right, choose your user name and then choose Security credentials . The account number appears under Account identifiers .
IAM user	In the navigation bar at the upper right, choose your user name and then choose

User type	Procedure
Assumed role	<p>Security credentials. The account number appears under Account details.</p> <p>In the navigation bar at the upper right, choose Support, and then Support Center. Your currently signed-in 12-digit account number (ID) appears in the Support Center navigation pane.</p>

View Your Account ID using the AWS CLI

Use the following command to view your user ID, account ID, and your user ARN:

- [aws sts get-caller-identity](#)

View Your Account ID using the API

Use the following API to view your user ID, account ID, and your user ARN:

- [GetCallerIdentity](#)

About account aliases

If you want the URL for your sign-in page to contain your company name (or other friendly identifier) instead of your AWS account ID, you can create an account alias. This section provides information about AWS account aliases and lists the API operations that you use to create an alias.

Your sign-in page URL has the following format, by default.

```
https://Your_Account_ID.signin.aws.amazon.com/console/
```

If you create an AWS account alias for your AWS account ID, your sign-in page URL looks like the following example.

```
https://Your_Account_Alias.signin.aws.amazon.com/console/
```

Considerations

- Your AWS account can have only one alias. If you create a new alias for your AWS account, the new alias overwrites the previous alias, and the URL containing the previous alias stops working.
- The account alias must contain only digits, lowercase letters, and hyphens. For more information on limitations on AWS account entities, see [IAM and AWS STS quotas](#).
- The account alias must be unique across all Amazon Web Services products within a given network *partition*.

A *partition* is a group of AWS Regions. Each AWS account is scoped to one partition.

The following are the supported partitions:

- `aws` - AWS Regions
- `aws-cn` - China Regions
- `aws-us-gov` - AWS GovCloud (US) Regions

Creating, deleting, and listing an AWS account alias

You can use the AWS Management Console, the IAM API, or the command line interface to create or delete your AWS account alias.

Note

Account aliases are not secrets, and they will appear in your public-facing sign-in page URL. Do not include any sensitive information in your account alias. The original URL containing your AWS account ID remains active and can be used after you create your AWS account alias.

Create or edit an account alias (console)

You can create, edit, and delete an account alias from the AWS Management Console.

Minimum permissions

To perform the following steps, you must have at least the following IAM permissions:

- `iam:ListAccountAliases`

- `iam:CreateAccountAlias`

To create or edit an account alias (console)

1. Sign in to the AWS Management Console and open the IAM console at <https://console.aws.amazon.com/iam/>.
2. In the navigation pane, choose **Dashboard**.
3. In the **AWS Account** section, next to **Account Alias**, choose **Create**. If an alias already exists, then choose **Edit**.
4. In the dialog box, enter the name you want to use for your alias, then choose **Save changes**.

Note

You can have only one alias associated with your AWS account at a time. If you create a new alias, the previous alias is removed, and the sign-in URL that was associated with the previous alias stops working.

Delete an account alias (console)

You can delete an account alias from the AWS Management Console.

Minimum permissions

To perform the following steps, you must have at least the following IAM permissions:

- `iam:ListAccountAliases`
- `iam:CreateAccountAlias`
- `iam>DeleteAccountAlias`

To delete an account alias (console)

1. Sign in to the AWS Management Console and open the IAM console at <https://console.aws.amazon.com/iam/>.
2. In the navigation pane, choose **Dashboard**.

3. In the **AWS Account** section, next to **Account Alias**, choose **Delete**.

Note

The only sign-in URL for your account is based off your account ID. Any attempts to connect to the alias URL are not redirected.

Creating, deleting, and listing aliases (AWS CLI)

Note

To use the following commands, you must have at least the following IAM permissions:

- `iam:ListAccountAliases`
- `iam:CreateAccountAlias`
- `iam>DeleteAccountAlias`

To create an alias for your AWS Management Console sign-in page URL, run the following command:

- [`aws iam create-account-alias`](#)

To delete an AWS account ID alias, run the following command:

- [`aws iam delete-account-alias`](#)

To display your AWS account ID alias, run the following command:

- [`aws iam list-account-aliases`](#)

Example Alias commands

To display your AWS account ID alias, run the following command.

```
$ aws iam list-account-aliases
```

```
{
  "AccountAliases": [
    "myaccountalias"
  ]
}
```

To create an alias for your AWS Management Console sign-in, run the following command:

```
$ aws iam create-account-alias \
  --account-alias myaliasname
```

This command produces no output if it's successful.

To delete an AWS account ID alias, run the following command.

```
$ aws iam delete-account-alias \
  --account-alias myaliasname
```

This command produces no output if it's successful.

Creating, deleting, and listing aliases (AWS API)

Note

To use the following API operations, you must have at least the following IAM permissions:

- `iam:ListAccountAliases`
- `iam:CreateAccountAlias`
- `iam>DeleteAccountAlias`

To create an alias for your AWS Management Console sign-in page URL, call the following operation:

- [CreateAccountAlias](#)

To delete an AWS account ID alias, call the following operation:

- [DeleteAccountAlias](#)

To display your AWS account ID alias, call the following operation:

- [ListAccountAliases](#)

Getting started with IAM

Use this tutorial to get started with AWS Identity and Access Management (IAM). You'll learn how to create roles, users, and policies using the AWS Management Console.

AWS Identity and Access Management is a feature of your AWS account offered at no additional charge. You will be charged only for use of other AWS products by your IAM users. For information about the pricing of other AWS products, see the [Amazon Web Services pricing page](#).

Note

This set of documentation deals primarily with the IAM service. To learn about getting started with AWS and using multiple services to solve a problem such as building and launching your first project, see the [Getting Started Resource Center](#).

Contents

- [Prerequisites](#)
- [Create your first IAM user](#)
- [Create your first role](#)
- [Create your first IAM policy](#)
- [Programmatic access](#)

Prerequisites

Before you begin, be sure that you've completed the steps in [Getting set up with IAM](#). This tutorial uses the administrator account you created in that procedure.

Create your first IAM user

An [IAM user](#) is an identity within your AWS account that has specific permissions for a single person or application. Users can be organized into groups that share the same permissions.

Note

As a security [best practice](#), we recommend that you provide access to your resources through identity federation instead of creating IAM users. For information about specific situations where an IAM user is required, see [When to create an IAM user \(instead of a role\)](#).

For the purpose of familiarizing yourself with the process of creating a IAM user, this tutorial steps you through creating an IAM user and group for emergency access.

To create your first IAM user

1. Follow the sign-in procedure appropriate to your user type as described in the topic [How to sign in to AWS](#) in the *AWS Sign-In User Guide*.
2. On the **Console Home** page, select the IAM service.
3. In the navigation pane, select **Users** and then select **Add users**.

Note

If you have IAM Identity Center enabled, the AWS Management Console displays a reminder that it is best to manage users' access in IAM Identity Center. In this tutorial, the IAM user you create is specifically for use only when your user in IAM Identity Center credentials are unavailable.

4. For **User name**, enter **EmergencyAccess**. Names cannot contain spaces.
5. Select the check box next to **Provide user access to the AWS Management Console– optional** and then choose **I want to create an IAM user**.
6. Under **Console password**, select **Autogenerated password**.
7. Clear the check box next to **User must create a new password at next sign-in (recommended)**. Because this IAM user is for emergency access, a trusted administrator retains the password and only provides it when needed.
8. On the **Set permissions** page, under **Permissions options**, select **Add user to group**. Then, under **User groups**, select **Create group**.
9. On the **Create user group** page, in **User group name**, enter **EmergencyAccessGroup**. Then, under **Permissions policies**, select **AdministratorAccess**.
10. Select **Create user group** to return to the **Set permissions** page.

11. Under **User groups**, select the name of the **EmergencyAccessGroup** you created previously.
12. Select **Next** to proceed to the **Review and create** page.
13. On the **Review and create** page, review the list of user group memberships to be added to the new user. When you are ready to proceed, select **Create user**.
14. On the **Retrieve password** page, select **Download .csv file** to save a .csv file with the user credential information (Connection URL, user name, and password).
15. Save this file to use if you need to sign-in to IAM and do not have access to your federated identity provider.

The new IAM user is displayed in the **Users** list. Select the **User name** link to view the user details. Under **Summary**, copy the **ARN** of the user to the clipboard. Paste the **ARN** into a text document, so that you can use it in the next procedure.

Create your first role

IAM roles are a secure way to grant permissions to entities you trust. An IAM role has some similarities to an IAM user. Roles and users are both principals with permissions policies that determine what the identity can and cannot do in AWS. However, instead of being uniquely associated with one person, a role is intended to be assumable by anyone who needs it. Also, a role does not have standard long-term credentials such as a password or access keys associated with it. Instead, when you assume a role, it provides you with temporary security credentials for your role session. Using roles helps you follow the IAM best practices. You can use a role to:

- Enable workforce identities and Identity Center enabled applications access to the AWS Management Console using AWS IAM Identity Center.
- Delegate permission to an AWS service to carry out actions on your behalf.
- Enable application code running on an Amazon EC2 instance to access or modify AWS resources.
- Grant access to another AWS account.

Note

You can use AWS Identity and Access Management Roles Anywhere to give access to machine identities. Using IAM Roles Anywhere means you don't need to manage long-term credentials for workloads running outside of AWS. For more information, see [What](#)

[is AWS Identity and Access Management Roles Anywhere?](#) in the *AWS Identity and Access Management Roles Anywhere User Guide*.

IAM Identity Center and other AWS services automatically create roles for their services. If you are using IAM users, we recommend that you create roles for your users to assume when they sign-in. This will give them temporary permissions during the session instead of long-term permissions.

The AWS Management Console wizard that guides you through the steps for creating a role displays slightly different steps depending on whether you're creating a role for an IAM user, AWS service, or for a federated user. Regular access to AWS accounts within an organization should be provided using federated access. If you are creating IAM users for specific purposes, such as emergency access or programmatic access, only grant those IAM users permission to assume a role and put those IAM users into role specific groups.

In this procedure, you create a role that provides SupportUser access for the EmergencyAccess IAM user. Before starting this procedure, copy the ARN of the IAM user to the clipboard.

To create a role for an IAM user

1. Follow the sign-in procedure appropriate to your user type as described in the topic [How to sign in to AWS](#) in the *AWS Sign-In User Guide*.
2. On the **Console Home** page, select the IAM service.
3. In the navigation pane of the IAM console, choose **Roles** and then choose **Create role**.
4. Choose **AWS account** role type.
5. In **Select trusted entity**, under **Trusted entity type**, choose **Custom trust policy**.
6. In the **Custom trust policy** section, review the basic trust policy. This is the one we will use for this role. Use the **Edit statement** editor to update the trust policy:
 1. In **Add actions for STS**, select **Assume Role**.
 2. Next to **Add a principal**, select, **Add**. The **Add principal** window opens.

Under **Principal type**, select **IAM Users**.

Under **ARN**, paste the IAM user ARN you copied to the clipboard.

Select **Add principal**.

3. Verify that the `Principal` line in the trust policy now contains the ARN you specified:

```
"Principal": { "AWS": "arn:aws:iam::123456789012:user/username" }
```

7. Resolve any security warnings, errors, or general warnings generated during [policy validation](#), and then choose **Next**.
8. In **Add permissions**, select the check box next to the permissions policy to apply. For this tutorial we are going to select the **SupportUser** trust policy. You can then use this role to troubleshoot and resolve issues with the AWS account and open support cases with AWS. We are not going to set a [permissions boundary](#) at this time.
9. Choose **Next**.
10. In **Name, review, and create** complete these settings:
 - For **Role name**, enter a name that identifies this role, such as *SupportUserRole*.
 - For **Description**, explain the intended use of the role.

Because other AWS resources might reference the role, you cannot edit the name of the role after it has been created.

11. Select **Create role**.

After the role is created, share the role information with the people who require the role. You can share the role information by:

- **Role link:** Send users a link that takes them to the **Switch Role** page with all the details already filled in.
- **Account ID or alias:** Provide each user with the role name along with the account ID number or account alias. The user then goes to the **Switch Role** page and adds the details manually.
- Saving the role link information along with the EmergencyAccess user credentials.

For details, see [Providing information to the user](#).

Create your first IAM policy

IAM policies are attached to IAM identities (users, groups of users, or roles) or AWS resources. A policy is an object in AWS that, when associated with an identity or resource, defines their permissions.

To create your first IAM policy

1. Follow the sign-in procedure appropriate to your user type as described in the topic [How to sign in to AWS](#) in the *AWS Sign-In User Guide*.
2. On the **Console Home** page, select the IAM service.
3. In the navigation pane, choose **Policies**.

If this is your first time choosing **Policies**, the **Welcome to Managed Policies** page appears. Choose **Get Started**.

4. Choose **Create policy**.
5. On the **Create policy** page, choose **Actions** and then choose **Import policy**.
6. In the **Import policy** window, in the **Find policies** box, type **power** to reduce the list of policies. Select the **PowerUserAccess** policy.
7. Select **Import policy**. The policy displays in the **JSON** tab.
8. Choose **Next**.
9. On the **Review and create** page, for **Policy name**, type **PowerUserExamplePolicy**. For **Description**, type **Allows full access to all services except those for user management**. Then choose **Create policy** to save the policy.

You can attach this policy to a role to provide users who assume that role the permissions associated with this policy. The **PowerUserAccess** policy is commonly used to provide access to developers.

Programmatic access

Users need programmatic access if they want to interact with AWS outside of the AWS Management Console. The way to grant programmatic access depends on the type of user that's accessing AWS:

- If you manage identities in IAM Identity Center, the AWS APIs require a profile, and the AWS Command Line Interface requires a profile or an environment variable.
- If you have IAM users, the AWS APIs and the AWS Command Line Interface require access keys. Whenever possible, create temporary credentials that consist of an access key ID, a secret access key, and a security token that indicates when the credentials expire.

To grant users programmatic access, choose one of the following options.

Which user needs programmatic access?	To	By
Workforce identity (Users managed in IAM Identity Center)	Use short-term credentials to sign programmatic requests to the AWS CLI or AWS APIs (directly or by using the AWS SDKs).	Following the instructions for the interface that you want to use: <ul style="list-style-type: none"> For the AWS CLI, follow the instructions in Getting IAM role credentials for CLI access in the <i>AWS IAM Identity Center User Guide</i>. For the AWS APIs, follow the instructions in SSO credentials in the <i>AWS SDKs and Tools Reference Guide</i>.
IAM	Use short-term credentials to sign programmatic requests to the AWS CLI or AWS APIs (directly or by using the AWS SDKs).	Following the instructions in Using temporary credentials with AWS resources .
IAM	Use long-term credentials to sign programmatic requests to the AWS CLI or AWS APIs (directly or by using the AWS SDKs). (Not recommended)	Following the instructions in Managing access keys for IAM users .

Security best practices and use cases in AWS Identity and Access Management

AWS Identity and Access Management (IAM) provides a number of security features to consider as you develop and implement your own security policies. The following best practices are general guidelines and don't represent a complete security solution. Because these best practices might not be appropriate or sufficient for your environment, treat them as helpful considerations rather than prescriptions.

To get the greatest benefits from IAM, take time to learn the recommended best practices. One way to do this is to see how IAM is used in real-world scenarios to work with other AWS services.

Require human users to use federation with an identity provider to access AWS using temporary credentials

Human users, also known as *human identities*, are the people, administrators, developers, operators, and consumers of your applications. They must have an identity to access your AWS environments and applications. Human users that are members of your organization are also known as *workforce identities*. Human users can also be external users with whom you collaborate, and who interact with your AWS resources. They can do this via a web browser, client application, mobile app, or interactive command-line tools.

Require your human users to use temporary credentials when accessing AWS. You can use an identity provider for your human users to provide federated access to AWS accounts by assuming roles, which provide temporary credentials. For centralized access management, we recommend that you use [AWS IAM Identity Center \(IAM Identity Center\)](#) to manage access to your accounts and permissions within those accounts. You can manage your user identities with IAM Identity Center, or manage access permissions for user identities in IAM Identity Center from an external identity provider. For more information, see [What is AWS IAM Identity Center](#) in the *AWS IAM Identity Center User Guide*.

For more information about roles, see [Roles terms and concepts](#).

Require workloads to use temporary credentials with IAM roles to access AWS

A *workload* is a collection of resources and code that delivers business value, such as an application or backend process. Your workload can have applications, operational tools, and components

that require an identity to make requests to AWS services, such as requests to read data. These identities include machines running in your AWS environments, such as Amazon EC2 instances or AWS Lambda functions.

You can also manage *machine identities* for external parties who need access. To give access to machine identities, you can use IAM roles. IAM roles have specific permissions and provide a way to access AWS by relying on temporary security credentials with a role session. Additionally, you might have machines outside of AWS that need access to your AWS environments. For machines that run outside of AWS you can use [AWS Identity and Access Management Roles Anywhere](#). For more information about roles, see [IAM roles](#). For details about how to use roles to delegate access across AWS accounts, see [IAM tutorial: Delegate access across AWS accounts using IAM roles](#).

Require multi-factor authentication (MFA)

We recommend using IAM roles for human users and workloads that access your AWS resources so that they use temporary credentials. However, for scenarios in which you need an IAM user or root user in your account, require MFA for additional security. With MFA, users have a device that generates a response to an authentication challenge. Each user's credentials and device-generated response are required to complete the sign-in process. For more information, see [Using multi-factor authentication \(MFA\) in AWS](#).

If you use IAM Identity Center for centralized access management for human users, you can use the IAM Identity Center MFA capabilities when your identity source is configured with the IAM Identity Center identity store, AWS Managed Microsoft AD, or AD Connector. For more information about MFA in IAM Identity Center see [Multi-factor authentication](#) in the *AWS IAM Identity Center User Guide*.

Update access keys when needed for use cases that require long-term credentials

Where possible, we recommend relying on temporary credentials instead of creating long-term credentials such as access keys. However, for scenarios in which you need IAM users with programmatic access and long-term credentials, we recommend that you update the access keys when needed, such as when an employee leaves your company. We recommend that you use *IAM access last used information* to update and remove access keys safely. For more information, see [Updating access keys](#).

There are specific use cases that require long-term credentials with IAM users in AWS. Some of the use cases include the following:

- **Workloads that cannot use IAM roles** – You might run a workload from a location that needs to access AWS. In some situations, you can't use IAM roles to provide temporary credentials, such as for WordPress plugins. In these situations, use IAM user long-term access keys for that workload to authenticate to AWS.
- **Third-party AWS clients** – If you are using tools that don't support access with IAM Identity Center, such as third-party AWS clients or vendors that are not hosted on AWS, use IAM user long-term access keys.
- **AWS CodeCommit access** – If you are using CodeCommit to store your code, you can use an IAM user with either SSH keys or service-specific credentials for CodeCommit to authenticate to your repositories. We recommend that you do this in addition to using a user in IAM Identity Center for normal authentication. Users in IAM Identity Center are the people in your workforce who need access to your AWS accounts or to your cloud applications. To give users access to your CodeCommit repositories without configuring IAM users, you can configure the **git-remote-codecommit** utility. For more information about IAM and CodeCommit, see [Using IAM with CodeCommit: Git credentials, SSH keys, and AWS access keys](#). For more information about configuring the **git-remote-codecommit** utility, see [Connecting to AWS CodeCommit repositories with rotating credentials](#) in the *AWS CodeCommit User Guide*.
- **Amazon Keyspaces (for Apache Cassandra) access** – In a situation where you are unable to use users in IAM Identity Center, such as for testing purposes for Cassandra compatibility, you can use an IAM user with service-specific credentials to authenticate with Amazon Keyspaces. Users in IAM Identity Center are the people in your workforce who need access to your AWS accounts or to your cloud applications. You can also connect to Amazon Keyspaces using temporary credentials. For more information, see [Using temporary credentials to connect to Amazon Keyspaces using an IAM role and the SigV4 plugin](#) in the *Amazon Keyspaces (for Apache Cassandra) Developer Guide*.

Follow best practices to protect your root user credentials

When you create an AWS account, you establish root user credentials to sign in to the AWS Management Console. Safeguard your root user credentials the same way you would protect other sensitive personal information. To better understand how to secure and scale your root user processes, see [Root user best practices for your AWS account](#).

Apply least-privilege permissions

When you set permissions with IAM policies, grant only the permissions required to perform a task. You do this by defining the actions that can be taken on specific resources under specific conditions, also known as *least-privilege permissions*. You might start with broad permissions while you explore the permissions that are required for your workload or use case. As your use case matures, you can work to reduce the permissions that you grant to work toward least privilege. For more information about using IAM to apply permissions, see [Policies and permissions in IAM](#).

Get started with AWS managed policies and move toward least-privilege permissions

To get started granting permissions to your users and workloads, use the *AWS managed policies* that grant permissions for many common use cases. They are available in your AWS account. Keep in mind that AWS managed policies might not grant least-privilege permissions for your specific use cases because they are available for use by all AWS customers. As a result, we recommend that you reduce permissions further by defining [customer managed policies](#) that are specific to your use cases. For more information, see [AWS managed policies](#). For more information about AWS managed policies that are designed for specific job functions, see [AWS managed policies for job functions](#).

Use IAM Access Analyzer to generate least-privilege policies based on access activity

To grant only the permissions required to perform a task, you can generate policies based on your access activity that is logged in AWS CloudTrail. [IAM Access Analyzer](#) analyzes the services and actions that your IAM roles use, and then generates a fine-grained policy that you can use. After you test each generated policy, you can deploy the policy to your production environment. This ensures that you grant only the required permissions to your workloads. For more information about policy generation, see [IAM Access Analyzer policy generation](#).

Regularly review and remove unused users, roles, permissions, policies, and credentials

You might have IAM users, roles, permissions, policies, or credentials that you no longer need in your AWS account. IAM provides *last accessed information* to help you identify the users, roles, permissions, policies, and credentials that you no longer need so that you can remove them. This

helps you reduce the number of users, roles, permissions, policies, and credentials that you have to monitor. You can also use this information to refine your IAM policies to better adhere to least-privilege permissions. For more information, see [Refining permissions in AWS using last accessed information](#).

Use conditions in IAM policies to further restrict access

You can specify conditions under which a policy statement is in effect. That way, you can grant access to actions and resources, but only if the access request meets specific conditions. For example, you can write a policy condition to specify that all requests must be sent using SSL. You can also use conditions to grant access to service actions, but only if they are used through a specific AWS service, such as AWS CloudFormation. For more information, see [IAM JSON policy elements: Condition](#).

Verify public and cross-account access to resources with IAM Access Analyzer

Before you grant permissions for public or cross-account access in AWS, we recommend that you verify if such access is required. You can use IAM Access Analyzer to help you preview and analyze public and cross-account access for supported resource types. You do this by reviewing the [findings](#) that IAM Access Analyzer generates. These findings help you verify that your resource access controls grant the access that you expect. Additionally, as you update public and cross-account permissions, you can verify the effect of your changes before deploying new access controls to your resources. IAM Access Analyzer also monitors supported resource types continuously and generates a finding for resources that allow public or cross-account access. For more information, see [Previewing access with IAM Access Analyzer APIs](#).

Use IAM Access Analyzer to validate your IAM policies to ensure secure and functional permissions

Validate the policies you create to ensure that they adhere to the [IAM policy language](#) (JSON) and IAM best practices. You can validate your policies by using IAM Access Analyzer policy validation. IAM Access Analyzer provides more than 100 policy checks and actionable recommendations to help you author secure and functional policies. As you author new policies or edit existing policies in the console, IAM Access Analyzer provides recommendations to help you refine and validate your policies before you save them. Additionally, we recommend that you review and validate all of your existing policies. For more information, see [IAM Access Analyzer policy validation](#). For more

information about policy checks provided by IAM Access Analyzer, see [IAM Access Analyzer policy check reference](#).

Establish permissions guardrails across multiple accounts

As you scale your workloads, separate them by using multiple accounts that are managed with AWS Organizations. We recommend that you use Organizations [service control policies](#) (SCPs) to establish permissions guardrails to control access for all IAM users and roles across your accounts. SCPs are a type of organization policy that you can use to manage permissions in your organization at the AWS organization, OU, or account level. The permissions guardrails that you establish apply to all users and roles within the covered accounts. However, SCPs alone are insufficient to grant permissions to the accounts in your organization. To do this, your administrator must attach [identity-based or resource-based policies](#) to IAM users, IAM roles, or the resources in your accounts. For more information, see [AWS Organizations, accounts, and IAM guardrails](#).

Use permissions boundaries to delegate permissions management within an account

In some scenarios, you might want to delegate permissions management within an account to others. For example, you could allow developers to create and manage roles for their workloads. When you delegate permissions to others, use *permissions boundaries* to set the maximum permissions that you delegate. A permissions boundary is an advanced feature for using a managed policy to set the maximum permissions that an identity-based policy can grant to an IAM role. A permissions boundary does not grant permissions on its own. For more information, see [Permissions boundaries for IAM entities](#).

Root user best practices for your AWS account

When you first create an AWS account, you begin with a default set of credentials with complete access to all AWS resources in your account. This identity is called the [AWS account root user](#). We strongly recommend you don't access the AWS account root user unless you have a [task that requires root user credentials](#). You need to secure your root user credentials and your account recovery mechanisms to help ensure you don't expose your highly privileged credentials for unauthorized use.

Instead of accessing the root user, create an administrative user for everyday tasks.

- For a single, standalone AWS account, see [Create an administrative user](#).

- For multiple AWS accounts managed through AWS Organizations, see [Set up AWS account access for an IAM Identity Center administrative user](#).

With your administrative user, you can then create additional identities for users that need access to resources in your AWS account. We strongly recommend you require users to authenticate with temporary credentials when accessing AWS.

- For a single, standalone AWS account, use [IAM roles](#) to create identities in your account with specific permissions. Roles are intended to be assumable by anyone who needs it. Also, a role does not have standard long-term credentials, such as a password or access keys, associated with it. Instead, when you assume a role, it provides you with temporary security credentials for your role session. Unlike IAM roles, [IAM users](#) have long-term credentials such as passwords and access keys. Where possible, [best practices](#) recommend relying on temporary credentials instead of creating IAM users who have long-term credentials such as passwords and access keys.
- For multiple AWS accounts managed through Organizations, use IAM Identity Center workforce users. With IAM Identity Center, you can centrally manage users across your AWS accounts and permissions within those accounts. Manage your user identities with IAM Identity Center or from an external identity provider. For more information, see [What is AWS IAM Identity Center](#) in the *AWS IAM Identity Center User Guide*.

Topics

- [Secure your root user credentials to prevent unauthorized use](#)
- [Use a strong root user password to help protect access](#)
- [Secure your root user sign-in with multi-factor authentication \(MFA\)](#)
- [Don't create access keys for the root user](#)
- [Use multi-person approval for root user sign-in wherever possible](#)
- [Use a group email address for root user credentials](#)
- [Restrict access to account recovery mechanisms](#)
- [Secure your Organizations account root user credentials](#)
- [Monitor access and usage](#)

Secure your root user credentials to prevent unauthorized use

Secure your root user credentials and use them for only [the tasks that require them](#). To help prevent unauthorized use, don't share your root user password, MFA, access keys, CloudFront key pairs, or signing certificates with anyone, except those that have a strict business need to access the root user.

Don't store the root user password with tools that depend on AWS services in an account that is accessed using that same password. If you lose or forget your root user password, you will not be able to access these tools. We recommend that you prioritize resiliency and consider requiring two or more people to authorize access to the storage location. Access to the password or its storage location should be logged and monitored.

Use a strong root user password to help protect access

We recommend that you use a password that is strong and unique. Tools such as password managers with strong password generation algorithms can help you achieve these goals. AWS requires that your password meet the following conditions:

- It must have a minimum of 8 characters and a maximum of 128 characters.
- It must include a minimum of three of the following mix of character types: uppercase, lowercase, numbers, and ! @ # \$ % ^ & * () < > [] { } | _ + = symbols.
- It must not be identical to your AWS account name or email address.

For more information, see [Change the password for the AWS account root user](#).

Secure your root user sign-in with multi-factor authentication (MFA)

Because a root user can perform privileged actions, it's crucial to add MFA for the root user as a second authentication factor in addition to the email address and password as sign-in credentials. We strongly recommend enabling multiple MFA for your root user credentials to provide additional flexibility and resiliency in your security strategy. You can register up to eight MFA devices of any combination of the currently supported MFA types with your AWS account root user.

- FIDO Certified hardware security keys are provided by third-party providers. For more information, see [Enable a FIDO security key for the AWS account root user](#).

- A hardware device that generates a six-digit numeric code based on the time-based one-time password (TOTP) algorithm. For more information, see [Enable a hardware TOTP token for the AWS account root user](#).
- A virtual authenticator application that runs on a phone or other device and emulates a physical device. For more information, see [Enable a virtual MFA device for your AWS account root user](#).

Don't create access keys for the root user

Access keys let you run commands in the AWS Command Line Interface (AWS CLI) or use API operations from one of the AWS SDKs. We strongly recommend that you do not create access key pairs for your root user because the root user has full access to all AWS services and resources in the account, including billing information.

Since only a few tasks require the root user and you typically perform those tasks infrequently, we recommend signing in to the AWS Management Console to perform root user tasks. Before creating access keys, review the [alternatives to long-term access keys](#).

Use multi-person approval for root user sign-in wherever possible

Consider using multi-person approval to ensure that no one person can access both MFA and password for the root user. Some companies add an additional layer of security by setting up one group of administrators with access to the password, and another group of administrators with access to MFA. One member from each group must come together to sign in as the root user.

Use a group email address for root user credentials

Use an email address that is managed by your business and forwards received messages directly to a group of users. If AWS must contact the owner of the account, this approach reduces the risk of delays in responding, even if individuals are on vacation, out sick, or have left the business. The email address used for the root user should not be used for other purposes.

Restrict access to account recovery mechanisms

Ensure you develop a process to manage root user credential recovery mechanisms in case you need access to it during emergency such as takeover of your administrative account.

- Ensure you have access to your root user email inbox so that you can [reset a lost or forgotten root user password](#).

- If MFA for your AWS account root user is lost, damaged, or not working, you can sign in using another MFA registered to the same root user credentials. If you lost access to all your MFAs, you need both the phone number and the email to be up to date and accessible to recover your MFA. For details, see [Recovering a root user MFA device](#).
- If you choose not to store your root user password and MFA, then the phone number registered in your account can be used as an alternate way to recover root user credentials. Ensure you have access to the contact phone number, keep the phone number updated, and limit who has access to manage the phone number.

No one person should have access to both the email inbox and phone number since both are verification channels to recover your root user password. It is important to have two groups of individuals managing these channels. One group having access to your primary email address and another group having access to the primary phone number to recover access to your account as root user.

Secure your Organizations account root user credentials

As you move to a multi-account strategy with Organizations, each of your AWS accounts has its own root user credentials that you need to secure. The account you use to create your organization is the **management account** and the rest of the accounts in your organization are **member accounts**.

Secure root user credentials for member accounts

If you use Organizations to manage multiple accounts, there are two strategies that you can take to secure root user access in your Organizations.

- Secure root user credentials of your Organizations accounts with MFA.
- Do not reset the root user password for your accounts, and only recover access to it when needed using the password reset process. When you create a member account in your organization, Organizations automatically creates an IAM role in the member account that allows the management account temporary access to the member account.

For details, see [Accessing member accounts in your organization](#) in the *Organizations User Guide*.

Set preventative security controls in Organizations using a service control policy (SCP)

If you use Organizations to manage multiple accounts, you can apply an SCP to restrict access to member account root user. Denying all root user actions in your member accounts, except for certain root-only actions, helps prevent unauthorized access. For details, see [Use an SCP to restrict what the root user in your member accounts can do](#).

Monitor access and usage

We recommend you use your current tracking mechanisms to monitor, alert, and report the sign in and use of root user credentials, including alerts that announce root user sign-in and usage. The following services can help to ensure that root user credential usage is tracked and perform security checks that can help prevent unauthorized use.

- If you want to be notified about root user sign-in activity in your account, you can leverage Amazon CloudWatch to create an Events rule that detects when root user credentials are used and triggers a notification to your security administrator. For details, see [Monitor and notify on AWS account root user activity](#).
- If you want to set up notifications to alert you of approved root user actions, you can leverage Amazon EventBridge along with Amazon SNS to write an EventBridge rule to track root user usage for the specific action and notify you using an Amazon SNS topic. For an example, see [Send a notification when an Amazon S3 object is created](#).
- If you already using GuardDuty as your threat detection service, you can [extend its capability](#) to notify you when root user credentials are being used in your account.

Alerts should include, but not be limited to, the email address for the root user. Have procedures in place for how to respond to alerts so that personnel who receive a root user access alert understand how to validate that root user access is expected, and how to escalate if they believe that a security incident is in progress. For an example of how to configure alerts, see [Monitor and notify on AWS account root user activity](#).

Evaluate root user MFA compliance

- AWS Config uses rules to help enforce root user best practices. You can use AWS managed rules to [require root users to have multi-factor authentication \(MFA\) enabled](#). AWS Config can also [identify access keys for the root user](#).

- Security Hub provides you with a comprehensive view of your security state in AWS and helps you assess your AWS environment against security industry standards and best practices, such as having MFA on the root user and not having root user access keys. For details on the rules available, see [AWS Identity and Access Management controls](#) in the *Security Hub User Guide*.
- Trusted Advisor provides a security check so you know if MFA isn't enabled on the root user account. For more information, see [MFA on Root Account](#) in the *AWS Support User Guide*.

If you need to report a security issue on your account, see [Report Suspicious Emails](#) or [Vulnerability Reporting](#). Alternatively, you can [Contact AWS](#) for assistance and additional guidance.

Business use cases for IAM

A simple business use case for IAM can help you understand basic ways you might implement the service to control the AWS access that your users have. The use case is described in general terms, without the mechanics of how you'd use the IAM API to achieve the results you want.

This use case looks at two typical ways a fictional company called Example Corp might use IAM. The first scenario considers Amazon Elastic Compute Cloud (Amazon EC2). The second considers Amazon Simple Storage Service (Amazon S3).

For more information about using IAM with other services from AWS, see [AWS services that work with IAM](#).

Topics

- [Initial setup of example corp](#)
- [Use case for IAM with Amazon EC2](#)
- [Use case for IAM with Amazon S3](#)

Initial setup of example corp

Nikki Wolf and Mateo Jackson are the founders of Example Corp. Upon starting the company, they create an AWS account and set up AWS IAM Identity Center (IAM Identity Center) to create administrative accounts to use with their AWS resources. When you set up account access for the administrative user, IAM Identity Center creates a corresponding IAM role. This role, which is controlled by IAM Identity Center, is created in the relevant AWS account, and the policies specified in the **AdministratorAccess** permission set are attached to the role.

Since they now have administrator accounts, Nikki and Mateo no longer need to use their root user to access their AWS account. They plan to only use the root user to complete the tasks that only the root user can perform. After reviewing the security best practices they configure multi-factor authentication (MFA) for their root user credentials and decide how to safeguard their root user credentials.

As their company grows, they hire employees to work as developers, admins, testers, managers, and system administrators. Nikki is in charge of operations, while Mateo manages the engineering teams. They set up an Active Directory Domain Server to manage the employees accounts and manage access to internal company resources.

To give their employees access to AWS resources, they use IAM Identity Center to connect their company's Active Directory to their AWS account.

Because they connected Active Directory to IAM Identity Center, the users, group, and group membership are synchronized and defined. They must assign permission sets and roles to the different groups to give the users the correct level of access to AWS resources. They use [AWS managed policies for job functions](#) in the AWS Management Console to create these permissions sets:

- *Administrator*
- *Billing*
- *Developers*
- *Network administrators*
- *Database administrators*
- *System administrators*
- *Support users*

Then they assign these permissions sets to the roles assigned to their Active Directory groups.

For a step-by-step guide describing the initial configuration of IAM Identity Center, see [Getting started](#) in the *AWS IAM Identity Center User Guide*. For more information about provisioning IAM Identity Center user access, see [Single sign-on access to AWS accounts](#) in the *AWS IAM Identity Center User Guide*.

Use case for IAM with Amazon EC2

A company like Example Corp typically uses IAM to interact with services like Amazon EC2. To understand this part of the use case, you need a basic understanding of Amazon EC2. For more information about Amazon EC2, go to the [Amazon EC2 User Guide for Linux Instances](#).

Amazon EC2 permissions for the user groups

To provide "perimeter" control, Nikki attaches a policy to the AllUsers user group. This policy denies any AWS request from a user if the originating IP address is outside Example Corp's corporate network.

At Example Corp, different user groups require different permissions:

- **System administrators** – Need permission to create and manage AMIs, instances, snapshots, volumes, security groups, and so on. Nikki attaches the AmazonEC2FullAccess AWS managed policy to the SysAdmins user group that gives members of the group permission to use all the Amazon EC2 actions.
- **Developers** – Need the ability to work with instances only. Mateo therefore creates and attaches a policy to the Developers user group that allows developers to call DescribeInstances, RunInstances, StopInstances, StartInstances, and TerminateInstances.

Note

Amazon EC2 uses SSH keys, Windows passwords, and security groups to control who has access to the operating system of specific Amazon EC2 instances. There's no method in the IAM system to allow or deny access to the operating system of a specific instance.

- **Support users** – Should not be able to perform any Amazon EC2 actions except listing the Amazon EC2 resources currently available. Therefore, Nikki creates and attaches a policy to the Support users group that only lets them call Amazon EC2 "Describe" API operations.

For examples of what these policies might look like, see [Example IAM identity-based policies](#) and [Using AWS Identity and Access Management](#) in the *Amazon EC2 User Guide for Linux Instances*.

User's job function change

At some point, one of the developers, Paulo Santos, changes job functions and becomes a manager. As a manager, Paulo becomes part of the Support users group so that he can open

support cases for his developers. Mateo moves Paulo from the Developers user group to the Support users group. As a result of this move, his ability to interact with Amazon EC2 instances is limited. He can't launch or start instances. He also can't stop or terminate existing instances, even if he was the user who launched or started the instance. He can list only the instances that Example Corp users have launched.

Use case for IAM with Amazon S3

Companies like Example Corp would also typically use IAM with Amazon S3. John has created an Amazon S3 bucket for the company called *aws-s3-bucket*.

Creation of other users and user groups

As employees, Zhang Wei and Mary Major each need to be able to create their own data in the company's bucket. They also need to read and write shared data that all developers work on. To enable this, Mateo logically arranges the data in *aws-s3-bucket* using an Amazon S3 key prefix scheme as shown in the following figure.

```
/aws-s3-bucket
  /home
    /zhang
    /major
  /share
    /developers
    /managers
```

Mateo divides the */aws-s3-bucket* into a set of home directories for each employee, and a shared area for groups of developers and managers.

Now Mateo creates a set of policies to assign permissions to the users and user groups:

- **Home directory access for Zhang** – Mateo attaches a policy to Wei that lets him read, write, and list any objects with the Amazon S3 key prefix */aws-s3-bucket/home/zhang/*
- **Home directory access for Major** – Mateo attaches a policy to Mary that lets her read, write, and list any objects with the Amazon S3 key prefix */aws-s3-bucket/home/major/*
- **Shared directory access for the developers user group** – Mateo attaches a policy to the user group that lets developers read, write, and list any objects in */aws-s3-bucket/share/developers/*

- **Shared directory access for the managers user group** – Mateo attaches a policy to the user group that lets managers read, write, and list objects in `/aws-s3-bucket/share/managers/`

Note

Amazon S3 doesn't automatically give a user who creates a bucket or object permission to perform other actions on that bucket or object. Therefore, in your IAM policies, you must explicitly give users permission to use the Amazon S3 resources they create.

For examples of what these policies might look like, see [Access Control](#) in the *Amazon Simple Storage Service User Guide*. For information on how policies are evaluated at runtime, see [Policy evaluation logic](#).

User's job function change

At some point, one of the developers, Zhang Wei, changes job functions and becomes a manager. We assume that he no longer needs access to the documents in the `share/developers` directory. Mateo, as an admin, moves Wei to the `Managers` user group and out of the `Developers` user group. With just that simple reassignment, Wei automatically gets all permissions granted to the `Managers` user group, but can no longer access data in the `share/developers` directory.

Integration with a third-party business

Organizations often work with partner companies, consultants, and contractors. Example Corp has a partner called the Widget Company, and a Widget Company employee named Shirley Rodriguez needs to put data into a bucket for Example Corp's use. Nikki creates a user group called `WidgetCo` and a user named `Shirley` and adds Shirley to the `WidgetCo` user group. Nikki also creates a special bucket called `aws-s3-bucket1` for Shirley to use.

Nikki updates existing policies or adds new ones to accommodate the partner Widget Company. For example, Nikki can create a new policy that denies members of the `WidgetCo` user group the ability to use any actions other than write. This policy would be necessary only if there's a broad policy that gives all users access to a wide set of Amazon S3 actions.

IAM tutorials

The following tutorials present complete end-to-end procedures for common tasks for AWS Identity and Access Management (IAM). They are intended for a lab-type environment, with fictitious company names, user names, and so on. Their purpose is to provide general guidance. They are not intended for direct use in a production environment without careful review and adaptation to meet the unique needs of your organization's environment.

Tutorials

- [IAM tutorial: Grant access to the billing console](#)
- [IAM tutorial: Delegate access across AWS accounts using IAM roles](#)
- [IAM tutorial: Create and attach your first customer managed policy](#)
- [IAM tutorial: Define permissions to access AWS resources based on tags](#)
- [IAM tutorial: Permit users to manage their credentials and MFA settings](#)

IAM tutorial: Grant access to the billing console

The AWS account owner ([AWS account root user](#)) can grant IAM users and roles access to the AWS Billing and Cost Management data for their AWS account. The instructions in this tutorial help you set up a pretested scenario. This scenario helps you gain hands-on experience configuring billing permissions without concern for affecting your main AWS production account.

Prerequisites

Make the following preparations before performing the steps in this tutorial:

- Create a test AWS account.
- Sign in to your test AWS account as the root user.
- Record the AWS account number of your test account so that you can use it in the tutorial. In this tutorial we use the example account number 111122223333. Whenever a step uses that account number, replace it with your test account number.

Step 1: Activate IAM access to billing information on your test AWS account

In this scenario, you sign in to your test AWS account as the root user to grant IAM access to billing information. When you grant IAM access to billing information it allows IAM users and

roles to access the AWS Billing and Cost Management console. This setting doesn't grant IAM users and roles the necessary permissions for these console pages, it enables access for IAM users or roles that have the required IAM policies. If policies are already attached to IAM users or roles, but this setting isn't enabled, the permissions granted by those policies aren't in effect.

 **Note**

AWS accounts created using AWS Organizations have IAM access to billing information enabled by default.

Step 2: Create test users and groups

In this scenario, you grant IAM users access to the billing console and you create two users:

- Pat Candella

Pat is a member of the finance department and works with billing and payments. Pat requires full access to the billing information in your AWS account.

- Terry Whitlock

Terry is part of your IT support department. Most of the time Terry doesn't require access to the billing console, but sometimes needs access to answer questions for employees in the finance department.

Step 3: Create a role to grant access to the AWS Billing console

An IAM role is an IAM identity that you can create in your account that has specific permissions. An IAM role is similar to an IAM user, in that it's an AWS identity with permission policies that determine what the identity can and can't do in AWS. However, instead of being uniquely associated with one person, a role is intended to be assumable by anyone who needs it. Also, a role doesn't have standard long-term credentials such as a password or access keys associated with it. Instead, when you assume a role, it provides you with temporary security credentials for your role session. You can use roles to delegate access to users, applications, or services that don't normally have access to your AWS resources. In this scenario you create a role that Terry Whitlock can assume to access the billing console.

Step 4: Test access to the console

After you've completed the core tasks, you're ready to test the policy. Testing ensures that the policy works the way you want it to. By testing the access of each user you can compare the user experiences.

Prerequisites

Make the following preparations before performing the steps in this tutorial:

- Create a test AWS account.
- Sign in to your test AWS account as the root user.
- Record the AWS account number of your test account so that you can use it in the tutorial. In this tutorial we use the example account number 111122223333. Whenever a step uses that account number, replace it with your test account number.

Step 1: Activate IAM access to billing information on your test AWS account

In this scenario, you sign in to your test AWS account as the root user to grant IAM access to billing information. When you grant access to billing information it allows IAM users and roles to access the AWS Billing and Cost Management console. This setting doesn't grant IAM users and roles the necessary permissions for these console pages, it just enables access for IAM users or roles that have the required IAM policies.

Note

AWS accounts created using AWS Organizations have IAM access to billing information enabled by default.

To activate IAM user and role access to the Billing and Cost Management console

1. Sign in to the AWS Management Console with your root user credentials (specifically, the email address and password that you used to create your AWS account).
2. On the navigation bar, select your account name, and then select [Account](#).

3. Scroll down the page until you find the section **IAM User and Role Access to Billing Information**, then select **Edit**.
4. Select the **Activate IAM Access** check box to activate access to the Billing and Cost Management console pages.
5. Choose **Update**.

The page displays the message **IAM user/role access to billing information is activated**.

In the next step of this tutorial you attach IAM policies to grant or deny access to specific billing features.

Step 2: Create test users and groups

Your test AWS account doesn't have any identities defined except for the root user. To provide access to billing information we create additional identities to whom we can grant permission to access billing information.

Create test users and groups

1. Sign in to the [IAM console](#) as the account owner by choosing **Root user** and entering your AWS account email address. On the next page, enter your password.

Note

As the root user, you can't sign in to the **Sign in as IAM user** page. If you see the **Sign in as IAM user** page, choose **Sign in using root user email** near the bottom of the page. For help signing in as the root user, see [Signing in to the AWS Management Console as the root user](#) in the *AWS Sign-In User Guide*.

2. In the navigation pane, select **Users** and then select **Add users**.

Note

If you have IAM Identity Center enabled, the AWS Management Console displays a reminder that it's best to manage users' access in IAM Identity Center. In this tutorial, the IAM users we create are to learn about providing access to billing information. If

you have created users in IAM Identity Center you assign the **Billing** permission set to those users or groups using IAM Identity Center instead of IAM.

3. For **User name**, enter **pcandella**. Names can't contain spaces.
4. Select the select box next to **Provide user access to the AWS Management Console– optional** and then choose **want to create an IAM user**.
5. Under **Console password**, select **Autogenerated password**.
6. Clear the select box next to **User must create a new password at next sign-in (recommended)** and then select **Next**. Because this IAM user is for testing, we're going to download the password for use during the verification procedure.
7. On the **Set permissions** page, under **Permissions options**, select **Add user to group**. Then, under **User groups**, select **Create group**.
8. On the **Create user group** page, in **User group name**, enter **BillingGroup**. Then, under **Permissions policies**, select the AWS managed job function policy **Billing**.
9. Select **Create user group** to return to the **Set permissions** page.
10. Under **User groups**, select the select box of the **BillingGroup** you created.
11. Select **Next** to proceed to the **Review and create** page.
12. On the **Review and create** page, review the list of user group memberships for the new user. When you are ready to proceed, select **Create user**.
13. On the **Retrieve password** page, select **Download .csv file** to save a .csv file with the user sign-in information (Connection URL, user name, and password).

Save this file to use as a reference when you sign in to AWS as this IAM user

14. Select **Return to users list**
15. Repeat this procedure using the following modifications to create the user for Terry Whitlock and a group for support users.
 - a. In step 3, for **User name**, enter **twhitlock**.
 - b. In step 8, for **User group name**, enter **SupportGroup**. Then, under **Permissions policies**, select the AWS managed-job function policy **SupportUser**.

You can review the new IAM users, groups and roles in the console lists. For each item you created you can select the name to view its details. When you view the user details, the console

displays **Billing** listed under **Permissions policies** for **pcandella** and **SupportUser** listed under **Permissions policies** for **twhitlock**.

For more information about using policies to grant IAM users access to AWS Billing and Cost Management features, see [Using identity-based policies \(IAM policies\) for AWS Billing](#) in the *AWS Billing User Guide*.

Step 3: Create a role to grant access to the AWS Billing console

You can use a role to grant IAM users access to the billing console. Roles provide temporary credentials that users can assume when needed. In this tutorial, the user **twhitlock** needs to be able to access billing information when a support request from the finance department requires he investigate an issue.

1. Sign in to the [IAM console](#) as the account owner by choosing **Root user** and entering your AWS account email address. On the next page, enter your password.

Note

As the root user, you can't sign in to the **Sign in as IAM user** page. If you see the **Sign in as IAM user** page, choose **Sign in using root user email** near the bottom of the page. For help signing in as the root user, see [Signing in to the AWS Management Console as the root user](#) in the *AWS Sign-In User Guide*.

2. In the navigation pane, select **Users** and then select the **twhitlock** user to view the user details. Copy the ARN for the **twhitlock** user to the clipboard.
3. In the navigation pane, select **Roles** and then select **Create role**.
4. On the **Select trusted entity** page, select **Custom trust policy** and then under **Edit statement** complete the following items:
 - **Add actions for STS** - Verify that **AssumeRole** is selected.
 - **Add a principal** select **Add** to display the **Add principal** dialog box. For **Principal type** select **IAM users** then for **ARN** paste the ARN for the *twhitlock* user that you copied to the clipboard in step 16. Then select **Add principal**.
5. Select **Next** to go to the **Add permissions** page.
6. Under **Permissions policies** in the filter box, enter **Billing** and then select the AWS managed-job function policy **Billing**.

7. Select **Next** to go to the **Name, review, and create** page. Under **Role name**, enter **TempBillingAccess** then select **Create role**.

You are notified that the role has been created. View the role to display the details about the role. In the **Summary** section take note of the following information:

- **Maximum session duration** is 1 hour by default. After that time the user who assumed the role reverts to their base account permissions. If the user wants to continue using the role permissions, they must switch roles again. You can edit the role to increase the maximum duration. The longest session duration possible is 12 hours.
- **Link to switch roles in console**. You can copy the link to provide it directly to the users that you add as principals in the trust policy. You can view and edit the trust policy from the **Trust relationships** tab.

Step 4: Test access to the console

We recommend that you test access by signing in as the test users to learn what your users might experience. Use the following steps to sign in using both test accounts to see the difference between access rights.

To test billing access by signing in with both test users

1. Use your AWS account ID or account alias, your IAM user name, and your password to sign in to the [IAM console](#).

Note

For your convenience, the AWS sign-in page uses a browser cookie to remember your IAM user name and account information. If you previously signed in as a different user, choose **Sign in to a different account** near the bottom of the page to return to the main sign-in page. From there, you can type your AWS account ID or account alias to be redirected to the IAM user sign-in page for your account.

2. Sign in with each user using the steps provided below so you can compare the different user experiences.

Full access

- a. Sign in to your AWS account as the user **pcandella**.

- b. On the navigation bar, choose **pcandella@111122223333** , and then choose **Billing Dashboard**.
- c. Browse through the pages and choose the various buttons to make sure that you have full modify permissions.

No access

- a. Sign in to your AWS account as the user **twhitlock**.
- b. On the navigation bar, choose **twhitlock@111122223333**, and then choose **Billing Dashboard**.
- c. A message displays stating **You need permissions**. No billing data is visible.

Switch role to elevate access

- a. Sign in to your AWS account as the user **twhitlock**.
- b. On the navigation bar, choose **twhitlock@111122223333**, and then choose **Switch role**.

The **Switch role** page opens. Complete the information as follows:

- **Account-111122223333**
- **Role-TempBillingAccess**

Select **Switch role**

Alternatively, you could use the URL provided in **Link to switch roles in console** to open the **Switch role** page.

- c. The console displays the **AWS Billing Dashboard** and the navigation bar displays **TempBillingAccess@111122223333**.

Summary

You've now completed the steps necessary to provide IAM users access to the AWS Billing console. As a result, you've seen firsthand what your users billing console experience is like. You can now proceed to implement this logic in your production environment at your convenience.

IAM tutorial: Delegate access across AWS accounts using IAM roles

This tutorial teaches you how to use a role to delegate access to resources in different AWS accounts that you own called **Production** and **Development**. You share resources in one account with users in a different account. By setting up cross-account access in this way, you don't have to create individual IAM users in each account. In addition, users don't have to sign out of one account and sign in to another account to access resources in different AWS accounts. After configuring the role, you see how to use the role from the AWS Management Console, the AWS CLI, and the API.

Note

IAM roles and resource-based policies delegate access across accounts only within a single partition. For example, assume that you have an account in US West (N. California) in the standard `aws` partition. You also have an account in China (Beijing) in the `aws-cn` partition. You can't use an Amazon S3 resource-based policy in your account in China (Beijing) to allow access for users in your standard `aws` account.

In this tutorial, the **Production** account manages live applications. Developers and testers use the **Development** account as a sandbox to freely test applications. In each account, you store

application information in Amazon S3 buckets. You manage IAM users in the **Development** account, where you have two IAM user groups: **Developers** and **Testers**. Users in both user groups have permissions to work in the Development account and access resources there. From time to time, a developer must update the live applications in the **Production** account. The developers store these applications in an Amazon S3 bucket called `productionapp`.

At the end of this tutorial, you have the following:

- Users in the **Development** account (the trusted account) allowed to assume a specific role in the **Production** account.
- A role in the **Production** account (the trusting account) allowed to access a specific Amazon S3 bucket.
- The `productionapp` bucket in the **Production** account.

Developers can use the role in the AWS Management Console to access the `productionapp` bucket in the **Production** account. They can also access the bucket by using API calls authenticated by temporary credentials provided by the role. Similar attempts by a Tester to use the role fail.

This workflow has three basic steps:

Create a role in the Production Account

First, you use the AWS Management Console to establish trust between the **Production** account (ID number 999999999999) and the **Development** account (ID number 111111111111). You start by creating an IAM role named `UpdateApp`. When you create the role, you define the **Development** account as a trusted entity and specify a permissions policy that allows trusted users to update the `productionapp` bucket.

Grant access to the role

In this section, you modify the IAM user group policy to deny Testers access to the `UpdateApp` role. Because Testers have `PowerUser` access in this scenario, and you must explicitly *deny* the ability to use the role.

Test access by switching roles

Finally, as a Developer, you use the UpdateApp role to update the `productionapp` bucket in the **Production** account. You see how to access the role through the AWS console, the AWS CLI, and the API.

Prerequisites

This tutorial assumes that you have the following already in place:

- **Two** separate AWS accounts that you can use, one to represent the **Development** account, and one to represent the **Production** account.
- Users and user groups in the **Development** account created and configured as follows:

User	User group	Permissions
David	Developers	Both users can sign in and use the AWS Management Console in the Development account.
Jane	Testers	

- You do not need any users or user groups created in the **Production** account.
- An Amazon S3 bucket created in the **Production** account. You can call it `ProductionApp` in this tutorial, but because S3 bucket names must be globally unique, you must use a bucket with a different name.

Create a role in the Production Account

You can allow users from one AWS account to access resources in another AWS account. To do this, create a role that defines who can access it and what permissions it grants to users that switch to it.

In this step of the tutorial, you create the role in the **Production** account and specify the **Development** account as a trusted entity. You also limit the role permissions to only read and write access to the `productionapp` bucket. Anyone granted permission to use the role can read and write to the `productionapp` bucket.

Before you can create a role, you need the *account ID* of the **Development** AWS account. Each AWS account has a unique account ID identifier assigned to it.

To obtain the Development AWS account ID

1. Sign in to the AWS Management Console as an administrator of the **Development** account, and open the IAM console at <https://console.aws.amazon.com/iam/>.
2. In the navigation bar, choose **Support**, and then **Support Center**. Your currently signed-in 12-digit account number (ID) appears in the **Support Center** navigation pane. For this scenario, you can use the account ID 111111111111 for the **Development** account. However, you should use a valid account ID if you use this scenario in your test environment.

To create a role in the production account that can be used by the Development account

1. Sign in to the AWS Management Console as an administrator of the **Production** account, and open the IAM console.
2. Before creating the role, prepare the managed policy that defines the permissions for the role requirements. You attach this policy to the role in a later step.

You want to set read and write access to the `productionapp` bucket. Although AWS provides some Amazon S3 managed policies, there isn't one that provides read and write access to a single Amazon S3 bucket. You can create your own policy instead.

In the navigation pane, choose **Policies** and then choose **Create policy**.

3. Choose the **JSON** tab and copy the text from the following JSON policy document. Paste this text into the **JSON** text box, replacing the resource ARN (`arn:aws:s3:::productionapp`) with the real one for your Amazon S3 bucket.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": "s3:ListAllMyBuckets",
      "Resource": "*"
    },
    {
      "Effect": "Allow",
      "Action": [
        "s3:ListBucket",
        "s3:GetBucketLocation"
      ],

```

```
    "Resource": "arn:aws:s3:::productionapp"
  },
  {
    "Effect": "Allow",
    "Action": [
      "s3:GetObject",
      "s3:PutObject",
      "s3:DeleteObject"
    ],
    "Resource": "arn:aws:s3:::productionapp/*"
  }
]
```

The `ListAllMyBuckets` action grants permission to list all buckets owned by the authenticated sender of the request. The `ListBucket` permission allows users to view objects in the `productionapp` bucket. The `GetObject`, `PutObject`, `DeleteObject` permissions allows users to view, update, and delete contents in the `productionapp` bucket.

4. Resolve any security warnings, errors, or general warnings generated during [policy validation](#), and then choose **Next**.

Note

You can switch between the **Visual** and **JSON** editor options anytime. However, if you make changes or choose **Next** in the **Visual** editor, IAM might restructure your policy to optimize it for the visual editor. For more information, see [Policy restructuring](#).

5. On the **Review and create** page, type **read-write-app-bucket** for the policy name. Review the permissions granted by your policy, and then choose **Create policy** to save your work.

The new policy appears in the list of managed policies.

6. In the navigation pane, choose **Roles** and then choose **Create role**.
7. Choose the **An AWS account** role type.
8. For **Account ID**, type the **Development** account ID.

This tutorial uses the example account ID **111111111111** for the **Development** account. You should use a valid account ID. If you use an invalid account ID, such as **111111111111**, IAM does not let you create the new role.

For now you do not need to require an external ID, or require users to have multi-factor authentication (MFA) in order to assume the role. Leave these options unselected. For more information, see [Using multi-factor authentication \(MFA\) in AWS](#).

9. Choose **Next: Permissions** to set the permissions associated with the role.
10. Select the check box next to the policy that you created previously.

 **Tip**

For **Filter**, choose **Customer managed** to filter the list to include only the policies that you created. This hides the AWS created policies and makes it much easier to find the one you need.

Then, choose **Next**.

11. (Optional) Add metadata to the role by attaching tags as key-value pairs. For more information about using tags in IAM, see [Tagging IAM resources](#).
12. (Optional) For **Description**, enter a description for the new role.
13. After reviewing the role, choose **Create role**.

The UpdateApp role appears in the list of roles.

Now you must obtain the Amazon Resource Name (ARN) of the role, a unique identifier for the role. When you modify the Developers and Testers user group policy, you specify the role ARN to grant or deny permissions.

To obtain the ARN for UpdateApp

1. In the navigation pane of the IAM console, choose **Roles**.
2. In the list of roles, choose the UpdateApp role.
3. In the **Summary** section of the details pane, copy the **Role ARN** value.

The Production account has an account ID of 999999999999, so the role ARN is `arn:aws:iam::999999999999:role/UpdateApp`. Ensure that you provide the real AWS account ID for the Production account.

At this point, you have established trust between the **Production** and **Development** accounts. You did this by creating a role in the **Production** account that identifies the **Development** account as a trusted principal. You also defined what the users who switch to the UpdateApp role can do.

Next, modify the permissions for the user groups.

Grant access to the role

At this point, both Testers and Developers user group members have permissions that allow them to freely test applications in the **Development** account. Use the following required steps for adding permissions to allow switching to the role.

To modify the Developers user group to allow them to switch to the UpdateApp role

1. Sign in as an administrator in the **Development** account, and open the IAM console.
2. Choose **User groups**, and then choose **Developers**.
3. Choose the **Permissions** tab, choose **Add permissions**, and then choose **Create inline policy**.
4. Choose the **JSON** tab.
5. Add the following policy statement to allow the AssumeRole action on the UpdateApp role in the Production account. Be sure that you change *PRODUCTION-ACCOUNT-ID* in the Resource element to the actual AWS account ID of the Production account.

```
{
  "Version": "2012-10-17",
  "Statement": {
    "Effect": "Allow",
    "Action": "sts:AssumeRole",
    "Resource": "arn:aws:iam::PRODUCTION-ACCOUNT-ID:role/UpdateApp"
  }
}
```

The Allow effect explicitly allows the Developers group access to the UpdateApp role in the Production account. Any developer who tries to access the role succeeds.

6. Choose **Review policy**.
7. Type a **Name** such as **allow-assume-S3-role-in-production**.
8. Choose **Create policy**.

In most environments, you may not need the following procedure. If, however, you use `PowerUserAccess` permissions, then some groups might already be able to switch roles. The following procedure shows how to add a "Deny" permission to the Testers group to ensure that they cannot assume the role. If you do not need this procedure in your environment, then we recommend that you do not add it. "Deny" permissions make the overall permissions picture more complicated to manage and understand. Use "Deny" permissions only when you do not have a better option.

To modify the testers user group to deny permission to assume the UpdateApp role

1. Choose **User groups**, and then choose **Testers**.
2. Choose the **Permissions** tab, choose **Add permissions**, and then choose **Create inline policy**.
3. Choose the **JSON** tab.
4. Add the following policy statement to deny the `AssumeRole` action on the `UpdateApp` role. Be sure that you change `PRODUCTION-ACCOUNT-ID` in the Resource element to the actual AWS account ID of the Production account.

```
{
  "Version": "2012-10-17",
  "Statement": {
    "Effect": "Deny",
    "Action": "sts:AssumeRole",
    "Resource": "arn:aws:iam::PRODUCTION-ACCOUNT-ID:role/UpdateApp"
  }
}
```

The Deny effect explicitly denies the Testers group access to the `UpdateApp` role in the Production account. Any tester who tries to access the role receives an access denied message.

5. Choose **Review policy**.
6. Type a **Name** like `deny-assume-S3-role-in-production`.
7. Choose **Create policy**.

The Developers user group now has permissions to use the `UpdateApp` role in the Production account. The Testers user group is prevented from using the `UpdateApp` role.

Next, you can see how David, a developer, can access the `productionapp` bucket in the Production account. David can access the bucket from the AWS Management Console, the AWS CLI, or the AWS API.

Test access by switching roles

After completing the first two steps of this tutorial, you have a role that grants access to a resource in the **Production** account. You also have one user group in the **Development** account with users allowed to use that role. This step discusses how to test switching to that role from the AWS Management Console, the AWS CLI, and the AWS API.

Important

You can switch to a role only after you sign in as an IAM user or a federated user. Additionally, if you launch an Amazon EC2 instance to run an application, the application can assume a role through its instance profile. You cannot switch to a role when you sign in as the AWS account root user.

Switch roles (console)

If David needs to work within the **Production** environment in the AWS Management Console, he can do so by using **Switch Role**. He specifies the account ID or alias and the role name, and his permissions immediately switch to those permitted by the role. He can then use the console to work with the `productionapp` bucket, but cannot work with any other resources in **Production**. While David uses the role, he also cannot make use of his power-user privileges in the **Development** account. That's because only one set of permissions can be in effect at a time.

Important

Switching roles using the AWS Management Console only works with accounts that do not require an `ExternalId`. For example, assume that you grant access to your account to a third party and require an `ExternalId` in a `Condition` element in your permissions policy. In that case, the third party can access your account only by using the AWS API or a command line tool. The third party cannot use the console because it cannot supply a value for `ExternalId`. For more information about this scenario, see [How to use an external ID when granting access to your AWS resources to a third party](#), and [How to Enable Cross-Account Access to the AWS Management Console](#) in the AWS Security Blog.

IAM provides two ways that David can use to enter the **Switch Role** page:

- David receives a link from their administrator that points to a predefined Switch Role configuration. The link is provided to the administrator on the final page of the **Create role** wizard or on the **Role Summary** page for a cross-account role. Choosing this link takes David to the **Switch Role** page with the **Account ID** and **Role name** fields already filled in. All David needs to do is choose **Switch Roles**.
- The administrator does not send the link in email, but instead sends the **Account ID** number and **Role Name** values. To switch roles, David must manually enter the values. This is illustrated in the following procedure.

To assume a role

1. David signs into the AWS Management Console using his normal user in the **Development** user group.
2. They choose the link that the administrator emailed to them. This takes David to the **Switch Role** page with the account ID or alias and the role name information already filled in.

—or—

David chooses their name (the Identity menu) on the navigation bar, and then chooses **Switch Roles**.

If this is the first time that David tries to access the Switch Role page this way, he first lands on a first-run **Switch Role** page. This page provides additional information on how switching roles can permit users to manage resources across AWS accounts. David must choose **Switch Role** on this page to complete the rest of this procedure.

3. Next, in order to access the role, David must manually type the Production account ID number (999999999999) and the role name (UpdateApp).

Also, David wants to monitor which roles and associated permissions currently active in IAM. To keep track of this information, he types PRODUCTION in the **Display Name** text box, chooses the red color option, and then chooses **Switch Role**.

4. David can now use the Amazon S3 console to work with the Amazon S3 bucket, or any other resource to which the UpdateApp role has permissions.

5. When done, David can return to their original permissions. To do that, they choose the **PRODUCTION** role display name on the navigation bar and then choose **Back to David @ 111111111111**.
6. The next time that David wants to switch roles and chooses the **Identity** menu in the navigation bar, he sees the PRODUCTION entry still there from last time. He can simply choose that entry to switch roles immediately without reentering the account ID and role name.

Switch roles (AWS CLI)

If David needs to work in the **Production** environment at the command line, he can do so by using the [AWS CLI](#). He runs the `aws sts assume-role` command and passes the role ARN to get temporary security credentials for that role. He then configures those credentials in environment variables so subsequent AWS CLI commands work using the role's permissions. While David uses the role, he cannot use his power-user privileges in the **Development** account, because only one set of permissions can be in effect at a time.

Note that all access keys and tokens are examples only and cannot be used as shown. Replace with the appropriate values from your live environment.

To assume a role

1. David opens a command prompt window, and confirms that the AWS CLI client is working by running the command:

```
aws help
```

Note

David's default environment uses the David user credentials from his default profile that he created with the `aws configure` command. For more information, see [Configuring the AWS Command Line Interface](#) in the *AWS Command Line Interface User Guide*.

2. He begins the switch role process by running the following command to switch to the UpdateApp role in the **Production** account. He received the role ARN from the administrator that created the role. The command requires that you provide a session name as well, you can choose any text you like for that.

```
aws sts assume-role --role-arn "arn:aws:iam::999999999999:role/UpdateApp" --role-session-name "David-ProdUpdate"
```

David then sees the following in the output:

```
{
  "Credentials": {
    "SecretAccessKey": "wJa1rXUtnFEMI/K7MDENG/bPxrFiCYEXAMPLEKEY",
    "SessionToken": "AQoDYXdzEGcaEXAMPLE2gsYULo
+Im5ZEXAMPLEeYjs1M2FUIgIJx9tQqNMBEXAMPLE
CvSRyh0FW7jEXAMPLEW+vE/7s1HRpXviG7b+qYf4nD00EXAMPLEmj4wxS04L/
uZEXAMPLECihzFB51TYLto9dyBgSDy
EXAMPLE9/
g7QRUhZp4bqbEXAMPLENwGPY0j59pFA41NKCIkVgkREXAMPLEj1zxQ7y52gekeVEXAMPLEDiB9ST3Uuysg
sKdEXAMPLE1TVastU1A0SKFEXAMPLEiywCC/Cs8EXAMPLEEpZg0s+6hz4AP4KEXAMPLERbASP
+4eZScEXAMPLEsnf87e
NhyDHq6ikBQ==",
    "Expiration": "2014-12-11T23:08:07Z",
    "AccessKeyId": "AKIAIOSFODNN7EXAMPLE"
  }
}
```

3. David sees the three pieces that they need in the Credentials section of the output.

- AccessKeyId
- SecretAccessKey
- SessionToken

David needs to configure the AWS CLI environment to use these parameters in subsequent calls. For information about the various ways to configure your credentials, see [Configuring the AWS Command Line Interface](#). You cannot use the `aws configure` command because it does not support capturing the session token. However, you can manually enter the information into a configuration file. Because these are temporary credentials with a relatively short expiration time, it is easiest to add them to the environment of your current command line session.

4. To add the three values to the environment, David cuts and pastes the output of the previous step into the following commands. You might want to cut and paste into a simple text editor

to address line wrap issues in the output of the session token. It must be added as a single long string, even though it is shown line wrapped here for clarity.

Note

The following example shows commands given in the Windows environment, where "set" is the command to create an environment variable. On a Linux or macOS computer, you would use the command "export" instead. All other parts of the example are valid in all three environments.

For details on using Tools for Windows Powershell, see [Switching to an IAM role \(Tools for Windows PowerShell\)](#)

```
set AWS_ACCESS_KEY_ID=AKIAIOSFODNN7EXAMPLE
set AWS_SECRET_ACCESS_KEY=wJa1rXUtnFEMI/K7MDENG/bPxRfiCYEXAMPLEKEY
set AWS_SESSION_TOKEN=AQoDYXdzEGcaEXAMPLE2gsYULo
+Im5ZEXAMPLEeYjs1M2FUIgIJx9tQqNMBEXAMPLEcV5
Ryh0FW7jEXAMPLEw+vE/7s1HRpXviG7b+qYf4nD00EXAMPLEEmj4wxS04L/
uZEXAMPLEcihzFB51TYLto9dyBgSDyEXA
MPLEKEY9/
g7QRUhZp4bqbEXAMPLENwGPy0j59pFA41NKCIkVgkREXAMPLEj1zxQ7y52gekeVEXAMPLEDiB9ST3UusKd
EXAMPLE1TVastU1A0SKFEXAMPLEiywCC/Cs8EXAMPLEpZg0s+6hz4AP4KEXAMPLERbASP
+4eZScEXAMPLENhykxiHen
DHq6ikBQ==
```

At this point, any following commands run under the permissions of the role identified by those credentials. In David's case, the UpdateApp role.

5. Run the command to access the resources in the Production account. In this example, David lists the contents of their S3 bucket with the following command.

```
aws s3 ls s3://productionapp
```

Because Amazon S3 bucket names are universally unique, there is no need to specify the account ID that owns the bucket. To access resources for other AWS services, refer to the AWS CLI documentation for that service for the commands and syntax required to reference its resources.

Using AssumeRole (AWS API)

When David needs to make an update to the **Production** account from code, he makes an `AssumeRole` call to assume the `UpdateApp` role. The call returns temporary credentials that he can use to access the `productionapp` bucket in the **Production** account. With those credentials, David can make API calls to update the `productionapp` bucket. However, he cannot make API calls to access any other resources in the **Production** account, even though he has power-user permissions in the **Development** account.

To assume a role

1. David calls `AssumeRole` as part of an application. They must specify the `UpdateApp` ARN: `arn:aws:iam::999999999999:role/UpdateApp`.

The response from the `AssumeRole` call includes the temporary credentials with an `AccessKeyId` and a `SecretAccessKey`. It also includes an `Expiration` time that indicates when the credentials expire and you must request new ones.

2. With the temporary credentials, David makes an `s3:PutObject` call to update the `productionapp` bucket. They would pass the credentials to the API call as the `AuthParams` parameter. Because the temporary role credentials have only read and write access to the `productionapp` bucket, any other actions in the **Production** account are denied.

For a code example (using Python), see [Switching to an IAM role \(AWS API\)](#).

Related resources

- For more information about IAM users and user groups, see [IAM Identities \(users, user groups, and roles\)](#).
- For more information about Amazon S3 buckets, see [Create a Bucket](#) in the *Amazon Simple Storage Service User Guide*.
- To learn whether principals in accounts outside of your zone of trust (trusted organization or account) have access to assume your roles, see [What is IAM Access Analyzer?](#).

Summary

You have completed the cross-account API access tutorial. You created a role to establish trust with another account and defined what actions trusted entities can take. Then, you modified a

user group policy to control which IAM users can access the role. As a result, developers from the **Development** account can make updates to the `productionapp` bucket in the **Production** account by using temporary credentials.

IAM tutorial: Create and attach your first customer managed policy

In this tutorial, you use the AWS Management Console to create a [customer managed policy](#) and then attach that policy to an IAM user in your AWS account. The policy you create allows an IAM test user to sign in directly to the AWS Management Console with read-only permissions.

This workflow has three basic steps:

[Step 1: Create the policy](#)

By default, IAM users do not have permissions to do anything. They cannot access the AWS Management Console or manage the data within unless you allow it. In this step, you create a customer managed policy that allows any attached user to sign in to the console.

[Step 2: Attach the policy](#)

When you attach a policy to a user, the user inherits all of the access permissions that are associated with that policy. In this step, you attach the new policy to a test user.

[Step 3: Test user access](#)

Once the policy is attached, you can sign in as the user and test the policy.

Prerequisites

To perform the steps in this tutorial, you need to already have the following:

- An AWS account that you can sign in to as an IAM user with administrative permissions.
- A test IAM user that has no permissions assigned or group memberships as follows:

User name	Group	Permissions
PolicyUser	<none>	<none>

Step 1: Create the policy

In this step, you create a customer managed policy that allows any attached user to sign in to the AWS Management Console with read-only access to IAM data.

To create the policy for your test user

1. Sign in to the IAM console at <https://console.aws.amazon.com/iam/> with your user that has administrator permissions.
2. In the navigation pane, choose **Policies**.
3. In the content pane, choose **Create policy**.
4. Choose the **JSON** option and copy the text from the following JSON policy document. Paste this text into the **JSON** text box.

```
{
  "Version": "2012-10-17",
  "Statement": [ {
    "Effect": "Allow",
    "Action": [
      "iam:GenerateCredentialReport",
      "iam:Get*",
      "iam:List*"
    ],
    "Resource": "*"
  } ]
}
```

5. Resolve any security warnings, errors, or general warnings generated during [policy validation](#), and then choose **Next**.

Note

You can switch between the **Visual** and **JSON** editor options anytime. However, if you make changes or choose **Review policy** in the **Visual** editor tab, IAM might restructure your policy to optimize it for the visual editor. For more information, see [Policy restructuring](#).

6. On the **Review and create** page, type **UsersReadOnlyAccessToIAMConsole** for the policy name. Review the permissions granted by your policy, and then choose **Create policy** to save your work.

The new policy appears in the list of managed policies and is ready to attach.

Step 2: Attach the policy

Next you attach the policy you just created to your test IAM user.

To attach the policy to your test user

1. In the IAM console, in the navigation pane, choose **Policies**.
2. At the top of the policy list, in the search box, start typing **UsersReadOnlyAccessToIAMConsole** until you can see your policy. Then choose the radio button next to **UsersReadOnlyAccessToIAMConsole** in the list.
3. Choose the **Actions** button, and then choose **Attach**.
4. In IAM entities choose the option to filter for **Users**.
5. In the search box, start typing **PolicyUser** until that user is visible on the list. Then check the box next to that user in the list.
6. Choose **Attach policy**.

You have attached the policy to your IAM test user, which means that user now has read-only access to the IAM console.

Step 3: Test user access

For this tutorial, we recommend that you test access by signing in as the test user so you can see what your users might experience.

To test access by signing in with your test user

1. Sign in to the IAM console at <https://console.aws.amazon.com/iam/> with your `PolicyUser` test user.
2. Browse through the pages of the console and try to create a new user or group. Notice that `PolicyUser` can display data but cannot create or modify existing IAM data.

Related resources

For related information, see the following resources:

- [Managed policies and inline policies](#)
- [Controlling IAM users access to the AWS Management Console](#)

Summary

You've now successfully completed all of the steps necessary to create and attach a customer managed policy. As a result, you are able to sign in to the IAM console with your test account to see what the experience is like for your users.

IAM tutorial: Define permissions to access AWS resources based on tags

Attribute-based access control (ABAC) is an authorization strategy that defines permissions based on attributes. In AWS, these attributes are called *tags*. You can attach tags to IAM resources, including IAM entities (users or roles) and to AWS resources. You can define policies that use tag condition keys to grant permissions to your principals based on their tags. When you use tags to control access to your AWS resources, you allow your teams and resources to grow with fewer changes to AWS policies. ABAC policies are more flexible than traditional AWS policies, which require you to list each individual resource. For more information about ABAC and its advantage over traditional policies, see [What is ABAC for AWS?](#)

Note

You must pass a single value for each session tag. AWS Security Token Service does not support multi-valued session tags.

Topics

- [Tutorial overview](#)
- [Prerequisites](#)
- [Step 1: Create test users](#)
- [Step 2: Create the ABAC policy](#)

- [Step 3: Create roles](#)
- [Step 4: Test creating secrets](#)
- [Step 5: Test viewing secrets](#)
- [Step 6: Test scalability](#)
- [Step 7: Test updating and deleting secrets](#)
- [Summary](#)
- [Related resources](#)
- [IAM tutorial: Use SAML session tags for ABAC](#)

Tutorial overview

This tutorial shows how to create and test a policy that allows IAM roles with principal tags to access resources with matching tags. When a principal makes a request to AWS, their permissions are granted based on whether the principal and resource tags match. This strategy allows individuals to view or edit only the AWS resources required for their jobs.

Scenario

Assume that you're a lead developer at a large company named Example Corporation, and you're an experienced IAM administrator. You're familiar with creating and managing IAM users, roles, and policies. You want to ensure that your development engineers and quality assurance team members can access the resources they need. You also need a strategy that scales as your company grows.

You choose to use AWS resource tags and IAM role principal tags to implement an ABAC strategy for services that support it, beginning with AWS Secrets Manager. To learn which services support authorization based on tags, see [AWS services that work with IAM](#). To learn which tagging condition keys you can use in a policy with each service's actions and resources, see [Actions, Resources, and Condition Keys for AWS Services](#). You can configure your SAML-based or web identity provider to pass [session tags](#) to AWS. When your employees federate into AWS, their attributes are applied to their resulting principal in AWS. You can then use ABAC to allow or deny permissions based on those attributes. To learn how using session tags with a SAML federated identity differs from this tutorial, see [IAM tutorial: Use SAML session tags for ABAC](#).

Your Engineering and Quality Assurance team members are on either the **Pegasus** or **Unicorn** project. You choose the following 3-character project and team tag values:

- `access-project = peg` for the **Pegasus** project
- `access-project = uni` for the **Unicorn** project
- `access-team = eng` for the Engineering team
- `access-team = qas` for the Quality Assurance team

Additionally, you choose to require the `cost-center` cost allocation tag to enable custom AWS billing reports. For more information, see [Using Cost Allocation Tags](#) in the *AWS Billing and Cost Management User Guide*.

Summary of key decisions

- Employees sign in with IAM user credentials and then assume the IAM role for their team and project. If your company has its own identity system, you can set up federation to allow employees to assume a role without IAM users. For more information, see [IAM tutorial: Use SAML session tags for ABAC](#).
- The same policy is attached to all of the roles. Actions are allowed or denied based on tags.
- Employees can create new resources, but only if they attach the same tags to the resource that are applied to their role. This ensures that employees can view the resource after they create it. Administrators are no longer required to update policies with the ARN of new resources.
- Employees can read resources owned by their team, regardless of the project.
- Employees can update and delete resources owned by their own team and project.
- IAM administrators can add a new role for new projects. They can create and tag a new IAM user to allow access to the appropriate role. Administrators are not required to edit a policy to support a new project or team member.

In this tutorial, you will tag each resource, tag your project roles, and add policies to the roles to allow the behavior previously described. The resulting policy allows the roles `Create`, `Read`, `Update`, and `Delete` access to resources that are tagged with the same project and team tags. The policy also allows cross-project `Read` access for resources that are tagged with the same team.

Prerequisites

To perform the steps in this tutorial, you must already have the following:

- An AWS account that you can sign in to as a user with administrative permissions.
- Your 12-digit account ID, which you use to create the roles in step 3.

To find your AWS account ID number using the AWS Management Console, choose **Support** on the navigation bar on the upper right, and then choose **Support Center**. The account number (ID) appears in the navigation pane on the left.

- Experience creating and editing IAM users, roles, and policies in the AWS Management Console. However, if you need help remembering an IAM management process, this tutorial provides links where you can view step-by-step instructions.

Step 1: Create test users

For testing, create four IAM users with permissions to assume roles with the same tags. This makes it easier to add more users to your teams. When you tag the users, they automatically get access to assume the correct role. You don't have to add the users to the trust policy of the role if they work on only one project and team.

1. Create the following customer managed policy named `access-assume-role`. For more information about creating a JSON policy, see [Creating IAM policies](#).

ABAC policy: Assume any ABAC role, but only when the user and role tags match

The following policy allows a user to assume any role in your account with the `access-` name prefix. The role must also be tagged with the same project, team, and cost center tags as the user.

To use this policy, replace the *italicized placeholder text* with your account information.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "TutorialAssumeRole",
      "Effect": "Allow",
```

```

    "Action": "sts:AssumeRole",
    "Resource": "arn:aws:iam::account-ID-without-hyphens:role/access-*",
    "Condition": {
      "StringEquals": {
        "iam:ResourceTag/access-project": "${aws:PrincipalTag/access-
project}",
        "iam:ResourceTag/access-team": "${aws:PrincipalTag/access-
team}",
        "iam:ResourceTag/cost-center": "${aws:PrincipalTag/cost-
center}"
      }
    }
  ]
}

```

To scale this tutorial to a large number of users, you can attach the policy to a group and add each user to the group. For more information, see [Creating IAM user groups](#) and [Adding and removing users in an IAM user group](#).

2. Create the following IAM users, attach the `access-assume-role` permissions policy. Make sure you select **Provide user access to the AWS Management Console**, and then add the following tags. For more information about creating and tagging a new user, see [Creating IAM users \(console\)](#).

ABAC users

User name	User tag key	User tag value
access-Arn timer-peg-eg	access-project	peg
	access-team	eng
	cost-center	987654
access-Mary-peg-qas	access-project	peg
	access-team	qas
	cost-center	987654

User name	User tag key	User tag value
access-Saanvi-uni-eng	access-project	uni
	access-team	eng
	cost-center	123456
access-Carlos-uni-qas	access-project	uni
	access-team	qas
	cost-center	123456

Step 2: Create the ABAC policy

Create the following policy named **access-same-project-team**. You will add this policy to the roles in a later step. For more information about creating a JSON policy, see [Creating IAM policies](#).

For additional policies that you can adapt for this tutorial, see the following pages:

- [Controlling access for IAM principals](#)
- [Amazon EC2: Allows starting or stopping EC2 instances a user has tagged, programmatically and in the console](#)
- [EC2: Start or stop instances based on matching principal and resource tags](#)
- [EC2: Start or stop instances based on tags](#)
- [IAM: Assume roles that have a specific tag](#)

ABAC Policy: Access Secrets Manager Resources Only When the Principal and Resource Tags Match

The following policy allows principals to create, read, edit, and delete resources, but only when those resources are tagged with the same key-value pairs as the principal. When a principal creates a resource, they must add `access-project`, `access-team`, and `cost-center` tags with values that match the principal's tags. The policy also allows adding optional `Name` or `OwnedBy` tags.

```
{
  "Version": "2012-10-17",
```

```

    ],
    "Resource": "*"
  },
  {
    "Sid": "ReadSecretsManagerSameTeam",
    "Effect": "Allow",
    "Action": [
      "secretsmanager:Describe*",
      "secretsmanager:Get*",

```

```
        "secretsmanager:List*"
    ],
    "Resource": "*",
    "Condition": {
        "StringEquals": {
            "aws:ResourceTag/access-team": "${aws:PrincipalTag/access-team}"
        }
    }
},
{
    "Sid": "DenyUntagSecretsManagerReservedTags",
    "Effect": "Deny",
    "Action": "secretsmanager:UntagResource",
    "Resource": "*",
    "Condition": {
        "ForAnyValue:StringLike": {
            "aws:TagKeys": "access-*"
        }
    }
},
{
    "Sid": "DenyPermissionsManagement",
    "Effect": "Deny",
    "Action": "secretsmanager:*Policy",
    "Resource": "*"
}
]
}
```

What does this policy do?

- The `AllActionsSecretsManagerSameProjectSameTeam` statement allows all of this service's actions on all related resources, but only if the resource tags match the principal tags. By adding `"Action": "secretsmanager:*"` to the policy, the policy grows as Secrets Manager grows. If Secrets Manager adds a new API operation, you are not required to add that action to the statement. The statement implements ABAC using three condition blocks. The request is allowed only if all three blocks return true.
- The first condition block of this statement returns true if the specified tag keys are present on the resource, and their values match the principal's tags. This block returns false for mismatched tags, or for actions that don't support resource tagging. To learn which actions are not allowed by this block, see [Actions, Resources, and Condition Keys for AWS Secrets](#)

[Manager](#). That page shows that actions performed on the [Secret resource type](#) support the `secretsmanager:ResourceTag/tag-key` condition key. Some [Secrets Manager actions](#) don't support that resource type, including `GetRandomPassword` and `ListSecrets`. You must create additional statements to allow those actions.

- The second condition block returns true if every tag key passed in the request is included in the specified list. This is done using `ForAllValues` with the `StringEquals` condition operator. If no keys or a subset of the set of keys is passed, then the condition returns true. This allows `Get*` operations that do not allow passing tags in the request. If the requester includes a tag key that is not in the list, the condition returns false. Every tag key that is passed in the request must match a member of this list. For more information, see [Multivalued context keys](#).
- The third condition block returns true if the request supports passing tags, if all three of the tags are present, and if they match the principal tag values. This block also returns true if the request does not support passing tags. This is thanks to `...IfExists` in the condition operator. The block returns false if there is no tag passed during an action that supports it, or if the tag keys and values don't match.
- The `AllResourcesSecretsManagerNoTags` statement allows the `GetRandomPassword` and `ListSecrets` actions that are not allowed by the first statement.
- The `ReadSecretsManagerSameTeam` statement allows read-only operations if the principal is tagged with the same access-team tag as the resource. This is allowed regardless of the project or cost-center tag.
- The `DenyUntagSecretsManagerReservedTags` statement denies requests to remove tags with keys that begin with "access-" from Secrets Manager. These tags are used to control access to resources, therefore removing tags might remove permissions.
- The `DenyPermissionsManagement` statement denies access to create, edit, or delete Secrets Manager resource-based policies. These policies could be used to change the permissions of the secret.

Important

This policy uses a strategy to allow all actions for a service, but explicitly deny permissions-altering actions. Denying an action overrides any other policy that allows the principal to perform that action. This can have unintended results. As a best practice, use explicit denies

only when there is no circumstance that should allow that action. Otherwise, allow a list of individual actions, and the unwanted actions are denied by default.

Step 3: Create roles

Create the following IAM roles and attach the **access-same-project-team** policy that you created in the previous step. For more information about creating IAM roles, see [Creating a role to delegate permissions to an IAM user](#). If you choose to use federation instead of IAM users and roles, see [IAM tutorial: Use SAML session tags for ABAC](#).

ABAC roles

Job function	Role name	Role tags	Role description
Project Pegasus Engineering	access-peg-engineering	access-project = peg access-team = eng cost-center = 987654	Allows engineers to read all engineering resources and create and manage Pegasus engineering resources.
Project Pegasus Quality Assurance	access-peg-quality-assurance	access-project = peg access-team = qas cost-center = 987654	Allows the QA team to read all QA resources and create and manage all Pegasus QA resources.
Project Unicorn Engineering	access-uni-engineering	access-project = uni	Allows engineers to read all engineering resources and

Job function	Role name	Role tags	Role description
		access-te am = eng cost- center = 123456	create and manage Unicorn engineering resources.
Project Unicorn Quality Assurance	access-uni-quality-assurance	access-pr oject = uni access-te am = qas cost- center = 123456	Allows the QA team to read all QA resources and create and manage all Unicorn QA resources.

Step 4: Test creating secrets

The permissions policy attached to the roles allows the employees to create secrets. This is allowed only if the secret is tagged with their project, team, and cost center. Confirm that your permissions are working as expected by signing in as your users, assuming the correct role, and testing activity in Secrets Manager.

To test creating a secret with and without the required tags

1. In your main browser window, remain signed in as the administrator user so that you can review users, roles, and policies in IAM. Use a browser incognito window or separate browser for your testing. There, sign in as the access-Arnav-peg-eng IAM user and open the Secrets Manager console at <https://console.aws.amazon.com/secretsmanager/>.
2. Attempt to switch to the access-uni-engineering role.

This operation fails because the access-project and cost-center tag values do not match for the access-Arnav-peg-eng user and access-uni-engineering role.

For more information about switching roles in the AWS Management Console, see [Switching to a role \(console\)](#)

3. Switch to the `access-peg-engineering` role.
4. Store a new secret using the following information. To learn how to store a secret, see [Creating a Basic Secret](#) in the *AWS Secrets Manager User Guide*.

Important

Secrets Manager displays alerts that you don't have permissions for additional AWS services that work with Secrets Manager. For example, to create credentials for an Amazon RDS database, you must have permission to describe RDS instances, RDS clusters, and Amazon Redshift clusters. You can ignore these alerts since you aren't using these specific AWS services in this tutorial.

1. In the **Select secret type** section, choose **Other type of secrets**. In the two text boxes, enter `test-access-key` and `test-access-secret`.
2. Enter `test-access-peg-eng` for the **Secret name** field.
3. Add different tag combinations from the following table and view the expected behavior.
4. Choose **Store** to attempt to create the secret. When the storage fails, return to the previous Secrets Manager console pages and use the next tag set from the following table. The last tag set is allowed and will successfully create the secret.

ABAC tag combinations for `test-access-peg-eng` role

access-project Tag value	access-team Tag value	cost-center Tag value	Additional tags	Expected behavior
(none)	(none)	(none)	(none)	Denied because the <code>access-project</code> tag value does not match the role's value of <code>peg</code> .

access-project Tag value	access-team Tag value	cost-center Tag value	Additional tags	Expected behavior
uni	eng	987654	(none)	Denied because the access-project tag value does not match the role's value of peg.
peg	qas	987654	(none)	Denied because the access-team tag value does not match the role's value of eng.
peg	eng	123456	(none)	Denied because the cost-center tag value does not match the role's value of 987654.
peg	eng	987654	owner = Jane	Denied because the additional tag owner is not allowed by the policy, even though all three required tags are present and their values match the role's values.
peg	eng	987654	Name = Jane	Allowed because all three required tags are present and their values match the role's values. You are also allowed to include the optional Name tag.

5. Sign out and repeat the first three steps of this procedure for each of the following roles and tag values. In the fourth step in this procedure, test any set of missing tags, optional tags, disallowed tags, and invalid tag values that you choose. Then use the required tags to create a secret with the following tags and name.

ABAC roles and tags

User name	Role name	Secret name	Secret tags
access-Mary-peg-qas	access-peg-quality-assurance	test-access-peg-qas	access-project = peg access-team = qas cost-center = 987654
access-Saanvi-uni-eng	access-uni-engineering	test-access-uni-eng	access-project = uni access-team = eng cost-center = 123456
access-Carlos-uni-qas	access-uni-quality-assurance	test-access-uni-qas	access-project = uni access-team = qas cost-center = 123456

Step 5: Test viewing secrets

The policy that you attached to each role allows the employees to view any secrets tagged with their team name, regardless of their project. Confirm that your permissions are working as expected by testing your roles in Secrets Manager.

To test viewing a secret with and without the required tags

1. Sign in as one of the following IAM users:

- access-Arn timer-peg-eng
- access-Mary-peg-qas
- access-Saanvi-uni-eng
- access-Carlos-uni-qas

2. Switch to the matching role:

- access-peg-engineering
- access-peg-quality-assurance
- access-uni-engineering
- access-uni-quality-assurance

For more information about switching roles in the AWS Management Console, see [Switching to a role \(console\)](#).

3. In the navigation pane on the left, choose the menu icon to expand the menu and then choose **Secrets**.
4. You should see all four secrets in the table, regardless of your current role. This is expected because the policy named `access-same-project-team` allows the `secretsmanager:ListSecrets` action for all resources.
5. Choose the name of one of the secrets.
6. On the details page for the secret, your role's tags determine whether you can view the page content. Compare the name of your role to the name of your secret. If they share the same team name, then the `access-team` tags match. If they don't match, then access is denied.

ABAC secret viewing behavior for each role

Role name	Secret name	Expected behavior
access-peg-engineering	test-access-peg-eng	Allowed
	test-access-peg-qas	Denied
	test-access-uni-eng	Allowed

Role name	Secret name	Expected behavior
access-peg-quality-assurance	test-access-uni-qas	Denied
	test-access-peg-eng	Denied
	test-access-peg-qas	Allowed
	test-access-uni-eng	Denied
access-uni-engineering	test-access-uni-qas	Allowed
	test-access-peg-eng	Allowed
	test-access-peg-qas	Denied
	test-access-uni-eng	Allowed
access-uni-quality-assurance	test-access-uni-qas	Denied
	test-access-peg-eng	Denied
	test-access-peg-qas	Allowed
	test-access-uni-eng	Denied
	test-access-uni-qas	Allowed
	test-access-peg-eng	Denied
	test-access-peg-qas	Allowed
	test-access-uni-eng	Denied
	test-access-uni-qas	Allowed
	test-access-peg-eng	Denied
	test-access-peg-qas	Allowed
	test-access-uni-eng	Denied

- From the breadcrumbs at the top of the page, choose **Secrets** to return to the list of secrets. Repeat the steps in this procedure using different roles to test whether you can view each of the secrets.

Step 6: Test scalability

An important reason for using attribute-based access control (ABAC) over role-based access control (RBAC) is scalability. As your company adds new projects, teams, or people to AWS, you don't need to update your ABAC-driven policies. For example, assume that Example Company is funding a new project, code named **Centaur**. An engineer named Saanvi Sarkar will be the lead engineer for **Centaur** while continuing to work on the **Unicorn** project. Saanvi will also review work for the **Peg**

project. There are also several newly hired engineers, including Nikhil Jayashankar, who will work on only the **Centaur** project.

To add the new project to AWS

1. Sign in as the IAM administrator user and open the IAM console at <https://console.aws.amazon.com/iam/>.
2. In the navigation pane on the left, choose **Roles** and add an IAM role named `access-cen-engineering`. Attach the **access-same-project-team** permissions policy to the role and add the following role tags:
 - `access-project = cen`
 - `access-team = eng`
 - `cost-center = 101010`
3. In the navigation pane on the left, choose **Users**.
4. Add a new user named `access-Nikhil-cen-eng`, attach the policy named `access-assume-role`, and add the following user tags:
 - `access-project = cen`
 - `access-team = eng`
 - `cost-center = 101010`
5. Use the procedures in [Step 4: Test creating secrets](#) and [Step 5: Test viewing secrets](#). In another browser window, test that Nikhil can create only **Centaur** engineering secrets, and that he can view all engineering secrets.
6. In the main browser window where you signed in as the administrator, choose the user `access-Saanvi-uni-eng`.
7. On the **Permissions** tab, remove the **access-assume-role** permissions policy.
8. Add the following inline policy named `access-assume-specific-roles`. For more information about adding an inline policy to a user, see [To embed an inline policy for a user or role \(console\)](#).

ABAC policy: Assume only specific roles

This policy allows Saanvi to assume the engineering roles for the **Pegasus** and **Centaur** projects. It is necessary to create this custom policy because IAM does not support multivalued tags. You can't tag Saanvi's user with `access-project = peg` and `access-project = cen`.

Additionally, the AWS authorization model can't match both values. For more information, see [Rules for tagging in IAM and AWS STS](#). Instead, you must manually specify the two roles that she can assume.

To use this policy, replace the *italicized placeholder text* with your account information.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "TutorialAssumeSpecificRoles",
      "Effect": "Allow",
      "Action": "sts:AssumeRole",
      "Resource": [
        "arn:aws:iam::account-ID-without-hyphens:role/access-peg-
engineering",
        "arn:aws:iam::account-ID-without-hyphens:role/access-cen-
engineering"
      ]
    }
  ]
}
```

9. Use the procedures in [Step 4: Test creating secrets](#) and [Step 5: Test viewing secrets](#). In another browser window, confirm that Saanvi can assume both roles. Check that she can create secrets for only her project, team, and cost center, depending on the role's tags. Also confirm that she can view details about any secrets owned by the engineering team, including the ones that she just created.

Step 7: Test updating and deleting secrets

The `access-same-project-team` policy that is attached to the roles allows the employees to update and delete any secrets tagged with their project, team, and cost center. Confirm that your permissions are working as expected by testing your roles in Secrets Manager.

To test updating and deleting a secret with and without the required tags

1. Sign in as one of the following IAM users:
 - `access-Arn timer-peg-eng`

- access-Mary-peg-qas
 - access-Saanvi-uni-eng
 - access-Carlos-uni-qas
 - access-Nikhil-cen-eng
2. Switch to the matching role:
- access-peg-engineering
 - access-peg-quality-assurance
 - access-uni-engineering
 - access-peg-quality-assurance
 - access-cen-engineering

For more information about switching roles in the AWS Management Console, see [Switching to a role \(console\)](#).

3. For each role, try to update the secret description and then try to delete the following secrets. For more information, see [Modifying a Secret](#) and [Deleting and Restoring a Secret](#) in the *AWS Secrets Manager User Guide*.

ABAC secret updating and deleting behavior for each role

Role name	Secret name	Expected behavior
access-peg-engineering	test-access-peg-eng	Allowed
	test-access-uni-eng	Denied
	test-access-uni-qas	Denied
access-peg-quality-assurance	test-access-peg-qas	Allowed
	test-access-uni-eng	Denied
access-uni-engineering	test-access-uni-eng	Allowed
	test-access-uni-qas	Denied

Role name	Secret name	Expected behavior
access-peg-quality-assurance	test-access-uni-qas	Allowed

Summary

You've now successfully completed all of the steps necessary to use tags for attribute-based access control (ABAC). You've learned how to define a tagging strategy. You applied that strategy to your principals and resources. You created and applied a policy that enforces the strategy for Secrets Manager. You also learned that ABAC scales easily when you add new projects and team members. As a result, you are able to sign in to the IAM console with your test roles and experience how to use tags for ABAC in AWS.

Note

You added policies that allow actions only under specific conditions. If you apply a different policy to your users or roles that has broader permissions, then the actions might not be limited to require tagging. For example, if you give a user full administrative permissions using the `AdministratorAccess` AWS managed policy, then these policies don't restrict that access. For more information about how permissions are determined when multiple policies are involved, see [Determining whether a request is allowed or denied within an account](#).

- [IAM tutorial: Use SAML session tags for ABAC](#)

To learn how to monitor the tags in your account, see [Monitor tag changes on AWS resources with serverless workflows and Amazon CloudWatch Events](#).

IAM tutorial: Use SAML session tags for ABAC

Attribute-based access control (ABAC) is an authorization strategy that defines permissions based on attributes. In AWS, these attributes are called tags. You can attach tags to IAM resources, including IAM entities (users or roles), and to AWS resources. When the entities are used to make requests to AWS, they become principals and those principals include tags.

You can also pass [session tags](#) when you assume a role or federate a user. You can then define policies that use tag condition keys to grant permissions to your principals based on their tags. When you use tags to control access to your AWS resources, you allow your teams and resources to grow with fewer changes to AWS policies. ABAC policies are more flexible than traditional AWS policies, which require you to list each individual resource. For more information about ABAC and its advantage over traditional policies, see [What is ABAC for AWS?](#)

If your company uses a SAML-based identity provider (IdP) to manage corporate user identities, you can use SAML attributes for fine-grained access control in AWS. Attributes can include cost center identifiers, user email addresses, department classifications, and project assignments. When you pass these attributes as session tags, you can then control access to AWS based on these session tags.

To complete the [ABAC tutorial](#) by passing SAML attributes to your session principal, complete the tasks in [IAM tutorial: Define permissions to access AWS resources based on tags](#), with the changes that are included in this topic.

Prerequisites

To perform the steps to use SAML session tags for ABAC, you must already have the following:

- Access to a SAML-based IdP where you can create test users with specific attributes.
- The ability to sign in as a user with administrative permissions.
- Experience creating and editing IAM users, roles, and policies in the AWS Management Console. However, if you need help remembering an IAM management process, the ABAC tutorial provides links where you can view step-by-step instructions.

- Experience setting up a SAML-based IdP in IAM. To view more details and links to detailed IAM documentation, see [Passing session tags using AssumeRoleWithSAML](#).

Step 1: Create test users

Skip the instructions in [Step 1: Create test users](#). Because your identities are defined in your provider, it's not necessary for you to add IAM users for your employees.

Step 2: Create the ABAC policy

Follow the instructions in [Step 2: Create the ABAC policy](#) to create the specified managed policy in IAM.

Step 3: Create and configure the SAML role

When you use the ABAC tutorial for SAML, you must perform additional steps to create the role, configure the SAML IdP, and enable AWS Management Console access. For more information, see [Step 3: Create roles](#).

Step 3A: Create the SAML role

Create a single role that trusts your SAML identity provider and the `test-session-tags` user that you created in step 1. The ABAC tutorial uses separate roles with different role tags. Because you are passing session tags from your SAML IdP, you need only one role. To learn how to create a SAML-based role, see [Create a role for SAML 2.0 federation \(console\)](#).

Name the role `access-session-tags`. Attach the `access-same-project-team` permissions policy to the role. Edit the role trust policy to use the following policy. For detailed instructions on how to edit the trust relationship of a role, see [Modifying a role \(console\)](#).

The following role trust policy allows your SAML identity provider and the `test-session-tags` user to assume the role. When they assume the role, they must pass the three specified session tags. The `sts:TagSession` action is required to allow passing session tags.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "AllowSamlIdentityAssumeRole",
```

```

    "Effect": "Allow",
    "Action": [
      "sts:AssumeRoleWithSAML",
      "sts:TagSession"
    ],
    "Principal": {"Federated": "arn:aws:iam::123456789012:saml-
provider/ExampleCorpProvider"},
    "Condition": {
      "StringLike": {
        "aws:RequestTag/cost-center": "*",
        "aws:RequestTag/access-project": "*",
        "aws:RequestTag/access-team": [
          "eng",
          "qas"
        ]
      },
      "StringEquals": {"SAML:aud": "https://signin.aws.amazon.com/saml"}
    }
  }
}
]
}

```

The `AllowSamlIdentityAssumeRole` statement allows members of the Engineering and Quality Assurance teams to assume this role when they federate into AWS from the Example Corporation IdP. The `ExampleCorpProvider` SAML provider is defined in IAM. The administrator has already set up the SAML assertion to pass the three required session tags. The assertion can pass additional tags, but these three must be present. The identity's attributes can have any value for the `cost-center` and `access-project` tags. However, the `access-team` attribute value must match `eng` or `qas` to indicate that the identity is on the Engineering or Quality Assurance team.

Step 3B: Configure the SAML IdP

Configure your SAML IdP to pass the `cost-center`, `access-project`, and `access-team` attributes as session tags. For more information, see [Passing session tags using AssumeRoleWithSAML](#).

To pass these attributes as session tags, include the following elements in your SAML assertion.

```

<Attribute Name="https://aws.amazon.com/SAML/Attributes/PrincipalTag:cost-center">
  <AttributeValue>987654</AttributeValue>
</Attribute>
<Attribute Name="https://aws.amazon.com/SAML/Attributes/PrincipalTag:access-project">

```

```
<AttributeValue>peg</AttributeValue>
</Attribute>
<Attribute Name="https://aws.amazon.com/SAML/Attributes/PrincipalTag:access-team">
  <AttributeValue>eng</AttributeValue>
</Attribute>
```

Step 3C: Enable console access

Enable console access for your federated SAML users. For more information, see [Enabling SAML 2.0 federated users to access the AWS Management Console](#).

Step 4: Test creating secrets

Federate into the AWS Management Console using the `access-session-tags` role. For more information, see [Enabling SAML 2.0 federated users to access the AWS Management Console](#). Then follow the instructions in [Step 4: Test creating secrets](#) to create secrets. Use different SAML identities with attributes to match the tags that are indicated in the ABAC tutorial. For more information, see [Step 4: Test creating secrets](#).

Step 5: Test viewing secrets

Follow the instructions in [Step 5: Test viewing secrets](#) to view the secrets that you created in the previous step. Use different SAML identities with attributes to match the tags that are indicated in the ABAC tutorial.

Step 6: Test scalability

Follow the instructions in [Step 6: Test scalability](#) to test scalability. Do this by adding a new identity in your SAML-based IdP with the following attributes:

- `cost-center` = 101010
- `access-project` = cen
- `access-team` = eng

Step 7: Test updating and deleting secrets

Follow the instructions in [Step 7: Test updating and deleting secrets](#) to update and delete secrets. Use different SAML identities with attributes to match the tags that are indicated in the ABAC tutorial.

⚠ Important

Delete all of the secrets that you created to avoid billing charges. For details about pricing in Secrets Manager, see [AWS Secrets Manager Pricing](#).

Summary

You've now successfully completed all of the steps necessary to use SAML session tags and resource tags for permissions management.

📘 Note

You added policies that allow actions only under specific conditions. If you apply a different policy to your users or roles that has broader permissions, then the actions might not be limited to require tagging. For example, if you give a user full administrative permissions using the `AdministratorAccess` AWS managed policy, then these policies don't restrict that access. For more information about how permissions are determined when multiple policies are involved, see [Determining whether a request is allowed or denied within an account](#).

IAM tutorial: Permit users to manage their credentials and MFA settings

You can permit your users to manage their own multi-factor authentication (MFA) devices and credentials on the **Security credentials** page. You can use the AWS Management Console to configure credentials (access keys, passwords, signing certificates, and SSH public keys), delete or deactivate credentials that are not needed, and enable MFA devices for your users. This is useful for a small number of users, but that task could quickly become time consuming as the number of users grows. This tutorial shows you how to enable these best practices without burdening your administrators.

This tutorial shows how to allow users to access AWS services, but **only** when they sign in with MFA. If they are not signed in with an MFA device, then users cannot access other services.

This workflow has three basic steps.

Step 1: Create a policy to enforce MFA sign-in

Create a customer managed policy that prohibits all actions *except* the few IAM actions. These exceptions allow a user to change their own credentials and manage their MFA devices on the **Security credentials** page. For more information about accessing that page, see [How IAM users change their own password \(console\)](#).

Step 2: Attach policies to your test user group

Create a user group whose members have full access to all Amazon EC2 actions if they sign in with MFA. To create such a user group, you attach both the AWS managed policy called AmazonEC2FullAccess and the customer managed policy you created in the first step.

Step 3: Test your user's access

Sign in as the test user to verify that access to Amazon EC2 is blocked *until* the user creates an MFA device. The user can then sign in using that device.

Prerequisites

To perform the steps in this tutorial, you must already have the following:

- An AWS account that you can sign in to as an IAM user with administrative permissions.
- Your account ID number, which you type into the policy in Step 1.

To find your account ID number, on the navigation bar at the top of the page, choose **Support** and then choose **Support Center**. You can find your account ID under this page's **Support** menu.

- A [virtual \(software-based\) MFA device](#), [FIDO security key](#), or [hardware-based MFA device](#).
- A test IAM user who is a member of a user group as follows:

<i>Create user</i>		<i>Create and configure user group account</i>		
User name	Other instructions	User group name	Add user as a member	Other instructions
MFAUser	Choose only the option for Enable console access	EC2MFA	MFAUser	Do NOT attach any policies or otherwise

Create user		Create and configure user group account		
User name	Other instructions	User group name	Add user as a member	Other instructions
	– <i>optional</i> , and assign a password.			grant permissions to this user group.

Step 1: Create a policy to enforce MFA sign-in

You begin by creating an IAM customer managed policy that denies all permissions except those required for IAM users to manage their own credentials and MFA devices.

1. Sign in to the AWS Management Console as a user with administrator credentials. To adhere to IAM best practices, don't sign in with your AWS account root user credentials.

Important

IAM [best practices](#) recommend that you require human users to use federation with an identity provider to access AWS using temporary credentials instead of using IAM users with long-term credentials.

2. Open the IAM console at <https://console.aws.amazon.com/iam/>.
3. In the navigation pane, choose **Policies**, and then choose **Create policy**.
4. Choose the **JSON** tab and copy the text from the following JSON policy document: [AWS: Allows MFA-authenticated IAM users to manage their own credentials on the Security credentials page](#).
5. Paste the policy text into the **JSON** text box. Resolve any security warnings, errors, or general warnings generated during policy validation, and then choose **Next**.

Note

You can switch between the **Visual editor** and **JSON** options anytime. However, the policy above includes the `NotAction` element, which is not supported in the visual

editor. For this policy, you will see a notification on the **Visual editor** tab. Return to **JSON** to continue working with this policy.

This example policy does not allow users to reset a password while signing in to the AWS Management Console for the first time. We recommend that you do not grant permissions to new users until after they sign in and reset their password.

6. On the **Review and create** page, type **Force_MFA** for the policy name. For the policy description, type **This policy allows users to manage their own passwords and MFA devices but nothing else unless they authenticate with MFA**. In the **Tags** area, you can optionally add tag key-value pairs to the customer managed policy. Review the permissions granted by your policy, and then choose **Create policy** to save your work.

The new policy appears in the list of managed policies and is ready to attach.

Step 2: Attach policies to your test user group

Next you attach two policies to the test IAM user group, which will be used to grant the MFA-protected permissions.

1. In the navigation pane, choose **User groups**.
2. In the search box, type **EC2MFA**, and then choose the group name (not the check box) in the list.
3. Choose the **Permissions** tab, choose **Add permissions**, and then choose **Attach policies**.
4. On the **Attach permission policies to EC2MFA group** page, in the search box, type **EC2Full**. Then select the check box next to **AmazonEC2FullAccess** in the list. Don't save your changes yet.
5. In the search box, type **Force**, and then select the check box next to **Force_MFA** in the list.
6. Choose **Attach policies**.

Step 3: Test your user's access

In this part of the tutorial, you sign in as the test user and verify that the policy works as intended.

1. Sign in to your AWS account as **MFAUser** with the password you assigned in the previous section. Use the URL: `https://<alias or account ID number>.signin.aws.amazon.com/console`

2. Choose **EC2** to open the Amazon EC2 console and verify that the user has no permissions to do anything.
3. In the navigation bar on the upper right, choose the MFAUser user name, and then choose **Security credentials**.

4. Now add an MFA device. In the **Multi-factor Authentication (MFA)** section, choose **Assign MFA device**.

Note

You might receive an error that you are not authorized to perform `iam:DeleteVirtualMFADevice`. This could happen if someone previously began assigning a virtual MFA device to this user and cancelled the process. To continue, you or another administrator must delete the user's existing unassigned virtual MFA device. For more information, see [I am not authorized to perform: iam:DeleteVirtualMFADevice](#).

5. For this tutorial, we use a virtual (software-based) MFA device, such as the Google Authenticator app on a mobile phone. Choose **Authenticator app**, and then click **Next**.

IAM generates and displays configuration information for the virtual MFA device, including a QR code graphic. The graphic is a representation of the secret configuration key that is available for manual entry on devices that do not support QR codes.

6. Open your virtual MFA app. (For a list of apps that you can use for hosting virtual MFA devices, see [Virtual MFA Applications](#).) If the virtual MFA app supports multiple accounts (multiple virtual MFA devices), choose the option to create a new account (a new virtual MFA device).
7. Determine whether the MFA app supports QR codes, and then do one of the following:
 - From the wizard, choose **Show QR code**. Then use the app to scan the QR code. For example, you might choose the camera icon or choose an option similar to **Scan code**, and then use the device's camera to scan the code.
 - In the **Set up device** wizard, choose **Show secret key**, and then type the secret key into your MFA app.

When you are finished, the virtual MFA device starts generating one-time passwords.

8. In the **Set up device** wizard, in the **Enter the code from your authenticator app** box, type the one-time password that currently appears in the virtual MFA device. Choose **Register MFA**.

Important

Submit your request immediately after generating the code. If you generate the codes and then wait too long to submit the request, the MFA device is successfully associated with the user. However, the MFA device is out of sync. This happens because time-based one-time passwords (TOTP) expire after a short period of time. If this happens, you can [resync the device](#).

The virtual MFA device is now ready to use with AWS.

9. Sign out of the console and then sign in as **MFAUser** again. This time AWS prompts you for an MFA code from your phone. When you get it, type the code in the box and then choose **Submit**.
10. Choose **EC2** to open the Amazon EC2 console again. Note that this time you can see all the information and perform any actions you want. If you go to any other console as this user, you see access denied messages. The reason is that the policies in this tutorial grant access only to Amazon EC2.

- [Enabling MFA devices for users in AWS](#)
- [Using MFA devices with your IAM sign-in page](#)

IAM Identities (users, user groups, and roles)

Tip

Having trouble signing in to AWS? Make sure that you're on the correct sign-in page.

- To sign in as the AWS account root user (account owner), use the credentials that you set up when you created the AWS account.
- To sign in as an IAM user, use the credentials your account administrator gave you to sign in to AWS.
- To sign in with your IAM Identity Center user, use the sign-in URL that was sent to your email address when you created the IAM Identity Center user.

For help signing in using an IAM Identity Center user, see [Signing in to the AWS access portal](#) in the *AWS Sign-In User Guide*.

For sign-in tutorials, see [How to sign in to AWS](#) in the *AWS Sign-In User Guide*.

Note

If you need to request support, do not use the **Feedback** link on this page. Feedback you enter is received by the AWS Documentation team, not AWS Support. Instead, choose the **Contact Us** link at the top of this page. There, you'll find links to resources to help you get the support that you need.

The AWS account root user or an administrative user for the account can create *IAM identities*. An IAM identity provides access to an AWS account. An *IAM user group* is a collection of IAM users managed as a unit. An IAM identity represents a human user or programmatic workload, and can be authenticated and then authorized to perform actions in AWS. Each IAM identity can be associated with one or more *policies*. Policies determine what actions a user, role, or member of a user group can perform, on which AWS resources, and under what conditions.

AWS account root user

When you first create an AWS account, you begin with one sign-in identity that has complete access to all AWS services and resources in the account. This identity is called the AWS account *root user* and is accessed by signing in with the email address and password that you used to create the account.

Important

We strongly recommend that you don't use the root user for your everyday tasks. Safeguard your root user credentials and use them to perform the tasks that only the root user can perform. For the complete list of tasks that require you to sign in as the root user, see [Tasks that require root user credentials](#).

IAM users

An *IAM user* is an identity within your AWS account that has specific permissions for a single person or application. Where possible, [best practices](#) recommend relying on temporary credentials instead of creating IAM users who have long-term credentials such as passwords and access keys. Before creating access keys, review the [alternatives to long-term access keys](#). If you have specific use cases that require access keys, we recommend that you update access keys when needed. For more information, see [Update access keys when needed for use cases that require long-term credentials](#). To add IAM users to your AWS account, see [Creating an IAM user in your AWS account](#).

Note

As a security [best practice](#), we recommend that you provide access to your resources through identity federation instead of creating IAM users. For information about specific situations where an IAM user is required, see [When to create an IAM user \(instead of a role\)](#).

IAM user groups

An *IAM group* is an identity that specifies a collection of IAM users. You can't use a group to sign-in. You can use groups to specify permissions for multiple users at a time. Groups make permissions easier to manage for large sets of users. For example, you could have a group named *IAMPublishers* and give that group the types of permissions that publishing workloads typically need.

IAM roles

An [IAM role](#) is an identity within your AWS account that has specific permissions. It's similar to an IAM user, but isn't associated with a specific person. You can temporarily assume an IAM role in the AWS Management Console by [switching roles](#). You can assume a role by calling an AWS CLI or AWS API operation or by using a custom URL. For more information about methods for using roles, see [Using IAM roles](#).

IAM roles with temporary credentials are used in the following situations:

- **Federated user access** – To assign permissions to a federated identity, you create a role and define permissions for the role. When a federated identity authenticates, the identity is associated with the role and is granted the permissions that are defined by the role. For information about roles for federation, see [Creating a role for a third-party Identity Provider](#) in the *IAM User Guide*. If you use IAM Identity Center, you configure a permission set. To control what your identities can access after they authenticate, IAM Identity Center correlates the permission set to a role in IAM. For information about permissions sets, see [Permission sets](#) in the *AWS IAM Identity Center User Guide*.
- **Temporary IAM user permissions** – An IAM user or role can assume an IAM role to temporarily take on different permissions for a specific task.
- **Cross-account access** – You can use an IAM role to allow someone (a trusted principal) in a different account to access resources in your account. Roles are the primary way to grant cross-account access. However, with some AWS services, you can attach a policy directly to a resource (instead of using a role as a proxy). To learn the difference between roles and resource-based policies for cross-account access, see [Cross account resource access in IAM](#).
- **Cross-service access** – Some AWS services use features in other AWS services. For example, when you make a call in a service, it's common for that service to run applications in Amazon EC2 or store objects in Amazon S3. A service might do this using the calling principal's permissions, using a service role, or using a service-linked role.
- **Principal permissions** – When you use an IAM user or role to perform actions in AWS, you are considered a principal. When you use some services, you might perform an action that then initiates another action in a different service. FAS uses the permissions of the principal calling an AWS service, combined with the requesting AWS service to make requests to downstream services. FAS requests are only made when a service receives a request that requires interactions with other AWS services or resources to complete. In this case, you must

have permissions to perform both actions. For policy details when making FAS requests, see [Forward access sessions](#).

- **Service role** – A service role is an [IAM role](#) that a service assumes to perform actions on your behalf. An IAM administrator can create, modify, and delete a service role from within IAM. For more information, see [Creating a role to delegate permissions to an AWS service](#) in the *IAM User Guide*.
- **Service-linked role** – A service-linked role is a type of service role that is linked to an AWS service. The service can assume the role to perform an action on your behalf. Service-linked roles appear in your AWS account and are owned by the service. An IAM administrator can view, but not edit the permissions for service-linked roles.
- **Applications running on Amazon EC2** – You can use an IAM role to manage temporary credentials for applications that are running on an EC2 instance and making AWS CLI or AWS API requests. This is preferable to storing access keys within the EC2 instance. To assign an AWS role to an EC2 instance and make it available to all of its applications, you create an instance profile that is attached to the instance. An instance profile contains the role and enables programs that are running on the EC2 instance to get temporary credentials. For more information, see [Using an IAM role to grant permissions to applications running on Amazon EC2 instances](#) in the *IAM User Guide*.

[Temporary credentials in IAM](#)

As a [best practice](#), use temporary credentials with both human users and workloads. Temporary credentials are primarily used with IAM roles, but there are also other uses. You can request temporary credentials that have a more restricted set of permissions than your standard IAM user. This prevents you from accidentally performing tasks that aren't permitted by the more restricted credentials. A benefit of temporary credentials is that they expire automatically after a set period of time. You have control over the duration that the credentials are valid.

When to use IAM Identity Center users?

We recommend that all human users use IAM Identity Center to access AWS resources. IAM Identity Center enables significant improvements over accessing AWS resources as an IAM user. IAM Identity Center provides:

- A central set of identities and assignments
- Access to accounts across an entire AWS Organization

- Connection to your existing identity provider
- Temporary credentials
- Multi-factor authentication (MFA)
- Self-service MFA configuration for end-users
- Administrative enforcement of MFA usage
- Single sign-on to all AWS account entitlements

For more information, see [What is IAM Identity Center](#) in the *AWS IAM Identity Center User Guide*.

When to create an IAM user (instead of a role)

We recommend you only use IAM users for use cases not supported by federated users. Some of the use cases include the following:

- **Workloads that cannot use IAM roles** – You might run a workload from a location that needs to access AWS. In some situations, you can't use IAM roles to provide temporary credentials, such as for WordPress plugins. In these situations, use IAM user long-term access keys for that workload to authenticate to AWS.
- **Third-party AWS clients** – If you are using tools that don't support access with IAM Identity Center, such as third-party AWS clients or vendors that aren't hosted on AWS, use IAM user long-term access keys.
- **AWS CodeCommit access** – If you are using CodeCommit to store your code, you can use an IAM user with either SSH keys or service-specific credentials for CodeCommit to authenticate to your repositories. We recommend that you do this in addition to using a user in IAM Identity Center for normal authentication. Users in IAM Identity Center are the people in your workforce who need access to your AWS accounts or to your cloud applications. To give users access to your CodeCommit repositories without configuring IAM users, you can configure the **git-remote-codecommit** utility. For more information about IAM and CodeCommit, see [Using IAM with CodeCommit: Git credentials, SSH keys, and AWS access keys](#). For more information about configuring the **git-remote-codecommit** utility, see [Connecting to AWS CodeCommit repositories with rotating credentials](#) in the *AWS CodeCommit User Guide*.
- **Amazon Keyspaces (for Apache Cassandra) access** – In a situation where you are unable to use users in IAM Identity Center, such as for testing purposes for Cassandra compatibility, you can use an IAM user with service-specific credentials to authenticate with Amazon Keyspaces. Users in IAM Identity Center are the people in your workforce who need access to your AWS

accounts or to your cloud applications. You can also connect to Amazon Keyspaces using temporary credentials. For more information, see [Using temporary credentials to connect to Amazon Keyspaces using an IAM role and the SigV4 plugin](#) in the *Amazon Keyspaces (for Apache Cassandra) Developer Guide*.

- **Emergency access** – In a situation where you can't access your identity provider and you must take action in your AWS account. Establishing emergency access IAM users can be part of your resiliency plan. We recommend that the emergency user credentials be tightly controlled and secured using multi-factor authentication (MFA).

When to create an IAM role (instead of a user)

Create an IAM role in the following situations:

You're creating an application that runs on an Amazon Elastic Compute Cloud (Amazon EC2) instance and that application makes requests to AWS.

Don't create an IAM user and pass the user's credentials to the application or embed the credentials in the application. Instead, create an IAM role that you attach to the EC2 instance to give temporary security credentials to applications running on the instance. When an application uses these credentials in AWS, it can perform all of the operations that are allowed by the policies attached to the role. For details, see [Using an IAM role to grant permissions to applications running on Amazon EC2 instances](#).

You're creating an app that runs on a mobile phone and that makes requests to AWS.

Don't create an IAM user and distribute the user's access key with the app. Instead, use an identity provider like Login with Amazon, Amazon Cognito, Facebook, or Google to authenticate users and map the users to an IAM role. The app can use the role to get temporary security credentials that have the permissions specified by the policies attached to the role. For more information, see the following:

- [Amazon Cognito User Guide](#)
- [About web identity federation](#)

Users in your company are authenticated in your corporate network and want to be able to use AWS without having to sign in again—that is, you want to allow users to federate into AWS.

Don't create IAM users. Configure a federation relationship between your enterprise identity system and AWS. You can do this in two ways:

- If your company's identity system is compatible with SAML 2.0, you can establish trust between your company's identity system and AWS. For more information, see [About SAML 2.0-based federation](#).
- Create and use a custom proxy server that translates user identities from the enterprise into IAM roles that provide temporary AWS security credentials. For more information, see [Enabling custom identity broker access to the AWS console](#).

Compare AWS account root user credentials and IAM user credentials

The root user is the account owner and is created when the AWS account is created. Other types of users, including IAM users, and AWS IAM Identity Center users are created by the root user or an administrator for the account. All AWS users have security credentials.

Root user credentials

The credentials of the account owner allow full access to all resources in the account. You can't use [IAM policies](#) to explicitly deny the root user access to resources. You can only use an AWS Organizations [service control policy \(SCP\)](#) to limit the permissions of the root user of a member account. Because of this, we recommend that you create an administrative user in IAM Identity Center to use for everyday AWS tasks. Then, safeguard the root user credentials and use them to perform only those few account and service management tasks that require you to sign in as the root user. For the list of those tasks, see [Tasks that require root user credentials](#). To learn how to set up an administrator for daily use in IAM Identity Center, see [Getting started](#) in the *IAM Identity Center User Guide*.

IAM credentials

An IAM user is an entity you create in AWS that represents the person or service that uses the IAM user to interact with AWS resources. These users are identities within your AWS account that have specific custom permissions. For example, you can create IAM users and give them permissions to create a directory in IAM Identity Center. IAM users have long-term credentials that they can use to access AWS using the AWS Management Console, or programmatically using the AWS CLI or AWS APIs. For step-by-step instructions for how IAM users sign in to the AWS Management Console, see [Sign in to the AWS Management Console as an IAM user](#) in the *AWS Sign-In User Guide*.

In general, we recommend that you avoid creating IAM users because they have long-term credentials such as a username and password. Instead, require human users to use temporary

credentials when accessing AWS. You can use an identity provider for your human users to provide federated access to AWS accounts by assuming IAM roles, which provide temporary credentials. For centralized access management, we recommend that you use [IAM Identity Center](#) to manage access to your accounts and permissions within those accounts. You can manage your user identities with IAM Identity Center, or manage access permissions for user identities in IAM Identity Center from an external identity provider. For more information, see [What is IAM Identity Center](#) in the *IAM Identity Center User Guide*.

AWS account root user

When you first create an Amazon Web Services (AWS) account, you begin with a single sign-in identity that has complete access to all AWS services and resources in the account. This identity is called the AWS account *root user* and is accessed by signing in with the email address and password that you used to create the account.

Important

We strongly recommend that you don't use the root user for your everyday tasks and that you follow the [root user best practices for your AWS account](#). Safeguard your root user credentials and use them to perform the tasks that only the root user can perform. For the complete list of tasks that require you to sign in as the root user, see [Tasks that require root user credentials](#).

The following topics detail management tasks associated with the root user.

Tasks

- [Enable a virtual MFA device for your AWS account root user \(console\)](#)
- [Enable a hardware TOTP token for the AWS account root user \(console\)](#)
- [Enable a FIDO security key for the AWS account root user \(console\)](#)
- [Change the password for the AWS account root user](#)
- [Resetting a lost or forgotten root user password](#)
- [Creating access keys for the root user](#)
- [Deleting access keys for the root user](#)
- [Tasks that require root user credentials](#)

- [Troubleshooting issues with the root user](#)
- [Related information](#)

Enable a virtual MFA device for your AWS account root user (console)

You can use the AWS Management Console to configure and enable a virtual MFA device for your root user. To enable MFA devices for the AWS account, you must be signed in to AWS using your root user credentials.

Before you enable MFA for your root user, review your account settings and contact information to make sure that you have access to the email and phone number. If your MFA device is lost, stolen, or not working, you can still sign in as the root user by verifying your identity using that email and phone number. To learn about signing in using these alternative factors of authentication, see [What if an MFA device is lost or stops working?](#).

To configure and enable a virtual MFA device for use with your root user (console)

1. Sign in to the AWS Management Console.
2. On the right side of the navigation bar, choose your account name, and choose **Security credentials**. If necessary, choose **Continue to Security credentials**.

3. In the **Multi-Factor Authentication (MFA)** section, choose **Assign MFA device**.
4. In the wizard, type a **Device name**, choose **Authenticator app**, and then choose **Next**.

IAM generates and displays configuration information for the virtual MFA device, including a QR code graphic. The graphic is a representation of the secret configuration key that is available for manual entry on devices that do not support QR codes.

5. Open the virtual MFA app on the device.

If the virtual MFA app supports multiple virtual MFA devices or accounts, choose the option to create a new virtual MFA device or account.

6. The easiest way to configure the app is to use the app to scan the QR code. If you cannot scan the code, you can type the configuration information manually. The QR code and secret configuration key generated by IAM are tied to your AWS account and cannot be used with a different account. They can, however, be reused to configure a new MFA device for your account in case you lose access to the original MFA device.
 - To use the QR code to configure the virtual MFA device, from the wizard, choose **Show QR code**. Then follow the app instructions for scanning the code. For example, you might need to choose the camera icon or choose a command like **Scan account barcode**, and then use the device's camera to scan the QR code.
 - In the **Set up device** wizard, choose **Show secret key**, and then type the secret key into your MFA app.

Important

Make a secure backup of the QR code or secret configuration key, or make sure that you enable multiple MFA devices for your account. You can register up to **eight** MFA devices of any combination of the [currently supported MFA types](#) with your AWS account root user and IAM users. A virtual MFA device might become unavailable, for example, if you lose the smartphone where the virtual MFA device is hosted. If that happens and you are not able to sign in to your account with no additional MFA devices attached to the user or even by [Recovering a root user MFA device](#), you will not be able to sign in to your account and you will have to [contact customer service](#) to remove MFA protection for the account.

The device starts generating six-digit numbers.

7. In the wizard, in the **MFA code 1** box, type the one-time password that currently appears in the virtual MFA device. Wait up to 30 seconds for the device to generate a new one-time password. Then type the second one-time password into the **MFA code 2** box. Choose **Add MFA**.

Important

Submit your request immediately after generating the code. If you generate the codes and then wait too long to submit the request, the MFA device successfully associates with the user but the MFA device is out of sync. This happens because time-based one-time passwords (TOTP) expire after a short period of time. If this happens, you can [resync the device](#).

The device is ready for use with AWS. For information about using MFA with the AWS Management Console, see [Using MFA devices with your IAM sign-in page](#).

Enable a hardware TOTP token for the AWS account root user (console)

You can configure and enable a physical MFA device for your root user from the AWS Management Console only, not from the AWS CLI or AWS API.

If your MFA device is lost, stolen, or not working, you can still sign in using alternative factors of authentication. If you can't sign in with your MFA device, you can sign in by verifying your identity using the email and phone that are registered with your account. Before you enable MFA for your root user, review your account settings and contact information to make sure that you have access to the email and phone number. To learn about signing in using alternative factors of authentication, see [What if an MFA device is lost or stops working?](#). To disable this feature, contact [AWS Support](#).

Note

You might see different text, such as **Sign in using MFA** and **Troubleshoot your authentication device**. However, the same features are provided. In either case, if you cannot verify your account email address and phone number using alternative factors of authentication, contact [AWS Support](#) to deactivate your MFA setting.

To enable the MFA device for your root user (console)

1. Sign in to the [IAM console](#) as the account owner by choosing **Root user** and entering your AWS account email address. On the next page, enter your password.

Note

As the root user, you can't sign in to the **Sign in as IAM user** page. If you see the **Sign in as IAM user** page, choose **Sign in using root user email** near the bottom of the page. For help signing in as the root user, see [Signing in to the AWS Management Console as the root user](#) in the *AWS Sign-In User Guide*.

2. On the right side of the navigation bar, choose on your account name, and then choose **Security credentials**. If necessary, choose **Continue to Security credentials**.

3. Expand the **Multi-factor authentication (MFA)** section.
4. Choose **Assign MFA device**.
5. In the wizard, type a **Device name**, choose **Hardware TOTP token**, and then choose **Next**.
6. In the **Serial number** box, type the serial number that is found on the back of the MFA device.
7. In the **MFA code 1** box, type the six-digit number displayed by the MFA device. You might need to press the button on the front of the device to display the number.

8. Wait 30 seconds while the device refreshes the code, and then type the next six-digit number into the **MFA code 2** box. You might need to press the button on the front of the device again to display the second number.
9. Choose **Add MFA**. The MFA device is now associated with the AWS account.

Important

Submit your request immediately after generating the authentication codes. If you generate the codes and then wait too long to submit the request, the MFA device successfully associates with the user but the MFA device becomes out of sync. This happens because time-based one-time passwords (TOTP) expire after a short period of time. If this happens, you can [resync the device](#).

The next time you use your root user credentials to sign in, you must type a code from the MFA device.

Enable a FIDO security key for the AWS account root user (console)

You can configure and enable a virtual MFA device for your root user from the AWS Management Console only, not from the AWS CLI or AWS API.

If your FIDO security key is lost, stolen, or not working, you can still sign in using another MFA device registered to the same AWS account root user. If you only have a single MFA device registered, you can sign in using alternate factors of identification. To learn about signing in using alternative factors of authentication, see [What if an MFA device is lost or stops working?](#). To disable this feature, contact [AWS Support](#).

Note

You should not choose any of the available options on the Google Chrome pop-up that asks to **Verify your identity with amazon.com**. You only need to tap on the security key.

To enable the FIDO key for your root user (console)

1. Sign in to the [IAM console](#) as the account owner by choosing **Root user** and entering your AWS account email address. On the next page, enter your password.

Note

As the root user, you can't sign in to the **Sign in as IAM user** page. If you see the **Sign in as IAM user** page, choose **Sign in using root user email** near the bottom of the page. For help signing in as the root user, see [Signing in to the AWS Management Console as the root user](#) in the *AWS Sign-In User Guide*.

2. On the right side of the navigation bar, choose your account name, and then choose **Security credentials**. If necessary, choose **Continue to Security credentials**.

3. Expand the **Multi-factor authentication (MFA)** section.
4. Choose **Assign MFA device**.
5. In the wizard, type a **Device name**, choose **Security Key**, and then choose **Next**.
6. Insert the FIDO security key into your computer's USB port.

7. Tap the FIDO security key.

The FIDO security key is ready for use with AWS. The next time you use your root user credentials to sign in, you must tap your FIDO security key to complete the sign-in process.

For help troubleshooting issues with your FIDO security key, see [Troubleshooting FIDO security keys](#).

Change the password for the AWS account root user

You can change the email address and password from either the [Security Credentials](#) or the **Account** page. You can also choose **Forgot password?** on the AWS sign-in page to reset your password.

To change the root user's password, you must sign in as the AWS account root user and not as an IAM user. To learn how to reset a *forgotten* root user password, see [Resetting a lost or forgotten root user password](#).

To protect your password, it's important to follow these best practices:

- Change your password periodically.
- Keep your password private because anyone who knows your password can access your account.
- Use a different password on AWS than you use on other sites.
- Avoid passwords that are easy to guess. These include passwords such as `secret`, `password`, `amazon`, or `123456`. Also avoid things like dictionary words, your name, email address, or other personal information that someone can easily obtain.

AWS Management Console

To change the password for the root user

Minimum permissions

To perform the following steps, you must have at least the following IAM permissions:

- You must sign in as the AWS account root user, which requires no additional AWS Identity and Access Management (IAM) permissions. You can't perform these steps as an IAM user or role.

1. Use your AWS account's email address and password to sign in to the [Getting Started with the AWS Management Console](#) as your AWS account root user.
2. In the upper right corner of the console, choose your account name or number and then choose **Account**.
3. On the **Account** page, next to **Account settings**, choose **Edit**. You are prompted to re-authenticate for security purposes.

Note

If you don't see the **Edit** option, it is likely that you are not signed in as the root user for your account. You can't modify account settings while signed in as an IAM user or role.

4. On the **Update account settings** page, under **Password**, choose **Edit**.
5. On the **Update your password** page, fill out the fields for **Current password**, **New password**, and **Confirm new password**.

Important

Make sure to choose a strong password. Although you can set an account password policy for IAM users, that policy doesn't apply to the root user.

AWS requires that your password meet the following conditions:

- It must have a minimum of 8 characters and a maximum of 128 characters.
- It must include a minimum of three of the following mix of character types: uppercase, lowercase, numbers, and ! @ # \$ % ^ & * () < > [] { } | _ + - = symbols.
- It must not be identical to your AWS account name or email address.

 **Note**

AWS is rolling out improvements to the sign-in process. One of those improvements is to enforce a more secure password policy for your account. If AWS has upgraded your account, you are required to meet the password policy described earlier. If AWS hasn't yet upgraded your account, then AWS doesn't yet enforce this policy. However, we strongly recommend that you follow its guidelines for a more secure password.

6. Choose **Save changes**.

AWS CLI or AWS SDK

This task isn't supported in the AWS CLI or by an API operation from one of the AWS SDKs. You can perform this task only by using the AWS Management Console.

Resetting a lost or forgotten root user password

When you first created your AWS account, you provided an email address and password. These are your AWS account root user credentials. If you forget your root user password, you can reset the password from the AWS Management Console.

To reset your root user password:

1. Use your AWS account email address to begin signing in to the [AWS Management Console](#) as the root user and then choose **Next**.

 **Note**

If you are signed in to the [AWS Management Console](#) with *IAM user* credentials, then you must sign out before you can reset the root user password. If you see the account-

specific IAM user sign-in page, choose **Sign-in using root account credentials** near the bottom of the page. If necessary, provide your account email address and choose **Next** to access the **Root user sign in** page.

2. Choose **Forgot your password?**.

 **Note**

If you are an IAM user, this option is not available. The **Forgot your password?** option is only available for the root user account. IAM users must ask their administrator to reset a forgotten password. For more information, see [I forgot my IAM user password for my AWS account](#). If you sign in through the AWS access portal, see [Resetting your IAM Identity Center user password](#).

3. Provide the email address that is associated with the account. Then provide the CAPTCHA text and choose **Continue**.
4. Check the email that is associated with your AWS account for a message from Amazon Web Services. The email will come from an address ending in @verify.signin.aws. Follow the directions in the email. If you don't see the email in your account, check your spam folder. If you no longer have access to the email, see [I don't have access to the email for my AWS account](#) in the *AWS Sign-In User Guide*.

Creating access keys for the root user

 **Warning**

We strongly recommend that you do **not** create access key pairs for your root user. Because [only a few tasks require the root user](#) and you typically perform those tasks infrequently, we recommend signing in to the AWS Management Console to perform the root user tasks. Before creating access keys, review the [alternatives to long-term access keys](#).

Although we don't recommend it, you can create access keys for your root user so that you can run commands in the AWS Command Line Interface (AWS CLI) or use API operations from one of the AWS SDKs using root user credentials. When you create access keys, you create the access key ID and secret access key as a set. During access key creation, AWS gives you one opportunity to view and download the secret access key part of the access key. If you don't download it or if you lose it,

you can delete the access key and then create a new one. You can create root user access keys with the console, AWS CLI, or AWS API.

A newly created access key has the status of *active*, which means that you can use the access key for CLI and API calls. You can assign up to two access keys to the root user.

Access keys that are not in use should be inactivated. Once an access key is inactive, you can't use it for API calls. Inactive keys still count toward your limit. You can create or delete an access key any time. However, when you delete an access key, it's gone forever and can't be retrieved.

AWS Management Console

To create an access key for the AWS account root user

Minimum permissions

To perform the following steps, you must have at least the following IAM permissions:

- You must sign in as the AWS account root user, which requires no additional AWS Identity and Access Management (IAM) permissions. You can't perform these steps as an IAM user or role.

1. Use your AWS account's email address and password to sign in to the [Getting Started with the AWS Management Console](#) as your AWS account root user.
2. In the upper right corner of the console, choose your account name or number and then choose **Security Credentials**.
3. In the **Access keys** section, choose **Create access key**. If this option is not available, then you already have the maximum number of access keys. You must delete one of the existing access keys before you can create a new key. For more information, see [IAM Object Quotas](#).
4. On the **Alternatives to root user access keys** page, review the security recommendations. To continue, select the check box, and then choose **Create access key**.
5. On the **Retrieve access key** page, your **Access key** ID is displayed.
6. Under **Secret access key**, choose **Show** and then copy the access key ID and secret key from your browser window and paste it somewhere secure. Alternatively, you can choose **Download .csv file** which will download a file named `rootkey.csv` that contains the access key ID and the secret key. Save the file somewhere safe.

7. Choose **Done**. When you no longer need the access key [we recommend that you delete it](#), or at least consider deactivating it so that no one can misuse it.

AWS CLI & SDKs

To create an access key for the root user

Note

To run the following command or API operation as the root user, you must already have one active access key pair. If you don't have any access keys, create the first access key using the AWS Management Console. Then, you can use the credentials from that first access key with the AWS CLI to create the second access key, or to delete an access key.

- AWS CLI: [aws iam create-access-key](#)

Example

```
$ aws iam create-access-key
{
  "AccessKey": {
    "UserName": "MyUserName",
    "AccessKeyId": "AKIAIOSFODNN7EXAMPLE",
    "Status": "Active",
    "SecretAccessKey": "wJalrXUtnFEMI/K7MDENG/bPxrFiCYEXAMPLEKEY",
    "CreateDate": "2021-04-08T19:30:16+00:00"
  }
}
```

- AWS API: [CreateAccessKey](#) in the *IAM API Reference*.

Deleting access keys for the root user

You can use the AWS Management Console, the AWS CLI or the AWS API to delete the root user access keys.

AWS Management Console

To delete an access key for the root user

Minimum permissions

To perform the following steps, you must have at least the following IAM permissions:

- You must sign in as the AWS account root user, which requires no additional AWS Identity and Access Management (IAM) permissions. You can't perform these steps as an IAM user or role.

1. Use your AWS account's email address and password to sign in to the [Getting Started with the AWS Management Console](#) as your AWS account root user.
2. In the upper right corner of the console, choose your account name or number and then choose **Security Credentials**.
3. In the **Access keys** section, select the access key that you want to delete, and then, under **Actions**, choose **Delete**.

Note

Alternatively, you can **Deactivate** an access key, instead of permanently deleting it. This way you can resume using it in the future without having to change either the key ID or secret key. While the key is inactive, any attempts to use it in requests to the AWS API fail with the error access denied.

4. On the **Delete <access key ID>** dialog box, choose **Deactivate**, enter the access key ID to confirm you want to delete it, and then choose **Delete**.

AWS CLI & SDKs

To delete an access key for the root user

Minimum permissions

To perform the following steps, you must have at least the following IAM permissions:

- You must sign in as the AWS account root user, which requires no additional AWS Identity and Access Management (IAM) permissions. You can't perform these steps as an IAM user or role.

- AWS CLI: [aws iam delete-access-key](#)

Example

```
$ aws iam delete-access-key \  
  --access-key-id AKIAIOSFODNN7EXAMPLE
```

This command produces no output when successful.

- AWS API: [DeleteAccessKey](#)

Tasks that require root user credentials

We recommend that you [configure an administrative user in AWS IAM Identity Center](#) to perform daily tasks and access AWS resources. However, you can perform the tasks listed below only when you sign in as the root user of an account.

Tasks

- [Change your account settings](#). This includes the account name, email address, root user password, and root user access keys. Other account settings, such as contact information, payment currency preference, and AWS Regions, don't require root user credentials.
- [Restore IAM user permissions](#). If the only IAM administrator accidentally revokes their own permissions, you can sign in as the root user to edit policies and restore those permissions.
- [Activate IAM access to the Billing and Cost Management console](#).
- View certain tax invoices. An IAM user with the [aws-portal:ViewBilling](#) permission can view and download VAT invoices from AWS Europe, but not AWS Inc. or Amazon Internet Services Private Limited (AISPL).
- [Close your AWS account](#).

For more information, see the following topics:

- [How do I transfer my AWS account to another person or business?](#)

- [How do I close my AWS account?](#)
- [Close a standalone AWS account](#)
- [Register as a seller](#) in the Reserved Instance Marketplace.
- [Configure an Amazon S3 bucket to enable MFA \(multi-factor authentication\).](#)
- [Edit or delete an Amazon Simple Queue Service \(Amazon SQS\) resource policy that denies all principals.](#)
- [Edit or delete an Amazon Simple Storage Service \(Amazon S3\) bucket policy that denies all principals.](#)
- [Sign up for AWS GovCloud \(US\).](#)
- Request AWS GovCloud (US) account root user access keys from AWS Support.
- In the event that an AWS Key Management Service key becomes unmanageable, you can recover it by contacting AWS Support as the root user.

Troubleshooting issues with the root user

Use the information here to help you troubleshoot issues related to the root user of an AWS account.

I can't perform tasks that I expect to be able to do when signed in as the account root user

If you can't complete tasks when you are signed in as the root user for the account, your account might be a member of an organization in AWS Organizations. If so, and your organizational administrator used a service control policy (SCP) to limit the permissions of your account, then all users, including the root user, are affected. For more information, see [Service control policies](#) in the *AWS Organizations User Guide*.

I forgot the root user password for my AWS account

If you're a root user and you have lost or forgot the password for your AWS account, you can reset your password. You must know the email address used to create the AWS account, and you must have access to the email account. For more information, see [Resetting a lost or forgotten root user password](#).

I don't have access to the email for my AWS account

When you create an AWS account, you provide an email address and password. These are the credentials for the AWS account root user. If you aren't sure of the email address associated with

your AWS account, search for messages sent from @signin.aws or @verify.signin.aws to any email address for your organization that might have been used to open the AWS account.

If you know the email address but no longer have access to the email, first try to recover access to the email using one of the following options:

- If you own the domain for the email address, you can restore a deleted email address. Alternatively, you can set up a catch-all for your email account, which "catches all" messages sent to email addresses that no longer exist in the mail server and redirects them to another email address.
- If the email address on the account is part of your corporate email system, we recommend that you contact your IT system administrators. They might be able to help you regain access to the email.

If you're still not able to sign in to your AWS account, you can find alternate support options at [Contact us](#).

Related information

The following articles provide additional information about working with the root user.

- [What are some best practices for securing my AWS account and its resources?](#)
- [How can I create an EventBridge event rule to notify me that my root user was used?](#)
- [Monitor and notify on AWS account root user activity](#)
- [Monitor IAM root user activity](#)

IAM users

Important

IAM [best practices](#) recommend that you require human users to use federation with an identity provider to access AWS using temporary credentials instead of using IAM users with long-term credentials.

An AWS Identity and Access Management (IAM) *user* is an entity that you create in AWS. The IAM user represents the human user or workload who uses the IAM user to interact with AWS. A user in AWS consists of a name and credentials.

An IAM user with administrator permissions is not the same thing as the AWS account root user. For more information about the root user, see [AWS account root user](#).

How AWS identifies an IAM user

When you create an IAM user, IAM creates these ways to identify that user:

- A "friendly name" for the IAM user, which is the name that you specified when you created the IAM user, such as Richard or Anaya. These are the names you see in the AWS Management Console.
- An Amazon Resource Name (ARN) for the IAM user. You use the ARN when you need to uniquely identify the IAM user across all of AWS. For example, you could use an ARN to specify the IAM user as a `Principal` in an IAM policy for an Amazon S3 bucket. An ARN for an IAM user might look like the following:

```
arn:aws:iam::account-ID-without-hyphens:user/Richard
```

- A unique identifier for the IAM user. This ID is returned only when you use the API, Tools for Windows PowerShell, or AWS CLI to create the IAM user; you do not see this ID in the console.

For more information about these identifiers, see [IAM identifiers](#).

IAM users and credentials

You can access AWS in different ways depending on the IAM user credentials:

- **[Console password](#)**: A password that the IAM user can type to sign in to interactive sessions such as the AWS Management Console. Disabling the password (console access) for an IAM user prevents them from signing in to the AWS Management Console using their sign-in credentials. It does not change their permissions or prevent them from accessing the console using an assumed role.
- **[Access keys](#)**: Used to make programmatic calls to AWS. However, there are more secure alternatives to consider before you create access keys for IAM users. For more information, see [Considerations and alternatives for long-term access keys](#) in the *AWS General Reference*. If the

IAM user has active access keys, they continue to function and allow access through the AWS CLI, Tools for Windows PowerShell, AWS API, or the AWS Console Mobile Application.

- [SSH keys for use with CodeCommit](#): An SSH public key in the OpenSSH format that can be used to authenticate with CodeCommit.
- [Server certificates](#): SSL/TLS certificates that you can use to authenticate with some AWS services. We recommend that you use AWS Certificate Manager (ACM) to provision, manage, and deploy your server certificates. Use IAM only when you must support HTTPS connections in a region that is not supported by ACM. To learn which regions support ACM, see [AWS Certificate Manager endpoints and quotas](#) in the *AWS General Reference*.

You can choose the credentials that are right for your IAM user. When you use the AWS Management Console to create an IAM user, you must choose to at least include a console password or access keys. By default, a brand new IAM user created using the AWS CLI or AWS API has no credentials of any kind. You must create the type of credentials for an IAM user based on your use case.

You have the following options to administer passwords, access keys, and multi-factor authentication (MFA) devices:

- [Manage passwords for your IAM users](#). Create and change the passwords that permit access to the AWS Management Console. Set a password policy to enforce a minimum password complexity. Allow users to change their own passwords.
- [Manage access keys for your IAM users](#). Create and update access keys for programmatic access to the resources in your account.
- [Enable multi-factor authentication \(MFA\) for the IAM user](#). As a [best practice](#), we recommend that you require multi-factor authentication for all IAM users in your account. With MFA, users must provide two forms of identification: First, they provide the credentials that are part of their user identity (a password or access key). In addition, they provide a temporary numeric code that's generated on a hardware device or by an application on a smartphone or tablet.
- [Find unused passwords and access keys](#). Anyone who has a password or access keys for your account or an IAM user in your account has access to your AWS resources. The security [best practice](#) is to remove passwords and access keys when users no longer need them.
- [Download a credential report for your account](#). You can generate and download a credential report that lists all IAM users in your account and the status of their various credentials, including passwords, access keys, and MFA devices. For passwords and access keys, the credential report shows how recently the password or access key has been used.

IAM users and permissions

By default, a new IAM user has no [permissions](#) to do anything. They are not authorized to perform any AWS operations or to access any AWS resources. An advantage of having individual IAM users is that you can assign permissions individually to each user. You might assign administrative permissions to a few users, who then can administer your AWS resources and can even create and manage other IAM users. In most cases, however, you want to limit a user's permissions to just the tasks (AWS actions or operations) and resources that are needed for the job.

Imagine a user named Diego. When you create the IAM user Diego, you create a password for him and attach permissions that let him launch a specific Amazon EC2 instance and read (GET) information from a table in an Amazon RDS database. For procedures on how to create users and grant them initial credentials and permissions, see [Creating an IAM user in your AWS account](#). For procedures on how to change the permissions for existing users, see [Changing permissions for an IAM user](#). For procedures on how to change the user's password or access keys, see [Managing user passwords in AWS](#) and [Managing access keys for IAM users](#).

You can also add a permissions boundary to your IAM users. A permissions boundary is an advanced feature that allows you to use AWS managed policies to limit the maximum permissions that an identity-based policy can grant to an IAM user or role. For more information about policy types and uses, see [Policies and permissions in IAM](#).

IAM users and accounts

Each IAM user is associated with one and only one AWS account. Because IAM users are defined within your AWS account, they don't need to have a payment method on file with AWS. Any AWS activity performed by IAM users in your account is billed to your account.

The number and size of IAM resources in an AWS account are limited. For more information, see [IAM and AWS STS quotas](#).

IAM users as service accounts

An IAM user is a resource in IAM that has associated credentials and permissions. An IAM user can represent a person or an application that uses its credentials to make AWS requests. This is typically referred to as a *service account*. If you choose to use the long-term credentials of an IAM user in your application, **do not embed access keys directly into your application code**. The AWS SDKs and the AWS Command Line Interface allow you to put access keys in known locations so that

you do not have to keep them in code. For more information, see [Manage IAM User Access Keys Properly](#) in the *AWS General Reference*. Alternatively, and as a best practice, you can [use temporary security credentials \(IAM roles\) instead of long-term access keys](#).

Creating an IAM user in your AWS account

 [Follow us on Twitter](#)

Important

IAM [best practices](#) recommend that you require human users to use federation with an identity provider to access AWS using temporary credentials instead of using IAM users with long-term credentials.

Note

If you found this page because you are looking for information about the Product Advertising API to sell Amazon products on your website, see the [Product Advertising API 5.0 Documentation](#).

If you arrived at this page from the IAM console, it is possible that your account does not include IAM users, even though you are signed in. You could be signed in as the AWS account root user, using a role, or signed in with temporary credentials. To learn more about these IAM identities, see [IAM Identities \(users, user groups, and roles\)](#).

The process of creating a user and enabling that user to perform work tasks consists of the following steps:

1. Create the user in the AWS Management Console, the AWS CLI, Tools for Windows PowerShell, or using an AWS API operation. If you create the user in the AWS Management Console, then steps 1–4 are handled automatically, based on your choices. If you create the users programmatically, then you must perform each of those steps individually.
2. Create credentials for the user, depending on the type of access the user requires:
 - **Enable console access – optional:** If the user needs to access the AWS Management Console, [create a password for the user](#). Disabling console access for a user prevents them from signing in to the AWS Management Console using their user name and password. It does not change their permissions or prevent them from accessing the console using an assumed role.

Tip

Create only the credentials that the user needs. For example, for a user who requires access only through the AWS Management Console, do not create access keys.

3. Give the user permissions to perform the required tasks by adding the user to one or more groups. You can also grant permissions by attaching permissions policies directly to the user. However, we recommend instead that you put your users in groups and manage permissions through policies that are attached to those groups. You can also use a [permissions boundary](#) to limit the permissions that a user can have, though this is not common.
4. (Optional) Add metadata to the user by attaching tags. For more information about using tags in IAM, see [Tagging IAM resources](#).
5. Provide the user with the necessary sign-in information. This includes the password and the console URL for the account sign-in page where the user provides those credentials. For more information, see [How IAM users sign in to AWS](#).
6. (Optional) Configure [multi-factor authentication \(MFA\)](#) for the user. MFA requires the user to provide a one-time-use code each time he or she signs into the AWS Management Console.
7. (Optional) Give users permissions to manage their own security credentials. (By default, users do not have permissions to manage their own credentials.) For more information, see [Permitting IAM users to change their own passwords](#).

For information about the permissions that you need in order to create a user, see [Permissions required to access IAM resources](#).

Topics

- [Creating IAM users \(console\)](#)
- [Creating IAM users \(AWS CLI\)](#)
- [Creating IAM users \(AWS API\)](#)

Creating IAM users (console)

You can use the AWS Management Console to create IAM users.

To create an IAM user (console)

1. Follow the sign-in procedure appropriate to your user type as described in the topic [How to sign in to AWS](#) in the *AWS Sign-In User Guide*.
2. On the **Console Home** page, select the IAM service.
3. In the navigation pane, select **Users** and then select **Add users**.
4. On the **Specify user details** page, under **User details**, in **User name**, enter the name for the new user. This is their sign-in name for AWS.

Note

The number and size of IAM resources in an AWS account are limited. For more information, see [IAM and AWS STS quotas](#). User names can be a combination of up to 64 letters, digits, and these characters: plus (+), equal (=), comma (,), period (.), at sign (@), underscore (_), and hyphen (-). Names must be unique within an account. They are not distinguished by case. For example, you cannot create two users named *TESTUSER* and *testuser*. When a user name is used in a policy or as part of an ARN, the name is case sensitive. When a user name appears to customers in the console, such as during the sign-in process, the user name is case insensitive.

5. Select **Provide user access to the – AWS Management Console *optional*** This produces AWS Management Console sign-in credentials for the new user.

You are asked whether you are providing console access to a person. We recommend that you create users in IAM Identity Center rather than IAM.

- To switch to creating the user in IAM Identity Center, select **Specify a user in Identity Center**.

If you have not enabled IAM Identity Center, selecting this option takes you to the service page in the console so that you can enable the service. For details on this procedure, see <https://docs.aws.amazon.com/singlesignon/latest/userguide/getting-started.html> in the *AWS IAM Identity Center User Guide*

If you have enabled IAM Identity Center, selecting this option takes you to the **Specify user details** page in IAM Identity Center. For details on this procedure, see <https://docs.aws.amazon.com/singlesignon/latest/userguide/addusers.html> in the *AWS IAM Identity Center User Guide*

- If you cannot use IAM Identity Center, select **I want to create an IAM user** and continue following this procedure.
- a. For **Console password**, select one of the following:
 - **Autogenerated password** – The user gets a randomly generated password that meets the [account password policy](#). You can view or download the password when you get to the **Retrieve password** page.
 - **Custom password** – The user is assigned the password that you enter in the box.
- b. (Optional) **Users must create a new password at next sign-in (recommended)** is selected by default to ensure that the user is forced to change their password the first time they sign in.

 **Note**

If an administrator has enabled the [Allow users to change their own password account password policy setting](#), then this check box does nothing. Otherwise, it automatically attaches an AWS managed policy named [IAMUserChangePassword](#) to the new users. The policy grants them permission to change their own passwords.

6. Select **Next**.
7. On the **Set permissions** page, specify how you want to assign permissions for this user. Select one of the following three options:
 - **Add user to group** – Select this option if you want to assign the user to one or more groups that already have permissions policies. IAM displays a list of the groups in your account, along with their attached policies. You can select one or more existing groups, or select **Create group** to create a new group. For more information, see [Changing permissions for an IAM user](#).
 - **Copy permissions** – Select this option to copy all of the group memberships, attached managed policies, embedded inline policies, and any existing [permissions boundaries](#) from an existing user to the new user. IAM displays a list of the users in your account. Select the one whose permissions most closely match the needs of your new user.
 - **Attach policies directly** – Select this option to see a list of the AWS managed and customer managed policies in your account. Select the policies that you want to attach to the user

or select **Create policy** to open a new browser tab and create a new policy. For more information, see step 4 in the procedure [Creating IAM policies](#). After you create the policy, close that tab and return to your original tab to add the policy to the user.

 **Tip**

Whenever possible, attach your policies to a group and then make users members of the appropriate groups.

8. (Optional) Set a [permissions boundary](#). This is an advanced feature.

Open the **Permissions boundary** section and select **Use a permissions boundary to control the maximum permissions**. IAM displays a list of the AWS managed and customer managed policies in your account. Select the policy to use for the permissions boundary or select **Create policy** to open a new browser tab and create a new policy. For more information, see step 4 in the procedure [Creating IAM policies](#). After you create the policy, close that tab and return to your original tab to select the policy to use for the permissions boundary.

9. Select **Next**.
10. (Optional) On the **Review and create** page, under **Tags**, select **Add new tag** to add metadata to the user by attaching tags as key-value pairs. For more information about using tags in IAM, see [Tagging IAM resources](#).
11. Review all of the choices you made up to this point. When you are ready to proceed, select **Create user**.
12. On the **Retrieve password** page, get the password assigned to the user:
 - Select **Show** next to the password to view the user's password so that you can record it manually.
 - Select **Download .csv** to download the user's sign in credentials as a .csv file that you can save to a safe location.
13. Select **Email sign-in instructions**. Your local mail client opens with a draft that you can customize and send to the user. The email template includes the following details to each user:
 - User name
 - URL to the account sign-in page. Use the following example, substituting the correct account ID number or account alias:

```
https://AWS-account-ID or alias.signin.aws.amazon.com/console
```

Important

The user's password is *not* included in the generated email. You must provide the password to the user in a way that complies with your organization's security guidelines.

14. If the user also requires access keys, refer to [Managing access keys for IAM users](#).

Creating IAM users (AWS CLI)

You can use the AWS CLI to create an IAM user.

To create an IAM user (AWS CLI)

1. Create a user.
 - [aws iam create-user](#)
2. (Optional) Give the user access to the AWS Management Console. This requires a password. You must also give the user the [URL of your account's sign-in page](#).
 - [aws iam create-login-profile](#)
3. (Optional) Give the user programmatic access. This requires access keys.
 - [aws iam create-access-key](#)
 - Tools for Windows PowerShell: [New-IAMAccessKey](#)
 - IAM API: [CreateAccessKey](#)

Important

This is your only opportunity to view or download the secret access keys, and you must provide this information to your users before they can use the AWS API. Save the user's new access key ID and secret access key in a safe and secure place. **You will not have access to the secret keys again after this step.**

4. Add the user to one or more groups. The groups that you specify should have attached policies that grant the appropriate permissions for the user.
 - [aws iam add-user-to-group](#)
5. (Optional) Attach a policy to the user that defines the user's permissions. **Note:** We recommend that you manage user permissions by adding the user to a group and attaching a policy to the group instead of attaching directly to a user.
 - [aws iam attach-user-policy](#)
6. (Optional) Add custom attributes to the user by attaching tags. For more information, see [Managing tags on IAM users \(AWS CLI or AWS API\)](#).
7. (Optional) Give the user permission to manage their own security credentials. For more information, see [AWS: Allows MFA-authenticated IAM users to manage their own credentials on the Security credentials page](#).

Creating IAM users (AWS API)

You can use the AWS API to create an IAM user.

To create an IAM user from the (AWS API)

1. Create a user.
 - [CreateUser](#)
2. (Optional) Give the user access to the AWS Management Console. This requires a password. You must also give the user the [URL of your account's sign-in page](#).
 - [CreateLoginProfile](#)
3. (Optional) Give the user programmatic access. This requires access keys.
 - [CreateAccessKey](#)

Important

This is your only opportunity to view or download the secret access keys, and you must provide this information to your users before they can use the AWS API. Save

the user's new access key ID and secret access key in a safe and secure place. **You will not have access to the secret keys again after this step.**

4. Add the user to one or more groups. The groups that you specify should have attached policies that grant the appropriate permissions for the user.
 - [AddUserToGroup](#)
5. (Optional) Attach a policy to the user that defines the user's permissions. **Note:** We recommend that you manage user permissions by adding the user to a group and attaching a policy to the group instead of attaching directly to a user.
 - [AttachUserPolicy](#)
6. (Optional) Add custom attributes to the user by attaching tags. For more information, see [Managing tags on IAM users \(AWS CLI or AWS API\)](#).
7. (Optional) Give the user permission to manage their own security credentials. For more information, see [AWS: Allows MFA-authenticated IAM users to manage their own credentials on the Security credentials page](#).

Controlling IAM users access to the AWS Management Console

IAM users with permission who sign in to your AWS account through the AWS Management Console can access your AWS resources. The following list shows the ways that you can grant IAM users access to your AWS account resources through the AWS Management Console. It also shows how IAM users can access other AWS account features through the AWS website.

Note

There is no charge to use IAM.

The AWS Management Console

You create a password for each IAM user who needs access to the AWS Management Console. Users access the console through your IAM-enabled AWS account sign-in page. For information about accessing the sign-in page, see [How to sign in to AWS](#) in the *AWS Sign-In User Guide*. For information about creating passwords, see [Managing user passwords in AWS](#).

You can prevent an IAM user from accessing the AWS Management Console by removing their password. This prevents them from signing into the AWS Management Console using their sign-in credentials. It does not change their permissions or prevent them from accessing the console using an assumed role. If the user has active access keys, they continue to function and allow access through the AWS CLI, Tools for Windows PowerShell, AWS API, or the AWS Console Mobile Application.

Your AWS resources, such as Amazon EC2 instances, Amazon S3 buckets, and so on

Even if your IAM users have passwords, they still need permission to access your AWS resources. When you create an IAM user, that user has no permissions by default. To give your IAM users the permissions they need, you attach policies to them. If you have many IAM users who perform the same tasks with the same resources, you can assign those IAM users to a group. Then assign the permissions to that group. For information about creating IAM users and groups, see [IAM Identities \(users, user groups, and roles\)](#). For information about using policies to set permissions, see [Access management for AWS resources](#).

AWS Discussion Forums

Anyone can read the posts on the [AWS Discussion Forums](#). Users who want to post questions or comments to the AWS Discussion Forum can do so using their user name. The first time a user posts to the AWS Discussion Forum, the user is prompted to enter a nickname and email address. Only that user can use that nickname in the AWS Discussion Forums.

Your AWS account billing and usage information

You can grant users access your AWS account billing and usage information. For more information, see [Controlling Access to Your Billing Information](#) in the *AWS Billing User Guide*.

Your AWS account profile information

Users cannot access your AWS account profile information.

Your AWS account security credentials

Users cannot access your AWS account security credentials.

Note

IAM policies control access regardless of the interface. For example, you could provide a user with a password to access the AWS Management Console. The policies for that user (or any groups the user belongs to) would control what the user can do in the AWS Management Console. Or, you could provide the user with AWS access keys for making API

calls to AWS. The policies would control which actions the user could call through a library or client that uses those access keys for authentication.

How IAM users sign in to AWS

To sign in to the AWS Management Console as an IAM user, you must provide your account ID or account alias in addition to your user name and password. When your administrator [created your IAM user in the console](#), they should have sent you your sign-in credentials, including your user name and the URL to your account sign-in page that includes your account ID or account alias.

```
https://My_AWS_Account_ID.signin.aws.amazon.com/console/
```

Tip

To create a bookmark for your account sign-in page in your web browser, you should manually type the sign-in URL for your account in the bookmark entry. Do not use your web browser bookmark feature because redirects can obscure the sign-in URL.

You can also sign in at the following general sign-in endpoint and type your account ID or account alias manually:

```
https://console.aws.amazon.com/
```

For convenience, the AWS sign-in page uses a browser cookie to remember the IAM user name and account information. The next time the user goes to any page in the AWS Management Console, the console uses the cookie to redirect the user to the account sign-in page.

You have access only to the AWS resources that your administrator specifies in the policy that is attached to your IAM user identity. To work in the console, you must have permissions to perform the actions that the console performs, such as listing and creating AWS resources. For more information, see [Access management for AWS resources](#) and [Example IAM identity-based policies](#).

Note

If your organization has an existing identity system, you might want to create a single sign-on (SSO) option. SSO gives users access to the AWS Management Console for your account

without requiring them to have an IAM user identity. SSO also eliminates the need for users to sign in to your organization's site and to AWS separately. For more information, see [Enabling custom identity broker access to the AWS console](#).

Logging sign-in details in CloudTrail

If you enable CloudTrail to log sign-in events to your logs, you need to be aware of how CloudTrail chooses where to log the events.

- If your users sign-in directly to a console, they are redirected to either a global or a regional sign-in endpoint, based on whether the selected service console supports regions. For example, the main console home page supports regions, so if you sign in to the following URL:

```
https://alias.signin.aws.amazon.com/console
```

you are redirected to a regional sign-in endpoint such as `https://us-east-2.signin.aws.amazon.com`, resulting in a regional CloudTrail log entry in the user's region's log:

On the other hand, the Amazon S3 console does not support regions, so if you sign in to the following URL

```
https://alias.signin.aws.amazon.com/console/s3
```

AWS redirects you to the global sign-in endpoint at `https://signin.aws.amazon.com`, resulting in a global CloudTrail log entry.

- You can manually request a certain regional sign-in endpoint by signing in to the region-enabled main console home page using a URL syntax like the following:

```
https://alias.signin.aws.amazon.com/console?region=ap-southeast-1
```

AWS redirects you to the `ap-southeast-1` regional sign-in endpoint and results in a regional CloudTrail log event.

For more information about CloudTrail and IAM, see [Logging IAM events with CloudTrail](#).

If users need programmatic access to work with your account, you can create an access key pair (an access key ID and a secret access key) for each user. However, there are more secure alternatives to consider before you create access keys for users. For more information, see [Considerations and alternatives for long-term access keys](#) in the *AWS General Reference*.

Using MFA devices with your IAM sign-in page

Users who are configured with [multi-factor authentication \(MFA\)](#) devices must use their MFA devices to sign in to the AWS Management Console. After the user enters their sign-in credentials, AWS checks the user's account to see if MFA is required for that user. The following topics provide information on how users complete signing in when MFA is required.

Topics

- [Signing in with multiple MFA devices enabled](#)
- [Signing in with a FIDO security key](#)
- [Signing in with a virtual MFA device](#)
- [Signing in with a hardware TOTP token](#)

Signing in with multiple MFA devices enabled

If a user signs in to the AWS Management Console as an AWS account root user or IAM user with multiple MFA devices enabled for that account, they only need to use one MFA device to sign in. After the user authenticates with the user's password, they select which MFA device type they would like to use to finish authenticating. Then the user is prompted to authenticate with the type of device that they selected.

Signing in with a FIDO security key

If MFA is required for the user, a second sign-in page appears. The user needs to tap the FIDO security key.

Note

Google Chrome users should not choose any of the available options on the pop-up that asks to **Verify your identity with amazon.com**. You only need to tap on the security key.

Unlike other MFA devices, FIDO security keys do not go out of sync. Administrators can deactivate a FIDO security key if it's lost or broken. For more information, see [Deactivating MFA devices \(console\)](#).

For information on browsers that support WebAuthn and FIDO-compliant devices that AWS supports, see [Supported configurations for using FIDO security keys](#).

Signing in with a virtual MFA device

If MFA is required for the user, a second sign-in page appears. In the **MFA code** box, the user must enter the numeric code provided by the MFA application.

If the MFA code is correct, the user can access the AWS Management Console. If the code is incorrect, the user can try again with another code.

A virtual MFA device can go out of sync. If a user cannot sign in to the AWS Management Console after several tries, the user is prompted to synchronize the virtual MFA device. The user can follow the on-screen prompts to synchronize the virtual MFA device. For information about how you can synchronize a device on behalf of a user in your AWS account, see [Resynchronizing virtual and hardware MFA devices](#).

Signing in with a hardware TOTP token

If MFA is required for the user, a second sign-in page appears. In the **MFA code** box, the user must enter the numeric code provided by a hardware TOTP token.

If the MFA code is correct, the user can access the AWS Management Console. If the code is incorrect, the user can try again with another code.

A hardware TOTP token can go out of sync. If a user can't sign in to the AWS Management Console after several tries, the user is prompted to synchronize the MFA token device. The user can follow the on-screen prompts to synchronize the MFA token device. For information about how you can synchronize a device on behalf of a user in your AWS account, see [Resynchronizing virtual and hardware MFA devices](#).

Managing IAM users

Note

As a [best practice](#), we recommend that you require human users to use federation with an identity provider to access AWS using temporary credentials. If you follow the best

practices, you are not managing IAM users and groups. Instead, your users and groups are managed outside of AWS and are able to access AWS resources as a *federated identity*. A federated identity is a user from your enterprise user directory, a web identity provider, the AWS Directory Service, the Identity Center directory, or any user that accesses AWS services by using credentials provided through an identity source. Federated identities use the groups defined by their identity provider. If you are using AWS IAM Identity Center, see [Manage identities in IAM Identity Center](#) in the *AWS IAM Identity Center User Guide* for information about creating users and groups in IAM Identity Center.

Amazon Web Services offers multiple tools for managing the IAM users in your AWS account. You can list the IAM users in your account or in a user group, or list all user groups that a user is a member of. You can rename or change the path of an IAM user. If you are moving to using federated identities instead of IAM users, you can delete an IAM user from your AWS account, or deactivate the user.

For more information about adding, changing, or removing managed policies for an IAM user, see [Changing permissions for an IAM user](#). For information about managing inline policies for IAM users, see [Adding and removing IAM identity permissions](#), [Editing IAM policies](#), and [Deleting IAM policies](#). As a best practice, use managed policies instead of inline policies. *AWS managed policies* grant permissions for many common use cases. Keep in mind that AWS managed policies might not grant least-privilege permissions for your specific use cases because they are available for use by all AWS customers. As a result, we recommend that you reduce permissions further by defining [customer managed policies](#) that are specific to your use cases. For more information, see [AWS managed policies](#). For more information about AWS managed policies that are designed for specific job functions, see [AWS managed policies for job functions](#).

To learn about validating IAM policies, see [Validating IAM policies](#).

Tip

[IAM Access Analyzer](#) can analyze the services and actions that your IAM roles use, and then generate a fine-grained policy that you can use. After you test each generated policy, you can deploy the policy to your production environment. This ensures that you grant only the required permissions to your workloads. For more information about policy generation, see [IAM Access Analyzer policy generation](#).

For information about managing IAM user passwords, see [Managing passwords for IAM users](#),

Topics

- [View user access](#)
- [Listing IAM users](#)
- [Renaming an IAM user](#)
- [Deleting an IAM user](#)
- [Deactivating an IAM user](#)

View user access

Before you delete a user, you should review its recent service-level activity. This is important because you don't want to remove access from a principal (person or application) who is using it. For more information about viewing last accessed information, see [Refining permissions in AWS using last accessed information](#).

Listing IAM users

You can list the IAM users in your AWS account or in a specific IAM user group, and list all the user groups that a user is in. For information about the permissions that you need in order to list users, see [Permissions required to access IAM resources](#).

To list all the users in the account

- [AWS Management Console](#): In the navigation pane, choose **Users**. The console displays the users in your AWS account.
- AWS CLI: [aws iam list-users](#)
- AWS API: [ListUsers](#)

To list the users in a specific user group

- [AWS Management Console](#): In the navigation pane, choose **User groups**, choose the name of the user group, and then choose the **Users** tab.
- AWS CLI: [aws iam get-group](#)
- AWS API: [GetGroup](#)

To list all the user groups that a user is in

- [AWS Management Console](#): In the navigation pane, choose **Users**, choose the user name, and then choose the **Groups** tab.
- AWS CLI: [aws iam list-groups-for-user](#)
- AWS API: [ListGroupsWithUser](#)

Renaming an IAM user

To change a user's name or path, you must use the AWS CLI, Tools for Windows PowerShell, or AWS API. There is no option in the console to rename a user. For information about the permissions that you need in order to rename a user, see [Permissions required to access IAM resources](#).

When you change a user's name or path, the following happens:

- Any policies attached to the user stay with the user under the new name.
- The user stays in the same user groups under the new name.
- The unique ID for the user remains the same. For more information about unique IDs, see [Unique identifiers](#).
- Any resource or role policies that refer to the user *as a principal* (the user is being granted access) are automatically updated to use the new name or path. For example, any queue-based policies in Amazon SQS or resource-based policies in Amazon S3 are automatically updated to use the new name and path.

IAM does not automatically update policies that refer to the user *as a resource* to use the new name or path; you must manually do that. For example, imagine that user Richard has a policy attached to him that lets him manage his security credentials. If an administrator renames Richard to Rich, the administrator also needs to update that policy to change the resource from this:

```
arn:aws:iam::111122223333:user/division_abc/subdivision_xyz/Richard
```

to this:

```
arn:aws:iam::111122223333:user/division_abc/subdivision_xyz/Rich
```

This is true also if an administrator changes the path; the administrator needs to update the policy to reflect the new path for the user.

To rename a user

- AWS CLI: [aws iam update-user](#)
- AWS API: [UpdateUser](#)

Deleting an IAM user

You might delete an IAM user from your AWS account if that user quits your company. If the user is away temporarily, you can deactivate the user's access instead of deleting them from the account as described in [Deactivating an IAM user](#).

Topics

- [Deleting an IAM user \(console\)](#)
- [Deleting an IAM user \(AWS CLI\)](#)

Deleting an IAM user (console)

When you use the AWS Management Console to delete an IAM user, IAM automatically deletes the following information for you:

- The user
- Any user group memberships—that is, the user is removed from any IAM user groups that the user was a member of
- Any password associated with the user
- Any access keys belonging to the user
- All inline policies embedded in the user (policies that are applied to a user via user group permissions are not affected)

Note

IAM removes any managed policies attached to the user when you delete the user, but does not delete managed policies.

- Any associated MFA device

To delete an IAM user (console)

1. Sign in to the AWS Management Console and open the IAM console at <https://console.aws.amazon.com/iam/>.
2. In the navigation pane, choose **Users**, and then select the check box next to the user name that you want to delete.
3. At the top of the page, choose **Delete**.
4. In the confirmation dialog box, enter the username in the text input field to confirm the deletion of the user. Choose **Delete**.

Deleting an IAM user (AWS CLI)

Unlike the AWS Management Console, when you delete a user with the AWS CLI, you must delete the items attached to the user manually. This procedure illustrates the process.

To delete a user from your account (AWS CLI)

1. Delete the user's password, if the user has one.
[aws iam delete-login-profile](#)
2. Delete the user's access keys, if the user has them.
[aws iam list-access-keys](#) (to list the user's access keys) and [aws iam delete-access-key](#)
3. Delete the user's signing certificate. Note that when you delete a security credential, it's gone forever and can't be retrieved.
[aws iam list-signing-certificates](#) (to list the user's signing certificates) and [aws iam delete-signing-certificate](#)
4. Delete the user's SSH public key, if the user has them.
[aws iam list-ssh-public-keys](#) (to list the user's SSH public keys) and [aws iam delete-ssh-public-key](#)
5. Delete the user's Git credentials.
[aws iam list-service-specific-credentials](#) (to list the user's git credentials) and [aws iam delete-service-specific-credential](#)
6. Deactivate the user's multi-factor authentication (MFA) device, if the user has one.

[aws iam list-mfa-devices](#) (to list the user's MFA devices), [aws iam deactivate-mfa-device](#) (to deactivate the device), and [aws iam delete-virtual-mfa-device](#) (to permanently delete a virtual MFA device)

7. Delete the user's inline policies.

[aws iam list-user-policies](#) (to list the inline policies for the user) and [aws iam delete-user-policy](#) (to delete the policy)

8. Detach any managed policies that are attached to the user.

[aws iam list-attached-user-policies](#) (to list the managed policies attached to the user) and [aws iam detach-user-policy](#) (to detach the policy)

9. Remove the user from any user groups.

[aws iam list-groups-for-user](#) (to list the user groups to which the user belongs) and [aws iam remove-user-from-group](#)

10. Delete the user.

[aws iam delete-user](#)

Deactivating an IAM user

You might need to deactivate an IAM user while they are temporarily away from your company. You can leave their IAM user credentials in place and still block their AWS access.

To deactivate a user, create and attach a policy to deny the user access to AWS. You can restore the user's access later.

Here are two examples of deny policies that you can attach to a user to deny their access.

The following policy does not include a time limit. You must remove the policy to restore the user's access.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Deny",
      "Action": "*"
    }
  ]
}
```

```
    "Resource": "*"
  }
]
}
```

The following policy includes a condition that starts the policy on December 24, 2024 at 11:59 PM (UTC) and ends it on February 28, 2025 at 11:59 PM (UTC).

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Deny",
      "Action": "*",
      "Resource": "*",
      "Condition": {
        "DateGreaterThan": {"aws:CurrentTime": "2024-12-24T23:59:59Z"},
        "DateLessThan": {"aws:CurrentTime": "2025-02-28T23:59:59Z"}
      }
    }
  ]
}
```

Changing permissions for an IAM user

You can change the permissions for an IAM user in your AWS account by changing its group memberships, by copying permissions from an existing user, by attaching policies directly to a user, or by setting a [permissions boundary](#). A permissions boundary controls the maximum permissions that a user can have. Permissions boundaries are an advanced AWS feature.

For information about the permissions that you need in order to modify the permissions for a user, see [Permissions required to access IAM resources](#).

Topics

- [View user access](#)
- [Generate a policy based on a user's access activity](#)
- [Adding permissions to a user \(console\)](#)
- [Changing permissions for a user \(console\)](#)
- [Removing a permissions policy from a user \(console\)](#)

- [Removing the permissions boundary from a user \(console\)](#)
- [Adding and removing a user's permissions \(AWS CLI or AWS API\)](#)

View user access

Before you change the permissions for a user, you should review its recent service-level activity. This is important because you don't want to remove access from a principal (person or application) who is using it. For more information about viewing last accessed information, see [Refining permissions in AWS using last accessed information](#).

Generate a policy based on a user's access activity

You might sometimes grant permissions to an IAM entity (user or role) beyond what they require. To help you refine the permissions that you grant, you can generate an IAM policy that is based on the access activity for an entity. IAM Access Analyzer reviews your AWS CloudTrail logs and generates a policy template that contains the permissions that have been used by the entity in your specified date range. You can use the template to create a managed policy with fine-grained permissions and then attach it to the IAM entity. That way, you grant only the permissions that the user or role needs to interact with AWS resources for your specific use case. To learn more, see [Generate policies based on access activity](#).

Adding permissions to a user (console)

IAM offers three ways to add permissions policies to a user:

- **Add user to group** – Make the user a member of a group. The policies from the group are attached to the user.
- **Copy permissions from existing user** – Copy all group memberships, attached managed policies, inline policies, and any existing permissions boundaries from the source user.
- **Attach policies directly to user** – Attach a managed policy directly to the user. For easier permissions management, attach your policies to a group and then make users members of the appropriate groups.

Important

If the user has a permissions boundary, then you cannot add more permissions to a user than are allowed by the permissions boundary.

Adding permissions by adding the user to a group

Adding a user to a group affects the user immediately.

To add permissions to a user by adding the user to a group

1. Sign in to the AWS Management Console and open the IAM console at <https://console.aws.amazon.com/iam/>.
 2. In the navigation pane, choose **Users**.
 3. Review the current group memberships for users in the **Groups** column of the console. If necessary, add the column to the users table by completing the following steps:
 1. Above the table on the far right, choose the settings symbol
().
 2. In the **Manage Columns** dialog box, select the **Groups** column. Optionally, you can also clear the check box for any column headings that you do not want to appear in the users table.
 3. Choose **Close** to return to the list of users.
- The **Groups** column tells you to which groups the user belongs. The column includes the group names for up to two groups. If the user is a member of three or more groups, the first two groups are shown (ordered alphabetically), and the number of additional group memberships is included. For example, if the user belongs to Group A, Group B, Group C, and Group D, then the field contains the value **Group A, Group B + 2 more**. To see the total number of groups to which the user belongs, you can add the **Group count** column to the users table.
4. Choose the name of the user whose permissions you want to modify.
 5. Choose the **Permissions** tab, and then choose **Add permissions**. Choose **Add user to group**.
 6. Select the check box for each group that you want the user to join. The list shows each group's name and the policies that the user receives if made a member of that group.
 7. (Optional) In addition to selecting from existing groups, you can choose **Create group** to define a new group:
 - a. In the new tab, for **User group name**, type a name for your new group.

Note

The number and size of IAM resources in an AWS account are limited. For more information, see [IAM and AWS STS quotas](#). Group names can be a combination of up to 128 letters, digits, and these characters: plus (+), equal (=), comma (,), period (.), at sign (@), and hyphen (-). Names must be unique within an account. They are not distinguished by case. For example, you cannot create two groups named *TESTGROUP* and *testgroup*.

- b. Select one or more check boxes for the managed policies that you want to attach to the group. You can also create a new managed policy by choosing **Create policy**. If you do, return to this browser tab or window when the new policy is done; choose **Refresh**; and then choose the new policy to attach it to your group. For more information, see [Creating IAM policies](#).
 - c. Choose **Create user group**.
 - d. Return to the original tab, refresh your list of groups. Then select the check box for your new group.
8. Choose **Next** to see the list of group memberships to be added to the user. Then choose **Add permissions**.

Adding permissions by copying from another user

Copying permissions affects the user immediately.

To add permissions to a user by copying permissions from another user

1. Sign in to the AWS Management Console and open the IAM console at <https://console.aws.amazon.com/iam/>.
2. Choose **Users** in the navigation pane, choose the name of the user whose permissions you want to modify, and then choose the **Permissions** tab.
3. Choose **Add permissions**, and then choose **Copy permissions from existing user**. The list displays available users along with their group memberships and attached policies. If the full list of groups or policies doesn't fit on one line, you can choose the link for **and *n* more**. Doing that opens a new browser tab and see the full list of policies (**Permissions** tab) and groups (**Groups** tab).
4. Select the radio button next to the user whose permissions you want to copy.

5. Choose **Next** to see the list of changes that are to be made to the user. Then choose **Add permissions**.

Adding permissions by attaching policies directly to the user

Attaching policies affects the user immediately.

To add permissions to a user by directly attaching managed policies

1. Sign in to the AWS Management Console and open the IAM console at <https://console.aws.amazon.com/iam/>.
2. Choose **Users** in the navigation pane, choose the name of the user whose permissions you want to modify, and then choose the **Permissions** tab.
3. Choose **Add permissions**, and then choose **Attach policies directly**.
4. Select one or more check boxes for the managed policies that you want to attach to the user. You can also create a new managed policy by choosing **Create policy**. If you do, return to this browser tab or window when the new policy is done. Choose **Refresh**; and then select the check box for the new policy to attach it to your user. For more information, see [Creating IAM policies](#).
5. Choose **Next** to see the list of policies that are to be attached to the user. Then choose **Add permissions**.

Setting the permissions boundary for a user

Setting a permissions boundary affects the user immediately.

To set the permissions boundary for a user

1. Sign in to the AWS Management Console and open the IAM console at <https://console.aws.amazon.com/iam/>.
2. In the navigation pane, choose **Users**.
3. Choose the name of the user whose permissions boundary you want to change.
4. Choose the **Permissions** tab. If necessary, open the **Permissions boundary** section and then choose **Set permissions boundary**.
5. Select the policy that you want to use for the permissions boundary.
6. Choose **Set boundary**.

Changing permissions for a user (console)

IAM allows you to change the permissions that are associated with a user in the following ways:

- **Edit a permissions policy** – Edit a user's inline policy, the inline policy of the user's group, or edit a managed policy that is attached to the user directly or from a group. If the user has a permissions boundary, then you cannot provide more permissions than are allowed by the policy that was used as the user's permissions boundary.
- **Changing the permissions boundary** – Change the policy that is used as the permissions boundary for the user. This can expand or restrict the maximum permissions that a user can have.

Editing a permissions policy attached to a user

Changing permissions affects the user immediately.

To edit a user's attached managed policies

1. Sign in to the AWS Management Console and open the IAM console at <https://console.aws.amazon.com/iam/>.
2. In the navigation pane, choose **Users**.
3. Choose the name of the user whose permissions policy you want to change.
4. Choose the **Permissions** tab. If necessary, open the **Permissions policies** section.
5. Choose the name of the policy that you want to edit to view details about the policy. Choose the **Policy usage** tab to view other entities that might be affected if you edit the policy.
6. Choose the **Permissions** tab and review the permissions granted by the policy. Then choose **Edit policy**.
7. Edit the policy and resolve any [policy validation](#) recommendations. For more information, see [Editing IAM policies](#).
8. Choose **Review policy**, review the policy summary, and then choose **Save changes**.

Changing the permissions boundary for a user

Changing a permissions boundary affects the user immediately.

To change the policy used to set the permissions boundary for a user

1. Sign in to the AWS Management Console and open the IAM console at <https://console.aws.amazon.com/iam/>.
2. In the navigation pane, choose **Users**.
3. Choose the name of the user whose permissions boundary you want to change.
4. Choose the **Permissions** tab. If necessary, open the **Permissions boundary** section and then choose **Change boundary**.
5. Select the policy that you want to use for the permissions boundary.
6. Choose **Set boundary**.

Removing a permissions policy from a user (console)

Removing a policy affects the user immediately.

To remove permissions for IAM users

1. Sign in to the AWS Management Console and open the IAM console at <https://console.aws.amazon.com/iam/>.
2. In the navigation pane, choose **Users**.
3. Choose the name of the user whose permissions boundary you want to remove.
4. Choose the **Permissions** tab.
5. If you want to remove permissions by removing an existing policy, view the **Type** to understand how the user is getting that policy before choosing **Remove** to remove the policy:
 - If the policy applies because of group membership, then choosing **Remove** removes the user from the group. Remember that you might have multiple policies attached to a single group. If you remove a user from a group, the user loses access to *all* policies that it received through that group membership.
 - If the policy is a managed policy attached directly to the user, then choosing **Remove** detaches the policy from the user. This does not affect the policy itself or any other entity that the policy might be attached to.
 - If the policy is an inline embedded policy, then choosing **X** removes the policy from IAM. Inline policies that are attached directly to a user exist only on that user.

Removing the permissions boundary from a user (console)

Removing a permissions boundary affects the user immediately.

To remove the permissions boundary from a user

1. Sign in to the AWS Management Console and open the IAM console at <https://console.aws.amazon.com/iam/>.
2. In the navigation pane, choose **Users**.
3. Choose the name of the user whose permissions boundary you want to remove.
4. Choose the **Permissions** tab. If necessary, open the **Permissions boundary** section and then choose **Remove boundary**.
5. Choose **Remove boundary** to confirm that you want to remove the permissions boundary.

Adding and removing a user's permissions (AWS CLI or AWS API)

To add or remove permissions programmatically, you must add or remove the group memberships, attach or detach the managed policies, or add or delete the inline policies. For more information, see the following topics:

- [Adding and removing users in an IAM user group](#)
- [Adding and removing IAM identity permissions](#)

Managing user passwords in AWS

You can manage passwords for IAM users in your account. IAM users need passwords in order to access the AWS Management Console. Users do not need passwords to access AWS resources programmatically by using the AWS CLI, Tools for Windows PowerShell, the AWS SDKs or APIs. For those environments, you have the option of assigning IAM users [access keys](#). However, there are other more secure alternatives to access keys that we recommend you consider first. For more information, see [AWS security credentials](#).

Contents

- [Setting an account password policy for IAM users](#)
- [Managing passwords for IAM users](#)

- [Permitting IAM users to change their own passwords](#)
- [How an IAM user changes their own password](#)

Setting an account password policy for IAM users

You can set a custom password policy on your AWS account to specify complexity requirements and mandatory rotation periods for your IAM users' passwords. If you don't set a custom password policy, IAM user passwords must meet the default AWS password policy. For more information, see [Custom password policy options](#).

Topics

- [Rules for setting a password policy](#)
- [Permissions required to set a password policy](#)
- [Default password policy](#)
- [Custom password policy options](#)
- [Setting a password policy \(console\)](#)
- [Setting a password policy \(AWS CLI\)](#)
- [Setting a password policy \(AWS API\)](#)

Rules for setting a password policy

The IAM password policy does not apply to the AWS account root user password or IAM user access keys. If a password expires, the IAM user can't sign in to the AWS Management Console but can continue to use their access keys.

When you create or change a password policy, most of the password policy settings are enforced the next time your users change their passwords. However, some of the settings are enforced immediately. For example:

- When the minimum length and character type requirements change, these settings are enforced the next time that your users change their passwords. Users are not forced to change their existing passwords, even if the existing passwords do not adhere to the updated password policy.
- When you set a password expiration period, the expiration period is enforced immediately. For example, assume that you set a password expiration period of 90 days. In that case, the password expires for all IAM users whose existing password is older than 90 days. Those users are required to change their password the next time that they sign in.

You can't create a "lockout policy" to lock a user out of the account after a specified number of failed sign-in attempts. For enhanced security, we recommend that you combine a strong password policy with multi-factor authentication (MFA). For more information about MFA, see [Using multi-factor authentication \(MFA\) in AWS](#).

Permissions required to set a password policy

You must configure permissions to allow an IAM entity (user or role) to view or edit their account password policy. You can include the following password policy actions in an IAM policy:

- `iam:GetAccountPasswordPolicy` – Allows the entity to view the password policy for their account
- `iam:DeleteAccountPasswordPolicy` – Allows the entity to delete the custom password policy for their account and revert to the default password policy
- `iam:UpdateAccountPasswordPolicy` – Allows the entity to create or change the custom password policy for their account

The following policy allows full access to view and edit the account password policy. To learn how to create an IAM policy using this example JSON policy document, see [the section called "Creating policies using the JSON editor"](#).

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "FullAccessPasswordPolicy",
      "Effect": "Allow",
      "Action": [
        "iam:GetAccountPasswordPolicy",
        "iam:DeleteAccountPasswordPolicy",
        "iam:UpdateAccountPasswordPolicy"
      ],
      "Resource": "*"
    }
  ]
}
```

For information about the permissions required for an IAM user to change their own password, see [Permitting IAM users to change their own passwords](#).

Default password policy

If an administrator does not set a custom password policy, IAM user passwords must meet the default AWS password policy.

The default password policy enforces the following conditions:

- Minimum password length of 8 characters and a maximum length of 128 characters
- Minimum of three of the following mix of character types: uppercase, lowercase, numbers, and non-alphanumeric character (! @ # \$ % ^ & * () _ + - = [] { } | ')
- Not be identical to your AWS account name or email address
- Never expire password

Custom password policy options

When you configure a custom password policy for your account, you can specify the following conditions:

- **Password minimum length** – You can specify a minimum of 6 characters and a maximum of 128 characters.
- **Password strength** – You can select any of the following check boxes to define the strength of your IAM user passwords:
 - Require at least one uppercase letter from the Latin alphabet (A–Z)
 - Require at least one lowercase letter from the Latin alphabet (a–z)
 - Require at least one number
 - Require at least one nonalphanumeric character ! @ # \$ % ^ & * () _ + - = [] { } | '
- **Turn on password expiration** – You can select and specify a minimum of 1 and a maximum of 1,095 days that IAM user passwords are valid after they are set. For example, if you specify an expiration of 90 days, it immediately impacts all of your users. For users with passwords older than 90 days, when they log into the console after the change, they must set a new password. Users with passwords 75–89 days old receive an AWS Management Console warning about their password expiration. IAM users can change their password at any time if they have permission. When they set a new password, the expiration period for that password starts over. An IAM user can have only one valid password at a time.

- **Password expiration requires administrator reset** – Select this option to prevent IAM users from using the AWS Management Console to update their own passwords after the password expires. Before you select this option, confirm that your AWS account has more than one user with administrative permissions to reset IAM user passwords. Administrators with `iam:UpdateLoginProfile` permission can reset IAM user passwords. IAM users with `iam:ChangePassword` permission and active access keys can reset their own IAM user console password programmatically. If you clear this check box, IAM users with expired passwords must still set a new password before they can access the AWS Management Console.
- **Allow users to change their own password** – You can permit all IAM users in your account to change their own password. This gives users access to the `iam:ChangePassword` action for only their user and to the `iam:GetAccountPasswordPolicy` action. This option does not attach a permissions policy to each user. Rather, IAM applies the permissions at the account-level for all users. Alternatively, you can allow only some users to manage their own passwords. To do so, you clear this check box. For more information about using policies to limit who can manage passwords, see [Permitting IAM users to change their own passwords](#).
- **Prevent password reuse** – You can prevent IAM users from reusing a specified number of previous passwords. You can specify a minimum number of 1 and a maximum number of 24 previous passwords that can't be repeated.

Setting a password policy (console)

You can use the AWS Management Console to create, change, or delete a custom password policy.

To create a custom password policy (console)

1. Sign in to the AWS Management Console and open the IAM console at <https://console.aws.amazon.com/iam/>.
2. In the navigation pane, choose **Account settings**.
3. In the **Password policy** section, choose **Edit**.
4. Choose **Custom** to use a custom password policy.
5. Select the options that you want to apply to your password policy and choose **Save changes**.
6. Confirm that you want to set a custom password policy by choosing **Set custom**.

To change a custom password policy (console)

1. Sign in to the AWS Management Console and open the IAM console at <https://console.aws.amazon.com/iam/>.
2. In the navigation pane, choose **Account settings**.
3. In the **Password policy** section, choose **Edit**.
4. Select the options that you want to apply to your password policy and choose **Save changes**.
5. Confirm that you want to set a custom password policy by choosing **Set custom**.

To delete a custom password policy (console)

1. Sign in to the AWS Management Console and open the IAM console at <https://console.aws.amazon.com/iam/>.
2. In the navigation pane, choose **Account settings**.
3. In the **Password policy** section, choose **Edit**.
4. Choose **IAM default** to delete the custom password policy and choose **Save changes**.
5. Confirm that you want to set the IAM default password policy by choosing **Set default**.

Setting a password policy (AWS CLI)

You can use the AWS Command Line Interface to set a password policy.

To manage the custom account password policy from the AWS CLI

Run the following commands:

- To create or change the custom password policy: [aws iam update-account-password-policy](#)
- To view the password policy: [aws iam get-account-password-policy](#)
- To delete the custom password policy: [aws iam delete-account-password-policy](#)

Setting a password policy (AWS API)

You can use AWS API operations to set a password policy.

To manage the custom account password policy from the AWS API

Call the following operations:

- To create or change the custom password policy: [UpdateAccountPasswordPolicy](#)
- To view the password policy: [GetAccountPasswordPolicy](#)
- To delete the custom password policy: [DeleteAccountPasswordPolicy](#)

Managing passwords for IAM users

IAM users who use the AWS Management Console to work with AWS resources must have a password in order to sign in. You can create, change, or delete a password for an IAM user in your AWS account.

After you have assigned a password to a user, the user can sign in to the AWS Management Console using the sign-in URL for your account, which looks like this:

```
https://12-digit-AWS-account-ID or alias.signin.aws.amazon.com/console
```

For more information about how IAM users sign in to the AWS Management Console, see [How to sign in to AWS](#) in the *AWS Sign-In User Guide*.

Even if your users have their own passwords, they still need permissions to access your AWS resources. By default, a user has no permissions. To give your users the permissions they need, you assign policies to them or to the groups they belong to. For information about creating users and groups, see [IAM Identities \(users, user groups, and roles\)](#). For information about using policies to set permissions, see [Changing permissions for an IAM user](#).

You can grant users permission to change their own passwords. For more information, see [Permitting IAM users to change their own passwords](#). For information about how users access your account sign-in page, see [How to sign in to AWS](#) in the *AWS Sign-In User Guide*.

Topics

- [Creating, changing, or deleting an IAM user password \(console\)](#)
- [Creating, changing, or deleting an IAM user password \(AWS CLI\)](#)
- [Creating, changing, or deleting an IAM user password \(AWS API\)](#)

Creating, changing, or deleting an IAM user password (console)

You can use the AWS Management Console to manage passwords for your IAM users.

When users leave your organization or no longer need AWS access, it is important to find the credentials that they were using and ensure that they are no longer operational. Ideally, you delete credentials if they are no longer needed. You can always recreate them at a later date if the need arises. At the very least, you should change the credentials so that the former users no longer have access.

To add a password for an IAM user (console)

1. Sign in to the AWS Management Console and open the IAM console at <https://console.aws.amazon.com/iam/>.
2. In the navigation pane, choose **Users**.
3. Choose the name of the user whose password you want to create.
4. Choose the **Security credentials** tab, and then under **Console sign-in**, choose **Enable console access**.
5. In **Manage console access**, for **Console access** choose **Enable** if not already selected. If console access is disabled, then no password is needed.
6. For **Set password**, choose whether to have IAM generate a password or create a custom password:
 - To have IAM generate a password, choose **Autogenerated password**.
 - To create a custom password, choose **Custom password**, and type the password.

Note

The password that you create must meet the account's [password policy](#).

7. To require the user to create a new password when signing in, choose **User must create a new password at next sign-in**. Then choose **Apply**.

Important

If you select the **User must create a new password at next sign-in** option, make sure that the user has permission to change his or her password. For more information, see [Permitting IAM users to change their own passwords](#).

8. If you choose the option to generate a password, choose **Show** in the **Console password** dialog box. This lets you view the password so you can share it with the user.

⚠ Important

For security reasons, you cannot access the password after completing this step, but you can create a new password at any time.

To change the password for an IAM user (console)

1. Sign in to the AWS Management Console and open the IAM console at <https://console.aws.amazon.com/iam/>.
2. In the navigation pane, choose **Users**.
3. Choose the name of the user whose password you want to change.
4. Choose the **Security credentials** tab, and then under **Console sign-in**, choose **Manage console access**.
5. In **Manage console access**, for **Console access** choose **Enable** if not already selected. If console access is disabled, then no password is needed.
6. For **Set password**, choose whether to have IAM generate a password or create a custom password:
 - To have IAM generate a password, choose **Autogenerated password**.
 - To create a custom password, choose **Custom password**, and type the password.

ℹ Note

The password that you create must meet the account's [password policy](#), if one is currently set.

7. To require the user to create a new password when signing in, choose **User must create a new password at next sign-in**. Then choose **Apply**.

⚠ Important

If you select the **User must create a new password at next sign-in** option, make sure that the user has permission to change his or her password. For more information, see [Permitting IAM users to change their own passwords](#).

8. If you choose the option to generate a password, choose **Show** in the **Console password** dialog box. This lets you view the password so you can share it with the user.

⚠ Important

For security reasons, you cannot access the password after completing this step, but you can create a new password at any time.

To delete (disable) an IAM user password (console)

1. Sign in to the AWS Management Console and open the IAM console at <https://console.aws.amazon.com/iam/>.
2. In the navigation pane, choose **Users**.
3. Choose the name of the user whose password you want to delete.
4. Choose the **Security credentials** tab, and then under **Console sign-in**, choose **Manage console access**.
5. For **Console access**, choose **Disable**, and then choose **Apply**.

⚠ Important

You can prevent an IAM user from accessing the AWS Management Console by removing their password. This prevents them from signing in to the AWS Management Console using their sign-in credentials. It does not change their permissions or prevent them from accessing the console using an assumed role. If the user has active access keys, they continue to function and allow access through the AWS CLI, Tools for Windows PowerShell, AWS API, or the AWS Console Mobile Application.

Creating, changing, or deleting an IAM user password (AWS CLI)

You can use the AWS CLI API to manage passwords for your IAM users.

To create a password (AWS CLI)

1. (Optional) To determine whether a user has a password, run this command: [aws iam get-login-profile](#)

2. To create a password, run this command: [aws iam create-login-profile](#)

To change a user's password (AWS CLI)

1. (Optional) To determine whether a user has a password, run this command: [aws iam get-login-profile](#)
2. To change a password, run this command: [aws iam update-login-profile](#)

To delete (disable) a user's password (AWS CLI)

1. (Optional) To determine whether a user has a password, run this command: [aws iam get-login-profile](#)
2. (Optional) To determine when a password was last used, run this command: [aws iam get-user](#)
3. To delete a password, run this command: [aws iam delete-login-profile](#)

Important

When you delete a user's password, the user can no longer sign in to the AWS Management Console. If the user has active access keys, they continue to function and allow access through the AWS CLI, Tools for Windows PowerShell, or AWS API function calls. When you use the AWS CLI, Tools for Windows PowerShell, or AWS API to delete a user from your AWS account, you must first delete the password using this operation. For more information, see [Deleting an IAM user \(AWS CLI\)](#).

Creating, changing, or deleting an IAM user password (AWS API)

You can use the AWS API to manage passwords for your IAM users.

To create a password (AWS API)

1. (Optional) To determine whether a user has a password, call this operation: [GetLoginProfile](#)
2. To create a password, call this operation: [CreateLoginProfile](#)

To change a user's password (AWS API)

1. (Optional) To determine whether a user has a password, call this operation: [GetLoginProfile](#)

2. To change a password, call this operation: [UpdateLoginProfile](#)

To delete (disable) a user's password (AWS API)

1. (Optional) To determine whether a user has a password, run this command: [GetLoginProfile](#)
2. (Optional) To determine when a password was last used, run this command: [GetUser](#)
3. To delete a password, run this command: [DeleteLoginProfile](#)

Important

When you delete a user's password, the user can no longer sign in to the AWS Management Console. If the user has active access keys, they continue to function and allow access through the AWS CLI, Tools for Windows PowerShell, or AWS API function calls. When you use the AWS CLI, Tools for Windows PowerShell, or AWS API to delete a user from your AWS account, you must first delete the password using this operation. For more information, see [Deleting an IAM user \(AWS CLI\)](#).

Permitting IAM users to change their own passwords

Note

Users with federated identities will use the process defined by their identity provider to change their passwords. As a [best practice](#), require human users to use federation with an identity provider to access AWS using temporary credentials.

You can grant IAM users the permission to change their own passwords for signing in to the AWS Management Console. You can do this in one of two ways:

- [Allow all IAM users in the account to change their own passwords.](#)
- [Allow only selected IAM users to change their own passwords.](#) In this scenario, you disable the option for all users to change their own passwords and you use an IAM policy to grant permissions to only some users. This approach allows those users to change their own passwords and optionally other credentials like their own access keys.

⚠ Important

We recommend that you [set a custom password policy](#) that requires IAM users to create strong passwords.

To allow all IAM users change their own passwords

1. Sign in to the AWS Management Console and open the IAM console at <https://console.aws.amazon.com/iam/>.
2. In the navigation pane, click **Account settings**.
3. In the **Password policy** section, choose **Edit**.
4. Choose **Custom** to use a custom password policy.
5. Select **Allow users to change their own password**, and then choose **Save changes**. This allows all users in the account access to the `iam:ChangePassword` action for only their user and to the `iam:GetAccountPasswordPolicy` action.
6. Provide users with the following instructions for changing their passwords: [How an IAM user changes their own password](#).

For information about the AWS CLI, Tools for Windows PowerShell, and API commands that you can use to change the account's password policy (which includes letting all users change their own passwords), see [Setting a password policy \(AWS CLI\)](#).

To allow selected IAM users change their own passwords

1. Sign in to the AWS Management Console and open the IAM console at <https://console.aws.amazon.com/iam/>.
2. In the navigation pane, click **Account settings**.
3. In the **Password policy** section, make sure that **Allow users to change their own password** is not selected. If this check box is selected, all users can change their own passwords. (See the previous procedure.)
4. Create the users who should be allowed to change their own password, if they do not already exist. For details, see [Creating an IAM user in your AWS account](#).

5. (Optional) Create an IAM group for the users who should be allowed to change their passwords, and then add the users from the previous step to the group. For details, see [Managing IAM user groups](#).
6. Assign the following policy to the group. For more information, see [Managing IAM policies](#).

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": "iam:GetAccountPasswordPolicy",
      "Resource": "*"
    },
    {
      "Effect": "Allow",
      "Action": "iam:ChangePassword",
      "Resource": "arn:aws:iam::*:user/${aws:username}"
    }
  ]
}
```

This policy grants access to the [ChangePassword](#) action, which lets users change only their own passwords from the console, the AWS CLI, Tools for Windows PowerShell, or the API. It also grants access to the [GetAccountPasswordPolicy](#) action, which lets the user view the current password policy; this permission is required so that the user can view the account password policy on the **Change password** page. The user must be allowed to read the current password policy to ensure that the changed password meets the requirements of the policy.

7. Provide users with the following instructions for changing their passwords: [How an IAM user changes their own password](#).

For more information

For more information on managing credentials, see the following topics:

- [Permitting IAM users to change their own passwords](#)
- [Managing user passwords in AWS](#)
- [Setting an account password policy for IAM users](#)
- [Managing IAM policies](#)

- [How an IAM user changes their own password](#)

How an IAM user changes their own password

If you have been granted permission to change your own IAM user password, you can use a special page in the AWS Management Console to do this. You can also use the AWS CLI or AWS API.

Topics

- [Permissions required](#)
- [How IAM users change their own password \(console\)](#)
- [How IAM users change their own password \(AWS CLI or AWS API\)](#)

Permissions required

To change the password for your own IAM user, you must have the permissions from the following policy: [AWS: Allows IAM users to change their own console password on the Security credentials page](#).

How IAM users change their own password (console)

The following procedure describes how IAM users can use the AWS Management Console to change their own password.

To change your own IAM user password (console)

1. Use your AWS account ID or account alias, your IAM user name, and your password to sign in to the [IAM console](#).

Note

For your convenience, the AWS sign-in page uses a browser cookie to remember your IAM user name and account information. If you previously signed in as a different user, choose **Sign in to a different account** near the bottom of the page to return to the main sign-in page. From there, you can type your AWS account ID or account alias to be redirected to the IAM user sign-in page for your account.

To get your AWS account ID, contact your administrator.

2. In the navigation bar on the upper right, choose your user name, and then choose **Security credentials**.

3. On the **AWS IAM credentials** tab, choose **Update password**.
4. For **Current password**, enter your current password. Enter a new password for **New password** and **Confirm new password**. Then choose **Update password**.

Note

The new password must meet the requirements of the account password policy. For more information, see [Setting an account password policy for IAM users](#).

How IAM users change their own password (AWS CLI or AWS API)

The following procedure describes how IAM users can use the AWS CLI or AWS API to change their own password.

To change your own IAM password, use the following:

- AWS CLI: [aws iam change-password](#)
- AWS API: [ChangePassword](#)

Managing access keys for IAM users

 [Follow us on Twitter](#)

Important

As a [best practice](#), use temporary security credentials (such as IAM roles) instead of creating long-term credentials like access keys. Before creating access keys, review the [alternatives to long-term access keys](#).

Access keys are long-term credentials for an IAM user or the AWS account root user. You can use access keys to sign programmatic requests to the AWS CLI or AWS API (directly or using the AWS SDK). For more information, see [Signing AWS API requests](#).

Access keys consist of two parts: an access key ID (for example, AKIAIOSFODNN7EXAMPLE) and a secret access key (for example, wJalrXUtnFEMI/K7MDENG/bPxrFiCYEXAMPLEKEY). You must use both the access key ID and secret access key together to authenticate your requests.

When you create an access key pair, save the access key ID and secret access key in a secure location. The secret access key is available only at the time you create it. If you lose your secret access key, you must delete the access key and create a new one. For more details, see [Resetting lost or forgotten passwords or access keys for AWS](#).

You can have a maximum of two access keys per user.

Important

Manage your access keys securely. Do not provide your access keys to unauthorized parties, even to help [find your account identifiers](#). By doing this, you might give someone permanent access to your account.

The following topics detail management tasks associated with access keys.

Topics

- [Permissions required to manage access keys](#)
- [Managing access keys \(console\)](#)
- [Managing access keys \(AWS CLI\)](#)

- [Managing access keys \(AWS API\)](#)
- [Updating access keys](#)
- [Securing access keys](#)
- [Auditing access keys](#)

Permissions required to manage access keys

Note

`iam:TagUser` is an optional permission for adding and editing descriptions for the access key. For more information, see [Tagging IAM users](#)

To create access keys for your own IAM user, you must have the permissions from the following policy:

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "CreateOwnAccessKeys",
      "Effect": "Allow",
      "Action": [
        "iam:CreateAccessKey",
        "iam:GetUser",
        "iam:ListAccessKeys",
        "iam:TagUser"
      ],
      "Resource": "arn:aws:iam::*:user/${aws:username}"
    }
  ]
}
```

To update access keys for your own IAM user, you must have the permissions from the following policy:

```
{
  "Version": "2012-10-17",
  "Statement": [
```

```
{
  "Sid": "ManageOwnAccessKeys",
  "Effect": "Allow",
  "Action": [
    "iam:CreateAccessKey",

```

Managing access keys (console)

You can use the AWS Management Console to manage the access keys of an IAM user.

To create, modify, or delete your own access keys (console)

1. Use your AWS account ID or account alias, your IAM user name, and your password to sign in to the [IAM console](#).

Note

For your convenience, the AWS sign-in page uses a browser cookie to remember your IAM user name and account information. If you previously signed in as a different user, choose **Sign in to a different account** near the bottom of the page to return to the main sign-in page. From there, you can type your AWS account ID or account alias to be redirected to the IAM user sign-in page for your account.

To get your AWS account ID, contact your administrator.

2. In the navigation bar on the upper right, choose your user name, and then choose **Security credentials**.

**Note**

The **Security credentials** tab is displayed only for the AWS account root user. IAM users can manage access keys from the navigation pane.

1. Choose **Users**.
2. In the Users list, choose the name of the IAM user.
3. Choose the **Security Credentials** tab. Under **Access keys**, choose **Create access key**.

Do one of the following:

To create an access key

1. In the **Access keys** section, choose **Create access key**. If you already have two access keys, this button is deactivated and you must delete an access key before you can create a new one.
2. On the **Access key best practices & alternatives** page, choose your use case to learn about additional options which can help you avoid creating a long-term access key. If you determine that your use case still requires an access key, choose **Other** and then choose **Next**.

3. (Optional) Set a description tag value for the access key. This adds a tag key-value pair to your IAM user. This can help you identify and update access keys later. The tag key is set to the access key id. The tag value is set to the access key description that you specify. When you are finished, choose **Create access key**.
4. On the **Retrieve access keys** page, choose either **Show** to reveal the value of your user's secret access key, or **Download .csv file**. This is your only opportunity to save your secret access key. After you've saved your secret access key in a secure location, choose **Done**.

To deactivate an access key

- In the **Access keys** section find the key you want to deactivate, then choose **Actions**, then choose **Deactivate**. When prompted for confirmation, choose **Deactivate**. A deactivated access key still counts toward your limit of two access keys.

To activate an access key

- In the **Access keys** section, find the key to activate, then choose **Actions**, then choose **Activate**.

To delete an access key when you no longer need it

- In the **Access keys** section, find the key you want to delete, then choose **Actions**, then choose **Delete**. Follow the instructions in the dialog to first **Deactivate** and then confirm the deletion. We recommend that you verify that the access key is no longer in use before you permanently delete it.

To create, modify, or delete the access keys of another IAM user (console)

1. Sign in to the AWS Management Console and open the IAM console at <https://console.aws.amazon.com/iam/>.
2. In the navigation pane, choose **Users**.
3. Choose the name of the user whose access keys you want to manage, and then choose the **Security credentials** tab.
4. In the **Access keys** section, do any of the following:
 - To create an access key, choose **Create access key**. If the button is deactivated, then you must delete one of the existing keys before you can create a new one. On the **Access key**

best practices & alternatives page, review the best practices and alternatives. Choose your use case to learn about additional options which can help you avoid creating a long-term access key. If you determine that your use case still requires an access key, choose **Other** and then choose **Next**. On the **Retrieve access key page**, choose **Show** to reveal the value of your user's secret access key. To save the access key ID and secret access key to a .csv file to a secure location on your computer, choose the **Download .csv file** button. When you create an access key for your user, that key pair is active by default, and your user can use the pair right away.

- To deactivate an active access key, choose **Actions**, and then choose **Deactivate**.
- To activate an inactive access key, choose **Actions**, and then choose **Activate**.
- To delete your access key, choose **Actions**, and then choose **Delete**. Follow the instructions in the dialog to first **Deactivate** and then confirm the deletion. AWS recommends that before you do this, you first deactivate the key and test that it's no longer in use. When you use the AWS Management Console, you must deactivate your key before deleting it.

To list the access keys for an IAM user (console)

1. Sign in to the AWS Management Console and open the IAM console at <https://console.aws.amazon.com/iam/>.
2. In the navigation pane, choose **Users**.
3. Choose the name of the intended user, and then choose the **Security credentials** tab. In the **Access keys** section, you will see the user's access keys and the status of each key displayed.

Note

Only the user's access key ID is visible. The secret access key can only be retrieved when the key is created.

To list the access key IDs for multiple IAM users (console)

1. Sign in to the AWS Management Console and open the IAM console at <https://console.aws.amazon.com/iam/>.
2. In the navigation pane, choose **Users**.
3. If necessary, add the **Access key ID** column to the users table by completing the following steps:

- a. Above the table on the far right, choose the settings icon
().
 - b. In **Manage columns**, select **Access key ID**.
 - c. Choose **Close** to return to the list of users.
4. The **Access key ID** column shows each access key ID, followed by its state; for example, **23478207027842073230762374023 (Active)** or **22093740239670237024843420327 (Inactive)**.

You can use this information to view and copy the access keys for users with one or two access keys. The column displays **None** for users with no access key.

 **Note**

Only the user's access key ID and status is visible. The secret access key can only be retrieved when the key is created.

To find which IAM user owns a specific access key (console)

1. Sign in to the AWS Management Console and open the IAM console at <https://console.aws.amazon.com/iam/>.
2. In the navigation pane, choose **Users**.
3. In the search box, type or paste the access key ID of the user you want to find.
4. If necessary, add the **Access key ID** column to the users table by completing the following steps:
 - a. Above the table on the far right, choose the settings icon
().
 - b. In **Manage columns**, select **Access key ID**.
 - c. Choose **Close** to return to the list of users and confirm that the filtered user owns the specified access key.

Managing access keys (AWS CLI)

To manage the IAM user access keys from the AWS CLI, run the following commands.

- To create an access key: [aws iam create-access-key](#)
- To deactivate or activate an access key: [aws iam update-access-key](#)
- To list a user's access keys: [aws iam list-access-keys](#)
- To determine when an access key was most recently used: [aws iam get-access-key-last-used](#)
- To delete an access key: [aws iam delete-access-key](#)

Managing access keys (AWS API)

To manage the access keys of an IAM user from the AWS API, call the following operations.

- To create an access key: [CreateAccessKey](#)
- To deactivate or activate an access key: [UpdateAccessKey](#)
- To list a user's access keys: [ListAccessKeys](#)
- To determine when an access key was most recently used: [GetAccessKeyLastUsed](#)
- To delete an access key: [DeleteAccessKey](#)

Updating access keys

As a security [best practice](#), we recommend that you update IAM user access keys when needed, such as when an employee leaves your company. IAM users can update their own access keys if they have been granted the necessary permissions.

For details about granting IAM users permissions to update their own access keys, see [AWS: Allows IAM users to manage their own password, access keys, and SSH public keys on the Security credentials page](#). You can also apply a password policy to your account to require that all of your IAM users periodically update their passwords and how often they must do so. For more information, see [Setting an account password policy for IAM users](#).

Topics

- [Updating IAM user access keys \(console\)](#)
- [Updating access keys \(AWS CLI\)](#)
- [Updating access keys \(AWS API\)](#)

Updating IAM user access keys (console)

You can update access keys from the AWS Management Console.

To update access keys for an IAM user without interrupting your applications (console)

1. While the first access key is still active, create a second access key.
 - a. Sign in to the AWS Management Console and open the IAM console at <https://console.aws.amazon.com/iam/>.
 - b. In the navigation pane, choose **Users**.
 - c. Choose the name of the intended user, and then choose the **Security credentials** tab.
 - d. In the **Access keys** section, choose **Create access key**. On the **Access key best practices & alternatives** page, choose **Other**, then choose **Next**.
 - e. (Optional) Set a description tag value for the access key to add a tag key-value pair to this IAM user. This can help you identify and update access keys later. The tag key is set to the access key id. The tag value is set to the access key description that you specify. When you are finished, choose **Create access key**.
 - f. On the **Retrieve access keys** page, choose either **Show** to reveal the value of your user's secret access key, or **Download .csv file**. This is your only opportunity to save your secret access key. After you've saved your secret access key in a secure location, choose **Done**.

When you create an access key for your user, that key pair is active by default, and your user can use the pair right away. At this point, the user has two active access keys.

2. Update all applications and tools to use the new access key.
3. Determine whether the first access key is still in use by reviewing the **Last used** information for the oldest access key. One approach is to wait several days and then check the old access key for any use before proceeding.
4. Even if the **Last used** information indicates that the old key has never been used, we recommend that you do not immediately delete the first access key. Instead, choose **Actions** and then choose **Deactivate** to deactivate the first access key.
5. Use only the new access key to confirm that your applications are working. Any applications and tools that still use the original access key will stop working at this point because they no longer have access to AWS resources. If you find such an application or tool, you can reactivate the first access key. Then return to [Step 3](#) and update this application to use the new key.

6. After you wait some period of time to ensure that all applications and tools have been updated, you can delete the first access key:
 - a. Sign in to the AWS Management Console and open the IAM console at <https://console.aws.amazon.com/iam/>.
 - b. In the navigation pane, choose **Users**.
 - c. Choose the name of the intended user, and then choose the **Security credentials** tab.
 - d. In the **Access keys** section for the access key you want to delete, choose **Actions**, and then choose **Delete**. Follow the instructions in the dialog to first **Deactivate** and then confirm the deletion.

To determine which access keys need to be updated or deleted(console)

1. Sign in to the AWS Management Console and open the IAM console at <https://console.aws.amazon.com/iam/>.
2. In the navigation pane, choose **Users**.
3. If necessary, add the **Access key age** column to the users table by completing the following steps:
 - a. Above the table on the far right, choose the settings icon ).
 - b. In **Manage columns**, select **Access key age**.
 - c. Choose **Close** to return to the list of users.
4. The **Access key age** column shows the number of days since the oldest active access key was created. You can use this information to find users with access keys that might need to be updated or deleted. The column displays **None** for users with no access key.

Updating access keys (AWS CLI)

You can update access keys from the AWS Command Line Interface.

To update access keys without interrupting your applications (AWS CLI)

1. While the first access key is still active, create a second access key, which is active by default. Run the following command:

- [aws iam create-access-key](#)

At this point, the user has two active access keys.

2. Update all applications and tools to use the new access key.
3. Determine whether the first access key is still in use by using this command:

- [aws iam get-access-key-last-used](#)

One approach is to wait several days and then check the old access key for any use before proceeding.

4. Even if step [Step 3](#) indicates no use of the old key, we recommend that you do not immediately delete the first access key. Instead, change the state of the first access key to `Inactive` using this command:

- [aws iam update-access-key](#)

5. Use only the new access key to confirm that your applications are working. Any applications and tools that still use the original access key will stop working at this point because they no longer have access to AWS resources. If you find such an application or tool, you can switch its state back to `Active` to reactivate the first access key. Then return to step [Step 2](#) and update this application to use the new key.
6. After you wait some period of time to ensure that all applications and tools have been updated, you can delete the first access key with this command:

- [aws iam delete-access-key](#)

Updating access keys (AWS API)

You can update access keys using the AWS API.

To update access keys without interrupting your applications (AWS API)

1. While the first access key is still active, create a second access key, which is active by default. Call the following operation:

- [CreateAccessKey](#)

At this point, the user has two active access keys.

2. Update all applications and tools to use the new access key.
3. Determine whether the first access key is still in use by calling this operation:
 - [GetAccessKeyLastUsed](#)

One approach is to wait several days and then check the old access key for any use before proceeding.

4. Even if step [Step 3](#) indicates no use of the old key, we recommend that you do not immediately delete the first access key. Instead, change the state of the first access key to `Inactive` calling this operation:
 - [UpdateAccessKey](#)
5. Use only the new access key to confirm that your applications are working. Any applications and tools that still use the original access key will stop working at this point because they no longer have access to AWS resources. If you find such an application or tool, you can switch its state back to `Active` to reactivate the first access key. Then return to step [Step 2](#) and update this application to use the new key.
6. After you wait some period of time to ensure that all applications and tools have been updated, you can delete the first access key calling this operation:
 - [DeleteAccessKey](#)

Securing access keys

Anyone who has your access keys has the same level of access to your AWS resources that you do. Consequently, AWS goes to significant lengths to protect your access keys, and, in keeping with our [shared-responsibility model](#), you should as well.

Expand the following sections for guidance to help you protect your access keys.

Note

Your organization may have different security requirements and policies than those described in this topic. The suggestions provided here are intended as general guidelines.

Remove (or don't generate) AWS account root user access keys

One of the best ways to protect your account is to not have access keys for your AWS account root user. Unless you must have root user access keys (which is rare), it is best not to generate them. Instead, create an administrative user in AWS IAM Identity Center for daily administrative tasks. For information about how to create an administrative user in IAM Identity Center, see [Getting started](#) in the *IAM Identity Center User Guide*.

If you already have root user access keys for your account, we recommend the following: Find places in your applications where you are currently using access keys (if any), and replace the root user access keys with IAM user access keys. Then disable and remove the root user access keys. For more information about how to update access keys, see [Updating access keys](#)

Use temporary security credentials (IAM roles) instead of long-term access keys

In many scenarios, you don't need long-term access keys that never expire (as you have with an IAM user). Instead, you can create IAM roles and generate temporary security credentials. Temporary security credentials consist of an access key ID and a secret access key, but they also include a security token that indicates when the credentials expire.

Long-term access keys, such as those associated with IAM users and the root user, remain valid until you manually revoke them. However, temporary security credentials obtained through IAM roles and other features of the AWS Security Token Service expire after a short period of time. Use temporary security credentials to help reduce your risk in case credentials are accidentally exposed.

Use an IAM role and temporary security credentials in these scenarios:

- **You have an application or AWS CLI scripts running on an Amazon EC2 instance.** Don't use access keys directly in your application. Don't pass access keys to the application, embed them in the application, or let the application read access keys from any source. Instead, define an IAM role that has appropriate permissions for your application and launch the Amazon Elastic Compute Cloud (Amazon EC2) instance with [roles for EC2](#). Doing this associates an IAM role with the Amazon EC2 instance. This practice also enables the application to get temporary security credentials that it can in turn use to make programmatic calls to AWS. The AWS SDKs and the AWS Command Line Interface (AWS CLI) can get temporary credentials from the role automatically.
- **You need to grant cross-account access.** Use an IAM role to establish trust between accounts, and then grant users in one account limited permissions to access the trusted account. For more information, see [IAM tutorial: Delegate access across AWS accounts using IAM roles](#).

- **You have a mobile app.** Don't embed access keys with the app, even in encrypted storage. Instead, use [Amazon Cognito](#) to manage user identities in your app. This service lets you authenticate users using Login with Amazon, Facebook, Google, or any OpenID Connect (OIDC)–compatible identity provider. You can then use the Amazon Cognito credentials provider to manage credentials that your app uses to make requests to AWS.
- **You want to federate into AWS and your organization supports SAML 2.0.** If you work for an organization that has an identity provider that supports SAML 2.0, configure the provider to use SAML. You can use SAML to exchange authentication information with AWS and get back a set of temporary security credentials. For more information, see [About SAML 2.0-based federation](#).
- **You want to federate into AWS and your organization has an on-premises identity store.** If users can authenticate inside your organization, you can write an application that can issue them temporary security credentials for access to AWS resources. For more information, see [Enabling custom identity broker access to the AWS console](#).

Note

Are you using an Amazon EC2 instance with an application that requires programmatic access to AWS resources? If so, use [IAM roles for EC2](#).

Manage IAM user access keys properly

If you must create access keys for programmatic access to AWS, create them for IAM users, granting the users only the permissions they require.

Observe these precautions to help protect IAM user access keys:

- **Don't embed access keys directly into code.** The [AWS SDKs](#) and the [AWS Command Line Tools](#) enable you to put access keys in known locations so that you don't have to keep them in code.

Put access keys in one of the following locations:

- **The AWS credentials file.** The AWS SDKs and AWS CLI automatically use the credentials that you store in the AWS credentials file.

For information about using the AWS credentials file, see the documentation for your SDK. Examples include [Set AWS Credentials and Region](#) in the *AWS SDK for Java Developer Guide* and [Configuration and credential files](#) in the *AWS Command Line Interface User Guide*.

To store credentials for the AWS SDK for .NET and the AWS Tools for Windows PowerShell, we recommend that you use the SDK Store. For more information, see [Using the SDK Store](#) in the *AWS SDK for .NET Developer Guide*.

- **Environment variables.** On a multi-tenant system, choose user environment variables, not system environment variables.

For more information about using environment variables to store credentials, see [Environment Variables](#) in the *AWS Command Line Interface User Guide*.

- **Use different access keys for different applications.** Do this so that you can isolate the permissions and revoke the access keys for individual applications if they are exposed. Having separate access keys for different applications also generates distinct entries in [AWS CloudTrail](#) log files. This configuration makes it easier for you to determine which application performed specific actions.
- **Update access keys when needed.** If there is a risk that the access key could be compromised, update the access key and delete the previous access key. For details, see [Updating access keys](#)
- **Remove unused access keys.** If a user leaves your organization, remove the corresponding IAM user so that the user can no longer access your resources. To find out when an access key was last used, use the [GetAccessKeyLastUsed](#) API (AWS CLI command: [aws iam get-access-key-last-used](#)).
- **Use temporary credentials and configure multi-factor authentication for your most sensitive API operations.** With IAM policies, you can specify which API operations a user is allowed to call. In some cases, you might want the additional security of requiring users to be authenticated with AWS MFA before you allow them to perform particularly sensitive actions. For example, you might have a policy that allows a user to perform the Amazon EC2 `RunInstances`, `DescribeInstances`, and `StopInstances` actions. But you might want to restrict a destructive action like `TerminateInstances` and ensure that users can perform that action only if they authenticate with an AWS MFA device. For more information, see [Configuring MFA-protected API access](#).

Access the mobile app using AWS access keys

You can access a limited set of AWS services and features using the AWS mobile app. The mobile app helps you support incident response while on the go. For more information and to download the app, see [AWS Console Mobile Application](#).

You can sign in to the mobile app using your console password or your access keys. As a best practice, do not use root user access keys. Instead, we strongly recommend that in addition to using a password or biometric lock on your mobile device, you create an IAM user specifically for managing AWS resources using the mobile app. If you lose your mobile device, you can remove the IAM user's access.

To sign in using access keys (mobile app)

1. Open the app on your mobile device.
2. If this is the first time that you're adding an identity to the device, choose **Add an identity** and then choose **Access keys**.

If you have already signed in using another identity, choose the menu icon and choose **Switch identity**. Then choose **Sign in as a different identity** and then **Access keys**.

3. On the **Access keys** page, enter your information:
 - **Access key ID** – Enter your access key ID.
 - **Secret access key** – Enter your secret access key.
 - **Identity name** – Enter the name of the identity that will appear in the mobile app. This does not need to match your IAM user name.
 - **Identity PIN** – Create a personal identification number (PIN) that you will use for future sign-ins.

Note

If you enable biometrics for the AWS mobile app, you will be prompted to use your fingerprint or facial recognition for verification instead of the PIN. If the biometrics fail, you might be prompted for the PIN instead.

4. Choose **Verify and add keys**.

You can now access a select set of your resources using the mobile app.

Related information

The following topics provide guidance for setting up the AWS SDKs and the AWS CLI to use access keys:

- [Set AWS credentials and Region](#) in the *AWS SDK for Java Developer Guide*
- [Using the SDK Store](#) in the *AWS SDK for .NET Developer Guide*
- [Providing Credentials to the SDK](#) in the *AWS SDK for PHP Developer Guide*
- [Configuration](#) in the Boto 3 (AWS SDK for Python) documentation
- [Using AWS Credentials](#) in the *AWS Tools for Windows PowerShell User Guide*
- [Configuration and credential files](#) in the *AWS Command Line Interface User Guide*
- [Granting access using an IAM role](#) in the *AWS SDK for .NET Developer Guide*
- [Configure IAM roles for Amazon EC2](#) in the *AWS SDK for Java 2.x*

Auditing access keys

You can review the AWS access keys in your code to determine whether the keys are from an account that you own. You can pass an access key ID using the [aws sts get-access-key-info](#) AWS CLI command or the [GetAccessKeyInfo](#) AWS API operation.

The AWS CLI and AWS API operations return the ID of the AWS account to which the access key belongs. Access key IDs beginning with AKIA are long-term credentials for an IAM user or an AWS account root user. Access key IDs beginning with ASIA are temporary credentials that are created using AWS STS operations. If the account in the response belongs to you, you can sign in as the root user and review your root user access keys. Then, you can pull a [credentials report](#) to learn which IAM user owns the keys. To learn who requested the temporary credentials for an ASIA access key, view the AWS STS events in your CloudTrail logs.

For security purposes, you can [review AWS CloudTrail logs](#) to learn who performed an action in AWS. You can use the `sts:SourceIdentity` condition key in the role trust policy to require users to specify an identity when they assume a role. For example, you can require that IAM users specify their own user name as their source identity. This can help you determine which user performed a specific action in AWS. For more information, see [sts:SourceIdentity](#).

This operation does not indicate the state of the access key. The key might be active, inactive, or deleted. Active keys might not have permissions to perform an operation. Providing a deleted access key might return an error that the key doesn't exist.

Resetting lost or forgotten passwords or access keys for AWS

Important

Having trouble signing in to AWS? Make sure that you're on the correct [AWS sign-in page](#) for your type of user. If you are the AWS account root user (account owner), you can sign in to AWS using the credentials that you set up when you created the AWS account. If you are an IAM user, your account administrator can give you the credentials that you can use to sign in to AWS. If you need to request support, do not use the feedback link on this page, as the form is received by the AWS Documentation team, not AWS Support. Instead, on the [Contact Us](#) page choose **Still unable to log into your AWS account** and then choose one of the available support options.

On the main sign-in page, you must enter your email address to sign in as the root user, or enter your account ID to sign in as an IAM user. You can provide your password only on the sign-in page that matches your user type. For more information, see [Signing in to the AWS Management Console](#).

If you are on the correct sign-in page and lose or forget your passwords or access keys, you *cannot* retrieve them from IAM. Instead, you can reset them using the following methods:

- **AWS account root user password** – If you forget your root user password, you can reset the password from the AWS Management Console. For details, see [the section called “Resetting a lost or forgotten root user password”](#) later in this topic.
- **AWS account access keys** – If you forget your account access keys, you can create new access keys without disabling the existing access keys. If you are not using the existing keys, you can delete those. For details, see [Creating access keys for the root user](#) and [Deleting access keys for the root user](#).
- **IAM user password** – If you are an IAM user and you forget your password, you must ask your administrator to reset your password. To learn how an administrator can manage your password, see [Managing passwords for IAM users](#).
- **IAM user access keys** – If you are an IAM user and you forget your access keys, you will need new access keys. If you have permission to create your own access keys, you can find instructions for creating a new one at [Managing access keys \(console\)](#). If you do not have the required permissions, you must ask your administrator to create new access keys. If you are still using your

old keys, ask your administrator not to delete the old keys. To learn how an administrator can manage your access keys, see [Managing access keys for IAM users](#).

Using multi-factor authentication (MFA) in AWS

 [Follow us on Twitter](#)

For increased security, we recommend that you configure multi-factor authentication (MFA) to help protect your AWS resources. You can enable MFA for the AWS account root user and IAM users. When you enable MFA for the root user, it affects only the root user credentials. IAM users in the account are distinct identities with their own credentials, and each identity has its own MFA configuration. You can register up to eight MFA devices of any combination of the currently supported MFA types with your AWS account root user and IAM users. For more information about supported MFA types see [What is MFA?](#). With multiple MFA devices, only one MFA device is needed to sign in to the AWS Management Console or create a session through the AWS CLI as that user.

Note

We recommend that you require your human users to use temporary credentials when accessing AWS. Have you considered using AWS IAM Identity Center? You can use IAM Identity Center to centrally manage access to multiple AWS accounts and provide users with MFA-protected, single sign-on access to all their assigned accounts from one place. With IAM Identity Center, you can create and manage user identities in IAM Identity Center or easily connect to your existing SAML 2.0 compatible identity provider. For more information, see [What is IAM Identity Center?](#) in the *AWS IAM Identity Center User Guide*.

What is MFA?

MFA adds extra security because it requires users to provide unique authentication from an AWS supported MFA mechanism in addition to their regular sign-in credentials when they access AWS websites or services. AWS supports the following MFA types.

FIDO security

FIDO Certified hardware security keys are provided by third-party providers.

The FIDO Alliance maintains a list of all [FIDO Certified products](#) that are compatible with FIDO specifications. FIDO authentication standards are based on public key cryptography, which

enables strong, phishing-resistant authentication that is more secure than passwords. FIDO security keys support multiple root accounts and IAM users using a single security key. For more information about enabling FIDO security keys, see [Enabling a FIDO security key \(console\)](#).

Virtual MFA devices

A virtual authenticator application that runs on a phone or other device and emulates a physical device.

Virtual authenticator apps implement the [time-based one-time password](#) (TOTP) algorithm and support multiple tokens on a single device. The user must type a valid code from the device on a second webpage during sign-in. Each virtual MFA device assigned to a user must be unique. A user can't type a code from another user's virtual MFA device to authenticate. Because they can run on unsecured mobile devices, virtual MFA might not provide the same level of security as FIDO security keys.

We do recommend that you use a virtual MFA device while waiting for hardware purchase approval or while you wait for your hardware to arrive. For a list of a few supported apps that you can use as virtual MFA devices, see [Multi-Factor Authentication](#). For instructions on setting up a virtual MFA device with AWS, see [Enabling a virtual multi-factor authentication \(MFA\) device \(console\)](#).

Hardware TOTP token

A hardware device that generates a six-digit numeric code based on the [time-based one-time password](#) (TOTP) algorithm.

The user must type a valid code from the device on a second webpage during sign-in. Each MFA device assigned to a user must be unique. A user cannot type a code from another user's device to be authenticated. For information on supported hardware MFA devices, see [Multi-Factor Authentication](#). For instructions on setting up a hardware TOTP token with AWS, see [Enabling a hardware TOTP token \(console\)](#).

We recommend that you use FIDO security keys as an alternative to hardware TOTP devices. FIDO security keys offer the benefits of no battery requirements, phishing resistance, and they support multiple IAM or root users on a single device for enhanced security.

Note

SMS text message-based MFA – AWS ended support for enabling SMS multi-factor authentication (MFA). We recommend that customers who have IAM users that use SMS

text message-based MFA switch to one of the following alternative methods: [FIDO security key](#), [virtual \(software-based\) MFA device](#), or [hardware MFA device](#). You can identify the users in your account with an assigned SMS MFA device. To do so, go to the IAM console, choose **Users** from the navigation pane, and look for users with **SMS** in the **MFA** column of the table.

Topics

- [Enabling MFA devices for users in AWS](#)
- [Checking MFA status](#)
- [Resynchronizing virtual and hardware MFA devices](#)

Enabling MFA devices for users in AWS

The steps for configuring MFA depend on the type of MFA device you are using.

Topics

- [General steps for enabling MFA devices](#)
- [Enabling a virtual multi-factor authentication \(MFA\) device \(console\)](#)
- [Enabling a FIDO security key \(console\)](#)
- [Enabling a hardware TOTP token \(console\)](#)
- [Enabling and managing virtual MFA devices \(AWS CLI or AWS API\)](#)

General steps for enabling MFA devices

The following overview procedure describes how to set up and use MFA and provides links to related information.

Note

You can also watch this English-language video, [How to Setup AWS Multi-Factor Authentication \(MFA\) and AWS Budget Alerts](#), for more information.

1. *Get an MFA device such as one of the following.* You can enable up to eight MFA devices per AWS account root user or IAM user of any combination of the following types.
 - A virtual MFA device, which is a software app that is compliant with [RFC 6238, a standards-based TOTP \(time-based one-time password\) algorithm](#). You can install the app on a phone or other device. For a list of a few supported apps that you can use as virtual MFA devices, see [Multi-Factor Authentication](#).
 - A FIDO security key with an [AWS supported configuration](#). The FIDO Alliance maintains a list of all [FIDO Certified products](#) that are compatible with FIDO specifications.
 - A hardware-based MFA device from a third-party provider, like a token device. These tokens are used exclusively with AWS accounts. For more information, see [Enabling a hardware TOTP token \(console\)](#). You can only use tokens that have their unique token seeds shared securely with AWS. Token seeds are secret keys generated at the time of token production. Tokens purchased from other sources will not function with IAM. To ensure compatibility, you must purchase your hardware MFA device from one of the following links: [OTP token](#) or [OTP display card](#).
2. *Enable the MFA device.*
 - **Virtual or Hardware TOTP tokens** –You can use AWS CLI commands or AWS API operations to enable a virtual MFA device for an IAM user. You cannot enable an MFA device for the AWS account root user with the AWS CLI, AWS API, Tools for Windows PowerShell, or any other command line tool. However, you can use the AWS Management Console to enable an MFA device for the root user.
 - **FIDO security keys** – Root users and IAM users with FIDO security keys can enable from the AWS Management Console only, not from the AWS CLI or AWS API.

For information about enabling each type of MFA device, see the following pages:

- Virtual MFA device: [Enabling a virtual multi-factor authentication \(MFA\) device \(console\)](#)
- FIDO security key: [Enabling a FIDO security key \(console\)](#)
- Hardware TOTP token: [Enabling a hardware TOTP token \(console\)](#)

3. *Enable Multiple MFA devices (recommended)*

- We recommend that you enable multiple MFA devices to the AWS account root user and IAM users in your AWS accounts. This allows you to raise the security bar in your AWS accounts and simplify managing access to highly privileged users, such as the AWS account root user.
 - You can register up to **eight** MFA devices of any combination of the [currently supported MFA types](#) with your AWS account root user and IAM users. With multiple MFA devices, you only need one MFA device to sign in to the AWS Management Console or create a session through the AWS CLI as that user. An IAM user must authenticate with an existing MFA device to enable or disable an additional MFA device.
 - In the event of a lost, stolen, or inaccessible MFA device you can use one of the remaining MFA devices to access the AWS account without performing the AWS account recovery procedure. If an MFA device is lost or stolen, it should be disassociated from the IAM principal with which it is associated.
 - The use of multiple MFAs allows your employees in geographically dispersed locations or working remotely to use hardware-based MFA to access AWS without having to coordinate the physical exchange of a single hardware device between employees.
 - The use of additional MFA devices for IAM principals allows you to use one or more MFAs for everyday usage, while also maintaining physical MFA devices in a secure physical location such as a vault or safe for backup and redundancy.
4. *Use the MFA device when you log in to or access AWS resources.* Note the following:
- **FIDO security keys** – To access an AWS website, enter your credentials and then tap the FIDO security key when prompted.
 - **Virtual MFA devices and hardware TOTP tokens** – To access an AWS website, you need an MFA code from the device in addition to your user name and password.

To access MFA-protected API operations, you need the following:

- An MFA code
- The identifier for the MFA device (the device serial number of a physical device or the ARN of a virtual device defined in AWS)
- The usual access key ID and secret access key

Notes

- You cannot pass the MFA information for a FIDO security key to AWS STS API operations to request temporary credentials.

- You cannot use AWS CLI commands or AWS API operations to enable [FIDO security keys](#).
- You cannot use the same name for more than one root or IAM MFA device.

For more information, see [Using MFA devices with your IAM sign-in page](#).

Enabling a virtual multi-factor authentication (MFA) device (console)

You can use a phone or other device as a virtual multi-factor authentication (MFA) device. To do this, install a mobile app that is compliant with [RFC 6238, a standards-based TOTP \(time-based one-time password\) algorithm](#). These apps generate a six-digit authentication code. Because they can run on unsecured mobile devices, virtual MFA might not provide the same level of security as FIDO security keys. We do recommend that you use a virtual MFA device while waiting for hardware purchase approval or while you wait for your hardware to arrive.

Most virtual MFA apps support creating multiple virtual devices, allowing you to use the same app for multiple AWS accounts or users. You can register up to **eight** MFA devices of any combination of the [currently supported MFA types](#) with your AWS account root user and IAM users. With multiple MFA devices, you only need one MFA device to sign in to the AWS Management Console or create a session through the AWS CLI as that user. We recommend that you register multiple MFA devices. For authenticator applications, we also recommend enabling the cloud backup or sync feature in those apps to help you avoid losing access to your account if you lose or break your device with the authenticator apps.

For a list of virtual MFA apps that you can use, see [Multi-Factor Authentication](#). AWS requires a virtual MFA app that produces a six-digit OTP.

Topics

- [Permissions required](#)
- [Enable a virtual MFA device for an IAM user \(console\)](#)
- [Replace a virtual MFA device](#)

Permissions required

To manage virtual MFA devices for your IAM user, you must have the permissions from the following policy: [AWS: Allows MFA-authenticated IAM users to manage their own MFA device on the Security credentials page](#).

Enable a virtual MFA device for an IAM user (console)

You can use IAM in the AWS Management Console to enable and manage a virtual MFA device for an IAM user in your account. You can attach tags to your IAM resources, including virtual MFA devices, to identify, organize, and control access to them. You can tag virtual MFA devices only when you use the AWS CLI or AWS API. To enable and manage an MFA device using the AWS CLI or AWS API, see [Enabling and managing virtual MFA devices \(AWS CLI or AWS API\)](#). For more information about tagging IAM resources, see [Tagging IAM resources](#).

Note

You must have physical access to the hardware that will host the user's virtual MFA device in order to configure MFA. For example, you might configure MFA for a user who will use a virtual MFA device running on a smartphone. In that case, you must have the smartphone available in order to finish the wizard. Because of this, you might want to let users configure and manage their own virtual MFA devices. In that case, you must grant users the permissions to perform the necessary IAM actions. For more information and for an example of an IAM policy that grants these permissions, see the [IAM tutorial: Permit users to manage their credentials and MFA settings](#) and example policy [AWS: Allows MFA-authenticated IAM users to manage their own MFA device on the Security credentials page](#).

To enable a virtual MFA device for an IAM user (console)

1. Sign in to the AWS Management Console and open the IAM console at <https://console.aws.amazon.com/iam/>.
2. In the navigation pane, choose **Users**.
3. In the **Users** list, choose the name of the IAM user.
4. Choose the **Security Credentials** tab. Under **Multi-factor authentication (MFA)**, choose **Assign MFA device**.
5. In the wizard, type a **Device name**, choose **Authenticator app**, and then choose **Next**.

IAM generates and displays configuration information for the virtual MFA device, including a QR code graphic. The graphic is a representation of the "secret configuration key" that is available for manual entry on devices that do not support QR codes.

6. Open your virtual MFA app. For a list of apps that you can use for hosting virtual MFA devices, see [Multi-Factor Authentication](#).

If the virtual MFA app supports multiple virtual MFA devices or accounts, choose the option to create a new virtual MFA device or account.

7. Determine whether the MFA app supports QR codes, and then do one of the following:
 - From the wizard, choose **Show QR code**, and then use the app to scan the QR code. For example, you might choose the camera icon or choose an option similar to **Scan code**, and then use the device's camera to scan the code.
 - From the wizard, choose **Show secret key**, and then type the secret key into your MFA app.

When you are finished, the virtual MFA device starts generating one-time passwords.

8. On the **Set up device** page, in the **MFA code 1** box, type the one-time password that currently appears in the virtual MFA device. Wait up to 30 seconds for the device to generate a new one-time password. Then type the second one-time password into the **MFA code 2** box. Choose **Add MFA**.

Important

Submit your request immediately after generating the codes. If you generate the codes and then wait too long to submit the request, the MFA device successfully associates with the user but the MFA device is out of sync. This happens because time-based one-time passwords (TOTP) expire after a short period of time. If this happens, you can [resync the device](#).

The virtual MFA device is now ready for use with AWS. For information about using MFA with the AWS Management Console, see [Using MFA devices with your IAM sign-in page](#).

Replace a virtual MFA device

You can register up to **eight** MFA devices of any combination of the [currently supported MFA types](#) with your AWS account root user and IAM users. If the user loses a device or needs to replace it for any reason, you must first deactivate the old device. Then you can add the new device for the user.

- To deactivate the device currently associated with another IAM user, see [Deactivating MFA devices](#).
- To add a replacement virtual MFA device for another IAM user, follow the steps in the procedure [Enable a virtual MFA device for an IAM user \(console\)](#) above.

- To add a replacement virtual MFA device for the AWS account root user, follow the steps in the procedure [Enable a virtual MFA device for your AWS account root user \(console\)](#).

Enabling a FIDO security key (console)

FIDO security keys are a type of [multi-factor authentication \(MFA\) device](#) that you can use to protect your AWS resources. You plug your FIDO security key into a USB port on your computer and enable it using the instructions that follow. After you enable it, you tap it when prompted to securely complete the sign-in process. If you already use a FIDO security key with other services, and it has an [AWS supported configuration](#) (for example, the YubiKey 5 Series from Yubico), you can also use it with AWS. Otherwise, you need to purchase a FIDO security key if you want to use WebAuthn for MFA in AWS. For specifications and purchase information, see [Multi-Factor Authentication](#).

FIDO2 is an open authentication standard and an extension of FIDO U2F, offering the same high level of security based on public key cryptography. FIDO2 consists of the W3C Web Authentication specification (WebAuthn API) and the FIDO Alliance Client-to-Authenticator Protocol (CTAP), an application layer protocol. CTAP enables communication between client or platform, like a browser or operating system, with an external authenticator. When you enable a FIDO Certified authenticator in AWS, the FIDO security key creates a new key pair for use with only AWS. First, you enter your credentials. When prompted, you tap the FIDO security key, which responds to the authentication challenge issued by AWS. To learn more about the FIDO2 standard, see the [FIDO2 Project](#).

You can register up to **eight** MFA devices of any combination of the [currently supported MFA types](#) with your AWS account root user and IAM users. With multiple MFA devices, you only need one MFA device to sign in to the AWS Management Console or create a session through the AWS CLI as that user. We recommend that you register multiple MFA devices. For example, you can register a built-in authenticator and also register a security key that you keep in a physically secure location. If you're unable to use your built-in authenticator, then you can use your registered security key. For authenticator applications, we also recommend enabling the cloud backup or sync feature in those apps to help you avoid losing access to your account if you lose or break your device with the authenticator apps.

Note

We recommend that you require your human users to use temporary credentials when accessing AWS. Your users can federate into AWS with an identity provider where they

authenticate with their corporate credentials and MFA configurations. To manage access to AWS and business applications, we recommend that you use IAM Identity Center. For more information, see the [The IAM Identity Center User Guide](#).

Topics

- [Permissions required](#)
- [Enable a FIDO security key for your own IAM user \(console\)](#)
- [Enable a FIDO security key for another IAM user \(console\)](#)
- [Replace a FIDO security key](#)
- [Supported configurations for using FIDO security keys](#)

Permissions required

To manage a FIDO security key for your own IAM user while protecting sensitive MFA-related actions, you must have the permissions from the following policy:

Note

The ARN values are static values and are not an indicator of what protocol was used to register the authenticator. We have deprecated U2F, so all new implementations use WebAuthn.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "AllowManageOwnUserMFA",
      "Effect": "Allow",

      "iam:ResyncMFADevice"
    ],
    "Resource": "*",
    "Condition": {
      "BoolIfExists": {
        "aws:MultiFactorAuthPresent": "false"
      }
    }
  }
]
```

Enable a FIDO security key for your own IAM user (console)

You can enable a FIDO security key for your own IAM user from the AWS Management Console only, not from the AWS CLI or AWS API.

Note

Before you can enable a FIDO security key, you must have physical access to the device.

Note

You should not choose any of the available options on the Google Chrome pop-up that asks to **Verify your identity with amazon.com**. You only need to tap on the security key.

To enable a FIDO security key for your own IAM user (console)

1. Use your AWS account ID or account alias, your IAM user name, and your password to sign in to the [IAM console](#).

Note

For your convenience, the AWS sign-in page uses a browser cookie to remember your IAM user name and account information. If you previously signed in as a different user, choose **Sign in to a different account** near the bottom of the page to return to the main sign-in page. From there, you can type your AWS account ID or account alias to be redirected to the IAM user sign-in page for your account.

To get your AWS account ID, contact your administrator.

2. In the navigation bar on the upper right, choose your user name, and then choose **Security credentials**.

3. On the **AWS IAM credentials** tab, in the **Multi-factor authentication (MFA)** section, choose **Assign MFA device**.
4. In the wizard, type a **Device name**, choose **Security Key**, and then choose **Next**.
5. Insert the FIDO security key into your computer's USB port.

6. Tap the FIDO security key.

The FIDO security key is ready for use with AWS. For information about using MFA with the AWS Management Console, see [Using MFA devices with your IAM sign-in page](#).

Enable a FIDO security key for another IAM user (console)

You can enable a FIDO security key for another IAM user from the AWS Management Console only, not from the AWS CLI or AWS API.

To enable a FIDO security key for another IAM user (console)

1. Sign in to the AWS Management Console and open the IAM console at <https://console.aws.amazon.com/iam/>.
2. In the navigation pane, choose **Users**.
3. Choose the name of the user for whom you want to enable MFA.
4. Choose the **Security Credentials** tab. Under **Multi-factor authentication (MFA)**, choose **Assign MFA device**.
5. In the wizard, type a **Device name**, choose **Security Key**, and then choose **Next**.
6. Insert the FIDO security key into your computer's USB port.

7. Tap the FIDO security key.

The FIDO security key is ready for use with AWS. For information about using MFA with the AWS Management Console, see [Using MFA devices with your IAM sign-in page](#).

Replace a FIDO security key

You can have up to eight MFA devices of any combination of the [currently supported MFA types](#) assigned to a user at a time with your AWS account root user and IAM users. If the user loses a FIDO authenticator or needs to replace it for any reason, you must first deactivate the old FIDO authenticator. Then you can add a new MFA device for the user.

- To deactivate the device currently associated with an IAM user, see [Deactivating MFA devices](#).
- To add a new FIDO security key for an IAM user, see [Enable a FIDO security key for your own IAM user \(console\)](#).

If you don't have access to a new FIDO security key, you can enable a new virtual MFA device or hardware TOTP token. See one of the following for instructions:

- [Enabling a virtual multi-factor authentication \(MFA\) device \(console\)](#)
- [Enabling a hardware TOTP token \(console\)](#)

Supported configurations for using FIDO security keys

You can use FIDO2 security keys as a multi-factor authentication (MFA) method with IAM using currently supported configurations. These include FIDO2 devices supported by IAM and browsers that support FIDO2. Before you register your FIDO2 device, check that you're using the latest browser and operating system (OS) version. Features may behave differently across different browsers, authenticators, and OS clients. If your device registration fails on one browser, you can try to register with another browser.

FIDO2 devices supported by AWS

IAM supports FIDO2 security devices that connect to your devices through USB, Bluetooth, or NFC. We don't support platform authenticators such as TouchID, FaceID, or Windows Hello.

Note

AWS requires access to the physical USB port on your computer to verify your FIDO2 device. FIDO2 security keys will not work with a virtual machine, a remote connection, or a browser's incognito mode.

The FIDO Alliance maintains a list of all [FIDO2 products](#) that are compatible with FIDO specifications.

Browsers that support FIDO2

The availability of FIDO2 security devices that run in a web browser depends on the combination of browser and operating system. The following browsers currently support the use of FIDO2 security keys:

	macOS 10.15+	Windows 10	Linux	iOS 14.5+	Android 7+
Chrome	Yes	Yes	Yes	Yes	No
Safari	Yes	No	No	Yes	No
Edge	Yes	Yes	No	Yes	No
Firefox	Yes	Yes	No	Yes	No

Note

Most Firefox versions that currently support FIDO2 don't enable support by default. For instructions on enabling FIDO2 support in Firefox, see [Troubleshooting FIDO security keys](#).

For more information about browser support for a FIDO2-certified device like YubiKey, see [Operating system and web browser support for FIDO2 and U2F](#).

Browser plugins

AWS supports only browsers that natively support FIDO2. AWS doesn't support using plugins to add FIDO2 browser support. Some browser plugins are incompatible with the FIDO2 standard and can cause unexpected results with FIDO2 security keys.

For information on disabling browser plugins and other troubleshooting tips, see [I can't enable my FIDO security key](#).

Device certifications

We capture and assign device-related certifications, such as FIPS validation and FIDO certification level, only during the registration of a FIDO security key. Your device certification is retrieved from the [FIDO Alliance Metadata Service \(MDS\)](#). If the certification status or level of your FIDO security key changes, it will not be reflected in the device tags automatically. To update the certification information of a device, register the device again to fetch the updated certification information.

AWS provides the following certification types as condition keys during device registration, obtained from the FIDO MDS: FIPS-140-2, FIPS-140-3, and FIDO certification levels. You have the ability to specify the registration of specific authenticators in their IAM policies, based on your preferred certification type and level. For more information, see the policies below.

Example policies for device certifications

The following use cases show sample policies that allow you to register MFA devices with FIPS certifications.

Topics

- [Use case 1: Allow registering only devices that have FIPS-140-2 L2 certifications](#)
- [Use case 2: Allow registering devices that have FIPS-140-2 L2 and FIDO L1 certifications](#)
- [Use case 3: Allow registering devices that have either FIPS-140-2 L2 or FIPS-140-3 L2 certifications](#)
- [Use case 4: Allow registering devices that have FIPS-140-2 L2 certification and support other MFA types like virtual authenticators and hardware TOTP](#)

Use case 1: Allow registering only devices that have FIPS-140-2 L2 certifications

```
{
  "Version": "2012-10-17",
```

```

"Statement": [{
  "Effect": "Allow",
  "Action": "iam:EnableMFADevice",
  "Resource": "*",
  "Condition": {
    "StringEquals": {
      "iam:RegisterSecurityKey" : "Create"
    }
  }
},
{
  "Effect": "Allow",
  "Action": "iam:EnableMFADevice",
  "Resource": "*",
  "Condition": {
    "StringEquals": {
      "iam:RegisterSecurityKey" : "Activate",
      "iam:FIDO-FIPS-140-2-certification": "L2"
    }
  }
}
]
}

```

Use case 2: Allow registering devices that have FIPS-140-2 L2 and FIDO L1 certifications

```

{
  "Version": "2012-10-17",
  "Statement": [{
    "Effect": "Allow",
    "Action": "iam:EnableMFADevice",
    "Resource": "*",
    "Condition": {
      "StringEquals": {
        "iam:RegisterSecurityKey" : "Create"
      }
    }
  },
  {
    "Effect": "Allow",
    "Action": "iam:EnableMFADevice",
    "Resource": "*",
    "Condition": {

```

```

        "StringEquals": {
            "iam:RegisterSecurityKey" : "Activate",
            "iam:FIDO-FIPS-140-2-certification": "L2",
            "iam:FIDO-certification": "L1"
        }
    }
}
]
}

```

Use case 3: Allow registering devices that have either FIPS-140-2 L2 or FIPS-140-3 L2 certifications

```

{
  "Version": "2012-10-17",
  "Statement": [{
    "Effect": "Allow",
    "Action": "iam:EnableMFADevice",
    "Resource": "*",
    "Condition": {
      "StringEquals": {
        "iam:RegisterSecurityKey" : "Create"
      }
    }
  },
  {
    "Effect": "Allow",
    "Action": "iam:EnableMFADevice",
    "Resource": "*",
    "Condition": {
      "StringEquals": {
        "iam:RegisterSecurityKey" : "Activate",
        "iam:FIDO-FIPS-140-2-certification": "L2"
      }
    }
  },
  {
    "Effect": "Allow",
    "Action": "iam:EnableMFADevice",
    "Resource": "*",
    "Condition": {
      "StringEquals": {
        "iam:RegisterSecurityKey" : "Activate",

```

```

        "iam:FIDO-FIPS-140-3-certification": "L2"
    }
}
]
}

```

Use case 4: Allow registering devices that have FIPS-140-2 L2 certification and support other MFA types like virtual authenticators and hardware TOTP

```

{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": "iam:EnableMFADevice",
      "Resource": "*",
      "Condition": {
        "StringEquals": {
          "iam:RegisterSecurityKey": "Create"
        }
      }
    },
    {
      "Effect": "Allow",
      "Action": "iam:EnableMFADevice",
      "Resource": "*",
      "Condition": {
        "StringEquals": {
          "iam:RegisterSecurityKey": "Activate",
          "iam:FIPS-140-2-certification": "L2"
        }
      }
    },
    {
      "Effect": "Allow",
      "Action": "iam:EnableMFADevice",
      "Resource": "*",
      "Condition": {
        "Null": {
          "iam:RegisterSecurityKey": "true"
        }
      }
    }
  ]
}

```

```
}  
  ]  
}
```

AWS CLI and AWS API

AWS supports using FIDO2 security keys only in the AWS Management Console. Using FIDO2 security keys for MFA is not supported in the [AWS CLI](#) and [AWS API](#), or for access to [MFA-protected API operations](#).

Additional resources

- For more information on using FIDO2 security keys in AWS, see [Enabling a FIDO security key \(console\)](#).
- For help with troubleshooting FIDO2 security keys in AWS, see [Troubleshooting FIDO security keys](#).
- For general industry information on FIDO2 support, see [FIDO2 Project](#).

Enabling a hardware TOTP token (console)

A hardware TOTP token generates a six-digit numeric code based upon a time-based one-time password (TOTP) algorithm. The user must type a valid code from the device when prompted during the sign-in process. Each MFA device assigned to a user must be unique; a user cannot type a code from another user's device to be authenticated. MFA devices cannot be shared across accounts or users.

Hardware TOTP tokens and [FIDO security keys](#) are both physical devices that you purchase. Hardware MFA devices generate TOTP codes for authentication when you sign in to AWS. They rely on batteries, which may need replacement and resynchronization with AWS over time. FIDO security keys, which utilize public key cryptography, do not require batteries and offer a seamless authentication process. We recommend using FIDO security keys for their phishing resistance, which provides a more secure alternative to TOTP devices. Additionally, FIDO security keys can support multiple IAM or root users on the same device, enhancing their utility for account security. For specifications and purchase information for both device types, see [Multi-Factor Authentication](#).

You can enable a hardware TOTP token for an IAM user from the AWS Management Console, the command line, or the IAM API. To enable an MFA device for your AWS account root user, see [Enable a hardware TOTP token for the AWS account root user \(console\)](#).

You can register up to **eight** MFA devices of any combination of the [currently supported MFA types](#) with your AWS account root user and IAM users. With multiple MFA devices, you only need one MFA device to sign in to the AWS Management Console or create a session through the AWS CLI as that user.

Important

We recommend that you enable multiple MFA devices for your users for continued access to your account in case of a lost or inaccessible MFA device.

Note

If you want to enable the MFA device from the command line, use [aws iam enable-mfa-device](#). To enable the MFA device with the IAM API, use the [EnableMFADevice](#) operation.

Topics

- [Permissions required](#)
- [Enable a hardware TOTP token for your own IAM user \(console\)](#)
- [Enable a hardware TOTP token for another IAM user \(console\)](#)
- [Replace a physical MFA device](#)

Permissions required

To manage a hardware TOTP token for your own IAM user while protecting sensitive MFA-related actions, you must have the permissions from the following policy:

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "AllowManageOwnUserMFA",
      "Effect": "Allow",
      "Action": [
        "iam:DeactivateMFADevice",
        "iam:EnableMFADevice",
        "iam:GetUser",

```

```

        "iam:ListMFADevices",
        "iam:ResyncMFADevice"
    ],
    "Resource": "arn:aws:iam::*:user/${aws:username}"
  },
  {
    "Sid": "DenyAllExceptListedIfNoMFA",
    "Effect": "Deny",
    "NotAction": [
      "iam:EnableMFADevice",
      "iam:GetUser",
      "iam:ListMFADevices",
      "iam:ResyncMFADevice"
    ],
    "Resource": "arn:aws:iam::*:user/${aws:username}",
    "Condition": {
      "BoolIfExists": {
        "aws:MultiFactorAuthPresent": "false"
      }
    }
  }
]
}

```

Enable a hardware TOTP token for your own IAM user (console)

You can enable your own hardware TOTP token from the AWS Management Console.

Note

Before you can enable a hardware TOTP token, you must have physical access to the device.

To enable a hardware TOTP token for your own IAM user (console)

1. Use your AWS account ID or account alias, your IAM user name, and your password to sign in to the [IAM console](#).

Note

For your convenience, the AWS sign-in page uses a browser cookie to remember your IAM user name and account information. If you previously signed in as a different user,

choose **Sign in to a different account** near the bottom of the page to return to the main sign-in page. From there, you can type your AWS account ID or account alias to be redirected to the IAM user sign-in page for your account.

To get your AWS account ID, contact your administrator.

2. In the navigation bar on the upper right, choose your user name, and then choose **Security credentials**.

3. On the **AWS IAM credentials** tab, in the **Multi-factor authentication (MFA)** section, choose **Assign MFA device**.
4. In the wizard, type a **Device name**, choose **Hardware TOTP token**, and then choose **Next**.
5. Type the device serial number. The serial number is usually on the back of the device.
6. In the **MFA code 1** box, type the six-digit number displayed by the MFA device. You might need to press the button on the front of the device to display the number.

7. Wait 30 seconds while the device refreshes the code, and then type the next six-digit number into the **MFA code 2** box. You might need to press the button on the front of the device again to display the second number.

8. Choose **Add MFA**.

⚠ Important

Submit your request immediately after generating the authentication codes. If you generate the codes and then wait too long to submit the request, the MFA device successfully associates with the user but the MFA device becomes out of sync. This happens because time-based one-time passwords (TOTP) expire after a short period of time. If this happens, you can [resync the device](#).

The device is ready for use with AWS. For information about using MFA with the AWS Management Console, see [Using MFA devices with your IAM sign-in page](#).

Enable a hardware TOTP token for another IAM user (console)

You can enable a hardware TOTP token for another IAM user from the AWS Management Console.

To enable a hardware TOTP token for another IAM user (console)

1. Sign in to the AWS Management Console and open the IAM console at <https://console.aws.amazon.com/iam/>.
2. In the navigation pane, choose **Users**.
3. Choose the name of the user for whom you want to enable MFA.
4. Choose the **Security Credentials** tab. Under **Multi-factor authentication (MFA)**, choose **Assign MFA device**.
5. In the wizard, type a **Device name**, choose **Hardware TOTP token**, and then choose **Next**.
6. Type the device serial number. The serial number is usually on the back of the device.
7. In the **MFA code 1** box, type the six-digit number displayed by the MFA device. You might need to press the button on the front of the device to display the number.

8. Wait 30 seconds while the device refreshes the code, and then type the next six-digit number into the **MFA code 2** box. You might need to press the button on the front of the device again to display the second number.

9. Choose **Add MFA**.

Important

Submit your request immediately after generating the authentication codes. If you generate the codes and then wait too long to submit the request, the MFA device successfully associates with the user but the MFA device becomes out of sync. This happens because time-based one-time passwords (TOTP) expire after a short period of time. If this happens, you can [resync the device](#).

The device is ready for use with AWS. For information about using MFA with the AWS Management Console, see [Using MFA devices with your IAM sign-in page](#).

Replace a physical MFA device

You can have up to eight MFA devices of any combination of the [currently supported MFA types](#) assigned to a user at a time with your AWS account root user and IAM users. If the user loses a device or needs to replace it for any reason, you must first deactivate the old device. Then you can add the new device for the user.

- To deactivate the device currently associated with a user, see [Deactivating MFA devices](#).
- To add a replacement hardware TOTP token for an IAM user, follow the steps in the procedure [Enable a hardware TOTP token for another IAM user \(console\)](#) earlier in this topic.
- To add a replacement hardware TOTP token for the AWS account root user, follow the steps in the procedure [Enable a hardware TOTP token for the AWS account root user \(console\)](#) earlier in this topic.

Enabling and managing virtual MFA devices (AWS CLI or AWS API)

You can use AWS CLI commands or AWS API operations to enable a virtual MFA device for an IAM user. You cannot enable an MFA device for the AWS account root user with the AWS CLI, AWS API, Tools for Windows PowerShell, or any other command line tool. However, you can use the AWS Management Console to enable an MFA device for the root user.

When you enable an MFA device from the AWS Management Console, the console performs multiple steps for you. If you instead create a virtual device using the AWS CLI, Tools for Windows PowerShell, or AWS API, then you must perform the steps manually and in the correct order. For

example, to create a virtual MFA device, you must create the IAM object and extract the code as either a string or a QR code graphic. Then you must sync the device and associate it with an IAM user. See the **Examples** section of [New-IAMVirtualMFADevice](#) for more details. For a physical device, you skip the creation step and go directly to syncing the device and associating it with the user.

You can attach tags to your IAM resources, including virtual MFA devices, to identify, organize, and control access to them. You can tag virtual MFA devices only when you use the AWS CLI or AWS API.

An IAM user using the SDK or CLI can enable an additional MFA device by calling [EnableMFADevice](#) or deactivate an existing MFA device by calling [DeactivateMFADevice](#). To do this successfully, they must first call [GetSessionToken](#) and submit MFA codes with an existing MFA device. This call returns temporary security credentials that can then be used to sign API operations that require MFA authentication. For an example request and response, see [GetSessionToken—temporary credentials for users in untrusted environments](#).

To create the virtual device entity in IAM to represent a virtual MFA device

These commands provide an ARN for the device that is used in place of a serial number in many of the following commands.

- AWS CLI: [aws iam create-virtual-mfa-device](#)
- AWS API: [CreateVirtualMFADevice](#)

To enable an MFA device for use with AWS

These commands synchronize the device with AWS and associate it with a user. If the device is virtual, use the ARN of the virtual device as the serial number.

Important

Submit your request immediately after generating the authentication codes. If you generate the codes and then wait too long to submit the request, the MFA device successfully associates with the user but the MFA device becomes out of sync. This happens because time-based one-time passwords (TOTP) expire after a short period of time. If this happens, you can resynchronize the device using the commands described below.

- AWS CLI: [aws iam enable-mfa-device](#)
- AWS API: [EnableMFADevice](#)

To deactivate a device

Use these commands to disassociate the device from the user and deactivate it. If the device is virtual, use the ARN of the virtual device as the serial number. You must also separately delete the virtual device entity.

- AWS CLI: [aws iam deactivate-mfa-device](#)
- AWS API: [DeactivateMFADevice](#)

To list virtual MFA device entities

Use these commands to list virtual MFA device entities.

- AWS CLI: [aws iam list-virtual-mfa-devices](#)
- AWS API: [ListVirtualMFADevices](#)

To tag a virtual MFA device

Use these commands to tag a virtual MFA device.

- AWS CLI: [aws iam tag-mfa-device](#)
- AWS API: [TagMFADevice](#)

To list tags for a virtual MFA device

Use these commands to list the tags attached to a virtual MFA device.

- AWS CLI: [aws iam list-mfa-device-tags](#)
- AWS API: [ListMFADeviceTags](#)

To untag a virtual MFA device

Use these commands to remove tags attached to a virtual MFA device.

- AWS CLI: [aws iam untag-mfa-device](#)

- AWS API: [UntagMFADevice](#)

To resynchronize an MFA device

Use these commands if the device is generating codes that are not accepted by AWS. If the device is virtual, use the ARN of the virtual device as the serial number.

- AWS CLI: [aws iam resync-mfa-device](#)
- AWS API: [ResyncMFADevice](#)

To delete a virtual MFA device entity in IAM

After the device is disassociated from the user, you can delete the device entity.

- AWS CLI: [aws iam delete-virtual-mfa-device](#)
- AWS API: [DeleteVirtualMFADevice](#)

To recover a virtual MFA device that is lost or not working

Sometimes, a user's device that hosts the virtual MFA app is lost, replaced, or not working. When this happens, the user can't recover it on their own. The user must contact an administrator to deactivate the device. For more information, see [What if an MFA device is lost or stops working?](#).

Checking MFA status

Use the IAM console to check whether an AWS account root user or IAM user has a valid MFA device enabled.

To check the MFA status of a root user

1. Sign in to the AWS Management Console with your root user credentials and then open the IAM console at <https://console.aws.amazon.com/iam/>.
2. In the navigation bar on the upper right, choose your user name, and then choose **Security credentials**.
3. Check under **Multi-factor Authentication (MFA)** to see whether MFA is enabled or disabled. If MFA has not been activated, an alert symbol  is displayed.

If you want to enable MFA for the account, see one of the following:

- [Enable a virtual MFA device for your AWS account root user \(console\)](#)
- [Enable a FIDO security key for the AWS account root user \(console\)](#)
- [Enable a hardware TOTP token for the AWS account root user \(console\)](#)

To check the MFA status of IAM users

1. Open the IAM console at <https://console.aws.amazon.com/iam/>.
 2. In the navigation pane, choose **Users**.
 3. If necessary, add the **MFA** column to the users table by completing the following steps:
 - a. Above the table on the far right, choose the settings icon ).
 - b. In **Manage Columns**, select **MFA**.
 - c. (Optional) Clear the check box for any column headings that you do not want to appear in the users table.
 - d. Choose **Close** to return to the list of users.
 4. The **MFA** column tells you about the MFA device that is enabled. If no MFA device is active for the user, the console displays **None**. If the user has an MFA device enabled, the **MFA** column shows the type of device that is enabled with a value of **Virtual**, **Security key**, **Hardware**, or **SMS**.
-  **Note**
- AWS ended support for enabling SMS multi-factor authentication (MFA). We recommend that customers who have IAM users that use SMS text message-based MFA switch to one of the following alternative methods: [virtual \(software-based\) MFA device](#), [FIDO security key](#), or [hardware MFA device](#). You can identify the users in your account with an assigned SMS MFA device. To do so, go to the IAM console, choose **Users** from the navigation pane, and look for users with **SMS** in the **MFA** column of the table.
5. To view additional information about the MFA device for a user, choose the name of the user whose MFA status you want to check. Then choose the **Security credentials** tab.

6. If no MFA device is active for the user, the console displays **No MFA devices. Assign an MFA device to improve the security of your AWS environment** in the **Multi-factor authentication (MFA)** section. If the user has MFA devices enabled, the **Multi-factor authentication (MFA)** section shows details about the devices:
 - The device name
 - The device type
 - The identifier for the device, such as a serial number for a physical device or the ARN in AWS for a virtual device
 - When the device was created

To remove or resync a device, choose the radio button next to the device and choose **Remove** or **Resync**.

For more information on enabling MFA, see the following:

- [Enabling a virtual multi-factor authentication \(MFA\) device \(console\)](#)
- [Enabling a FIDO security key \(console\)](#)
- [Enabling a hardware TOTP token \(console\)](#)

Resynchronizing virtual and hardware MFA devices

You can use AWS to resynchronize your virtual and hardware multi-factor authentication (MFA) devices. If your device is not synchronized when you try to use it, the sign-in attempt fails and IAM prompts you to resynchronize the device.

Note

FIDO security keys do not go out of sync. If a FIDO security key is lost or broken, you can deactivate it. For instructions on deactivating any MFA device type, see [To deactivate an MFA device for another IAM user \(console\)](#).

As an AWS administrator, you can resynchronize your IAM users' virtual and hardware MFA devices if they get out of synchronization.

If your AWS account root user MFA device is not working, you can resynchronize your device using the IAM console with or without completing the sign-in process. If you aren't able to successfully resynchronize your device, you may need to de-associate and re-associate it. For more information on how to do this, see [Deactivating MFA devices](#) and [Enabling MFA devices for users in AWS](#).

Topics

- [Permissions required](#)
- [Resynchronizing virtual and hardware MFA devices \(IAM console\)](#)
- [Resynchronizing virtual and hardware MFA devices \(AWS CLI\)](#)
- [Resynchronizing virtual and hardware MFA devices \(AWS API\)](#)

Permissions required

To resynchronize virtual or hardware MFA devices for your own IAM user, you must have the permissions from the following policy. This policy does not allow you to create or deactivate a device.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "AllowListActions",
      "Effect": "Allow",
      "Action": [
        "iam:ListVirtualMFADevices"
      ],
      "Resource": "*"
    },
    {
      "Sid": "AllowUserToViewAndManageTheirOwnUserMFA",
      "Effect": "Allow",
      "Action": [
        "iam:ListMFADevices",
        "iam:ResyncMFADevice"
      ],
      "Resource": "arn:aws:iam::*:user/${aws:username}"
    },
    {
      "Sid": "BlockAllExceptListedIfNoMFA",
      "Effect": "Deny",
```

```
    "NotAction": [
      "iam:ListMFADevices",
      "iam:ListVirtualMFADevices",
      "iam:ResyncMFADevice"
    ],
    "Resource": "*",
    "Condition": {
      "BoolIfExists": {
        "aws:MultiFactorAuthPresent": "false"
      }
    }
  }
]
```

Resynchronizing virtual and hardware MFA devices (IAM console)

You can use the IAM console to resynchronize virtual and hardware MFA devices.

To resynchronize a virtual or hardware MFA device for your own IAM user (console)

1. Use your AWS account ID or account alias, your IAM user name, and your password to sign in to the [IAM console](#).

Note

For your convenience, the AWS sign-in page uses a browser cookie to remember your IAM user name and account information. If you previously signed in as a different user, choose **Sign in to a different account** near the bottom of the page to return to the main sign-in page. From there, you can type your AWS account ID or account alias to be redirected to the IAM user sign-in page for your account.

To get your AWS account ID, contact your administrator.

2. In the navigation bar on the upper right, choose your user name, and then choose **Security credentials**.

3. On the **AWS IAM credentials** tab, in the **Multi-factor authentication (MFA)** section, choose the radio button next to the MFA device and choose **Resync**.
4. Type the next two sequentially generated codes from the device into **MFA code 1** and **MFA code 2**. Then choose **Resync**.

Important

Submit your request immediately after generating the codes. If you generate the codes and then wait too long to submit the request, the request appears to work but the device remains out of sync. This happens because time-based one-time passwords (TOTP) expire after a short period of time.

To resynchronize a virtual or hardware MFA device for another IAM user (console)

1. Sign in to the AWS Management Console and open the IAM console at <https://console.aws.amazon.com/iam/>.
2. In the navigation pane, choose **Users**, and then choose the name of the user whose MFA device needs to be resynchronized.
3. Choose the **Security credentials** tab. In the **Multi-factor authentication (MFA)** section, choose the radio button next to the MFA device and choose **Resync**.

4. Type the next two sequentially generated codes from the device into **MFA code 1** and **MFA code 2**. Then choose **Resync**.

 **Important**

Submit your request immediately after generating the codes. If you generate the codes and then wait too long to submit the request, the request appears to work but the device remains out of sync. This happens because time-based one-time passwords (TOTP) expire after a short period of time.

To resynchronize your root user MFA before signing in (console)

1. On the **Amazon Web Services Sign In With Authentication Device** page, choose **Having problems with your authentication device? Click here**.

 **Note**

You might see different text, such as **Sign in using MFA** and **Troubleshoot your authentication device**. However, the same features are provided.

2. In the **Re-Sync With Our Servers** section, type the next two sequentially generated codes from the device into **MFA code 1** and **MFA code 2**. Then choose **Re-sync authentication device**.
3. If necessary, type your password again and choose **Sign in**. Then complete the sign-in using your MFA device.

To resynchronize your root user MFA device after signing in (console)

1. Sign in to the [IAM console](#) as the account owner by choosing **Root user** and entering your AWS account email address. On the next page, enter your password.

 **Note**

As the root user, you can't sign in to the **Sign in as IAM user** page. If you see the **Sign in as IAM user** page, choose **Sign in using root user email** near the bottom of the page. For help signing in as the root user, see [Signing in to the AWS Management Console as the root user](#) in the *AWS Sign-In User Guide*.

2. On the right side of the navigation bar, choose on your account name, and then choose **Security credentials**. If necessary, choose **Continue to Security credentials**.

3. Expand the **Multi-factor authentication (MFA)** section on the page.
4. Choose the radio button next to the device and choose **Resync**.
5. In the **Resync MFA device** dialog box, type the next two sequentially generated codes from the device into **MFA code 1** and **MFA code 2**. Then choose **Resync**.

⚠ Important

Submit your request immediately after generating the codes. If you generate the codes and then wait too long to submit the request, the MFA device is successfully associated with the user, but the MFA device is out of sync. This happens because time-based one-time passwords (TOTP) expire after a short period of time.

Resynchronizing virtual and hardware MFA devices (AWS CLI)

You can resynchronize virtual and hardware MFA devices from the AWS CLI.

To resynchronize a virtual or hardware MFA device for an IAM user (AWS CLI)

At a command prompt, issue the [aws iam resync-mfa-device](#) command:

- **Virtual MFA device:** Specify Amazon Resource Name (ARN) of device as the serial number.

```
aws iam resync-mfa-device --user-name Richard --serial-number  
arn:aws:iam::123456789012:mfa/RichardsMFA --authentication-code1 123456 --  
authentication-code2 987654
```

- **Hardware MFA device:** Specify hardware device's serial number as serial number. The format is vendor-specific. For example, you can purchase a gemalto token from Amazon. Its serial number is typically four letters followed by four numbers.

```
aws iam resync-mfa-device --user-name Richard --serial-number ABCD12345678 --  
authentication-code1 123456 --authentication-code2 987654
```

Important

Submit your request immediately after generating the codes. If you generate the codes and then wait too long to submit the request, the request fails because the codes expire after a short time.

Resynchronizing virtual and hardware MFA devices (AWS API)

IAM has an API call that performs synchronization. In this case, we recommend that you give your virtual and hardware MFA device users permission to access this API call. Then build a tool based on that API call so your users can resynchronize their devices whenever they need to.

To resynchronize a virtual or hardware MFA device for an IAM user (AWS API)

- Send the [ResyncMFADevice](#) request.

Deactivating MFA devices

If you are having trouble signing in with a multi-factor authentication (MFA) device as an IAM user, contact your administrator for help.

As an administrator, you can deactivate the device for another IAM user. This allows the user to sign in without using MFA. You might do this as a temporary solution while the MFA device is replaced, or if the device is temporarily unavailable. However, we recommend that you enable a new device

for the user as soon as possible. To learn how to enable a new MFA device, see [the section called “Enabling MFA devices”](#).

Note

If you use the API or AWS CLI to delete a user from your AWS account, you must deactivate or delete the user's MFA device. You make this change as part of the process of removing the user. For more information about deleting users, see [Managing IAM users](#).

Topics

- [Deactivating MFA devices \(console\)](#)
- [Deactivating MFA devices \(AWS CLI\)](#)
- [Deactivating MFA devices \(AWS API\)](#)

Deactivating MFA devices (console)

To deactivate an MFA device for another IAM user (console)

1. Sign in to the AWS Management Console and open the IAM console at <https://console.aws.amazon.com/iam/>.
2. In the navigation pane, choose **Users**.
3. To deactivate the MFA device for a user, choose the name of the user whose MFA you want to remove.
4. Choose the **Security credentials** tab.
5. Under **Multi-factor authentication (MFA)**, choose the radio button next to the MFA device, choose **Remove**, and then choose **Remove**.

The device is removed from AWS. It cannot be used to sign in or authenticate requests until it is reactivated and associated with an AWS user or AWS account root user.

To deactivate the MFA device for your AWS account root user (console)

1. Sign in to the [IAM console](#) as the account owner by choosing **Root user** and entering your AWS account email address. On the next page, enter your password.

Note

As the root user, you can't sign in to the **Sign in as IAM user** page. If you see the **Sign in as IAM user** page, choose **Sign in using root user email** near the bottom of the page. For help signing in as the root user, see [Signing in to the AWS Management Console as the root user](#) in the *AWS Sign-In User Guide*.

2. On the right side of the navigation bar, choose on your account name, and then choose **Security credentials**. If necessary, choose **Continue to Security credentials**.

3. In the **Multi-factor authentication (MFA)** section, choose the radio button next the MFA device that you want to deactivate and choose **Remove**.
4. Choose **Remove**.

The MFA device is deactivated for the AWS account. Check the email that is associated with your AWS account for a confirmation message from Amazon Web Services. The email informs you that your Amazon Web Services multi-factor authentication (MFA) has been deactivated. The message will come from @amazon.com or @aws.amazon.com.

Deactivating MFA devices (AWS CLI)

To deactivate an MFA device for an IAM user (AWS CLI)

- Run this command: [aws iam deactivate-mfa-device](#)

Deactivating MFA devices (AWS API)

To deactivate an MFA device for an IAM user (AWS API)

- Call this operation: [DeactivateMFADevice](#)

What if an MFA device is lost or stops working?

If your [virtual MFA device](#) or [hardware TOTP token](#) appears to be functioning properly, but you can't use it to access your AWS resources, it might be out of synchronization with AWS. For information about synchronizing a virtual MFA device or hardware MFA device, see [Resynchronizing virtual and hardware MFA devices](#). [FIDO security keys](#) do not go out of sync.

If your AWS account root user [multi-factor authentication \(MFA\) device](#) is lost, damaged, or not working, you can recover access to your account. IAM users must contact an administrator to deactivate the device.

Important

We recommend that you enable multiple MFA devices for your IAM users to ensure continued access to your account in case of lost or inaccessible MFA device. You can register up to eight MFA devices of any combination of the currently supported MFA types with your AWS account root user and IAM users.

Recovering a root user MFA device

If your AWS account root user [multi-factor authentication \(MFA\) device](#) is lost, damaged, or not working, you can sign in using another MFA device registered to the same AWS account root user. If the root user only has one MFA device enabled, you can use alternative methods of authentication. This means that if you can't sign in with your MFA device, you can sign in by verifying your identity using the email and the primary contact phone number registered with your account.

Before you use alternative factors of authentication to sign in as a root user, you must be able to access the email and primary contact phone number that are associated with your account. If you need to update the primary contact phone number, you can sign in as an IAM user with *Administrator* access instead of the root user. For additional instructions on updating the account contact information, see [Editing contact information](#) in the *AWS Billing User Guide*. If you do not have access to an email and primary contact phone number, you must contact [AWS Support](#).

Important

We recommend that you keep the email address and contact phone number linked to your root user up to date for a successful account recovery. For more information, see [Update the primary contact for your AWS account](#) in the *AWS Account Management Reference Guide*.

To sign in using alternative factors of authentication as an AWS account root user

1. Sign in to the [AWS Management Console](#) as the account owner by choosing **Root user** and entering your AWS account email address. On the next page, enter your password.
2. On the **Additional verification required** page, select an MFA method to authenticate with and choose **Next**.

Note

You might see alternative text, such as **Sign in using MFA, Troubleshoot your authentication device**, or **Troubleshoot MFA**, but the functionality is the same. If you can't use alternative factors of authentication to verify your account email address and primary contact phone number, contact [AWS Support](#) to deactivate your MFA device.

3. Depending on the type of MFA you are using, you will see a different page, but the **Troubleshoot MFA** option functions the same. On the **Additional verification required** page or **Multi-factor authentication** page, choose **Troubleshoot MFA**.
4. If required, type your password again and choose **Sign in**.
5. On the **Troubleshoot your authentication device** page, in the **Sign in using alternative factors of authentication** section, choose **Sign in using alternative factors**.
6. On the **Sign in using alternative factors of authentication** page, authenticate your account by verifying the email address, choose **Send verification email**.

7. Check the email that is associated with your AWS account for a message from Amazon Web Services (recover-mfa-no-reply@verify.signin.aws). Follow the directions in the email.

If you don't see the email in your account, check your spam folder, or return to your browser and choose **Resend the email**.

8. After you verify your email address, you can continue authenticating your account. To verify your primary contact phone number, choose **Call me now**.
9. Answer the call from AWS and, when prompted, enter the 6-digit number from the AWS website on your phone keypad.

If you don't receive a call from AWS, choose **Sign in** to sign in to the console again and start over. Or see [Lost or unusable Multi-Factor Authentication \(MFA\) device](#) to contact support for help.

10. After you verify your phone number, you can sign in to your account by choosing **Sign in to the console**.
11. The next step varies depending on the type of MFA you are using:
 - For a virtual MFA device, remove the account from your device. Then go to the [AWS Security Credentials](#) page and delete the old MFA virtual device entity before you create a new one.
 - For a FIDO security key, go to the [AWS Security Credentials](#) page and deactivate the old FIDO security key before enabling a new one.
 - For a hardware TOTP token, contact the third-party provider for help fixing or replacing the device. You can continue to sign in using alternative factors of authentication until you receive your new device. After you have the new hardware MFA device, go to the [AWS Security Credentials](#) page and delete the old MFA hardware device entity before you create a new one.

 **Note**

You don't have to replace a lost or stolen MFA device with the same type of device. For example, if you break your FIDO security key and order a new one, you can use virtual MFA or a hardware TOTP token until you receive a new FIDO security key.

⚠ Important

If your MFA device is missing or stolen, after signing in using alternative factors of authentication and establishing your replacement MFA device, change your root user password in case an attacker has stolen the authentication device and might also have your current password. For more information, see [Change the password for the AWS account root user](#) in the *AWS Account Management Reference Guide*.

Recovering an IAM user MFA device

If you are an IAM user and your device is lost or stops working, you can't recover it by yourself. You must contact an administrator to deactivate the device. Then you can enable a new device.

To get help for an MFA device as an IAM user

1. Contact the AWS administrator or other person who gave you the user name and password for the IAM user. The administrator must deactivate the MFA device as described in [Deactivating MFA devices](#) so that you can sign in.
2. The next step varies depending on the type of MFA you are using:
 - For a virtual MFA device, remove the account from your device. Then enable the virtual device as described in [Enabling a virtual multi-factor authentication \(MFA\) device \(console\)](#).
 - For a FIDO security key, contact the third-party provider for help replacing the device. When you receive the new FIDO security key, enable it as described in [Enabling a FIDO security key \(console\)](#).
 - For a hardware TOTP token, contact the third-party provider for help fixing or replacing the device. After you have the new physical MFA device, enable the device as described in [Enabling a hardware TOTP token \(console\)](#).

ℹ Note

You don't have to replace a lost or stolen MFA device with the same type of device. You can have up to eight MFA devices of any combination. For example, if you break your FIDO security key and order a new one, you can use virtual MFA or a hardware TOTP token until you receive a new FIDO security key.

3. If your MFA device is missing or stolen, also change your password in case an attacker has stolen the authentication device and might also have your current password. For more information, see [Managing passwords for IAM users](#)

Configuring MFA-protected API access

With IAM policies, you can specify which API operations a user is allowed to call. In some cases, you might want the additional security of requiring users to be authenticated with AWS multi-factor authentication (MFA) before you allow them to perform particularly sensitive actions.

For example, you might have a policy that allows a user to perform the Amazon EC2 `RunInstances`, `DescribeInstances`, and `StopInstances` actions. But you might want to restrict a destructive action like `TerminateInstances` and ensure that users can perform that action only if they authenticate with an AWS MFA device.

Topics

- [Overview](#)
- [Scenario: MFA protection for cross-account delegation](#)
- [Scenario: MFA protection for access to API operations in the current account](#)
- [Scenario: MFA protection for resources that have resource-based policies](#)

Overview

Adding MFA protection to API operations involves these tasks:

1. The administrator configures an AWS MFA device for each user who needs to make API requests that require MFA authentication. This process is described at [Enabling MFA devices for users in AWS](#).
2. The administrator creates policies for the users that include a `Condition` element that checks whether the user authenticated with an AWS MFA device.
3. The user calls one of the AWS STS API operations that support the MFA parameters [AssumeRole](#) or [GetSessionToken](#), depending on the scenario for MFA protection, as explained later. As part of the call, the user includes the device identifier for the device that's associated with the user. The user also includes the time-based one-time password (TOTP) that the device generates. In either case, the user gets back temporary security credentials that the user can then use to make additional requests to AWS.

Note

MFA protection for a service's API operations is available only if the service supports temporary security credentials. For a list of these services, see [Using Temporary Security Credentials to Access AWS](#).

If authorization fails, AWS returns an access denied error message (as it does for any unauthorized access). With MFA-protected API policies in place, AWS denies access to the API operations specified in the policies if the user attempts to call an API operation without valid MFA authentication. The operation is also denied if the time stamp of the request for the API operation is outside of the allowed range specified in the policy. The user must be reauthenticated with MFA by requesting new temporary security credentials with an MFA code and device serial number.

IAM policies with MFA conditions

Policies with MFA conditions can be attached to the following:

- An IAM user or group
- A resource such as an Amazon S3 bucket, Amazon SQS queue, or Amazon SNS topic
- The trust policy of an IAM role that can be assumed by a user

You can use an MFA condition in a policy to check the following properties:

- **Existence**—To simply verify that the user did authenticate with MFA, check that the `aws:MultiFactorAuthPresent` key is `True` in a `Bool` condition. The key is only present when the user authenticates with short-term credentials. Long-term credentials, such as access keys, do not include this key.
- **Duration**—If you want to grant access only within a specified time after MFA authentication, use a numeric condition type to compare the `aws:MultiFactorAuthAge` key's age to a value (such as 3600 seconds). Note that the `aws:MultiFactorAuthAge` key is not present if MFA was not used.

The following example shows the trust policy of an IAM role that includes an MFA condition to test for the existence of MFA authentication. With this policy, users from the AWS account specified in the `Principal` element (replace `ACCOUNT-B-ID` with a valid AWS account ID) can assume

the role that this policy is attached to. However such users can only assume the role if the user is authenticated using MFA.

```
{
  "Version": "2012-10-17",
  "Statement": {
    "Effect": "Allow",
    "Principal": {"AWS": "ACCOUNT-B-ID"},
    "Action": "sts:AssumeRole",
    "Condition": {"Bool": {"aws:MultiFactorAuthPresent": "true"}}
  }
}
```

For more information on the condition types for MFA, see [AWS global condition context keys](#), [Numeric condition operators](#), and [Condition operator to check existence of condition keys](#).

Choosing between `GetSessionToken` and `AssumeRole`

AWS STS provides two API operations that let users pass MFA information: `GetSessionToken` and `AssumeRole`. The API operation that the user calls to get temporary security credentials depends on which of the following scenarios applies.

Use `GetSessionToken` for the following scenarios:

- Call API operations that access resources in the same AWS account as the IAM user who makes the request. Note that temporary credentials from a `GetSessionToken` request can access IAM and AWS STS API operations *only* if you include MFA information in the request for credentials. Because temporary credentials returned by `GetSessionToken` include MFA information, you can check for MFA in individual API operations made by the credentials.
- Access to resources that are protected with resource-based policies that include an MFA condition.

The purpose of the `GetSessionToken` operation is to authenticate the user using MFA. You cannot use policies to control authentication operations.

Use `AssumeRole` for the following scenarios:

- Call API operations that access resources in the same or a different AWS account. The API calls can include any IAM or AWS STS API. Note that to protect access you enforce MFA at the time when the user assumes the role. The temporary credentials returned by `AssumeRole` do not

include MFA information in the context, so you cannot check individual API operations for MFA. This is why you must use `GetSessionToken` to restrict access to resources protected by resource-based policies.

Details about how to implement these scenarios are provided later in this document.

Important points about MFA-protected API access

It's important to understand the following aspects of MFA protection for API operations:

- MFA protection is available only with temporary security credentials, which must be obtained with `AssumeRole` or `GetSessionToken`.
- You cannot use MFA-protected API access with AWS account root user credentials.
- You cannot use MFA-protected API access with U2F security keys.
- Federated users cannot be assigned an MFA device for use with AWS services, so they cannot access AWS resources controlled by MFA. (See next point.)
- Other AWS STS API operations that return temporary credentials do not support MFA. For `AssumeRoleWithWebIdentity` and `AssumeRoleWithSAML`, the user is authenticated by an external provider and AWS cannot determine whether that provider required MFA. For `GetFederationToken`, MFA is not necessarily associated with a specific user.
- Similarly, long-term credentials (IAM user access keys and root user access keys) cannot be used with MFA-protected API access because they don't expire.
- `AssumeRole` and `GetSessionToken` can also be called without MFA information. In that case, the caller gets back temporary security credentials, but the session information for those temporary credentials does not indicate that the user authenticated with MFA.
- To establish MFA protection for API operations, you add MFA conditions to policies. A policy must include the `aws:MultiFactorAuthPresent` condition key to enforce the use of MFA. For cross-account delegation, the role's trust policy must include the condition key.
- When you allow another AWS account to access resources in your account, the security of your resources depends on the configuration of the trusted account (the other account, not yours). This is true even when you require multi-factor authentication. Any identity in the trusted account that has permission to create virtual MFA devices can construct an MFA claim to satisfy that part of your role's trust policy. Before you allow members of another account access to your AWS resources that require multi-factor authentication, you should ensure that the trusted account's owner follows security best practices. For example, the trusted account should restrict

access to sensitive API operations, such as MFA device-management API operations, to specific, trusted identities.

- If a policy includes an MFA condition, a request is denied if users have not been MFA authenticated, or if they provide an invalid MFA device identifier or invalid TOTP.

Scenario: MFA protection for cross-account delegation

In this scenario, you want to delegate access to IAM users in another account, but only if the users are authenticated with an AWS MFA device. (For more information about cross-account delegation, see [Roles terms and concepts](#).)

Imagine that you have account A (the trusting account that owns the resource to be accessed), with the IAM user Anaya, who has administrator permission. She wants to grant access to user Richard in account B (the trusted account), but wants to make sure that Richard is authenticated with MFA before he assumes the role.

1. In the trusting account A, Anaya creates an IAM role named `CrossAccountRole` and sets the principal in the role's trust policy to the account ID of account B. The trust policy grants permission to the AWS STS `AssumeRole` action. Anaya also adds an MFA condition to the trust policy, as in the following example.

```
{
  "Version": "2012-10-17",
  "Statement": {
    "Effect": "Allow",
    "Principal": {"AWS": "ACCOUNT-B-ID"},
    "Action": "sts:AssumeRole",
    "Condition": {"Bool": {"aws:MultiFactorAuthPresent": "true"}}
  }
}
```

2. Anaya adds a permissions policy to the role that specifies what the role is allowed to do. The permissions policy for a role with MFA protection is no different than any other role-permission policy. The following example shows the policy that Anaya adds to the role; it allows an assuming user to perform any Amazon DynamoDB action on the table `Books` in account A. This policy also allows the `dynamodb:ListTables` action, which is required to perform actions in the console.

Note

The permissions policy does not include an MFA condition. It is important to understand that the MFA authentication is used only to determine whether a user can assume the role. Once the user has assumed the role, no further MFA checks are made.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "TableActions",
      "Effect": "Allow",
      "Action": "dynamodb:*",
      "Resource": "arn:aws:dynamodb:*:ACCOUNT-A-ID:table/Books"
    },
    {
      "Sid": "ListTables",
      "Effect": "Allow",
      "Action": "dynamodb:ListTables",
      "Resource": "*"
    }
  ]
}
```

- In trusted account B, the administrator makes sure that IAM user Richard is configured with an AWS MFA device and that he knows the ID of the device. The device ID is the serial number if it's a hardware MFA device, or the device's ARN if it's a virtual MFA device.
- In account B, the administrator attaches the following policy to user Richard (or a group that he's a member of) that allows him to call the `AssumeRole` action. The resource is set to the ARN of the role that Anaya created in step 1. Notice that this policy does not contain an MFA condition.

```
{
  "Version": "2012-10-17",
  "Statement": [{
    "Effect": "Allow",
    "Action": ["sts:AssumeRole"],
    "Resource": ["arn:aws:iam::ACCOUNT-A-ID:role/CrossAccountRole"]
  }]
}
```

```
}
```

5. In account B, Richard (or an application that Richard is running) calls `AssumeRole`. The API call includes the ARN of the role to assume (`arn:aws:iam::ACCOUNT-A-ID:role/CrossAccountRole`), the ID of the MFA device, and the current TOTP that Richard gets from his device.

When Richard calls `AssumeRole`, AWS determines whether he has valid credentials, including the requirement for MFA. If so, Richard successfully assumes the role and can perform any DynamoDB action on the table named `Books` in account A while using the role's temporary credentials.

For an example of a program that calls `AssumeRole`, see [Calling AssumeRole with MFA authentication](#).

Scenario: MFA protection for access to API operations in the current account

In this scenario, you should ensure that a user in your AWS account can access sensitive API operations only when the user is authenticated using an AWS MFA device.

Imagine that you have account A that contains a group of developers who need to work with EC2 instances. Ordinary developers can work with the instances, but they are not granted permissions for the `ec2:StopInstances` or `ec2:TerminateInstances` actions. You want to limit those "destructive" privileged actions to just a few trusted users, so you add MFA protection to the policy that allows these sensitive Amazon EC2 actions.

In this scenario, one of those trusted users is user Sofía. User Anaya is an administrator in account A.

1. Anaya makes sure that Sofía is configured with an AWS MFA device and that Sofía knows the ID of the device. The device ID is the serial number if it's a hardware MFA device, or the device's ARN if it's a virtual MFA device.
2. Anaya creates a group named `EC2-Admins` and adds user Sofía to the group.
3. Anaya attaches the following policy to the `EC2-Admins` group. This policy grants users permission to call the Amazon EC2 `StopInstances` and `TerminateInstances` actions only if the user has authenticated using MFA.

```
{  
  "Version": "2012-10-17",
```

```
"Statement": [{
  "Effect": "Allow",
  "Action": [
    "ec2:StopInstances",
    "ec2:TerminateInstances"
  ],
  "Resource": ["*"],
  "Condition": {"Bool": {"aws:MultiFactorAuthPresent": "true"}}
}]
}
```

4.

Note

For this policy to take effect, users must first sign out and then sign in again.

If user Sofía needs to stop or terminate an Amazon EC2 instance, she (or an application that she is running) calls `GetSessionToken`. This API operation passes the ID of the MFA device and the current TOTP that Sofía gets from her device.

5. User Sofía (or an application that Sofía is using) uses the temporary credentials provided by `GetSessionToken` to call the Amazon EC2 `StopInstances` or `TerminateInstances` action.

For an example of a program that calls `GetSessionToken`, see [Calling GetSessionToken with MFA authentication](#) later in this document.

Scenario: MFA protection for resources that have resource-based policies

In this scenario, you are the owner of an S3 bucket, an SQS queue, or an SNS topic. You want to make sure that any user from any AWS account who accesses the resource is authenticated by an AWS MFA device.

This scenario illustrates a way to provide cross-account MFA protection without requiring users to assume a role first. In this case, the user can access the resource if three conditions are met: The user must be authenticated by MFA, be able to get temporary security credentials from `GetSessionToken`, and be in an account that is trusted by the resource's policy.

Imagine that you are in account A and you create an S3 bucket. You want to grant access to this bucket to users who are in several different AWS accounts, but only if those users are authenticated with MFA.

In this scenario, user Anaya is an administrator in account A. User Nikhil is an IAM user in account C.

1. In account A, Anaya creates a bucket named Account-A-bucket.
2. Anaya adds the bucket policy to the bucket. The policy allows any user in account A, account B, or account C to perform the Amazon S3 PutObject and DeleteObject actions in the bucket. The policy includes an MFA condition.

```
{
  "Version": "2012-10-17",
  "Statement": [{
    "Effect": "Allow",
    "Principal": {"AWS": [
      "ACCOUNT-A-ID",
      "ACCOUNT-B-ID",
      "ACCOUNT-C-ID"
    ]},
    "Action": [
      "s3:PutObject",
      "s3:DeleteObject"
    ],
    "Resource": ["arn:aws:s3:::ACCOUNT-A-BUCKET-NAME/*"],
    "Condition": {"Bool": {"aws:MultiFactorAuthPresent": "true"}}
  ]
}
```

Note

Amazon S3 offers an MFA Delete feature for *root* account access (only). You can enable Amazon S3 MFA Delete when you set the versioning state of the bucket. Amazon S3 MFA Delete cannot be applied to an IAM user, and is managed independently from MFA-protected API access. An IAM user with permissions to delete a bucket cannot delete a bucket with Amazon S3 MFA Delete enabled. For more information on Amazon S3 MFA Delete, see [MFA Delete](#).

3. In account C, an administrator makes sure that user Nikhil is configured with an AWS MFA device and that he knows the ID of the device. The device ID is the serial number if it's a hardware MFA device, or the device's ARN if it's a virtual MFA device.
4. In account C, Nikhil (or an application that he is running) calls `GetSessionToken`. The call includes the ID or ARN of the MFA device and the current TOTP that Nikhil gets from his device.

5. Nikhil (or an application that he is using) uses the temporary credentials returned by `GetSessionToken` to call the Amazon S3 `PutObject` action to upload a file to `Account-A-bucket`.

For an example of a program that calls `GetSessionToken`, see [Calling `GetSessionToken` with MFA authentication](#) later in this document.

Note

The temporary credentials that `AssumeRole` returns won't work in this case. Although the user can provide MFA information to assume a role, the temporary credentials returned by `AssumeRole` don't include the MFA information. That information is required in order to meet the MFA condition in the policy.

Sample code: Requesting credentials with multi-factor authentication

The following examples show how to call `GetSessionToken` and `AssumeRole` operations and pass MFA authentication parameters. No permissions are required to call `GetSessionToken`, but you must have a policy that allows you to call `AssumeRole`. The credentials returned are then used to list all S3 buckets in the account.

Calling `GetSessionToken` with MFA authentication

The following example shows how to call `GetSessionToken` and pass MFA authentication information. The temporary security credentials returned by the `GetSessionToken` operation are then used to list all S3 buckets in the account.

The policy attached to the user who runs this code (or to a group that the user is in) provides the permissions for the returned temporary credentials. For this example code, the policy must grant the user permission to request the Amazon S3 `ListBuckets` operation.

The following code examples show how to get a session token with AWS STS and use it to perform a service action that requires an MFA token.

CLI

AWS CLI

To get a set of short term credentials for an IAM identity

The following `get-session-token` command retrieves a set of short-term credentials for the IAM identity making the call. The resulting credentials can be used for requests where multi-factor authentication (MFA) is required by policy. The credentials expire 15 minutes after they are generated.

```
aws sts get-session-token \  
  --duration-seconds 900 \  
  --serial-number "YourMFADeviceSerialNumber" \  
  --token-code 123456
```

Output:

```
{  
  "Credentials": {  
    "AccessKeyId": "ASIAIOSFODNN7EXAMPLE",  
    "SecretAccessKey": "wJalrXUtnFEMI/K7MDENG/bPxrFiCYzEXAMPLEKEY",  
    "SessionToken": "AQoEXAMPLEH4aoAH0gNCAPyJxz4B1CFFxWNE10PTgk5TthT  
+FvwqnKwRc0IfrrRh3c/LTo6UDdyJw00vEVPvLXCrrrUtdnniCEXAMPLE/  
IvU1dYUg2RVAJBanLiHb4IgRmpRV3zrkuWJ0gQs8IZZaIv2BXIa2R40lgkBN9bkUDNCJiBeb/  
AXlzBBko7b15fjrBs2+cTQtpZ3CYWFXG8C5zqx37wn0E49mRl/+0tkIKG07fAE",  
    "Expiration": "2020-05-19T18:06:10+00:00"  
  }  
}
```

Get a session token by passing an MFA token and use it to list Amazon S3 buckets for the account.

```
def list_buckets_with_session_token_with_mfa(mfa_serial_number, mfa_totp,
      sts_client):
    """
    Gets a session token with MFA credentials and uses the temporary session
    credentials to list Amazon S3 buckets.

    Requires an MFA device serial number and token.

    :param mfa_serial_number: The serial number of the MFA device. For a virtual
    MFA
                               device, this is an Amazon Resource Name (ARN).
    :param mfa_totp: A time-based, one-time password issued by the MFA device.
    :param sts_client: A Boto3 STS instance that has permission to assume the
    role.
    """
    if mfa_serial_number is not None:
        response = sts_client.get_session_token(
            SerialNumber=mfa_serial_number, TokenCode=mfa_totp
        )
    else:
        response = sts_client.get_session_token()
    temp_credentials = response["Credentials"]

    s3_resource = boto3.resource(
        "s3",
        aws_access_key_id=temp_credentials["AccessKeyId"],
        aws_secret_access_key=temp_credentials["SecretAccessKey"],
        aws_session_token=temp_credentials["SessionToken"],
    )

    print(f"Buckets for the account:")
    for bucket in s3_resource.buckets.all():
        print(bucket.name)
```

- For API details, see [GetSessionToken](#) in *AWS SDK for Python (Boto3) API Reference*.

Calling AssumeRole with MFA authentication

The following examples show how to call `AssumeRole` and pass MFA authentication information. The temporary security credentials returned by `AssumeRole` are then used to list all Amazon S3 buckets in the account.

For more information about this scenario, see [Scenario: MFA protection for cross-account delegation](#).

The following code examples show how to assume a role with AWS STS.

Note

There's more on GitHub. Find the complete example and learn how to set up and run in the [AWS Code Examples Repository](#).

```
bool AwsDoc::STS::assumeRole(const Aws::String &roleArn,  
                             const Aws::String &roleSessionName,  
                             const Aws::String &externalId,  
                             Aws::Auth::AWSCredentials &credentials,  
                             const Aws::Client::ClientConfiguration  
&clientConfig) {  
    Aws::STS::STSClient sts(clientConfig);  
    Aws::STS::Model::AssumeRoleRequest sts_req;  
  
    sts_req.SetRoleArn(roleArn);  
    sts_req.SetRoleSessionName(roleSessionName);  
    sts_req.SetExternalId(externalId);
```

```
const Aws::STS::Model::AssumeRoleOutcome outcome = sts.AssumeRole(sts_req);

if (!outcome.IsSuccess()) {
    std::cerr << "Error assuming IAM role. " <<
        outcome.GetError().GetMessage() << std::endl;
}
else {
    std::cout << "Credentials successfully retrieved." << std::endl;
    const Aws::STS::Model::AssumeRoleResult result = outcome.GetResult();
    const Aws::STS::Model::Credentials &temp_credentials =
result.GetCredentials();

    // Store temporary credentials in return argument.
    // Note: The credentials object returned by assumeRole differs
    // from the AWSCredentials object used in most situations.
    credentials.SetAWSAccessKeyId(temp_credentials.GetAccessKeyId());
    credentials.SetAWSSecretKey(temp_credentials.GetSecretAccessKey());
    credentials.SetSessionToken(temp_credentials.GetSessionToken());
}

return outcome.IsSuccess();
}
```

- For API details, see [AssumeRole](#) in *AWS SDK for C++ API Reference*.

CLI

AWS CLI

To assume a role

The following `assume-role` command retrieves a set of short-term credentials for the IAM role `s3-access-example`.

```
aws sts assume-role \
  --role-arn arn:aws:iam::123456789012:role/xaccounts3access \
  --role-session-name s3-access-example
```

Output:

```
{
```

```

    "AssumedRoleUser": {
      "AssumedRoleId": "AROAZXFRBF535PLBIFPI4:s3-access-example",
      "Arn": "arn:aws:sts::123456789012:assumed-role/xaccounts3access/s3-
access-example"
    },
    "Credentials": {
      "SecretAccessKey": "9drTJvcXLB89EXAMPLELb8923FB892xMFI",
      "SessionToken": "AQoXdzELDDY//////////
wEaoAK1wvxJY12r2IrDFT2IvAzTCn3zHoZ7YNtpiQLF0MqZye/
qwjzP2iEXAMPLEbw/m3hsj8VBTKPORGvr9jM5sgP+w9IZWZnU+LWhmg
+a5fDi2oTGUYcdg9uexQ4mtCHIHfi4citgqZTgco40Yqr4lIlo4V2b2Dyauk0eYFNebHtY1FVgAUj
+7Indz3LU0aTWk1WKIjHmMCIoTkyYp/k7kUG7moeEYKSitwQIi6Gjn+nyzM
+PtoA3685ixzv0R7i5rjQi0YE0lf1oeie3bDiNHncmzosRM6SFIPzSvp6h/32xQuZsjcypmwsPSDtTPYcs0+YN/8B
IcrxSpnWEXAMPLEXSDFTAQAM6Dl9zR0tXoybnlrZIwMLlMi1Kcgo50ytwU=",
      "Expiration": "2016-03-15T00:05:07Z",
      "AccessKeyId": "ASIAJEXAMPLEXEG2JICEA"
    }
  }
}

```

The output of the command contains an access key, secret key, and session token that you can use to authenticate to AWS.

For AWS CLI use, you can set up a named profile associated with a role. When you use the profile, the AWS CLI will call `assume-role` and manage credentials for you. For more information, see [Use an IAM role in the AWS CLI](#) in the *AWS CLI User Guide*.

- For API details, see [AssumeRole](#) in *AWS CLI Command Reference*.

        roleArn: role.arn,
        roleSessionName: sessionName
    )
    do {
        let output = try await stsClient.assumeRole(input: input)

        guard let credentials = output.credentials else {
            throw ServiceHandlerError.authError
        }

        return credentials
    } catch {
        throw error
    }
}
```

- For API details, see [AssumeRole](#) in *AWS SDK for Swift API reference*.

Finding unused credentials

To increase the security of your AWS account, remove IAM user credentials (that is, passwords and access keys) that are not needed. For example, when users leave your organization or no longer need AWS access, find the credentials that they were using and ensure that they are no longer operational. Ideally, you delete credentials if they are no longer needed. You can always recreate them at a later date if the need arises. At the very least, you should change the password or deactivate the access keys so that the former users no longer have access.

Of course, the definition of *unused* can vary and usually means a credential that has not been used within a specified period of time.

Finding unused passwords

You can use the AWS Management Console to view password usage information for your users. If you have a large number of users, you can use the console to download a credential report with information about when each user last used their console password. You can also access the information from the AWS CLI or the IAM API.

To find unused passwords (console)

1. Sign in to the AWS Management Console and open the IAM console at <https://console.aws.amazon.com/iam/>.
2. In the navigation pane, choose **Users**.
3. If necessary, add the **Console last sign-in** column to the users table:
 - a. Above the table on the far right, choose the settings icon ).
 - b. In **Select visible columns**, select **Console last sign-in**.
 - c. Choose **Confirm** to return to the list of users.
4. The **Console last sign-in** column shows the date when the user last signed in to AWS through the console. You can use this information to find users with passwords who have not signed in for more than a specified period of time. The column displays **Never** for users with passwords that have never signed in. **None** indicates users with no passwords. Passwords that have not been used recently might be good candidates for removal.

⚠ Important

Due to a service issue, password last used data does not include password use from May 3rd 2018 22:50 PDT to May 23rd 2018 14:08 PDT. This affects [last sign-in](#) dates shown in the IAM console and password last used dates in the [IAM credential report](#), and returned by the [GetUser API operation](#). If users signed in during the affected time, the password last used date that is returned is the date the user last signed in before May 3rd 2018. For users that signed in after May 23rd 2018 14:08 PDT, the returned password last used date is accurate.

If you use password last used information to identify unused credentials for deletion, such as deleting users who did not sign in to AWS in the last 90 days, we recommend that you adjust your evaluation window to include dates after May 23rd 2018.

Alternatively, if your users use access keys to access AWS programmatically you can refer to access key last used information because it is accurate for all dates.

To find unused passwords by downloading the credentials report (console)

1. Sign in to the AWS Management Console and open the IAM console at <https://console.aws.amazon.com/iam/>.
2. In the navigation pane, choose **Credential report**.
3. Choose **Download Report** to download a comma-separated value (CSV) file named `status_reports_<date>T<time>.csv`. The fifth column contains the `password_last_used` column with the dates or one of the following:
 - **N/A** – Users that do not have a password assigned at all.
 - **no_information** – Users that have not used their password since IAM began tracking password age on October 20, 2014.

To find unused passwords (AWS CLI)

Run the following command to find unused passwords:

- [aws iam list-users](#) returns a list of users, each with a `PasswordLastUsed` value. If the value is missing, then the user either has no password or the password has not been used since IAM began tracking password age on October 20, 2014.

To find unused passwords (AWS API)

Call the following operation to find unused passwords:

- [ListUsers](#) returns a collection of users, each of which has a <PasswordLastUsed> value. If the value is missing, then the user either has no password or the password has not been used since IAM began tracking password age on October 20, 2014.

For information about the commands to download the credentials report, see [Getting credential reports \(AWS CLI\)](#).

Finding unused access keys

You can use the AWS Management Console to view access key usage information for your users. If you have a large number of users, you can use the console to download a credentials report to find when each user last used their access keys. You can also access the information from the AWS CLI or the IAM API.

To find unused access keys (console)

1. Sign in to the AWS Management Console and open the IAM console at <https://console.aws.amazon.com/iam/>.
2. In the navigation pane, choose **Users**.
3. If necessary, add the **Access key last used** column to the users table:
 - a. Above the table on the far right, choose the settings icon ).
 - b. In **Select visible columns**, select **Access key last used**.
 - c. Choose **Confirm** to return to the list of users.
4. The **Access key last used** column shows the number of days since the user last accessed AWS programmatically. You can use this information to find users with access keys that have not been used for more than a specified period of time. The column displays – for users with no access keys. Access keys that have not been used recently might be good candidates for removal.

To find unused access keys by downloading the credentials report (console)

1. Sign in to the AWS Management Console and open the IAM console at <https://console.aws.amazon.com/iam/>.
2. In the navigation pane, choose **Credential Report**.
3. Choose **Download Report** to download a comma-separated value (CSV) file named `status_reports_<date>T<time>.csv`. Columns 11 through 13 contain the last used date, Region, and service information for access key 1. Columns 16 through 18 contain the same information for access key 2. The value is **N/A** if the user does not have an access key or the user has not used the access key since IAM began tracking access key age on April 22, 2015.

To find unused access keys (AWS CLI)

Run the following commands to find unused access keys:

- [aws iam list-access-keys](#) returns information about the access keys for a user, including the AccessKeyID.
- [aws iam get-access-key-last-used](#) takes an access key ID and returns output that includes the LastUsedDate, the Region in which the access key was last used, and the ServiceName of the last service requested. If LastUsedDate is missing, then the access key has not been used since IAM began tracking access key age on April 22, 2015.

To find unused access keys (AWS API)

Call the following operations to find unused access keys:

- [ListAccessKeys](#) returns a list of AccessKeyID values for access keys that are associated with the specified user.
- [GetAccessKeyLastUsed](#) takes an access key ID and returns a collection of values. Included are the LastUsedDate, the Region in which the access key was last used, and the ServiceName of the last service requested. If the value is missing, then either the user has no access key or the access key has not been used since IAM began tracking access key age on April 22, 2015.

For information about the commands to download the credentials report, see [Getting credential reports \(AWS CLI\)](#).

Getting credential reports for your AWS account

You can generate and download a *credential report* that lists all users in your account and the status of their various credentials, including passwords, access keys, and MFA devices. You can get a credential report from the AWS Management Console, the [AWS SDKs](#) and [Command Line Tools](#), or the IAM API.

You can use credential reports to assist in your auditing and compliance efforts. You can use the report to audit the effects of credential lifecycle requirements, such as password and access key updates. You can provide the report to an external auditor, or grant permissions to an auditor so that he or she can download the report directly.

You can generate a credential report as often as once every four hours. When you request a report, IAM first checks whether a report for the AWS account has been generated within the past four hours. If so, the most recent report is downloaded. If the most recent report for the account is older than four hours, or if there are no previous reports for the account, IAM generates and downloads a new report.

Topics

- [Required permissions](#)
- [Understanding the report format](#)
- [Getting credential reports \(console\)](#)
- [Getting credential reports \(AWS CLI\)](#)
- [Getting credential reports \(AWS API\)](#)

Required permissions

The following permissions are needed to create and download reports:

- To create a credential report: `iam:GenerateCredentialReport`
- To download the report: `iam:GetCredentialReport`

Understanding the report format

Credential reports are formatted as comma-separated values (CSV) files. You can open CSV files with common spreadsheet software to perform analysis, or you can build an application that consumes the CSV files programmatically and performs custom analysis.

The CSV file contains the following columns:

user

The friendly name of the user.

arn

The Amazon Resource Name (ARN) of the user. For more information about ARNs, see [IAM ARNs](#).

user_creation_time

The date and time when the user was created, in [ISO 8601 date-time format](#).

password_enabled

When the user has a password, this value is TRUE. Otherwise it is FALSE. The value for the AWS account root user is always not_supported.

password_last_used

The date and time when the AWS account root user or user's password was last used to sign in to an AWS website, in [ISO 8601 date-time format](#). AWS websites that capture a user's last sign-in time are the AWS Management Console, the AWS Discussion Forums, and the AWS Marketplace. When a password is used more than once in a 5-minute span, only the first use is recorded in this field.

- The value in this field is no_information in these cases:
 - The user's password has never been used.
 - There is no sign-in data associated with the password, such as when user's password has not been used after IAM started tracking this information on October 20, 2014.
- The value in this field is N/A (not applicable) when the user does not have a password.

 Important

Due to a service issue, password last used data does not include password use from May 3rd 2018 22:50 PDT to May 23rd 2018 14:08 PDT. This affects [last sign-in](#) dates shown in the IAM console and password last used dates in the [IAM credential report](#), and returned by the [GetUser API operation](#). If users signed in during the affected time, the password last used date that is returned is the date the user last signed in before May 3rd 2018. For users that signed in after May 23rd 2018 14:08 PDT, the returned password last used date is accurate.

If you use password last used information to identify unused credentials for deletion, such as deleting users who did not sign in to AWS in the last 90 days, we recommend that you adjust your evaluation window to include dates after May 23rd 2018. Alternatively, if your users use access keys to access AWS programmatically you can refer to access key last used information because it is accurate for all dates.

password_last_changed

The date and time when the user's password was last set, in [ISO 8601 date-time format](#). If the user does not have a password, the value in this field is N/A (not applicable). The value for the AWS account (root) is always `not_supported`.

password_next_rotation

When the account has a [password policy](#) that requires password rotation, this field contains the date and time, in [ISO 8601 date-time format](#), when the user is required to set a new password. The value for the AWS account (root) is always `not_supported`.

mfa_active

When a [multi-factor authentication](#) (MFA) device has been enabled for the user, this value is TRUE. Otherwise it is FALSE.

access_key_1_active

When the user has an access key and the access key's status is `Active`, this value is TRUE. Otherwise it is FALSE.

access_key_1_last_rotated

The date and time, in [ISO 8601 date-time format](#), when the user's access key was created or last changed. If the user does not have an active access key, the value in this field is N/A (not applicable).

access_key_1_last_used_date

The date and time, in [ISO 8601 date-time format](#), when the user's access key was most recently used to sign an AWS API request. When an access key is used more than once in a 15-minute span, only the first use is recorded in this field.

The value in this field is N/A (not applicable) in these cases:

- The user does not have an access key.
- The access key has never been used.
- The access key has not been used after IAM started tracking this information on April 22, 2015.

access_key_1_last_used_region

The [AWS Region](#) in which the access key was most recently used. When an access key is used more than once in a 15-minute span, only the first use is recorded in this field.

The value in this field is N/A (not applicable) in these cases:

- The user does not have an access key.
- The access key has never been used.
- The access key was last used before IAM started tracking this information on April 22, 2015.
- The last used service is not Region-specific, such as Amazon S3.

access_key_1_last_used_service

The AWS service that was most recently accessed with the access key. The value in this field uses the service's namespace—for example, s3 for Amazon S3 and ec2 for Amazon EC2. When an access key is used more than once in a 15-minute span, only the first use is recorded in this field.

The value in this field is N/A (not applicable) in these cases:

- The user does not have an access key.
- The access key has never been used.
- The access key was last used before IAM started tracking this information on April 22, 2015.

access_key_2_active

When the user has a second access key and the second key's status is `Active`, this value is `TRUE`. Otherwise it is `FALSE`.

Note

Users can have up to two access keys, to make rotation easier by updating the key first and then deleting the previous key. For more information about updating access keys, see [Updating access keys](#).

access_key_2_last_rotated

The date and time, in [ISO 8601 date-time format](#), when the user's second access key was created or last updated. If the user does not have a second active access key, the value in this field is N/A (not applicable).

access_key_2_last_used_date

The date and time, in [ISO 8601 date-time format](#), when the user's second access key was most recently used to sign an AWS API request. When an access key is used more than once in a 15-minute span, only the first use is recorded in this field.

The value in this field is N/A (not applicable) in these cases:

- The user does not have a second access key.
- The user's second access key has never been used.
- The user's second access key was last used before IAM started tracking this information on April 22, 2015.

access_key_2_last_used_region

The [AWS Region](#) in which the user's second access key was most recently used. When an access key is used more than once in a 15-minute span, only the first use is recorded in this field. The value in this field is N/A (not applicable) in these cases:

- The user does not have a second access key.
- The user's second access key has never been used.
- The user's second access key was last used before IAM started tracking this information on April 22, 2015.
- The last used service is not Region-specific, such as Amazon S3.

access_key_2_last_used_service

The AWS service that was most recently accessed with the user's second access key. The value in this field uses the service's namespace—for example, s3 for Amazon S3 and ec2 for Amazon EC2. When an access key is used more than once in a 15-minute span, only the first use is recorded in this field. The value in this field is N/A (not applicable) in these cases:

- The user does not have a second access key.
- The user's second access key has never been used.

- The user's second access key was last used before IAM started tracking this information on April 22, 2015.

cert_1_active

When the user has an X.509 signing certificate and that certificate's status is `Active`, this value is `TRUE`. Otherwise it is `FALSE`.

cert_1_last_rotated

The date and time, in [ISO 8601 date-time format](#), when the user's signing certificate was created or last changed. If the user does not have an active signing certificate, the value in this field is N/A (not applicable).

cert_2_active

When the user has a second X.509 signing certificate and that certificate's status is `Active`, this value is `TRUE`. Otherwise it is `FALSE`.

Note

Users can have up to two X.509 signing certificates, to make certificate rotation easier.

cert_2_last_rotated

The date and time, in [ISO 8601 date-time format](#), when the user's second signing certificate was created or last changed. If the user does not have a second active signing certificate, the value in this field is N/A (not applicable).

Getting credential reports (console)

You can use the AWS Management Console to download a credential report as a comma-separated values (CSV) file.

To download a credential report (console)

1. Sign in to the AWS Management Console and open the IAM console at <https://console.aws.amazon.com/iam/>.
2. In the navigation pane, choose **Credential report**.
3. Choose **Download Report**.

Getting credential reports (AWS CLI)

To download a credentials report (AWS CLI)

1. Generate a credentials report. AWS stores a single report. If a report exists, generating a credentials report overwrites the previous report. [aws iam generate-credential-report](#)
2. View the last report that was generated: [aws iam get-credential-report](#)

Getting credential reports (AWS API)

To download a credentials report (AWS API)

1. Generate a credentials report. AWS stores a single report. If a report exists, generating a credentials report overwrites the previous report. [GenerateCredentialReport](#)
2. View the last report that was generated: [GetCredentialReport](#)

Using IAM with CodeCommit: Git credentials, SSH keys, and AWS access keys

CodeCommit is a managed version control service that hosts private Git repositories in the AWS cloud. To use CodeCommit, you configure your Git client to communicate with CodeCommit repositories. As part of this configuration, you provide IAM credentials that CodeCommit can use to authenticate you. IAM supports CodeCommit with three types of credentials:

- Git credentials, an IAM-generated user name and password pair you can use to communicate with CodeCommit repositories over HTTPS.
- SSH keys, a locally generated public-private key pair that you can associate with your IAM user to communicate with CodeCommit repositories over SSH.
- [AWS access keys](#), which you can use with the credential helper included with the AWS CLI to communicate with CodeCommit repositories over HTTPS.

Note

You cannot use SSH keys or Git credentials to access repositories in another AWS account. To learn how to configure access to CodeCommit repositories for IAM users and groups

in another AWS account, see [Configure cross-account access to an AWS CodeCommit repository using roles](#) in the *AWS CodeCommit User Guide*.

See the following sections for more information about each option.

Use Git credentials and HTTPS with CodeCommit (recommended)

With Git credentials, you generate a static user name and password pair for your IAM user, and then use those credentials for HTTPS connections. You can also use these credentials with any third-party tool or integrated development environment (IDE) that supports static Git credentials.

Because these credentials are universal for all supported operating systems and compatible with most credential management systems, development environments, and other software development tools, this is the recommended method. You can reset the password for Git credentials at any time. You can also make the credentials inactive or delete them if you no longer need them.

Note

You cannot choose your own user name or password for Git credentials. IAM generates these credentials for you to help ensure they meet the security standards for AWS and secure repositories in CodeCommit. You can download the credentials only once, at the time they are generated. Make sure that you save the credentials in a secure location. If necessary, you can reset the password at any time, but doing so invalidates any connections configured with the old password. You must reconfigure connections to use the new password before you can connect.

See the following topics for more information:

- To create an IAM user, see [Creating an IAM user in your AWS account](#).
- To generate and use Git credentials with CodeCommit, see [For HTTPS Users Using Git Credentials](#) in the *AWS CodeCommit User Guide*.

Note

Changing the name of an IAM user after generating Git credentials does not change the user name of the Git credentials. The user name and password remain the same and are still valid.

To update service specific credentials

1. Create a second service-specific credential set in addition to the set currently in use.
2. Update all of your applications to use the new set of credentials and validate that the applications are working.
3. Change the state of the original credentials to "Inactive".
4. Ensure that all of your applications are still working.
5. Delete the inactive service-specific credentials.

Use SSH keys and SSH with CodeCommit

With SSH connections, you create public and private key files on your local machine that Git and CodeCommit use for SSH authentication. You associate the public key with your IAM user and store the private key on your local machine. See the following topics for more information:

- To create an IAM user, see [Creating an IAM user in your AWS account](#).
- To create an SSH public key and associate it with an IAM user, see [For SSH Connections on Linux, macOS, or Unix](#) or see [For SSH Connections on Windows](#) in the *AWS CodeCommit User Guide*.

Note

The public key must be encoded in ssh-rsa format or PEM format. The minimum bit-length of the public key is 2048 bits, and the maximum length is 16384 bits. This is separate from the size of the file you upload. For example, you can generate a 2048-bit key, and the resulting PEM file is 1679 bytes long. If you provide your public key in another format or size, you will see an error message stating that the key format is not valid.

Use HTTPS with the AWS CLI credential helper and CodeCommit

As an alternative to HTTPS connections with Git credentials, you can allow Git to use a cryptographically signed version of your IAM user credentials or Amazon EC2 instance role whenever Git needs to authenticate with AWS to interact with CodeCommit repositories. This is the only connection method for CodeCommit repositories that does not require an IAM user. This is also the only method that works with federated access and temporary credentials. See the following topics for more information:

- To learn more about federated access, see [Identity providers and federation](#) and [Providing access to externally authenticated users \(identity federation\)](#).
- To learn more about temporary credentials, see [Temporary security credentials in IAM](#) and [Temporary Access to CodeCommit Repositories](#).

The AWS CLI credential helper is not compatible with other credential helper systems, such as Keychain Access or Windows Credential Management. There are additional configuration considerations when you configure HTTPS connections with the credential helper. For more information, see [For HTTPS Connections on Linux, macOS, or Unix with the AWS CLI Credential Helper](#) or [HTTPS Connections on Windows with the AWS CLI Credential Helper](#) in the *AWS CodeCommit User Guide*.

Using IAM with Amazon Keyspaces (for Apache Cassandra)

Amazon Keyspaces (for Apache Cassandra) is a scalable, highly available, and managed Apache Cassandra-compatible database service. You can access Amazon Keyspaces through the AWS Management Console, or programmatically. To access Amazon Keyspaces programmatically with service-specific credentials, you can use `cqlsh` or open-source Cassandra drivers. *Service-specific credentials* include a user name and password like those that Cassandra uses for authentication and access management. You can have a maximum of two sets of service-specific credentials for each supported service per user.

To access Amazon Keyspaces programmatically with AWS access keys, you can use the AWS SDK, the AWS Command Line Interface (AWS CLI) or open-source Cassandra drivers with the SigV4 plugin. To learn more, see [Connecting programmatically to Amazon Keyspaces](#) in the *Amazon Keyspaces (for Apache Cassandra) Developer Guide*.

Note

If you plan to interact with Amazon Keyspaces only through the console, you don't need to generate service-specific credentials. For more information, see [Accessing Amazon Keyspaces using the console](#) in the *Amazon Keyspaces (for Apache Cassandra) Developer Guide*.

For more information about the permissions required to access Amazon Keyspaces, see [Amazon Keyspaces \(for Apache Cassandra\) Identity-Based Policy Examples](#) in the *Amazon Keyspaces (for Apache Cassandra) Developer Guide*.

Generating Amazon Keyspaces credentials (console)

You can use the AWS Management Console to generate Amazon Keyspaces (for Apache Cassandra) credentials for your IAM users.

To generate Amazon Keyspaces service-specific credentials (console)

1. Sign in to the AWS Management Console and open the IAM console at <https://console.aws.amazon.com/iam/>.
2. In the navigation pane, choose **Users** and then choose the name of the user that requires the credentials.
3. On the **Security Credentials** tab beneath **Credentials for Amazon Keyspaces (for Apache Cassandra)**, choose **Generate credentials**.
4. Your service-specific credentials are now available. This is the only time that the password can be viewed or downloaded. You cannot recover it later. However, you can reset your password at any time. Save the user and password in a secure location, because you'll need them later.

Generating Amazon Keyspaces credentials (AWS CLI)

You can use the AWS CLI to generate Amazon Keyspaces (for Apache Cassandra) credentials for your IAM users.

To generate Amazon Keyspaces service-specific credentials (AWS CLI)

- Use the following command:

- [aws iam create-service-specific-credential](#)

Generating Amazon Keyspaces credentials (AWS API)

You can use the AWS API to generate Amazon Keyspaces (for Apache Cassandra) credentials for your IAM users.

To generate Amazon Keyspaces service-specific credentials (AWS API)

- Complete the following operation:
 - [CreateServiceSpecificCredential](#)

Managing server certificates in IAM

To enable HTTPS connections to your website or application in AWS, you need an SSL/TLS *server certificate*. For certificates in a Region supported by AWS Certificate Manager (ACM), we recommend that you use ACM to provision, manage, and deploy your server certificates. In unsupported Regions, you must use IAM as a certificate manager. To learn which Regions ACM supports, see [AWS Certificate Manager endpoints and quotas](#) in the *AWS General Reference*.

ACM is the preferred tool to provision, manage, and deploy your server certificates. With ACM you can request a certificate or deploy an existing ACM or external certificate to AWS resources. Certificates provided by ACM are free and automatically renew. In a [supported Region](#), you can use ACM to manage server certificates from the console or programmatically. For more information about using ACM, see the [AWS Certificate Manager User Guide](#). For more information about requesting an ACM certificate, see [Request a Public Certificate](#) or [Request a Private Certificate](#) in the *AWS Certificate Manager User Guide*. For more information about importing third-party certificates into ACM, see [Importing Certificates](#) in the *AWS Certificate Manager User Guide*.

Use IAM as a certificate manager only when you must support HTTPS connections in a Region that is not [supported by ACM](#). IAM securely encrypts your private keys and stores the encrypted version in IAM SSL certificate storage. IAM supports deploying server certificates in all Regions, but you must obtain your certificate from an external provider for use with AWS. You cannot upload an ACM certificate to IAM. Additionally, you cannot manage your certificates from the IAM Console.

For more information about uploading third-party certificates to IAM, see the following topics.

Contents

- [Uploading a server certificate \(AWS API\)](#)
- [Retrieving a server certificate \(AWS API\)](#)
- [Listing server certificates \(AWS API\)](#)
- [Tagging and Untagging Server Certificates \(AWS API\)](#)
- [Renaming a server certificate or updating its path \(AWS API\)](#)
- [Deleting a server certificate \(AWS API\)](#)
- [Troubleshooting](#)

Uploading a server certificate (AWS API)

To upload a server certificate to IAM, you must provide the certificate and its matching private key. When the certificate is not self-signed, you must also provide a certificate chain. (You don't need a certificate chain when uploading a self-signed certificate.) Before you upload a certificate, ensure that you have all these items and that they meet the following criteria:

- The certificate must be valid at the time of upload. You cannot upload a certificate before its validity period begins (the certificate's `NotBefore` date) or after it expires (the certificate's `NotAfter` date).
- The private key must be unencrypted. You cannot upload a private key that is protected by a password or passphrase. For help decrypting an encrypted private key, see [Troubleshooting](#).
- The certificate, private key, and certificate chain must all be PEM-encoded. For help converting these items to PEM format, see [Troubleshooting](#).

To use the [IAM API](#) to upload a certificate, send an [UploadServerCertificate](#) request. The following example shows how to do this with the [AWS Command Line Interface \(AWS CLI\)](#). The example assumes the following:

- The PEM-encoded certificate is stored in a file named `Certificate.pem`.
- The PEM-encoded certificate chain is stored in a file named `CertificateChain.pem`.
- The PEM-encoded, unencrypted private key is stored in a file named `PrivateKey.pem`.
- (Optional) You want to tag the server certificate with a key–value pair. For example, you might add the tag key `Department` and the tag value `Engineering` to help you identify and organize your certificates.

To use the following example command, replace these file names with your own. Replace *ExampleCertificate* with a name for your uploaded certificate. If you want to tag the certificate, replace the *ExampleKey* and *ExampleValue* tag key-value pair with your own values. Type the command on one continuous line. The following example includes line breaks and extra spaces to make it easier to read.

```
aws iam upload-server-certificate --server-certificate-name ExampleCertificate
                                --certificate-body file://Certificate.pem
                                --certificate-chain file://CertificateChain.pem
                                --private-key file://PrivateKey.pem
                                --tags '{"Key": "ExampleKey", "Value":
"ExampleValue"}'
```

When the preceding command is successful, it returns metadata about the uploaded certificate, including its [Amazon Resource Name \(ARN\)](#), its friendly name, its identifier (ID), its expiration date, tags, and more.

Note

If you are uploading a server certificate to use with Amazon CloudFront, you must specify a path using the `--path` option. The path must begin with `/cloudfront` and must include a trailing slash (for example, `/cloudfront/test/`).

To use the AWS Tools for Windows PowerShell to upload a certificate, use [Publish-IAMServerCertificate](#).

Retrieving a server certificate (AWS API)

To use the IAM API to retrieve a certificate, send a [GetServerCertificate](#) request. The following example shows how to do this with the AWS CLI. Replace *ExampleCertificate* with the name of the certificate to retrieve.

```
aws iam get-server-certificate --server-certificate-name ExampleCertificate
```

When the preceding command is successful, it returns the certificate, the certificate chain (if one was uploaded), and metadata about the certificate.

Note

You cannot download or retrieve a private key from IAM after you upload it.

To use the AWS Tools for Windows PowerShell to retrieve a certificate, use [Get-IAMServerCertificate](#).

Listing server certificates (AWS API)

To use the IAM API to list your uploaded server certificates, send a [ListServerCertificates](#) request. The following example shows how to do this with the AWS CLI.

```
aws iam list-server-certificates
```

When the preceding command is successful, it returns a list that contains metadata about each certificate.

To use the AWS Tools for Windows PowerShell to list your uploaded server certificates, use [Get-IAMServerCertificates](#).

Tagging and Untagging Server Certificates (AWS API)

You can attach tags to your IAM resources to organize and control access to them. To use the IAM API to tag an existing server certificate, send a [TagServerCertificate](#) request. The following example shows how to do this with the AWS CLI.

```
aws iam tag-server-certificate --server-certificate-name ExampleCertificate
                               --tags '{"Key": "ExampleKey", "Value":
"ExampleValue"}'
```

When the preceding command is successful, no output is returned.

To use the IAM API to untag a server certificate, send a [UntagServerCertificate](#) request. The following example shows how to do this with the AWS CLI.

```
aws iam untag-server-certificate --server-certificate-name ExampleCertificate
                                 --tag-keys ExampleKeyName
```

When the preceding command is successful, no output is returned.

Renaming a server certificate or updating its path (AWS API)

To use the IAM API to rename a server certificate or update its path, send an [UpdateServerCertificate](#) request. The following example shows how to do this with the AWS CLI.

To use the following example command, replace the old and new certificate names and the certificate path, and type the command on one continuous line. The following example includes line breaks and extra spaces to make it easier to read.

```
aws iam update-server-certificate --server-certificate-name ExampleCertificate
                                --new-server-certificate-name CloudFrontCertificate
                                --new-path /cloudfront/
```

When the preceding command is successful, it does not return any output.

To use the AWS Tools for Windows PowerShell to rename a server certificate or update its path, use [Update-IAMServerCertificate](#).

Deleting a server certificate (AWS API)

To use the IAM API to delete a server certificate, send a [DeleteServerCertificate](#) request. The following example shows how to do this with the AWS CLI.

To use the following example command, replace *ExampleCertificate* with the name of the certificate to delete.

```
aws iam delete-server-certificate --server-certificate-name ExampleCertificate
```

When the preceding command is successful, it does not return any output.

To use the AWS Tools for Windows PowerShell to delete a server certificate, use [Remove-IAMServerCertificate](#).

Troubleshooting

Before you can upload a certificate to IAM, you must make sure that the certificate, private key, and certificate chain are all PEM-encoded. You must also ensure that the private key is unencrypted. See the following examples.

Example Example PEM-encoded certificate

```
-----BEGIN CERTIFICATE-----  
Base64-encoded certificate  
-----END CERTIFICATE-----
```

Example Example PEM-encoded, unencrypted private key

```
-----BEGIN RSA PRIVATE KEY-----  
Base64-encoded private key  
-----END RSA PRIVATE KEY-----
```

Example Example PEM-encoded certificate chain

A certificate chain contains one or more certificates. You can use a text editor, the copy command in Windows, or the Linux cat command to concatenate your certificate files into a chain. When you include multiple certificates, each certificate must certify the preceding certificate. You accomplish this by concatenating the certificates, including the root CA certificate last.

The following example contains three certificates, but your certificate chain might contain more or fewer certificates.

```
-----BEGIN CERTIFICATE-----  
Base64-encoded certificate  
-----END CERTIFICATE-----  
-----BEGIN CERTIFICATE-----  
Base64-encoded certificate  
-----END CERTIFICATE-----  
-----BEGIN CERTIFICATE-----  
Base64-encoded certificate  
-----END CERTIFICATE-----
```

If these items are not in the right format for uploading to IAM, you can use [OpenSSL](#) to convert them to the right format.

To convert a certificate or certificate chain from DER to PEM

Use the [OpenSSL x509 command](#), as in the following example. In the following example command, replace *Certificate.der* with the name of the file that contains your DER-encoded certificate. Replace *Certificate.pem* with the preferred name of the output file to contain the PEM-encoded certificate.

```
openssl x509 -inform DER -in Certificate.der -outform PEM -out Certificate.pem
```

To convert a private key from DER to PEM

Use the [OpenSSL rsa command](#), as in the following example. In the following example command, replace *PrivateKey.der* with the name of the file that contains your DER-encoded private key. Replace *PrivateKey.pem* with the preferred name of the output file to contain the PEM-encoded private key.

```
openssl rsa -inform DER -in PrivateKey.der -outform PEM -out PrivateKey.pem
```

To decrypt an encrypted private key (remove the password or passphrase)

Use the [OpenSSL rsa command](#), as in the following example. To use the following example command, replace *EncryptedPrivateKey.pem* with the name of the file that contains your encrypted private key. Replace *PrivateKey.pem* with the preferred name of the output file to contain the PEM-encoded unencrypted private key.

```
openssl rsa -in EncryptedPrivateKey.pem -out PrivateKey.pem
```

To convert a certificate bundle from PKCS#12 (PFX) to PEM

Use the [OpenSSL pkcs12 command](#), as in the following example. In the following example command, replace *CertificateBundle.p12* with the name of the file that contains your PKCS#12-encoded certificate bundle. Replace *CertificateBundle.pem* with the preferred name of the output file to contain the PEM-encoded certificate bundle.

```
openssl pkcs12 -in CertificateBundle.p12 -out CertificateBundle.pem -nodes
```

To convert a certificate bundle from PKCS#7 to PEM

Use the [OpenSSL pkcs7 command](#), as in the following example. In the following example command, replace *CertificateBundle.p7b* with the name of the file that contains your

PKCS#7-encoded certificate bundle. Replace *CertificateBundle.pem* with the preferred name of the output file to contain the PEM-encoded certificate bundle.

```
openssl pkcs7 -in CertificateBundle.p7b -print_certs -out CertificateBundle.pem
```

IAM user groups

An IAM [user group](#) is a collection of IAM users. User groups let you specify permissions for multiple users, which can make it easier to manage the permissions for those users. For example, you could have a user group called *Admins* and give that user group typical administrator permissions. Any user in that user group automatically has *Admins* group permissions. If a new user joins your organization and needs administrator privileges you can assign the appropriate permissions by adding the user to the *Admins* user group. If a person changes jobs in your organization, instead of editing that user's permissions you can remove them from the old user groups and add them to the appropriate new user groups.

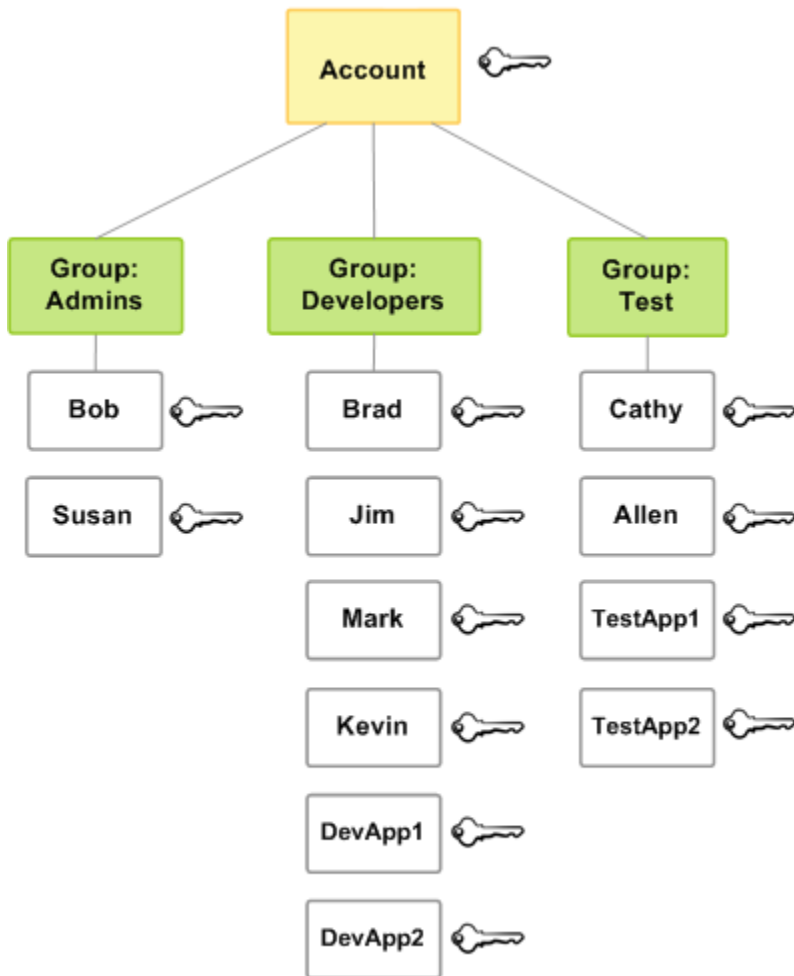

You can attach an identity-based policy to a user group so that all of the users in the user group receive the policy's permissions. You cannot identify a user group as a Principal in a policy (such as a resource-based policy) because groups relate to permissions, not authentication, and principals are authenticated IAM entities. For more information about policy types, see [Identity-based policies and resource-based policies](#).

Here are some important characteristics of user groups:

- A user group can contain many users, and a user can belong to multiple user groups.
- User groups can't be nested; they can contain only users, not other user groups.
- There is no default user group that automatically includes all users in the AWS account. If you want to have a user group like that, you must create it and assign each new user to it.
- The number and size of IAM resources in an AWS account, such as the number of groups, and the number of groups that a user can be a member of, are limited. For more information, see [IAM and AWS STS quotas](#).

The following diagram shows a simple example of a small company. The company owner creates an *Admins* user group for users to create and manage other users as the company grows. The *Admins* user group creates a *Developers* user group and a *Test* user group. Each of these user groups consists of users (humans and applications) that interact with AWS (Jim, Brad, DevApp1, and so

on). Each user has an individual set of security credentials. In this example, each user belongs to a single user group. However, users can belong to multiple user groups.

Creating IAM user groups

Note

As a [best practice](#), we recommend that you require human users to use federation with an identity provider to access AWS using temporary credentials. If you follow the best practices, you are not managing IAM users and groups. Instead, your users and groups are managed outside of AWS and are able to access AWS resources as a *federated identity*. A federated identity is a user from your enterprise user directory, a web identity provider, the AWS Directory Service, the Identity Center directory, or any user that accesses AWS services by using credentials provided through an identity source. Federated identities use the groups defined by their identity provider. If you are using AWS IAM Identity Center,

see [Manage identities in IAM Identity Center](#) in the *AWS IAM Identity Center User Guide* for information about creating users and groups in IAM Identity Center.

To set up a user group, you need to create the group. Then give the group permissions based on the type of work that you expect the users in the group to do. Finally, add users to the group.

For information about the permissions that you need in order to create a user group, see [Permissions required to access IAM resources](#).

To create an IAM user group and attach policies (console)

1. Sign in to the AWS Management Console and open the IAM console at <https://console.aws.amazon.com/iam/>.
2. In the navigation pane, choose **User groups** and then choose **Create group**.
3. For **User group name**, type the name of the group.

Note

The number and size of IAM resources in an AWS account are limited. For more information, see [IAM and AWS STS quotas](#). Group names can be a combination of up to 128 letters, digits, and these characters: plus (+), equal (=), comma (,), period (.), at sign (@), underscore (_), and hyphen (-). Names must be unique within an account. They are not distinguished by case. For example, you cannot create groups named both **ADMINS** and **admins**.

4. In the list of users, select the check box for each user that you want to add to the group.
5. In the list of policies, select the check box for each policy that you want to apply to all members of the group.
6. Choose **Create group**.

To create IAM user groups (AWS CLI or AWS API)

Use one of the following:

- AWS CLI: [aws iam create-group](#)
- AWS API: [CreateGroup](#)

Managing IAM user groups

Amazon Web Services offers multiple tools for managing IAM user groups. For information about the permissions that you need in order to add and remove users in a user group, see [Permissions required to access IAM resources](#).

Topics

- [Listing IAM user groups](#)
- [Adding and removing users in an IAM user group](#)
- [Attaching a policy to an IAM user group](#)
- [Renaming an IAM user group](#)
- [Deleting an IAM user group](#)

Listing IAM user groups

You can list all the user groups in your account, list the users in a user group, and list the user groups a user belongs to. If you use the AWS CLI or AWS API, you can list all the user groups with a particular path prefix.

To list all the user groups in your account

Do any of the following:

- [AWS Management Console](#): In the navigation pane, choose **User groups**.
- AWS CLI: [aws iam list-groups](#)
- AWS API: [ListGroups](#)

To list the users in a specific user group

Do any of the following:

- [AWS Management Console](#): In the navigation pane, choose **User groups**, choose the name of the group, and then choose the **Users** tab.
- AWS CLI: [aws iam get-group](#)
- AWS API: [GetGroup](#)

To list all the user groups that a user is in

Do any of the following:

- [AWS Management Console](#): In the navigation pane, choose **Users**, choose the user name, and then choose the **Groups** tab.
- AWS CLI: [aws iam list-groups-for-user](#)
- AWS API: [ListGroupsWithUser](#)

Adding and removing users in an IAM user group

Use user groups to apply the same permissions policies across multiple users at once. You can then add users to or remove users from an IAM user group. This is useful as people enter and leave your organization.

View policy access

Before you change the permissions for a policy, you should review its recent service-level activity. This is important because you don't want to remove access from a principal (person or application) who is using it. For more information about viewing last accessed information, see [Refining permissions in AWS using last accessed information](#).

Add or remove a user in a user group (console)

You can use the AWS Management Console to add or remove a user from a user group.

To add a user to an IAM user group (console)

1. Sign in to the AWS Management Console and open the IAM console at <https://console.aws.amazon.com/iam/>.
2. In the navigation pane, choose **User groups** and then choose the name of the group.
3. Choose the **Users** tab and then choose **Add users**. Select the check box next to the users you want to add.
4. Choose **Add users**.

To remove a user from an IAM group (console)

1. Sign in to the AWS Management Console and open the IAM console at <https://console.aws.amazon.com/iam/>.

2. In the navigation pane, choose **User groups** and then choose the name of the group.
3. Choose the **Users** tab. Select the check box next to the users you want to remove and then choose **Remove users**.

Add or remove a user in a user group (AWS CLI)

You can use the AWS CLI to add or remove a user from a user group.

To add a user to an IAM user group (AWS CLI)

- Use the following command:
 - [aws iam add-user-to-group](#)

To remove a user from an IAM user group (AWS CLI)

- Use the following command:
 - [aws iam remove-user-from-group](#)

Add or remove a user in a user group (AWS API)

You can use the AWS API to add or remove a user in a user group.

To add a user to an IAM group (AWS API)

- Complete the following operation:
 - [AddUserToGroup](#)

To remove a user from an IAM user group (AWS API)

- Complete the following operation:
 - [RemoveUserFromGroup](#)

Attaching a policy to an IAM user group

You can attach an [AWS managed policy](#)—that is, a prewritten policy provided by AWS—to a user group, as explained in the following steps. To attach a customer managed policy—that is, a policy with custom permissions that you create—you must first create the policy. For information about creating customer managed policies, see [Creating IAM policies](#).

For more information about permissions and policies, see [Access management for AWS resources](#).

To attach a policy to a user group (console)

1. Sign in to the AWS Management Console and open the IAM console at <https://console.aws.amazon.com/iam/>.
2. In the navigation pane, choose **User groups** and then choose the name of the group.
3. Choose the **Permissions** tab.
4. Choose **Add permissions** and then choose **Attach policies**.
5. The current policies attached to the user group are displayed in the **Current permissions policies** list. In the list of **Other permissions policies**, select the check box next to the names of the policies to attach. You can use the search box to filter the list of policies by type and policy name.
6. Select the policy you want to attach to your IAM user group and choose **Attach policies**.

To attach a policy to a user group (AWS CLI or AWS API)

Do either of the following:

- AWS CLI: [aws iam attach-group-policy](#)
- AWS API: [AttachGroupPolicy](#)

Renaming an IAM user group

When you change a user group's name or path, the following happens:

- Any policies attached to the user group stay with the group under the new name.
- The user group retains all its users under the new name.
- The unique ID for the user group remains the same. For more information about unique IDs, see [Unique identifiers](#).

IAM does not automatically update policies that refer to the user group as a resource to use the new name. Therefore, you must be careful when you rename a user group. Before you rename your user group, you must manually check all of your policies to find any policies where that user group is mentioned by name. For example, let's say Bob is the manager of the testing part of the organization. Bob has a policy attached to his IAM user entity that lets him add and remove users from the Test user group. If an administrator changes the name of the user group (or changes the group path), the administrator must also update the policy attached to Bob to use the new name or path. Otherwise Bob won't be able to add and remove users from the user group.

To find policies that refer to a user group as a resource:

1. From the navigation pane of the IAM console, choose **Policies**.
2. Sort by the **Type** column to find your **Customer managed** custom policies.
3. Choose the policy name of the policy to edit.
4. Choose the **Permissions** tab, and then choose **Summary**.
5. Choose **IAM** from the list of services, if it exists.
6. Look for the name of your user group in the **Resource** column.
7. Choose **Edit** to change the name of your user group in the policy.

To change the name of an IAM user group

Do any of the following:

- [AWS Management Console](#): In the navigation pane, choose **User groups** and then select the group name. Choose **Edit**. Type the new user group name and then choose **Save changes**.
- AWS CLI: [aws iam update-group](#)
- AWS API: [UpdateGroup](#)

Deleting an IAM user group

When you delete a user group in the AWS Management Console, the console automatically removes all group members, detaches all attached managed policies, and deletes all inline policies. However, because IAM does not automatically delete policies that refer to the user group as a resource, you must be careful when you delete a user group. Before you delete your user group, you must manually check all of your policies to find any policies that mention the group by name. For example, John, the Test Team manager, has a policy attached to his IAM user entity that

lets him add and remove users from the Test user group. If an administrator deletes the group, the administrator must also delete the policy attached to John. Otherwise, if the administrator recreates the deleted group and give it the same name, John's permissions remain in place, even if he left the Test Team.

To find policies that refer to a user group as a resource

1. From the navigation pane of the IAM console, choose **Policies**.
2. Sort by the **Type** column to find your **Customer managed** custom policies.
3. Choose the policy name of the policy to delete.
4. Choose the **Permissions** tab, and then choose **Summary**.
5. Choose **IAM** from the list of services, if it exists.
6. Look for the name of your user group in the **Resource** column.
7. Choose **Delete** to delete the policy.
8. Type the policy name to confirm deletion of the policy and choose **Delete**.

In contrast, when you use the AWS CLI, Tools for Windows PowerShell, or AWS API to delete a user group, you must first remove the users in the group. Then delete any inline policies embedded in the user group. Next, detach any managed policies that are attached to the group. Only then can you delete the user group itself.

Deleting an IAM user group (console)

You can delete an IAM user group from the AWS Management Console.

To delete an IAM user group (console)

1. Sign in to the AWS Management Console and open the IAM console at <https://console.aws.amazon.com/iam/>.
2. In the navigation pane, choose **User groups**.
3. In the list of user groups, select the check box next to the names of the user groups to delete. You can use the search box to filter the list of user groups by type, permissions, and user group name.
4. Choose **Delete**.
5. In the confirmation box, if you want to delete a single user group, type the user group name and choose **Delete**. If you want to delete multiple user groups, type the number of user groups

to delete followed by **user groups** and choose **Delete**. For example, if you delete three user groups, type **3 user groups**.

Deleting an IAM user group (AWS CLI)

You can delete an IAM user group from the AWS CLI.

To delete an IAM user group (AWS CLI)

1. Remove all users from the user group.
 - [aws iam get-group](#) (to get the list of users in the user group), and [aws iam remove-user-from-group](#) (to remove a user from the user group)
2. Delete all inline policies embedded in the user group.
 - [aws iam list-group-policies](#) (to get a list of the user group's inline policies), and [aws iam delete-group-policy](#) (to delete the user group's inline policies)
3. Detach all managed policies attached to the user group.
 - [aws iam list-attached-group-policies](#) (to get a list of the managed policies attached to the user group), and [aws iam detach-group-policy](#) (to detach a managed policy from the user group)
4. Delete the user group.
 - [aws iam delete-group](#)

Deleting an IAM user group (AWS API)

You can use the AWS API to delete an IAM user group.

To delete an IAM user group (AWS API)

1. Remove all users from the user group.
 - [GetGroup](#) (to get the list of users in the user group) and [RemoveUserFromGroup](#) (to remove a user from the user group)
2. Delete all inline policies embedded in the user group.

- [ListGroupPolicies](#) (to get a list of the user group's inline policies) and [DeleteGroupPolicy](#) (to delete the user group's inline policies)
3. Detach all managed policies attached to the user group.
 - [ListAttachedGroupPolicies](#) (to get a list of the managed policies attached to the user group) and [DetachGroupPolicy](#) (to detach a managed policy from the user group)
 4. Delete the user group.
 - [DeleteGroup](#)

IAM roles

An IAM *role* is an IAM identity that you can create in your account that has specific permissions. An IAM role is similar to an IAM user, in that it is an AWS identity with permission policies that determine what the identity can and cannot do in AWS. However, instead of being uniquely associated with one person, a role is intended to be assumable by anyone who needs it. Also, a role does not have standard long-term credentials such as a password or access keys associated with it. Instead, when you assume a role, it provides you with temporary security credentials for your role session.

You can use roles to delegate access to users, applications, or services that don't normally have access to your AWS resources. For example, you might want to grant users in your AWS account access to resources they don't usually have, or grant users in one AWS account access to resources in another account. Or you might want to allow a mobile app to use AWS resources, but not want to embed AWS keys within the app (where they can be difficult to update and where users can potentially extract them). Sometimes you want to give AWS access to users who already have identities defined outside of AWS, such as in your corporate directory. Or, you might want to grant access to your account to third parties so that they can perform an audit on your resources.

For these scenarios, you can delegate access to AWS resources using an *IAM role*. This section introduces roles and the different ways you can use them, when and how to choose among approaches, and how to create, manage, switch to (or assume), and delete roles.

Note

When you first create your AWS account, no roles are created by default. As you add services to your account, they may add service-linked roles to support their use cases.

A service-linked role is a type of service role that is linked to an AWS service. The service can assume the role to perform an action on your behalf. Service-linked roles appear in your AWS account and are owned by the service. An IAM administrator can view, but not edit the permissions for service-linked roles.

Before you can delete service-linked roles you must first delete their related resources. This protects your resources because you can't inadvertently remove permission to access the resources.

For information about which services support using service-linked roles, see [AWS services that work with IAM](#) and look for the services that have **Yes** in the **Service-Linked Role** column. Choose a **Yes** with a link to view the service-linked role documentation for that service.

Roles terms and concepts

Here are some basic terms to help you get started with roles.

Role

An IAM identity that you can create in your account that has specific permissions. An IAM role has some similarities to an IAM user. Roles and users are both AWS identities with permissions policies that determine what the identity can and cannot do in AWS. However, instead of being uniquely associated with one person, a role is intended to be assumable by anyone who needs it. Also, a role does not have standard long-term credentials such as a password or access keys associated with it. Instead, when you assume a role, it provides you with temporary security credentials for your role session.

Roles can be used by the following:

- An IAM user in the same AWS account as the role
- An IAM user in a different AWS account than the role
- A web service offered by AWS such as Amazon Elastic Compute Cloud (Amazon EC2)
- An external user authenticated by an external identity provider (IdP) service that is compatible with SAML 2.0 or OpenID Connect, or a custom-built identity broker.

AWS service role

A service role is an [IAM role](#) that a service assumes to perform actions on your behalf. An IAM administrator can create, modify, and delete a service role from within IAM. For more information, see [Creating a role to delegate permissions to an AWS service](#) in the *IAM User Guide*.

AWS service role for an EC2 instance

A special type of service role that an application running on an Amazon EC2 instance can assume to perform actions in your account. This role is assigned to the EC2 instance when it is launched. Applications running on that instance can retrieve temporary security credentials and perform actions that the role allows. For details about using a service role for an EC2 instance, see [Using an IAM role to grant permissions to applications running on Amazon EC2 instances](#).

AWS service-linked role

A service-linked role is a type of service role that is linked to an AWS service. The service can assume the role to perform an action on your behalf. Service-linked roles appear in your AWS account and are owned by the service. An IAM administrator can view, but not edit the permissions for service-linked roles.

Note

If you are already using a service when it begins supporting service-linked roles, you might receive an email announcing a new role in your account. In this case, the service automatically created the service-linked role in your account. You don't need to take any action to support this role, and you should not manually delete it. For more information, see [A new role appeared in my AWS account](#).

For information about which services support using service-linked roles, see [AWS services that work with IAM](#) and look for the services that have **Yes** in the **Service-Linked Role** column.

Choose a **Yes** with a link to view the service-linked role documentation for that service. For more information, see [Using service-linked roles](#).

Role chaining

Role chaining is when you use a role to assume a second role through the AWS CLI or API. For example, RoleA has permission to assume RoleB. You can enable User1 to assume RoleA by using their long-term user credentials in the AssumeRole API operation. This returns RoleA short-term credentials. With role chaining, you can use RoleA's short-term credentials to enable User1 to assume RoleB.

When you assume a role, you can pass a session tag and set the tag as transitive. Transitive session tags are passed to all subsequent sessions in a role chain. To learn more about session tags, see [Passing session tags in AWS STS](#).

Role chaining limits your AWS CLI or AWS API role session to a maximum of one hour. When you use the [AssumeRole](#) API operation to assume a role, you can specify the duration of your role session with the DurationSeconds parameter. You can specify a parameter value of up to 43200 seconds (12 hours), depending on the [maximum session duration setting](#) for your role. However, if you assume a role using role chaining and provide a DurationSeconds parameter value greater than one hour, the operation fails.

AWS does not treat using roles to [grant permissions to applications that run on EC2 instances](#) as role chaining.

Delegation

The granting of permissions to someone to allow access to resources that you control. Delegation involves setting up a trust between two accounts. The first is the account that owns the resource (the trusting account). The second is the account that contains the users that need to access the resource (the trusted account). The trusted and trusting accounts can be any of the following:

- The same account.
- Separate accounts that are both under your organization's control.
- Two accounts owned by different organizations.

To delegate permission to access a resource, you [create an IAM role](#) in the trusting account that has two [policies](#) attached. The *permissions policy* grants the user of the role the needed permissions to carry out the intended tasks on the resource. The *trust policy* specifies which trusted account members are allowed to assume the role.

When you create a trust policy, you cannot specify a wildcard (*) as part of an ARN in the principal element. The trust policy is attached to the role in the trusting account, and is one-half of the permissions. The other half is a permissions policy attached to the user in the trusted account that [allows that user to switch to, or assume the role](#). A user who assumes a role temporarily gives up his or her own permissions and instead takes on the permissions of the role. When the user exits, or stops using the role, the original user permissions are restored. An additional parameter called [external ID](#) helps ensure secure use of roles between accounts that are not controlled by the same organization.

Federation

The creation of a trust relationship between an external identity provider and AWS. Users can sign in to a web identity provider, such as **Login with Amazon, Facebook, Google**, or any IdP that is compatible with **OpenID Connect (OIDC)**. Users can also sign in to an enterprise identity system that is compatible with Security Assertion Markup Language (SAML) 2.0, such as Microsoft Active Directory Federation Services. When you use OIDC and SAML 2.0 to configure a trust relationship between these external identity providers and AWS, the user is assigned to an IAM role. The user also receives temporary credentials that allow the user to access your AWS resources.

Federated user

Instead of creating an IAM user, you can use existing identities from AWS Directory Service, your enterprise user directory, or a web identity provider. These are known as *federated users*. AWS assigns a role to a federated user when access is requested through an [identity provider](#). For more information about federated users, see [Federated users and roles](#).

Trust policy

A [JSON policy document](#) in which you define the principals that you *trust* to assume the role. A role trust policy is a required [resource-based policy](#) that is attached to a role in IAM. The [principals](#) that you can specify in the trust policy include users, roles, accounts, and services.

Permissions policy

A permissions document in [JSON](#) format in which you define what actions and resources the role can use. The document is written according to the rules of the [IAM policy language](#).

Permissions boundary

An advanced feature in which you use policies to limit the maximum permissions that an identity-based policy can grant to a role. You cannot apply a permissions boundary to a service-linked role. For more information, see [Permissions boundaries for IAM entities](#).

Principal

An entity in AWS that can perform actions and access resources. A principal can be an AWS account root user, an IAM user, or a role. You can grant permissions to access a resource in one of two ways:

- You can attach a permissions policy to a user (directly, or indirectly through a group) or to a role.
- For those services that support [resource-based policies](#), you can identify the principal in the `Principal` element of a policy attached to the resource.

If you reference an AWS account as principal, it generally means any principal defined within that account.

Note

You cannot use a wildcard (*) to match part of a principal name or ARN in a role's trust policy. For details, see [AWS JSON policy elements: Principal](#).

Role for cross-account access

A role that grants access to resources in one account to a trusted principal in a different account. Roles are the primary way to grant cross-account access. However, some AWS services allow you to attach a policy directly to a resource (instead of using a role as a proxy). These are called resource-based policies, and you can use them to grant principals in another AWS account access to the resource. Some of these resources include Amazon Simple Storage Service (S3) buckets, S3 Glacier vaults, Amazon Simple Notification Service (SNS) topics, and Amazon Simple Queue Service (SQS) queues. To learn which services support resource-based policies, see [AWS services that work with IAM](#). For more information about resource-based policies, see [Cross account resource access in IAM](#).

Common scenarios for roles: Users, applications, and services

As with most AWS features, you generally have two ways to use a role: interactively in the IAM console, or programmatically with the AWS CLI, Tools for Windows PowerShell, or API.

- IAM users in your account using the IAM console can *switch to* a role to temporarily use the permissions of the role in the console. The users give up their original permissions and take on

the permissions assigned to the role. When the users exit the role, their original permissions are restored.

- An application or a service offered by AWS (like Amazon EC2) can *assume* a role by requesting temporary security credentials for a role with which to make programmatic requests to AWS. You use a role this way so that you don't have to share or maintain long-term security credentials (for example, by creating an IAM user) for each entity that requires access to a resource.

 **Note**

This guide uses the phrases *switch to a role* and *assume a role* interchangeably.

The simplest way to use roles is to grant your IAM users permissions to switch to roles that you create within your own or another AWS account. They can switch roles easily using the IAM console to use permissions that you don't ordinarily want them to have, and then exit the role to surrender those permissions. This can help prevent *accidental* access to or modification of sensitive resources.

For more complex uses of roles, such as granting access to applications and services, or federated external users, you can call the `AssumeRole` API. This API call returns a set of temporary credentials that the application can use in subsequent API calls. Actions attempted with the temporary credentials have only the permissions granted by the associated role. An application doesn't have to "exit" the role the way a user in the console does; rather the application simply stops using the temporary credentials and resumes making calls with the original credentials.

Federated users sign in by using credentials from an identity provider (IdP). AWS then provides temporary credentials to the trusted IdP to pass on to the user for including in subsequent AWS resource requests. Those credentials provide the permissions granted to the assigned role.

This section provides overviews of the following scenarios:

- [Provide access for an IAM user in one AWS account that you own to access resources in another account that you own](#)
- [Provide access to non AWS workloads](#)
- [Provide access to IAM users in AWS accounts owned by third parties](#)
- [Provide access for services offered by AWS to AWS resources](#)
- [Provide access for externally authenticated users \(identity federation\)](#)

Providing access to an IAM user in another AWS account that you own

You can grant your IAM users permission to switch to roles within your AWS account or to roles defined in other AWS accounts that you own.

Note

If you want to grant access to an account that you do not own or control, see [Providing access to AWS accounts owned by third parties](#) later in this topic.

Imagine that you have Amazon EC2 instances that are critical to your organization. Instead of directly granting your users permission to terminate the instances, you can create a role with those privileges. Then allow administrators to switch to the role when they need to terminate an instance. Doing this adds the following layers of protection to the instances:

- You must explicitly grant your users permission to assume the role.
- Your users must actively switch to the role using the AWS Management Console or assume the role using the AWS CLI or AWS API.
- You can add multi-factor authentication (MFA) protection to the role so that only users who sign in with an MFA device can assume the role. To learn how to configure a role so that users who assume the role must first be authenticated using multi-factor authentication (MFA), see [Configuring MFA-protected API access](#).

We recommend using this approach to enforce the *principle of least privilege*. That means restricting the use of elevated permissions to only those times when they are needed for specific tasks. With roles you can help prevent accidental changes to sensitive environments, especially if you combine them with [auditing](#) to help ensure that roles are only used when needed.

When you create a role for this purpose, you specify the accounts by ID whose users need access in the `Principal` element of the role's trust policy. You can then grant specific users in those other accounts permissions to switch to the role. To learn whether principals in accounts outside of your zone of trust (trusted organization or account) have access to assume your roles, see [What is IAM Access Analyzer?](#)

A user in one account can switch to a role in the same or a different account. While using the role, the user can perform only the actions and access only the resources permitted by the role; their

original user permissions are suspended. When the user exits the role, the original user permissions are restored.

Example scenario using separate development and production accounts

Imagine that your organization has multiple AWS accounts to isolate a development environment from a production environment. Users in the development account might occasionally need to access resources in the production account. For example, you might need cross-account access when you are promoting an update from the development environment to the production environment. Although you could create separate identities (and passwords) for users who work in both accounts, managing credentials for multiple accounts makes identity management difficult. In the following figure, all users are managed in the development account, but some developers require limited access to the production account. The development account has two groups: Testers and Developers, and each group has its own policy.

1. In the production account, an administrator uses IAM to create the `UpdateApp` role in that account. In the role, the administrator defines a trust policy that specifies the development account as a `Principal`, meaning that authorized users from the development account can use the `UpdateApp` role. The administrator also defines a permissions policy for the role that specifies the read and write permissions to the Amazon S3 bucket named `productionapp`.

The administrator then shares the appropriate information with anyone who needs to assume the role. That information is the account number and name of the role (for AWS console users) or the Amazon Resource Name (ARN) (for AWS CLI or AWS API access). The role ARN might look

like `arn:aws:iam::123456789012:role/UpdateApp`, where the role is named `UpdateApp` and the role was created in account number `123456789012`.

 **Note**

The administrator can optionally configure the role so that users who assume the role must first be authenticated using multi-factor authentication (MFA). For more information, see [Configuring MFA-protected API access](#).

2. In the development account, an administrator grants members of the Developers group permission to switch to the role. This is done by granting the Developers group permission to call the AWS Security Token Service (AWS STS) `AssumeRole` API for the `UpdateApp` role. Any IAM user that belongs to the Developers group in the development account can now switch to the `UpdateApp` role in the production account. Other users who are not in the developer group do not have permission to switch to the role and therefore cannot access the S3 bucket in the production account.
3. The user requests switches to the role:
 - **AWS console:** The user chooses the account name on the navigation bar and chooses **Switch Role**. The user specifies the account ID (or alias) and role name. Alternatively, the user can click on a link sent in email by the administrator. The link takes the user to the **Switch Role** page with the details already filled in.
 - **AWS API/AWS CLI:** A user in the Developers group of the development account calls the `AssumeRole` function to obtain credentials for the `UpdateApp` role. The user specifies the ARN of the `UpdateApp` role as part of the call. If a user in the Testers group makes the same request, the request fails because Testers do not have permission to call `AssumeRole` for the `UpdateApp` role ARN.
4. AWS STS returns temporary credentials:
 - **AWS console:** AWS STS verifies the request with the role's trust policy to ensure that the request is from a trusted entity (which it is: the development account). After verification, AWS STS returns [temporary security credentials](#) to the AWS console.
 - **API/CLI:** AWS STS verifies the request against the role's trust policy to ensure that the request is from a trusted entity (which it is: the Development account). After verification, AWS STS returns [temporary security credentials](#) to the application.
5. The temporary credentials allow access to the AWS resource:

- **AWS console:** The AWS console uses the temporary credentials on behalf of the user for all subsequent console actions, in this case, to read and write to the `productionapp` bucket. The console cannot access any other resource in the production account. When the user exits the role, the user's permissions revert to the original permissions held before switching to the role.
- **API/CLI:** The application uses the temporary security credentials to update the `productionapp` bucket. With the temporary security credentials, the application can only read from and write to the `productionapp` bucket and cannot access any other resource in the Production account. The application does not have to exit the role, but instead stops using the temporary credentials and uses the original credentials in subsequent API calls.

More information

For more information, see the following:

- [IAM tutorial: Delegate access across AWS accounts using IAM roles](#)

Providing access for non AWS workloads

An [IAM role](#) is an object in AWS Identity and Access Management (IAM) that is assigned [permissions](#). When you [assume that role](#) using an IAM identity or an identity from outside of AWS, it provides you with temporary security credentials for your role session. You might have workloads running in your data center or other infrastructure outside of AWS that need to access your AWS resources. Instead of creating, distributing, and managing long-term access keys, you can use AWS Identity and Access Management Roles Anywhere (IAM Roles Anywhere) to authenticate your non AWS workloads. IAM Roles Anywhere uses X.509 certificates from your certificate authority (CA) to authenticate identities and securely provide access to AWS services with the temporary credentials provided by an IAM role.

To use IAM Roles Anywhere, you set up a CA using [AWS Private Certificate Authority](#) or use a CA from your own PKI infrastructure. After you have set up a CA, you create an object in IAM Roles Anywhere called a *trust anchor* to establish trust between IAM Roles Anywhere and your CA for authentication. You can then configure your existing IAM roles, or create new roles that trust the IAM Roles Anywhere service. When your non AWS workloads authenticate with IAM Roles Anywhere using the trust anchor, they can get temporary credentials for your IAM roles to access your AWS resources.

For more information about configuring IAM Roles Anywhere, see [What is AWS Identity and Access Management Roles Anywhere](#) in the *IAM Roles Anywhere User Guide*.

Providing access to AWS accounts owned by third parties

When third parties require access to your organization's AWS resources, you can use roles to delegate access to them. For example, a third party might provide a service for managing your AWS resources. With IAM roles, you can grant these third parties access to your AWS resources without sharing your AWS security credentials. Instead, the third party can access your AWS resources by assuming a role that you create in your AWS account. To learn whether principals in accounts outside of your zone of trust (trusted organization or account) have access to assume your roles, see [What is IAM Access Analyzer?](#)

Third parties must provide you with the following information for you to create a role that they can assume:

- The third party's AWS account ID. You specify their AWS account ID as the principal when you define the trust policy for the role.
- An external ID to uniquely associate with the role. The external ID can be any identifier that is known only by you and the third party. For example, you can use an invoice ID between you and the third party, but do not use something that can be guessed, like the name or phone number of the third party. You must specify this ID when you define the trust policy for the role. The third party must provide this ID when they assume the role. For more information about the external ID, see [How to use an external ID when granting access to your AWS resources to a third party](#).
- The permissions that the third party requires to work with your AWS resources. You must specify these permissions when defining the role's permission policy. This policy defines what actions they can take and what resources they can access.

After you create the role, you must provide the role's Amazon Resource Name (ARN) to the third party. They require your role's ARN in order to assume the role.

Important

When you grant third parties access to your AWS resources, they can access any resource that you specify in the policy. Their use of your resources is billed to you. Ensure that you limit their use of your resources appropriately.

How to use an external ID when granting access to your AWS resources to a third party

At times, you need to give a third party access to your AWS resources (delegate access). One important aspect of this scenario is the *External ID*, optional information that you can use in an IAM role trust policy to designate who can assume the role.

Important

AWS does not treat the external ID as a secret. After you create a secret like an access key pair or a password in AWS, you cannot view them again. The external ID for a role can be seen by anyone with permission to view the role.

In a multi-tenant environment where you support multiple customers with different AWS accounts, we recommend using one external ID per AWS account. This ID should be a random string generated by the third party.

To require that the third party provides an external ID when assuming a role, update the role's trust policy with the external ID of your choice.

To provide an external ID when you assume a role, use the AWS CLI or AWS API to assume that role. For more information, see the STS [AssumeRole](#) API operation, or the STS [assume-role](#) CLI operation.

For example, let's say that you decide to hire a third-party company called Example Corp to monitor your AWS account and help optimize costs. In order to track your daily spending, Example Corp needs to access your AWS resources. Example Corp also monitors many other AWS accounts for other customers.

Do not give Example Corp access to an IAM user and its long-term credentials in your AWS account. Instead, use an IAM role and its temporary security credentials. An IAM role provides a mechanism to allow a third party to access your AWS resources without needing to share long-term credentials (such as an IAM user access key).

You can use an IAM role to establish a trusted relationship between your AWS account and the Example Corp account. After this relationship is established, a member of the Example Corp account can call the AWS Security Token Service [AssumeRole](#) API to obtain temporary security credentials. The Example Corp members can then use the credentials to access AWS resources in your account.

Note

For more information about the AssumeRole and other AWS API operations that you can call to obtain temporary security credentials, see [Requesting temporary security credentials](#).

Here's a more detailed breakdown of this scenario:

1. You hire Example Corp, so they create a unique customer identifier for you. They provide you with this unique customer ID and their AWS account number. You need this information to create an IAM role in the next step.

Note

Example Corp can use any string value they want for the ExternalId, as long as it is unique for each customer. It can be a customer account number or even a random string of characters, as long as no two customers have the same value. It is not intended to be a 'secret'. Example Corp must provide the ExternalId value to each customer. What is crucial is that it must be generated by Example Corp and **not** their customers to ensure each external ID is unique.

2. You sign in to AWS and create an IAM role that gives Example Corp access to your resources. Like any IAM role, the role has two policies, a permission policy and a trust policy. The role's trust policy specifies who can assume the role. In our sample scenario, the policy specifies the AWS account number of Example Corp as the Principal. This allows identities from that account to assume the role. In addition, you add a [Condition](#) element to the trust policy. This Condition tests the ExternalId context key to ensure that it matches the unique customer ID from Example Corp. For example:

```
"Principal": {"AWS": "Example Corp's AWS account ID"},  
"Condition": {"StringEquals": {"sts:ExternalId": "Unique ID Assigned by Example Corp"}}
```

3. The permission policy for the role specifies what the role allows someone to do. For example, you could specify that the role allows someone to manage only your Amazon EC2 and Amazon RDS resources but not your IAM users or groups. In our sample scenario, you use the permission policy to give Example Corp read-only access to all of the resources in your account.

4. After you create the role, you provide the Amazon Resource Name (ARN) of the role to Example Corp.
5. When Example Corp needs to access your AWS resources, someone from the company calls the `AWS sts:AssumeRole` API. The call includes the ARN of the role to assume and the `ExternalId` parameter that corresponds to their customer ID.

If the request comes from someone using Example Corp's AWS account, and if the role ARN and the external ID are correct, the request succeeds. It then provides temporary security credentials that Example Corp can use to access the AWS resources that your role allows.

In other words, when a role policy includes an external ID, anyone who wants to assume the role must be a principal in the role and must include the correct external ID.

Why use an external ID?

In abstract terms, the external ID allows the user that is assuming the role to assert the circumstances in which they are operating. It also provides a way for the account owner to permit the role to be assumed only under specific circumstances. The primary function of the external ID is to address and prevent [The confused deputy problem](#).

When should I use an external ID?

Use an external ID in the following situations:

- You are an AWS account owner and you have configured a role for a third party that accesses other AWS accounts in addition to yours. You should ask the third party for an external ID that it includes when it assumes your role. Then you check for that external ID in your role's trust policy. Doing so ensures that the external party can assume your role only when it is acting on your behalf.
- You are in the position of assuming roles on behalf of different customers like Example Corp in our previous scenario. You should assign a unique external ID to each customer and instruct them to add the external ID to their role's trust policy. You must then ensure that you always include the correct external ID in your requests to assume roles.

You probably already have a unique identifier for each of your customers, and this unique ID is sufficient for use as an external ID. The external ID is not a special value that you need to create explicitly, or track separately, just for this purpose.

You should always specify the external ID in your AssumeRole API calls. In addition when a customer gives you a role ARN, test whether you can assume the role both with and without the correct external ID. If you can assume the role without the correct external ID, don't store the customer's role ARN in your system. Wait until your customer has updated the role trust policy to require the correct external ID. In this way you help your customers to do the right thing, which helps to keep both of you protected against the confused deputy problem.

Providing access to an AWS service

Many AWS services require that you use roles to control what that service can access. A role that a service assumes to perform actions on your behalf is called a [service role](#). When a role serves a specialized purpose for a service, it can be categorized as a [service role for EC2 instances](#), or a [service-linked role](#). See the [AWS documentation](#) for each service to see if it uses roles and to learn how to assign a role for the service to use.

For details about creating a role to delegate access to a service offered by AWS, see [Creating a role to delegate permissions to an AWS service](#).

The confused deputy problem

The confused deputy problem is a security issue where an entity that doesn't have permission to perform an action can coerce a more-privileged entity to perform the action. To prevent this, AWS provides tools that help you protect your account if you provide third parties (known as *cross-account*) or other AWS services (known as *cross-service*) access to resources in your account.

At times, you might need to give a third party access to your AWS resources (delegate access). For example, let's say that you decide to hire a third-party company called Example Corp to monitor your AWS account and help optimize costs. In order to track your daily spending, Example Corp needs to access your AWS resources. Example Corp also monitors many other AWS accounts for other customers. You can use an IAM role to establish a trusted relationship between your AWS account and the Example Corp account. One important aspect of this scenario is the *external ID*, optional information that you can use in an IAM role trust policy to designate who can assume the role. The primary function of the external ID is to address and prevent the confused deputy problem.

In AWS, cross-service impersonation can result in the confused deputy problem. Cross-service impersonation can occur when one service (the *calling service*) calls another service (the *called*

service). The calling service can be manipulated to use its permissions to act on another customer's resources in a way it should not otherwise have permission to access.

Cross-account confused deputy prevention

The following diagram illustrates the cross-account confused deputy problem.

This scenario assumes the following:

- **AWS1** is your AWS account.
- **AWS1:ExampleRole** is a role in your account. This role's trust policy trusts Example Corp by specifying Example Corp's AWS account as the one that can assume the role.

Here's what happens:

1. When you start using Example Corp's service, you provide the ARN of **AWS1:ExampleRole** to Example Corp.
2. Example Corp uses that role ARN to obtain temporary security credentials to access resources in your AWS account. In this way, you are trusting Example Corp as a "deputy" that can act on your behalf.
3. Another AWS customer also starts using Example Corp's service, and this customer also provides the ARN of **AWS1:ExampleRole** for Example Corp to use. Presumably the other customer learned or guessed the **AWS1:ExampleRole**, which isn't a secret.
4. When the other customer asks Example Corp to access AWS resources in (what it claims to be) its account, Example Corp uses **AWS1:ExampleRole** to access resources in your account.

This is how the other customer could gain unauthorized access to your resources. Because this other customer was able to trick Example Corp into unwittingly acting on your resources, Example Corp is now a "confused deputy."

Example Corp can address the confused deputy problem by requiring that you include the `ExternalId` condition check in the role's trust policy. Example Corp generates a unique `ExternalId` value for each customer and uses that value in its request to assume the role. The `ExternalId` value must be unique among Example Corp's customers and controlled by Example Corp, not its customers. This is why you get it from Example Corp and you don't come up with it on your own. This prevents Example Corp from being a confused deputy and granting access to another account's AWS resources.

In our scenario, imagine Example Corp's unique identifier for you is 12345, and its identifier for the other customer is 67890. These identifiers are simplified for this scenario. Generally, these identifiers are GUIDs. Assuming that these identifiers are unique among Example Corp's customers, they are sensible values to use for the external ID.

Example Corp gives the external ID value of 12345 to you. You must then add a `Condition` element to the role's trust policy that requires the [sts:ExternalId](#) value to be 12345, like this:

```
{
  "Version": "2012-10-17",
  "Statement": {
    "Effect": "Allow",
    "Principal": {
      "AWS": "Example Corp's AWS Account ID"
    },
    "Action": "sts:AssumeRole",
    "Condition": {
      "StringEquals": {
        "sts:ExternalId": "12345"
      }
    }
  }
}
```

The `Condition` element in this policy allows Example Corp to assume the role only when the `AssumeRole` API call includes the external ID value of 12345. Example Corp makes sure that whenever it assumes a role on behalf of a customer, it always includes that customer's external ID value in the `AssumeRole` call. Even if another customer supplies Example Corp with your ARN, it cannot control the external ID that Example Corp includes in its request to AWS. This helps prevent an unauthorized customer from gaining access to your resources.

The following diagram illustrates this.

1. As before, when you start using Example Corp's service, you provide the ARN of **AWS1:ExampleRole** to Example Corp.
2. When Example Corp uses that role ARN to assume the role **AWS1:ExampleRole**, Example Corp includes your external ID (12345) in the AssumeRole API call. The external ID matches the role's trust policy, so the AssumeRole API call succeeds and Example Corp obtains temporary security credentials to access resources in your AWS account.
3. Another AWS customer also starts using Example Corp's service, and as before, this customer also provides the ARN of **AWS1:ExampleRole** for Example Corp to use.
4. But this time, when Example Corp attempts to assume the role **AWS1:ExampleRole**, it provides the external ID associated with the other customer (67890). The other customer has no way to change this. Example Corp does this because the request to use the role came from the other customer, so 67890 indicates the circumstance in which Example Corp is acting. Because you added a condition with your own external ID (12345) to the trust policy of **AWS1:ExampleRole**, the AssumeRole API call fails. The other customer is prevented from gaining unauthorized access to resources in your account (indicated by the red "X" in the diagram).

The external ID helps prevent any other customer from tricking Example Corp into unwittingly accessing your resources.

Cross-service confused deputy prevention

We recommend using the [aws:SourceArn](#), [aws:SourceAccount](#), [aws:SourceOrgID](#), or [aws:SourceOrgPaths](#) global condition context keys in resource-based policies to limit the permissions that a service has to a specific resource. Use `aws:SourceArn` to associate only one resource with cross-service access. Use `aws:SourceAccount` to let any resource in that account be associated with the cross-service use. Use `aws:SourceOrgID` to allow any resource from any account within an organization be associated with the cross-service use. Use `aws:SourceOrgPaths` to associate any resource from accounts within an AWS Organizations

path with the cross-service use. For more information about using and understanding paths, see [Understand the AWS Organizations entity path](#).

The most granular way to protect against the confused deputy problem is to use the `aws:SourceArn` global condition context key with the full ARN of the resource in your resource-based policies. If you don't know the full ARN of the resource or if you are specifying multiple resources, use the `aws:SourceArn` global condition context key with wildcards (*) for the unknown portions of the ARN. For example, `arn:aws:service:*:123456789012:*`.

If the `aws:SourceArn` value does not contain the account ID, such as an Amazon S3 bucket ARN, you must use both `aws:SourceAccount` and `aws:SourceArn` to limit permissions.

To protect against the confused deputy problem at scale, use the `aws:SourceOrgID` or `aws:SourceOrgPaths` global condition context key with the organization ID or organization path of the resource in your resource-based policies. Policies that include the `aws:SourceOrgID` or `aws:SourceOrgPaths` key will automatically include the correct accounts and you don't have to manually update the policies when you add, remove, or move accounts in your organization.

For non-service-linked role [trust policies](#), every service in the trust policy has performed the `iam:PassRole` action to verify that the role is in the same account as the calling service. As a result, using `aws:SourceAccount`, `aws:SourceOrgID`, or `aws:SourceOrgPaths` with those trust policies is not necessary. Using `aws:SourceArn` in a trust policy allows you to specify resources a role can be assumed on behalf of, such as a Lambda function ARN. Some AWS services use `aws:SourceAccount` and `aws:SourceArn` in trust policies for newly created roles, but using the keys isn't required for existing roles in your account.

Note

AWS services that integrate with AWS Key Management Service using KMS key grants do not support the `aws:SourceArn`, `aws:SourceAccount`, `aws:SourceOrgID`, or `aws:SourceOrgPaths` condition keys. Usage of these condition keys in a KMS key policy will result in unexpected behavior if the key is also used by AWS services via KMS key grants.

Cross-service confused deputy prevention for AWS Security Token Service

Many AWS services require that you use roles to allow the service to access another service's resources on your behalf. A role that a service assumes to perform actions on your behalf is called

a [service role](#). A role requires two policies: a role trust policy that specifies the principal that is allowed to assume the role and a permissions policy that specifies what can be done with the role. A role trust policy is the only type of resource-based policy in IAM. Other AWS services have resource-based policies, such as an Amazon S3 bucket policy.

When a service assumes a role on your behalf, the service principal must be allowed to perform the [sts:AssumeRole](#) action in the role trust policy. When a service calls `sts:AssumeRole`, AWS STS returns a set of temporary security credentials that the service principal uses to access the resources that are permitted by the role's permissions policy. When a service assumes a role in your account, you can include the `aws:SourceArn`, `aws:SourceAccount`, `aws:SourceOrgID`, or `aws:SourceOrgPaths` global condition context keys in your role trust policy to limit access to the role to only requests that are generated by expected resources.

For example, in AWS Systems Manager Incident Manager, you must choose a role to allow Incident Manager to run a Systems Manager automation document on your behalf. The automation document can include automated response plans for incidents that are initiated by CloudWatch alarms or EventBridge events. In the following role trust policy example, you can use the `aws:SourceArn` condition key to restrict access to the service role based on the incident record's ARN. Only incident records that are created from the response plan resource `myresponseplan` are able to use this role.

```
{
  "Version": "2012-10-17",
  "Statement": {
    "Effect": "Allow",
    "Principal": {
      "Service": "ssm-incidents.amazonaws.com"
    },
    "Action": "sts:AssumeRole",
    "Condition": {
      "ArnLike": {
        "aws:SourceArn": "arn:aws:ssm-incidents:*:111122223333:incident-
record/myresponseplan/*"
      }
    }
  }
}
```

Note

Not all service integrations with AWS STS support `aws:SourceArn`, `aws:SourceAccount`, `aws:SourceOrgID`, or `aws:SourceOrgPaths` condition keys. Usage of these keys in IAM trust policies with unsupported integrations may result in unexpected behavior.

Providing access to externally authenticated users (identity federation)

Your users might already have identities outside of AWS, such as in your corporate directory. If those users need to work with AWS resources (or work with applications that access those resources), then those users also need AWS security credentials. You can use an IAM role to specify permissions for users whose identity is federated from your organization or a third-party identity provider (IdP).

Note

As a security best practice, we recommend you manage user access in [IAM Identity Center](#) with identity federation instead of creating IAM users. For information about specific situations where an IAM user is required, see [When to create an IAM user \(instead of a role\)](#).

Federating users of a mobile or web-based app with Amazon Cognito

If you create a mobile or web-based app that accesses AWS resources, the app needs security credentials in order to make programmatic requests to AWS. For most mobile application scenarios, we recommend that you use [Amazon Cognito](#). You can use this service with the [AWS Mobile SDK for iOS](#) and the [AWS Mobile SDK for Android and Fire OS](#) to create unique identities for users and authenticate them for secure access to your AWS resources. Amazon Cognito supports the same identity providers as those listed in the next section, and it also supports [developer authenticated identities](#) and unauthenticated (guest) access. Amazon Cognito also provides API operations for synchronizing user data so that it is preserved as users move between devices. For more information, see [Using Amazon Cognito for mobile apps](#).

Federating users with public identity service providers or OpenID Connect

Whenever possible, use Amazon Cognito for mobile and web-based application scenarios. Amazon Cognito does most of the behind-the-scenes work with public identity provider services for you.

It works with the same third-party services and also supports anonymous sign-ins. However, for more advanced scenarios, you can work directly with a third-party service like Login with Amazon, Facebook, Google, or any IdP that is compatible with OpenID Connect (OIDC). For more information about using web identity federation using one of these services, see [About web identity federation](#).

Federating users with SAML 2.0

If your organization already uses an identity provider software package that supports SAML 2.0 (Security Assertion Markup Language 2.0), you can create trust between your organization as an identity provider (IdP) and AWS as the service provider. You can then use SAML to provide your users with federated single-sign on (SSO) to the AWS Management Console or federated access to call AWS API operations. For example, if your company uses Microsoft Active Directory and Active Directory Federation Services, then you can federate using SAML 2.0. For more information about federating users with SAML 2.0, see [About SAML 2.0-based federation](#).

Federating users by creating a custom identity broker application

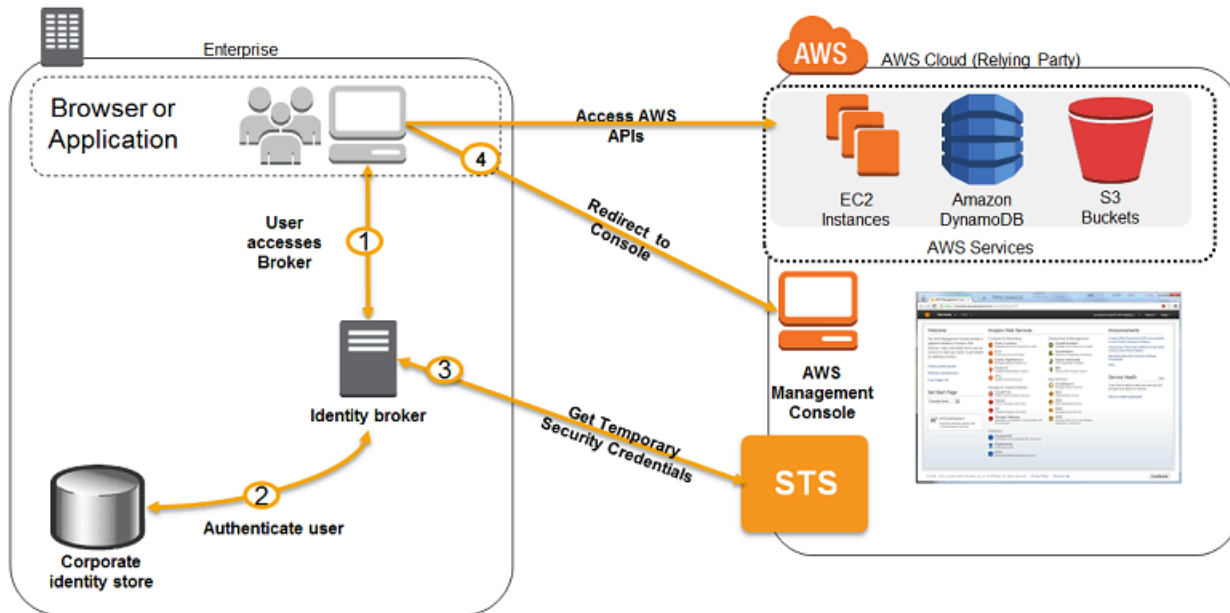

If your identity store is not compatible with SAML 2.0, then you can build a custom identity broker application to perform a similar function. The broker application authenticates users, requests temporary credentials for users from AWS, and then provides them to the user to access AWS resources.

For example, Example Corp. has many employees who need to run internal applications that access the company's AWS resources. The employees already have identities in the company identity and authentication system, and Example Corp. doesn't want to create a separate IAM user for each company employee.

Bob is a developer at Example Corp. To enable Example Corp. internal applications to access the company's AWS resources, Bob develops a custom identity broker application. The application verifies that employees are signed into the existing Example Corp. identity and authentication system, which might use LDAP, Active Directory, or another system. The identity broker application then obtains temporary security credentials for the employees. This scenario is similar to the previous one (a mobile app that uses a custom authentication system), except that the applications that need access to AWS resources all run within the corporate network, and the company has an existing authentication system.

To get temporary security credentials, the identity broker application calls either `AssumeRole` or `GetFederationToken` to obtain temporary security credentials, depending on how Bob

wants to manage the policies for users and when the temporary credentials should expire. (For more information about the differences between these API operations, see [Temporary security credentials in IAM](#) and [Controlling permissions for temporary security credentials](#).) The call returns temporary security credentials consisting of an AWS access key ID, a secret access key, and a session token. The identity broker application makes these temporary security credentials available to the internal company application. The app can then use the temporary credentials to make calls to AWS directly. The app caches the credentials until they expire, and then requests a new set of temporary credentials. The following figure illustrates this scenario.

This scenario has the following attributes:

- The identity broker application has permissions to access IAM's token service (STS) API to create temporary security credentials.
- The identity broker application is able to verify that employees are authenticated within the existing authentication system.
- Users are able to get a temporary URL that gives them access to the AWS Management Console (which is referred to as single sign-on).

For information about creating temporary security credentials, see [Requesting temporary security credentials](#). For more information about federated users getting access to the AWS Management Console, see [Enabling SAML 2.0 federated users to access the AWS Management Console](#).

Identity providers and federation

If you already manage user identities outside of AWS, you can use *identity providers* instead of creating IAM users in your AWS account. With an identity provider (IdP), you can manage your user identities outside of AWS and give these external user identities permissions to use AWS resources in your account. This is useful if your organization already has its own identity system, such as a corporate user directory. It is also useful if you are creating a mobile app or web application that requires access to AWS resources.

An external IdP provides identity information to AWS using either [OpenID Connect \(OIDC\)](#) or [SAML 2.0 \(Security Assertion Markup Language 2.0\)](#). Examples of well-known OIDC identity providers are: Login with Amazon, Facebook, and Google. Examples of well-known SAML identity providers are: Shibboleth and Active Directory Federation Services.

Note

As a security best practice, we recommend you manage human users in [IAM Identity Center](#) with an external SAML identity provider instead of using SAML federation in IAM. For information about specific situations where an IAM user is required, see [When to create an IAM user \(instead of a role\)](#).

When you use an identity provider, you don't have to create custom sign-in code or manage your own user identities. The IdP provides that for you. Your external users sign in through an IdP, and you can give those external identities permissions to use AWS resources in your account. Identity providers help keep your AWS account secure because you don't have to distribute or embed long-term security credentials, such as access keys, in your application.

This guide covers IAM federation. Your use case might be better supported by IAM Identity Center or Amazon Cognito. The following summaries and table provide an overview of the methods that your users can employ to gain federated access to AWS resources.

	Account type	Access management of..	Supported identity source
Federation with IAM Identity Center	Multiple accounts managed by AWS Organizations	Your workforce's human users	<ul style="list-style-type: none"> SAML 2.0

	Account type	Access management of..	Supported identity source
			<ul style="list-style-type: none"> • Managed Active Directory • Identity Center directory
Federation with IAM	Single, standalone account	<ul style="list-style-type: none"> • Human users in short-term, small scale deployments • Machine users 	<ul style="list-style-type: none"> • SAML 2.0 • OIDC
Federation with Amazon Cognito identity pools	Any	The users of apps that require IAM authorization to access resources	<ul style="list-style-type: none"> • SAML 2.0 • OIDC • Select OAuth 2.0 social identity providers

Federation with IAM Identity Center

For centralized access management of human users, we recommend that you use [IAM Identity Center](#) to manage access to your accounts and permissions within those accounts. Users in IAM Identity Center are granted short-term credentials to your AWS resources. You can use Active Directory, an external identity provider (IdP), or an IAM Identity Center directory as the identity source for users and groups to assign access to your AWS resources.

IAM Identity Center supports identity federation with SAML (Security Assertion Markup Language) 2.0 to provide federated single sign-on access for users who are authorized to use applications within the AWS access portal. Users can then single sign-on into services that support SAML, including the AWS Management Console and third-party applications, such as Microsoft 365, SAP Concur, and Salesforce.

Federation with IAM

While we strongly recommend managing human users in IAM Identity Center, you can enable federated user access with IAM for human users in short-term, small scale deployments. IAM allows

you to use separate SAML 2.0 and Open ID Connect (OIDC) IdPs and use federated user attributes for access control. With IAM, you can pass user attributes, such as cost center, title, or locale, from your IdPs to AWS, and implement fine-grained access permissions based on these attributes.

A *workload* is a collection of resources and code that delivers business value, such as an application or backend process. Your workload can require an IAM identity to make requests to AWS services, applications, operational tools, and components. These identities include machines running in your AWS environments, such as Amazon EC2 instances or AWS Lambda functions.

You can also manage machine identities for external parties who need access. To give access to machine identities, you can use IAM roles. IAM roles have specific permissions and provide a way to access AWS by relying on temporary security credentials with a role session. Additionally, you might have machines outside of AWS that need access to your AWS environments. For machines that run outside of AWS you can use [IAM Roles Anywhere](#). For more information about roles, see [IAM roles](#). For details about how to use roles to delegate access across AWS accounts, see [IAM tutorial: Delegate access across AWS accounts using IAM roles](#).

To link an IdP directly to IAM, you create an identity provider entity to establish a trust relationship between your AWS account and the IdP. IAM supports IdPs that are compatible with [OpenID Connect \(OIDC\)](#) or [SAML 2.0 \(Security Assertion Markup Language 2.0\)](#). For more information about using one of these IdPs with AWS, see the following sections:

- [About web identity federation](#)
- [About SAML 2.0-based federation](#)

For details about creating the IAM identity provider entity to establish a trust relationship between a compatible IdP and AWS, see [Creating IAM identity providers](#).

Federation with Amazon Cognito identity pools

Amazon Cognito is designed for developers who want to authenticate and authorize users in their mobile and web apps. Amazon Cognito user pools add sign-in and sign-up features to your app, and identity pools deliver IAM credentials that grant your users access to protected resources that you manage in AWS. Identity pools acquire credentials for temporary sessions through the [AssumeRoleWithWebIdentity](#) API operation.

Amazon Cognito works with external identity providers that support SAML and OpenID Connect, and with social identity providers like Facebook, Google, and Amazon. Your app can sign in a

user with a user pool or an external IdP, then retrieve resources on their behalf with customized temporary sessions in an IAM role.

About web identity federation

Imagine that you are creating a mobile app that accesses AWS resources, such as a game that runs on a mobile device and stores player and score information using Amazon S3 and DynamoDB.

When you write such an app, you make requests to AWS services that must be signed with an AWS access key. However, we **strongly** recommend that you do **not** embed or distribute long-term AWS credentials with apps that a user downloads to a device, even in an encrypted store. Instead, build your app so that it requests temporary AWS security credentials dynamically when needed using *web identity federation*. The supplied temporary credentials map to an AWS role that has only the permissions needed to perform the tasks required by the mobile app.

With web identity federation, you don't need to create custom sign-in code or manage your own user identities. Instead, users of your app can sign in using a well-known external identity provider (IdP), such as Login with Amazon, Facebook, Google, or any other [OpenID Connect \(OIDC\)](#)-compatible IdP. They can receive an authentication token, known as a JSON Web Token (JWT), and then exchange that token for temporary security credentials in AWS that map to an IAM role with permissions to use the resources in your AWS account. Using an IdP helps you keep your AWS account secure, because you don't have to embed and distribute long-term security credentials with your application.

For most scenarios, we recommend that you use [Amazon Cognito](#) because it acts as an identity broker and does much of the federation work for you. For details, see the following section, [Using Amazon Cognito for mobile apps](#).

If you don't use Amazon Cognito, then you must write code that interacts with a web IdP, such as Facebook, and then calls the `AssumeRoleWithWebIdentity` API to trade the authentication token you get from those IdPs for AWS temporary security credentials. If you have already used this approach for existing apps, you can continue to use it.

Note

JSON Web Tokens (JWTs) issued by OpenID Connect (OIDC) identity providers contain an expiration time in the `exp` claim that specifies when the token expires. IAM provides a five-minute window beyond the expiration time specified in the JWT to account for clock skew, as allowed by the [OpenID Connect \(OIDC\) Core 1.0 standard](#). This means OIDC JWTs

received by IAM after the expiration time but within this five-minute window are accepted for further evaluation and processing.

Using Amazon Cognito for mobile apps

The preferred way to use web identity federation is to use [Amazon Cognito](#). For example, Adele the developer is building a game for a mobile device where user data such as scores and profiles is stored in Amazon S3 and Amazon DynamoDB. Adele could also store this data locally on the device and use Amazon Cognito to keep it synchronized across devices. She knows that for security and maintenance reasons, long-term AWS security credentials should not be distributed with the game. She also knows that the game might have a large number of users. For all of these reasons, she does not want to create new user identities in IAM for each player. Instead, she builds the game so that users can sign in using an identity that they've already established with a well-known external identity provider (IdP), such as **Login with Amazon, Facebook, Google**, or any **OpenID Connect (OIDC)**-compatible IdP. Her game can take advantage of the authentication mechanism from one of these providers to validate the user's identity.

To enable the mobile app to access her AWS resources, Adele first registers for a developer ID with her chosen IdPs. She also configures the application with each of these providers. In her AWS account that contains the Amazon S3 bucket and DynamoDB table for the game, Adele uses Amazon Cognito to create IAM roles that precisely define permissions that the game needs. If she is using an OIDC IdP, she also creates an IAM OIDC identity provider entity to establish trust between an [Amazon Cognito identity pool](#) in her AWS account and the IdP.

In the app's code, Adele calls the sign-in interface for the IdP that she configured previously. The IdP handles all the details of letting the user sign in, and the app gets an OAuth access token or OIDC ID token from the provider. Adele's app can trade this authentication information for a set of temporary security credentials that consist of an AWS access key ID, a secret access key, and a session token. The app can then use these credentials to access web services offered by AWS. The app is limited to the permissions that are defined in the role that it assumes.

The following figure shows a simplified flow for how this might work, using Login with Amazon as the IdP. For Step 2, the app can also use Facebook, Google, or any OIDC-compatible IdP, but that's not shown here.

1. A customer starts your app on a mobile device. The app asks the user to sign in.
2. The app uses Login with Amazon resources to accept the user's credentials.
3. The app uses the Amazon Cognito API operations `GetId` and `GetCredentialsForIdentity` to exchange the Login with Amazon ID token for an Amazon Cognito token. Amazon Cognito, which has been configured to trust your Login with Amazon project, generates a token that it exchanges for temporary session credentials with AWS STS.
4. The app receives temporary security credentials from Amazon Cognito. Your app can also use the Basic (Classic) workflow in Amazon Cognito to retrieve tokens from AWS STS using `AssumeRoleWithWebIdentity`. For more information, see [Identity pools \(federated identities\) authentication flow](#) in the Amazon Cognito Developer Guide.
5. The temporary security credentials can be used by the app to access any AWS resources required by the app to operate. The role associated with the temporary security credentials and the assigned policies determines what can be accessed.

Use the following process to configure your app to use Amazon Cognito to authenticate users and give your app access to AWS resources. For specific steps to accomplish this scenario, consult the documentation for Amazon Cognito.

1. (Optional) Sign up as a developer with Login with Amazon, Facebook, Google, or any other OpenID Connect (OIDC)–compatible IdP and configure one or more apps with the provider. This step is optional because Amazon Cognito also supports unauthenticated (guest) access for your users.
2. Go to [Amazon Cognito in the AWS Management Console](#). Use the Amazon Cognito wizard to create an identity pool, which is a container that Amazon Cognito uses to keep end user identities organized for your apps. You can share identity pools between apps. When you set up an identity pool, Amazon Cognito creates one or two IAM roles (one for authenticated identities, and one for unauthenticated "guest" identities) that define permissions for Amazon Cognito users.
3. Integrate [AWS Amplify](#) with your app, and import the files required to use Amazon Cognito.
4. Create an instance of the Amazon Cognito credentials provider, passing the identity pool ID, your AWS account number, and the Amazon Resource Name (ARN) of the roles that you associated with the identity pool. The Amazon Cognito wizard in the AWS Management Console provides sample code to help you get started.
5. When your app accesses an AWS resource, pass the credentials provider instance to the client object, which passes temporary security credentials to the client. The permissions for the credentials are based on the role or roles that you defined earlier.

For more information, see the following:

- [Sign in \(Android\)](#) in the AWS Amplify Framework Documentation.
- [Sign in \(iOS\)](#) in the AWS Amplify Framework Documentation.

Using web identity federation API operations for mobile apps

For best results, use Amazon Cognito as your identity broker for almost all web identity federation scenarios. Amazon Cognito is easy to use and provides additional capabilities like anonymous (unauthenticated) access, and synchronizing user data across devices and providers. However, if you have already created an app that uses web identity federation by manually calling the `AssumeRoleWithWebIdentity` API, you can continue to use it and your apps will still work fine.

The process for using web identity federation *without* Amazon Cognito follows this general outline:

1. Sign up as a developer with the external identity provider (IdP) and configure your app with the IdP, who gives you a unique ID for your app. (Different IdPs use different terminology for this process. This outline uses the term *configure* for the process of identifying your app with the IdP.) Each IdP gives you an app ID that's unique to that IdP, so if you configure the same app with multiple IdPs, your app will have multiple app IDs. You can configure multiple apps with each provider.

The following external links provide information about using some of the commonly used identity providers (IdPs):

- [Login with Amazon Developer Center](#)
- [Add Facebook Login to Your App or Website](#) on the Facebook developers site.
- [Using OAuth 2.0 for Login \(OpenID Connect\)](#) on the Google developers site.

Important

If you use an OIDC identity provider from Google, Facebook, or Amazon Cognito, do not create a separate IAM identity provider in the AWS Management Console. AWS has these OIDC identity providers built-in and available for your use. Skip the following step and move directly to creating new roles using your identity provider.

2. If you use an IdP other than Google, Facebook or Amazon Cognito compatible with OIDC, then create an IAM identity provider entity for it.
3. In IAM, [create one or more roles](#). For each role, define who can assume the role (the trust policy) and what permissions the app's users have (the permissions policy). Typically, you create one role for each IdP that an app supports. For example, you might create a role assumed by an app if the user signs in through Login with Amazon, a second role for the same app if the user signs in through Facebook, and a third role for the app if the user signs in through Google. For the trust relationship, specify the IdP (like Amazon.com) as the Principal (the trusted entity), and include a Condition that matches the IdP assigned app ID. Examples of roles for different providers are described in [Creating a role for a third-party Identity Provider \(federation\)](#).
4. In your application, authenticate your users with the IdP. The specifics of how to do this vary both according to which IdP you use (Login with Amazon, Facebook, or Google) and on which platform your app runs. For example, an Android app's method of authentication can differ from that of an iOS app or a JavaScript-based web app.

Typically, if the user is not already signed in, the IdP takes care of displaying a sign-in page. After the IdP authenticates the user, the IdP returns an authentication token with information about

- the user to your app. The information included depends on what the IdP exposes and what information the user is willing to share. You can use this information in your app.
5. In your app, make an *unsigned* call to the `AssumeRoleWithWebIdentity` action to request temporary security credentials. In the request, you pass the IdP's authentication token and specify the Amazon Resource Name (ARN) for the IAM role that you created for that IdP. AWS verifies that the token is trusted and valid and if so, returns temporary security credentials to your app that have the permissions for the role that you name in the request. The response also includes metadata about the user from the IdP, such as the unique user ID that the IdP associates with the user.
 6. Using the temporary security credentials from the `AssumeRoleWithWebIdentity` response, your app makes signed requests to AWS API operations. The user ID information from the IdP can distinguish users in your app—for example, you can put objects into Amazon S3 folders that include the user ID as prefixes or suffixes. This lets you create access control policies that lock the folder so only the user with that ID can access it. For more information, see [Identifying users with web identity federation](#) later in this topic.
 7. Your app should cache the temporary security credentials so that you do not have to get new ones each time the app needs to make a request to AWS. By default, the credentials are good for one hour. When the credentials expire (or before then), you make another call to `AssumeRoleWithWebIdentity` to obtain a new set of temporary security credentials. Depending on the IdP and how they manage their tokens, you might have to refresh the IdP's token before you make a new call to `AssumeRoleWithWebIdentity`, since the IdP's tokens also usually expire after a fixed time. If you use the AWS SDK for iOS or the AWS SDK for Android, you can use the [AmazonSTSCredentialsProvider](#) action, which manages the IAM temporary credentials, including refreshing them as required.

Identifying users with web identity federation

When you create access policies in IAM, it's often useful to be able to specify permissions based on configured apps and on the ID of users who have authenticated using an external identity provider (IdP). For example, your mobile app uses web identity federation might keep information in Amazon S3 using a structure like this:

```
myBucket/app1/user1
myBucket/app1/user2
myBucket/app1/user3
...
myBucket/app2/user1
```

```
myBucket/app2/user2
myBucket/app2/user3
...
```

You might also want to additionally distinguish these paths by provider. In that case, the structure might look like the following (only two providers are listed to save space):

```
myBucket/Amazon/app1/user1
myBucket/Amazon/app1/user2
myBucket/Amazon/app1/user3
...
myBucket/Amazon/app2/user1
myBucket/Amazon/app2/user2
myBucket/Amazon/app2/user3

myBucket/Facebook/app1/user1
myBucket/Facebook/app1/user2
myBucket/Facebook/app1/user3
...
myBucket/Facebook/app2/user1
myBucket/Facebook/app2/user2
myBucket/Facebook/app2/user3
...
```

For these structures, app1 and app2 represent different apps, such as different games, and each user of the app has a distinct folder. The values for app1 and app2 might be friendly names that you assign (for example, `mynumbersgame`) or they might be the app IDs that the providers assign when you configure your app. If you decide to include provider names in the path, those can also be friendly names like Cognito, Amazon, Facebook, and Google.

You can typically create the folders for app1 and app2 through the AWS Management Console, since the application names are static values. That's true also if you include the provider name in the path, since the provider name is also a static value. In contrast, the user-specific folders (*user1*, *user2*, *user3*, etc.) have to be created at run time from the app, using the user ID that's available in the `SubjectFromWebIdentityToken` value that is returned by the request to `AssumeRoleWithWebIdentity`.

To write policies that allow exclusive access to resources for individual users, you can match the complete folder name, including the app name and provider name, if you're using that. You can then include the following provider-specific context keys that reference the user ID that the provider returns:

- `cognito-identity.amazonaws.com:sub`
- `www.amazon.com:user_id`
- `graph.facebook.com:id`
- `accounts.google.com:sub`

For OIDC providers, use the fully qualified URL of the OIDC provider with the subcontext key, like the following example:

- `server.example.com:sub`

The following example shows a permission policy that grants access to a bucket in Amazon S3 only if the prefix for the bucket matches the string:

`myBucket/Amazon/mynumbersgame/user1`

The example assumes that the user signs in using Login with Amazon, and that the user uses an app called `mynumbersgame`. The user's unique ID is presented as an attribute called `user_id`.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": ["s3:ListBucket"],
      "Resource": ["arn:aws:s3:::myBucket"],
      "Condition": {"StringLike": {"s3:prefix": ["Amazon/mynumbersgame/
${www.amazon.com:user_id}/*"]}}
    },
    {
      "Effect": "Allow",
      "Action": [
        "s3:GetObject",
        "s3:PutObject",
        "s3:DeleteObject"
      ],
      "Resource": [
        "arn:aws:s3:::myBucket/amazon/mynumbersgame/${www.amazon.com:user_id}",
        "arn:aws:s3:::myBucket/amazon/mynumbersgame/${www.amazon.com:user_id}/*"
      ]
    }
  ]
}
```

```
]
}
```

You would create similar policies for users who sign in using Amazon Cognito, Facebook, Google, or another OpenID Connect–compatible IdP. Those policies would use a different provider name as part of the path as well as different app IDs.

For more information about the web identity federation keys available for condition checks in policies, see [Available keys for AWS web identity federation](#).

Additional resources for web identity federation

The following resources can help you learn more about web identity federation:

- [Amazon Cognito Identity](#) in the *Amplify Libraries for Android Guide* and [Amazon Cognito Identity](#) in the *Amplify Libraries for Swift Guide*.
- The [Web Identity Federation Playground](#) is an interactive website that lets you walk through the process of authenticating via Login with Amazon, Facebook, or Google, getting temporary security credentials, and then using those credentials to make a request to AWS.
- The entry [Web Identity Federation using the AWS SDK for .NET](#) on the AWS .NET Development blog walks through how to use web identity federation with Facebook and includes code snippets in C# that show how to call `AssumeRoleWithWebIdentity` and how to use the temporary security credentials from that API call to access an S3 bucket.
- The article [Web Identity Federation with Mobile Applications](#) discusses web identity federation and shows an example of how to use web identity federation to get access to content in Amazon S3.

About SAML 2.0-based federation

AWS supports identity federation with [SAML 2.0 \(Security Assertion Markup Language 2.0\)](#), an open standard that many identity providers (IdPs) use. This feature enables federated single sign-on (SSO), so users can log into the AWS Management Console or call the AWS API operations without you having to create an IAM user for everyone in your organization. By using SAML, you can simplify the process of configuring federation with AWS, because you can use the IdP's service instead of [writing custom identity proxy code](#).

IAM federation supports these use cases:

- [Federated access to allow a user or application in your organization to call AWS API operations](#). You use a SAML assertion (as part of the authentication response) that is generated in your organization to get temporary security credentials. This scenario is similar to other federation scenarios that IAM supports, like those described in [Requesting temporary security credentials](#) and [About web identity federation](#). However, SAML 2.0–based IdPs in your organization handle many of the details at run time for performing authentication and authorization checking. This is the scenario discussed in this topic.
- [Web-based single sign-on \(SSO\) to the AWS Management Console from your organization](#). Users can sign in to a portal in your organization hosted by a SAML 2.0–compatible IdP, select an option to go to AWS, and be redirected to the console without having to provide additional sign-in information. You can use a third-party SAML IdP to establish SSO access to the console or you can create a custom IdP to enable console access for your external users. For more information about building a custom IdP, see [Enabling custom identity broker access to the AWS console](#).

Topics

- [Using SAML-based federation for API access to AWS](#)
- [Overview of configuring SAML 2.0-based federation](#)
- [Overview of the role to allow SAML-federated access to your AWS resources](#)
- [Uniquely identifying users in SAML-based federation](#)

Using SAML-based federation for API access to AWS

Assume that you want to provide a way for employees to copy data from their computers to a backup folder. You build an application that users can run on their computers. On the back end, the application reads and writes objects in an S3 bucket. Users don't have direct access to AWS. Instead, the following process is used:

1. A user in your organization uses a client app to request authentication from your organization's IdP.
2. The IdP authenticates the user against your organization's identity store.
3. The IdP constructs a SAML assertion with information about the user and sends the assertion to the client app.
4. The client app calls the AWS STS [AssumeRoleWithSAML](#) API, passing the ARN of the SAML provider, the ARN of the role to assume, and the SAML assertion from IdP.
5. The API response to the client app includes temporary security credentials.
6. The client app uses the temporary security credentials to call Amazon S3 API operations.

Overview of configuring SAML 2.0-based federation

Before you can use SAML 2.0-based federation as described in the preceding scenario and diagram, you must configure your organization's IdP and your AWS account to trust each other. The general process for configuring this trust is described in the following steps. Inside your organization, you must have an [IdP that supports SAML 2.0](#), like Microsoft Active Directory Federation Service (AD FS, part of Windows Server), Shibboleth, or another compatible SAML 2.0 provider.

Note

To improve federation resiliency, we recommend that you configure your IdP and AWS federation to support multiple SAML sign-in endpoints. For details, see the AWS Security Blog article [How to use regional SAML endpoints for failover](#).

To configure your organization's IdP and AWS to trust each other

1. Register AWS as a service provider (SP) with the IdP of your organization. Use the SAML metadata document from `https://region-code.signin.aws.amazon.com/static/saml-metadata.xml`

For a list of possible *region-code* values, see the **Region** column in [AWS Sign-In endpoints](#).

You can optionally use the SAML metadata document from `https://signin.aws.amazon.com/static/saml-metadata.xml`.

2. Using your organization's IdP, you generate an equivalent metadata XML file that can describe your IdP as an IAM identity provider in AWS. It must include the issuer name, a creation date, an expiration date, and keys that AWS can use to validate authentication responses (assertions) from your organization.
3. In the IAM console, you create a SAML identity provider entity. As part of this process, you upload the SAML metadata document that was produced by the IdP in your organization in [Step 2](#). For more information, see [Creating IAM SAML identity providers](#).
4. In IAM, you create one or more IAM roles. In the role's trust policy, you set the SAML provider as the principal, which establishes a trust relationship between your organization and AWS. The role's permission policy establishes what users from your organization are allowed to do in AWS. For more information, see [Creating a role for a third-party Identity Provider \(federation\)](#).

Note

SAML IDPs used in a role trust policy must be in the same account that the role is in.

5. In your organization's IdP, you define assertions that map users or groups in your organization to the IAM roles. Note that different users and groups in your organization might map to different IAM roles. The exact steps for performing the mapping depend on what IdP you're using. In the [earlier scenario](#) of an Amazon S3 folder for users, it's possible that all users

will map to the same role that provides Amazon S3 permissions. For more information, see [Configuring SAML assertions for the authentication response](#).

If your IdP enables SSO to the AWS console, then you can configure the maximum duration of the console sessions. For more information, see [Enabling SAML 2.0 federated users to access the AWS Management Console](#).

Note

The AWS implementation of SAML 2.0 federation does not support encrypted SAML assertions between the IAM identity provider and AWS. However, the traffic between the customer's systems and AWS is transmitted over an encrypted (TLS) channel.

6. In the application that you're creating, you call the AWS Security Token Service `AssumeRoleWithSAML` API, passing it the ARN of the SAML provider you created in [Step 3](#), the ARN of the role to assume that you created in [Step 4](#), and the SAML assertion about the current user that you get from your IdP. AWS makes sure that the request to assume the role comes from the IdP referenced in the SAML provider.

For more information, see [AssumeRoleWithSAML](#) in the *AWS Security Token Service API Reference*.

7. If the request is successful, the API returns a set of temporary security credentials, which your application can use to make signed requests to AWS. Your application has information about the current user and can access user-specific folders in Amazon S3, as described in the previous scenario.

Overview of the role to allow SAML-federated access to your AWS resources

The role or roles that you create in IAM define what federated users from your organization are allowed to do in AWS. When you create the trust policy for the role, you specify the SAML provider that you created earlier as the `Principal`. You can additionally scope the trust policy with a `Condition` to allow only users that match certain SAML attributes to access the role. For example, you can specify that only users whose SAML affiliation is `staff` (as asserted by `https://openidp.feide.no`) are allowed to access the role, as illustrated by the following sample policy:

```
{
  "Version": "2012-10-17",
  "Statement": [{
```

```
"Effect": "Allow",
"Principal": {"Federated": "arn:aws:iam::account-id:saml-provider/
ExampleOrgSSOProvider"},
"Action": "sts:AssumeRoleWithSAML",
"Condition": {
  "StringEquals": {
    "saml:aud": "https://signin.aws.amazon.com/saml",
    "saml:iss": "https://openidp.feide.no"
  },
  "ForAllValues:StringLike": {"saml:edupersonaffiliation": ["staff"]}
}
}]
}
```

Note

SAML IDPs used in a role trust policy must be in the same account that the role is in.

For more information about the SAML keys that you can check in a policy, see [Available keys for SAML-based AWS STS federation](#).

You can include regional endpoints for the `saml:aud` attribute at `https://region-code.signin.aws.amazon.com/static/saml-metadata.xml`. For a list of possible *region-code* values, see the **Region** column in [AWS Sign-In endpoints](#).

For the permission policy in the role, you specify permissions as you would for any role. For example, if users from your organization are allowed to administer Amazon Elastic Compute Cloud instances, you must explicitly allow Amazon EC2 actions in the permissions policy, such as those in the **AmazonEC2FullAccess** managed policy.

Uniquely identifying users in SAML-based federation

When you create access policies in IAM, it's often useful to be able to specify permissions based on the identity of users. For example, for users who have been federated using SAML, an application might want to keep information in Amazon S3 using a structure like this:

```
myBucket/app1/user1
myBucket/app1/user2
myBucket/app1/user3
```

You can create the bucket (myBucket) and folder (app1) through the Amazon S3 console or the AWS CLI, since those are static values. However, the user-specific folders (*user1*, *user2*, *user3*, etc.) have to be created at run time using code, since the value that identifies the user isn't known until the first time the user signs in through the federation process.

To write policies that reference user-specific details as part of a resource name, the user identity has to be available in SAML keys that can be used in policy conditions. The following keys are available for SAML 2.0–based federation for use in IAM policies. You can use the values returned by the following keys to create unique user identifiers for resources like Amazon S3 folders.

- `saml:namequalifier`. A hash value based on the concatenation of the `Issuer` response value (`saml:iss`) and a string with the AWS account ID and the friendly name (the last part of the ARN) of the SAML provider in IAM. The concatenation of the account ID and friendly name of the SAML provider is available to IAM policies as the key `saml:doc`. The account ID and provider name must be separated by a '/' as in "123456789012/provider_name". For more information, see the `saml:doc` key at [Available keys for SAML-based AWS STS federation](#).

The combination of `NameQualifier` and `Subject` can be used to uniquely identify a federated user. The following pseudocode shows how this value is calculated. In this pseudocode + indicates concatenation, `SHA1` represents a function that produces a message digest using SHA-1, and `Base64` represents a function that produces Base-64 encoded version of the hash output.

```
Base64 ( SHA1 ( "https://example.com/saml" + "123456789012" + "/  
MySAMLIdP" ) )
```

For more information about the policy keys that are available for SAML-based federation, see [Available keys for SAML-based AWS STS federation](#).

- `saml:sub` (string). This is the subject of the claim, which includes a value that uniquely identifies an individual user within an organization (for example, `_cbb88bf52c2510eabe00c1642d4643f41430fe25e3`).
- `saml:sub_type` (string). This key can be persistent, transient, or the full Format URI from the `Subject` and `NameID` elements used in your SAML assertion. A value of `persistent` indicates that the value in `saml:sub` is the same for a user across all sessions. If the value is `transient`, the user has a different `saml:sub` value for each session. For information about the `NameID` element's `Format` attribute, see [Configuring SAML assertions for the authentication response](#).

The following example shows a permission policy that uses the preceding keys to grant permissions to a user-specific folder in Amazon S3. The policy assumes that the Amazon S3 objects are identified using a prefix that includes both `saml:namequalifier` and `saml:sub`. Notice that the `Condition` element includes a test to be sure that `saml:sub_type` is set to `persistent`. If it is set to `transient`, the `saml:sub` value for the user can be different for each session, and the combination of values should not be used to identify user-specific folders.

```
{
  "Version": "2012-10-17",
  "Statement": {
    "Effect": "Allow",
    "Action": [
      "s3:GetObject",
      "s3:PutObject",
      "s3:DeleteObject"
    ],
    "Resource": [
      "arn:aws:s3:::exampleorgBucket/backup/${saml:namequalifier}/${saml:sub}",
      "arn:aws:s3:::exampleorgBucket/backup/${saml:namequalifier}/${saml:sub}/*"
    ],
    "Condition": {"StringEquals": {"saml:sub_type": "persistent"}}
  }
}
```

For more information about mapping assertions from the IdP to policy keys, see [Configuring SAML assertions for the authentication response](#).

Creating IAM identity providers

Note

We recommend that you require your human users to use temporary credentials when accessing AWS. Have you considered using AWS IAM Identity Center? You can use IAM Identity Center to centrally manage access to multiple AWS accounts and provide users with MFA-protected, single sign-on access to all their assigned accounts from one place. With IAM Identity Center, you can create and manage user identities in IAM Identity Center or easily connect to your existing SAML 2.0 compatible identity provider. For more information, see [What is IAM Identity Center?](#) in the *AWS IAM Identity Center User Guide*.

You can use an external identity provider (IdP) to manage user identities outside of AWS. An external IdP can provide identity information to AWS using either OpenID Connect (OIDC) or Security Assertion Markup Language (SAML). Examples of well-known OIDC identity providers are: Login with Amazon, Facebook, and Google. Examples of well-known SAML identity providers are: Shibboleth and Active Directory Federation Services.

When you want to configure federation with an external IdP, you create an IAM *identity provider* to inform AWS about the external IdP and its configuration. This establishes "trust" between your AWS account and the external IdP. The following topics include details about how to create an IAM identity provider for each of the external IdP types.

Topics

- [Creating OpenID Connect \(OIDC\) identity providers](#)
- [Creating IAM SAML identity providers](#)

Creating OpenID Connect (OIDC) identity providers

IAM OIDC identity providers are entities in IAM that describe an external identity provider (IdP) service that supports the [OpenID Connect](#) (OIDC) standard, such as Google or Salesforce. You use an IAM OIDC identity provider when you want to establish trust between an OIDC-compatible IdP and your AWS account. This is useful when creating a mobile app or web application that requires access to AWS resources, but you don't want to create custom sign-in code or manage your own user identities. For more information about this scenario, see [the section called "About web identity federation"](#).

You can create and manage an IAM OIDC identity provider using the AWS Management Console, the AWS Command Line Interface, the Tools for Windows PowerShell, or the IAM API.

After you create an IAM OIDC identity provider, you must create one or more IAM roles. A role is an identity in AWS that doesn't have its own credentials (as a user does). But in this context, a role is dynamically assigned to a federated user that is authenticated by your organization's IdP. The role permits your organization's IdP to request temporary security credentials for access to AWS. The policies assigned to the role determine what the federated users are allowed to do in AWS. To create a role for a third-party identity provider, see [Creating a role for a third-party Identity Provider \(federation\)](#).

⚠ Important

When you configure identity-based policies for actions that support `oidc-provider` resources, IAM evaluates the full OIDC identity provider URL, including any specified paths. If your OIDC identity provider URL has a path, you must include that path in the `oidc-provider` ARN as a Resource element value. You also have the option to append a forward slash and wildcard (`/*`) to the URL domain or use wildcard characters (`*` and `?`) at any point in the URL path. If the OIDC identity provider URL in the request doesn't match the value set in the policy's Resource element, the request fails.

Topics

- [Creating and managing an OIDC provider \(console\)](#)

- [Creating and managing an OIDC Identity Provider \(AWS API\)](#)
- [Obtaining the thumbprint for an OpenID Connect Identity Provider](#)

Creating and managing an OIDC provider (console)

Follow these instructions to create and manage an IAM OIDC identity provider in the AWS Management Console.

⚠ Important

If you are using an OIDC identity provider from either Google, Facebook, or Amazon Cognito, do not create a separate IAM identity provider using this procedure. These OIDC identity providers are already built-in to AWS and are available for your use. Instead, follow the steps to create new roles for your identity provider, see [Create a role for OpenID Connect federation \(console\)](#).

To create an IAM OIDC identity provider (console)

1. Before you create an IAM OIDC identity provider, you must register your application with the IdP to receive a *client ID*. The client ID (also known as *audience*) is a unique identifier for your app that is issued to you when you register your app with the IdP. For more information about obtaining a client ID, see the documentation for your IdP.

Note

AWS secures communication with some OIDC identity providers (IdPs) through our library of trusted root certificate authorities (CAs) instead of using a certificate thumbprint to verify your IdP server certificate. In these cases, your legacy thumbprint remains in your configuration, but is no longer used for validation. These OIDC IdPs include Auth0, GitHub, GitLab, Google, and those that use an Amazon S3 bucket to host a JSON Web Key Set (JWKS) endpoint.

2. Open the IAM console at <https://console.aws.amazon.com/iam/>.
3. In the navigation pane, choose **Identity providers**, and then choose **Add provider**.
4. For **Configure provider**, choose **OpenID Connect**.
5. For **Provider URL**, type the URL of the IdP. The URL must comply with these restrictions:
 - The URL is case-sensitive.
 - The URL must begin with **https://**.
 - The URL should not contain a port number.
 - Within your AWS account, each IAM OIDC identity provider must use a unique URL.
6. Choose **Get thumbprint** to verify the server certificate of your IdP. To learn how, see [Obtaining the thumbprint for an OpenID Connect Identity Provider](#).

Note

The OIDC identity provider's certificate chain must start with the domain or issuer URL, then the intermediate certificate, and end with the root certificate. If the certificate chain order is different or includes duplicate or additional certificates, then you receive a signature mismatch error and STS fails to validate the JSON Web Token (JWT). Correct the order of the certificates in the chain returned from the server to resolve the error. For more information about certificate chain standards, see [certificate_list in RFC 5246](#) on the RFC Series website.

7. For **Audience**, type the client ID of the application that you registered with the IdP and received in [Step 1](#), and that make requests to AWS. If you have additional client IDs (also known as *audiences*) for this IdP, you can add them later on the provider detail page.

8. (Optional) For **Add tags**, you can add key–value pairs to help you identify and organize your IdPs. You can also use tags to control access to AWS resources. To learn more about tagging IAM OIDC identity providers, see [Tagging OpenID Connect \(OIDC\) identity providers](#). Choose **Add tag**. Enter values for each tag key-value pair.
9. Verify the information that you have provided. When you are done choose **Add provider**.
10. Assign an IAM role to your identity provider to give external user identities managed by your identity provider permissions to access AWS resources in your account. To learn more about creating roles for identity federation, see [Creating a role for a third-party Identity Provider \(federation\)](#).

Note

OIDC IDPs used in a role trust policy must be in the same account that the role is in.

To add or remove a thumbprint for an IAM OIDC identity provider (console)

1. Open the IAM console at <https://console.aws.amazon.com/iam/>.
2. In the navigation pane, choose **Identity providers**. Then choose the name of the IAM identity provider that you want to update.
3. In the **Thumbprints** section, choose **Manage**. To enter a new thumbprint value, choose **Add thumbprint**. To remove a thumbprint, choose **Remove** next to the thumbprint that you want to remove.

Note

An IAM OIDC identity provider must have at least one and can have a maximum of five thumbprints.

When you are done, choose **Save changes**.

To add an audience for an IAM OIDC identity provider (console)

1. In the navigation pane, choose **Identity providers**, then choose the name of the IAM identity provider that you want to update.

2. In the **Audiences** section, choose **Actions** and select **Add audience**.
3. Type the client ID of the application that you registered with the IdP and received in [Step 1](#), and that will make requests to AWS. Then choose **Add audiences**.

 **Note**

An IAM OIDC identity provider must have at least one and can have a maximum of 100 audiences.

To remove an audience for an IAM OIDC identity provider (console)

1. In the navigation pane, choose **Identity providers**, then choose the name of the IAM identity provider that you want to update.
2. In the **Audiences** section, select the radio button next to the audience that you want to remove, then select **Actions**.
3. Choose **Remove audience**. A new window opens.
4. If you remove an audience, identities federating with the audience cannot assume roles associated with the audience. In the window, read the warning and confirm that you want to remove the audience by typing the word `remove` in the field.
5. Choose **Remove** to remove the audience.

To delete an IAM OIDC identity provider (console)

1. Open the IAM console at <https://console.aws.amazon.com/iam/>.
2. In the navigation pane, choose **Identity providers**.
3. Select the check box next to the IAM identity provider that you want to delete. A new window opens.
4. Confirm that you want to delete the provider by typing the word `delete` in the field. Then, choose **Delete**.

Creating and managing an IAM OIDC identity provider (AWS CLI)

You can use the following AWS CLI commands to create and manage IAM OIDC identity providers.

To create an IAM OIDC identity provider (AWS CLI)

1. (Optional) To get a list of all the IAM OIDC identity providers in your AWS account, run the following command:
 - [aws iam list-open-id-connect-providers](#)
2. To create a new IAM OIDC identity provider, run the following command:
 - [aws iam create-open-id-connect-provider](#)

To update the list of server certificate thumbprints for an existing IAM OIDC identity provider (AWS CLI)

- To update the list of server certificate thumbprints for an IAM OIDC identity provider, run the following command:
 - [aws iam update-open-id-connect-provider-thumbprint](#)

To tag an existing IAM OIDC identity provider (AWS CLI)

- To tag an existing IAM OIDC identity provider, run the following command:
 - [aws iam tag-open-id-connect-provider](#)

To list tags for an existing IAM OIDC identity provider (AWS CLI)

- To list tags for an existing IAM OIDC identity provider, run the following command:
 - [aws iam list-open-id-connect-provider-tags](#)

To remove tags on an IAM OIDC identity provider (AWS CLI)

- To remove tags on an existing IAM OIDC identity provider, run the following command:
 - [aws iam untag-open-id-connect-provider](#)

To add or remove a client ID from an existing IAM OIDC identity provider (AWS CLI)

1. (Optional) To get a list of all the IAM OIDC identity provider in your AWS account, run the following command:
 - [aws iam list-open-id-connect-providers](#)
2. (Optional) To get detailed information about an IAM OIDC identity provider, run the following command:
 - [aws iam get-open-id-connect-provider](#)
3. To add a new client ID to an existing IAM OIDC identity provider, run the following command:
 - [aws iam add-client-id-to-open-id-connect-provider](#)
4. To remove a client from an existing IAM OIDC identity provider, run the following command:
 - [aws iam remove-client-id-from-open-id-connect-provider](#)

To delete an IAM OIDC identity provider (AWS CLI)

1. (Optional) To get a list of all the IAM OIDC identity provider in your AWS account, run the following command:
 - [aws iam list-open-id-connect-providers](#)
2. (Optional) To get detailed information about an IAM OIDC identity provider, run the following command:
 - [aws iam get-open-id-connect-provider](#)
3. To delete an IAM OIDC identity provider, run the following command:
 - [aws iam delete-open-id-connect-provider](#)

Creating and managing an OIDC Identity Provider (AWS API)

You can use the following IAM API commands to create and manage OIDC providers.

To create an IAM OIDC identity provider (AWS API)

1. (Optional) To get a list of all the IAM OIDC identity provider in your AWS account, call the following operation:

- [ListOpenIDConnectProviders](#)
2. To create a new IAM OIDC identity provider, call the following operation:
 - [CreateOpenIDConnectProvider](#)

To update the list of server certificate thumbprints for an existing IAM OIDC identity provider (AWS API)

- To update the list of server certificate thumbprints for an IAM OIDC identity provider, call the following operation:
 - [UpdateOpenIDConnectProviderThumbprint](#)

To tag an existing IAM OIDC identity provider (AWS API)

- To tag an existing IAM OIDC identity provider, call the following operation:
 - [TagOpenIDConnectProvider](#)

To list tags for an existing IAM OIDC identity provider (AWS API)

- To list tags for an existing IAM OIDC identity provider, call the following operation:
 - [ListOpenIDConnectProviderTags](#)

To remove tags on an existing IAM OIDC identity provider (AWS API)

- To remove tags on an existing IAM OIDC identity provider, call the following operation:
 - [UntagOpenIDConnectProvider](#)

To add or remove a client ID from an existing IAM OIDC identity provider (AWS API)

1. (Optional) To get a list of all the IAM OIDC identity provider in your AWS account, call the following operation:
 - [ListOpenIDConnectProviders](#)

2. (Optional) To get detailed information about an IAM OIDC identity provider, call the following operation:
 - [GetOpenIDConnectProvider](#)
3. To add a new client ID to an existing IAM OIDC identity provider, call the following operation:
 - [AddClientIDToOpenIDConnectProvider](#)
4. To remove a client ID from an existing IAM OIDC identity provider, call the following operation:
 - [RemoveClientIDFromOpenIDConnectProvider](#)

To delete an IAM OIDC identity provider (AWS API)

1. (Optional) To get a list of all the IAM OIDC identity provider in your AWS account, call the following operation:
 - [ListOpenIDConnectProviders](#)
2. (Optional) To get detailed information about an IAM OIDC identity provider, call the following operation:
 - [GetOpenIDConnectProvider](#)
3. To delete an IAM OIDC identity provider, call the following operation:
 - [DeleteOpenIDConnectProvider](#)

Obtaining the thumbprint for an OpenID Connect Identity Provider

When you [create an OpenID Connect \(OIDC\) identity provider](#) in IAM, you must supply a thumbprint. IAM requires the thumbprint for the top intermediate certificate authority (CA) that signed the certificate used by the external identity provider (IdP). The thumbprint is a signature for the CA's certificate that was used to issue the certificate for the OIDC-compatible IdP. When you create an IAM OIDC identity provider, you are trusting identities authenticated by that IdP to have access to your AWS account. By supplying the CA's certificate thumbprint, you trust any certificate issued by that CA with the same DNS name as the one registered. This eliminates the need to update trusts in each account when you renew the IdP's signing certificate.

⚠ Important

In most cases, the federation server uses two different certificates:

- The first establishes an HTTPS connection between AWS and your IdP. This should be issued by a well-known public root CA, such as AWS Certificate Manager. This enables the client to check the reliability and status of the certificate.
- The second is used to encrypt tokens, and should be signed by a private or public *root* CA.

You can create an IAM OIDC identity provider with [the AWS Command Line Interface, the Tools for Windows PowerShell, or the IAM API](#). When you use these methods, you must obtain the thumbprint manually and supply it to AWS. When you create an OIDC identity provider with [the IAM console](#), the console attempts to fetch the thumbprint for you. We recommend that you also obtain the thumbprint for your OIDC IdP manually and verify that the console fetched the correct thumbprint.

You use a web browser and the OpenSSL command line tool to obtain the thumbprint for an OIDC provider. For more information, see the following sections.

To obtain the thumbprint for an OIDC IdP

1. Before you can obtain the thumbprint for an OIDC IdP, you need to obtain the OpenSSL command line tool. You use this tool to download the OIDC IdP certificate chain and produce a thumbprint of the final certificate in the certificate chain. If you need to install and configure OpenSSL, follow the instructions at [Install OpenSSL](#) and [Configure OpenSSL](#).

i Note

AWS secures communication with some OIDC identity providers (IdPs) through our library of trusted root certificate authorities (CAs) instead of using a certificate thumbprint to verify your IdP server certificate. In these cases, your legacy thumbprint remains in your configuration, but is no longer used for validation. These OIDC IdPs include Auth0, GitHub, GitLab, Google, and those that use an Amazon S3 bucket to host a JSON Web Key Set (JWKS) endpoint.

2. Start with the OIDC IdP URL (for example, `https://server.example.com`), and then add `/.well-known/openid-configuration` to form the URL for the IdP's configuration document, such as the following:

`https://server.example.com/.well-known/openid-configuration`

Open this URL in a web browser, replacing `server.example.com` with your IdP server name.

3. In the displayed document, use your web browser **Find** feature to locate the text `"jwks_uri"`. Immediately following the text `"jwks_uri"`, there is a colon (`:`) followed by a URL. Copy the fully qualified domain name of the URL. Do not include `https://` or any path that comes after the top-level domain.

```
{
  "issuer": "https://accounts.example.com",
  "authorization_endpoint": "https://accounts.example.com/o/oauth2/v2/auth",
  "device_authorization_endpoint": "https://oauth2.exampleapis.com/device/code",
  "token_endpoint": "https://oauth2.exampleapis.com/token",
  "userinfo_endpoint": "https://openidconnect.exampleapis.com/v1/userinfo",
  "revocation_endpoint": "https://oauth2.exampleapis.com/revoke",
  "jwks_uri": "https://www.exampleapis.com/oauth2/v3/certs",
  ...
}
```

4. Use the OpenSSL command line tool to run the following command. Replace `keys.example.com` with the domain name you obtained in [Step 3](#).

```
openssl s_client -servername keys.example.com -showcerts -
connect keys.example.com:443
```

5. In your command window, scroll up until you see a certificate similar to the following example. If you see more than one certificate, find the last certificate displayed (at the end of the command output). This contains the certificate of the top intermediate CA in the certificate authority chain.

```
-----BEGIN CERTIFICATE-----
MIICiTCCAfICCD6m7oRw0uX0jANBgkqhkiG9w0BAQUFADCBiDELMaKGA1UEBhMC
VVMxCzAJBgNVBAGTAldBMRAwDgYDVoQQHEwdTZWF0dGx1MQ8wDQYDVQQKEwZBbWF6

Ibb30hjZnzcvcQAaRHhd1QWIMm2nrAgMBAAEwDQYJKoZIhvcNAQEFBQADgYEAAtCu4
nUhVVxYUntneD9+h8Mg9q6q+auNKyExzyLwax1Aoo7TJHidbtS4J5iNmZgXL0Fkb
FFBjvSfpJI1J00zbhNYS5f6GuoEDmFJ10ZxBHjJnyp3780D8uTs7fLvJx79LjStb
NYiytVbZPQUQ5Yaxu2jXnimvw3rrszlaEXAMPLE=
-----END CERTIFICATE-----
```

Copy the certificate (including the -----BEGIN CERTIFICATE----- and -----END CERTIFICATE----- lines) and paste it into a text file. Then save the file with the file name **certificate.crt**.

Note

The OIDC identity provider's certificate chain must start with the domain or issuer URL, then the intermediate certificate, and end with the root certificate. If the certificate chain order is different or includes duplicate or additional certificates, then you receive a signature mismatch error and STS fails to validate the JSON Web Token (JWT). Correct the order of the certificates in the chain returned from the server to resolve the error. For more information about certificate chain standards, see [certificate_list in RFC 5246](#) on the RFC Series website.

6. Use the OpenSSL command line tool to run the following command.

```
openssl x509 -in certificate.crt -fingerprint -sha1 -noout
```

Your command window displays the certificate thumbprint, which looks similar to the following example:

```
SHA1 Fingerprint=99:0F:41:93:97:2F:2B:EC:F1:2D:DE:DA:52:37:F9:C9:52:F2:0D:9E
```

Remove the colon characters (:) from this string to produce the final thumbprint, like this:

```
990F4193972F2BECF12DDEDA5237F9C952F20D9E
```

7. If you are creating the IAM OIDC identity provider with the AWS CLI, Tools for Windows PowerShell, or the IAM API, supply this thumbprint when creating the provider.

If you are creating the IAM OIDC identity provider in the IAM console, compare this thumbprint to the thumbprint shown on the console **Verify Provider Information** page when you create an OIDC provider.

Important

If the thumbprint you obtained does not match the one you see in the console, you should not create the OIDC provider in the console. Instead, you should wait a while and then try again to create the OIDC provider, ensuring that the thumbprints match before you create the provider. If the thumbprints still do not match after a second attempt, use the [IAM Forum](#) to contact AWS.

Install OpenSSL

If you don't already have OpenSSL installed, follow the instructions in this section.

To install OpenSSL on Linux or Unix

1. Go to [OpenSSL: Source, Tarballs](https://openssl.org/source/) (https://openssl.org/source/).
2. Download the latest source and build the package.

To install OpenSSL on Windows

1. Go to [OpenSSL: Binary Distributions](https://wiki.openssl.org/index.php/Binaries) (https://wiki.openssl.org/index.php/Binaries) for a list of sites from which you can install the Windows version.
2. Follow the instructions on your selected site to start the installation.
3. If you are asked to install the **Microsoft Visual C++ 2008 Redistributables** and it is not already installed on your system, choose the download link appropriate for your environment. Follow the instructions provided by the **Microsoft Visual C++ 2008 Redistributable Setup Wizard**.

Note

If you are not sure whether the Microsoft Visual C++ 2008 Redistributables is already installed on your system, you can try installing OpenSSL first. The OpenSSL installer displays an alert if the Microsoft Visual C++ 2008 Redistributables is not yet installed.

Make sure that you install the architecture (32-bit or 64-bit) that matches the version of OpenSSL that you install.

4. After you have installed the Microsoft Visual C++ 2008 Redistributables, select the appropriate version of the OpenSSL binaries for your environment and save the file locally. Start the **OpenSSL Setup Wizard**.
5. Follow the instructions described in the **OpenSSL Setup Wizard**.

Configure OpenSSL

Before you use OpenSSL commands, you must configure the operating system so that it has information about the location where OpenSSL is installed.

To configure OpenSSL on Linux or Unix

1. At the command line, set the `OpenSSL_HOME` variable to the location of the OpenSSL installation:

```
$ export OpenSSL_HOME=path_to_your_OpenSSL_installation
```

2. Set the path to include the OpenSSL installation:

```
$ export PATH=$PATH:$OpenSSL_HOME/bin
```

Note

Any changes you make to environment variables with the `export` command are valid only for the current session. You can make persistent changes to the environment variables by setting them in your shell configuration file. For more information, see the documentation for your operating system.

To configure OpenSSL on Windows

1. Open a **Command Prompt** window.
2. Set the `OpenSSL_HOME` variable to the location of the OpenSSL installation:

```
C:\> set OpenSSL_HOME=path_to_your_OpenSSL_installation
```

3. Set the OpenSSL_CONF variable to the location of the configuration file in your OpenSSL installation:

```
C:\> set OpenSSL_CONF=path_to_your_OpenSSL_installation\bin\openssl.cfg
```

4. Set the path to include the OpenSSL installation:

```
C:\> set Path=%Path%;%OpenSSL_HOME%\bin
```

Note

Any changes you make to Windows environment variables in a **Command Prompt** window are valid only for the current command line session. You can make persistent changes to the environment variables by setting them as system properties. The exact procedures depend on what version of Windows you're using. (For example, in Windows 7, open **Control Panel, System and Security, System**. Then choose **Advanced system settings, Advanced tab, Environment Variables**.) For more information, see the Windows documentation.

Creating IAM SAML identity providers

An IAM SAML 2.0 identity provider is an entity in IAM that describes an external identity provider (IdP) service that supports the [SAML 2.0 \(Security Assertion Markup Language 2.0\)](#) standard. You use an IAM identity provider when you want to establish trust between a SAML-compatible IdP such as Shibboleth or Active Directory Federation Services and AWS, so that users in your organization can access AWS resources. IAM SAML identity providers are used as principals in an IAM trust policy.

For more information about this scenario, see [About SAML 2.0-based federation](#).

You can create and manage an IAM identity provider in the AWS Management Console or with AWS CLI, Tools for Windows PowerShell, or AWS API calls.

After you create a SAML provider, you must create one or more IAM roles. A role is an identity in AWS that doesn't have its own credentials (as a user does). But in this context, a role is dynamically

assigned to a federated user that is authenticated by your organization's IdP. The role permits your organization's IdP to request temporary security credentials for access to AWS. The policies assigned to the role determine what the federated users are allowed to do in AWS. To create a role for SAML federation, see [Creating a role for a third-party Identity Provider \(federation\)](#).

Finally, after you create the role, you complete the SAML trust by configuring your IdP with information about AWS and the roles that you want your federated users to use. This is referred to as configuring relying party trust between your IdP and AWS. To configure relying party trust, see [Configuring your SAML 2.0 IdP with relying party trust and adding claims](#).

Topics

- [Creating and managing an IAM SAML identity provider \(console\)](#)
- [Creating and managing an IAM SAML Identity Provider \(AWS CLI\)](#)
- [Creating and managing an IAM SAML identity provider \(AWS API\)](#)
- [Configuring your SAML 2.0 IdP with relying party trust and adding claims](#)
- [Integrating third-party SAML solution providers with AWS](#)
- [Configuring SAML assertions for the authentication response](#)

Creating and managing an IAM SAML identity provider (console)

You can use the AWS Management Console to create and delete IAM SAML identity providers.

To create an IAM SAML identity provider (console)

1. Before you can create an IAM SAML identity provider, you need the SAML metadata document that you get from the IdP. This document includes the issuer's name, expiration information, and keys that can be used to validate the SAML authentication response (assertions) that are received from the IdP. To generate the metadata document, use the identity management software your organization uses as its IdP. For instructions on how to configure many of the available IdPs to work with AWS, including how to generate the required SAML metadata document, see [Integrating third-party SAML solution providers with AWS](#).

Important

This metadata file includes the issuer name, expiration information, and keys that can be used to validate the SAML authentication response (assertions) received from the IdP. The metadata file must be encoded in UTF-8 format without a byte order mark

(BOM). To remove the BOM, you can encode the file as UTF-8 using a text editing tool, such as Notepad++.

The x.509 certificate included as part of the SAML metadata document must use a key size of at least 1024 bits. Also, the x.509 certificate must also be free of any repeated extensions. You can use extensions, but the extensions can only appear once in the certificate. If the x.509 certificate does not meet either condition, IdP creation fails and returns an "Unable to parse metadata" error.

As defined by the [SAML V2.0 Metadata Interoperability Profile Version 1.0](#), IAM neither evaluates nor takes action regarding the expiration of the metadata document's X.509 certificate.

2. Sign in to the AWS Management Console and open the IAM console at <https://console.aws.amazon.com/iam/>.
3. In the navigation pane, choose **Identity providers** and then choose **Add provider**.
4. For **Configure provider**, choose **SAML**.
5. Type a name for the identity provider.
6. For **Metadata document**, choose **Choose file**, specify the SAML metadata document that you downloaded in [Step 1](#).
7. (Optional) For **Add tags** you can add key–value pairs to help you identify and organize your IdPs. You can also use tags to control access to AWS resources. To learn more about tagging SAML identity providers, see [Tagging IAM SAML identity providers](#).

Choose **Add tag**. Enter values for each tag key-value pair.

8. Verify the information that you have provided. When you are done, choose **Add provider**.
9. Assign an IAM role to your identity provider to give external user identities managed by your identity provider permissions to access AWS resources in your account. To learn more about creating roles for identity federation, see [Creating a role for a third-party Identity Provider \(federation\)](#).

Note

SAML IDPs used in a role trust policy must be in the same account that the role is in.

To delete a SAML provider (console)

1. Sign in to the AWS Management Console and open the IAM console at <https://console.aws.amazon.com/iam/>.
2. In the navigation pane, choose **Identity providers**.
3. Select the radio button next to the identity provider that you want to delete.
4. Choose **Delete**. A new window opens.
5. Confirm that you want to delete the provider by typing the word `delete` in the field. Then, choose **Delete**.

Creating and managing an IAM SAML Identity Provider (AWS CLI)

You can use the AWS CLI to create and manage SAML providers.

Before you can create an IAM identity provider, you need the SAML metadata document that you get from the IdP. This document includes the issuer's name, expiration information, and keys that can be used to validate the SAML authentication response (assertions) that are received from the IdP. To generate the metadata document, use the identity management software your organization uses as its IdP. For instructions on how to configure many of the available IdPs to work with AWS, including how to generate the required SAML metadata document, see [Integrating third-party SAML solution providers with AWS](#).

Important

This metadata file includes the issuer name, expiration information, and keys that can be used to validate the SAML authentication response (assertions) received from the IdP. The metadata file must be encoded in UTF-8 format without a byte order mark (BOM). To remove the BOM, you can encode the file as UTF-8 using a text editing tool, such as Notepad++.

The x.509 certificate included as part of the SAML metadata document must use a key size of at least 1024 bits. Also, the x.509 certificate must also be free of any repeated extensions. You can use extensions, but the extensions can only appear once in the certificate. If the x.509 certificate does not meet either condition, IdP creation fails and returns an "Unable to parse metadata" error.

As defined by the [SAML V2.0 Metadata Interoperability Profile Version 1.0](#), IAM neither evaluates nor takes action regarding the expiration of the metadata document's X.509 certificate.

To create an IAM identity provider and upload a metadata document (AWS CLI)

- Run this command: [aws iam create-saml-provider](#)

To upload a new metadata document for an IAM identity provider (AWS CLI)

- Run this command: [aws iam update-saml-provider](#)

To tag an existing IAM identity provider (AWS CLI)

- Run this command: [aws iam tag-saml-provider](#)

To list tags for existing IAM identity provider (AWS CLI)

- Run this command: [aws iam list-saml-provider-tags](#)

To remove tags on an existing IAM identity provider (AWS CLI)

- Run this command: [aws iam untag-saml-provider](#)

To delete an IAM SAML identity provider (AWS CLI)

1. (Optional) To list information for all providers, such as the ARN, creation date, and expiration, run the following command:
 - [aws iam list-saml-providers](#)
2. (Optional) To get information about a specific provider, such as the ARN, creation date, and expiration, run the following command:
 - [aws iam get-saml-provider](#)
3. To delete an IAM identity provider, run the following command:

- [aws iam delete-saml-provider](#)

Creating and managing an IAM SAML identity provider (AWS API)

You can use the AWS API to create and manage SAML providers.

Before you can create an IAM identity provider, you need the SAML metadata document that you get from the IdP. This document includes the issuer's name, expiration information, and keys that can be used to validate the SAML authentication response (assertions) that are received from the IdP. To generate the metadata document, use the identity management software your organization uses as its IdP. For instructions on how to configure many of the available IdPs to work with AWS, including how to generate the required SAML metadata document, see [Integrating third-party SAML solution providers with AWS](#).

Important

The metadata file must be encoded in UTF-8 format without a byte order mark (BOM). Also, the X.509 certificate that is included as part of the SAML metadata document must use a key size of at least 1024 bits. If the key size is smaller, the IdP creation fails with an "Unable to parse metadata" error. To remove the BOM, you can encode the file as UTF-8 using a text editing tool, such as Notepad++.

To create an IAM identity provider and upload a metadata document (AWS API)

- Call this operation: [CreateSAMLProvider](#)

To upload a new metadata document for an IAM identity provider (AWS API)

- Call this operation: [UpdateSAMLProvider](#)

To tag an existing IAM identity provider (AWS API)

- Call this operation: [TagSAMLProvider](#)

To list tags for an existing IAM identity provider (AWS API)

- Call this operation: [ListSAMLProviderTags](#)

To remove tags on an existing IAM identity provider (AWS API)

- Call this operation: [UntagSAMLProvider](#)

To delete an IAM identity provider (AWS API)

1. (Optional) To list information for all IdPs, such as the ARN, creation date, and expiration, call the following operation:
 - [ListSAMLProviders](#)
2. (Optional) To get information about a specific provider, such as the ARN, creation date, and expiration, call the following operation:
 - [GetSAMLProvider](#)
3. To delete an IdP, call the following operation:
 - [DeleteSAMLProvider](#)

Configuring your SAML 2.0 IdP with relying party trust and adding claims

When you create an IAM identity provider and role for SAML access, you are telling AWS about the external identity provider (IdP) and what its users are allowed to do. Your next step is to then tell the IdP about AWS as a service provider. This is called adding *relying party trust* between your IdP and AWS. The exact process for adding relying party trust depends on what IdP you're using. For details, see the documentation for your identity management software.

Many IdPs allow you to specify a URL from which the IdP can read an XML document that contains relying party information and certificates. For AWS, use `https://region-code.signin.aws.amazon.com/static/saml-metadata.xml` or `https://signin.aws.amazon.com/static/saml-metadata.xml`. For a list of possible *region-code* values, see the **Region** column in [AWS Sign-In endpoints](#).

If you can't specify a URL directly, then download the XML document from the preceding URL and import it into your IdP software.

You also need to create appropriate claim rules in your IdP that specify AWS as a relying party. When the IdP sends a SAML response to the AWS endpoint, it includes a SAML *assertion* that contains one or more *claims*. A claim is information about the user and its groups. A claim rule maps that information into SAML attributes. This lets you make sure that SAML authentication responses from your IdP contain the necessary attributes that AWS uses in IAM policies to check permissions for federated users. For more information, see the following topics:

- [Overview of the role to allow SAML-federated access to your AWS resources](#). This topic discusses using SAML-specific keys in IAM policies and how to use them to restrict permissions for SAML-federated users.
- [Configuring SAML assertions for the authentication response](#). This topic discusses how to configure SAML claims that include information about the user. The claims are bundled into a SAML assertion and included in the SAML response that is sent to AWS. You must ensure that the information needed by AWS policies is included in the SAML assertion in a form that AWS can recognize and use.
- [Integrating third-party SAML solution providers with AWS](#). This topic provides links to documentation provided by third-party organizations about how to integrate identity solutions with AWS.

Note

To improve federation resiliency, we recommend that you configure your IdP and AWS federation to support multiple SAML sign-in endpoints. For details, see the AWS Security Blog article [How to use regional SAML endpoints for failover](#).

Integrating third-party SAML solution providers with AWS

Note

We recommend that you require your human users to use temporary credentials when accessing AWS. Have you considered using AWS IAM Identity Center? You can use IAM Identity Center to centrally manage access to multiple AWS accounts and provide users with MFA-protected, single sign-on access to all their assigned accounts from one place. With IAM Identity Center, you can create and manage user identities in IAM Identity

Center or easily connect to your existing SAML 2.0 compatible identity provider. For more information, see [What is IAM Identity Center?](#) in the *AWS IAM Identity Center User Guide*.

The following links help you configure third-party SAML 2.0 identity provider (IdP) solutions to work with AWS federation.

Tip

AWS Support engineers can assist customers who have business and enterprise support plans with some integration tasks that involve third-party software. For a current list of supported platforms and applications, see [What third-party software is supported?](#) in the *AWS Support FAQs*.

Solution	More information
Auth0	Integrate with Amazon Web Services – This page on the Auth0 documentation website has links to resources that describe how to set up single sign-on (SSO) with the AWS Management Console and includes a JavaScript example. You can configure Auth0 to pass session tags . For more information, see Auth0 Announces Partnership with AWS for IAM Session Tags .
Microsoft Entra	Tutorial: Microsoft Entra SSO integration with AWS Single-Account Access – This tutorial on the Microsoft website describes how to set up Microsoft Entra (formerly known as Azure AD) as an identity provider (IdP) using SAML federation.
Centrify	Configure Centrify and Use SAML for SSO to AWS – This page on the Centrify website explains how to configure Centrify to use SAML for SSO to AWS.

Solution	More information
Shibboleth	How to Use Shibboleth for SSO to the AWS Management Console – This entry on the AWS Security Blog provides a step-by-step tutorial on how to set up Shibboleth and configure it as an identity provider for AWS. You can configure Shibboleth to pass session tags .

For more details, see the [IAM Partners](#) page on the AWS website.

Configuring SAML assertions for the authentication response

After you have verified a user's identity in your organization, the external identity provider (IdP) sends an authentication response to the AWS SAML endpoint at `https://region-code.signin.aws.amazon.com/saml`. For a list of potential *region-code* replacements, see the **Region** column in [AWS Sign-In endpoints](#). This response is a POST request that includes a SAML token that adheres to the [HTTP POST Binding for SAML 2.0](#) standard and that contains the following elements, or *claims*. You configure these claims in your SAML-compatible IdP. Refer to the documentation for your IdP for instructions on how to enter these claims.

When the IdP sends the response containing the claims to AWS, many of the incoming claims map to AWS context keys. These context keys can be checked in IAM policies using the Condition element. A listing of the available mappings follows in the section [Mapping SAML attributes to AWS trust policy context keys](#).

Subject and NameID

The following excerpt shows an example. Substitute your own values for the marked ones. There must be exactly one SubjectConfirmation element with a SubjectConfirmationData element that includes both the NotOnOrAfter attribute and a Recipient attribute.

These attributes include a value that must match the AWS endpoint `https://region-code.signin.aws.amazon.com/saml`. For a list of possible *region-code* values, see the **Region** column in [AWS Sign-In endpoints](#). For the AWS value, you can also use `https://signin.aws.amazon.com/static/saml`, as shown in the following example.

NameID elements can have the value persistent, transient, or consist of the full Format URI as provided by the IdP solution. A value of persistent indicates that the value in NameID is the same

for a user between sessions. If the value is transient, the user has a different NameID value for each session. Single sign-on interactions support the following types of identifiers:

- `urn:oasis:names:tc:SAML:2.0:nameid-format:persistent`
- `urn:oasis:names:tc:SAML:2.0:nameid-format:transient`
- `urn:oasis:names:tc:SAML:1.1:nameid-format:emailAddress`
- `urn:oasis:names:tc:SAML:1.1:nameid-format:unspecified`
- `urn:oasis:names:tc:SAML:1.1:nameid-format:X509SubjectName`
- `urn:oasis:names:tc:SAML:1.1:nameid-format:WindowsDomainQualifiedName`
- `urn:oasis:names:tc:SAML:2.0:nameid-format:kerberos`
- `urn:oasis:names:tc:SAML:2.0:nameid-format:entity`

```
<Subject>
  <NameID Format="urn:oasis:names:tc:SAML:2.0:nameid-
format:persistent">_cbb88bf52c2510eabe00c1642d4643f41430fe25e3</NameID>
  <SubjectConfirmation Method="urn:oasis:names:tc:SAML:2.0:cm:bearer">
    <SubjectConfirmationData NotOnOrAfter="2013-11-05T02:06:42.876Z"
Recipient="https://signin.aws.amazon.com/saml"/>
  </SubjectConfirmation>
</Subject>
```

Important

The `saml:aud` context key comes from the SAML *recipient* attribute because it is the SAML equivalent to the OIDC audience field, for example, `accounts.google.com:aud`.

PrincipalTag SAML attribute

(Optional) You can use an `Attribute` element with the `Name` attribute set to `https://aws.amazon.com/SAML/Attributes/PrincipalTag:{TagKey}`. This element allows you to pass attributes as session tags in the SAML assertion. For more information about session tags, see [Passing session tags in AWS STS](#).

To pass attributes as session tags, include the `AttributeValue` element that specifies the value of the tag. For example, to pass the tag key-value pairs `Project = Marketing` and `CostCenter = 12345`, use the following attribute. Include a separate `Attribute` element for each tag.

```
<Attribute Name="https://aws.amazon.com/SAML/Attributes/PrincipalTag:Project">
  <AttributeValue>Marketing</AttributeValue>
</Attribute>
<Attribute Name="https://aws.amazon.com/SAML/Attributes/PrincipalTag:CostCenter">
  <AttributeValue>12345</AttributeValue>
</Attribute>
```

To set the tags above as transitive, include another `Attribute` element with the `Name` attribute set to `https://aws.amazon.com/SAML/Attributes/TransitiveTagKeys`. This is an optional multivalued attribute that sets your session tags as transitive. Transitive tags persist when you use the SAML session to assume another role in AWS. This is known as [role chaining](#). For example, to set both the `Principal` and `CostCenter` tags as transitive, use the following attribute to specify the keys.

```
<Attribute Name="https://aws.amazon.com/SAML/Attributes/TransitiveTagKeys">
  <AttributeValue>Project</AttributeValue>
  <AttributeValue>CostCenter</AttributeValue>
</Attribute>
```

Role SAML attribute

You can use an `Attribute` element with the `Name` attribute set to `https://aws.amazon.com/SAML/Attributes/Role`. This element contains one or more `AttributeValue` elements that list the IAM identity provider and role to which the user is mapped by your IdP. The IAM role and IAM identity provider are specified as a comma-delimited pair of ARNs in the same format as the `RoleArn` and `PrincipalArn` parameters that are passed to [AssumeRoleWithSAML](#). This element must contain at least one role-provider pair (`AttributeValue` element), and can contain multiple pairs. If the element contains multiple pairs, then the user is asked to choose which role to assume when they use WebSSO to sign in to the AWS Management Console.

Important

The value of the `Name` attribute in the `Attribute` tag is case-sensitive. It must be set to `https://aws.amazon.com/SAML/Attributes/Role` exactly.

```
<Attribute Name="https://aws.amazon.com/SAML/Attributes/Role">
  <AttributeValue>arn:aws:iam::account-number:role/role-name1,arn:aws:iam::account-
number:saml-provider/provider-name</AttributeValue>
```

```
<AttributeValue>arn:aws:iam::account-number:role/role-name2,arn:aws:iam::account-number:saml-provider/provider-name</AttributeValue>
  <AttributeValue>arn:aws:iam::account-number:role/role-name3,arn:aws:iam::account-number:saml-provider/provider-name</AttributeValue>
</Attribute>
```

RoleSessionName SAML attribute

You can use an `Attribute` element with the `Name` attribute set to `https://aws.amazon.com/SAML/Attributes/RoleSessionName`. This element contains one `AttributeValue` element that provides an identifier for the temporary credentials that are issued when the role is assumed. You can use this to associate the temporary credentials with the user who is using your application. This element is used to display user information in the AWS Management Console. The value in the `AttributeValue` element must be between 2 and 64 characters long, can contain only alphanumeric characters, underscores, and the following characters: `. , + = @ -` (hyphen). It cannot contain spaces. The value is typically a user ID (johndoe) or an email address (johndoe@example.com). It should not be a value that includes a space, like a user's display name (John Doe).

Important

The value of the `Name` attribute in the `Attribute` tag is case-sensitive. It must be set to `https://aws.amazon.com/SAML/Attributes/RoleSessionName` exactly.

```
<Attribute Name="https://aws.amazon.com/SAML/Attributes/RoleSessionName">
  <AttributeValue>user-id-name</AttributeValue>
</Attribute>
```

SessionDuration SAML attribute

(Optional) You can use an `Attribute` element with the `Name` attribute set to `https://aws.amazon.com/SAML/Attributes/SessionDuration`. This element contains one `AttributeValue` element that specifies how long the user can access the AWS Management Console before having to request new temporary credentials. The value is an integer representing the number of seconds for the session. The value can range from 900 seconds (15 minutes) to 43200 seconds (12 hours). If this attribute is not present, then the credential last for one hour (the default value of the `DurationSeconds` parameter of the `AssumeRoleWithSAML` API).

To use this attribute, you must configure the SAML provider to provide single sign-on access to the AWS Management Console through the console sign-in web endpoint at `https://region-code.signin.aws.amazon.com/saml`. For a list of possible *region-code* values, see the **Region** column in [AWS Sign-In endpoints](#). You can optionally use the following URL: `https://signin.aws.amazon.com/static/saml`. Note that this attribute extends sessions only to the AWS Management Console. It cannot extend the lifetime of other credentials. However, if it is present in an AssumeRoleWithSAML API call, it can be used to *shorten* the duration of the session. The default lifetime of the credentials returned by the call is 60 minutes.

Note, too, that if a SessionNotOnOrAfter attribute is also defined, then the *lesser* value of the two attributes, SessionDuration or SessionNotOnOrAfter, establishes the maximum duration of the console session.

When you enable console sessions with an extended duration the risk of compromise of the credentials rises. To help you mitigate this risk, you can immediately disable the active console sessions for any role by choosing **Revoke Sessions** on the **Role Summary** page in the IAM console. For more information, see [Revoking IAM role temporary security credentials](#).

Important

The value of the Name attribute in the Attribute tag is case-sensitive. It must be set to `https://aws.amazon.com/SAML/Attributes/SessionDuration` exactly.

```
<Attribute Name="https://aws.amazon.com/SAML/Attributes/SessionDuration">
  <AttributeValue>1800</AttributeValue>
</Attribute>
```

SourceIdentity SAML attribute

(Optional) You can use an Attribute element with the Name attribute set to `https://aws.amazon.com/SAML/Attributes/SourceIdentity`. This element contains one AttributeValue element that provides an identifier for the person or application that is using an IAM role. The value for source identity persists when you use the SAML session to assume another role in AWS known as [role chaining](#). The value for source identity is present in the request for every action taken during the role session. The value that is set cannot be changed during the role session. Administrators can then use AWS CloudTrail logs to monitor and audit the source identity information to determine who performed actions with shared roles.

The value in the `AttributeValue` element must be between 2 and 64 characters long, can contain only alphanumeric characters, underscores, and the following characters: `. , + = @ -` (hyphen). It cannot contain spaces. The value is typically an attribute that is associated with the user such as a user id (johndoe) or an email address (johndoe@example.com). It should not be a value that includes a space, like a user's display name (John Doe). For more information about using source identity, see [Monitor and control actions taken with assumed roles](#).

Important

If your SAML assertion is configured to use the [SourceIdentity](#) attribute, then your role trust policy must also include the `sts:SetSourceIdentity` action, otherwise the assume role operation will fail. For more information about using source identity, see [Monitor and control actions taken with assumed roles](#).

To pass a source identity attribute, include the `AttributeValue` element that specifies the value of the source identity. For example, to pass the source identity `DiegoRamirez` use the following attribute.

```
<Attribute Name="https://aws.amazon.com/SAML/Attributes/SourceIdentity">  
  <AttributeValue>DiegoRamirez</AttributeValue>
```

Mapping SAML attributes to AWS trust policy context keys

The tables in this section list commonly used SAML attributes and how they map to trust policy condition context keys in AWS. You can use these keys to control access to a role. To do that, compare the keys to the values that are included in the assertions that accompany a SAML access request.

Important

These keys are available only in IAM trust policies (policies that determine who can assume a role) and are not applicable to permissions policies.

In the `eduPerson` and `eduOrg` attributes table, values are typed either as strings or as lists of strings. For string values, you can test these values in IAM trust policies using `StringEquals` or

StringLike conditions. For values that contain a list of strings, you can use the ForAnyValue and ForAllValues [policy set operators](#) to test the values in trust policies.

Note

You should include only one claim per AWS context key. If you include more than one, only one claim will be mapped.

eduPerson and eduOrg attributes

Enabling SAML 2.0 federated users to access the AWS Management Console

You can use a role to configure your SAML 2.0-compliant identity provider (IdP) and AWS to permit your federated users to access the AWS Management Console. The role grants the user permissions

to carry out tasks in the console. If you want to give SAML federated users other ways to access AWS, see one of these topics:

- AWS CLI: [Switching to an IAM role \(AWS CLI\)](#)
- Tools for Windows PowerShell: [Switching to an IAM role \(Tools for Windows PowerShell\)](#)
- AWS API: [Switching to an IAM role \(AWS API\)](#)

Overview

The following diagram illustrates the flow for SAML-enabled single sign-on.

Note

This specific use of SAML differs from the more general one illustrated at [About SAML 2.0-based federation](#) because this workflow opens the AWS Management Console on behalf of the user. This requires the use of the AWS sign-in endpoint instead of directly calling the `AssumeRoleWithSAML` API. The endpoint calls the API for the user and returns a URL that automatically redirects the user's browser to the AWS Management Console.

The diagram illustrates the following steps:

1. The user browses to your organization's portal and selects the option to go to the AWS Management Console. In your organization, the portal is typically a function of your IdP that handles the exchange of trust between your organization and AWS. For example, in Active Directory Federation Services, the portal URL is: `https://ADFSServiceName/adfs/ls/IdpInitiatedSignOn.aspx`
2. The portal verifies the user's identity in your organization.
3. The portal generates a SAML authentication response that includes assertions that identify the user and include attributes about the user. You can also configure your IdP to include a SAML assertion attribute called `SessionDuration` that specifies how long the console session is valid. You can also configure the IdP to pass attributes as [session tags](#). The portal sends this response to the client browser.
4. The client browser is redirected to the AWS single sign-on endpoint and posts the SAML assertion.
5. The endpoint requests temporary security credentials on behalf of the user and creates a console sign-in URL that uses those credentials.

6. AWS sends the sign-in URL back to the client as a redirect.
7. The client browser is redirected to the AWS Management Console. If the SAML authentication response includes attributes that map to multiple IAM roles, the user is first prompted to select the role for accessing the console.

From the user's perspective, the process happens transparently: The user starts at your organization's internal portal and ends up at the AWS Management Console, without ever having to supply any AWS credentials.

Consult the following sections for an overview of how to configure this behavior along with links to detailed steps.

Configure your network as a SAML provider for AWS

Inside your organization's network, you configure your identity store (such as Windows Active Directory) to work with a SAML-based IdP like Windows Active Directory Federation Services, Shibboleth, etc. Using your IdP, you generate a metadata document that describes your organization as an IdP and includes authentication keys. You also configure your organization's portal to route user requests for the AWS Management Console to the AWS SAML endpoint for authentication using SAML assertions. How you configure your IdP to produce the metadata.xml file depends on your IdP. Refer to your IdP's documentation for instructions, or see [Integrating third-party SAML solution providers with AWS](#) for links to the web documentation for many of the SAML providers supported.

Create a SAML provider in IAM

Next, you sign in to the AWS Management Console and go to the IAM console. There you create a new SAML provider, which is an entity in IAM that holds information about your organization's IdP. As part of this process, you upload the metadata document produced by the IdP software in your organization in the previous section. For details, see [Creating IAM SAML identity providers](#).

Configure permissions in AWS for your federated users

The next step is to create an IAM role that establishes a trust relationship between IAM and your organization's IdP. This role must identify your IdP as a principal (trusted entity) for purposes of federation. The role also defines what users authenticated by your organization's IdP are allowed to do in AWS. You can use the IAM console to create this role. When you create the trust policy that indicates who can assume the role, you specify the SAML provider that you created earlier in IAM. You also specify one or more SAML attributes that a user must match to be allowed to

assume the role. For example, you can specify that only users whose SAML [eduPersonOrgDN](#) value is ExampleOrg are allowed to sign in. The role wizard automatically adds a condition to test the `saml:aud` attribute to make sure that the role is assumed only for sign-in to the AWS Management Console. The trust policy for the role might look like this:

```
{
  "Version": "2012-10-17",
  "Statement": [{
    "Effect": "Allow",
    "Principal": {"Federated": "arn:aws:iam::account-id:saml-provider/ExampleOrgSSOProvider"},
    "Action": "sts:AssumeRoleWithSAML",
    "Condition": {"StringEquals": {
      "saml:edupersonorgdn": "ExampleOrg",
      "saml:aud": "https://signin.aws.amazon.com/saml"
    }}
  }]
}
```

Note

SAML IDPs used in a role trust policy must be in the same account that the role is in.

You can include regional endpoints for the `saml:aud` attribute at `https://region-code.signin.aws.amazon.com/static/saml-metadata.xml`. For a list of possible *region-code* values, see the **Region** column in [AWS Sign-In endpoints](#).

For the [permission policy](#) in the role, you specify permissions as you would for any role, user, or group. For example, if users from your organization are allowed to administer Amazon EC2 instances, you explicitly allow Amazon EC2 actions in the permission policy. You can do this by assigning a [managed policy](#), such as the **Amazon EC2 Full Access** managed policy.

For details about creating a role for a SAML IdP, see [Create a role for SAML 2.0 federation \(console\)](#).

Finish configuration and create SAML assertions

Notify your SAML IdP that AWS is your service provider by installing the `saml-metadata.xml` file found at `https://region-code.signin.aws.amazon.com/static/saml-metadata.xml` or `https://signin.aws.amazon.com/static/saml-metadata.xml`. For a list of possible *region-code* values, see the **Region** column in [AWS Sign-In endpoints](#).

How you install that file depends on your IdP. Some providers give you the option to type the URL, whereupon the IdP gets and installs the file for you. Others require you to download the file from the URL and then provide it as a local file. Refer to your IdP documentation for details, or see [Integrating third-party SAML solution providers with AWS](#) for links to the web documentation for many of the supported SAML providers.

You also configure the information that you want the IdP to pass as SAML attributes to AWS as part of the authentication response. Most of this information appears in AWS as condition context keys that you can evaluate in your policies. These condition keys ensure that only authorized users in the right contexts are granted permissions to access your AWS resources. You can specify time windows that restrict when the console may be used. You can also specify the maximum time (up to 12 hours) that users can access the console before having to refresh their credentials. For details, see [Configuring SAML assertions for the authentication response](#).

Enabling custom identity broker access to the AWS console

You can write and run code to create a URL that lets users who sign in to your organization's network securely access the AWS Management Console. The URL includes a sign-in token that you get from AWS and that authenticates the user to AWS. The resulting console session might include a distinct `AccessKeyId` due to federation. To trace the access key usage for federation sign-in through related CloudTrail events, see [Logging IAM and AWS STS API calls with AWS CloudTrail](#) and [AWS Management Console sign-in events](#).

Note

If your organization uses an identity provider (IdP) that is compatible with SAML, you can set up access to the console without writing code. This works with providers like Microsoft's Active Directory Federation Services or open-source Shibboleth. For details, see [Enabling SAML 2.0 federated users to access the AWS Management Console](#).

To enable your organization's users to access the AWS Management Console, you can create a custom *identity broker* that performs the following steps:

1. Verify that the user is authenticated by your local identity system.
2. Call the AWS Security Token Service (AWS STS) [AssumeRole](#) (recommended) or [GetFederationToken](#) API operations to obtain temporary security credentials for the user. To learn about the different methods that you can use to assume a role, see [Using IAM roles](#). To

learn how to pass optional session tags when you obtain your security credentials, see [Passing session tags in AWS STS](#).

- If you use one of the AssumeRole* API operations to get the temporary security credentials for a role, you can include the DurationSeconds parameter in your call. This parameter specifies the duration of your role session, from 900 seconds (15 minutes) up to the maximum session duration setting for the role. When you use DurationSeconds in an AssumeRole* operation, you must call it as an IAM user with long-term credentials. Otherwise, the call to the federation endpoint in step 3 fails. To learn how to view or change the maximum value for a role, see [View the maximum session duration setting for a role](#).
 - If you use the GetFederationToken API operation to get the credentials, you can include the DurationSeconds parameter in your call. This parameter specifies the duration of your role session. The value can range from 900 seconds (15 minutes) to 129,600 seconds (36 hours). You can make this API call only by using the long-term AWS security credentials of an IAM user. You can also make these calls using AWS account root user credentials, but we do not recommend it. If you make this call as the root user, the default session lasts for one hour. Or you can specify a session from 900 seconds (15 minutes) up to 3,600 seconds (one hour).
3. Call the AWS federation endpoint and supply the temporary security credentials to request a sign-in token.
 4. Construct a URL for the console that includes the token:
 - If you use one of the AssumeRole* API operations in your URL, you can include the SessionDuration HTTP parameter. This parameter specifies the duration of the console session, from 900 seconds (15 minutes) to 43200 seconds (12 hours).
 - If you use the GetFederationToken API operation in your URL, you can include the DurationSeconds parameter. This parameter specifies the duration of the federated console session. The value can range from 900 seconds (15 minutes) to 129,600 seconds (36 hours).

Note

- Do not use the SessionDuration HTTP parameter if you got the temporary credentials with GetFederationToken. Doing so will cause the operation to fail.
- Using the credentials for one role to assume a different role is called [role chaining](#). When you use role chaining, your new credentials are limited to a maximum duration of one hour. When you use roles to [grant permissions to applications that run on EC2 instances](#), those applications are not subject to this limitation.

5. Give the URL to the user or invoke the URL on the user's behalf.

The URL that the federation endpoint provides is valid for 15 minutes after it is created. This differs from the duration (in seconds) of the temporary security credential session that is associated with the URL. Those credentials are valid for the duration you specified when you created them, starting from the time they were created.

Important

The URL grants access to your AWS resources through the AWS Management Console if you have enabled permissions in the associated temporary security credentials. For this reason, you should treat the URL as a secret. We recommend returning the URL through a secure redirect, for example, by using a 302 HTTP response status code over an SSL connection. For more information about the 302 HTTP response status code, go to [RFC 2616, section 10.3.3](#).

To complete these tasks, you can use the [HTTPS Query API for AWS Identity and Access Management \(IAM\)](#) and the [AWS Security Token Service \(AWS STS\)](#). Or, you can use programming languages, such as Java, Ruby, or C#, along with the appropriate [AWS SDK](#). Each of these methods is described in the following topics.

Topics

- [Example code using IAM query API operations](#)
- [Example code using Python](#)
- [Example code using Java](#)
- [Example showing how to construct the URL \(Ruby\)](#)

Example code using IAM query API operations

You can construct a URL that gives your federated users direct access to the AWS Management Console. This task uses the IAM and AWS STS HTTPS Query API. For more information about making query requests, see [Making Query Requests](#).

Note

The following procedure contains examples of text strings. To enhance readability, line breaks have been added to some of the longer examples. When you create these strings for your own use, you should omit any line breaks.

To give a federated user access to your resources from the AWS Management Console

1. Authenticate the user in your identity and authorization system.
2. Obtain temporary security credentials for the user. The temporary credentials consist of an access key ID, a secret access key, and a session token. For more information about creating temporary credentials, see [Temporary security credentials in IAM](#).

To get temporary credentials, you call either the AWS STS [AssumeRole](#) API (recommended) or the [GetFederationToken](#) API. For more information about the differences between these API operations, see [Understanding the API Options for Securely Delegating Access to Your AWS Account](#) in the AWS Security Blog.

Important

When you use the [GetFederationToken](#) API to create temporary security credentials, you must specify the permissions that the credentials grant to the user who assumes the role. For any of the API operations that begin with `AssumeRole*`, you use an IAM role to assign permissions. For the other API operations, the mechanism varies with the API. For more details, see [Controlling permissions for temporary security credentials](#). Additionally, if you use the `AssumeRole*` API operations, you must call them as an IAM user with long-term credentials. Otherwise, the call to the federation endpoint in step 3 fails.

3. After you obtain the temporary security credentials, build them into a JSON session string to exchange them for a sign-in token. The following example shows how to encode the credentials. You replace the placeholder text with the appropriate values from the credentials that you receive in the previous step.

```
{"sessionId": "*** temporary access key ID ***",  
"sessionKey": "*** temporary secret access key ***",  
"sessionToken": "*** session token ***"}
```

4. [URL encode](#) the session string from the previous step. Because the information that you are encoding is sensitive, we recommend that you avoid using a web service for this encoding. Instead, use a locally installed function or feature in your development toolkit to securely encode this information. You can use the `urllib.quote_plus` function in Python, the `URLEncoder.encode` function in Java, or the `CGI.escape` function in Ruby. See the examples later in this topic.

5.

 **Note**

AWS supports POST requests here.

Send your request to the AWS federation endpoint:

```
https://region-code.signin.aws.amazon.com/federation
```

For a list of possible *region-code* values, see the **Region** column in [AWS Sign-In endpoints](#). You can optionally use the default AWS Sign-In federation endpoint:

```
https://signin.aws.amazon.com/federation
```

The request must include the `Action` and `Session` parameters, and (optionally) if you used an [AssumeRole*](#) API operation, a `SessionDuration` HTTP parameter as shown in the following example.

```
Action = getSigninToken  
SessionDuration = time in seconds  
Session = *** the URL encoded JSON string created in steps 3 & 4 ***
```

 **Note**

The following instructions in this step only work using GET requests.

The `SessionDuration` HTTP parameter specifies the duration of the console session. This is separate from the duration of the temporary credentials that you specify using the `DurationSeconds` parameter. You can specify a `SessionDuration` maximum value of 43,200 (12 hours). If the `SessionDuration` parameter is missing, then the session defaults to the duration of the credentials that you retrieved from AWS STS in step 2 (which defaults

to one hour). See the [documentation for the AssumeRole API](#) for details about how to specify a duration using the `DurationSeconds` parameter. The ability to create a console session that is longer than one hour is intrinsic to the `getSignInToken` operation of the federation endpoint.

Note

- Do not use the `SessionDuration` HTTP parameter if you got the temporary credentials with `GetFederationToken`. Doing so will cause the operation to fail.
- Using the credentials for one role to assume a different role is called [role chaining](#). When you use role chaining, your new credentials are limited to a maximum duration of one hour. When you use roles to [grant permissions to applications that run on EC2 instances](#), those applications are not subject to this limitation.

When you enable console sessions with an extended duration, you increase the risk of credential exposure. To help you mitigate this risk, you can immediately disable the active console sessions for any role by choosing **Revoke Sessions** on the **Role Summary** IAM console page. For more information, see [Revoking IAM role temporary security credentials](#).

The following is an example of what your request might look like. The lines are wrapped here for readability, but you should submit it as a one-line string.

```
https://signin.aws.amazon.com/federation
?Action=getSignInToken
&SessionDuration=1800
&Session=%7B%22sessionId%22%3A+%22ASIAJUMHIZPTOKTBMK5A%22%2C+%22sessionKey%22
%3A+%22LSD7LWI%2FL%2FN%2BgYpan5QFz0XUpc8s7HYjRsgcsrsm%22%2C+%22sessionToken%2
2%3A+%22FQoDYxdzEBQaDLbj3VWv2u50NN%2F3yyLSASwYtWhPnGPMNmzZFFZsL0Qd3vtYHw5A5dW
Aj0srkdPkghomIe3mJip5%2F0djDBbo7Sm0%2FENDEiCdpsQKodTpleKA8xQq0CwFg6a69xdEBQT8
FipATnLbKoyS4b%2FebhnsTUjZZQWp0wXXqFF7gSm%2FMe2tXe0jzsdP0012obez9lijPSdF1k2b5
PfGhiuyAR9aD5%2BubM0pY86fKex1qsytjvyTbZ9nXe6DvxVDCnCOh0GETJ7XfkSFdH0v%2FYR25C
UAhJ3nXIkIbG7Ucv9c0EpCf%2Fg23ijRgILIBQ%3D%3D%22%7D
```

The response from the federation endpoint is a JSON document with a `SignInToken` value. It will look similar to the following example.

```
{"SignInToken": "*** the SignInToken string ***"}
```

6.

Note

AWS supports POST requests here.

Finally, create the URL that your federated users can use to access the AWS Management Console. The URL is the same federation URL endpoint that you used in [Step 5](#), plus the following parameters:

```
?Action = login
&Issuer = *** the form-urlencoded URL for your internal sign-in page ***
&Destination = *** the form-urlencoded URL to the desired AWS console page ***
&SigninToken = *** the value of SigninToken received in the previous step ***
```

Note

The following instructions in this step only work using GET API.

The following example shows what the final URL might look like. The URL is valid for 15 minutes from the time it is created. The temporary security credentials and console session embedded within the URL are valid for the duration you specify in the `SessionDuration` HTTP parameter when you initially request them.

```
https://signin.aws.amazon.com/federation
?Action=login
&Issuer=https%3A%2F%2Fexample.com
&Destination=https%3A%2F%2Fconsole.aws.amazon.com%2F

```

Example code using Python

The following examples show how to use Python to programmatically construct a URL that gives federated users direct access to the AWS Management Console. There are two examples:

- Federate via GET requests to AWS
- Federate via POST requests to AWS

Both examples use the the [AWS SDK for Python \(Boto3\)](#) and [AssumeRole](#) API to obtain temporary security credentials.

Use GET Requests

```
import urllib, json, sys
import requests # 'pip install requests'
import boto3 # AWS SDK for Python (Boto3) 'pip install boto3'

# Step 1: Authenticate user in your own identity system.

# Step 2: Using the access keys for an IAM user in your AWS account,
# call "AssumeRole" to get temporary access keys for the federated user

# Note: Calls to AWS STS AssumeRole must be signed using the access key ID
# and secret access key of an IAM user or using existing temporary credentials.
# The credentials can be in Amazon EC2 instance metadata, in environment variables,
# or in a configuration file, and will be discovered automatically by the
# client('sts') function. For more information, see the Python SDK docs:
# http://boto3.readthedocs.io/en/latest/reference/services/sts.html
# http://boto3.readthedocs.io/en/latest/reference/services/
sts.html#STS.Client.assume_role
sts_connection = boto3.client('sts')

assumed_role_object = sts_connection.assume_role(
    RoleArn="arn:aws:iam::account-id:role/ROLE-NAME",
    RoleSessionName="AssumeRoleSession",
)

# Step 3: Format resulting temporary credentials into JSON
url_credentials = {}
url_credentials['sessionId'] =
    assumed_role_object.get('Credentials').get('AccessKeyId')
```

```
url_credentials['sessionKey'] =
    assumed_role_object.get('Credentials').get('SecretAccessKey')
url_credentials['sessionToken'] =
    assumed_role_object.get('Credentials').get('SessionToken')
json_string_with_temp_credentials = json.dumps(url_credentials)

# Step 4. Make request to AWS federation endpoint to get sign-in token. Construct the
# parameter string with
# the sign-in action request, a 12-hour session duration, and the JSON document with
# temporary credentials
# as parameters.
request_parameters = "?Action=getSigninToken"
request_parameters += "&SessionDuration=43200"
if sys.version_info[0] < 3:
    def quote_plus_function(s):
        return urllib.quote_plus(s)
else:
    def quote_plus_function(s):
        return urllib.parse.quote_plus(s)
request_parameters += "&Session=" +
    quote_plus_function(json_string_with_temp_credentials)
request_url = "https://signin.aws.amazon.com/federation" + request_parameters
r = requests.get(request_url)
# Returns a JSON document with a single element named SigninToken.
signin_token = json.loads(r.text)

# Step 5: Create URL where users can use the sign-in token to sign in to
# the console. This URL must be used within 15 minutes after the
# sign-in token was issued.
request_parameters = "?Action=login"
request_parameters += "&Issuer=Example.org"
request_parameters += "&Destination=" + quote_plus_function("https://
console.aws.amazon.com/")
request_parameters += "&SigninToken=" + signin_token["SigninToken"]
request_url = "https://signin.aws.amazon.com/federation" + request_parameters

# Send final URL to stdout
print (request_url)
```

Use POST Requests

```
import urllib, json, sys
import requests # 'pip install requests'
```

```
import boto3 # AWS SDK for Python (Boto3) 'pip install boto3'
import os
from selenium import webdriver # 'pip install selenium', 'brew install chromedriver'

# Step 1: Authenticate user in your own identity system.

# Step 2: Using the access keys for an IAM user in your AAWS account,
# call "AssumeRole" to get temporary access keys for the federated user

# Note: Calls to AWS STS AssumeRole must be signed using the access key ID
# and secret access key of an IAM user or using existing temporary credentials.
# The credentials can be in Amazon EC2 instance metadata, in environment variables,

# or in a configuration file, and will be discovered automatically by the
# client('sts') function. For more information, see the Python SDK docs:
# http://boto3.readthedocs.io/en/latest/reference/services/sts.html
# http://boto3.readthedocs.io/en/latest/reference/services/
sts.html#STS.Client.assume_role
if sys.version_info[0] < 3:
    def quote_plus_function(s):
        return urllib.quote_plus(s)
else:
    def quote_plus_function(s):
        return urllib.parse.quote_plus(s)

sts_connection = boto3.client('sts')

assumed_role_object = sts_connection.assume_role(
    RoleArn="arn:aws:iam::account-id:role/ROLE-NAME",
    RoleSessionName="AssumeRoleDemoSession",
)

# Step 3: Format resulting temporary credentials into JSON
url_credentials = {}
url_credentials['sessionId'] =
    assumed_role_object.get('Credentials').get('AccessKeyId')
url_credentials['sessionKey'] =
    assumed_role_object.get('Credentials').get('SecretAccessKey')
url_credentials['sessionToken'] =
    assumed_role_object.get('Credentials').get('SessionToken')
json_string_with_temp_credentials = json.dumps(url_credentials)

# Step 4. Make request to AWS federation endpoint to get sign-in token. Construct the
parameter string with
```

```
# the sign-in action request, a 12-hour session duration, and the JSON document with
temporary credentials
# as parameters.
request_parameters = {}
request_parameters['Action'] = 'getSignInToken'
request_parameters['SessionDuration'] = '43200'
request_parameters['Session'] = json_string_with_temp_credentials

request_url = "https://signin.aws.amazon.com/federation"
r = requests.post( request_url, data=request_parameters)

# Returns a JSON document with a single element named SignInToken.
signin_token = json.loads(r.text)

# Step 5: Create a POST request where users can use the sign-in token to sign in to
# the console. The POST request must be made within 15 minutes after the
# sign-in token was issued.
request_parameters = {}
request_parameters['Action'] = 'login'
request_parameters['Issuer']='Example.org'
request_parameters['Destination'] = 'https://console.aws.amazon.com/'
request_parameters['SignInToken'] =signin_token['SignInToken']

jsrequest = '''
var form = document.createElement('form');
form.method = 'POST';
form.action = '{request_url}';
request_parameters = {request_parameters}
for (var param in request_parameters) {{
    if (request_parameters.hasOwnProperty(param)) {{
        const hiddenField = document.createElement('input');
        hiddenField.type = 'hidden';
        hiddenField.name = param;
        hiddenField.value = request_parameters[param];
        form.appendChild(hiddenField);
    }}
}}
document.body.appendChild(form);
form.submit();
'''.format(request_url=request_url, request_parameters=request_parameters)

driver = webdriver.Chrome()
driver.execute_script(jsrequest);
```

Example code using Java

The following example shows how to use Java to programmatically construct a URL that gives federated users direct access to the AWS Management Console. The following code snippet uses the [AWS SDK for Java](#).

```
import java.net.URLEncoder;
import java.net.URL;
import java.net.URLConnection;
import java.io.BufferedReader;
import java.io.InputStreamReader;
// Available at http://www.json.org/java/index.html
import org.json.JSONObject;
import com.amazonaws.auth.AWSCredentials;
import com.amazonaws.auth.BasicAWSCredentials;
import com.amazonaws.services.securitytoken.AWSSecurityTokenServiceClient;
import com.amazonaws.services.securitytoken.model.Credentials;
import com.amazonaws.services.securitytoken.model.GetFederationTokenRequest;
import com.amazonaws.services.securitytoken.model.GetFederationTokenResult;

/* Calls to AWS STS API operations must be signed using the access key ID
   and secret access key of an IAM user or using existing temporary
   credentials. The credentials should not be embedded in code. For
   this example, the code looks for the credentials in a
   standard configuration file.
*/
AWSCredentials credentials =
    new PropertiesCredentials(
        AwsConsoleApp.class.getResourceAsStream("AwsCredentials.properties"));

AWSSecurityTokenServiceClient stsClient =
    new AWSSecurityTokenServiceClient(credentials);

GetFederationTokenRequest getFederationTokenRequest =
    new GetFederationTokenRequest();
getFederationTokenRequest.setDurationSeconds(1800);
getFederationTokenRequest.setName("UserName");

// A sample policy for accessing Amazon Simple Notification Service (Amazon SNS) in the
// console.

String policy = "{\"Version\":\"2012-10-17\",\"Statement\":[\"Action\":\"sns:*\", \" +
```

```
"\"Effect\": \"Allow\", \"Resource\": \"*\"]}]";

getFederationTokenRequest.setPolicy(policy);

GetFederationTokenResult federationTokenResult =
    stsClient.getFederationToken(getFederationTokenRequest);

Credentials federatedCredentials = federationTokenResult.getCredentials();

// The issuer parameter specifies your internal sign-in
// page, for example https://mysignin.internal.mycompany.com/.
// The console parameter specifies the URL to the destination console of the
// AWS Management Console. This example goes to Amazon SNS.
// The signin parameter is the URL to send the request to.

String issuerURL = "https://mysignin.internal.mycompany.com/";
String consoleURL = "https://console.aws.amazon.com/sns";
String signInURL = "https://signin.aws.amazon.com/federation";

// Create the sign-in token using temporary credentials,
// including the access key ID, secret access key, and session token.
String sessionJson = String.format(
    "{ \"%1$s\": \"%2$s\", \"%3$s\": \"%4$s\", \"%5$s\": \"%6$s\" }",
    "sessionId", federatedCredentials.getAccessKeyId(),
    "sessionKey", federatedCredentials.getSecretAccessKey(),
    "sessionToken", federatedCredentials.getSessionToken());

// Construct the sign-in request with the request sign-in token action, a
// 12-hour console session duration, and the JSON document with temporary
// credentials as parameters.

String getSigninTokenURL = signInURL +
    "?Action=getSigninToken" +
    "&DurationSeconds=43200" +
    "&SessionType=json&Session=" +
    URLEncoder.encode(sessionJson, "UTF-8");

URL url = new URL(getSigninTokenURL);

// Send the request to the AWS federation endpoint to get the sign-in token
URLConnection conn = url.openConnection ();

BufferedReader bufferReader = new BufferedReader(new
    InputStreamReader(conn.getInputStream()));
```

```
String returnContent = bufferedReader.readLine();

String signinToken = new JSONObject(returnContent).getString("SigninToken");

String signinTokenParameter = "&SigninToken=" + URLEncoder.encode(signinToken, "UTF-8");

// The issuer parameter is optional, but recommended. Use it to direct users
// to your sign-in page when their session expires.

String issuerParameter = "&Issuer=" + URLEncoder.encode(issuerURL, "UTF-8");

// Finally, present the completed URL for the AWS console session to the user

String destinationParameter = "&Destination=" + URLEncoder.encode(consoleURL, "UTF-8");
String loginURL = signInURL + "?Action=login" +
                signinTokenParameter + issuerParameter + destinationParameter;
```

Example showing how to construct the URL (Ruby)

The following example shows how to use Ruby to programmatically construct a URL that gives federated users direct access to the AWS Management Console. This code snippet uses the [AWS SDK for Ruby](#).

```
require 'rubygems'
require 'json'
require 'open-uri'
require 'cgi'
require 'aws-sdk'

# Create a new STS instance
#
# Note: Calls to AWS STS API operations must be signed using an access key ID
# and secret access key. The credentials can be in EC2 instance metadata
# or in environment variables and will be automatically discovered by
# the default credentials provider in the AWS Ruby SDK.
sts = Aws::STS::Client.new()

# The following call creates a temporary session that returns
# temporary security credentials and a session token.
# The policy grants permissions to work
# in the AWS SNS console.

session = sts.get_federation_token({
```

```
duration_seconds: 1800,
name: "UserName",
policy: "{\"Version\":\"2012-10-17\",\"Statement\":[{\"Effect\":\"Allow\",\"Action\":[\"sns:*\",\"Resource\":\"*\"]}]}",
})

# The issuer value is the URL where users are directed (such as
# to your internal sign-in page) when their session expires.
#
# The console value specifies the URL to the destination console.
# This example goes to the Amazon SNS console.
#
# The sign-in value is the URL of the AWS STS federation endpoint.
issuer_url = "https://mysignin.internal.mycompany.com/"
console_url = "https://console.aws.amazon.com/sns"
signin_url = "https://signin.aws.amazon.com/federation"

# Create a block of JSON that contains the temporary credentials
# (including the access key ID, secret access key, and session token).
session_json = {
  :sessionId => session.credentials[:access_key_id],
  :sessionKey => session.credentials[:secret_access_key],
  :sessionToken => session.credentials[:session_token]
}.to_json

# Call the federation endpoint, passing the parameters
# created earlier and the session information as a JSON block.
# The request returns a sign-in token that's valid for 15 minutes.
# Signing in to the console with the token creates a session
# that is valid for 12 hours.
get_signin_token_url = signin_url +
  "?Action=getSignInToken" +
  "&SessionType=json&Session=" +
  CGI.escape(session_json)

returned_content = URI.parse(get_signin_token_url).read

# Extract the sign-in token from the information returned
# by the federation endpoint.
signin_token = JSON.parse(returned_content)['SignInToken']
signin_token_param = "&SignInToken=" + CGI.escape(signin_token)

# Create the URL to give to the user, which includes the
# sign-in token and the URL of the console to open.
```

```
# The "issuer" parameter is optional but recommended.
issuer_param = "&Issuer=" + CGI.escape(issuer_url)
destination_param = "&Destination=" + CGI.escape(console_url)
login_url = signin_url + "?Action=login" + signin_token_param +
  issuer_param + destination_param
```

Using service-linked roles

A service-linked role is a unique type of IAM role that is linked directly to an AWS service. Service-linked roles are predefined by the service and include all the permissions that the service requires to call other AWS services on your behalf. The linked service also defines how you create, modify, and delete a service-linked role. A service might automatically create or delete the role. It might allow you to create, modify, or delete the role as part of a wizard or process in the service. Or it might require that you use IAM to create or delete the role. Regardless of the method, service-linked roles simplify the process of setting up a service because you don't have to manually add permissions for the service to complete actions on your behalf.

Note

Remember that service roles are different from service-linked roles. A service role is an [IAM role](#) that a service assumes to perform actions on your behalf. An IAM administrator can create, modify, and delete a service role from within IAM. For more information, see [Creating a role to delegate permissions to an AWS service](#) in the *IAM User Guide*. A service-linked role is a type of service role that is linked to an AWS service. The service can assume the role to perform an action on your behalf. Service-linked roles appear in your AWS account and are owned by the service. An IAM administrator can view, but not edit the permissions for service-linked roles.

The linked service defines the permissions of its service-linked roles, and unless defined otherwise, only that service can assume the roles. The defined permissions include the trust policy and the permissions policy, and that permissions policy cannot be attached to any other IAM entity.

Before you can delete the roles, you must first delete their related resources. This protects your resources because you can't inadvertently remove permission to access the resources.

Tip

For information about which services support using service-linked roles, see [AWS services that work with IAM](#) and look for the services that have **Yes** in the **Service-Linked Role** column. Choose a **Yes** with a link to view the service-linked role documentation for that service.

Service-linked role permissions

You must configure permissions for an IAM entity (user or role) to allow the user or role to create or edit the service-linked role.

Note

The ARN for a service-linked role includes a service principal, which is indicated in the policies below as *SERVICE-NAME*.amazonaws.com. Do not try to guess the service principal, because it is case sensitive and the format can vary across AWS services. To view the service principal for a service, see its service-linked role documentation.

To allow an IAM entity to create a specific service-linked role

Add the following policy to the IAM entity that needs to create the service-linked role.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": "iam:CreateServiceLinkedRole",
      "Resource": "arn:aws:iam::*:role/aws-service-role/SERVICE-NAME.amazonaws.com/SERVICE-LINKED-ROLE-NAME-PREFIX*",
      "Condition": {"StringLike": {"iam:AWSServiceName": "SERVICE-NAME.amazonaws.com"}}
    },
    {
      "Effect": "Allow",
      "Action": [
        "iam:AttachRolePolicy",
```

```
        "iam:PutRolePolicy"
    ],
    "Resource": "arn:aws:iam::*:role/aws-service-role/SERVICE-
NAME.amazonaws.com/SERVICE-LINKED-ROLE-NAME-PREFIX*"
}
]
```

To allow an IAM entity to create any service-linked role

Add the following statement to the permissions policy for the IAM entity that needs to create a service-linked role, or any service role that includes the needed policies. This policy statement does not allow the IAM entity to attach a policy to the role.

```
{
  "Effect": "Allow",
  "Action": "iam:CreateServiceLinkedRole",
  "Resource": "arn:aws:iam::*:role/aws-service-role/*"
}
```

To allow an IAM entity to edit the description of any service roles

Add the following statement to the permissions policy for the IAM entity that needs to edit the description of a service-linked role, or any service role.

```
{
  "Effect": "Allow",
  "Action": "iam:UpdateRoleDescription",
  "Resource": "arn:aws:iam::*:role/aws-service-role/*"
}
```

To allow an IAM entity to delete a specific service-linked role

Add the following statement to the permissions policy for the IAM entity that needs to delete the service-linked role.

```
{
  "Effect": "Allow",
  "Action": [
    "iam:DeleteServiceLinkedRole",
```

```

    "iam:GetServiceLinkedRoleDeletionStatus"
  ],
  "Resource": "arn:aws:iam::*:role/aws-service-role/SERVICE-NAME.amazonaws.com/SERVICE-LINKED-ROLE-NAME-PREFIX*"
}

```

To allow an IAM entity to delete any service-linked role

Add the following statement to the permissions policy for the IAM entity that needs to delete a service-linked role, but not service role.

```

{
  "Effect": "Allow",
  "Action": [
    "iam:DeleteServiceLinkedRole",
    "iam:GetServiceLinkedRoleDeletionStatus"
  ],
  "Resource": "arn:aws:iam::*:role/aws-service-role/*"
}

```

To allow an IAM entity to pass an existing role to the service

Some AWS services allow you to pass an existing role to the service, instead of creating a new service-linked role. To do this, a user must have permissions to *pass the role* to the service. Add the following statement to the permissions policy for the IAM entity that needs to pass a role. This policy statement also allows the entity to view a list of roles from which they can choose the role to pass. For more information, see [Granting a user permissions to pass a role to an AWS service](#).

```

{
  "Sid": "PolicyStatementToAllowUserToListRoles",
  "Effect": "Allow",
  "Action": ["iam:ListRoles"],
  "Resource": "*"
},
{
  "Sid": "PolicyStatementToAllowUserToPassOneSpecificRole",
  "Effect": "Allow",
  "Action": [ "iam:PassRole" ],
  "Resource": "arn:aws:iam::account-id:role/my-role-for-XYZ"
}

```

Indirect permissions with service-linked roles

The permissions granted by a service-linked role can be indirectly transferred to other users and roles. When a service-linked role is used by an AWS service, that service-linked role can use its own permissions to call other AWS services. This means that users and roles with permissions to call a service that uses a service-linked role may have indirect access to services that can be accessed by that service-linked role.

For example, when you create an Amazon RDS DB instance, [a service-linked role for RDS](#) is automatically created if one does not already exist. This service-linked role allows RDS to call Amazon EC2, Amazon SNS, Amazon CloudWatch Logs, and Amazon Kinesis on your behalf. If you allow users and roles in your account to modify or create RDS databases, then they may be able to indirectly interact with Amazon EC2, Amazon SNS, Amazon CloudWatch Logs logs, and Amazon Kinesis resources by calling RDS, as RDS would use its service-linked role to access those resources.

Creating a service-linked role

The method that you use to create a service-linked role depends on the service. In some cases, you don't need to manually create a service-linked role. For example, when you complete a specific action (such as creating a resource) in the service, the service might create the service-linked role for you. Or if you were using a service before it began supporting service-linked roles, then the service might have automatically created the role in your account. To learn more, see [A new role appeared in my AWS account](#).

In other cases, the service might support creating a service-linked role manually using the service console, API, or CLI. For information about which services support using service-linked roles, see [AWS services that work with IAM](#) and look for the services that have **Yes** in the **Service-Linked Role** column. To learn whether the service supports creating the service-linked role, choose the **Yes** link to view the service-linked role documentation for that service.

If the service does not support creating the role, then you can use IAM to create the service-linked role.

Important

Service-linked roles count toward your [IAM roles in an AWS account](#) limit, but if you have reached your limit, you can still create service-linked roles in your account. Only service-linked roles can exceed the limit.

Creating a service-linked role (console)

Before you create a service-linked role in IAM, find out whether the linked service automatically creates service-linked roles. In addition, learn whether you can create the role from the service's console, API, or CLI.

To create a service-linked role (console)

1. Sign in to the AWS Management Console and open the IAM console at <https://console.aws.amazon.com/iam/>.
2. In the navigation pane of the IAM console, choose **Roles**. Then, choose **Create role**.
3. Choose the **AWS Service** role type.
4. Choose the use case for your service. Use cases are defined by the service to include the trust policy required by the service. Then, choose **Next**.
5. Choose one or more permissions policies to attach to the role. Depending on the use case that you selected, the service might do any of the following:
 - Define the permissions used by the role.
 - Allow you to choose from a limited set of permissions.
 - Allow you to choose from any permissions.
 - Allow you to select no policies at this time, create the policies later, and then attach them to the role.

Select the check box next to the policy that assigns the permissions that you want the role to have, and then choose **Next**.

Note

The permissions that you specify are available to any entity that uses the role. By default, a role has no permissions.

6. For **Role name**, the degree of role name customization is defined by the service. If the service defines the role's name, then this option is not editable. In other cases, the service might define a prefix for the role and let you enter an optional suffix.

If possible, enter a role name suffix to add to the default name. This suffix helps you identify the purpose of this role. Role names must be unique within your AWS account. They are

not distinguished by case. For example, you cannot create roles named both `<service-linked-role-name>_SAMPLE` and `<service-linked-role-name>_sample`. Because various entities might reference the role, you cannot edit the name of the role after it has been created.

7. (Optional) For **Description**, edit the description for the new service-linked role.
8. You cannot attach tags to service-linked roles during creation. For more information about using tags in IAM, see [Tagging IAM resources](#).
9. Review the role and then choose **Create role**.

Creating a service-linked role (AWS CLI)

Before creating a service-linked role in IAM, find out whether the linked service automatically creates service-linked roles and whether you can create the role from the service's CLI. If the service CLI is not supported, you can use IAM commands to create a service-linked role with the trust policy and inline policies that the service needs to assume the role.

To create a service-linked role (AWS CLI)

Run the following command:

```
aws iam create-service-linked-role --aws-service-name SERVICE-NAME.amazonaws.com
```

Creating a service-linked role (AWS API)

Before creating a service-linked role in IAM, find out whether the linked service automatically creates service-linked roles and whether you can create the role from the service's API. If the service API is not supported, you can use the AWS API to create a service-linked role with the trust policy and inline policies that the service needs to assume the role.

To create a service-linked role (AWS API)

Use the [CreateServiceLinkedRole](#) API call. In the request, specify a service name of `SERVICE_NAME_URL.amazonaws.com`.

For example, to create the **Lex Bots** service-linked role, use `lex.amazonaws.com`.

Editing a service-linked role

The method that you use to edit a service-linked role depends on the service. Some services might allow you to edit the permissions for a service-linked role from the service console, API, or CLI.

However, after you create a service-linked role, you cannot change the name of the role because various entities might reference the role. You can edit the description of any role from the IAM console, API, or CLI.

For information about which services support using service-linked roles, see [AWS services that work with IAM](#) and look for the services that have **Yes** in the **Service-Linked Role** column. To learn whether the service supports editing the service-linked role, choose the **Yes** link to view the service-linked role documentation for that service.

Editing a service-linked role description (console)

You can use the IAM console to edit the description of a service-linked role.

To edit the description of a service-linked role (console)

1. In the navigation pane of the IAM console, choose **Roles**.
2. Choose the name of the role to modify.
3. To the far right of **Role description**, choose **Edit**.
4. Enter a new description in the box and choose **Save**.

Editing a service-linked role description (AWS CLI)

You can use IAM commands from the AWS CLI to edit the description of a service-linked role.

To change the description of a service-linked role (AWS CLI)

1. (Optional) To view the current description for a role, run the following commands:

```
aws iam get-role --role-name ROLE-NAME
```

Use the role name, not the ARN, to refer to roles with the CLI commands. For example, if a role has the following ARN: `arn:aws:iam::123456789012:role/myrole`, you refer to the role as **myrole**.

2. To update a service-linked role's description, run the following command:

```
aws iam update-role --role-name ROLE-NAME --description OPTIONAL-DESCRIPTION
```

Editing a service-linked role description (AWS API)

You can use the AWS API to edit the description of a service-linked role.

To change the description of a service-linked role (AWS API)

1. (Optional) To view the current description for a role, call the following operation, and specify the name of the role:

AWS API: [GetRole](#)

2. To update a role's description, call the following operation, and specify the name (and optional description) of the role:

AWS API: [UpdateRole](#)

Deleting a service-linked role

The method that you use to create a service-linked role depends on the service. In some cases, you don't need to manually delete a service-linked role. For example, when you complete a specific action (such as removing a resource) in the service, the service might delete the service-linked role for you.

In other cases, the service might support deleting a service-linked role manually from the service console, API, or AWS CLI.

For information about which services support using service-linked roles, see [AWS services that work with IAM](#) and look for the services that have **Yes** in the **Service-Linked Role** column. To learn whether the service supports deleting the service-linked role, choose the **Yes** link to view the service-linked role documentation for that service.

If the service does not support deleting the role, then you can delete the service-linked role from the IAM console, API, or AWS CLI. If you no longer need to use a feature or service that requires a service-linked role, we recommend that you delete that role. That way you don't have an unused entity that is not actively monitored or maintained. However, you must clean up your service-linked role before you can delete it.

Cleaning up a service-linked role

Before you can use IAM to delete a service-linked role, you must first confirm that the role has no active sessions and remove any resources used by the role.

To check whether the service-linked role has an active session in the IAM console

1. Sign in to the AWS Management Console and open the IAM console at <https://console.aws.amazon.com/iam/>.
2. In the navigation pane of the IAM console, choose **Roles**. Then choose the name (not the check box) of the service-linked role.
3. On the **Summary** page for the selected role, choose the **Access Advisor** tab.
4. On the **Access Advisor** tab, review recent activity for the service-linked role.

Note

If you are unsure whether the service is using the service-linked role, you can try to delete the role. If the service is using the role, then the deletion fails and you can view the regions where the role is being used. If the role is being used, then you must wait for the session to end before you can delete the role. You cannot revoke the session for a service-linked role.

To remove resources used by a service-linked role

For information about which services support using service-linked roles, see [AWS services that work with IAM](#) and look for the services that have **Yes** in the **Service-Linked Role** column. To learn whether the service supports deleting the service-linked role, choose the **Yes** link to view the service-linked role documentation for that service. See the documentation for that service to learn how to remove resources used by your service-linked role.

Deleting a service-linked role (console)

You can use the IAM console to delete a service-linked role.

To delete a service-linked role (console)

1. Sign in to the AWS Management Console and open the IAM console at <https://console.aws.amazon.com/iam/>.
2. In the navigation pane of the IAM console, choose **Roles**. Then select the check box next to the role name that you want to delete, not the name or row itself.
3. For **Role actions** at the top of the page, choose **Delete**.

4. In the confirmation dialog box, review the last accessed information, which shows when each of the selected roles last accessed an AWS service. This helps you to confirm whether the role is currently active. If you want to proceed, choose **Yes, Delete** to submit the service-linked role for deletion.
5. Watch the IAM console notifications to monitor the progress of the service-linked role deletion. Because the IAM service-linked role deletion is asynchronous, after you submit the role for deletion, the deletion task can succeed or fail.
 - If the task succeeds, then the role is removed from the list and a notification of success appears at the top of the page.
 - If the task fails, you can choose **View details** or **View Resources** from the notifications to learn why the deletion failed. If the deletion fails because the role is using the service's resources, then the notification includes a list of resources, if the service returns that information. You can then [clean up the resources](#) and submit the deletion again.

Note

You might have to repeat this process several times, depending on the information that the service returns. For example, your service-linked role might use six resources and your service might return information about five of them. If you clean up the five resources and submit the role for deletion again, the deletion fails and the service reports the one remaining resource. A service might return all of the resources, a few of them, or it might not report any resources.

- If the task fails and the notification does not include a list of resources, then the service might not return that information. To learn how to clean up the resources for that service, see [AWS services that work with IAM](#). Find your service in the table, and choose the **Yes** link to view the service-linked role documentation for that service.

Deleting a service-linked role (AWS CLI)

You can use IAM commands from the AWS CLI to delete a service-linked role.

To delete a service-linked role (AWS CLI)

1. If you know the name of the service-linked role that you want to delete, enter the following command to list the role in your account:

```
aws iam get-role --role-name role-name
```

Use the role name, not the ARN, to refer to roles with the CLI commands. For example, if a role has the following ARN: `arn:aws:iam::123456789012:role/myrole`, you refer to the role as **myrole**.

2. Because a service-linked role cannot be deleted if it is being used or has associated resources, you must submit a deletion request. That request can be denied if these conditions are not met. You must capture the `deletion-task-id` from the response to check the status of the deletion task. Enter the following command to submit a service-linked role deletion request:

```
aws iam delete-service-linked-role --role-name role-name
```

3. Enter the following command to check the status of the deletion task:

```
aws iam get-service-linked-role-deletion-status --deletion-task-id deletion-task-id
```

The status of the deletion task can be `NOT_STARTED`, `IN_PROGRESS`, `SUCCEEDED`, or `FAILED`. If the deletion fails, the call returns the reason that it failed so that you can troubleshoot. If the deletion fails because the role is using the service's resources, then the notification includes a list of resources, if the service returns that information. You can then [clean up the resources](#) and submit the deletion again.

Note

You might have to repeat this process several times, depending on the information that the service returns. For example, your service-linked role might use six resources and your service might return information about five of them. If you clean up the five resources and submit the role for deletion again, the deletion fails and the service reports the one remaining resource. A service might return all of the resources, a few of them, or it might not report any resources. To learn how to clean up the resources for a service that does not report any resources, see [AWS services that work with IAM](#). Find your service in the table, and choose the **Yes** link to view the service-linked role documentation for that service.

Deleting a service-linked role (AWS API)

You can use the AWS API to delete a service-linked role.

To delete a service-linked role (AWS API)

1. To submit a deletion request for a service-linked role, call [DeleteServiceLinkedRole](#). In the request, specify a role name.

Because a service-linked role cannot be deleted if it is being used or has associated resources, you must submit a deletion request. That request can be denied if these conditions are not met. You must capture the `DeletionTaskId` from the response to check the status of the deletion task.

2. To check the status of the deletion, call [GetServiceLinkedRoleDeletionStatus](#). In the request, specify the `DeletionTaskId`.

The status of the deletion task can be `NOT_STARTED`, `IN_PROGRESS`, `SUCCEEDED`, or `FAILED`. If the deletion fails, the call returns the reason that it failed so that you can troubleshoot. If the deletion fails because the role is using the service's resources, then the notification includes a list of resources, if the service returns that information. You can then [clean up the resources](#) and submit the deletion again.

Note

You might have to repeat this process several times, depending on the information that the service returns. For example, your service-linked role might use six resources and your service might return information about five of them. If you clean up the five resources and submit the role for deletion again, the deletion fails and the service reports the one remaining resource. A service might return all of the resources, a few of them, or it might not report any resources. To learn how to clean up the resources for a service that does not report any resources, see [AWS services that work with IAM](#). Find your service in the table, and choose the **Yes** link to view the service-linked role documentation for that service.

Creating IAM roles

To create a role, you can use the AWS Management Console, the AWS CLI, the Tools for Windows PowerShell, or the IAM API.

If you use the AWS Management Console, a wizard guides you through the steps for creating a role. The wizard has slightly different steps depending on whether you're creating a role for an AWS service, for an AWS account, or for a federated user.

Topics

- [Creating a role to delegate permissions to an IAM user](#)
- [Creating a role to delegate permissions to an AWS service](#)
- [Creating a role for a third-party Identity Provider \(federation\)](#)
- [Creating a role using custom trust policies \(console\)](#)
- [Examples of policies for delegating access](#)

Creating a role to delegate permissions to an IAM user

You can use IAM roles to delegate access to your AWS resources. With IAM roles, you can establish trust relationships between your *trusting* account and other *AWS trusted* accounts. The trusting account owns the resource to be accessed and the trusted account contains the users who need access to the resource. However, it is possible for another account to own a resource in your account. For example, the trusting account might allow the trusted account to create new resources, such as creating new objects in an Amazon S3 bucket. In that case, the account that creates the resource owns the resource and controls who can access that resource.

After you create the trust relationship, an IAM user or an application from the trusted account can use the AWS Security Token Service (AWS STS) [AssumeRole](#) API operation. This operation provides temporary security credentials that enable access to AWS resources in your account.

The accounts can both be controlled by you, or the account with the users can be controlled by a third party. If the other account with the users is an AWS account that you do not control, then you can use the `externalId` attribute. The external ID can be any word or number that is agreed upon between you and the administrator of the third-party account. This option automatically adds a condition to the trust policy that allows the user to assume the role only if the request includes the correct `sts:ExternalID`. For more information, see [How to use an external ID when granting access to your AWS resources to a third party](#).

For information about how to use roles to delegate permissions, see [Roles terms and concepts](#). For information about using a service role to allow services to access resources in your account, see [Creating a role to delegate permissions to an AWS service](#).

Creating an IAM role (console)

You can use the AWS Management Console to create a role that an IAM user can assume. For example, assume that your organization has multiple AWS accounts to isolate a development environment from a production environment. For high-level information about creating a role that allows users in the development account to access resources in the production account, see [Example scenario using separate development and production accounts](#).

To create a role (console)

1. Sign in to the AWS Management Console and open the IAM console at <https://console.aws.amazon.com/iam/>.
2. In the navigation pane of the console, choose **Roles** and then choose **Create role**.
3. Choose **AWS account** role type.
4. To create a role for your account, choose **This account**. To create a role for another account, choose **Another AWS account** and enter the **Account ID** to which you want to grant access to your resources.

The administrator of the specified account can grant permission to assume this role to any IAM user in that account. To do this, the administrator attaches a policy to the user or a group that grants permission for the `sts:AssumeRole` action. That policy must specify the role's ARN as the Resource.

5. If you are granting permissions to users from an account that you do not control, and the users will assume this role programmatically, select **Require external ID**. The external ID can be any word or number that is agreed upon between you and the administrator of the third party account. This option automatically adds a condition to the trust policy that allows the user to assume the role only if the request includes the correct `sts:ExternalID`. For more information, see [How to use an external ID when granting access to your AWS resources to a third party](#).

Important

Choosing this option restricts access to the role only through the AWS CLI, Tools for Windows PowerShell, or the AWS API. This is because you cannot use the AWS console

to switch to a role that has an `externalId` condition in its trust policy. However, you can create this kind of access programmatically by writing a script or an application using the relevant SDK. For more information and a sample script, see [How to Enable Cross-Account Access to the AWS Management Console](#) in the AWS Security Blog.

6. If you want to restrict the role to users who sign in with multi-factor authentication (MFA), select **Require MFA**. This adds a condition to the role's trust policy that checks for an MFA sign-in. A user who wants to assume the role must sign in with a temporary one-time password from a configured MFA device. Users without MFA authentication cannot assume the role. For more information about MFA, see [Using multi-factor authentication \(MFA\) in AWS](#)
7. Choose **Next**.
8. IAM includes a list of the AWS managed and customer managed policies in your account. Select the policy to use for the permissions policy or choose **Create policy** to open a new browser tab and create a new policy from scratch. For more information, see [Creating IAM policies](#). After you create the policy, close that tab and return to your original tab. Select the check box next to the permissions policies that you want anyone who assumes the role to have. If you prefer, you can select no policies at this time, and then attach policies to the role later. By default, a role has no permissions.
9. (Optional) Set a [permissions boundary](#). This is an advanced feature.

Open the **Set permissions boundary** section and choose **Use a permissions boundary to control the maximum role permissions**. Select the policy to use for the permissions boundary.

10. Choose **Next**.
11. For **Role name**, enter a name for your role. Role names must be unique within your AWS account. When a role name is used in a policy or as part of an ARN, the role name is case sensitive. When a role name appears to customers in the console, such as during the sign-in process, the role name is case insensitive. Because various entities might reference the role, you can't edit the name of the role after it is created.
12. (Optional) For **Description**, enter a description for the new role.
13. Choose **Edit** in the **Step 1: Select trusted entities** or **Step 2: Add permissions** sections to edit the use cases and permissions for the role. You will be returned to previous pages to make the edits.
14. (Optional) Add metadata to the role by attaching tags as key–value pairs. For more information about using tags in IAM, see [Tagging IAM resources](#).
15. Review the role and then choose **Create role**.

⚠ Important

Remember that this is only the first half of the configuration required. You must also give individual users in the trusted account permissions to switch to the role in the console, or assume the role programmatically. For more information about this step, see [Granting a user permissions to switch roles](#).

Creating an IAM role (AWS CLI)

Creating a role from the AWS CLI involves multiple steps. When you use the console to create a role, many of the steps are done for you, but with the AWS CLI you must explicitly perform each step yourself. You must create the role and then assign a permissions policy to the role. Optionally, you can also set the [permissions boundary](#) for your role.

To create a role for cross-account access (AWS CLI)

1. Create a role: [aws iam create-role](#)
2. Attach a managed permissions policy to the role: [aws iam attach-role-policy](#)

or

Create an inline permissions policy for the role: [aws iam put-role-policy](#)

3. (Optional) Add custom attributes to the role by attaching tags: [aws iam tag-role](#)

For more information, see [Managing tags on IAM roles \(AWS CLI or AWS API\)](#).

4. (Optional) Set the [permissions boundary](#) for the role: [aws iam put-role-permissions-boundary](#)

A permissions boundary controls the maximum permissions that a role can have. Permissions boundaries are an advanced AWS feature.

The following example shows the first two, and most common steps for creating a cross-account role in a simple environment. This example allows any user in the 123456789012 account to assume the role and view the example_bucket Amazon S3 bucket. This example also assumes that you are using a client computer running Windows, and have already configured your command line interface with your account credentials and Region. For more information, see [Configuring the AWS Command Line Interface](#).

In this example, include the following trust policy in the first command when you create the role. This trust policy allows users in the 123456789012 account to assume the role using the `AssumeRole` operation, but only if the user provides MFA authentication using the `SerialNumber` and `TokenCode` parameters. For more information about MFA, see [Using multi-factor authentication \(MFA\) in AWS](#).

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Principal": { "AWS": "arn:aws:iam::123456789012:root" },
      "Action": "sts:AssumeRole",
      "Condition": { "Bool": { "aws:MultiFactorAuthPresent": "true" } }
    }
  ]
}
```

Important

If your `Principal` element contains the ARN for a specific IAM role or user, then that ARN is transformed to a unique principal ID when the policy is saved. This helps mitigate the risk of someone escalating their permissions by removing and recreating the role or user. You don't normally see this ID in the console because there is also a reverse transformation back to the ARN when the trust policy is displayed. However, if you delete the role or user, then the principal ID appears in the console because AWS can no longer map it back to an ARN. Therefore, if you delete and recreate a user or role referenced in a trust policy's `Principal` element, you must edit the role to replace the ARN.

When you use the second command, you must attach an existing managed policy to the role. The following permissions policy allows anyone who assumes the role to perform only the `ListBucket` action on the `example_bucket` Amazon S3 bucket.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
```

```
        "Action": "s3:ListBucket",
        "Resource": "arn:aws:s3:::example_bucket"
    }
]
}
```

To create this `Test-UserAccess-Role` role, you must first save the previous trust policy with the name `trustpolicyforacct123456789012.json` to the `policies` folder in your local `C:` drive. Then save the previous permissions policy as a customer managed policy in your AWS account with the name `PolicyForRole`. You can then use the following commands to create the role and attach the managed policy.

```
# Create the role and attach the trust policy file that allows users in the specified
account to assume the role.
$ aws iam create-role --role-name Test-UserAccess-Role --assume-role-policy-document
file://C:\policies\trustpolicyforacct123456789012.json

# Attach the permissions policy (in this example a managed policy) to the role to
specify what it is allowed to do.
$ aws iam attach-role-policy --role-name Test-UserAccess-Role --policy-arn
arn:aws:iam::123456789012:policy/PolicyForRole
```

Important

Remember that this is only the first half of the configuration required. You must also give individual users in the trusted account permissions to switch to the role. For more information about this step, see [Granting a user permissions to switch roles](#).

After you create the role and grant it permissions to perform AWS tasks or access AWS resources, any users in the `123456789012` account can assume the role. For more information, see [Switching to an IAM role \(AWS CLI\)](#).

Creating an IAM role (AWS API)

Creating a role from the AWS API involves multiple steps. When you use the console to create a role, many of the steps are done for you, but with the API you must explicitly perform each step yourself. You must create the role and then assign a permissions policy to the role. Optionally, you can also set the [permissions boundary](#) for your role.

To create a role in code (AWS API)

1. Create a role: [CreateRole](#)

For the role's trust policy, you can specify a file location.

2. Attach a managed permission policy to the role: [AttachRolePolicy](#)

or

Create an inline permission policy for the role: [PutRolePolicy](#)

Important

Remember that this is only the first half of the configuration required. You must also give individual users in the trusted account permissions to switch to the role. For more information about this step, see [Granting a user permissions to switch roles](#).

3. (Optional) Add custom attributes to the user by attaching tags: [TagRole](#)

For more information, see [Managing tags on IAM users \(AWS CLI or AWS API\)](#).

4. (Optional) Set the [permissions boundary](#) for the role: [PutRolePermissionsBoundary](#)

A permissions boundary controls the maximum permissions that a role can have. Permissions boundaries are an advanced AWS feature.

After you create the role and grant it permissions to perform AWS tasks or access AWS resources, you must grant permissions to users in the account to allow them to assume the role. For more information about assuming a role, see [Switching to an IAM role \(AWS API\)](#).

Creating an IAM role (AWS CloudFormation)

For information about creating an IAM role in AWS CloudFormation, see the [resource and property reference](#) and [examples](#) in the *AWS CloudFormation User Guide*.

For more information about IAM templates in AWS CloudFormation, see [AWS Identity and Access Management template snippets](#) in the *AWS CloudFormation User Guide*.

Creating a role to delegate permissions to an AWS service

Many AWS services require that you use roles to allow the service to access resources in other services on your behalf. A role that a service assumes to perform actions on your behalf is called a [service role](#). When a role serves a specialized purpose for a service, it is categorized as a [service role for EC2 instances](#) (for example), or a [service-linked role](#). To see what services support using service-linked roles, or whether a service supports any form of temporary credentials, see [AWS services that work with IAM](#). To learn how an individual service uses roles, choose the service name in the table to view the documentation for that service.

When setting the `PassRole` permission, you should make sure that a user doesn't pass a role where the role has more permissions than you want the user to have. For example, Alice might not be allowed to perform any Amazon S3 actions. If Alice could pass a role to a service that allows Amazon S3 actions, the service could perform Amazon S3 actions on behalf of Alice when executing the job.

For information about how roles help you to delegate permissions, see [Roles terms and concepts](#).

Service role permissions

You must configure permissions to allow an IAM entity (user or role) to create or edit a service role.

Note

The ARN for a service-linked role includes a service principal, which is indicated in the following policies as *SERVICE-NAME*.amazonaws.com. Do not try to guess the service principal, because it is case-sensitive and the format can vary across AWS services. To view the service principal for a service, see its service-linked role documentation.

To allow an IAM entity to create a specific service role

Add the following policy to the IAM entity that needs to create the service role. This policy allows you to create a service role for the specified service and with a specific name. You can then attach managed or inline policies to that role.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
```

```

    "Effect": "Allow",
    "Action": [
      "iam:AttachRolePolicy",
      "iam:CreateRole",
      "iam:PutRolePolicy"
    ],
    "Resource": "arn:aws:iam::*:role/SERVICE-ROLE-NAME"
  }
]
}

```

To allow an IAM entity to create any service role

AWS recommends that you allow only administrative users to create any service role. A person with permissions to create a role and attach any policy can escalate their own permissions. Instead, create a policy that allows them to create only the roles that they need or have an administrator create the service role on their behalf.

To attach a policy that allows an administrator to access your entire AWS account, use the [AdministratorAccess](#) AWS managed policy.

To allow an IAM entity to edit a service role

Add the following policy to the IAM entity that needs to edit the service role.

```

{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "EditSpecificServiceRole",
      "Effect": "Allow",
      "Action": [
        "iam:AttachRolePolicy",
        "iam>DeleteRolePolicy",
        "iam:DetachRolePolicy",
        "iam:GetRole",
        "iam:GetRolePolicy",
        "iam>ListAttachedRolePolicies",
        "iam>ListRolePolicies",
        "iam:PutRolePolicy",
        "iam:UpdateRole",
        "iam:UpdateRoleDescription"
      ]
    }
  ],
}

```

```

        "Resource": "arn:aws:iam::*:role/SERVICE-ROLE-NAME"
    },
    {
        "Sid": "ViewRolesAndPolicies",
        "Effect": "Allow",
        "Action": [
            "iam:GetPolicy",
            "iam:ListRoles"
        ],
        "Resource": "*"
    }
]
}

```

To allow an IAM entity to delete a specific service role

Add the following statement to the permissions policy for the IAM entity that needs to delete the specified service role.

```

{
    "Effect": "Allow",
    "Action": "iam:DeleteRole",
    "Resource": "arn:aws:iam::*:role/SERVICE-ROLE-NAME"
}

```

To allow an IAM entity to delete any service role

AWS recommends that you allow only administrative users to delete any service role. Instead, create a policy that allows them to delete only the roles that they need or have an administrator delete the service role on their behalf.

To attach a policy that allows an administrator to access your entire AWS account, use the [AdministratorAccess](#) AWS managed policy.

Creating a role for an AWS service (console)

You can use the AWS Management Console to create a role for a service. Because some services support more than one service role, see the [AWS documentation](#) for your service to see which use case to choose. You can learn how to assign the necessary trust and permissions policies to the role so that the service can assume the role on your behalf. The steps that you can use to control the permissions for your role can vary, depending on how the service defines the use cases, and whether or not you create a service-linked role.

To create a role for an AWS service (IAM console)

1. Sign in to the AWS Management Console and open the IAM console at <https://console.aws.amazon.com/iam/>.
2. In the navigation pane of the IAM console, choose **Roles**, and then choose **Create role**.
3. For **Trusted entity type**, choose **AWS service**.
4. For **Service or use case**, choose a service, and then choose the use case. Use cases are defined by the service to include the trust policy that the service requires.
5. Choose **Next**.
6. For **Permissions policies**, the options depend on the use case that you selected:
 - If the service defines the permissions for the role, you can't select permissions policies.
 - Select from a limited set of permission polices.
 - Select from all permission policies.
 - Select no permissions policies, create the policies after the role is create, and then attach the policies to the role.
7. (Optional) Set a [permissions boundary](#). This is an advanced feature that is available for service roles, but not service-linked roles.
 - a. Open the **Set permissions boundary** section, and then choose **Use a permissions boundary to control the maximum role permissions**.

IAM includes a list of the AWS managed and customer-managed policies in your account.
 - b. Select the policy to use for the permissions boundary.
8. Choose **Next**.
9. For **Role name**, the options depend on the service:
 - If the service defines the role name, you can't edit the role name.
 - If the service defines a prefix for the role name, you can enter an optional suffix.
 - If the service doesn't define the role name, you can name the role.

Important

When you name a role, note the following:

- Role names must be unique within your AWS account, and can't be made unique by case.

For example, don't create roles named both **PRODRole** and **prodrole**. When a role name is used in a policy or as part of an ARN, the role name is case sensitive, however when a role name appears to customers in the console, such as during the sign-in process, the role name is case insensitive.

- You can't edit the name of the role after it's created because other entities might reference the role.

10. (Optional) For **Description**, enter a description for the role.
11. (Optional) To edit the use cases and permissions for the role, in the **Step 1: Select trusted entities** or **Step 2: Add permissions** sections, choose **Edit**.
12. (Optional) To help identify, organize, or search for the role, add tags as key-value pairs. For more information about using tags in IAM, see [Tagging IAM resources](#) in the *IAM User Guide*.
13. Review the role, and then choose **Create role**.

Creating a role for a service (AWS CLI)

Creating a role from the AWS CLI involves multiple steps. When you use the console to create a role, many of the steps are done for you, but with the AWS CLI you must explicitly perform each step yourself. You must create the role and then assign a permissions policy to the role. If the service you are working with is Amazon EC2, then you must also create an instance profile and add the role to it. Optionally, you can also set the [permissions boundary](#) for your role.

To create a role for an AWS service from the AWS CLI

1. The following [create-role](#) command creates a role named *Test-Role* and attaches a trust policy to it:

```
aws iam create-role --role-name Test-Role --assume-role-policy-document
file:///Test-Role-Trust-Policy.json
```

2. Attach a managed permissions policy to the role: [aws iam attach-role-policy](#).

For example, the following `attach-role-policy` command attaches the AWS managed policy named `ReadOnlyAccess` to the IAM role named `ReadOnlyRole`:

```
aws iam attach-role-policy --policy-arn arn:aws:iam::aws:policy/
ReadOnlyAccess --role-name ReadOnlyRole
```

or

Create an inline permissions policy for the role: [aws iam put-role-policy](#)

To add an inline permissions policy, see the following example:

```
aws iam put-role-policy --role-name Test-Role --policy-name
ExamplePolicy --policy-document file://AdminPolicy.json
```

3. (Optional) Add custom attributes to the role by attaching tags: [aws iam tag-role](#)

For more information, see [Managing tags on IAM roles \(AWS CLI or AWS API\)](#).

4. (Optional) Set the [permissions boundary](#) for the role: [aws iam put-role-permissions-boundary](#)

A permissions boundary controls the maximum permissions that a role can have. Permissions boundaries are an advanced AWS feature.

If you are going to use the role with Amazon EC2 or another AWS service that uses Amazon EC2, you must store the role in an instance profile. An instance profile is a container for a role that can be attached to an Amazon EC2 instance when launched. An instance profile can contain only one role, and that limit cannot be increased. If you create the role using the AWS Management Console, the instance profile is created for you with the same name as the role. For more information about instance profiles, see [Using instance profiles](#). For information about how to launch an EC2 instance with a role, see [Controlling Access to Amazon EC2 Resources](#) in the *Amazon EC2 User Guide for Linux Instances*.

To create an instance profile and store the role in it (AWS CLI)

1. Create an instance profile: [aws iam create-instance-profile](#)
2. Add the role to the instance profile: [aws iam add-role-to-instance-profile](#)

The AWS CLI example command set below demonstrates the first two steps for creating a role and attaching permissions. It also shows the two steps for creating an instance profile and adding the role to the profile. This example trust policy allows the Amazon EC2 service to assume the role and view the `example_bucket` Amazon S3 bucket. The example also assumes that you are running on a client computer running Windows and have already configured your command line interface with your account credentials and Region. For more information, see [Configuring the AWS Command Line Interface](#).

In this example, include the following trust policy in the first command when you create the role. This trust policy allows the Amazon EC2 service to assume the role.

```
{
  "Version": "2012-10-17",
  "Statement": {
    "Effect": "Allow",
    "Principal": {"Service": "ec2.amazonaws.com"},
    "Action": "sts:AssumeRole"
  }
}
```

When you use the second command, you must attach a permissions policy to the role. The following example permissions policy allows the role to perform only the ListBucket action on the example_bucket Amazon S3 bucket.

```
{
  "Version": "2012-10-17",
  "Statement": {
    "Effect": "Allow",
    "Action": "s3:ListBucket",
    "Resource": "arn:aws:s3:::example_bucket"
  }
}
```

To create this Test-Role-for-EC2 role, you must first save the previous trust policy with the name trustpolicyforec2.json and the previous permissions policy with the name permissionspolicyforec2.json to the policies directory in your local C: drive. You can then use the following commands to create the role, attach the policy, create the instance profile, and add the role to the instance profile.

```
# Create the role and attach the trust policy that allows EC2 to assume this role.
$ aws iam create-role --role-name Test-Role-for-EC2 --assume-role-policy-document
  file://C:\policies\trustpolicyforec2.json
```

```
# Embed the permissions policy (in this example an inline policy) to the role to
  specify what it is allowed to do.
```

```
$ aws iam put-role-policy --role-name Test-Role-for-EC2 --policy-name Permissions-
  Policy-For-Ec2 --policy-document file://C:\policies\permissionspolicyforec2.json
```

```
# Create the instance profile required by EC2 to contain the role
```

```
$ aws iam create-instance-profile --instance-profile-name EC2-ListBucket-S3

# Finally, add the role to the instance profile
$ aws iam add-role-to-instance-profile --instance-profile-name EC2-ListBucket-S3 --
role-name Test-Role-for-EC2
```

When you launch the EC2 instance, specify the instance profile name in the **Configure Instance Details** page if you use the AWS console. If you use the `aws ec2 run-instances` CLI command, specify the `--iam-instance-profile` parameter.

Creating a role for a service (AWS API)

Creating a role from the AWS API involves multiple steps. When you use the console to create a role, many of the steps are done for you, but with the API you must explicitly perform each step yourself. You must create the role and then assign a permissions policy to the role. If the service you are working with is Amazon EC2, then you must also create an instance profile and add the role to it. Optionally, you can also set the [permissions boundary](#) for your role.

To create a role for an AWS service (AWS API)

1. Create a role: [CreateRole](#)

For the role's trust policy, you can specify a file location.

2. Attach a managed permissions policy to the role: [AttachRolePolicy](#)

or

Create an inline permissions policy for the role: [PutRolePolicy](#)

3. (Optional) Add custom attributes to the user by attaching tags: [TagRole](#)

For more information, see [Managing tags on IAM users \(AWS CLI or AWS API\)](#).

4. (Optional) Set the [permissions boundary](#) for the role: [PutRolePermissionsBoundary](#)

A permissions boundary controls the maximum permissions that a role can have. Permissions boundaries are an advanced AWS feature.

If you are going to use the role with Amazon EC2 or another AWS service that uses Amazon EC2, you must store the role in an instance profile. An instance profile is a container for a role. Each instance profile can contain only one role, and that limit cannot be increased. If you create the role

in the AWS Management Console, the instance profile is created for you with the same name as the role. For more information about instance profiles, see [Using instance profiles](#). For information about how to launch an Amazon EC2 instance with a role, see [Controlling Access to Amazon EC2 Resources](#) in the *Amazon EC2 User Guide for Linux Instances*.

To create an instance profile and store the role in it (AWS API)

1. Create an instance profile: [CreateInstanceProfile](#)
2. Add the role to the instance profile: [AddRoleToInstanceProfile](#)

Creating a role for a third-party Identity Provider (federation)

You can use identity providers instead of creating IAM users in your AWS account. With an identity provider (IdP), you can manage your user identities outside of AWS and give these external user identities permissions to access AWS resources in your account. For more information about federation and identity providers, see [Identity providers and federation](#).

Creating a role for federated users (console)

The procedures for creating a role for federated users depend on your choice of third party providers:

- For Web Identity or OpenID Connect (OIDC), see [Create a role for OpenID Connect federation \(console\)](#).
- For SAML 2.0, see [Create a role for SAML 2.0 federation \(console\)](#).

Creating a role for federated access (AWS CLI)

The steps to create a role for the supported identity providers (OIDC or SAML) from the AWS CLI are identical. The difference is in the contents of the trust policy that you create in the prerequisite steps. Begin by following the steps in the **Prerequisites** section for the type of provider you are using:

- For an OIDC provider, see [Prerequisites for creating a role for OIDC](#).
- For a SAML provider, see [Prerequisites for creating a role for SAML](#).

Creating a role from the AWS CLI involves multiple steps. When you use the console to create a role, many of the steps are done for you, but with the AWS CLI you must explicitly perform each

step yourself. You must create the role and then assign a permissions policy to the role. Optionally, you can also set the [permissions boundary](#) for your role.

To create a role for identity federation (AWS CLI)

1. Create a role: [aws iam create-role](#)
2. Attach a permissions policy to the role: [aws iam attach-role-policy](#)

or

Create an inline permissions policy for the role: [aws iam put-role-policy](#)

3. (Optional) Add custom attributes to the role by attaching tags: [aws iam tag-role](#)

For more information, see [Managing tags on IAM roles \(AWS CLI or AWS API\)](#).

4. (Optional) Set the [permissions boundary](#) for the role: [aws iam put-role-permissions-boundary](#)

A permissions boundary controls the maximum permissions that a role can have. Permissions boundaries are an advanced AWS feature.

The following example shows the first two, and most common, steps for creating an identity provider role in a simple environment. This example allows any user in the 123456789012 account to assume the role and view the `example_bucket` Amazon S3 bucket. This example also assumes that you are running the AWS CLI on a computer running Windows, and have already configured the AWS CLI with your credentials. For more information, see [Configuring the AWS Command Line Interface](#).

The following example trust policy is designed for a mobile app if the user signs in using Amazon Cognito. In this example, `us-east:12345678-ffff-ffff-ffff-123456` represents the identity pool ID assigned by Amazon Cognito.

```
{
  "Version": "2012-10-17",
  "Statement": {
    "Sid": "RoleForCognito",
    "Effect": "Allow",
    "Principal": {"Federated": "cognito-identity.amazonaws.com"},
    "Action": "sts:AssumeRoleWithWebIdentity",
    "Condition": {"StringEquals": {"cognito-identity.amazonaws.com:aud": "us-east:12345678-ffff-ffff-ffff-123456"}}
  }
}
```

```
}
```

The following permissions policy allows anyone who assumes the role to perform only the `ListBucket` action on the `example_bucket` Amazon S3 bucket.

```
{
  "Version": "2012-10-17",
  "Statement": {
    "Effect": "Allow",
    "Action": "s3:ListBucket",
    "Resource": "arn:aws:s3:::example_bucket"
  }
}
```

To create this `Test-Cognito-Role` role, you must first save the previous trust policy with the name `trustpolicyforcognitofederation.json` and the previous permissions policy with the name `permpolicyforcognitofederation.json` to the `policies` folder in your local `C:` drive. You can then use the following commands to create the role and attach the inline policy.

```
# Create the role and attach the trust policy that enables users in an account to
assume the role.
$ aws iam create-role --role-name Test-Cognito-Role --assume-role-policy-document
file://C:\policies\trustpolicyforcognitofederation.json

# Attach the permissions policy to the role to specify what it is allowed to do.
aws iam put-role-policy --role-name Test-Cognito-Role --policy-name
Perms-Policy-For-CognitoFederation --policy-document file://C:\policies
\permpolicyforcognitofederation.json
```

Creating a role for federated access (AWS API)

The steps to create a role for the supported identity providers (OIDC or SAML) from the AWS CLI are identical. The difference is in the contents of the trust policy that you create in the prerequisite steps. Begin by following the steps in the **Prerequisites** section for the type of provider you are using:

- For an OIDC provider, see [Prerequisites for creating a role for OIDC](#).
- For a SAML provider, see [Prerequisites for creating a role for SAML](#).

To create a role for identity federation (AWS API)

1. Create a role: [CreateRole](#)
2. Attach a permissions policy to the role: [AttachRolePolicy](#)

or

Create an inline permissions policy for the role: [PutRolePolicy](#)

3. (Optional) Add custom attributes to the user by attaching tags: [TagRole](#)

For more information, see [Managing tags on IAM users \(AWS CLI or AWS API\)](#).

4. (Optional) Set the [permissions boundary](#) for the role: [PutRolePermissionsBoundary](#)

A permissions boundary controls the maximum permissions that a role can have. Permissions boundaries are an advanced AWS feature.

Create a role for OpenID Connect federation (console)

You can use OpenID Connect (OIDC) federated identity providers instead of creating AWS Identity and Access Management users in your AWS account. With an identity provider (IdP), you can manage your user identities outside of AWS and give these external user identities permissions to access AWS resources in your account. For more information about federation and IdPs, see [Identity providers and federation](#).

Prerequisites for creating a role for OIDC

Before you can create a role for OIDC federation, you must first complete the following prerequisite steps.

To prepare to create a role for OIDC federation

1. Sign up with one or more services offering federated OIDC identity. If you are creating an app that needs access to your AWS resources, you also configure your app with the provider information. When you do, the provider gives you an application or audience ID that is unique to your app. (Different providers use different terminology for this process. This guide uses the term *configure* for the process of identifying your app with the provider.) You can configure multiple apps with each provider, or multiple providers with a single app. View information about using the identity providers as follows:
 - [Login with Amazon Developer Center](#)

- [Add Facebook Login to Your App or Website](#) on the Facebook developers site.
 - [Using OAuth 2.0 for Login \(OpenID Connect\)](#) on the Google developers site.
2. After you receive the required information from the IdP, create an IdP in IAM. For more information, see [Creating OpenID Connect \(OIDC\) identity providers](#).

⚠ Important

If you are using an OIDC IdP from Google, Facebook, or Amazon Cognito, don't create a separate IAM IdP in the AWS Management Console. These OIDC identity providers are already built into AWS and are available for you to use. Skip this step and create new roles using your IdP in the following step.

3. Prepare the policies for the role that the IdP-authenticated users will assume. As with any role, a role for a mobile app includes two policies. One is the trust policy that specifies who can assume the role. The other is the permissions policy that specifies the AWS actions and resources that the mobile app is allowed or denied access to.

For web IdPs, we recommend that you use [Amazon Cognito](#) to manage identities. In this case, use a trust policy similar to this example.

```
{
  "Version": "2012-10-17",
  "Statement": {
    "Effect": "Allow",
    "Principal": {"Federated": "cognito-identity.amazonaws.com"},
    "Action": "sts:AssumeRoleWithWebIdentity",
    "Condition": {
      "StringEquals": {"cognito-identity.amazonaws.com:aud": "us-east-2:12345678-abcd-abcd-abcd-123456"},
      "ForAnyValue:StringLike": {"cognito-identity.amazonaws.com:amr": "unauthenticated"}
    }
  }
}
```

Replace `us-east-2:12345678-abcd-abcd-abcd-123456` with the identity pool ID that Amazon Cognito assigns to you.

If you manually configure an OIDC IdP, when you create the trust policy, you must use three values that ensure that only your app can assume the role:

- For the Action element, use the `sts:AssumeRoleWithWebIdentity` action.
- For the Principal element, use the string `{"Federated":providerUrl/providerArn}`.
- For some common OIDC IdPs, the *providerUrl* is a URL. The following examples include methods to specify the principal for some common IdPs:

```
"Principal":{"Federated":"cognito-identity.amazonaws.com"}
```

```
"Principal":{"Federated":"www.amazon.com"}
```

```
"Principal":{"Federated":"graph.facebook.com"}
```

```
"Principal":{"Federated":"accounts.google.com"}
```

- For other OIDC providers, use the Amazon Resource Name (ARN) of the OIDC IdP that you created in [Step 2](#), such as the following example:

```
"Principal":{"Federated":"arn:aws:iam::123456789012:oidc-provider/server.example.com"}
```

- For the Condition element, use a `StringEquals` condition to limit permissions. Test the identity pool ID for Amazon Cognito) or the app ID for other providers. The identity pool ID should match the app ID that you received when you configured the app with the IdP. This match between the IDs ensures that the request comes from your app.

Note

A role trust policy that trusts Amazon Cognito identity pools (`cognito-identity.amazonaws.com`) must contain at least one condition key to limit the principals who can assume the role. For more information, see [Trust policies for IAM roles in Basic \(Classic\) authentication](#) in the *Amazon Cognito Developer Guide*.

Create a condition element similar to one of the following examples, depending on the IdP that you are using:

```
"Condition": {"StringEquals": {"cognito-identity.amazonaws.com:aud":  
"us-east:12345678-ffff-ffff-ffff-123456"}}
```

```
"Condition": {"StringEquals": {"www.amazon.com:app_id":  
"amzn1.application-oa2-123456"}}
```

```
"Condition": {"StringEquals": {"graph.facebook.com:app_id":  
"111222333444555"}}
```

```
"Condition": {"StringEquals": {"accounts.google.com:aud":  
"66677788899900pro0"}}
```

For OIDC providers, use the fully qualified URL of the OIDC IdP with the aud context key, such as the following example:

```
"Condition": {"StringEquals": {"server.example.com:aud":  
"appid_from_oidc_idp"}}
```

Note

The values for the principal in the trust policy for the role are specific to an IdP. A role for OIDC can specify only one principal. Therefore, if the mobile app allows users to sign in from more than one IdP, create a separate role for each IdP that you want to support. Create separate trust policies for each IdP.

If a user uses a mobile app to sign in from Login with Amazon, the following example trust policy would apply. In the example, *amzn1.application-oa2-123456* represents the app ID that Amazon assigns when you configured the app using Login with Amazon.

```
{  
  "Version": "2012-10-17",  
  "Statement": [{  
    "Sid": "RoleForLoginWithAmazon",  
    "Effect": "Allow",  
    "Principal": {"Federated": "www.amazon.com"},  
    "Action": "sts:AssumeRoleWithWebIdentity",
```

```

    "Condition": {"StringEquals": {"www.amazon.com:app_id":
"amzn1.application-oa2-123456"}}
  }}
}

```

If a user uses a mobile app to sign in from Facebook, the following example trust policy would apply. In this example, *111222333444555* represents the app ID that Facebook assigns.

```

{
  "Version": "2012-10-17",
  "Statement": [{
    "Sid": "RoleForFacebook",
    "Effect": "Allow",
    "Principal": {"Federated": "graph.facebook.com"},
    "Action": "sts:AssumeRoleWithWebIdentity",
    "Condition": {"StringEquals": {"graph.facebook.com:app_id":
"111222333444555"}}
  }}
}

```

If a user uses a mobile app to sign in from Google, the following example trust policy would apply. In this example, *666777888999000* represents the app ID that Google assigns.

```

{
  "Version": "2012-10-17",
  "Statement": [{
    "Sid": "RoleForGoogle",
    "Effect": "Allow",
    "Principal": {"Federated": "accounts.google.com"},
    "Action": "sts:AssumeRoleWithWebIdentity",
    "Condition": {"StringEquals": {"accounts.google.com:aud":
"666777888999000"}}
  }}
}

```

If a user uses a mobile app to sign in from Amazon Cognito, the following example trust policy would apply. In this example, *us-east:12345678-ffff-ffff-ffff-123456* represents the identity pool ID that Amazon Cognito assigns.

```
{
  "Version": "2012-10-17",
  "Statement": [{
    "Sid": "RoleForCognito",
    "Effect": "Allow",
    "Principal": {"Federated": "cognito-identity.amazonaws.com"},
    "Action": "sts:AssumeRoleWithWebIdentity",
    "Condition": {"StringEquals": {"cognito-identity.amazonaws.com:aud": "us-east:12345678-ffff-ffff-ffff-123456"}}
  }]
}
```

Creating a role for OIDC

After you complete the prerequisites, you can create the role in IAM. The following procedure describes how to create the role for OIDC federation in the AWS Management Console. To create a role from the AWS CLI or AWS API, see the procedures at [Creating a role for a third-party Identity Provider \(federation\)](#).

Important

If you use Amazon Cognito, use the Amazon Cognito console to set up the roles. Otherwise, use the IAM console to create a role for OIDC federation.

To create an IAM role for OIDC federation

1. Sign in to the AWS Management Console and open the IAM console at <https://console.aws.amazon.com/iam/>.
2. In the navigation pane, choose **Roles** and then choose **Create role**.
3. Choose the **OIDC** role type.
4. For **Identity provider**, choose the IdP for your role:
 - If you want to create a role for an individual web IdP, choose **Login with Amazon, Facebook, or Google**.

Note

You must create a separate role for each IdP that you want to support.

- If you want to create an advanced scenario role for Amazon Cognito, choose **Amazon Cognito**.

Note

You must manually create a role to use with Amazon Cognito only when you work on an advanced scenario. Otherwise, Amazon Cognito can create roles for you. For more information about Amazon Cognito, see [Identity pools \(federated identities\) external identity providers](#) in the *Amazon Cognito Developer Guide*.

- If you want to create a role for GitHub Actions, you must start by adding the GitHub OIDC provider to IAM. After you've added the GitHub OIDC provider to IAM, choose **token.actions.githubusercontent.com**.

Note

For information about how to configure AWS to trust GitHub's OIDC as a federated identity, see [GitHub Docs - Configuring OpenID Connect in Amazon Web Services](#). For information about best practices for limiting access for roles associated with the IAM IdP for GitHub, see [Configuring a role for GitHub OIDC identity provider](#) on this page.

5. Enter the identifier for your application. The label of the identifier changes based on the provider you choose:
 - If you want to create a role for Login with Amazon, enter the app ID into the **Application ID** box.
 - If you want to create a role for Facebook, enter the app ID into the **Application ID** box.
 - If you want to create a role for Google, enter the audience name into the **Audience** box.
 - If you want to create a role for Amazon Cognito, enter the ID of the identity pool that you have created for your Amazon Cognito applications into the **Identity Pool ID** box.
 - If you want to create a role for GitHub Actions, enter the following details:

- For **Audience**, choose `sts.amazonaws.com`.
 - For **GitHub organization**, enter your GitHub organization name. The GitHub organization name is required and must be alphanumeric including dashes (-). You can't use wildcard characters (* and ?) in the GitHub organization name.
 - (Optional) For **GitHub repository**, enter the GitHub repository name. If you don't specify a value, it defaults to a wildcard (*).
 - (Optional) For **GitHub branch**, enter the GitHub branch name. If you don't specify a value, it defaults to a wildcard (*).
6. (Optional) For **Condition (optional)**, choose **Add Condition** to create additional conditions that must be met before users of your application can use the permissions that the role grants. For example, you can add a condition that grants access to AWS resources only for a specific IAM user ID. You can also add conditions to the trust policy after the role is created. For more information, see [Modifying a role trust policy \(console\)](#).
 7. Review your OIDC information and then choose **Next**.
 8. IAM includes a list of the AWS managed and customer managed policies in your account. Select the policy to use for the permissions policy, or choose **Create policy** to open a new browser tab and create a new policy from scratch. For more information, see [Creating IAM policies](#). After you create the policy, close that tab and return to your original tab. Select the check box next to the permissions policies that you want OIDC users to have. If you prefer, you can select no policies at this time, and then attach policies to the role later. By default, a role has no permissions.
 9. (Optional) Set a [permissions boundary](#). This is an advanced feature.

Open the **Permissions boundary** section and choose **Use a permissions boundary to control the maximum role permissions**. Select the policy to use for the permissions boundary.
 10. Choose **Next**.
 11. For **Role name**, enter a role name. Role names must be unique within your AWS account. They are not case dependent. For example, you can't create roles named both **PRODROLE** and **prodrole**. Because other AWS resources might reference the role, you can't edit the name of the role after you create it.
 12. (Optional) For **Description**, enter a description for the new role.
 13. To edit the use cases and permissions for the role, choose **Edit** in the **Step 1: Select trusted entities** or **Step 2: Add permissions** sections.

14. (Optional) To add metadata to the role, attach tags as key–value pairs. For more information about using tags in IAM, see [Tagging IAM resources](#).
15. Review the role and then choose **Create role**.

Configuring a role for GitHub OIDC identity provider

If you use GitHub as an OpenID Connect (OIDC) identity provider (IdP), best practice is to limit the entities that can assume the role associated with the IAM IdP. When you include a condition statement in the trust policy, you can limit the role to a specific GitHub organization, repository, or branch. You can use the condition key `token.actions.githubusercontent.com:sub` with string condition operators to limit access. We recommend that you limit the condition to a specific set of repositories or branches within your GitHub organization. For information about how to configure AWS to trust GitHub's OIDC as a federated identity, see [GitHub Docs - Configuring OpenID Connect in Amazon Web Services](#).

If you use GitHub environments in action workflows or in OIDC policies, we strongly recommend adding protection rules to the environment for additional security. Use deployment branches and tags to restrict which branches and tags can deploy to the environment. For more information on configuring environments with protection rules, see [Deployment branches and tags](#) in GitHub's *Using environments for deployment* article.

When GitHub's OIDC IdP is the trusted Principal for your role, IAM checks the role trust policy condition to verify that the condition key `token.actions.githubusercontent.com:sub` is present and that its value is not solely a wildcard character (* and ?) or null. IAM performs this check when the trust policy is created or updated. If the condition key `token.actions.githubusercontent.com:sub` is not present, or the key value doesn't satisfy the mentioned value criteria, the request will fail and return an error.

Important

If you do not limit the condition key `token.actions.githubusercontent.com:sub` to a specific organization or repository, then GitHub Actions from organizations or repositories outside of your control are able to assume roles associated with the GitHub IAM IdP in your AWS account.

The following example trust policy limits access to the defined GitHub organization, repository, and branch. The condition key `token.actions.githubusercontent.com:sub` value in the following example is the default subject value format documented by GitHub.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Principal": {
        "Federated": "arn:aws:iam::012345678910:oidc-provider/
token.actions.githubusercontent.com"
      },
      "Action": "sts:AssumeRoleWithWebIdentity",
      "Condition": {
        "StringEquals": {
          "token.actions.githubusercontent.com:aud": "sts.amazonaws.com",
          "token.actions.githubusercontent.com:sub":
"repo:GitHubOrg/GitHubRepo:ref:refs/heads/GitHubBranch"
        }
      }
    }
  ]
}
```

The following example condition limits access to the defined GitHub organization and repository, but grants access to any branch within the repository.

```
"Condition": {
  "StringEquals": {
    "token.actions.githubusercontent.com:aud": "sts.amazonaws.com"
  },
  "StringLike": {
    "token.actions.githubusercontent.com:sub": "repo:GitHubOrg/GitHubRepo:*"
  }
}
```

The following example condition limits access to any repository or branch within the defined GitHub organization. We recommend that you limit the condition key `token.actions.githubusercontent.com:sub` to a specific value that limits access to GitHub Actions from within your GitHub organization.

```
"Condition": {
  "StringEquals": {
    "token.actions.githubusercontent.com:aud": "sts.amazonaws.com"
  },
  "StringLike": {
    "token.actions.githubusercontent.com:sub": "repo:GitHubOrg/*"
  }
}
```

For more information about the OIDC federation keys available for condition checks in policies, see [Available keys for AWS web identity federation](#).

Create a role for SAML 2.0 federation (console)

You can use SAML 2.0 federation instead of creating IAM users in your AWS account. With an identity provider (IdP), you can manage your user identities outside of AWS and give these external user identities permissions to access AWS resources in your account. For more information about federation and identity providers, see [Identity providers and federation](#).

Note

To improve federation resiliency, we recommend that you configure your IdP and AWS federation to support multiple SAML sign-in endpoints. For details, see the AWS Security Blog article [How to use regional SAML endpoints for failover](#).

Prerequisites for creating a role for SAML

Before you can create a role for SAML 2.0 federation, you must first complete the following prerequisite steps.

To prepare to create a role for SAML 2.0 federation

1. Before you create a role for SAML-based federation, you must create a SAML provider in IAM. For more information, see [Creating IAM SAML identity providers](#).
2. Prepare the policies for the role that the SAML 2.0–authenticated users will assume. As with any role, a role for the SAML federation includes two policies. One is the role trust policy that specifies who can assume the role. The other is the IAM permissions policy that specifies the AWS actions and resources that the federated user is allowed or denied access to.

When you create the trust policy for your role, you must use three values to ensure that only your application can assume the role:

- For the Action element, use the `sts:AssumeRoleWithSAML` action.
- For the Principal element, use the string `{"Federated": ARNofIdentityProvider}`. Replace *ARNofIdentityProvider* with the ARN of the [SAML identity provider](#) that you created in [Step 1](#).
- For the Condition element, use a `StringEquals` condition to test that the `saml:aud` attribute from the SAML response matches the SAML federation endpoint for AWS.

The following example trust policy is designed for a SAML federated user:

```
{
  "Version": "2012-10-17",
  "Statement": {
    "Effect": "Allow",
    "Action": "sts:AssumeRoleWithSAML",
    "Principal": {"Federated": "arn:aws:iam::account-id:saml-provider/PROVIDER-NAME"},
    "Condition": {"StringEquals": {"SAML:aud": "https://signin.aws.amazon.com/saml"}}
  }
}
```

Replace the principal ARN with the actual ARN for the SAML provider that you created in IAM. It will have your own account ID and provider name.

Creating a role for SAML

After you complete the prerequisite steps, you can create the role for SAML-based federation.

To create a role for SAML-based federation

1. Sign in to the AWS Management Console and open the IAM console at <https://console.aws.amazon.com/iam/>.
2. In the navigation pane of the IAM console, choose **Roles** and then choose **Create role**.
3. Choose the **SAML 2.0 federation** role type.

4. For **Select a SAML provider**, choose the provider for your role.
5. Choose the SAML 2.0 access level method.
 - Choose **Allow programmatic access only** to create a role that can be assumed programmatically from the AWS API or AWS CLI.
 - Choose **Allow programmatic and AWS Management Console access** to create a role that can be assumed programmatically and from the AWS Management Console.

The roles created by both are similar, but the role that can also be assumed from the console includes a trust policy with a particular condition. That condition explicitly ensures that the SAML audience (SAML : aud attribute) is set to the AWS sign-in endpoint for SAML (<https://signin.aws.amazon.com/saml>).

6. If you're creating a role for programmatic access, choose an attribute from the **Attribute** list. Then, in the **Value** box, enter a value to include in the role. This restricts role access to users from the identity provider whose SAML authentication response (assertion) includes the attributes that you specify. You must specify at least one attribute to ensure that your role is limited to a subset of users at your organization.

If you're creating a role for programmatic and console access, the SAML : aud attribute is automatically added and set to the URL of the AWS SAML endpoint (<https://signin.aws.amazon.com/saml>).

7. To add more attribute-related conditions to the trust policy, choose **Condition (optional)**, select the additional condition, and specify a value.

Note

The list includes the most commonly used SAML attributes. IAM supports additional attributes that you can use to create conditions. For a list of the supported attributes, see [Available Keys for SAML Federation](#). If you need a condition for a supported SAML attribute that's not in the list, you can manually add that condition. To do that, edit the trust policy after you create the role.

8. Review your SAML 2.0 trust information and then choose **Next**.
9. IAM includes a list of the AWS managed and customer managed policies in your account. Select the policy to use for the permissions policy, or choose **Create policy** to open a new browser tab and create a new policy from scratch. For more information, see [Creating IAM](#)

[policies](#). After you create the policy, close that tab and return to your original tab. Select the check box next to the permissions policies that you want web identity users to have. If you prefer, you can select no policies at this time, and then attach policies to the role later. By default, a role has no permissions.

10. (Optional) Set a [permissions boundary](#). This is an advanced feature.

Open the **Permissions boundary** section and choose **Use a permissions boundary to control the maximum role permissions**. Select the policy to use for the permissions boundary.

11. Choose **Next**.

12. Choose **Next: Review**.

13. For **Role name**, enter a role name. Role names must be unique within your AWS account. They are not distinguished by case. For example, you cannot create roles named both **PRODRole** and **prodrole**. Because other AWS resources might reference the role, you cannot edit the name of the role after it has been created.

14. (Optional) For **Description**, enter a description for the new role.

15. Choose **Edit** in the **Step 1: Select trusted entities** or **Step 2: Add permissions** sections to edit the use cases and permissions for the role.

16. (Optional) Add metadata to the role by attaching tags as key–value pairs. For more information about using tags in IAM, see [Tagging IAM resources](#).

17. Review the role and then choose **Create role**.

After you create the role, you complete the SAML trust by configuring your identity provider software with information about AWS. This information includes the roles that you want your federated users to use. This is referred to as configuring the relying party trust between your IdP and AWS. For more information, see [Configuring your SAML 2.0 IdP with relying party trust and adding claims](#).

Creating a role using custom trust policies (console)

You can create a custom trust policy to delegate access and allow others to perform actions in your AWS account. For more information, see [Creating IAM policies](#).

For information about how to use roles to delegate permissions, see [Roles terms and concepts](#).

Creating an IAM role using a custom trust policy (console)

You can use the AWS Management Console to create a role that an IAM user can assume. For example, assume that your organization has multiple AWS accounts to isolate a development environment from a production environment. For high-level information about creating a role that allows users in the development account to access resources in the production account, see [Example scenario using separate development and production accounts](#).

To create a role using a custom trust policy (console)

1. Sign in to the AWS Management Console and open the IAM console at <https://console.aws.amazon.com/iam/>.
2. In the navigation pane of the console, choose **Roles** and then choose **Create role**.
3. Choose the **Custom trust policy** role type.
4. In the **Custom trust policy** section, enter or paste the custom trust policy for the role. For more information, see [Creating IAM policies](#).
5. Resolve any security warnings, errors, or general warnings generated during [policy validation](#), and then choose **Next**.
6. Select the check box next to the custom trust policy you created.
7. (Optional) Set a [permissions boundary](#). This is an advanced feature that is available for service roles, but not service-linked roles.

Open the **Permissions boundary** section and choose **Use a permissions boundary to control the maximum role permissions**. IAM includes a list of the AWS managed and customer managed policies in your account. Select the policy to use for the permissions boundary.

8. Choose **Next**.
9. For **Role name**, the degree of role name customization is defined by the service. If the service defines the role's name, this option is not editable. In other cases, the service might define a prefix for the role and allow you to enter an optional suffix. Some services allow you to specify the entire name of your role.

If possible, enter a role name or role name suffix. Role names must be unique within your AWS account. They are not distinguished by case. For example, you cannot create roles named both **PRODRole** and **prodrole**. Because other AWS resources might reference the role, you cannot edit the name of the role after it has been created.

10. (Optional) For **Description**, enter a description for the new role.

11. Choose **Edit** in the **Step 1: Select trusted entities** or **Step 2: Add permissions** sections to edit the custom policy and permissions for the role.
12. (Optional) Add metadata to the role by attaching tags as key–value pairs. For more information about using tags in IAM, see [Tagging IAM resources](#).
13. Review the role and then choose **Create role**.

Examples of policies for delegating access

The following examples show how you can allow or grant an AWS account access to the resources in another AWS account. To learn how to create an IAM policy using these example JSON policy documents, see [the section called “Creating policies using the JSON editor”](#).

Topics

- [Using roles to delegate access to the resources of another AWS account resources](#)
- [Using a policy to delegate access to services](#)
- [Using a resource-based policy to delegate access to an Amazon S3 bucket in another account](#)
- [Using a resource-based policy to delegate access to an Amazon SQS queue in another account](#)
- [Cannot delegate access when the account is denied access](#)

Using roles to delegate access to the resources of another AWS account resources

For a tutorial that shows how to use IAM roles to grant users in one account access to AWS resources that are in another account, see [IAM tutorial: Delegate access across AWS accounts using IAM roles](#).

Important

You can include the ARN for a specific role or user in the `Principal` element of a role trust policy. When you save the policy, AWS transforms the ARN to a unique principal ID. This helps mitigate the risk of someone escalating their privileges by removing and recreating the role or user. You don't normally see this ID in the console, because there is also a reverse transformation back to the ARN when the trust policy is displayed. However, if you delete the role or user, then the relationship is broken. The policy no longer applies, even if you recreate the user or role because it does not match the principal ID stored in the trust policy. When this happens, the principal ID shows up in the console because AWS can no longer map it back to an ARN. The result is that if you delete and recreate a user or

role referenced in a trust policy's `Principal` element, you must edit the role to replace the ARN. It is transformed into the new principal ID when you save the policy.

Using a policy to delegate access to services

The following example shows a policy that can be attached to a role. The policy enables two services, Amazon EMR and AWS Data Pipeline, to assume the role. The services can then perform any tasks granted by the permissions policy assigned to the role (not shown). To specify multiple service principals, you do not specify two `Service` elements; you can have only one. Instead, you use an array of multiple service principals as the value of a single `Service` element.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Principal": {
        "Service": [
          "elasticmapreduce.amazonaws.com",
          "datapipeline.amazonaws.com"
        ]
      },
      "Action": "sts:AssumeRole"
    }
  ]
}
```

Using a resource-based policy to delegate access to an Amazon S3 bucket in another account

In this example, account A uses a resource-based policy (an Amazon S3 [bucket policy](#)) to grant account B full access to account A's S3 bucket. Then account B creates an IAM user policy to delegate that access to account A's bucket to one of the users in account B.

The S3 bucket policy in account A might look like the following policy. In this example, account A's S3 bucket is named *mybucket*, and account B's account number is 111122223333. It does not specify any individual users or groups in account B, only the account itself.

```
{
  "Version": "2012-10-17",
  "Statement": {
```

```
"Sid": "AccountBAccess1",
"Effect": "Allow",
"Principal": {"AWS": "111122223333"},
"Action": "s3:*",
"Resource": [
  "arn:aws:s3:::mybucket",
  "arn:aws:s3:::mybucket/*"
]
}
```

Alternatively, account A can use Amazon S3 [Access Control Lists \(ACLs\)](#) to grant account B access to an S3 bucket or a single object within a bucket. In that case, the only thing that changes is how account A grants access to account B. Account B still uses a policy to delegate access to an IAM group in account B, as described in the next part of this example. For more information about controlling access on S3 buckets and objects, go to [Access Control](#) in the *Amazon Simple Storage Service User Guide*.

The administrator of account B might create the following policy sample. The policy allows read access to a group or user in account B. The preceding policy grants access to account B. However, individual groups and users in account B cannot access the resource until a group or user policy explicitly grants permissions to the resource. The permissions in this policy can only be a subset of those in the preceding cross-account policy. Account B cannot grant more permissions to its groups and users than account A granted to account B in the first policy. In this policy, the `Action` element is explicitly defined to allow only `List` actions, and the `Resource` element of this policy matches the `Resource` for the bucket policy implemented by account A.

To implement this policy account B uses IAM to attach it to the appropriate user (or group) in account B.

```
{
  "Version": "2012-10-17",
  "Statement": {
    "Effect": "Allow",
    "Action": "s3:List*",
    "Resource": [
      "arn:aws:s3:::mybucket",
      "arn:aws:s3:::mybucket/*"
    ]
  }
}
```

Using a resource-based policy to delegate access to an Amazon SQS queue in another account

In the following example, account A has an Amazon SQS queue that uses a resource-based policy attached to the queue to grant queue access to account B. Then account B uses an IAM group policy to delegate access to a group in account B.

The following example queue policy gives account B permission to perform the `SendMessage` and `ReceiveMessage` actions on account A's queue named `queue1`, but only between noon and 3:00 p.m. on November 30, 2014. Account B's account number is 1111-2222-3333. Account A uses Amazon SQS to implement this policy.

```
{
  "Version": "2012-10-17",
  "Statement": {
    "Effect": "Allow",
    "Principal": {"AWS": "111122223333"},
    "Action": [
      "sqs:SendMessage",
      "sqs:ReceiveMessage"
    ],
    "Resource": ["arn:aws:sqs:*:123456789012:queue1"],
    "Condition": {
      "DateGreaterThan": {"aws:CurrentTime": "2014-11-30T12:00Z"},
      "DateLessThan": {"aws:CurrentTime": "2014-11-30T15:00Z"}
    }
  }
}
```

Account B's policy for delegating access to a group in account B might look like the following example. Account B uses IAM to attach this policy to a group (or user).

```
{
  "Version": "2012-10-17",
  "Statement": {
    "Effect": "Allow",
    "Action": "sqs:*",
    "Resource": "arn:aws:sqs:*:123456789012:queue1"
  }
}
```

In the preceding IAM user policy example, account B uses a wildcard to grant its user access to all Amazon SQS actions on account A's queue. However account B can delegate access only to the

extent that account B has been granted access. The account B group that has the second policy can access the queue only between noon and 3:00 p.m. on November 30, 2014. The user can only perform the `SendMessage` and `ReceiveMessage` actions, as defined in account A's Amazon SQS queue policy.

Cannot delegate access when the account is denied access

An AWS account cannot delegate access to another account's resources if the other account has explicitly denied access to the user's parent account. The deny propagates to the users under that account whether or not the users have existing policies granting them access.

For example, account A writes a bucket policy on account A's S3 bucket that explicitly denies account B access to account A's bucket. But account B writes an IAM user policy that grants a user in account B access to account A's bucket. The explicit deny applied to account A's S3 bucket propagates to the users in account B. It overrides the IAM user policy granting access to the user in account B. (For detailed information how permissions are evaluated, see [Policy evaluation logic](#).)

Account A's bucket policy might look like the following policy. In this example, account A's S3 bucket is named *mybucket*, and account B's account number is 1111-2222-3333. Account A uses Amazon S3 to implement this policy.

```
{
  "Version": "2012-10-17",
  "Statement": {
    "Sid": "AccountBDeny",
    "Effect": "Deny",
    "Principal": {"AWS": "111122223333"},
    "Action": "s3:*",
    "Resource": "arn:aws:s3:::mybucket/*"
  }
}
```

This explicit deny overrides any policies in account B that provide permission to access the S3 bucket in account A.

Using IAM roles

Before a user, application, or service can use a role that you created, you must grant permissions to switch to the role. You can use any policy attached to groups or users to grant the necessary permissions. This section describes how to grant users permission to use a role. It also explains

how the user can switch to a role from the AWS Management Console, the Tools for Windows PowerShell, the AWS Command Line Interface (AWS CLI) and the [AssumeRole](#) API.

Important

When you create a role programmatically instead of in the IAM console, you have an option to add a Path of up to 512 characters in addition to the RoleName, which can be up to 64 characters long. However, if you intend to use a role with the **Switch Role** feature in the AWS Management Console, then the combined Path and RoleName cannot exceed 64 characters.

You can switch roles from the AWS Management Console. You can assume a role by calling an AWS CLI or API operation or by using a custom URL. The method that you use determines who can assume the role and how long the role session can last. When using AssumeRole* API operations, the IAM role that you assume is the resource. The user or role that calls AssumeRole* API operations is the principal.

Comparing methods for using roles

Method of assuming the role	Who can assume the role	Method to specify credential lifetime	Credential lifetime (min max default)
AWS Management Console	User (by switching roles)	Maximum session duration on the Role Summary page	15m Maximum session duration setting ² 1hr
assume-role CLI or AssumeRole API operation	User or role ¹	duration-seconds CLI or DurationSeconds API parameter	15m Maximum session duration setting ² 1hr
assume-role-with-saml CLI or	Any user authenticated using SAML	duration-seconds CLI or DurationS	15m Maximum session duration setting ² 1hr

Method of assuming the role	Who can assume the role	Method to specify credential lifetime	Credential lifetime (min max default)
AssumeRoleWithSAML API operation		econds API parameter	
assume-role-with-web-identity CLI or AssumeRoleWithWebIdentity API operation	Any user authenticated using a web identity provider	duration-seconds CLI or DurationSeconds API parameter	15m Maximum session duration setting ² 1hr
Console URL constructed with AssumeRole	User or role	SessionDuration HTML parameter in the URL	15m 12hr 1hr
Console URL constructed with AssumeRoleWithSAML	Any user authenticated using SAML	SessionDuration HTML parameter in the URL	15m 12hr 1hr
Console URL constructed with AssumeRoleWithWebIdentity	Any user authenticated using a web identity provider	SessionDuration HTML parameter in the URL	15m 12hr 1hr

¹ Using the credentials for one role to assume a different role is called [role chaining](#). When you use role chaining, your new credentials are limited to a maximum duration of one hour. When you use

roles to [grant permissions to applications that run on EC2 instances](#), those applications are not subject to this limitation.

² This setting can have a value from 1 hour to 12 hours. For details about modifying the maximum session duration setting, see [Modifying a role](#). This setting determines the maximum session duration that you can request when you get the role credentials. For example, when you use the [AssumeRole*](#) API operations to assume a role, you can specify a session length using the `DurationSeconds` parameter. Use this parameter to specify the length of the role session from 900 seconds (15 minutes) up to the maximum session duration setting for the role. IAM users who switch roles in the console are granted the maximum session duration, or the remaining time in their user session, whichever is less. Assume that you set a maximum duration of 5 hours on a role. An IAM user that has been signed into the console for 10 hours (out of the default maximum of 12) switches to the role. The available role session duration is 2 hours. To learn how to view the maximum value for your role, see [View the maximum session duration setting for a role](#) later in this page.

Notes

- The maximum session duration setting does not limit sessions that are assumed by AWS services.
- Amazon EC2 IAM role credentials are not subject to maximum session durations configured in the role.
- To allow users to assume the current role again within a role session, specify the role ARN or AWS account ARN as a principal in the role trust policy. AWS services that provide compute resources such as Amazon EC2, Amazon ECS, Amazon EKS, and Lambda provide temporary credentials and automatically update these credentials. This ensures that you always have a valid set of credentials. For these services, it's not necessary to assume the current role again to obtain temporary credentials. However, if you intend to pass [session tags](#) or a [session policy](#), you need to assume the current role again. To learn how to modify a role trust policy to add the principal role ARN or AWS account ARN, see [Modifying a role trust policy \(console\)](#).

View the maximum session duration setting for a role

You can specify the maximum session duration for a role using the AWS Management Console or by using the AWS CLI or AWS API. When you use an AWS CLI or API operation to assume a role, you can specify a value for the `DurationSeconds` parameter. You can use this parameter to specify the duration of the role session, from 900 seconds (15 minutes) up to the maximum session duration setting for the role. Before you specify the parameter, you should view this setting for your role. If you specify a value for the `DurationSeconds` parameter that is higher than the maximum setting, the operation fails.

To view a role's maximum session duration (console)

1. In the navigation pane of the IAM console, choose **Roles**.
2. Choose the name of the role that you want to view.
3. Next to **Maximum session duration**, view the maximum session length that is granted for the role. This is the maximum session duration that you can specify in your AWS CLI, or API operation.

To view a role's maximum session duration setting (AWS CLI)

1. If you don't know the name of the role that you want to assume, run the following command to list the roles in your account:
 - [aws iam list-roles](#)
2. To view the role's maximum session duration, run the following command. Then view the maximum session duration parameter.
 - [aws iam get-role](#)

To view a role's maximum session duration setting (AWS API)

1. If you don't know the name of the role that you want to assume, call the following operation to list the roles in your account:
 - [ListRoles](#)
2. To view the role's maximum session duration, run the following operation. Then view the maximum session duration parameter.
 - [GetRole](#)

Granting a user permissions to switch roles

When an administrator [creates a role for cross-account access](#), they establish trust between the account that owns the role, the resources (trusting account), and the account that contains the users (trusted account). To do this, the administrator of the trusting account specifies the trusted account number as the `Principal` in the role's trust policy. That *potentially* allows any user in the trusted account to assume the role. To complete the configuration, the administrator of the trusted account must give specific groups or users in that account permission to switch to the role.

To grant permission to switch to a role

1. As the administrator of the trusted account, create a new policy for the user, or edit an existing policy to add the required elements. For details, see [Creating or editing the policy](#).
2. Then, choose how you want to share the role information:
 - **Role link:** Send users a link that takes them to the **Switch Role** page with all the details already filled in.
 - **Account ID or alias:** Provide each user with the role name along with the account ID number or account alias. The user then goes to the **Switch Role** page and adds the details manually.

For details, see [Providing information to the user](#).

Note that you can switch roles only when you sign in as an IAM user, a SAML-federated role, or a web-identity federated role. You cannot switch roles when you sign in as the AWS account root user.

Important

You cannot switch roles in the AWS Management Console to a role that requires an [ExternalId](#) value. You can switch to such a role only by calling the [AssumeRole](#) API that supports the `ExternalId` parameter.

Notes

- This topic discusses policies for a *user*, because you are ultimately granting permissions to a user to accomplish a task. However, we don't recommend that you grant permissions directly to an individual user. When a user assumes a role, they are assigned the permissions associated with that role.
- When you switch roles in the AWS Management Console, the console always uses your original credentials to authorize the switch. This applies whether you sign in as an IAM user, as a SAML-federated role, or as a web-identity federated role. For example, if you switch to RoleA, IAM uses your original user or federated role credentials to determine if you are allowed to assume RoleA. If you then try to switch to RoleB *while you are using RoleA*, your **original** user or federated role credentials are used to authorize your attempt. The credentials for RoleA are not used for this action.

Topics

- [Creating or editing the policy](#)
- [Providing information to the user](#)

Creating or editing the policy

A policy that grants a user permission to assume a role must include a statement with the `Allow` effect on the following:

- The `sts:AssumeRole` action
- The Amazon Resource Name (ARN) of the role in a `Resource` element

Users that get the policy are allowed to switch roles on the resource listed (either through group membership or directly attached).

Note

If Resource is set to *, the user can assume any role in any account that trusts the user's account. (In other words, the role's trust policy specifies the user's account as Principal). As a best practice, we recommend that you follow the [principle of least privilege](#) and specify the complete ARN for only the roles that the user needs.

The following example shows a policy that lets the user assume roles in only one account. In addition, the policy uses a wildcard (*) to specify that the user can switch to a role only if the role name begins with the letters Test.

```
{
  "Version": "2012-10-17",
  "Statement": {
    "Effect": "Allow",
    "Action": "sts:AssumeRole",
    "Resource": "arn:aws:iam::account-id:role/Test*"
  }
}
```

Note

The permissions that the role grants to the user do not add to the permissions already granted to the user. When a user switches to a role, the user temporarily gives up his or her original permissions in exchange for those granted by the role. When the user exits the role, then the original user permissions are automatically restored. For example, let's say the user's permissions allow working with Amazon EC2 instances, but the role's permissions policy does not grant those permissions. In that case, while using the role, the user cannot work with Amazon EC2 instances in the console. In addition, temporary credentials obtained via AssumeRole do not work with Amazon EC2 instances programmatically.

Providing information to the user

After you create a role and grant your user permissions to switch to it, you must provide the user with the following:

- The name of the role

- The ID or alias of the account that contains the role

You can streamline access for your users by sending them a link that is preconfigured with the account ID and role name. You can see the role link after completing the **Create Role** wizard by selecting the **View Role** banner, or on the **Role Summary** page for any cross-account enabled role.

You can also use the following format to manually construct the link. Substitute your account ID or alias and the role name for the two parameters in the following example.

```
https://signin.aws.amazon.com/switchrole?  
account=your_account_ID_or_alias&roleName=optional_path/role_name
```

We recommend that you direct your users to [Switching to a role \(console\)](#) to walk them through the process. To troubleshoot common issues that you might encounter when you assume a role, see [I can't assume a role](#).

Considerations

- If you create the role programmatically, you can create the role with a path and a name. If you do so, you must provide the complete path and role name to your users so they can enter it on the **Switch Role** page of the AWS Management Console. For example: `division_abc/subdivision_efg/role_XYZ`.
- If you create the role programmatically, you can add a Path of up to 512 characters and a RoleName. The role name can be up to 64 characters long. However, to use a role with the **Switch Role** feature in the AWS Management Console, the combined Path and RoleName cannot exceed 64 characters.
- For security purposes, you can [review AWS CloudTrail logs](#) to learn who performed an action in AWS. You can use the `sts:SourceIdentity` condition key in the role trust policy to require users to specify an identity when they assume a role. For example, you can require that IAM users specify their own user name as their source identity. This can help you determine which user performed a specific action in AWS. For more information, see [sts:SourceIdentity](#). You can also use [sts:RoleSessionName](#) to require users to specify a session name when they assume a role. This can help you differentiate between role sessions when a role is used by different principals.

Granting a user permissions to pass a role to an AWS service

To configure many AWS services, you must *pass* an IAM role to the service. This allows the service to assume the role later and perform actions on your behalf. For most services, you only have to pass the role to the service once during setup, and not every time that the service assumes the role. For example, assume that you have an application running on an Amazon EC2 instance. That application requires temporary credentials for authentication, and permissions to authorize the application to perform actions in AWS. When you set up the application, you must pass a role to Amazon EC2 to use with the instance that provides those credentials. You define the permissions for the applications running on the instance by attaching an IAM policy to the role. The application assumes the role every time it needs to perform the actions that are allowed by the role.

To pass a role (and its permissions) to an AWS service, a user must have permissions to *pass the role* to the service. This helps administrators ensure that only approved users can configure a service with a role that grants permissions. To allow a user to pass a role to an AWS service, you must grant the `PassRole` permission to the user's IAM user, role, or group.

Warning

- You can only use the `PassRole` permission to pass an IAM role to a service that shares the same AWS account. To pass a role in Account A to a service in Account B, you must first create an IAM role in Account B that can assume the role from Account A, and then the role in Account B can be passed to the service. For details, see [Cross account resource access in IAM](#).
- Do not try to control who can pass a role by tagging the role and then using the `ResourceTag` condition key in a policy with the `iam:PassRole` action. This approach does not have reliable results.

When setting the `PassRole` permission, you should make sure that a user doesn't pass a role where the role has more permissions than you want the user to have. For example, Alice might not be allowed to perform any Amazon S3 actions. If Alice could pass a role to a service that allows Amazon S3 actions, the service could perform Amazon S3 actions on behalf of Alice when executing the job.

When you specify a service-linked role, you must also have permission to pass that role to the service. Some services automatically create a service-linked role in your account when

you perform an action in that service. For example, Amazon EC2 Auto Scaling creates the `AWSServiceRoleForAutoScaling` service-linked role for you when you create an Auto Scaling group for the first time. If you try to specify the service-linked role when you create an Auto Scaling group and you don't have the `iam:PassRole` permission, you receive an error. If you don't explicitly specify the role, the `iam:PassRole` permission is not required, and the default is to use `AWSServiceRoleForAutoScaling` role for all operations that are performed on that group. To learn which services support service-linked roles, see [AWS services that work with IAM](#). To learn which services automatically create a service-linked role when you perform an action in that service, choose the **Yes** link and view the service-linked role documentation for the service.

A user can pass a role ARN as a parameter in any API operation that uses the role to assign permissions to the service. The service then checks whether that user has the `iam:PassRole` permission. To limit the user to passing only approved roles, you can filter the `iam:PassRole` permission with the `Resources` element of the IAM policy statement.

You can use the `Condition` element in a JSON policy to test the value of keys included in the request context of all AWS requests. To learn more about using condition keys in a policy, see [IAM JSON policy elements: Condition](#). The `iam:PassedToService` condition key can be used to specify the service principal of the service to which a role can be passed. To learn more about using the `iam:PassedToService` condition key in a policy, see [iam:PassedToService](#).

Example 1

Suppose you want to grant a user the ability to pass any of an approved set of roles to the Amazon EC2 service upon launching an instance. You need three elements:

- An IAM *permissions policy* attached to the role that determines what the role can do. Scope permissions to only the actions that the role must perform, and to only the resources that the role needs for those actions. You can use an AWS managed or customer-created IAM permissions policy.

```
{
  "Version": "2012-10-17",
  "Statement": {
    "Effect": "Allow",
    "Action": [ "A list of the permissions the role is allowed to use" ],
    "Resource": [ "A list of the resources the role is allowed to access" ]
  }
}
```

- A *trust policy* for the role that allows the service to assume the role. For example, you could attach the following trust policy to the role with the `UpdateAssumeRolePolicy` action. This trust policy allows Amazon EC2 to use the role and the permissions attached to the role.

```
{
  "Version": "2012-10-17",
  "Statement": {
    "Sid": "TrustPolicyStatementThatAllowsEC2ServiceToAssumeTheAttachedRole",
    "Effect": "Allow",
    "Principal": { "Service": "ec2.amazonaws.com" },
    "Action": "sts:AssumeRole"
  }
}
```

- An IAM *permissions policy* attached to the IAM user that allows the user to pass only those approved roles. You usually add `iam:GetRole` to `iam:PassRole` so the user can get the details of the role to be passed. In this example, the user can pass only roles that exist in the specified account with names beginning with `EC2-roles-for-XYZ-`:

```
{
  "Version": "2012-10-17",
  "Statement": [{
    "Effect": "Allow",
    "Action": [
      "iam:GetRole",
      "iam:PassRole"
    ],
    "Resource": "arn:aws:iam::account-id:role/EC2-roles-for-XYZ-*"
  }]
}
```

Now the user can start an Amazon EC2 instance with an assigned role. Applications running on the instance can access temporary credentials for the role through the instance profile metadata. The permissions policies attached to the role determine what the instance can do.

Example 2

Amazon Relational Database Service (Amazon RDS) supports a feature called **Enhanced Monitoring**. This feature enables Amazon RDS to monitor a database instance using an agent. It also allows Amazon RDS to log metrics to Amazon CloudWatch Logs. To enable this feature, you

must create a service role to give Amazon RDS permissions to monitor and write metrics to your logs.

To create a role for Amazon RDS enhanced monitoring

1. Sign in to the AWS Management Console and open the IAM console at <https://console.aws.amazon.com/iam/>.
2. Choose **Roles**, and then choose **Create role**.
3. Choose the **AWS Service** role type, and then for **Use cases for other AWS services**, choose the **RDS** service. Choose **RDS – Enhanced Monitoring**, and then choose **Next**.
4. Choose the **AmazonRDSEnhancedMonitoringRole** permissions policy.
5. Choose **Next**.
6. For **Role name**, enter a role name that helps you identify the purpose of this role. Role names must be unique within your AWS account. When a role name is used in a policy or as part of an ARN, the role name is case sensitive. When a role name appears to customers in the console, such as during the sign-in process, the role name is case insensitive. Because various entities might reference the role, you can't edit the name of the role after it is created.
7. (Optional) For **Description**, enter a description for the new role.
8. (Optional) Add metadata to the user by attaching tags as key-value pairs. For more information about using tags in IAM, see [Tagging IAM resources](#).
9. Review the role and then choose **Create role**.

The role automatically gets a trust policy that grants the `monitoring.rds.amazonaws.com` service permissions to assume the role. After it does, Amazon RDS can perform all of the actions that the `AmazonRDSEnhancedMonitoringRole` policy allows.

The user that you want to access Enhanced Monitoring needs a policy that includes a statement that allows the user to list the RDS roles and a statement that allows the user to pass the role, like the following. Use your account number and replace the role name with the name you provided in step 6.

```
{
  "Sid": "PolicyStatementToAllowUserToListRoles",
  "Effect": "Allow",
  "Action": ["iam:ListRoles"],
  "Resource": "*"
},
```

```
{
  "Sid": "PolicyStatementToAllowUserToPassOneSpecificRole",
  "Effect": "Allow",
  "Action": [ "iam:PassRole" ],
  "Resource": "arn:aws:iam::account-id:role/RDS-Monitoring-Role"
}
```

You can combine this statement with statements in another policy or put it in its own policy. To instead specify that the user can pass any role that begins with RDS-, you can replace the role name in the resource ARN with a wildcard, as follows.

```
"Resource": "arn:aws:iam::account-id:role/RDS-*
```

iam:PassRole actions in AWS CloudTrail logs

PassRole is not an API call. PassRole is a permission, meaning no CloudTrail logs are generated for IAM PassRole. To review what roles are passed to which AWS services in CloudTrail, you must review the CloudTrail log that created or modified the AWS resource receiving the role. For example, a role is passed to an AWS Lambda function when it's created. The log for the CreateFunction action shows a record of role that was passed to the function.

Switching to a role (console)

A *role* specifies a set of permissions that you can use to access AWS resources that you need. In that sense, it is similar to a [user in AWS Identity and Access Management](#) (IAM). When you sign in as a user, you get a specific set of permissions. However, you don't sign in to a role, but once signed in you can switch to a role. This temporarily sets aside your original user permissions and instead gives you the permissions assigned to the role. The role can be in your own account or any other AWS account. For more information about roles, their benefits, and how to create them, see [IAM roles](#), and [Creating IAM roles](#).

Important

The permissions of your user and any roles that you switch to are not cumulative. Only one set of permissions is active at a time. When you switch to a role, you temporarily give up your user permissions and work with the permissions that are assigned to the role. When you exit the role, your user permissions are automatically restored.

When you switch roles in the AWS Management Console, the console always uses your original credentials to authorize the switch. This applies whether you sign in as an IAM user, a user in IAM Identity Center, as a SAML-federated role, or as a web-identity federated role. For example, if you switch to RoleA, IAM uses your original user or federated role credentials to determine whether you are allowed to assume RoleA. If you then switch to RoleB *while you are using RoleA*, AWS still uses your **original** user or federated role credentials to authorize the switch, not the credentials for RoleA.

Things to know about switching roles in the console

This section provides additional information about using the IAM console to switch to a role.

Notes:

- You cannot switch roles if you sign in as the AWS account root user. You can switch roles when you sign in as an IAM user, a user in IAM Identity Center, a SAML-federated role, or a web-identity federated role.
 - You cannot switch roles in the AWS Management Console to a role that requires an [ExternalId](#) value. You can switch to such a role only by calling the [AssumeRole](#) API that supports the `ExternalId` parameter.
- If your administrator gives you a link, choose the link and then skip to step [Step 5](#) in the following procedure. The link takes you to the appropriate webpage and fills in the account ID (or alias) and the role name.
 - You can manually construct the link and then skip to step [Step 5](#) in the following procedure. To construct your link, use the following format:

```
https://signin.aws.amazon.com/switchrole?  
account=account_id_number&roleName=role_name&displayName=text_to_display
```

Where you replace the following text:

- *account_id_number* – The 12-digit account identifier provided to you by your administrator. Alternatively, your administrator might create an account alias so that the URL includes your account name instead of an account ID. For more information, see [User Types](#) in the *AWS Sign-In User Guide*.

- *role_name* – The name of the role that you want to assume. You can get this from the end of the role's ARN. For example, provide the TestRole role name from the following role ARN: `arn:aws:iam::123456789012:role/TestRole`.
- (Optional) *text_to_display* – The text that you want to appear on the navigation bar in place of your user name when this role is active.
- You can manually switch roles using the information your administrator provides by using the procedures that follow.

By default, when you switch roles, your AWS Management Console session lasts for 1 hour. IAM user sessions are 12 hours by default. IAM users who switch roles in the console are granted the role maximum session duration, or the remaining time in the user's session, whichever is less. For example, assume that a maximum session duration of 10 hours is set for a role. An IAM user has been signed in to the console for 8 hours when they decide to switch to the role. There are 4 hours remaining in the user session, so the allowed role session duration is 4 hours. The following table shows how to determine the session duration for an IAM user when switching roles in the console.

IAM users console role session duration

IAM user session time remaining is...	Role session duration is...		
Less than role maximum session duration	Time remaining in user session		
Greater than role maximum session duration	Maximum session duration value		
Equal to role maximum session duration	Maximum session duration value (approximate)		

Note

Some AWS service consoles can autorenew your role session when it expires without you taking any action. Some might prompt you to reload your browser page to reauthenticate your session.

To troubleshoot common issues that you might encounter when you assume a role, see [I can't assume a role](#).

To switch to a role (console)

1. Sign in to the AWS Management Console as an IAM user and open the IAM console at <https://console.aws.amazon.com/iam/>.
2. In the IAM console, choose your user name on the navigation bar in the upper right. It typically looks like this: **username@account_ID_number_or_alias**.
3. Choose **Switch Role**. If this is the first time choosing this option, a page appears with more information. After reading it, choose **Switch Role**. If you clear your browser cookies, this page can appear again.
4. On the **Switch Role** page, type the account ID number or the account alias and the name of the role that was provided by your administrator.

Note

If your administrator created the role with a path, such as `division_abc/subdivision_efg/roleToDoX`, then you must type that complete path and name in the **Role** box. If you type only the role name, or if the combined Path and RoleName exceed 64 characters, the role switch fails. This is a limit of the browser cookies that store the role name. If this happens, contact your administrator and ask them to reduce the size of the path and role name.

5. (Optional) Choose a **Display name**. Type text that you want to appear on the navigation bar in place of your user name when this role is active. A name is suggested, based on the account and role information, but you can change it to whatever has meaning for you. You can also select a color to highlight the display name. The name and color can help remind you when this role is active, which changes your permissions. For example, for a role that gives you access to the test environment, you might specify a **Display name** of **Test** and select the

green **Color**. For the role that gives you access to production, you might specify a **Display name** of **Production** and select red as the **Color**.

6. Choose **Switch Role**. The display name and color replace your user name on the navigation bar, and you can start using the permissions that the role grants you.

 **Tip**

The last several roles that you used appear on the menu. The next time you need to switch to one of those roles, you can simply choose the role you want. You only need to type the account and role information manually if the role is not displayed on the menu.

To stop using a role (console)

1. In the IAM console, choose your role's **Display name** on the navigation bar in the upper right. It typically looks like this: *rolename@account_ID_number_or_alias*.
2. Choose **Back to *username***. The role and its permissions are deactivated, and the permissions associated with your IAM user and groups are automatically restored.

For example, assume you are signed in to account number 123456789012 using the user name RichardRoe. After you use the AdminRole role, you want to stop using the role and return to your original permissions. To stop using a role, choose **AdminRole @ 123456789012**, and then choose **Back to RichardRoe**.

Switching to an IAM role (AWS CLI)

A *role* specifies a set of permissions that you can use to access AWS resources that you need. In that sense, it is similar to a [user in AWS Identity and Access Management \(IAM\)](#). When you sign in as a user, you get a specific set of permissions. However, you don't sign in to a role, but after signing in as a user, you can switch to a role. This temporarily sets aside your original user permissions and instead gives you the permissions assigned to the role. The role can be in your own account or any other AWS account. For more information about roles, their benefits, and how to create and configure them, see [IAM roles](#), and [Creating IAM roles](#). To learn about the different methods that you can use to assume a role, see [Using IAM roles](#).

⚠ Important

The permissions of your IAM user and any roles that you assume are not cumulative. Only one set of permissions is active at a time. When you assume a role, you temporarily give up your previous user or role permissions and work with the permissions that are assigned to the role. When you exit the role, your user permissions are automatically restored.

You can use a role to run an AWS CLI command when you are signed in as an IAM user. You can also use a role to run an AWS CLI command when you are signed in as an [externally authenticated](#)

[user](#) ([SAML](#) or [OIDC](#)) that is already using a role. In addition, you can use a role to run an AWS CLI command from within an Amazon EC2 instance that is attached to a role through its instance profile. You cannot assume a role when you are signed in as the AWS account root user.

[Role chaining](#) – You can also use role chaining, which is using permissions from a role to access a second role.

By default, your role session lasts for one hour. When you assume this role using the `assume-role*` CLI operations, you can specify a value for the `duration-seconds` parameter. This value can range from 900 seconds (15 minutes) up to the maximum session duration setting for the role. If you switch roles in the console, your session duration is limited to maximum of one hour. To learn how to view the maximum value for your role, see [View the maximum session duration setting for a role](#).

If you use role chaining, your session duration is limited to a maximum of one hour. If you then use the `duration-seconds` parameter to provide a value greater than one hour, the operation fails.

Example scenario: Switch to a production role

Imagine that you are an IAM user for working in the development environment. In this scenario, you occasionally need to work with the production environment at the command line with the [AWS CLI](#). You already have an access key credential set available to you. This can be the access key pair that is assigned to your standard IAM user. Or, if you signed in as a federated user, it can be the access key pair for the role that was initially assigned to you. If your current permissions grant you the ability to assume a specific IAM role, then you can identify that role in a "profile" in the AWS CLI configuration files. That command is then run with the permissions of the specified IAM role, not the original identity. Note that when you specify that profile in an AWS CLI command, you are using the new role. In this situation, you cannot make use of your original permissions in the development account at the same time. The reason is that only one set of permissions can be in effect at a time.

Note

For security purposes, administrators can [review AWS CloudTrail logs](#) to learn who performed an action in AWS. Your administrator might require that you specify a source identity or a role session name when you assume the role. For more information, see [sts:SourceIdentity](#) and [sts:RoleSessionName](#).

To switch to a production role (AWS CLI)

1. If you have never used the AWS CLI, then you must first configure your default CLI profile. Open a command prompt and set up your AWS CLI installation to use the access key from your IAM user or from your federated role. For more information, see [Configuring the AWS Command Line Interface](#) in the *AWS Command Line Interface User Guide*.

Run the [aws configure](#) command as follows:

```
aws configure
```

When prompted, provide the following information:

```
AWS Access Key ID [None]: AKIAIOSFODNN7EXAMPLE
AWS Secret Access Key [None]: wJalrXUtnFEMI/K7MDENG/bPxrFiCYEXAMPLEKEY
Default region name [None]: us-east-2
Default output format [None]: json
```

2. Create a new profile for the role in the `.aws/config` file in Unix or Linux, or the `C:\Users\USERNAME\.aws\config` file in Windows. The following example creates a profile called `prodaccess` that switches to the role `ProductionAccessRole` in the `123456789012` account. You get the role ARN from the account administrator who created the role. When this profile is invoked, the AWS CLI uses the credentials of the `source_profile` to request credentials for the role. Because of that, the identity referenced as the `source_profile` must have `sts:AssumeRole` permissions to the role that is specified in the `role_arn`.

```
[profile prodaccess]
  role_arn = arn:aws:iam::123456789012:role/ProductionAccessRole
  source_profile = default
```

3. After you create the new profile, any AWS CLI command that specifies the parameter `--profile prodaccess` runs under the permissions that are attached to the IAM role `ProductionAccessRole` instead of the default user.

```
aws iam list-users --profile prodaccess
```

This command works if the permissions assigned to the `ProductionAccessRole` enable listing the users in the current AWS account.

4. To return to the permissions granted by your original credentials, run commands without the `--profile` parameter. The AWS CLI reverts to using the credentials in your default profile, which you configured in [Step 1](#).

For more information, see [Assuming a Role](#) in the *AWS Command Line Interface User Guide*.

Example scenario: Allow an instance profile role to switch to a role in another account

Imagine that you are using two AWS accounts, and you want to allow an application running on an Amazon EC2 instance to run [AWS CLI](#) commands in both accounts. Assume that the EC2 instance exists in account 111111111111. That instance includes the `abcd` instance profile role that allows the application to perform read-only Amazon S3 tasks on the `my-bucket-1` bucket within the same 111111111111 account. However, the application must also be allowed to assume the `efgh` cross-account role to perform tasks in account 222222222222. To do this, the `abcd` EC2 instance profile role must have the following permissions policy:

Account 111111111111 abcd role permissions policy

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "AllowAccountLevelS3Actions",
      "Effect": "Allow",
      "Action": [
        "s3:GetBucketLocation",
        "s3:GetAccountPublicAccessBlock",
        "s3:ListAccessPoints",
        "s3:ListAllMyBuckets"
      ],
      "Resource": "arn:aws:s3::*:*"
    },
    {
      "Sid": "AllowListAndReadS3ActionOnMyBucket",
      "Effect": "Allow",
      "Action": [
        "s3:Get*",
        "s3:List*"
      ],
      "Resource": [
        "arn:aws:s3:::my-bucket-1/*",
        "arn:aws:s3:::my-bucket-1"
      ]
    }
  ]
}
```

```

    ]
  },
  {
    "Sid": "AllowIPToAssumeCrossAccountRole",
    "Effect": "Allow",
    "Action": "sts:AssumeRole",
    "Resource": "arn:aws:iam::222222222222:role/efgh"
  }
]
}

```

Assume that the `efgh` cross-account role allows read-only Amazon S3 tasks on the `my-bucket-2` bucket within the same `222222222222` account. To do this, the `efgh` cross-account role must have the following permissions policy:

Account 222222222222 `efgh` role permissions policy

```

{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "AllowAccountLevelS3Actions",
      "Effect": "Allow",
      "Action": [
        "s3:GetBucketLocation",
        "s3:GetAccountPublicAccessBlock",
        "s3:ListAccessPoints",
        "s3:ListAllMyBuckets"
      ],
      "Resource": "arn:aws:s3:::*"
    },
    {
      "Sid": "AllowListAndReadS3ActionOnMyBucket",
      "Effect": "Allow",
      "Action": [
        "s3:Get*",
        "s3:List*"
      ],
      "Resource": [
        "arn:aws:s3:::my-bucket-2/*",
        "arn:aws:s3:::my-bucket-2"
      ]
    }
  ]
}

```

```
    ]
  }
}
```

The `efgh` role must allow the `abcd` instance profile role to assume it. To do this, the `efgh` role must have the following trust policy:

Account 222222222222 `efgh` role trust policy

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "efghTrustPolicy",
      "Effect": "Allow",
      "Action": "sts:AssumeRole",
      "Principal": {"AWS": "arn:aws:iam::111111111111:role/abcd"}
    }
  ]
}
```

To then run AWS CLI commands in account 222222222222, you must update the CLI configuration file. Identify the `efgh` role as the "profile" and the `abcd` EC2 instance profile role as the "credential source" in the AWS CLI configuration file. Then your CLI commands are run with the permissions of the `efgh` role, not the original `abcd` role.

Note

For security purposes, you can use AWS CloudTrail to audit the use of roles in the account. To differentiate between role sessions when a role is used by different principals in CloudTrail logs, you can use the role session name. When the AWS CLI assumes a role on a user's behalf as described in this topic, a role session name is automatically created as `AWS-CLI-session-nnnnnnnn`. Here *nnnnnnnn* is an integer that represents the time in [Unix epoch time](#) (the number of seconds since midnight UTC on January 1, 1970). For more information, see [CloudTrail Event Reference](#) in the *AWS CloudTrail User Guide*.

To allow an EC2 instance profile role to switch to a cross-account role (AWS CLI)

1. You do not have to configure a default CLI profile. Instead, you can load credentials from the EC2 instance profile metadata. Create a new profile for the role in the `.aws/config` file. The

following example creates an `instancecrossaccount` profile that switches to the role `efgh` in the `222222222222` account. When this profile is invoked, the AWS CLI uses the credentials of the EC2 instance profile metadata to request credentials for the role. Because of that, the EC2 instance profile role must have `sts:AssumeRole` permissions to the role specified in the `role_arn`.

```
[profile instancecrossaccount]
role_arn = arn:aws:iam::222222222222:role/efgh
credential_source = Ec2InstanceMetadata
```

2. After you create the new profile, any AWS CLI command that specifies the parameter `--profile instancecrossaccount` runs under the permissions that are attached to the `efgh` role in account `222222222222`.

```
aws s3 ls my-bucket-2 --profile instancecrossaccount
```

This command works if the permissions that are assigned to the `efgh` role allow listing the users in the current AWS account.

3. To return to the original EC2 instance profile permissions in account `111111111111`, run the CLI commands without the `--profile` parameter.

For more information, see [Assuming a Role](#) in the *AWS Command Line Interface User Guide*.

Switching to an IAM role (Tools for Windows PowerShell)

A *role* specifies a set of permissions that you can use to access AWS resources that you need. In that sense, it is similar to a [user in AWS Identity and Access Management](#) (IAM). When you sign in as a user, you get a specific set of permissions. However, you don't sign in to a role, but once signed in you can switch to a role. This temporarily sets aside your original user permissions and instead gives you the permissions assigned to the role. The role can be in your own account or any other AWS account. For more information about roles, their benefits, and how to create and configure them, see [IAM roles](#), and [Creating IAM roles](#).

Important

The permissions of your IAM user and any roles that you switch to are not cumulative. Only one set of permissions is active at a time. When you switch to a role, you temporarily

give up your user permissions and work with the permissions that are assigned to the role. When you exit the role, your user permissions are automatically restored.

This section describes how to switch roles when you work at the command line with the AWS Tools for Windows PowerShell.

Imagine that you have an account in the development environment and you occasionally need to work with the production environment at the command line using the [Tools for Windows PowerShell](#). You already have one access key credential set available to you. These can be an access key pair assigned to your standard IAM user. Or, if you signed-in as a federated user, they can be the access key pair for the role initially assigned to you. You can use these credentials to run the `Use-STSRole` cmdlet that passes the ARN of a new role as a parameter. The command returns temporary security credentials for the requested role. You can then use those credentials in subsequent PowerShell commands with the role's permissions to access resources in production. While you use the role, you cannot use your user permissions in the Development account because only one set of permissions is in effect at a time.

Note

For security purposes, administrators can [review AWS CloudTrail logs](#) to learn who performed an action in AWS. Your administrator might require that you specify a source identity or a role session name when you assume the role. For more information, see [sts:SourceIdentity](#) and [sts:RoleSessionName](#).

Note that all access keys and tokens are examples only and cannot be used as shown. Replace with the appropriate values from your live environment.

To switch to a role (Tools for Windows PowerShell)

1. Open a PowerShell command prompt and configure the default profile to use the access key from your current IAM user or from your federated role. If you have previously used the Tools for Windows PowerShell, then this is likely already done. Note that you can switch roles only if you are signed in as an IAM user, not the AWS account root user.

```
PS C:\> Set-AWSCredentials -AccessKey AKIAIOSFODNN7EXAMPLE -  
SecretKey wJalrXUtnFEMI/K7MDENG/bPxrFiCYEXAMPLEKEY -StoreAs MyMainUserProfile
```

```
PS C:\> Initialize-AWSDefaults -ProfileName MyMainUserProfile -Region us-east-2
```

For more information, see [Using AWS Credentials](#) in the *AWS Tools for Windows PowerShell User Guide*.

2. To retrieve credentials for the new role, run the following command to switch to the **RoLeName** role in the 123456789012 account. You get the role ARN from the account administrator who created the role. The command requires that you provide a session name as well. You can choose any text for that. The following command requests the credentials and then captures the `Credentials` property object from the returned results object and stores it in the `$Creds` variable.

```
PS C:\> $Creds = (Use-STSRole -RoleArn "arn:aws:iam::123456789012:role/RoLeName" -  
RoleSessionName "MyRoLeSessionName").Credentials
```

`$Creds` is an object that now contains the `AccessKeyId`, `SecretAccessKey`, and `SessionToken` elements that you need in the following steps. The following sample commands illustrate typical values:

```
PS C:\> $Creds.AccessKeyId  
AKIAIOSFODNN7EXAMPLE
```

```
PS C:\> $Creds.SecretAccessKey  
wJalrXUtnFEMI/K7MDENG/bPxRfiCYEXAMPLEKEY
```

```
PS C:\> $Creds.SessionToken  
AQoDYXdzEGcaEXAMPLE2gsYULo  
+Im5ZEXAMPLEeYjs1M2FUIgIJx9tQqNMBEXAMPLECvSRyh0FW7jEXAMPLEW+vE/7s1HRp  
XviG7b+qYf4nD00EXAMPLEmj4wxS04L/uZEXAMPLECiHzFB51TYLto9dyBgSDyEXAMPLE9/  
g7QRUhZp4bqbEXAMPLENwGPY  
0j59pFA41NKCikVgkREXAMPLEj1zxQ7y52gekeVEXAMPLEDiB9ST3UuysgsKdEXAMPLE1TVastU1A0SKFEXAMPLEIyw  
C  
s8EXAMPLEpZg0s+6hz4AP4KEXAMPLERbASP+4eZScEXAMPLEsnf87eNhyDHq6ikBQ==
```

```
PS C:\> $Creds.Expiration  
Thursday, June 18, 2018 2:28:31 PM
```

3. To use these credentials for any subsequent command, include them with the `-Credential` parameter. For example, the following command uses the credentials from the role and works only if the role is granted the `iam:ListRoles` permission and can therefore run the `Get-IAMRoles` cmdlet:

```
PS C:\> get-iamroles -Credential $Creds
```

4. To return to your original credentials, simply stop using the `-Credentials $Creds` parameter and allow PowerShell to revert to the credentials that are stored in the default profile.

Switching to an IAM role (AWS API)

A *role* specifies a set of permissions that you can use to access AWS resources. In that sense, it is similar to an [IAM user](#). A principal (person or application) assumes a role to receive temporary permissions to carry out required tasks and interact with AWS resources. The role can be in your own account or any other AWS account. For more information about roles, their benefits, and how to create and configure them, see [IAM roles](#), and [Creating IAM roles](#). To learn about the different methods that you can use to assume a role, see [Using IAM roles](#).

Important

The permissions of your IAM user and any roles that you assume are not cumulative. Only one set of permissions is active at a time. When you assume a role, you temporarily give up your previous user or role permissions and work with the permissions that are assigned to the role. When you exit the role, your original permissions are automatically restored.

To assume a role, an application calls the AWS STS [AssumeRole](#) API operation and passes the ARN of the role to use. The operation creates a new session with temporary credentials. This session has the same permissions as the identity-based policies for that role.

When you call [AssumeRole](#), you can optionally pass inline or managed [session policies](#). Session policies are advanced policies that you pass as a parameter when you programmatically create a temporary credential session for a role or federated user. You can pass a single JSON inline session policy document using the `Policy` parameter. You can use the `PolicyArns` parameter to specify up to 10 managed session policies. The resulting session's permissions are the intersection of the entity's identity-based policies and the session policies. Session policies are useful when you need to give the role's temporary credentials to someone else. They can use the role's temporary credentials in subsequent AWS API calls to access resources in the account that owns the role. You

cannot use session policies to grant more permissions than those allowed by the identity-based policy. To learn more about how AWS determines the effective permissions of a role, see [Policy evaluation logic](#).

You can call `AssumeRole` when you are signed in as an IAM user, or as an [externally authenticated user](#) ([SAML](#) or [OIDC](#)) already using a role. You can also use [role chaining](#), which is using a role to assume a second role. You cannot assume a role when you are signed in as the AWS account root user.

By default, your role session lasts for one hour. When you assume this role using the AWS STS [AssumeRole*](#) API operations, you can specify a value for the `DurationSeconds` parameter. This value can range from 900 seconds (15 minutes) up to the maximum session duration setting for the role. To learn how to view the maximum value for your role, see [View the maximum session duration setting for a role](#).

If you use role chaining, your session is limited to a maximum of one hour. If you then use the `DurationSeconds` parameter to provide a value greater than one hour, the operation fails.

Note

For security purposes, administrators can [review AWS CloudTrail logs](#) to learn who performed an action in AWS. Your administrator might require that you specify a source identity or a role session name when you assume the role. For more information, see [sts:SourceIdentity](#) and [sts:RoleSessionName](#).

The following code examples show how to create a user and assume a role.

⚠ Warning

To avoid security risks, don't use IAM users for authentication when developing purpose-built software or working with real data. Instead, use federation with an identity provider such as [AWS IAM Identity Center](#).

- Create a user with no permissions.
- Create a role that grants permission to list Amazon S3 buckets for the account.
- Add a policy to let the user assume the role.
- Assume the role and list S3 buckets using temporary credentials, then clean up resources.

.NET

AWS SDK for .NET**📘 Note**

There's more on GitHub. Find the complete example and learn how to set up and run in the [AWS Code Examples Repository](#).

```
#####
# function iam_create_user_assume_role
#
# Scenario to create an IAM user, create an IAM role, and apply the role to the
# user.
#
# "IAM access" permissions are needed to run this code.
# "STS assume role" permissions are needed to run this code. (Note: It might
# be necessary to
# create a custom policy).
#
# Returns:
# 0 - If successful.
# 1 - If an error occurred.

Go

SDK for Go V2

Note

There's more on GitHub. Find the complete example and learn how to set up and run in the [AWS Code Examples Repository](#).

Run an interactive scenario at a command prompt.

```
// AssumeRoleScenario shows you how to use the AWS Identity and Access Management
// (IAM)
// service to perform the following actions:
//
// 1. Create a user who has no permissions.
// 2. Create a role that grants permission to list Amazon Simple Storage Service
//    (Amazon S3) buckets for the account.
// 3. Add a policy to let the user assume the role.
// 4. Try and fail to list buckets without permissions.
// 5. Assume the role and list S3 buckets using temporary credentials.
// 6. Delete the policy, role, and user.

Java

SDK for Java 2.x

Note

There's more on GitHub. Find the complete example and learn how to set up and run in the [AWS Code Examples Repository](#).

Create functions that wrap IAM user actions.

```
/*  
  To run this Java V2 code example, set up your development environment,  
  including your credentials.  
  
  For information, see this documentation topic:  
  
  https://docs.aws.amazon.com/sdk-for-java/latest/developer-guide/get-  
  started.html  
  
  This example performs these operations:
```

1. Creates a user that has no permissions.
2. Creates a role and policy that grants Amazon S3 permissions.
3. Creates a role.
4. Grants the user permissions.
5. Gets temporary credentials by assuming the role. Creates an Amazon S3 Service client object with the temporary credentials.
6. Deletes the resources.

```
*/
```

```

Using an IAM role to grant permissions to applications running on Amazon EC2 instances

Applications that run on an Amazon EC2 instance must include AWS credentials in the AWS API requests. You could have your developers store AWS credentials directly within the Amazon EC2 instance and allow applications in that instance to use those credentials. But developers would

then have to manage the credentials and ensure that they securely pass the credentials to each instance and update each Amazon EC2 instance when it's time to update the credentials. That's a lot of additional work.

Instead, you can and should use an IAM role to manage *temporary* credentials for applications that run on an Amazon EC2 instance. When you use a role, you don't have to distribute long-term credentials (such as sign-in credentials or access keys) to an Amazon EC2 instance. Instead, the role supplies temporary permissions that applications can use when they make calls to other AWS resources. When you launch an Amazon EC2 instance, you specify an IAM role to associate with the instance. Applications that run on the instance can then use the role-supplied temporary credentials to sign API requests.

Using roles to grant permissions to applications that run on Amazon EC2 instances requires a bit of extra configuration. An application running on an Amazon EC2 instance is abstracted from AWS by the virtualized operating system. Because of this extra separation, you need an additional step to assign an AWS role and its associated permissions to an Amazon EC2 instance and make them available to its applications. This extra step is the creation of an [instance profile](#) attached to the instance. The instance profile contains the role and can provide the role's temporary credentials to an application that runs on the instance. Those temporary credentials can then be used in the application's API calls to access resources and to limit access to only those resources that the role specifies.

Note

Only one role can be assigned to an Amazon EC2 instance at a time, and all applications on the instance share the same role and permissions. When you leverage Amazon ECS to manage your Amazon EC2 instances, you can assign roles to Amazon ECS tasks that can be distinguished from the role of the Amazon EC2 instance that it's running on. Assigning each task a role aligns with the principle of least privileged access and allows for greater granular control over actions and resources.

For more information, see [Using IAM roles with Amazon ECS tasks](#) in the *Amazon Elastic Container Service Best Practices Guide*.

Using roles in this way has several benefits. Because role credentials are temporary and updated automatically, you don't have to manage credentials, and you don't have to worry about long-term security risks. In addition, if you use a single role for multiple instances, you can make a change to that one role and the change propagates automatically to all the instances.

Note

Although a role is usually assigned to an Amazon EC2 instance when you launch it, a role can also be attached to an Amazon EC2 instance currently running. To learn how to attach a role to a running instance, see [IAM Roles for Amazon EC2](#).

How do roles for Amazon EC2 instances work?

In the following figure, a developer runs an application on an Amazon EC2 instance that requires access to the S3 bucket named photos. An administrator creates the Get-pics service role and attaches the role to the Amazon EC2 instance. The role includes a permissions policy that grants read-only access to the specified S3 bucket. It also includes a trust policy that allows the Amazon EC2 instance to assume the role and retrieve the temporary credentials. When the application runs on the instance, it can use the role's temporary credentials to access the photos bucket. The administrator doesn't have to grant the developer permission to access the photos bucket, and the developer never has to share or manage credentials.

1. The administrator uses IAM to create the **Get-pics** role. In the role's trust policy, the administrator specifies that only Amazon EC2 instances can assume the role. In the role's permission policy, the administrator specifies read-only permissions for the photos bucket.
2. A developer launches an Amazon EC2 instance and assigns the `Get-pics` role to that instance.

 **Note**

If you use the IAM console, the instance profile is managed for you and is mostly transparent to you. However, if you use the AWS CLI or API to create and manage the role and Amazon EC2 instance, then you must create the instance profile and assign the role to it as separate steps. Then, when you launch the instance, you must specify the instance profile name instead of the role name.

3. When the application runs, it obtains temporary security credentials from Amazon EC2 [instance metadata](#), as described in [Retrieving Security Credentials from Instance Metadata](#). These are [temporary security credentials](#) that represent the role and are valid for a limited period of time.

With some [AWS SDKs](#), the developer can use a provider that manages the temporary security credentials transparently. (The documentation for individual AWS SDKs describes the features supported by that SDK for managing credentials.)

Alternatively, the application can get the temporary credentials directly from the instance metadata of the Amazon EC2 instance. Credentials and related values are available from the `iam/security-credentials/role-name` category (in this case, `iam/security-credentials/Get-pics`) of the metadata. If the application gets the credentials from the instance metadata, it can cache the credentials.

4. Using the retrieved temporary credentials, the application accesses the photo bucket. Because of the policy attached to the **Get-pics** role, the application has read-only permissions.

The temporary security credentials available on the instance automatically update before they expire so that a valid set is always available. The application just needs to make sure that it gets a new set of credentials from the instance metadata before the current ones expire. It is possible to use the AWS SDK to manage credentials so the application does not need to include additional logic to refresh the credentials. For example, instantiating clients with Instance Profile Credential Providers. However, if the application gets temporary security credentials from the instance metadata and has cached them, it should get a refreshed set of credentials every hour,

or at least 15 minutes before the current set expires. The expiration time is included in the information returned in the `iam/security-credentials/role-name` category.

Permissions required for using roles with Amazon EC2

To launch an instance with a role, the developer must have permission to launch Amazon EC2 instances and permission to pass IAM roles.

The following sample policy allows users to use the AWS Management Console to launch an instance with a role. The policy includes wildcards (*) to allow a user to pass any role and to perform the listed Amazon EC2 actions. The `ListInstanceProfiles` action allows users to view all of the roles available in the AWS account.

Example Example policy that grants a user permission to use the Amazon EC2 console to launch an instance with any role

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "IamPassRole",
      "Effect": "Allow",
      "Action": "iam:PassRole",
      "Resource": "*",
      "Condition": {
        "StringEquals": {
          "iam:PassedToService": "ec2.amazonaws.com"
        }
      }
    },
    {
      "Sid": "ListEc2AndListInstanceProfiles",
      "Effect": "Allow",
      "Action": [
        "iam:ListInstanceProfiles",
        "ec2:Describe*",
        "ec2:Search*",
        "ec2:Get*"
      ],
      "Resource": "*"
    }
  ]
}
```

```
}
```

Restricting which roles can be passed to Amazon EC2 instances (using PassRole)

You can use the `PassRole` permission to restrict which role a user can pass to an Amazon EC2 instance when the user launches the instance. This helps prevent the user from running applications that have more permissions than the user has been granted—that is, from being able to obtain elevated privileges. For example, imagine that user Alice has permissions only to launch Amazon EC2 instances and to work with Amazon S3 buckets, but the role she passes to an Amazon EC2 instance has permissions to work with IAM and Amazon DynamoDB. In that case, Alice might be able to launch the instance, log into it, get temporary security credentials, and then perform IAM or DynamoDB actions that she's not authorized for.

To restrict which roles a user can pass to an Amazon EC2 instance, you create a policy that allows the `PassRole` action. You then attach the policy to the user (or to an IAM group that the user belongs to) who will launch Amazon EC2 instances. In the `Resource` element of the policy, you list the role or roles that the user is allowed to pass to Amazon EC2 instances. When the user launches an instance and associates a role with it, Amazon EC2 checks whether the user is allowed to pass that role. Of course, you should also ensure that the role that the user can pass does not include more permissions than the user is supposed to have.

Note

`PassRole` is not an API action in the same way that `RunInstances` or `ListInstanceProfiles` is. Instead, it's a permission that AWS checks whenever a role ARN is passed as a parameter to an API (or the console does this on the user's behalf). It helps an administrator to control which roles can be passed by which users. In this case, it ensures that the user is allowed to attach a specific role to an Amazon EC2 instance.

Example Example policy that grants a user permission to launch an Amazon EC2 instance with a specific role

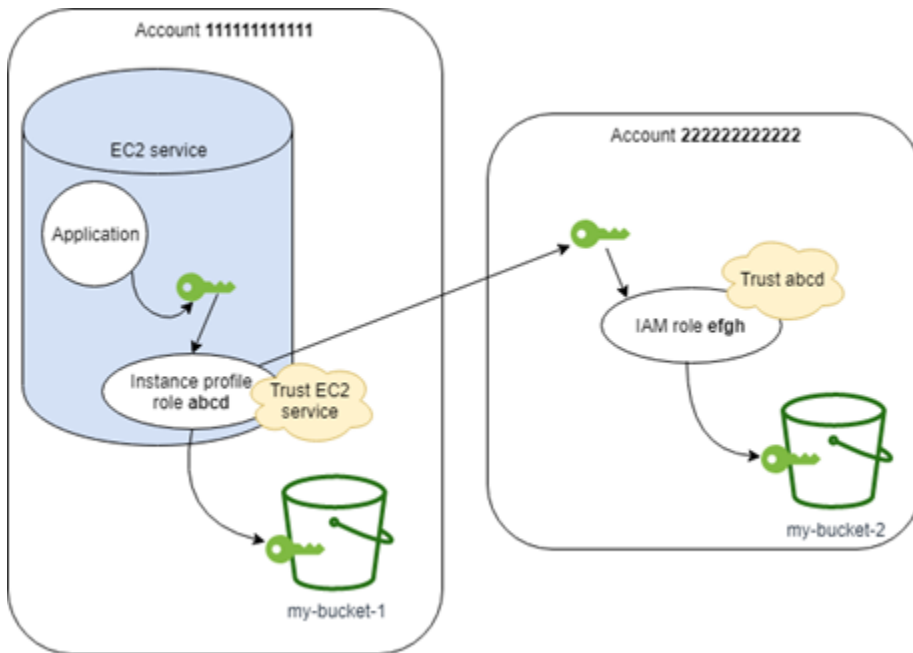

The following sample policy allows users to use the Amazon EC2 API to launch an instance with a role. The `Resource` element specifies the Amazon Resource Name (ARN) of a role. By specifying the ARN, the policy grants the user the permission to pass only the `Get-pics` role. If the user tries to specify a different role when launching an instance, the action fails. The user does have permissions to run any instance, regardless of whether they pass a role.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": "ec2:RunInstances",
      "Resource": "*"
    },
    {
      "Effect": "Allow",
      "Action": "iam:PassRole",
      "Resource": "arn:aws:iam::account-id:role/Get-pics"
    }
  ]
}
```

Allowing an instance profile role to switch to a role in another account

You can allow an application running on an Amazon EC2 instance to run commands in another account. To do this, you must allow the Amazon EC2 instance role in the first account to switch to a role in the second account.

Imagine that you are using two AWS accounts and you want to allow an application running on an Amazon EC2 instance to run [AWS CLI](#) commands in both accounts. Assume that the Amazon EC2 instance exists in account 111111111111. That instance includes the abcd instance profile role that allows the application to perform read-only Amazon S3 tasks on the my-bucket-1 bucket within the same 111111111111 account. However, the application must also be allowed to assume the efgh cross-account role to access the my-bucket-2 Amazon S3 bucket in account 222222222222.

The abcd Amazon EC2 instance profile role must have the following permissions policy to allow the application to access the my-bucket-1 Amazon S3 bucket:

Account 111111111111 abcd Role Permissions Policy

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "AllowAccountLevelS3Actions",
      "Effect": "Allow",
      "Action": [
        "s3:GetBucketLocation",
        "s3:GetAccountPublicAccessBlock",
        "s3:ListAccessPoints",
        "s3:ListAllMyBuckets"
      ],
      "Resource": "arn:aws:s3::*:*"
    },
    {
      "Sid": "AllowListAndReadS3ActionOnMyBucket",
      "Effect": "Allow",
      "Action": [
        "s3:Get*",
        "s3:List*"
      ],
    }
  ]
}
```

```

    "Resource": [
      "arn:aws:s3:::my-bucket-1/*",
      "arn:aws:s3:::my-bucket-1"
    ],
    {
      "Sid": "AllowIPToAssumeCrossAccountRole",
      "Effect": "Allow",
      "Action": "sts:AssumeRole",
      "Resource": "arn:aws:iam::222222222222:role/efgh"
    }
  ]
}

```

The abcd role must trust the Amazon EC2 service to assume the role. To do this, the abcd role must have the following trust policy:

Account 111111111111 abcd Role Trust Policy

```

{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "abcdTrustPolicy",
      "Effect": "Allow",
      "Action": "sts:AssumeRole",
      "Principal": {"Service": "ec2.amazonaws.com"}
    }
  ]
}

```

Assume that the efgh cross-account role allows read-only Amazon S3 tasks on the my-bucket-2 bucket within the same 222222222222 account. To do this, the efgh cross-account role must have the following permissions policy:

Account 222222222222 efgh Role Permissions Policy

```

{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "AllowAccountLevelS3Actions",

```

```

    "Effect": "Allow",
    "Action": [
      "s3:GetBucketLocation",
      "s3:GetAccountPublicAccessBlock",
      "s3:ListAccessPoints",
      "s3:ListAllMyBuckets"
    ],
    "Resource": "arn:aws:s3:::*"
  },
  {
    "Sid": "AllowListAndReadS3ActionOnMyBucket",
    "Effect": "Allow",
    "Action": [
      "s3:Get*",
      "s3:List*"
    ],
    "Resource": [
      "arn:aws:s3:::my-bucket-2/*",
      "arn:aws:s3:::my-bucket-2"
    ]
  }
]
}

```

The `efgh` role must trust the `abcd` instance profile role to assume it. To do this, the `efgh` role must have the following trust policy:

Account 222222222222 e fgh Role Trust Policy

```

{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "efghTrustPolicy",
      "Effect": "Allow",
      "Action": "sts:AssumeRole",
      "Principal": {"AWS": "arn:aws:iam::111111111111:role/abcd"}
    }
  ]
}

```

How do I get started?

To understand how roles work with Amazon EC2 instances, you need to use the IAM console to create a role, launch an Amazon EC2 instance that uses that role, and then examine the running instance. You can examine the [instance metadata](#) to see how the role's temporary credentials are made available to an instance. You can also see how an application that runs on an instance can use the role. Use the following resources to learn more.

-
- SDK walkthroughs. The AWS SDK documentation includes walkthroughs that show an application running on an Amazon EC2 instance that uses temporary credentials for roles to read an Amazon S3 bucket. Each of the following walkthroughs presents similar steps with a different programming language:
 - [Configure IAM Roles for Amazon EC2 with the SDK for Java](#) in the *AWS SDK for Java Developer Guide*
 - [Launch an Amazon EC2 Instance using the SDK for .NET](#) in the *AWS SDK for .NET Developer Guide*
 - [Creating an Amazon EC2 Instance with the SDK for Ruby](#) in the *AWS SDK for Ruby Developer Guide*

Related information

For more information about creating roles or roles for Amazon EC2 instances, see the following information:

- For more information about [using IAM roles with Amazon EC2 instances](#), go to the *Amazon EC2 User Guide for Linux Instances*.
- To create a role, see [Creating IAM roles](#)
- For more information about using temporary security credentials, see [Temporary security credentials in IAM](#).
- If you work with the IAM API or CLI, you must create and manage IAM instance profiles. For more information about instance profiles, see [Using instance profiles](#).
- For more information about temporary security credentials for roles in the instance metadata, see [Retrieving Security Credentials from Instance Metadata](#) in the *Amazon EC2 User Guide for Linux Instances*.

Using instance profiles

Use an instance profile to pass an IAM role to an EC2 instance. For more information, see [IAM roles for Amazon EC2](#) in the *Amazon EC2 User Guide for Linux Instances*.

Managing instance profiles (console)

If you use the AWS Management Console to create a role for Amazon EC2, the console automatically creates an instance profile and gives it the same name as the role. When you then use the Amazon EC2 console to launch an instance with an IAM role, you can select a role to associate with the instance. In the console, the list that's displayed is actually a list of instance profile names. The console does not create an instance profile for a role that is not associated with Amazon EC2.

You can use the AWS Management Console to delete IAM roles and instance profiles for Amazon EC2 if the role and the instance profile have the same name. To learn more about deleting instance profiles, see [Deleting roles or instance profiles](#).

Managing instance profiles (AWS CLI or AWS API)

If you manage your roles from the AWS CLI or the AWS API, you create roles and instance profiles as separate actions. Because roles and instance profiles can have different names, you must know the names of your instance profiles as well as the names of roles they contain. That way you can choose the correct instance profile when you launch an EC2 instance.

You can attach tags to your IAM resources, including instance profiles, to identify, organize, and control access to them. You can tag instance profiles only when you use the AWS CLI or AWS API.

Note

An instance profile can contain only one IAM role, although a role can be included in multiple instance profiles. This limit of one role per instance profile cannot be increased. You can remove the existing role and then add a different role to an instance profile. You must then wait for the change to appear across all of AWS because of [eventual consistency](#). To force the change, you must [disassociate the instance profile](#) and then [associate the instance profile](#), or you can stop your instance and then restart it.

Managing instance profiles (AWS CLI)

You can use the following AWS CLI commands to work with instance profiles in an AWS account.

- Create an instance profile: [aws iam create-instance-profile](#)
- Tag an instance profile: [aws iam tag-instance-profile](#)
- List tags for an instance profile: [aws iam list-instance-profile-tags](#)
- Untag an instance profile: [aws iam untag-instance-profile](#)
- Add a role to an instance profile: [aws iam add-role-to-instance-profile](#)
- List instance profiles: [aws iam list-instance-profiles](#), [aws iam list-instance-profiles-for-role](#)
- Get information about an instance profile: [aws iam get-instance-profile](#)
- Remove a role from an instance profile: [aws iam remove-role-from-instance-profile](#)
- Delete an instance profile: [aws iam delete-instance-profile](#)

You can also attach a role to an already running EC2 instance by using the following commands. For more information, see [IAM Roles for Amazon EC2](#).

- Attach an instance profile with a role to a stopped or running EC2 instance: [aws ec2 associate-iam-instance-profile](#)
- Get information about an instance profile attached to an EC2 instance: [aws ec2 describe-iam-instance-profile-associations](#)
- Detach an instance profile with a role from a stopped or running EC2 instance: [aws ec2 disassociate-iam-instance-profile](#)

Managing instance profiles (AWS API)

You can call the following AWS API operations to work with instance profiles in an AWS account.

- Create an instance profile: [CreateInstanceProfile](#)
- Tag an instance profile: [TagInstanceProfile](#)
- List tags on an instance profile: [ListInstanceProfileTags](#)
- Untag an instance profile: [UntagInstanceProfile](#)
- Add a role to an instance profile: [AddRoleToInstanceProfile](#)
- List instance profiles: [ListInstanceProfiles](#), [ListInstanceProfilesForRole](#)
- Get information about an instance profile: [GetInstanceProfile](#)
- Remove a role from an instance profile: [RemoveRoleFromInstanceProfile](#)

- Delete an instance profile: [DeleteInstanceProfile](#)

You can also attach a role to an already running EC2 instance by calling the following operations. For more information, see [IAM Roles for Amazon EC2](#).

- Attach an instance profile with a role to a stopped or running EC2 instance: [AssociateIamInstanceProfile](#)
- Get information about an instance profile attached to an EC2 instance: [DescribeIamInstanceProfileAssociations](#)
- Detach an instance profile with a role from a stopped or running EC2 instance: [DisassociateIamInstanceProfile](#)

Revoking IAM role temporary security credentials

Warning

If you follow the steps on this page, all users with current sessions created by assuming the role are denied access to all AWS actions and resources. This can result in users losing unsaved work.

When you permit users to access the AWS Management Console with a long session duration time (such as 12 hours), their temporary credentials do not expire as quickly. If users inadvertently expose their credentials to an unauthorized third-party, that party has access for the duration of the session. However, you can immediately revoke all permissions to the role's credentials issued before a certain point in time if you need to. All temporary credentials for that role issued before the specified time become invalid. This forces all users to re-authenticate and request new credentials.

Note

You cannot revoke the session for a [service-linked role](#).

When you revoke permissions for a role using the procedure in this topic, AWS attaches a new inline policy to the role that denies all permissions to all actions. It includes a condition that applies

the restrictions only if the user assumed the role *before* the point in time when you revoke the permissions. If the user assumes the role *after* you revoked the permissions, then the deny policy does not apply to that user.

For more information on denying access, see [Disabling permissions for temporary security credentials](#).

Important

This deny policy applies to all users of the specified role, not just those with longer duration console sessions.

Minimum permissions to revoke session permissions from a role

To successfully revoke session permissions from a role, you must have the `PutRolePolicy` permission for the role. This allows you to attach the `AWSRevokeOlderSessions` inline policy to the role.

Revoking session permissions

You can revoke the session permissions from a role.

To immediately deny all permissions to any current user of role credentials

1. Sign in to the AWS Management Console and open the IAM console at <https://console.aws.amazon.com/iam/>.
2. In the navigation pane, choose **Roles**, and then choose the name (not the check box) of the role whose permissions you want to revoke.
3. On the **Summary** page for the selected role, choose the **Revoke sessions** tab.
4. On the **Revoke sessions** tab, choose **Revoke active sessions**.
5. AWS asks you to confirm the action. Select the **I acknowledge that I am revoking all active sessions for this role** check box and choose **Revoke active sessions** on the dialog box.

IAM immediately attaches a policy named `AWSRevokeOlderSessions` to the role. The policy denies all access to users who assumed the role before the moment you choose **Revoke active sessions**. Any user who assumes the role *after* you choose **Revoke active sessions** is not affected.

When you apply a new policy to a user or a resource, it can take a few minutes for policy updates to take effect. To learn why changes are not always immediately visible, see [Changes that I make are not always immediately visible](#).

Note

Don't worry about remembering to delete the policy. Any user who assumes the role *after* you revoke sessions is not affected by the policy. If you choose to **Revoke Sessions** again later, then the date and time stamp in the policy is refreshed and it again denies all permissions to any user who assumed the role before the new specified time.

Valid users whose sessions are revoked in this way must acquire temporary credentials for a new session to continue working. The AWS CLI caches credentials until they expire. To force the CLI to delete and refresh cached credentials that are no longer valid, run one of the following commands:

Linux, macOS, or Unix

```
$ rm -r ~/.aws/cli/cache
```

Windows

```
C:\> del /s /q %UserProfile%\aws\cli\cache
```

Revoking session permissions before a specified time

You can also revoke session permissions programmatically by specifying a value for the [aws:TokenIssueTime](#) key in the `Condition` element of a policy.

This policy denies all permissions when the value of `aws:TokenIssueTime` is earlier than the specified date and time. The value of `aws:TokenIssueTime` corresponds to the exact time at which the temporary security credentials were created. The `aws:TokenIssueTime` value is only present in the context of AWS requests that are signed with temporary security credentials, so the Deny statement in the policy does not affect requests that are signed with the long-term credentials of the IAM user.

This policy can also be attached to a role. In that case, the policy affects only the temporary security credentials that were created by the role before the specified date and time.

```
{
  "Version": "2012-10-17",
  "Statement": {
    "Effect": "Deny",
    "Action": "*",
    "Resource": "*",
    "Condition": {
      "DateLessThan": {"aws:TokenIssueTime": "2014-05-07T23:47:00Z"}
    }
  }
}
```

Valid users whose sessions are revoked in this way must acquire temporary credentials for a new session to continue working. The AWS CLI caches credentials until they expire. To force the CLI to delete and refresh cached credentials that are no longer valid, run one of the following commands:

Linux, macOS, or Unix

```
$ rm -r ~/.aws/cli/cache
```

Windows

```
C:\> del /s /q %UserProfile%\aws\cli\cache
```

Managing IAM roles

Occasionally you need to modify or delete the roles that you have created. To change a role, you can do any of the following:

- Modify the policies that are associated with the role
- Change who can access the role
- Edit the permissions that the role grants to users
- Change the maximum session duration setting for roles that are assumed using the AWS Management Console, AWS CLI or API

You can also delete roles that are no longer needed. You can manage your roles from the AWS Management Console, the AWS CLI, and the API.

Topics

- [Modifying a role](#)
- [Deleting roles or instance profiles](#)

Modifying a role

You can use the AWS Management Console, the AWS CLI, or the IAM API to make changes to a role.

Topics

- [View role access](#)
- [Generate a policy based on access information](#)
- [Modifying a role \(console\)](#)
- [Modifying a role \(AWS CLI\)](#)
- [Modifying a role \(AWS API\)](#)

View role access

Before you change the permissions for a role, you should review its recent service-level activity. This is important because you don't want to remove access from a principal (person or application) who is using it. For more information about viewing last accessed information, see [Refining permissions in AWS using last accessed information](#).

Generate a policy based on access information

You might sometimes grant permissions to an IAM entity (user or role) beyond what they require. To help you refine the permissions that you grant, you can generate an IAM policy that is based on the access activity for an entity. IAM Access Analyzer reviews your AWS CloudTrail logs and generates a policy template that contains the permissions that have been used by the entity in your specified date range. You can use the template to create a managed policy with fine-grained permissions and then attach it to the IAM entity. That way, you grant only the permissions that the user or role needs to interact with AWS resources for your specific use case. To learn more, see [Generate policies based on access activity](#).

Modifying a role (console)

You can use the AWS Management Console to modify a role. To change the set of tags on a role, see [Managing tags on IAM roles \(console\)](#).

Topics

- [Modifying a role trust policy \(console\)](#)
- [Modifying a role permissions policy \(console\)](#)
- [Modifying a role description \(console\)](#)
- [Modifying a role maximum session duration \(console\)](#)
- [Modifying a role permissions boundary \(console\)](#)

Modifying a role trust policy (console)

To change who can assume a role, you must modify the role's trust policy. You cannot modify the trust policy for a [service-linked role](#).

Notes

- If a user is listed as the principal in a role's trust policy but cannot assume the role, check the user's [permissions boundary](#). If a permissions boundary is set for the user, then it must allow the `sts:AssumeRole` action.
- To allow users to assume the current role again within a role session, specify the role ARN or AWS account ARN as a principal in the role trust policy. AWS services that provide compute resources such as Amazon EC2, Amazon ECS, Amazon EKS, and Lambda provide temporary credentials and automatically update these credentials. This ensures that you always have a valid set of credentials. For these services, it's not necessary to assume the current role again to obtain temporary credentials. However, if you intend to pass [session tags](#) or a [session policy](#), you need to assume the current role again.

To modify a role trust policy (console)

1. Sign in to the AWS Management Console and open the IAM console at <https://console.aws.amazon.com/iam/>.
2. In the navigation pane of the IAM console, choose **Roles**.
3. In the list of roles in your account, choose the name of the role that you want to modify.
4. Choose the **Trust relationships** tab, and then choose **Edit trust policy**.

5. Edit the trust policy as needed. To add additional principals that can assume the role, specify them in the `Principal` element. For example, the following policy snippet shows how to reference two AWS accounts in the `Principal` element:

```
"Principal": {
  "AWS": [
    "arn:aws:iam::111122223333:root",
    "arn:aws:iam::444455556666:root"
  ]
},
```

If you specify a principal in another account, adding an account to the trust policy of a role is only half of establishing the cross-account trust relationship. By default, no users in the trusted accounts can assume the role. The administrator for the newly trusted account must grant the users the permission to assume the role. To do that, the administrator must create or edit a policy that is attached to the user to allow the user access to the `sts:AssumeRole` action. For more information, see the following procedure or [Granting a user permissions to switch roles](#).

The following policy snippet shows how to reference two AWS services in the `Principal` element:

```
"Principal": {
  "Service": [
    "opsworks.amazonaws.com",
    "ec2.amazonaws.com"
  ]
},
```

6. When you are finished editing your trust policy, choose **Update policy** to save your changes.

For more information about policy structure and syntax, see [Policies and permissions in IAM](#) and the [IAM JSON policy elements reference](#).

To allow users in a trusted external account to use the role (console)

For more information and detail about this procedure, see [Granting a user permissions to switch roles](#).

1. Sign in to the trusted external AWS account.

2. Decide whether to attach the permissions to a user or to a group. In the navigation pane of the IAM console, choose **Users** or **User groups** accordingly.
3. Choose the name of the user or group to which you want to grant access, and then choose the **Permissions** tab.
4. Do one of the following:

- To edit a customer managed policy, choose the name of the policy, choose **Edit policy**, and then choose the **JSON** tab. You cannot edit an AWS managed policy. AWS managed policies appear with the AWS icon

For more information about the difference between AWS managed policies and customer managed policies, see [Managed policies and inline policies](#).

- To edit an inline policy, choose the arrow next to the name of the policy and choose **Edit policy**.
5. In the policy editor, add a new Statement element that specifies the following:

```
{
  "Effect": "Allow",
  "Action": "sts:AssumeRole",
  "Resource": "arn:aws:iam::ACCOUNT-ID:role/ROLE-NAME"
}
```

Replace the ARN in the statement with the ARN of the role that the user can assume.

6. Follow the prompts on screen to finish editing the policy.

Modifying a role permissions policy (console)

To change the permissions allowed by the role, modify the role's permissions policy (or policies). You cannot modify the permissions policy for a [service-linked role](#) in IAM. You might be able to modify the permissions policy within the service that depends on the role. To check whether a service supports this feature, see [AWS services that work with IAM](#) and look for the services that have **Yes** in the **Service-linked roles** column. Choose a **Yes** with a link to view the service-linked role documentation for that service.

To change the permissions allowed by a role (console)

1. Open the IAM console at <https://console.aws.amazon.com/iam/>.

2. In the navigation pane of the IAM console, choose **Roles**.
3. Choose the name of the role that you want to modify, and then choose the **Permissions** tab.
4. Do one of the following:
 - To edit an existing customer managed policy, choose the name of the policy and then choose **Edit policy**.

Note

You cannot edit an AWS managed policy. AWS managed policy appear with the AWS icon

For more information about the difference between AWS managed policies and customer managed policies, see [Managed policies and inline policies](#).

- To attach an existing managed policy to the role, choose **Add permissions** and then choose **Attach policies**.
- To edit an existing inline policy, expand the policy and choose **Edit**.
- To embed a new inline policy, choose **Add permissions** and then choose **Create inline policy**.

Modifying a role description (console)

To change the description of the role, modify the description text.

To change the description of a role (console)

1. Sign in to the AWS Management Console and open the IAM console at <https://console.aws.amazon.com/iam/>.
2. In the navigation pane of the IAM console, choose **Roles**.
3. Choose the name of the role to modify.
4. In the **Summary** section, choose **Edit**.
5. Enter a new description in the box and choose **Save changes**.

Modifying a role maximum session duration (console)

To specify the maximum session duration setting for roles that are assumed using the console, the AWS CLI, or AWS API, modify the maximum session duration setting value. This setting can have a value from 1 hour to 12 hours. If you do not specify a value, the default maximum of 1 hour is applied. This setting does not limit sessions assumed by AWS services.

To change the maximum session duration setting for roles that are assumed using the console, AWS CLI, or AWS API (console)

1. Sign in to the AWS Management Console and open the IAM console at <https://console.aws.amazon.com/iam/>.
2. In the navigation pane of the IAM console, choose **Roles**.
3. Choose the name of the role to modify.
4. In the **Summary** section, choose **Edit**.
5. For **Maximum session duration**, choose a value. Alternatively, choose **Custom duration** and enter a value (in seconds).
6. Choose **Save changes**.

Your changes don't take effect until the next time someone assumes this role. To learn how to revoke existing sessions for this role, see [Revoking IAM role temporary security credentials](#).

In the AWS Management Console, IAM user sessions are 12 hours by default. IAM users who switch roles in the console are granted the role maximum session duration, or the remaining time in the user's session, whichever is less.

Anyone who assumes the role from the AWS CLI or AWS API can request a longer session, up to this maximum. The `MaxSessionDuration` setting determines the maximum duration of the role session that can be requested.

- To specify a session duration using the AWS CLI use the `duration-seconds` parameter. To learn more, see [Switching to an IAM role \(AWS CLI\)](#).
- To specify a session duration using the AWS API, use the `DurationSeconds` parameter. To learn more, see [Switching to an IAM role \(AWS API\)](#).

Modifying a role permissions boundary (console)

To change the maximum permissions allowed for a role, modify the role's [permissions boundary](#).

To change the policy used to set the permissions boundary for a role

1. Sign in to the AWS Management Console and open the IAM console at <https://console.aws.amazon.com/iam/>.
2. In the navigation pane, choose **Roles**.
3. Choose the name of the role with the [permissions boundary](#) that you want to change.
4. Choose the **Permissions** tab. If necessary, open the **Permissions boundary** section and then choose **Change boundary**.
5. Select the policy that you want to use for the permissions boundary.
6. Choose **Change boundary**.

Your changes don't take effect until the next time someone assumes this role.

Modifying a role (AWS CLI)

You can use the AWS Command Line Interface to modify a role. To change the set of tags on a role, see [Managing tags on IAM roles \(AWS CLI or AWS API\)](#).

Topics

- [Modifying a role trust policy \(AWS CLI\)](#)
- [Modifying a role permissions policy \(AWS CLI\)](#)
- [Modifying a role description \(AWS CLI\)](#)
- [Modifying a role maximum session duration \(AWS CLI\)](#)
- [Modifying a role permissions boundary \(AWS CLI\)](#)

Modifying a role trust policy (AWS CLI)

To change who can assume a role, you must modify the role's trust policy. You cannot modify the trust policy for a [service-linked role](#).

Notes

- If a user is listed as the principal in a role's trust policy but cannot assume the role, check the user's [permissions boundary](#). If a permissions boundary is set for the user, then it must allow the `sts:AssumeRole` action.
- To allow users to assume the current role again within a role session, specify the role ARN or AWS account ARN as a principal in the role trust policy. AWS services that provide compute resources such as Amazon EC2, Amazon ECS, Amazon EKS, and Lambda provide temporary credentials and automatically update these credentials. This ensures that you always have a valid set of credentials. For these services, it's not necessary to assume the current role again to obtain temporary credentials. However, if you intend to pass [session tags](#) or a [session policy](#), you need to assume the current role again. To learn how to modify a role trust policy to add the principal role ARN or AWS account ARN, see [Modifying a role trust policy \(console\)](#).

To modify a role trust policy (AWS CLI)

1. (Optional) If you don't know the name of the role that you want to modify, run the following command to list the roles in your account:
 - [aws iam list-roles](#)
2. (Optional) To view the current trust policy for a role, run the following command:
 - [aws iam get-role](#)
3. To modify the trusted principals that can access the role, create a text file with the updated trust policy. You can use any text editor to construct the policy.

For example, the following trust policy shows how to reference two AWS accounts in the `Principal` element. This allows users within two separate AWS accounts to assume this role.

```
{
  "Version": "2012-10-17",
  "Statement": {
    "Effect": "Allow",
    "Principal": {"AWS": [
      "arn:aws:iam::111122223333:root",
      "arn:aws:iam::444455556666:root"
    ]}
  }
}
```

```
    ]},  
    "Action": "sts:AssumeRole"  
  }  
}
```

If you specify a principal in another account, adding an account to the trust policy of a role is only half of establishing the cross-account trust relationship. By default, no users in the trusted accounts can assume the role. The administrator for the newly trusted account must grant the users the permission to assume the role. To do that, the administrator must create or edit a policy that is attached to the user to allow the user access to the `sts:AssumeRole` action. For more information, see the following procedure or [Granting a user permissions to switch roles](#).

4. To use the file that you just created to update the trust policy, run the following command:
 - [aws iam update-assume-role-policy](#)

To allow users in a trusted external account to use the role (AWS CLI)

For more information and detail about this procedure, see [Granting a user permissions to switch roles](#).

1. Create a JSON file that contains a permissions policy that grants permissions to assume the role. For example, the following policy contains the minimum necessary permissions:

```
{  
  "Version": "2012-10-17",  
  "Statement": {  
    "Effect": "Allow",  
    "Action": "sts:AssumeRole",  
    "Resource": "arn:aws:iam::ACCOUNT-ID-THAT-CONTAINS-ROLE:role/ROLE-NAME"  
  }  
}
```

Replace the ARN in the statement with the ARN of the role that the user can assume.

2. Run the following command to upload the JSON file that contains the trust policy to IAM:
 - [aws iam create-policy](#)

The output of this command includes the ARN of the policy. Make a note of this ARN because you will need it in a later step.

3. Decide which user or group to attach the policy to. If you don't know the name of the intended user or group, use one of the following commands to list the users or groups in your account:
 - [aws iam list-users](#)
 - [aws iam list-groups](#)
4. Use one of the following commands to attach the policy that you created in the previous step to the user or group:
 - [aws iam attach-user-policy](#)
 - [aws iam attach-group-policy](#)

Modifying a role permissions policy (AWS CLI)

To change the permissions allowed by the role, modify the role's permissions policy (or policies). You cannot modify the permissions policy for a [service-linked role](#) in IAM. You might be able to modify the permissions policy within the service that depends on the role. To check whether a service supports this feature, see [AWS services that work with IAM](#) and look for the services that have **Yes** in the **Service-linked roles** column. Choose a **Yes** with a link to view the service-linked role documentation for that service.

To change the permissions allowed by a role (AWS CLI)

1. (Optional) To view the current permissions associated with a role, run the following commands:
 1. [aws iam list-role-policies](#) to list inline policies
 2. [aws iam list-attached-role-policies](#) to list managed policies
2. The command to update permissions for the role differs depending on whether you are updating a managed policy or an inline policy.

To update a managed policy, run the following command to create a new version of the managed policy:

- [aws iam create-policy-version](#)

To update an inline policy, run the following command:

- [aws iam put-role-policy](#)

Modifying a role description (AWS CLI)

To change the description of the role, modify the description text.

To change the description of a role (AWS CLI)

1. (Optional) To view the current description for a role, run the following command:
 - [aws iam get-role](#)
2. To update a role's description, run the following command with the description parameter:
 - [aws iam update-role](#)

Modifying a role maximum session duration (AWS CLI)

To specify the maximum session duration setting for roles that are assumed using the AWS CLI or API, modify the maximum session duration setting's value. This setting can have a value from 1 hour to 12 hours. If you do not specify a value, the default maximum of 1 hour is applied. This setting does not limit sessions assumed by AWS services.

Note

Anyone who assumes the role from the AWS CLI or API can use the `duration-seconds` CLI parameter or the `DurationSeconds` API parameter to request a longer session. The `MaxSessionDuration` setting determines the maximum duration of the role session that can be requested using the `DurationSeconds` parameter. If users don't specify a value for the `DurationSeconds` parameter, their security credentials are valid for one hour.

To change the maximum session duration setting for roles that are assumed using the AWS CLI (AWS CLI)

1. (Optional) To view the current maximum session duration setting for a role, run the following command:

- [aws iam get-role](#)
2. To update a role's maximum session duration setting, run the following command with the `max-session-duration` CLI parameter or the `MaxSessionDuration` API parameter:
 - [aws iam update-role](#)

Your changes don't take effect until the next time someone assumes this role. To learn how to revoke existing sessions for this role, see [Revoking IAM role temporary security credentials](#).

Modifying a role permissions boundary (AWS CLI)

To change the maximum permissions allowed for a role, modify the role's [permissions boundary](#).

To change the managed policy used to set the permissions boundary for a role (AWS CLI)

1. (Optional) To view the current [permissions boundary](#) for a role, run the following command:
 - [aws iam get-role](#)
2. To use a different managed policy to update the permissions boundary for a role, run the following command:
 - [aws iam put-role-permissions-boundary](#)

A role can have only one managed policy set as a permissions boundary. If you change the permissions boundary, you change the maximum permissions allowed for a role.

Modifying a role (AWS API)

You can use the AWS API to modify a role. To change the set of tags on a role, see [Managing tags on IAM roles \(AWS CLI or AWS API\)](#).

Topics

- [Modifying a role trust policy \(AWS API\)](#)
- [Modifying a role permissions policy \(AWS API\)](#)
- [Modifying a role description \(AWS API\)](#)
- [Modifying a role maximum session duration \(AWS API\)](#)

- [Modifying a role permissions boundary \(AWS API\)](#)

Modifying a role trust policy (AWS API)

To change who can assume a role, you must modify the role's trust policy. You cannot modify the trust policy for a [service-linked role](#).

Notes

- If a user is listed as the principal in a role's trust policy but cannot assume the role, check the user's [permissions boundary](#). If a permissions boundary is set for the user, then it must allow the `sts:AssumeRole` action.
- To allow users to assume the current role again within a role session, specify the role ARN or AWS account ARN as a principal in the role trust policy. AWS services that provide compute resources such as Amazon EC2, Amazon ECS, Amazon EKS, and Lambda provide temporary credentials and automatically update these credentials. This ensures that you always have a valid set of credentials. For these services, it's not necessary to assume the current role again to obtain temporary credentials. However, if you intend to pass [session tags](#) or a [session policy](#), you need to assume the current role again. To learn how to modify a role trust policy to add the principal role ARN or AWS account ARN, see [Modifying a role trust policy \(console\)](#).

To modify a role trust policy (AWS API)

1. (Optional) If you don't know the name of the role that you want to modify, call the following operation to list the roles in your account:
 - [ListRoles](#)
2. (Optional) To view the current trust policy for a role, call the following operation:
 - [GetRole](#)
3. To modify the trusted principals that can access the role, create a text file with the updated trust policy. You can use any text editor to construct the policy.

For example, the following trust policy shows how to reference two AWS accounts in the `Principal` element. This allows users within two separate AWS accounts to assume this role.

```
{
  "Version": "2012-10-17",
  "Statement": {
    "Effect": "Allow",
    "Principal": {"AWS": [
      "arn:aws:iam::111122223333:root",
      "arn:aws:iam::444455556666:root"
    ]},
    "Action": "sts:AssumeRole"
  }
}
```

If you specify a principal in another account, adding an account to the trust policy of a role is only half of establishing the cross-account trust relationship. By default, no users in the trusted accounts can assume the role. The administrator for the newly trusted account must grant the users the permission to assume the role. To do that, the administrator must create or edit a policy that is attached to the user to allow the user access to the `sts:AssumeRole` action. For more information, see the following procedure or [Granting a user permissions to switch roles](#).

4. To use the file that you just created to update the trust policy, call the following operation:
 - [UpdateAssumeRolePolicy](#)

To allow users in a trusted external account to use the role (AWS API)

For more information and detail about this procedure, see [Granting a user permissions to switch roles](#).

1. Create a JSON file that contains a permissions policy that grants permissions to assume the role. For example, the following policy contains the minimum necessary permissions:

```
{
  "Version": "2012-10-17",
  "Statement": {
    "Effect": "Allow",
    "Action": "sts:AssumeRole",
    "Resource": "arn:aws:iam::ACCOUNT-ID-THAT-CONTAINS-ROLE:role/ROLE-NAME"
  }
}
```

Replace the ARN in the statement with the ARN of the role that the user can assume.

2. Call the following operation to upload the JSON file that contains the trust policy to IAM:
 - [CreatePolicy](#)

The output of this operation includes the ARN of the policy. Make a note of this ARN because you will need it in a later step.

3. Decide which user or group to attach the policy to. If you don't know the name of the intended user or group, call one of the following operations to list the users or groups in your account:
 - [ListUsers](#)
 - [ListGroupPolicy](#)
4. Call one of the following operations to attach the policy that you created in the previous step to the user or group:
 - API: [AttachUserPolicy](#)
 - [AttachGroupPolicy](#)

Modifying a role permissions policy (AWS API)

To change the permissions allowed by the role, modify the role's permissions policy (or policies). You cannot modify the permissions policy for a [service-linked role](#) in IAM. You might be able to modify the permissions policy within the service that depends on the role. To check whether a service supports this feature, see [AWS services that work with IAM](#) and look for the services that have **Yes** in the **Service-linked roles** column. Choose a **Yes** with a link to view the service-linked role documentation for that service.

To change the permissions allowed by a role (AWS API)

1. (Optional) To view the current permissions associated with a role, call the following operations:
 1. [ListRolePolicies](#) to list inline policies
 2. [ListAttachedRolePolicies](#) to list managed policies
2. The operation to update permissions for the role differs depending on whether you are updating a managed policy or an inline policy.

To update a managed policy, call the following operation to create a new version of the managed policy:

- [CreatePolicyVersion](#)

To update an inline policy, call the following operation:

- [PutRolePolicy](#)

Modifying a role description (AWS API)

To change the description of the role, modify the description text.

To change the description of a role (AWS API)

1. (Optional) To view the current description for a role, call the following operation:
 - [GetRole](#)
2. To update a role's description, call the following operation with the description parameter:
 - [UpdateRole](#)

Modifying a role maximum session duration (AWS API)

To specify the maximum session duration setting for roles that are assumed using the AWS CLI or API, modify the maximum session duration setting's value. This setting can have a value from 1 hour to 12 hours. If you do not specify a value, the default maximum of 1 hour is applied. This setting does not limit sessions assumed by AWS services.

Note

Anyone who assumes the role from the AWS CLI or API can use the `duration-seconds` CLI parameter or the `DurationSeconds` API parameter to request a longer session. The `MaxSessionDuration` setting determines the maximum duration of the role session that can be requested using the `DurationSeconds` parameter. If users don't specify a value for the `DurationSeconds` parameter, their security credentials are valid for one hour.

To change the maximum session duration setting for roles that are assumed using the API (AWS API)

1. (Optional) To view the current maximum session duration setting for a role, call the following operation:
 - [GetRole](#)
2. To update a role's maximum session duration setting, call the following operation with the `max-sessionduration` CLI parameter or the `MaxSessionDuration` API parameter:
 - [UpdateRole](#)

Your changes don't take effect until the next time someone assumes this role. To learn how to revoke existing sessions for this role, see [Revoking IAM role temporary security credentials](#).

Modifying a role permissions boundary (AWS API)

To change the maximum permissions allowed for a role, modify the role's [permissions boundary](#).

To change the managed policy used to set the permissions boundary for a role (AWS API)

1. (Optional) To view the current [permissions boundary](#) for a role, call the following operation:
 - [GetRole](#)
2. To use a different managed policy to update the permissions boundary for a role, call the following operation:
 - [PutRolePermissionsBoundary](#)

A role can have only one managed policy set as a permissions boundary. If you change the permissions boundary, you change the maximum permissions allowed for a role.

Deleting roles or instance profiles

If you no longer need a role, we recommend that you delete the role and its associated permissions. That way you don't have an unused entity that is not actively monitored or maintained.

If the role was associated with an EC2 instance, you can also remove the role from the instance profile and then delete the instance profile.

Warning

Make sure that you do not have any Amazon EC2 instances running with the role or instance profile you are about to delete. Deleting a role or instance profile that is associated with a running instance will break any applications that are running on the instance.

If you prefer not to permanently delete a role, you can disable a role. To do this, change the role policies and then revoke all current sessions. For example, you could add a policy to the role that denied access to all of AWS. You could also edit the trust policy to deny access to anyone attempting to assume the role. For more information about revoking sessions, see [Revoking IAM role temporary security credentials](#).

Topics

- [View role access](#)
- [Deleting a service-linked role](#)
- [Deleting an IAM role \(console\)](#)
- [Deleting an IAM role \(AWS CLI\)](#)
- [Deleting an IAM role \(AWS API\)](#)
- [Related information](#)

View role access

Before you delete a role, we recommend that you review when the role was last used. You can do this using the AWS Management Console, the AWS CLI, or the AWS API. You should view this information because you don't want to remove access from someone using the role.

The date of the role last activity might not match the last date reported in the **Access Advisor** tab. The [Access Advisor](#) tab reports activity only for services allowed by the role permissions policies. The date of the role last activity includes the last attempt to access any service in AWS.

Note

The tracking period for a role last activity and Access Advisor data is for the trailing 400 days. This period can be shorter if your Region began supporting these features within the last year. The role might have been used more than 400 days ago. For more information about the tracking period, see [Where AWS tracks last accessed information](#).

To view when a role was last used (console)

1. Sign in to the AWS Management Console and open the IAM console at <https://console.aws.amazon.com/iam/>.
2. In the navigation pane, choose **Roles**.
3. Find the row of the role with the activity you want to view. You can use the search field to narrow the results. View the **Last activity** column to see the number of days since the role was last used. If the role has not been used within the tracking period, then the table displays **None**.
4. Choose the name of the role to view more information. The role **Summary** page also includes **Last activity**, which displays the last used date for the role. If the role has not been used within the last 400 days, then **Last activity** displays **Not accessed in the tracking period**.

To view when a role was last used (AWS CLI)

[aws iam get-role](#) - Run this command to return information about a role, including the `RoleLastUsed` object. This object contains the `LastUsedDate` and the `Region` in which the role was last used. If `RoleLastUsed` is present but does not contain a value, then the role has not been used within the tracking period.

To view when a role was last used (AWS API)

[GetRole](#) - Call this operation to return information about a role, including the `RoleLastUsed` object. This object contains the `LastUsedDate` and the `Region` in which the role was last used. If `RoleLastUsed` is present but does not contain a value, then the role has not been used within the tracking period.

Deleting a service-linked role

If the role is a [service-linked role](#), review the documentation for the linked service to learn how to delete the role. You can view the service-linked roles in your account by going to the IAM **Roles** page in the console. Service-linked roles appear with **(Service-linked role)** in the **Trusted entities** column of the table. A banner on the role **Summary** page also indicates that the role is a service-linked role.

If the service does not include documentation for deleting the service-linked role, you can use the IAM console, AWS CLI, or API to delete the role. For more information, see [Deleting a service-linked role](#).

Deleting an IAM role (console)

When you use the AWS Management Console to delete a role, IAM automatically detaches managed policies associated with the role. It also automatically deletes any inline policies associated with the role, and any Amazon EC2 instance profile that contains the role.

Important

In some cases, a role might be associated with an Amazon EC2 instance profile, and the role and the instance profile might have the same name. In that case you can use the AWS Management Console to delete the role and the instance profile. This linkage happens automatically for roles and instance profiles that you create in the console. If you created the role from the AWS CLI, Tools for Windows PowerShell, or the AWS API, then the role and the instance profile might have different names. In that case you cannot use the console to delete them. Instead, you must use the AWS CLI, Tools for Windows PowerShell, or AWS API to first remove the role from the instance profile. You must then take a separate step to delete the role.

To delete a role (console)

1. Sign in to the AWS Management Console and open the IAM console at <https://console.aws.amazon.com/iam/>.
2. In the navigation pane, choose **Roles**, and then select the check box next to the role name that you want to delete.
3. At the top of the page, choose **Delete**.

4. In the confirmation dialog box, review the last accessed information, which shows when each of the selected roles last accessed an AWS service. This helps you to confirm if the role is currently active. If you want to proceed, enter the name of the role in the text input field and choose **Delete**. If you are sure, you can proceed with the deletion even if the last accessed information is still loading.

Note

You cannot use the console to delete an instance profile unless it has the same name as the role. The instance profile is deleted as part of the process of deleting a role as described in the preceding procedure. To delete an instance profile without also deleting the role, you must use the AWS CLI or AWS API. For more information, see the following sections.

Deleting an IAM role (AWS CLI)

When you use the AWS CLI to delete a role, you must first delete inline policies associated with the role. You must also detach managed policies associated with the role. If you want to delete the associated instance profile that contains the role, you must delete it separately.

To delete a role (AWS CLI)

1. If you don't know the name of the role that you want to delete, enter the following command to list the roles in your account:

```
aws iam list-roles
```

The list includes the Amazon Resource Name (ARN) of each role. Use the role name, not the ARN, to refer to roles with the CLI commands. For example, if a role has the following ARN: `arn:aws:iam::123456789012:role/myrole`, you refer to the role as **myrole**.

2. Remove the role from all instance profiles that the role is associated with.
 - a. To list all instance profiles that the role is associated with, enter the following command:

```
aws iam list-instance-profiles-for-role --role-name role-name
```

- b. To remove the role from an instance profile, enter the following command for each instance profile:

```
aws iam remove-role-from-instance-profile --instance-profile-name instance-profile-name --role-name role-name
```

3. Delete all policies that are associated with the role.

a. To list all inline policies that are in the role, enter the following command:

```
aws iam list-role-policies --role-name role-name
```

b. To delete each inline policy from the role, enter the following command for each policy:

```
aws iam delete-role-policy --role-name role-name --policy-name policy-name
```

c. To list all managed policies that are attached to the role, enter the following command:

```
aws iam list-attached-role-policies --role-name role-name
```

d. To detach each managed policy from the role, enter the following command for each policy:

```
aws iam detach-role-policy --role-name role-name --policy-arn policy-arn
```

4. Enter the following command to delete the role:

```
aws iam delete-role --role-name role-name
```

5. If you do not plan to reuse the instance profiles that were associated with the role, you can enter the following command to delete them:

```
aws iam delete-instance-profile --instance-profile-name instance-profile-name
```

Deleting an IAM role (AWS API)

When you use the IAM API to delete a role, you must first delete inline policies associated with the role. You must also detach managed policies associated with the role. If you want to delete the associated instance profile that contains the role, you must delete it separately.

To delete a role (AWS API)

1. To list all instance profiles that a role is associated with, call [ListInstanceProfilesForRole](#).

To remove the role from an instance profile, call [RemoveRoleFromInstanceProfile](#). You must pass the role name and instance profile name.

If you are not going to reuse an instance profile that was associated with the role, call [DeleteInstanceProfile](#) to delete it.

2. To list all inline policies for a role, call [ListRolePolicies](#).

To delete inline policies that are associated with the role, call [DeleteRolePolicy](#). You must pass the role name and inline policy name.

3. To list all managed policies that are attached to a role, call [ListAttachedRolePolicies](#).

To detach managed policies that are attached to the role, call [DetachRolePolicy](#). You must pass the role name and managed policy ARN.

4. Call [DeleteRole](#) to delete the role.

Related information

For general information about instance profiles, see [Using instance profiles](#).

For general information about service-linked roles, see [Using service-linked roles](#).

Tagging IAM resources

A *tag* is a custom attribute label that you can assign to an AWS resource. Each tag has two parts:

- A *tag key* (for example, `CostCenter`, `Environment`, `Project`, or `Purpose`).
- An optional field known as a *tag value* (for example, `111122223333`, `Production`, or a team name). Omitting the tag value is the same as using an empty string.

Together these are known as key-value pairs. For limits on the number of tags you can have on IAM resources, see [IAM and AWS STS quotas](#).

Note

For details about case sensitivity for tag keys and tag key values, see [Case sensitivity](#).

Tags help you identify and organize your AWS resources. Many AWS services support tagging, so you can assign the same tag to resources from different services to indicate that the resources are related. For example, you can assign the same tag to an IAM role that you assign to an Amazon S3 bucket. For more information about tagging strategies, see the [Tagging AWS resources User Guide](#).

In addition to identifying, organizing, and tracking your IAM resources with tags, you can use tags in IAM policies to help control who can view and interact with your resources. To learn more about using tags to control access, see [Controlling access to and for IAM users and roles using tags](#).

You can also use tags in AWS STS to add custom attributes when you assume a role or federate a user. For more information, see [Passing session tags in AWS STS](#).

Choose an AWS tag naming convention

When you begin attaching tags to your IAM resources, choose your tag naming convention carefully. Apply the same convention to all of your AWS tags. This is especially important if you use tags in policies to control access to AWS resources. If you already use tags in AWS, review your naming convention and adjust it accordingly.

Note

If your account is a member of AWS Organizations, see [Tag policies](#) in the Organizations user guide to learn more about using tags in Organizations.

Best practices for tag naming

These are some best practices and naming conventions for tags.

Ensure that tag names are used consistently. For example, the tags `CostCenter` and `costcenter` are different, so one might be configured as a cost allocation tag for financial analysis and reporting and the other one might not be. Similarly, the `Name` tag appears in the AWS Console for many resources, but the `name` tag does not. For details about case sensitivity for tag keys and tag key values, see [Case sensitivity](#).

A number of tags are predefined by AWS or created automatically by various AWS services. Many AWS-defined tags names use all lowercase, with hyphens separating words in the name, and prefixes to identify the source service for the tag. For example:

- `aws:ec2spot:fleet-request-id` identifies the Amazon EC2 Spot Instance Request that launched the instance.
- `aws:cloudformation:stack-name` identifies the AWS CloudFormation stack that created the resource.
- `elasticbeanstalk:environment-name` identifies the application that created the resource.

Consider naming your tags using all lowercase, with hyphens separating words, and a prefix identifying the organization name or abbreviated name. For example, for a fictitious company named *AnyCompany*, you might define tags such as:

- `anycompany:cost-center` to identify the internal Cost Center code
- `anycompany:environment-type` to identify whether the environment is development, test, or production
- `anycompany:application-id` to identify the application the resource was created for

The prefix ensures that tags are clearly identified as having been defined by your organization and not by AWS or a third-party tool that you may be using. Using all lowercase with hyphens for separators avoids confusion about how to capitalize a tag name. For example, `anycompany:project-id` is simpler to remember than `ANYCOMPANY:ProjectID`, `anycompany:projectID`, or `Anycompany:ProjectId`.

Rules for tagging in IAM and AWS STS

A number of conventions govern the creation and application of tags in IAM and AWS STS.

Naming tags

Observe the following conventions when formulating a tag naming convention for IAM resources, AWS STS assume-role sessions, and AWS STS federated user sessions:

Character requirements – Tag keys and values can include any combination of letters, numbers, spaces, and `_ . : / = + - @` symbols.

Case sensitivity – Case sensitivity for tag keys differs depending on the type of IAM resource that is tagged. Tag key values for IAM users and roles are not case sensitive, but case is preserved. This means that you cannot have separate **Department** and **department** tag keys. If you have tagged a user with the **Department=finance** tag and you add the **department=hr** tag, it replaces the first tag. A second tag is not added.

For other IAM resource types, tag key values are case sensitive. That means you can have separate **Costcenter** and **costcenter** tag keys. For example, if you have tagged a customer managed policy with the **Costcenter = 1234** tag and you add the **costcenter = 5678** tag, the policy will have both the **Costcenter** and **costcenter** tag keys.

As a best practice, we recommend that you avoid using similar tags with inconsistent case treatment. We recommend that you decide on a strategy for capitalizing tags, and consistently implement that strategy across all resource types. To learn more about best practices for tagging, see [Tagging AWS Resources](#) in the AWS General Reference.

The following lists show the differences in case sensitivity for tag keys that are attached to IAM resources.

Tag key values are **not** case sensitive:

- IAM roles
- IAM users

Tag key values are case sensitive:

- Customer managed policies
- Instance profiles
- OpenID Connect identity providers
- SAML identity providers
- Server certificates
- Virtual MFA devices

Additionally, the following rules apply:

- You cannot create a tag key or value that begins with the text **aws:.** This tag prefix is reserved for AWS internal use.

- You can create a tag with an empty value such as **phoneNumber** = . You cannot create an empty tag key.
- You cannot specify multiple values in a single tag, but you can create a custom multivalue structure in the single value. For example, assume that the user Zhang works on the engineering team and the QA team. If you attach the **team = Engineering** tag and then attach the **team = QA** tag, you change the value of the tag from **Engineering** to **QA**. Instead, you can include multiple values in a single tag with a custom separator. In this example, you could attach the **team = Engineering:QA** tag to Zhang.

Note

To control access to engineers in this example using the **team** tag, you must create a policy that allows for every configuration that might include **Engineering**, including **Engineering:QA**. To learn more about using tags in policies, see [Controlling access to and for IAM users and roles using tags](#).

Applying and editing tags

Observe the following conventions when attaching tags to IAM resources:

- You can tag most IAM resources, but not groups, assumed roles, access reports, or hardware-based MFA devices.
- You cannot use Tag Editor to tag IAM resources. Tag Editor does not support IAM tags. For information about using Tag Editor with other services, see [Working with Tag Editor](#) in the *AWS Resource Groups User Guide*.
- To tag an IAM resource, you must have specific permissions. To tag or untag resources, you must also have permission to list tags. For more information, see the list of topics for each IAM resource at the end of this page.
- The number and size of IAM resources in an AWS account are limited. For more information, see [IAM and AWS STS quotas](#).
- You can apply the same tag to multiple IAM resources. For example, suppose you have a department named `AWS_Development` with 12 members. You can have 12 users and a role with the tag key of **department** and a value of `awsDevelopment` (**department = awsDevelopment**). You can also use the same tag on resources in other [services that support tagging](#).

- IAM entities (users or roles) cannot have multiple instances of the same tag key. For example, if you have a user with the tag key-value pair **costCenter** = **1234**, you can then attach the tag key-value pair **costCenter** = **5678**. IAM updates the value of the **costCenter** tag to **5678**.
- To edit a tag that is attached to an IAM entity (user or role), attach a tag with a new value to overwrite the existing tag. For example, assume that you have a user with the tag key-value pair **department** = **Engineering**. If you need to move the user to the QA department, then you can attach the **department** = **QA** tag key-value pair to the user. This results in the **Engineering** value of the **department** tag key being replaced with the **QA** value.

Topics

- [Tagging customer managed policies](#)
- [Tagging IAM identity providers](#)
- [Tagging instance profiles for Amazon EC2 roles](#)
- [Tagging server certificates](#)
- [Tagging virtual MFA devices](#)
- [Passing session tags in AWS STS](#)

Tagging IAM users

You can use IAM tag key-value pairs to add custom attributes to an IAM user. For example, to add location information to a user, you can add the tag key **location** and the tag value **us_wa_seattle**. Or you could use three separate location tag key-value pairs: **loc-country** = **us**, **loc-state** = **wa**, and **loc-city** = **seattle**. You can use tags to control a user's access to resources or to control what tags can be attached to a user. To learn more about using tags to control access, see [Controlling access to and for IAM users and roles using tags](#).

You can also use tags in AWS STS to add custom attributes when you assume a role or federate a user. For more information, see [Passing session tags in AWS STS](#).

Permissions required for tagging IAM users

You must configure permissions to allow an IAM user to tag other users. You can specify one or all of the following IAM tag actions in an IAM policy:

- iam:ListUserTags
- iam:TagUser
- iam:UntagUser

To allow an IAM user to add, list, or remove a tag for a specific user

Add the following statement to the permissions policy for the IAM user that needs to manage tags. Use your account number and replace *<username>* with the name of the user whose tags need to be managed. To learn how to create a policy using this example JSON policy document, see [the section called "Creating policies using the JSON editor"](#).

```
{
  "Effect": "Allow",
  "Action": [
    "iam:ListUserTags",
    "iam:TagUser",
    "iam:UntagUser"
  ],
  "Resource": "arn:aws:iam::<account-number>:user/<username>"
}
```

To allow an IAM user to self-manage tags

Add the following statement to the permissions policy for users to allow users to manage their own tags. To learn how to create a policy using this example JSON policy document, see [the section called "Creating policies using the JSON editor"](#).

```
{
  "Effect": "Allow",
  "Action": [
    "iam:ListUserTags",
    "iam:TagUser",
    "iam:UntagUser"
  ],
  "Resource": "arn:aws:iam::user/${aws:username}"
}
```

To allow an IAM user to add a tag to a specific user

Add the following statement to the permissions policy for the IAM user that needs to add, but not remove, tags for a specific user.

Note

The `iam:TagUser` action requires that you also include the `iam:ListUserTags` action.

To use this policy, replace `<username>` with the name of the user whose tags need to be managed. To learn how to create a policy using this example JSON policy document, see [the section called "Creating policies using the JSON editor"](#).

```
{
  "Effect": "Allow",
  "Action": [
    "iam:ListUserTags",
    "iam:TagUser"
  ],
  "Resource": "arn:aws:iam::<account-number>:user/<username>"
}
```

Alternatively, you can use an AWS managed policy such as [IAMFullAccess](#) to provide full access to IAM.

Managing tags on IAM users (console)

You can manage tags for IAM users from the AWS Management Console.

To manage tags on users (console)

1. Sign in to the AWS Management Console and open the IAM console at <https://console.aws.amazon.com/iam/>.
2. In the navigation pane of the console, choose **Users** and then choose the name of the user that you want to edit.
3. Choose the **Tags** tab and then complete one of the following actions:
 - Choose **Add new tag** if the user does not yet have tags.
 - Choose **Manage tags** to manage the existing set of tags.
4. Add or remove tags to complete the set of tags. Then choose **Save changes**.

Managing tags on IAM users (AWS CLI or AWS API)

You can list, attach, or remove tags for IAM users. You can use the AWS CLI or the AWS API to manage tags for IAM users.

To list the tags currently attached to an IAM user (AWS CLI or AWS API)

- AWS CLI: [aws iam list-user-tags](#)
- AWS API: [ListUserTags](#)

To attach tags to an IAM user (AWS CLI or AWS API)

- AWS CLI: [aws iam tag-user](#)
- AWS API: [TagUser](#)

To remove tags from an IAM user (AWS CLI or AWS API)

- AWS CLI: [aws iam untag-user](#)
- AWS API: [UntagUser](#)

For information about attaching tags to resources for other AWS services, see the documentation for those services.

For information about using tags to set more granular permissions with IAM permissions policies, see [IAM policy elements: Variables and tags](#).

Tagging IAM roles

You can use IAM tag key-value pairs to add custom attributes to an IAM role. For example, to add location information to a role, you can add the tag key **location** and the tag value **us_wa_seattle**. Or you could use three separate location tag key-value pairs: **loc-country = us**, **loc-state = wa**, and **loc-city = seattle**. You can use tags to control a role's access to resources or to control what tags can be attached to a role. To learn more about using tags to control access, see [Controlling access to and for IAM users and roles using tags](#).

You can also use tags in AWS STS to add custom attributes when you assume a role or federate a user. For more information, see [Passing session tags in AWS STS](#).

Permissions required for tagging IAM roles

You must configure permissions to allow an IAM role to tag other entities (users or roles). You can specify one or all of the following IAM tag actions in an IAM policy:

- `iam:ListRoleTags`
- `iam:TagRole`
- `iam:UntagRole`
- `iam:ListUserTags`
- `iam:TagUser`
- `iam:UntagUser`

To allow an IAM role to add, list, or remove a tag for a specific user

Add the following statement to the permissions policy for the IAM role that needs to manage tags. Use your account number and replace `<username>` with the name of the user whose tags need to be managed. To learn how to create a policy using this example JSON policy document, see [the section called "Creating policies using the JSON editor"](#).

```
{
  "Effect": "Allow",
  "Action": [
    "iam:ListUserTags",
    "iam:TagUser",
    "iam:UntagUser"
  ],
  "Resource": "arn:aws:iam::<account-number>:user/<username>"
}
```

To allow an IAM role to add a tag to a specific user

Add the following statement to the permissions policy for the IAM role that needs to add, but not remove, tags for a specific user.

Note

The `iam:TagRole` action requires that you also include the `iam:ListRoleTags` action.

To use this policy, replace `<username>` with the name of the user whose tags need to be managed. To learn how to create a policy using this example JSON policy document, see [the section called “Creating policies using the JSON editor”](#).

```
{
  "Effect": "Allow",
  "Action": [
    "iam:ListUserTags",
    "iam:TagUser"
  ],
  "Resource": "arn:aws:iam::<account-number>:user/<username>"
}
```

To allow an IAM role to add, list, or remove a tag for a specific role

Add the following statement to the permissions policy for the IAM role that needs to manage tags. Replace `<rolename>` with the name of the role whose tags need to be managed. To learn how to create a policy using this example JSON policy document, see [the section called “Creating policies using the JSON editor”](#).

```
{
  "Effect": "Allow",
  "Action": [
    "iam:ListRoleTags",
    "iam:TagRole",
    "iam:UntagRole"
  ],
  "Resource": "arn:aws:iam::<account-number>:role/<rolename>"
}
```

Alternatively, you can use an AWS managed policy such as [IAMFullAccess](#) to provide full access to IAM.

Managing tags on IAM roles (console)

You can manage tags for IAM roles from the AWS Management Console.

To manage tags on roles (console)

1. Sign in to the AWS Management Console and open the IAM console at <https://console.aws.amazon.com/iam/>.

2. In the navigation pane of the console, choose **Roles** and then choose the name of the role that you want to edit.
3. Choose the **Tags** tab and then complete one of the following actions:
 - Choose **Add new tag** if the role does not yet have tags.
 - Choose **Manage tags** to manage the existing set of tags.
4. Add or remove tags to complete the set of tags. Then, choose **Save changes**.

Managing tags on IAM roles (AWS CLI or AWS API)

You can list, attach, or remove tags for IAM roles. You can use the AWS CLI or the AWS API to manage tags for IAM roles.

To list the tags currently attached to an IAM role (AWS CLI or AWS API)

- AWS CLI: [aws iam list-role-tags](#)
- AWS API: [ListRoleTags](#)

To attach tags to an IAM role (AWS CLI or AWS API)

- AWS CLI: [aws iam tag-role](#)
- AWS API: [TagRole](#)

To remove tags from an IAM role (AWS CLI or AWS API)

- AWS CLI: [aws iam untag-role](#)
- AWS API: [UntagRole](#)

For information about attaching tags to resources for other AWS services, see the documentation for those services.

For information about using tags to set more granular permissions with IAM permissions policies, see [IAM policy elements: Variables and tags](#).

Tagging customer managed policies

You can use IAM tag key-value pairs to add custom attributes to your customer managed policies. For example, to tag a policy with department information, you can add the tag key **Department** and the tag value **eng**. Or, you might want to tag policies to indicate that they are for a specific environment, such as **Environment = lab**. You can use tags to control access to resources or to control what tags can be attached to a resource. To learn more about using tags to control access, see [Controlling access to and for IAM users and roles using tags](#).

You can also use tags in AWS STS to add custom attributes when you assume a role or federate a user. For more information, see [Passing session tags in AWS STS](#).

Permissions required for tagging customer managed policies

You must configure permissions to allow an IAM entity (users or roles) to tag customer managed policies. You can specify one or all of the following IAM tag actions in an IAM policy:

- `iam:ListPolicyTags`
- `iam:TagPolicy`
- `iam:UntagPolicy`

To allow an IAM entity (user or role) to add, list, or remove a tag for a customer managed policy

Add the following statement to the permissions policy for the IAM entity that needs to manage tags. Use your account number and replace `<polycyname>` with the name of the policy whose tags need to be managed. To learn how to create a policy using this example JSON policy document, see [the section called "Creating policies using the JSON editor"](#).

```
{
  "Effect": "Allow",
  "Action": [
    "iam:ListPolicyTags",
    "iam:TagPolicy",
    "iam:UntagPolicy"
  ],
  "Resource": "arn:aws:iam::<account-number>:policy/<polycyname>"
}
```

To allow an IAM entity (user or role) to add a tag to a specific customer managed policy

Add the following statement to the permissions policy for the IAM entity that needs to add, but not remove, tags for a specific policy.

Note

The `iam:TagPolicy` action requires that you also include the `iam:ListPolicyTags` action.

To use this policy, replace `<policyname>` with the name of the policy whose tags need to be managed. To learn how to create a policy using this example JSON policy document, see [the section called "Creating policies using the JSON editor"](#).

```
{
  "Effect": "Allow",
  "Action": [
    "iam:ListPolicyTags",
    "iam:TagPolicy"
  ],
  "Resource": "arn:aws:iam::<account-number>:policy/<policyname>"
}
```

Alternatively, you can use an AWS managed policy such as [IAMFullAccess](#) to provide full access to IAM.

Managing tags on IAM customer managed policies (console)

You can manage tags for IAM customer managed policies from the AWS Management Console.

To manage tags on customer managed policies (console)

1. Sign in to the AWS Management Console and open the IAM console at <https://console.aws.amazon.com/iam/>.
2. In the navigation pane of the console, choose **Policies** and then choose the name of the customer managed policy that you want to edit.
3. Choose the **Tags** tab and then choose **Manage tags**.
4. Add or remove tags to complete the set of tags. Then choose **Save changes**.

Managing tags on IAM customer managed policies (AWS CLI or AWS API)

You can list, attach, or remove tags for IAM customer managed policies. You can use the AWS CLI or the AWS API to manage tags for IAM customer managed policies.

To list the tags currently attached to an IAM customer managed policy (AWS CLI or AWS API)

- AWS CLI: [aws iam list-policy-tags](#)
- AWS API: [ListPolicyTags](#)

To attach tags to an IAM customer managed policy (AWS CLI or AWS API)

- AWS CLI: [aws iam tag-policy](#)
- AWS API: [TagPolicy](#)

To remove tags from an IAM customer managed policy (AWS CLI or AWS API)

- AWS CLI: [aws iam untag-policy](#)
- AWS API: [UntagPolicy](#)

For information about attaching tags to resources for other AWS services, see the documentation for those services.

For information about using tags to set more granular permissions with IAM permissions policies, see [IAM policy elements: Variables and tags](#).

Tagging IAM identity providers

You can use IAM tag key-value pairs to add custom attributes to IAM identity providers (IdPs).

You can also use tags in AWS STS to add custom attributes when you assume a role or federate a user. For more information, see [Passing session tags in AWS STS](#).

To learn about tagging IdPs in IAM, see the following topics:

Topics

- [Tagging OpenID Connect \(OIDC\) identity providers](#)
- [Tagging IAM SAML identity providers](#)

Tagging OpenID Connect (OIDC) identity providers

You can use IAM tag key-values to add custom attributes to IAM OpenID Connect (OIDC) identity providers. For example, to identify an OIDC identity provider, you can add the tag key **google** and the tag value **oidc**. You can use tags to control access to resources or to control what tags can be attached to an object. To learn more about using tags to control access, see [Controlling access to and for IAM users and roles using tags](#).

Permissions required for tagging IAM OIDC identity providers

You must configure permissions to allow an IAM entity (user or role) to tag IAM OIDC identity providers. You can specify one or all of the following IAM tag actions in an IAM policy:

- `iam:ListOpenIDConnectProviderTags`
- `iam:TagOpenIDConnectProvider`
- `iam:UntagOpenIDConnectProvider`

To allow an IAM entity (user or role) to add, list, or remove a tag for an IAM OIDC identity provider

Add the following statement to the permissions policy for the IAM entity that needs to manage tags. Use your account number and replace `<OIDCProviderName>` with the name of the OIDC provider whose tags need to be managed. To learn how to create a policy using this example JSON policy document, see [the section called "Creating policies using the JSON editor"](#).

```
{
  "Effect": "Allow",
  "Action": [
    "iam:ListOpenIDConnectProviderTags",
    "iam:TagOpenIDConnectProvider",
    "iam:UntagOpenIDConnectProvider"
  ],
  "Resource": "arn:aws:iam::<account-number>:oidc-provider/<OIDCProviderName>"
}
```

To allow an IAM entity (user or role) to add a tag to a specific IAM OIDC identity provider

Add the following statement to the permissions policy for the IAM entity that needs to add, but not remove, tags for a specific identity provider.

Note

The `iam:TagOpenIDConnectProvider` action requires that you also include the `iam:ListOpenIDConnectProviderTags` action.

To use this policy, replace `<OIDCProviderName>` with the name of the OIDC provider whose tags need to be managed. To learn how to create a policy using this example JSON policy document, see [the section called "Creating policies using the JSON editor"](#).

```
{
  "Effect": "Allow",
  "Action": [
    "iam:ListOpenIDConnectProviderTags",
    "iam:TagOpenIDConnectProvider"
  ],
  "Resource": "arn:aws:iam::<account-number>:oidc-provider/<OIDCProviderName>"
}
```

Alternatively, you can use an AWS managed policy such as [IAMFullAccess](#) to provide full access to IAM.

Managing tags on IAM OIDC identity providers (console)

You can manage tags for IAM OIDC identity providers from the AWS Management Console.

Note

You can manage tags using the new Identity providers console experience only.

To manage tags on OIDC identity providers (console)

1. Sign in to the AWS Management Console and open the IAM console at <https://console.aws.amazon.com/iam/>.
2. In the navigation pane of the console, choose **Identity providers** and then choose the name of the identity provider that you want to edit.
3. In the **Tags** section, choose **Manage tags** and then complete one of the following actions:

- Choose **Add tag** if the OIDC identity provider does not yet have tags or to add a new tag.
 - Edit existing tag keys and values.
 - Choose **Remove tag** to remove a tag.
4. Then choose **Save changes**.

Managing tags on IAM OIDC identity providers (AWS CLI or AWS API)

You can list, attach, or remove tags for IAM OIDC identity providers. You can use the AWS CLI or the AWS API to manage tags for IAM OIDC identity providers.

To list the tags currently attached to an IAM OIDC identity provider (AWS CLI or AWS API)

- AWS CLI: [aws iam list-open-id-connect-provider-tags](#)
- AWS API: [ListOpenIDConnectProviderTags](#)

To attach tags to an IAM OIDC identity provider (AWS CLI or AWS API)

- AWS CLI: [aws iam tag-open-id-connect-provider](#)
- AWS API: [TagOpenIDConnectProvider](#)

To remove tags from an IAM OIDC identity provider (AWS CLI or AWS API)

- AWS CLI: [aws iam untag-open-id-connect-provider](#)
- AWS API: [UntagOpenIDConnectProvider](#)

For information about attaching tags to resources for other AWS services, see the documentation for those services.

For information about using tags to set more granular permissions with IAM permissions policies, see [IAM policy elements: Variables and tags](#).

Tagging IAM SAML identity providers

You can use IAM tag key-value pairs to add custom attributes to SAML identity providers. For example, to identify a provider, you can add the tag key **okta** and the tag value **saml**. You can use tags to control access to resources or to control what tags can be attached to an object. To learn

more about using tags to control access, see [Controlling access to and for IAM users and roles using tags](#).

Permissions required for tagging SAML identity providers

You must configure permissions to allow an IAM entity (users or roles) to tag SAML 2.0–based Identity Providers (IdPs). You can specify one or all of the following IAM tag actions in an IAM policy:

- `iam:ListSAMLProviderTags`
- `iam:TagSAMLProvider`
- `iam:UntagSAMLProvider`

To allow an IAM entity (user or role) to add, list, or remove a tag for a SAML identity provider

Add the following statement to the permissions policy for the IAM entity that needs to manage tags. Use your account number and replace `<SAMLProviderName>` with the name of the SAML provider whose tags need to be managed. To learn how to create a policy using this example JSON policy document, see [the section called “Creating policies using the JSON editor”](#).

```
{
  "Effect": "Allow",
  "Action": [
    "iam:ListSAMLProviderTags",
    "iam:TagSAMLProvider",
    "iam:UntagSAMLProvider"
  ],
  "Resource": "arn:aws:iam::<account-number>:saml-provider/<SAMLProviderName>"
}
```

To allow an IAM entity (user or role) to add a tag to a specific SAML identity provider

Add the following statement to the permissions policy for the IAM entity that needs to add, but not remove, tags for a specific SAML provider.

Note

The `iam:TagSAMLProvider` action requires that you also include the `iam:ListSAMLProviderTags` action.

To use this policy, replace `<SAMLProviderName>` with the name of the SAML provider whose tags need to be managed. To learn how to create a policy using this example JSON policy document, see [the section called "Creating policies using the JSON editor"](#).

```
{
  "Effect": "Allow",
  "Action": [
    "iam:ListSAMLProviderTags",
    "iam:TagSAMLProvider"
  ],
  "Resource": "arn:aws:iam::<account-number>:saml-provider/<SAMLProviderName>"
}
```

Alternatively, you can use an AWS managed policy such as [IAMFullAccess](#) to provide full access to IAM.

Managing tags on IAM SAML identity providers (console)

You can manage tags for IAM SAML Identity Providers from the AWS Management Console.

Note

You can manage tags using the new Identity providers console experience only.

To manage tags on SAML identity providers (console)

1. Sign in to the AWS Management Console and open the IAM console at <https://console.aws.amazon.com/iam/>.
2. In the navigation pane of the console, choose **Identity providers** and then choose the name of the SAML identity provider that you want to edit.
3. In the **Tags** section, choose **Manage tags** and then complete one of the following actions:
 - Choose **Add tag** if the SAML identity provider does not yet have tags or to add a new tag.
 - Edit existing tag keys and values.
 - Choose **Remove tag** to remove a tag.
4. Add or remove tags to complete the set of tags. Then choose **Save changes**.

Managing tags on IAM SAML identity providers (AWS CLI or AWS API)

You can list, attach, or remove tags for IAM SAML identity providers. You can use the AWS CLI or the AWS API to manage tags for IAM SAML identity providers.

To list the tags currently attached to a SAML identity provider (AWS CLI or AWS API)

- AWS CLI: [aws iam list-saml-provider-tags](#)
- AWS API: [ListSAMLProviderTags](#)

To attach tags to a SAML identity provider (AWS CLI or AWS API)

- AWS CLI: [aws iam tag-saml-provider](#)
- AWS API: [TagSAMLProvider](#)

To remove tags from a SAML identity provider (AWS CLI or AWS API)

- AWS CLI: [aws iam untag-saml-provider](#)
- AWS API: [UntagSAMLProvider](#)

For information about attaching tags to resources for other AWS services, see the documentation for those services.

For information about using tags to set more granular permissions with IAM permissions policies, see [IAM policy elements: Variables and tags](#).

Tagging instance profiles for Amazon EC2 roles

When you launch an Amazon EC2 instance, you specify an IAM role to associate with the instance. An instance profile is a container for an IAM role that you can use to pass role information to an Amazon EC2 instance when the instance starts. You can tag instance profiles when you use the AWS CLI or AWS API.

You can use IAM tag key-value pairs to add custom attributes to an instance profile. For example, to add department information to an instance profile, you can add the tag key **access-team** and the tag value **eng**. Doing this gives principals with matching tags access to instance profiles with the same tag. You could use multiple tag key-value pairs to specify a team and project: **access-**

team = eng , and **project = peg**. You can use tags to control a user's access to resources or to control what tags can be attached to a user. To learn more about using tags to control access, see [Controlling access to and for IAM users and roles using tags](#).

You can also use tags in AWS STS to add custom attributes when you assume a role or federate a user. For more information, see [Passing session tags in AWS STS](#).

Permissions required for tagging instance profiles

You must configure permissions to allow an IAM entity (user or role) to tag instance profiles. You can specify one or all of the following IAM tag actions in an IAM policy:

- iam:ListInstanceProfileTags
- iam:TagInstanceProfile
- iam:UntagInstanceProfile

To allow an IAM entity (user or role) to add, list, or remove a tag for an instance profile

Add the following statement to the permissions policy for the IAM entity that needs to manage tags. Use your account number and replace *<InstanceProfileName>* with the name of the instance profile whose tags need to be managed. To learn how to create a policy using this example JSON policy document, see [the section called "Creating policies using the JSON editor"](#).

```
{
  "Effect": "Allow",
  "Action": [
    "iam:ListInstanceProfileTags",
    "iam:TagInstanceProfile",
    "iam:UntagInstanceProfile"
  ],
  "Resource": "arn:aws:iam::<account-number>:instance-profile/<InstanceProfileName>"
}
```

To allow an IAM entity (user or role) to add a tag to a specific instance profile

Add the following statement to the permissions policy for the IAM entity that needs to add, but not remove, tags for a specific instance profile.

Note

The `iam:TagInstanceProfile` action requires that you also include the `iam:ListInstanceProfileTags` action.

To use this policy, replace `<InstanceProfileName>` with the name of the instance profile whose tags need to be managed. To learn how to create a policy using this example JSON policy document, see [the section called "Creating policies using the JSON editor"](#).

```
{
  "Effect": "Allow",
  "Action": [
    "iam:ListInstanceProfileTags",
    "iam:TagInstanceProfile"
  ],
  "Resource": "arn:aws:iam::<account-number>:instance-profile/<InstanceProfileName>"
}
```

Alternatively, you can use an AWS managed policy such as [IAMFullAccess](#) to provide full access to IAM.

Managing tags on instance profiles (AWS CLI or AWS API)

You can list, attach, or remove tags for instance profiles. You can use the AWS CLI or the AWS API to manage tags for instance profiles.

To list the tags currently attached to an instance profile (AWS CLI or AWS API)

- AWS CLI: [aws iam list-instance-profile-tags](#)
- AWS API: [ListInstanceProfileTags](#)

To attach tags to an instance profile (AWS CLI or AWS API)

- AWS CLI: [aws iam tag-instance-profile](#)
- AWS API: [TagInstanceProfile](#)

To remove tags from an instance profile (AWS CLI or AWS API)

- AWS CLI: [aws iam untag-instance-profile](#)
- AWS API: [UntagInstanceProfile](#)

For information about attaching tags to resources for other AWS services, see the documentation for those services.

For information about using tags to set more granular permissions with IAM permissions policies, see [IAM policy elements: Variables and tags](#).

Tagging server certificates

If you use IAM to manage SSL/TLS certificates, you can tag server certificates in IAM using the AWS CLI or AWS API. For certificates in a Region supported by AWS Certificate Manager (ACM), we recommend that you use ACM instead of IAM to provision, manage, and deploy your server certificates. In unsupported Regions, you must use IAM as a certificate manager. To learn which Regions ACM supports, see [AWS Certificate Manager endpoints and quotas](#) in the *AWS General Reference*.

You can use IAM tag key-value pairs to add custom attributes to a server certificate. For example, to add information about the owner or administrator of a server certificate, add the tag key **owner** and the tag value **net-eng**. Or you can specify a cost center by adding the tag key **CostCenter** and the tag value **1234**. You can use tags to control access to resources or to control what tags can be attached to resources. To learn more about using tags to control access, see [Controlling access to and for IAM users and roles using tags](#).

You can also use tags in AWS STS to add custom attributes when you assume a role or federate a user. For more information, see [Passing session tags in AWS STS](#).

Permissions required for tagging server certificates

You must configure permissions to allow an IAM entity (user or role) to tag server certificates. You can specify one or all of the following IAM tag actions in an IAM policy:

- `iam:ListServerCertificateTags`
- `iam:TagServerCertificate`
- `iam:UntagServerCertificate`

To allow an IAM entity (user or role) to add, list, or remove a tag for a server certificate

Add the following statement to the permissions policy for the IAM entity that needs to manage tags. Use your account number and replace *<CertificateName>* with the name of the server certificate whose tags need to be managed. To learn how to create a policy using this example JSON policy document, see [the section called “Creating policies using the JSON editor”](#).

```
{
  "Effect": "Allow",
  "Action": [
    "iam:ListServerCertificateTags",
    "iam:TagServerCertificate",
    "iam:UntagServerCertificate"
  ],
  "Resource": "arn:aws:iam::<account-number>:server-certificate/<CertificateName>"
}
```

To allow an IAM entity (user or role) to add a tag to a specific server certificate

Add the following statement to the permissions policy for the IAM entity that needs to add, but not remove, tags for a specific server certificate.

Note

The `iam:TagServerCertificate` action requires that you also include the `iam:ListServerCertificateTags` action.

To use this policy, replace *<CertificateName>* with the name of the server certificate whose tags need to be managed. To learn how to create a policy using this example JSON policy document, see [the section called “Creating policies using the JSON editor”](#).

```
{
  "Effect": "Allow",
  "Action": [
    "iam:ListServerCertificateTags",
    "iam:TagServerCertificate"
  ],
  "Resource": "arn:aws:iam::<account-number>:server-certificate/<CertificateName>"
}
```

Alternatively, you can use an AWS managed policy such as [IAMFullAccess](#) to provide full access to IAM.

Managing tags on server certificates (AWS CLI or AWS API)

You can list, attach, or remove tags for server certificates. You can use the AWS CLI or the AWS API to manage tags for server certificates.

To list the tags currently attached to a server certificate (AWS CLI or AWS API)

- AWS CLI: [aws iam list-server-certificate-tags](#)
- AWS API: [ListServerCertificateTags](#)

To attach tags to a server certificate (AWS CLI or AWS API)

- AWS CLI: [aws iam tag-server-certificate](#)
- AWS API: [TagServerCertificate](#)

To remove tags from a server certificate (AWS CLI or AWS API)

- AWS CLI: [aws iam untag-server-certificate](#)
- AWS API: [UntagServerCertificate](#)

For information about attaching tags to resources for other AWS services, see the documentation for those services.

For information about using tags to set more granular permissions with IAM permissions policies, see [IAM policy elements: Variables and tags](#).

Tagging virtual MFA devices

You can use IAM tag key-value pairs to add custom attributes to a virtual MFA device. For example, to add cost center information for a user's virtual MFA device, you can add the tag key **CostCenter** and the tag value **1234**. You can use tags to control access to resources or to control what tags can be attached to an object. To learn more about using tags to control access, see [Controlling access to and for IAM users and roles using tags](#).

You can also use tags in AWS STS to add custom attributes when you assume a role or federate a user. For more information, see [Passing session tags in AWS STS](#).

Permissions required for tagging virtual MFA devices

You must configure permissions to allow an IAM entity (user or role) to tag virtual MFA devices. You can specify one or all of the following IAM tag actions in an IAM policy:

- `iam:ListMFADeviceTags`
- `iam:TagMFADevice`
- `iam:UntagMFADevice`

To allow an IAM entity (user or role) to add, list, or remove a tag for a virtual MFA device

Add the following statement to the permissions policy for the IAM entity that needs to manage tags. Use your account number and replace `<MFATokenID>` with the name of the virtual MFA device whose tags need to be managed. To learn how to create a policy using this example JSON policy document, see [the section called "Creating policies using the JSON editor"](#).

```
{
  "Effect": "Allow",
  "Action": [
    "iam:ListMFADeviceTags",
    "iam:TagMFADevice",
    "iam:UntagMFADevice"
  ],
  "Resource": "arn:aws:iam::<account-number>:mfa/<MFATokenID>"
}
```

To allow an IAM entity (user or role) to add a tag to a specific virtual MFA device

Add the following statement to the permissions policy for the IAM entity that needs to add, but not remove, tags for a specific MFA device.

Note

The `iam:TagMFADevice` action requires that you also include the `iam:ListMFADeviceTags` action.

To use this policy, replace `<MFATokenID>` with the name of the virtual MFA device whose tags need to be managed. To learn how to create a policy using this example JSON policy document, see [the section called "Creating policies using the JSON editor"](#).

```
{
  "Effect": "Allow",
  "Action": [
    "iam:ListMFADeviceTags",
    "iam:TagMFADevice"
  ],
  "Resource": "arn:aws:iam::<account-number>:mfa/<MFATokenID>"
}
```

Alternatively, you can use an AWS managed policy such as [IAMFullAccess](#) to provide full access to IAM.

Managing tags on virtual MFA devices (AWS CLI or AWS API)

You can list, attach, or remove tags for a virtual MFA device. You can use the AWS CLI or the AWS API to manage tags for a virtual MFA device.

To list the tags currently attached to a virtual MFA device (AWS CLI or AWS API)

- AWS CLI: [aws iam list-mfa-device-tags](#)
- AWS API: [ListMFADeviceTags](#)

To attach tags to a virtual MFA device (AWS CLI or AWS API)

- AWS CLI: [aws iam tag-mfa-device](#)
- AWS API: [TagMFADevice](#)

To remove tags from a virtual MFA device (AWS CLI or AWS API)

- AWS CLI: [aws iam untag-mfa-device](#)
- AWS API: [UntagMFADevice](#)

For information about attaching tags to resources for other AWS services, see the documentation for those services.

For information about using tags to set more granular permissions with IAM permissions policies, see [IAM policy elements: Variables and tags](#).

Passing session tags in AWS STS

Session tags are key-value pair attributes that you pass when you assume an IAM role or federate a user in AWS STS. You do this by making an AWS CLI or AWS API request through AWS STS or through your identity provider (IdP). When you use AWS STS to request temporary security credentials, you generate a session. Sessions expire and have [credentials](#), such as an access key pair and a session token. When you use the session credentials to make a subsequent request, the [request context](#) includes the [aws:PrincipalTag](#) context key. You can use the `aws:PrincipalTag` key in the `Condition` element of your policies to allow or deny access based on those tags.

When you use temporary credentials to make a request, your principal might include a set of tags. These tags come from the following sources:

1. **Session tags** – The tags passed when you assume the role or federate the user using the AWS CLI or AWS API. For more information about these operations, see [Session tagging operations](#).
2. **Incoming transitive session tags** – The tags inherited from a previous session in a role chain. For more information, see [Chaining roles with session tags](#) later in this topic.
3. **IAM tags** – The tags attached to your IAM assumed role.

Topics

- [Session tagging operations](#)
- [Things to know about session tags](#)
- [Permissions required to add session tags](#)
- [Passing session tags using AssumeRole](#)
- [Passing session tags using AssumeRoleWithSAML](#)
- [Passing session tags using AssumeRoleWithWebIdentity](#)
- [Passing session tags using GetFederationToken](#)
- [Chaining roles with session tags](#)
- [Using session tags for ABAC](#)
- [Viewing session tags in CloudTrail](#)

Session tagging operations

You can pass session tags using the following AWS CLI or AWS API operations in AWS STS. *The AWS Management Console [Switch Role](#) feature does not allow you to pass session tags.*

You can also set the session tags as transitive. Transitive tags persist during role chaining. For more information, see [Chaining roles with session tags](#).

Comparing methods for passing session tags

Operation	Who can assume the role	Method to pass tags	Method to set transitive tags
assume-role CLI or AssumeRole API operation	IAM user or a session	Tags API parameter or --tags CLI option	TransitiveTagKeys API parameter or --transitive-tag-keys CLI option
assume-role-with-saml CLI or AssumeRoleWithSAML API operation	Any user authenticated using a SAML identity provider	PrincipalTag SAML attribute	TransitiveTagKeys SAML Attribute
assume-role-with-web-identity CLI or AssumeRoleWithWebIdentity API operation	Any user authenticated using a web identity provider	PrincipalTag web identity token	TransitiveTagKeys web identity token
get-federation-token CLI or GetFederationToken API operation	IAM user or root user	Tags API parameter or --tags CLI option	Not supported

Operations that support session tagging can fail under the following conditions:

- You pass more than 50 session tags.
- The plaintext of your session tag keys exceeds 128 characters.
- The plaintext of your session tag values exceeds 256 characters.
- The total size of the plaintext of session policies exceeds 2048 characters.
- The total packed size of the combined session policies and tags is too large. If the operation fails, the error message shows how close the policies and tags combined come to the upper size limit, by percentage.

Things to know about session tags

Before you use session tags, review the following details about sessions and tags.

- When using session tags, trust policies for all roles connected to the identity provider (IdP) passing tags must have the [sts:TagSession](#) permission. For roles without this permission in the trust policy, the `AssumeRole` operation fails.
- When you request a session, you can specify principal tags as the session tags. The tags apply to requests that you make using the session's credentials.
- Session tags use key-value pairs. For example, to add contact information to a session, you can add the session tag key `email` and the tag value `johndoe@example.com`.
- Session tags must follow the [rules for naming tags in IAM and AWS STS](#). This topic includes information about case sensitivity and restricted prefixes that apply to your session tags.
- New session tags override existing assumed role or federated user tags with the same tag key, regardless of character case.
- You cannot pass session tags using the AWS Management Console.
- Session tags are valid only for the current session.
- Session tags support [role chaining](#). By default, AWS STS does not pass tags to subsequent role sessions. However, you can set session tags as transitive. Transitive tags persist during role chaining and replace matching `ResourceTag` values after the evaluation of the role trust policy. For more information, see [Chaining roles with session tags](#).
- You can use session tags to control access to resources or to control what tags can be passed into a subsequent session. For more information, see [IAM tutorial: Use SAML session tags for ABAC](#).

- You can view the principal tags for your session, including the session tags, in the AWS CloudTrail logs. For more information, see [Viewing session tags in CloudTrail](#).
- You must pass a single value for each session tag. AWS STS does not support multi-valued session tags.
- You can pass a maximum of 50 session tags. The number and size of IAM resources in an AWS account are limited. For more information, see [IAM and AWS STS quotas](#).
- An AWS conversion compresses the passed session policies and session tags combined into a packed binary format with a separate limit. If you exceed this limit, the AWS CLI or AWS API error message shows how close the policies and tags combined come to the upper size limit, by percentage.

Permissions required to add session tags

In addition to the action that matches the API operation, you must have the following permissions-only action in your policy:

```
sts:TagSession
```

Important

When using session tags, the role trust policies for all roles connected to an identity provider (IdP) must have the `sts:TagSession` permission. The `AssumeRole` operation fails for any role connected to an IdP passing session tags without this permission. If you don't want to update the role trust policy for each role, you can use a separate IdP instance for passing session tags. Then, add the `sts:TagSession` permission to only the roles connected to the separate IdP.

You can use the `sts:TagSession` action with the following condition keys.

- [aws:PrincipalTag](#) – Compares the tag attached to the principal making the request with the tag you specified in the policy. For example, you can allow a principal to pass session tags only if the principal making the request has the specified tags.
- [aws:RequestTag](#) – Compares the tag key-value pair passed in the request with the tag pair you specified in the policy. For example, you can allow the principal to pass the specified session tags, but only with the specified values.

- [aws:ResourceTag](#) – Compares the tag key-value pair you specified in the policy with the key-value pair attached to the resource. For example, you can allow the principal to pass session tags only if the role they assume includes the specified tags.
- [aws:TagKeys](#) – Compares the tag keys in a request with the keys you specified in the policy. For example, you can allow the principal to pass only session tags with the specified tag keys. This condition key limits the maximum set of session tags that can be passed.
- [sts:TransitiveTagKeys](#) - Compares the transitive session tag keys in the request with those specified in the policy. For example, you can write a policy to allow a principal to set only specific tags as transitive. Transitive tags persist during role chaining. For more information, see [Chaining roles with session tags](#).

For example, the following [role trust policy](#) allows the `test-session-tags` user to assume the role with the attached policy. When that user assumes the role, they must use the AWS CLI or AWS API to pass the three required session tags and the required [external ID](#). Additionally, the user can choose to set the Project and Department tags as transitive.

Example Example role trust policy for session tags

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "AllowIamUserAssumeRole",
      "Effect": "Allow",
      "Action": "sts:AssumeRole",
      "Principal": {"AWS": "arn:aws:iam::123456789012:user/test-session-tags"},
      "Condition": {
        "StringLike": {
          "aws:RequestTag/Project": "*",
          "aws:RequestTag/CostCenter": "*",
          "aws:RequestTag/Department": "*"
        },
        "StringEquals": {"sts:ExternalId": "Example987"}
      }
    },
    {
      "Sid": "AllowPassSessionTagsAndTransitive",
      "Effect": "Allow",
      "Action": "sts:TagSession",
      "Principal": {"AWS": "arn:aws:iam::123456789012:user/test-session-tags"},
```

```
    "Condition": {
      "StringLike": {
        "aws:RequestTag/Project": "*",
        "aws:RequestTag/CostCenter": "*"
      },
      "StringEquals": {
        "aws:RequestTag/Department": [
          "Engineering",
          "Marketing"
        ]
      },
      "ForAllValues:StringEquals": {
        "sts:TransitiveTagKeys": [
          "Project",
          "Department"
        ]
      }
    }
  }
}
```

What does this policy do?

- The AllowIamUserAssumeRole statement allows the test-session-tags user to assume the role with the attached policy. When that user assumes the role, they must pass the required session tags and [external ID](#).
- The first condition block of this statement requires the user to pass the Project, CostCenter, and Department session tags. The tag values do not matter in this statement, so you can use wildcards (*) for the tag values. This block ensures that user passes at least these three session tags. Otherwise, the operation fails. The user can pass additional tags.
- The second condition block requires the user to pass an [external ID](#) with the value Example987.
- The AllowPassSessionTagsAndTransitive statement allows the sts:TagSession permissions-only action. This action must be allowed before the user can pass session tags. If your policy includes the first statement without the second statement, the user can't assume the role.

- The first condition block of this statement allows the user to pass any value for the `CostCenter` and `Project` session tags. You do this by using wildcards (*) for the tag value in the policy, which requires that you use the [StringLike](#) condition operator.
- The second condition block allows the user to pass only the `Engineering` or `Marketing` value for the `Department` session tag.
- The third condition block lists the maximum set of tags you can set as transitive. The user can choose to set a subset or no tags as transitive. They cannot set additional tags as transitive. You can require that they set at least one of the tags as transitive by adding another condition block that includes `"Null":{"sts:TransitiveTagKeys":"false"}`.

Passing session tags using AssumeRole

The `AssumeRole` operation returns a set of temporary credentials you can use to access AWS resources. You can use IAM user or role credentials to call `AssumeRole`. To pass session tags while assuming a role, use the `--tags` AWS CLI option or the `Tags` AWS API parameter.

To set tags as transitive, use the `--transitive-tag-keys` AWS CLI option or the `TransitiveTagKeys` AWS API parameter. Transitive tags persist during role chaining. For more information, see [Chaining roles with session tags](#).

The following example shows a sample request that uses `AssumeRole`. In this example, when you assume the `my-role-example` role, you create a session named `my-session`. You add the session tag key-value pairs `Project = Automation`, `CostCenter = 12345`, and `Department = Engineering`. You also set the `Project` and `Department` tags as transitive by specifying their keys.

Example Example AssumeRole CLI request

```
aws sts assume-role \  
--role-arn arn:aws:iam::123456789012:role/my-role-example \  
--role-session-name my-session \  
--tags Key=Project,Value=Automation Key=CostCenter,Value=12345 \  
Key=Department,Value=Engineering \  
--transitive-tag-keys Project Department \  
--external-id Example987
```

Passing session tags using AssumeRoleWithSAML

The AssumeRoleWithSAML operation authenticates with SAML-based federation. This operation returns a set of temporary credentials you can use to access AWS resources. For more information about using SAML-based federation for AWS Management Console access, see [Enabling SAML 2.0 federated users to access the AWS Management Console](#). For details about AWS CLI or AWS API access, see [About SAML 2.0-based federation](#). For a tutorial on configuring SAML federation for your Active Directory users, see [AWS Federated Authentication with Active Directory Federation Services \(ADFS\)](#) in the AWS Security Blog.

As an administrator, you can allow members of your company directory to federate into AWS using the AWS STS AssumeRoleWithSAML operation. To do this, you must complete the following tasks:

1. [Configure your network as a SAML provider for AWS](#).
2. [Create a SAML provider in IAM](#)
3. [Configure a role and permissions in AWS for your federated users](#)
4. [Finish configuring the SAML IdP and create assertions for the SAML authentication response](#)

AWS includes identity providers with certified end-to-end experience for session tags with their identity solutions. To learn how to use these identity providers to configure session tags, see [Integrating third-party SAML solution providers with AWS](#).

To pass SAML attributes as session tags, include the `Attribute` element with the `Name` attribute set to `https://aws.amazon.com/SAML/Attributes/PrincipalTag:{TagKey}`. Use the `AttributeValue` element to specify the value of the tag. Include a separate `Attribute` element for each session tag.

For example, assume that you want to pass the following identity attributes as session tags:

- `Project:Automation`
- `CostCenter:12345`
- `Department:Engineering`

To pass these attributes, include the following elements in your SAML assertion.

Example Example snippet of a SAML assertion

```
<Attribute Name="https://aws.amazon.com/SAML/Attributes/PrincipalTag:Project">
```

```
<AttributeValue>Automation</AttributeValue>
</Attribute>
<Attribute Name="https://aws.amazon.com/SAML/Attributes/PrincipalTag:CostCenter">
  <AttributeValue>12345</AttributeValue>
</Attribute>
<Attribute Name="https://aws.amazon.com/SAML/Attributes/PrincipalTag:Department">
  <AttributeValue>Engineering</AttributeValue>
</Attribute>
```

To set the preceding tags as transitive, include another `Attribute` element with the `Name` attribute set to `https://aws.amazon.com/SAML/Attributes/TransitiveTagKeys`. Transitive tags persist during role chaining. For more information, see [Chaining roles with session tags](#).

To set the `Project` and `Department` tags as transitive, use the following multi-valued attribute:

Example Example snippet of a SAML assertion

```
<Attribute Name="https://aws.amazon.com/SAML/Attributes/TransitiveTagKeys">
  <AttributeValue>Project</AttributeValue>
  <AttributeValue>Department</AttributeValue>
</Attribute>
```

Passing session tags using AssumeRoleWithWebIdentity

Use OpenID Connect (OIDC)-compliant web identity federation to authenticate the `AssumeRoleWithWebIdentity` operation. This operation returns a set of temporary credentials you can use to access AWS resources. For more information about using web identity federation for AWS Management Console access, see [About web identity federation](#).

To pass session tags from OpenID Connect (OIDC), you must include the session tags in the JSON Web Token (JWT). Include session tags in the `https://aws.amazon.com/` tags namespace in the token when you submit the `AssumeRoleWithWebIdentity` request. To learn more about OIDC tokens and claims, see [Using Tokens with User Pools](#) in the *Amazon Cognito Developer Guide*.

For example, the following decoded JWT uses a token to call `AssumeRoleWithWebIdentity` with the `Project`, `CostCenter`, and `Department` session tags. The token also sets the `Project` and `CostCenter` tags as transitive. Transitive tags persist during role chaining. For more information, see [Chaining roles with session tags](#).

Example Example decoded JSON Web Token

```
{
  "sub": "johndoe",
  "aud": "ac_oic_client",
  "jti": "ZYUCeRMQVtqHypVPWAN3VB",
  "iss": "https://xyz.com",
  "iat": 1566583294,
  "exp": 1566583354,
  "auth_time": 1566583292,
  "https://aws.amazon.com/tags": {
    "principal_tags": {
      "Project": ["Automation"],
      "CostCenter": ["987654"],
      "Department": ["Engineering"]
    },
    "transitive_tag_keys": [
      "Project",
      "CostCenter"
    ]
  }
}
```

Passing session tags using GetFederationToken

The `GetFederationToken` allows you to federate your user. This operation returns a set of temporary credentials you can use to access AWS resources. To add tags to your federated user session, use the `--tags` AWS CLI option or the `Tags` AWS API parameter. You can't set session tags as transitive when you use `GetFederationToken`, because you can't use the temporary credentials to assume a role. You cannot use role chaining in this case.

The following example shows a sample request using `GetFederationToken`. In this example, when you request the token, you create a session named `my-fed-user`. You add the session tag key-value pairs `Project = Automation` and `Department = Engineering`.

Example Example GetFederationToken CLI request

```
aws sts get-federation-token \
--name my-fed-user \
--tags key=Project,value=Automation key=Department,value=Engineering
```

When you use the temporary credentials returned by the `GetFederationToken` operation, the session principal tags include the user tags and the passed session tags.

Chaining roles with session tags

You can assume one role and then use the temporary credentials to assume another role. You can continue from session to session. This is called [role chaining](#). When you pass session tags while assuming a role, you can set the keys as transitive. This ensures that those session tags pass to subsequent sessions in a role chain. You cannot set role tags as transitive. To pass these tags to subsequent sessions, specify them as session tags.

Note

Transitive tags persist during role chaining and replace matching `ResourceTag` values after the evaluation of the role trust policy.

The following example shows how AWS STS passes session tags, transitive tags, and role tags into subsequent sessions in a role chain.

In this example role chaining scenario, you use an IAM user access key in the AWS CLI to assume a role named `Role1`. You then use the resulting session credentials to assume a second role named `Role2`. You can then use the second session credentials to assume a third role named `Role3`. These requests occur as three separate operations. Each role is already tagged in IAM. And during each request, you pass additional session tags.

When you chain roles, you can ensure that tags from an earlier session persist to the later sessions. To do this using the `assume-role` CLI command, you must pass the tag as a session tag and set the tag as transitive. You pass the tag `Star = 1` as a session tag. The command also attaches the tag `Heart = 1` to the role and applies as a principal tag when you use the session. However, you also want the `Heart = 1` tag to automatically pass to the second or third session. To do that, you manually include it as a session tag. The resulting session principal tags include both of these tags, and sets them as transitive.

You perform this request using the following AWS CLI command:

Example Example AssumeRole CLI request

```
aws sts assume-role \
```

```
--role-arn arn:aws:iam::123456789012:role/Role1 \  
--role-session-name Session1 \  
--tags Key=Star,Value=1 Key=Heart,Value=1 \  
--transitive-tag-keys Star Heart
```

You then use the credentials for that session to assume Role2. The command attaches the tag `Sun = 2` to the second role and applies as a principal tag when you use the second session. The `Heart` and `Star` tags inherits the transitive session tags in the first session. The second session resulting principal tags are `Heart = 1`, `Star = 1`, and `Sun = 2`. `Heart` and `Star` continue to be transitive. The `Sun` tag attached to Role2 is not marked as transitive because it is not a session tag. Future sessions do not inherit this tag.

You perform this second request using the following AWS CLI command:

Example Example AssumeRole CLI request

```
aws sts assume-role \  
--role-arn arn:aws:iam::123456789012:role/Role2 \  
--role-session-name Session2
```

You then use the second session credentials to assume Role3. The principal tags for the third session come from any new session tags, the inherited transitive session tags, and the role tags. The `Heart = 1` and `Star = 1` tags on the second session are inherited from the transitive session tag in the first session. If you try to pass the `Sun = 2` session tag, the operation fails. The inherited `Star = 1` session tag overrides the role `Star = 3` tag. In role chaining, the value of a transitive tag overrides the role matching the `ResourceTag` value after the evaluation of the role trust policy. In this example, if Role3 uses `Star` as a `ResourceTag` in the role trust policy, and sets `ResourceTag` value to the transitive tag value from the calling role session. The role `Lightning` tag also applies to the third session, and not set as transitive.

You perform the third request using the following AWS CLI command:

Example Example AssumeRole CLI request

```
aws sts assume-role \  
--role-arn arn:aws:iam::123456789012:role/Role3 \  
--role-session-name Session3
```

Using session tags for ABAC

Attribute-based access control (ABAC) uses an authorization strategy that defines permissions based on tag attributes.

If your company uses an OIDC or SAML-based identity provider (IdP) to manage user identities, you can configure your assertion to pass session tags to AWS. For example, with corporate user identities, when your employees federate into AWS, AWS applies their attributes to their resulting principal. You can then use ABAC to allow or deny permissions based on those attributes. For details, see [IAM tutorial: Use SAML session tags for ABAC](#).

For more information about using IAM Identity Center with ABAC, see [Attributes for access control](#) in the *AWS IAM Identity Center User Guide*.

Viewing session tags in CloudTrail

You can use AWS CloudTrail to view the requests used to assume roles or federate users. The CloudTrail log file includes information about the principal tags for the assumed-role or federated user session. For more information, see [Logging IAM and AWS STS API calls with AWS CloudTrail](#).

For example, assume that you make an AWS STS AssumeRoleWithSAML request, pass session tags, and set those tags as transitive. You can find the following information in your CloudTrail log.

Example Example AssumeRoleWithSAML CloudTrail log

```
"requestParameters": {
  "sAMLAssertionID": "_c0046cEXAMPLEb9d4b8eEXAMPLE2619aEXAMPLE",
  "roleSessionName": "MyRoleSessionName",
  "principalTags": {
    "CostCenter": "987654",
    "Project": "Unicorn"
  },
  "transitiveTagKeys": [
    "CostCenter",
    "Project"
  ],
  "durationSeconds": 3600,
  "roleArn": "arn:aws:iam::123456789012:role/SAMLTSTRoleShibboleth",
  "principalArn": "arn:aws:iam::123456789012:saml-provider/Shibboleth"
},
```

You can view the following example CloudTrail logs to view events that use session tags.

- [Example AWS STS role chaining API event in CloudTrail log file](#)
- [Example SAML AWS STS API event in CloudTrail log file](#)
- [Example web identity AWS STS API event in CloudTrail log file](#)

Temporary security credentials in IAM

You can use the AWS Security Token Service (AWS STS) to create and provide trusted users with temporary security credentials that can control access to your AWS resources. Temporary security credentials work almost identically to long-term access key credentials, with the following differences:

- Temporary security credentials are *short-term*, as the name implies. They can be configured to last for anywhere from a few minutes to several hours. After the credentials expire, AWS no longer recognizes them or allows any kind of access from API requests made with them.
- Temporary security credentials are not stored with the user but are generated dynamically and provided to the user when requested. When (or even before) the temporary security credentials expire, the user can request new credentials, as long as the user requesting them still has permissions to do so.

As a result, temporary credentials have the following advantages over long-term credentials:

- You do not have to distribute or embed long-term AWS security credentials with an application.
- You can provide access to your AWS resources to users without having to define an AWS identity for them. Temporary credentials are the basis for [roles and identity federation](#).
- The temporary security credentials have a limited lifetime, so you do not have to update them or explicitly revoke them when they're no longer needed. After temporary security credentials expire, they cannot be reused. You can specify how long the credentials are valid, up to a maximum limit.

AWS STS and AWS regions

Temporary security credentials are generated by AWS STS. By default, AWS STS is a global service with a single endpoint at `https://sts.amazonaws.com`. However, you can also choose to make AWS STS API calls to endpoints in any other supported Region. This can reduce latency (server lag) by sending the requests to servers in a Region that is geographically closer to you. No matter which

Region your credentials come from, they work globally. For more information, see [Managing AWS STS in an AWS Region](#).

Common scenarios for temporary credentials

Temporary credentials are useful in scenarios that involve identity federation, delegation, cross-account access, and IAM roles.

Identity federation

You can manage your user identities in an external system outside of AWS and grant users who sign in from those systems access to perform AWS tasks and access your AWS resources. IAM supports two types of identity federation. In both cases, the identities are stored outside of AWS. The distinction is where the external system resides—in your data center or an external third party on the web. For more information about external identity providers, see [Identity providers and federation](#).

- **Enterprise identity federation** – You can authenticate users in your organization's network, and then provide those users access to AWS without creating new AWS identities for them and requiring them to sign in with different sign-in credentials. This is known as the *single sign-on* approach to temporary access. AWS STS supports open standards like Security Assertion Markup Language (SAML) 2.0, with which you can use Microsoft AD FS to leverage your Microsoft Active Directory. You can also use SAML 2.0 to manage your own solution for federating user identities. For more information, see [About SAML 2.0-based federation](#).
- **Custom federation broker** – You can use your organization's authentication system to grant access to AWS resources. For an example scenario, see [Enabling custom identity broker access to the AWS console](#).
- **Federation using SAML 2.0** – You can use your organization's authentication system and SAML to grant access to AWS resources. For more information and an example scenario, see [About SAML 2.0-based federation](#).
- **Web identity federation** – You can let users sign in using a well-known third-party identity provider such as Login with Amazon, Facebook, Google, or any OpenID Connect (OIDC) 2.0 compatible provider. You can exchange the credentials from that provider for temporary permissions to use resources in your AWS account. This is known as the *web identity federation* approach to temporary access. When you use web identity federation for your mobile or web application, you don't need to create custom sign-in code or manage your own user identities. Using web identity federation helps you keep your AWS account secure, because you don't have

to distribute long-term security credentials, such as IAM user access keys, with your application. For more information, see [About web identity federation](#).

AWS STS web identity federation supports Login with Amazon, Facebook, Google, and any OpenID Connect (OIDC)-compatible identity provider.

Note

For mobile applications, we recommend that you use Amazon Cognito. You can use this service with AWS SDKs for mobile development to create unique identities for users and authenticate them for secure access to your AWS resources. Amazon Cognito supports the same identity providers as AWS STS, and also supports unauthenticated (guest) access and lets you migrate user data when a user signs in. Amazon Cognito also provides API operations for synchronizing user data so that it is preserved as users move between devices. For more information, see [Authentication with Amplify](#) in the *Amplify Documentation*.

Roles for cross-account access

Many organizations maintain more than one AWS account. Using roles and cross-account access, you can define user identities in one account, and use those identities to access AWS resources in other accounts that belong to your organization. This is known as the *delegation* approach to temporary access. For more information about creating cross-account roles, see [Creating a role to delegate permissions to an IAM user](#). To learn whether principals in accounts outside of your zone of trust (trusted organization or account) have access to assume your roles, see [What is IAM Access Analyzer?](#).

Roles for Amazon EC2

If you run applications on Amazon EC2 instances and those applications need access to AWS resources, you can provide temporary security credentials to your instances when you launch them. These temporary security credentials are available to all applications that run on the instance, so you don't need to store any long-term credentials on the instance. For more information, see [Using an IAM role to grant permissions to applications running on Amazon EC2 instances](#).

Other AWS services

You can use temporary security credentials to access most AWS services. For a list of the services that accept temporary security credentials, see [AWS services that work with IAM](#).

Requesting temporary security credentials

To request temporary security credentials, you can use AWS Security Token Service (AWS STS) operations in the AWS API. These include operations to create and provide trusted users with temporary security credentials that can control access to your AWS resources. For more information about AWS STS, see [Temporary security credentials in IAM](#). To learn about the different methods that you can use to request temporary security credentials by assuming a role, see [Using IAM roles](#).

To call the API operations, you can use one of the [AWS SDKs](#). The SDKs are available for a variety of programming languages and environments, including Java, .NET, Python, Ruby, Android, and iOS. The SDKs take care of tasks such as cryptographically signing your requests, retrying requests if necessary, and handling error responses. You can also use the AWS STS Query API, which is described in the [AWS Security Token Service API Reference](#). Finally, two command line tools support the AWS STS commands: the [AWS Command Line Interface](#), and the [AWS Tools for Windows PowerShell](#).

The AWS STS API operations create a new session with temporary security credentials that include an access key pair and a session token. The access key pair consists of an access key ID and a secret key. Users (or an application that the user runs) can use these credentials to access your resources. You can create a role session and pass session policies and session tags programmatically using AWS STS API operations. The resulting session permissions are the intersection of the role's identity-based policies and the session policies. For more information about session policies, see [Session policies](#). For more information about session tags, see [Passing session tags in AWS STS](#).

Note

The size of the session token that AWS STS API operations return is not fixed. We strongly recommend that you make no assumptions about the maximum size. The typical token size is less than 4096 bytes, but that can vary.

Using AWS STS with AWS Regions

You can send AWS STS API calls either to a global endpoint or to one of the Regional endpoints. If you choose an endpoint closer to you, you can reduce latency and improve the performance of your API calls. You also can choose to direct your calls to an alternative Regional endpoint if you can no longer communicate with the original endpoint. If you are using one of the various AWS SDKs, then use that SDK method to specify a Region before you make the API call. If you manually construct HTTP API requests, then you must direct the request to the correct endpoint yourself. For more information, see the [AWS STS section of *Regions and Endpoints*](#) and [Managing AWS STS in an AWS Region](#).

The following are the API operations that you can use to acquire temporary credentials for use in your AWS environment and applications.

AssumeRole—cross-account delegation and federation through a custom identity broker

The `AssumeRole` API operation is useful for allowing existing IAM users to access AWS resources that they don't already have access to. For example, the user might need access to resources in another AWS account. It is also useful as a means to temporarily gain privileged access—for example, to provide multi-factor authentication (MFA). You must call this API using active credentials. To learn who can call this operation, see [Comparing the AWS STS API operations](#). For more information, see [Creating a role to delegate permissions to an IAM user](#) and [Configuring MFA-protected API access](#).

This call must be made using valid AWS security credentials. When you make this call, you pass the following information:

- The Amazon Resource Name (ARN) of the role that the app should assume.
- (Optional) Duration, which specifies the duration of the temporary security credentials. Use the `DurationSeconds` parameter to specify the duration of the role session from 900 seconds (15 minutes) up to the maximum session duration setting for the role. To learn how to view the maximum value for your role, see [View the maximum session duration setting for a role](#). If you do not pass this parameter, the temporary credentials expire in one hour. The `DurationSeconds` parameter from this API is separate from the `SessionDuration` HTTP parameter that you use to specify the duration of a console session. Use the `SessionDuration` HTTP parameter in the request to the federation endpoint for a console sign-in token. For more information, see [Enabling custom identity broker access to the AWS console](#).

- Role session name. Use this string value to identify the session when a role is used by different principals. For security purposes, administrators can view this field in [AWS CloudTrail logs](#) to help identify who performed an action in AWS. Your administrator might require that you specify your IAM user name as the session name when you assume the role. For more information, see [sts:RoleSessionName](#).
- (Optional) Source identity. You can require users to specify a source identity when they assume a role. After the source identity is set, the value cannot be changed. It is present in the request for all actions that are taken during the role session. The source identity value persists across [chained role](#) sessions. You can use source identity information in AWS CloudTrail logs to determine who took actions with a role. For more information about using source identity, see [Monitor and control actions taken with assumed roles](#).
- (Optional) Inline or managed session policies. These policies limit the permissions from the role's identity-based policy that are assigned to the role session. The resulting session's permissions are the intersection of the role's identity-based policies and the session policies. Session policies cannot be used to grant more permissions than those allowed by the identity-based policy of the role that is being assumed. For more information about role session permissions, see [Session policies](#).
- (Optional) Session tags. You can assume a role and then use the temporary credentials to make a request. When you do, the session's principal tags include the role's tags and the passed session tags. If you make this call using temporary credentials, the new session also inherits transitive session tags from the calling session. For more information about session tags, see [Passing session tags in AWS STS](#).
- (Optional) MFA information. If configured to use multi-factor authentication (MFA), then you include the identifier for an MFA device and the one-time code provided by that device.
- (Optional) ExternalId value that can be used when delegating access to your account to a third party. This value helps ensure that only the specified third party can access the role. For more information, see [How to use an external ID when granting access to your AWS resources to a third party](#).

The following example shows a sample request and response using AssumeRole. This example request assumes the demo role for the specified duration with the included [session policy](#), [session tags](#), [external ID](#), and [source identity](#). The resulting session is named John-session.

Example Example request

```
https://sts.amazonaws.com/
```

```
?Version=2011-06-15
&Action=AssumeRole
&RoleSessionName=John-session
&RoleArn=arn:aws::iam::123456789012:role/demo
&Policy=%7B%22Version%22%3A%222012-10-17%22%2C%22Statement%22%3A%5B%7B%22Sid%22%3A%20%22Stmnt1%22%2C%22Effect%22%3A%20%22Allow%22%2C%22Action%22%3A%20%22s3%3A%22%2C%22Resource%22%3A%20%22%22%7D%5D%7D
&DurationSeconds=1800
&Tags.member.1.Key=Project
&Tags.member.1.Value=Pegasus
&Tags.member.2.Key=Cost-Center
&Tags.member.2.Value=12345
&ExternalId=123ABC
&SourceIdentity=DevUser123
&AUTHPARAMS
```

The policy value shown in the preceding example is the URL-encoded version of the following policy:

```
{"Version": "2012-10-17", "Statement":
[{"Sid": "Stmnt1", "Effect": "Allow", "Action": "s3:*", "Resource": "*"}]}
```

The AUTHPARAMS parameter in the example is a placeholder for your *signature*. A signature is the authentication information that you must include with AWS HTTP API requests. We recommend using the [AWS SDKs](#) to create API requests, and one benefit of doing so is that the SDKs handle request signing for you. If you must create and sign API requests manually, see [Signing AWS Requests By Using Signature Version 4](#) in the *Amazon Web Services General Reference* to learn how to sign a request.

In addition to the temporary security credentials, the response includes the Amazon Resource Name (ARN) for the federated user and the expiration time of the credentials.

Example Example response

```
<AssumeRoleResponse xmlns="https://sts.amazonaws.com/doc/2011-06-15/">
  <AssumeRoleResult>
    <SourceIdentity>DevUser123</SourceIdentity>
    <Credentials>
      <SessionToken>
        AQoDYXdzEPT//////////wEXAMPLEtc764bNrc9SAPBSM22wD0k4x4HIZ8j4FZTwdQW
        LwSKWHGBuFqwAeMicRXmxfpSPfIeoIYRqTf1fKD8YUuwthAx7mSEI/qkPpKPi/kMcGd
        QrmGdeehM4IC1NtBmUpp2wUE8phUZampKsburEDy0KPkyQDYwT7WZ0wq5V5XDvp75YU
```

```
9HFv1Rd8Tx6q6fE8YQcHNvXAKiY9q6d+xo0rKwT38xVqr7ZD0u0iPPkUL641IZbqBAz
+scqKmlzm8FDrypNC9Yjc8fP0Ln9FX9KSYvKTr4rvx3iS1LTJabIQwj2ICCR/oLxBA==
</SessionToken>
<SecretAccessKey>
wJalrXUtnFEMI/K7MDENG/bPxRfiCYzEXAMPLEKEY
</SecretAccessKey>
<Expiration>2019-07-15T23:28:33.359Z</Expiration>
<AccessKeyId>AKIAIOSFODNN7EXAMPLE</AccessKeyId>
</Credentials>
<AssumedRoleUser>
  <Arn>arn:aws:sts::123456789012:assumed-role/demo/John</Arn>
  <AssumedRoleId>AR0123EXAMPLE123:John</AssumedRoleId>
</AssumedRoleUser>
<PackedPolicySize>8</PackedPolicySize>
</AssumeRoleResult>
<ResponseMetadata>
  <RequestId>c6104cbe-af31-11e0-8154-cbc7ccf896c7</RequestId>
</ResponseMetadata>
</AssumeRoleResponse>
```

Note

An AWS conversion compresses the passed session policies and session tags into a packed binary format that has a separate limit. Your request can fail for this limit even if your plaintext meets the other requirements. The `PackedPolicySize` response element indicates by percentage how close the policies and tags for your request are to the upper size limit.

[AssumeRoleWithWebIdentity](#)—federation through a web-based identity provider

The `AssumeRoleWithWebIdentity` API operation returns a set of temporary security credentials for federated users who are authenticated through a public identity provider. Examples of public identity providers include Login with Amazon, Facebook, Google, or any OpenID Connect (OIDC)-compatible identity provider. This operation is useful for creating mobile applications or client-based web applications that require access to AWS. Using this operation means that your users do not need their own AWS or IAM identities. For more information, see [About web identity federation](#).

Instead of directly calling `AssumeRoleWithWebIdentity`, we recommend that you use Amazon Cognito and the Amazon Cognito credentials provider with the AWS SDKs for mobile development. For more information, see [Authentication with Amplify](#) in the *Amplify Documentation*.

If you are not using Amazon Cognito, you call the `AssumeRoleWithWebIdentity` action of AWS STS. This is an unsigned call, meaning that the app does not need to have access to any AWS security credentials to make the call. When you make this call, you pass the following information:

- The Amazon Resource Name (ARN) of the role that the app should assume. If your app supports multiple ways for users to sign in, you must define multiple roles, one per identity provider. The call to `AssumeRoleWithWebIdentity` should include the ARN of the role that is specific to the provider through which the user signed in.
- The token that the app gets from the IdP after the app authenticates the user.
- You can configure your IdP to pass attributes into your token as [session tags](#).
- (Optional) Duration, which specifies the duration of the temporary security credentials. Use the `DurationSeconds` parameter to specify the duration of the role session from 900 seconds (15 minutes) up to the maximum session duration setting for the role. To learn how to view the maximum value for your role, see [View the maximum session duration setting for a role](#). If you do not pass this parameter, the temporary credentials expire in one hour. The `DurationSeconds` parameter from this API is separate from the `SessionDuration` HTTP parameter that you use to specify the duration of a console session. Use the `SessionDuration` HTTP parameter in the request to the federation endpoint for a console sign-in token. For more information, see [Enabling custom identity broker access to the AWS console](#).
- Role session name. Use this string value to identify the session when a role is used by different principals. For security purposes, administrators can view this field in [AWS CloudTrail logs](#) to learn who performed an action in AWS. Your administrator might require that you provide a specific value for the session name when you assume the role. For more information, see [sts:RoleSessionName](#).
- (Optional) Source identity. You can require federated users to specify a source identity when they assume a role. After the source identity is set, the value cannot be changed. It is present in the request for all actions that are taken during the role session. The source identity value persists across [chained role](#) sessions. You can use source identity information in AWS CloudTrail logs to determine who took actions with a role. For more information about using source identity, see [Monitor and control actions taken with assumed roles](#).
- (Optional) Inline or managed session policies. These policies limit the permissions from the role's identity-based policy that are assigned to the role session. The resulting session's permissions

are the intersection of the role's identity-based policies and the session policies. Session policies cannot be used to grant more permissions than those allowed by the identity-based policy of the role that is being assumed. For more information about role session permissions, see [Session policies](#).

 **Note**

A call to `AssumeRoleWithWebIdentity` is not signed (encrypted). Therefore, you should only include optional session policies if the request is transmitted through a trusted intermediary. In this case, someone could alter the policy to remove the restrictions.

When you call `AssumeRoleWithWebIdentity`, AWS verifies the authenticity of the token. For example, depending on the provider, AWS might make a call to the provider and include the token that the app has passed. Assuming that the identity provider validates the token, AWS returns the following information to you:

- A set of temporary security credentials. These consist of an access key ID, a secret access key, and a session token.
- The role ID and the ARN of the assumed role.
- A `SubjectFromWebIdentityToken` value that contains the unique user ID.

When you have the temporary security credentials, you can use them to make AWS API calls. This is the same process as making an AWS API call with long-term security credentials. The difference is that you must include the session token, which lets AWS verify that the temporary security credentials are valid.

Your app should cache the credentials. As noted, by default the credentials expire after an hour. If you don't use the [AmazonSTSCredentialsProvider](#) operation in the AWS SDK, it's up to you and your app to call `AssumeRoleWithWebIdentity` again. Call this operation to get a new set of temporary security credentials before the old ones expire.

[AssumeRoleWithSAML](#)—federation through an enterprise Identity Provider compatible with SAML 2.0

The `AssumeRoleWithSAML` API operation returns a set of temporary security credentials for federated users who are authenticated by your organization's existing identity system. The users must also use [SAML 2.0](#) (Security Assertion Markup Language) to pass authentication and authorization information to AWS. This API operation is useful in organizations that have integrated their identity systems (such as Windows Active Directory or OpenLDAP) with software that can produce SAML assertions. Such an integration provides information about user identity and permissions (such as Active Directory Federation Services or Shibboleth). For more information, see [About SAML 2.0-based federation](#).

Note

A call to `AssumeRoleWithSAML` is not signed (encrypted). Therefore, you should only include optional session policies if the request is transmitted through a trusted intermediary. In this case, someone could alter the policy to remove the restrictions.

This is an unsigned call, which means that the app does not need to have access to any AWS security credentials in order to make the call. When you make this call, you pass the following information:

- The Amazon Resource Name (ARN) of the role that the app should assume.
- The ARN of the SAML provider created in IAM that describes the identity provider.
- The SAML assertion, encoded in base64, that was provided by the SAML identity provider in its authentication response to the sign-in request from your app.
- You can configure your IdP to pass attributes into your SAML assertion as [session tags](#).
- (Optional) `Duration`, which specifies the duration of the temporary security credentials. Use the `DurationSeconds` parameter to specify the duration of the role session from 900 seconds (15 minutes) up to the maximum session duration setting for the role. To learn how to view the maximum value for your role, see [View the maximum session duration setting for a role](#). If you do not pass this parameter, the temporary credentials expire in one hour. The `DurationSeconds` parameter from this API is separate from the `SessionDuration` HTTP parameter that you use to specify the duration of a console session. Use the `SessionDuration` HTTP parameter in the request to the federation endpoint for a console sign-in token. For more information, see [Enabling custom identity broker access to the AWS console](#).

- (Optional) Inline or managed session policies. These policies limit the permissions from the role's identity-based policy that are assigned to the role session. The resulting session's permissions are the intersection of the role's identity-based policies and the session policies. Session policies cannot be used to grant more permissions than those allowed by the identity-based policy of the role that is being assumed. For more information about role session permissions, see [Session policies](#).
- Role session name. Use this string value to identify the session when a role is used by different principals. For security purposes, administrators can view this field in [AWS CloudTrail logs](#) to learn who performed an action in AWS. Your administrator might require that you provide a specific value for the session name when you assume the role. For more information, see [sts:RoleSessionName](#).
- (Optional) Source identity. You can require federated users to specify a source identity when they assume a role. After the source identity is set, the value cannot be changed. It is present in the request for all actions that are taken during the role session. The source identity value persists across [chained role](#) sessions. You can use source identity information in AWS CloudTrail logs to determine who took actions with a role. For more information about using source identity, see [Monitor and control actions taken with assumed roles](#).

When you call `AssumeRoleWithSAML`, AWS verifies the authenticity of the SAML assertion. Assuming that the identity provider validates the assertion, AWS returns the following information to you:

- A set of temporary security credentials. These consist of an access key ID, a secret access key, and a session token.
- The role ID and the ARN of the assumed role.
- An `Audience` value that contains the value of the `Recipient` attribute of the `SubjectConfirmationData` element of the SAML assertion.
- An `Issuer` value that contains the value of the `Issuer` element of the SAML assertion.
- A `NameQualifier` element that contains a hash value built from the `Issuer` value, the AWS account ID, and the friendly name of the SAML provider. When combined with the `Subject` element, they can uniquely identify the federated user.
- A `Subject` element that contains the value of the `NameID` element in the `Subject` element of the SAML assertion.
- A `SubjectType` element that indicates the format of the `Subject` element. The value can be `persistent`, `transient`, or the full `Format` URI from the `Subject` and `NameID` elements

used in your SAML assertion. For information about the NameID element's Format attribute, see [Configuring SAML assertions for the authentication response](#).

When you have the temporary security credentials, you can use them to make AWS API calls. This is the same process as making an AWS API call with long-term security credentials. The difference is that you must include the session token, which lets AWS verify that the temporary security credentials are valid.

Your app should cache the credentials. By default the credentials expire after an hour. If you are not using the [AmazonSTSCredentialsProvider](#) action in the AWS SDK, it's up to you and your app to call AssumeRoleWithSAML again. Call this operation to get a new set of temporary security credentials before the old ones expire.

[GetFederationToken](#)—federation through a custom identity broker

The GetFederationToken API operation returns a set of temporary security credentials for federated users. This API differs from AssumeRole in that the default expiration period is substantially longer (12 hours instead of one hour). Additionally, you can use the DurationSeconds parameter to specify a duration for the temporary security credentials to remain valid. The resulting credentials are valid for the specified duration, between 900 seconds (15 minutes) to 129,600 seconds (36 hours). The longer expiration period can help reduce the number of calls to AWS because you do not need to get new credentials as often.

When you make this request, you use the credentials of a specific IAM user. The permissions for the temporary security credentials are determined by the session policies that you pass when you call GetFederationToken. The resulting session permissions are the intersection of the IAM user policies and the session policies that you pass. Session policies cannot be used to grant more permissions than those allowed by the identity-based policy of the IAM user that is requesting federation. For more information about role session permissions, see [Session policies](#).

When you use the temporary credentials that are returned by the GetFederationToken operation, the session's principal tags include the user's tags and the passed session tags. For more information about session tags, see [Passing session tags in AWS STS](#).

The GetFederationToken call returns temporary security credentials that consist of the session token, access key, secret key, and expiration. You can use GetFederationToken if you want to manage permissions inside your organization (for example, using the proxy application to assign permissions). To view a sample application that uses GetFederationToken, go to [Identity](#)

[Federation Sample Application for an Active Directory Use Case](#) in the *AWS Sample Code & Libraries*.

The following example shows a sample request and response that uses `GetFederationToken`. This example request federates the calling user for the specified duration with the [session policy](#) ARN and [session tags](#). The resulting session is named `Jane-session`.

Example Example request

```
https://sts.amazonaws.com/
?Version=2011-06-15
&Action=GetFederationToken
&Name=Jane-session
&PolicyArns.member.1.arn==arn%3Aaws%3Aiam%3A%3A123456789012%3Apolicy%2FRole1policy
&DurationSeconds=1800
&Tags.member.1.Key=Project
&Tags.member.1.Value=Pegasus
&Tags.member.2.Key=Cost-Center
&Tags.member.2.Value=12345
&AUTHPARAMS
```

The policy ARN shown in the preceding example includes the following URL-encoded ARN:

```
arn:aws:iam::123456789012:policy/Role1policy
```

Also, note that the `&AUTHPARAMS` parameter in the example is meant as a placeholder for the authentication information. This is the *signature*, which you must include with AWS HTTP API requests. We recommend using the [AWS SDKs](#) to create API requests, and one benefit of doing so is that the SDKs handle request signing for you. If you must create and sign API requests manually, go to [Signing AWS Requests By Using Signature Version 4](#) in the *Amazon Web Services General Reference* to learn how to sign a request.

In addition to the temporary security credentials, the response includes the Amazon Resource Name (ARN) for the federated user and the expiration time of the credentials.

Example Example response

```
<GetFederationTokenResponse xmlns="https://sts.amazonaws.com/doc/2011-06-15/">
  <GetFederationTokenResult>
    <Credentials>
```

```

<SessionToken>
AQoDYXdzEPT//////////wEXAMPLEtc764bNrC9SAPBSM22wD0k4x4HIZ8j4FZTwdQW

QrmGdeehM4IC1NtBmUpp2wUE8phUZampKsburEDy0KPKyQDYwT7WZ0wq5VSXDvp75YU
9HFv1Rd8Tx6q6fE8YQcHNvXAKiY9q6d+xo0rKwT38xVqr7ZD0u0iPPkUL64lIZbqBAz
+scqKmlzm8FDrypNC9Yjc8fP0Ln9FX9KSYvKTr4rvx3iS1lTJabIQwj2ICCEXAMPLE==
</SessionToken>
<SecretAccessKey>
wJalrXUtnFEMI/K7MDENG/bPxrFiCYzEXAMPLEKEY
</SecretAccessKey>
<Expiration>2019-04-15T23:28:33.359Z</Expiration>
<AccessKeyId>AKIAIOSFODNN7EXAMPLE;</AccessKeyId>
</Credentials>
<FederatedUser>
  <Arn>arn:aws:sts::123456789012:federated-user/Jean</Arn>
  <FederatedUserId>123456789012:Jean</FederatedUserId>
</FederatedUser>
<PackedPolicySize>4</PackedPolicySize>
</GetFederationTokenResult>
<ResponseMetadata>
  <RequestId>c6104cbe-af31-11e0-8154-cbc7ccf896c7</RequestId>
</ResponseMetadata>
</GetFederationTokenResponse>

```

Note

An AWS conversion compresses the passed session policies and session tags into a packed binary format that has a separate limit. Your request can fail for this limit even if your plaintext meets the other requirements. The `PackedPolicySize` response element indicates by percentage how close the policies and tags for your request are to the upper size limit.

AWS recommends that you grant permissions at the resource level (for example, you attach a resource-based policy to an Amazon S3 bucket), you can omit the `Policy` parameter. However, if you do not include a policy for the federated user, the temporary security credentials will not grant any permissions. In this case, you *must* use resource policies to grant the federated user access to your AWS resources.

For example, assume your AWS account number is 111122223333, and you have an Amazon S3 bucket that you want to allow Susan to access. Susan's temporary security credentials don't include

a policy for the bucket. In that case, you would need to ensure that the bucket has a policy with an ARN that matches Susan's ARN, such as `arn:aws:sts::111122223333:federated-user/Susan`.

GetSessionToken—temporary credentials for users in untrusted environments

The `GetSessionToken` API operation returns a set of temporary security credentials to an existing IAM user. This is useful for providing enhanced security, such as allowing AWS requests only when MFA is enabled for the IAM user. Because the credentials are temporary, they provide enhanced security when you have an IAM user who accesses your resources through a less secure environment. Examples of less secure environments include a mobile device or web browser. For more information, see [Requesting temporary security credentials](#) or [GetSessionToken](#) in the *AWS Security Token Service API Reference*.

By default, temporary security credentials for an IAM user are valid for a maximum of 12 hours. But you can request a duration as short as 15 minutes or as long as 36 hours using the `DurationSeconds` parameter. For security reasons, a token for an AWS account root user is restricted to a duration of one hour.

`GetSessionToken` returns temporary security credentials consisting of a session token, an access key ID, and a secret access key. The following example shows a sample request and response using `GetSessionToken`. The response also includes the expiration time of the temporary security credentials.

Example Example request

```
https://sts.amazonaws.com/  
?Version=2011-06-15  
&Action=GetSessionToken  
&DurationSeconds=1800  
&AUTHPARAMS
```

The `AUTHPARAMS` parameter in the example is a placeholder for your *signature*. A signature is the authentication information that you must include with AWS HTTP API requests. We recommend using the [AWS SDKs](#) to create API requests, and one benefit of doing so is that the SDKs handle request signing for you. If you must create and sign API requests manually, go to [Signing AWS Requests By Using Signature Version 4](#) in the *Amazon Web Services General Reference* to learn how to sign a request.

Example Example response

```
<GetSessionTokenResponse xmlns="https://sts.amazonaws.com/doc/2011-06-15/">
  <GetSessionTokenResult>
    <Credentials>
      <SessionToken>
        AQoEXAMPLEH4aoAH0gNCAPyJxz4B1CFFxWNE10PTgk5TthT+FvwqnKwRc0IfRrh3c/L
        To6UddyJw00vEVPvLXCrrrUtdnniCEXAMPLE/IvU1dYUg2RVAJBanLiHb4IgRmpRV3z
        rkuWJ0gQs8IZZaIv2BXIa2R40lglkBN9bkUDNCJiBeb/AXlzBBko7b15fjrBs2+cTQtp
        Z3CYWFXG8C5zqx37wn0E49mRl/+0tkIKG07fAE
      </SessionToken>
      <SecretAccessKey>
        wJalrXUtnFEMI/K7MDENG/bPxrFiCYzEXAMPLEKEY
      </SecretAccessKey>
      <Expiration>2011-07-11T19:55:29.611Z</Expiration>
      <AccessKeyId>AKIAIOSFODNN7EXAMPLE</AccessKeyId>
    </Credentials>
  </GetSessionTokenResult>
  <ResponseMetadata>
    <RequestId>58c5dbae-abef-11e0-8cfe-09039844ac7d</RequestId>
  </ResponseMetadata>
</GetSessionTokenResponse>
```

Optionally, the `GetSessionToken` request can include `SerialNumber` and `TokenCode` values for AWS multi-factor authentication (MFA) verification. If the provided values are valid, AWS STS provides temporary security credentials that include the state of MFA authentication. The temporary security credentials can then be used to access the MFA-protected API operations or AWS websites for as long as the MFA authentication is valid.

The following example shows a `GetSessionToken` request that includes an MFA verification code and device serial number.

```
https://sts.amazonaws.com/
?Version=2011-06-15
&Action=GetSessionToken
&DurationSeconds=7200
&SerialNumber=YourMFADeviceSerialNumber
&TokenCode=123456
&AUTHPARAMS
```

Note

The call to AWS STS can be to the global endpoint or to any of the Regional endpoints that you activate your AWS account. For more information, see the [AWS STS section of *Regions and Endpoints*](#).

The AUTHPARAMS parameter in the example is a placeholder for your *signature*. A signature is the authentication information that you must include with AWS HTTP API requests. We recommend using the [AWS SDKs](#) to create API requests, and one benefit of doing so is that the SDKs handle request signing for you. If you must create and sign API requests manually, see [Signing AWS Requests By Using Signature Version 4](#) in the *Amazon Web Services General Reference* to learn how to sign a request.

Comparing the AWS STS API operations

The following table compares features of the API operations in AWS STS that return temporary security credentials. To learn about the different methods you can use to request temporary security credentials by assuming a role, see [Using IAM roles](#). To learn about the different AWS STS API operations that allow you to pass session tags, see [Passing session tags in AWS STS](#).

Comparing your API options

AWS STS API	Who can call	Credential lifetime (min max default)	MFA support ¹	Session policy support ²	Restrictions on resulting temporary credentials
AssumeRole	IAM user or IAM role with existing temporary security credentials	15 m Maximum session duration setting ³ 1 hr	Yes	Yes	Cannot call GetFederationToken or GetSessionToken .

AWS STS API	Who can call	Credential lifetime (min max default)	MFA support ¹	Session policy support ²	Restrictions on resulting temporary credentials
AssumeRoleWithSAML	Any user; caller must pass a SAML authentication response that indicates authentication from a known identity provider	15 m Maximum session duration setting ³ 1 hr	No	Yes	Cannot call <code>GetFederationToken</code> or <code>GetSessionToken</code> .
AssumeRoleWithWebIdentity	Any user; caller must pass a web identity token that indicates authentication from a known identity provider	15 m Maximum session duration setting ³ 1 hr	No	Yes	Cannot call <code>GetFederationToken</code> or <code>GetSessionToken</code> .
GetFederationToken	IAM user or AWS account root user	IAM user: 15 m 36 hr 12 hr Root user: 15 m 1 hr 1 hr	No	Yes	Cannot call IAM operations using the AWS CLI or AWS API. This limitation does not apply to console sessions. Cannot call AWS STS operations except <code>GetCallerIdentity</code> . ⁴ SSO to console is allowed. ⁵

AWS STS API	Who can call	Credential lifetime (min max default)	MFA support ¹	Session policy support ²	Restrictions on resulting temporary credentials
GetSessionToken	IAM user or AWS account root user	IAM user: 15 m 36 hr 12 hr Root user: 15 m 1 hr 1 hr	Yes	No	Cannot call IAM API operations unless MFA information is included with the request. Cannot call AWS STS API operations except <code>AssumeRole</code> or <code>GetCallerIdentity</code> . SSO to console is not allowed. ⁶

¹ **MFA support.** You can include information about a multi-factor authentication (MFA) device when you call the `AssumeRole` and `GetSessionToken` API operations. This ensures that the temporary security credentials that result from the API call can be used only by users who are authenticated with an MFA device. For more information, see [Configuring MFA-protected API access](#).

² **Session policy support.** Session policies are policies that you pass as a parameter when you programmatically create a temporary session for a role or federated user. This policy limits the permissions from the role or user's identity-based policy that are assigned to the session. The resulting session's permissions are the intersection of the entity's identity-based policies and the session policies. Session policies cannot be used to grant more permissions than those allowed by the identity-based policy of the role that is being assumed. For more information about role session permissions, see [Session policies](#).

³ **Maximum session duration setting.** Use the `DurationSeconds` parameter to specify the duration of your role session from 900 seconds (15 minutes) up to the maximum session duration setting for the role. To learn how to view the maximum value for your role, see [View the maximum session duration setting for a role](#).

⁴ **GetCallerIdentity.** No permissions are required to perform this operation. If an administrator adds a policy to your IAM user or role that explicitly denies access to the `sts:GetCallerIdentity` action, you can still perform this operation. Permissions are not required because the same information is returned when an IAM user or role is denied access. To view an example response, see [I am not authorized to perform: iam:DeleteVirtualMFADevice](#).

⁵ **Single sign-on (SSO) to the console.** To support SSO, AWS lets you call a federation endpoint (<https://signin.aws.amazon.com/federation>) and pass temporary security credentials. The endpoint returns a token that you can use to construct a URL that signs a user directly into the console without requiring a password. For more information, see [Enabling SAML 2.0 federated users to access the AWS Management Console](#) and [How to Enable Cross-Account Access to the AWS Management Console](#) in the AWS Security Blog.

⁶ After you retrieve your temporary credentials, you can't access the AWS Management Console by passing the credentials to the federation single sign-on endpoint. For more information, see [Enabling custom identity broker access to the AWS console](#).

Using temporary credentials with AWS resources

You can use temporary security credentials to make programmatic requests for AWS resources using the AWS CLI or AWS API (using the [AWS SDKs](#)). The temporary credentials provide the same permissions as long-term security credentials, such as IAM user credentials. However, there are a few differences:

- When you make a call using temporary security credentials, the call must include a session token, which is returned along with those temporary credentials. AWS uses the session token to validate the temporary security credentials.
- Temporary credentials expire after a specified interval. After temporary credentials expire, any calls that you make with those credentials will fail, so you must generate a new set of temporary credentials. Temporary credentials cannot be extended or refreshed beyond the original specified interval.
- When you use temporary credentials to make a request, your principal might include a set of tags. These tags come from session tags and tags that are attached to the role that you assume. For more information about session tags, see [Passing session tags in AWS STS](#).

If you are using the [AWS SDKs](#), the [AWS Command Line Interface](#) (AWS CLI), or the [Tools for Windows PowerShell](#), the way to get and use temporary security credentials differs with the

context. If you are running code, AWS CLI, or Tools for Windows PowerShell commands inside an EC2 instance, you can take advantage of roles for Amazon EC2. Otherwise, you can call an [AWS STS API](#) to get the temporary credentials, and then use them explicitly to make calls to AWS services.

Note

You can use AWS Security Token Service (AWS STS) to create and provide trusted users with temporary security credentials that can control access to your AWS resources. For more information about AWS STS, see [Temporary security credentials in IAM](#). AWS STS is a global service that has a default endpoint at `https://sts.amazonaws.com`. This endpoint is in the US East (N. Virginia) Region, although credentials that you get from this and other endpoints are valid globally. These credentials work with services and resources in any Region. You can also choose to make AWS STS API calls to endpoints in any of the supported Regions. This can reduce latency by making the requests from servers in a Region that is geographically closer to you. No matter which Region your credentials come from, they work globally. For more information, see [Managing AWS STS in an AWS Region](#).

Contents

- [Using temporary credentials in Amazon EC2 instances](#)
- [Using temporary security credentials with the AWS SDKs](#)
- [Using temporary security credentials with the AWS CLI](#)
- [Using temporary security credentials with API operations](#)
- [More information](#)

Using temporary credentials in Amazon EC2 instances

If you want to run AWS CLI commands or code inside an EC2 instance, the recommended way to get credentials is to use [roles for Amazon EC2](#). You create an IAM role that specifies the permissions that you want to grant to applications that run on the EC2 instances. When you launch the instance, you associate the role with the instance.

Applications, AWS CLI, and Tools for Windows PowerShell commands that run on the instance can then get automatic temporary security credentials from the instance metadata. You do not have to explicitly get the temporary security credentials. The AWS SDKs, AWS CLI, and Tools for Windows PowerShell automatically get the credentials from the EC2 Instance Metadata Service

(IMDS) and use them. The temporary credentials have the permissions that you define for the role that is associated with the instance.

For more information and for examples, see the following:

- [Using IAM Roles to Grant Access to AWS Resources on Amazon Elastic Compute Cloud](#) — AWS SDK for Java
- [Granting Access Using an IAM Role](#) — AWS SDK for .NET
- [Creating a Role](#) — AWS SDK for Ruby

Using temporary security credentials with the AWS SDKs

To use temporary security credentials in code, you programmatically call an AWS STS API like `AssumeRole` and extract the resulting credentials and session token. You then use those values as credentials for subsequent calls to AWS. The following example shows pseudocode for how to use temporary security credentials if you're using an AWS SDK:

```
assumeRoleResult = AssumeRole(role-arn);
tempCredentials = new SessionAWSCredentials(
    assumeRoleResult.AccessKeyId,
    assumeRoleResult.SecretAccessKey,
    assumeRoleResult.SessionToken);
s3Request = CreateAmazonS3Client(tempCredentials);
```

For an example written in Python (using the [AWS SDK for Python \(Boto\)](#)), see [Switching to an IAM role \(AWS API\)](#). This example shows how to call `AssumeRole` to get temporary security credentials and then use those credentials to make a call to Amazon S3.

For details about how to call `AssumeRole`, `GetFederationToken`, and other API operations, see the [AWS Security Token Service API Reference](#). For information on getting the temporary security credentials and session token from the result, see the documentation for the SDK that you're working with. You can find the documentation for all the AWS SDKs on the main [AWS documentation page](#), in the **SDKs and Toolkits** section.

You must make sure that you get a new set of credentials before the old ones expire. In some SDKs, you can use a provider that manages the process of refreshing credentials for you; check the documentation for the SDK you're using.

Using temporary security credentials with the AWS CLI

You can use temporary security credentials with the AWS CLI. This can be useful for testing policies.

Using the [AWS CLI](#), you can call an [AWS STS API](#) like `AssumeRole` or `GetFederationToken` and then capture the resulting output. The following example shows a call to `AssumeRole` that sends the output to a file. In the example, the `profile` parameter is assumed to be a profile in the AWS CLI configuration file. It is also assumed to reference credentials for an IAM user who has permissions to assume the role.

```
aws sts assume-role --role-arn arn:aws:iam::123456789012:role/role-name --role-session-name "RoleSession1" --profile IAM-user-name > assume-role-output.txt
```

When the command is finished, you can extract the access key ID, secret access key, and session token from wherever you've routed it. You can do this either manually or by using a script. You can then assign these values to environment variables.

When you run AWS CLI commands, the AWS CLI looks for credentials in a specific order—first in environment variables and then in the configuration file. Therefore, after you've put the temporary credentials into environment variables, the AWS CLI uses those credentials by default. (If you specify a `profile` parameter in the command, the AWS CLI skips the environment variables. Instead, the AWS CLI looks in the configuration file, which lets you override the credentials in the environment variables if you need to.)

The following example shows how you might set the environment variables for temporary security credentials and then call an AWS CLI command. Because no `profile` parameter is included in the AWS CLI command, the AWS CLI looks for credentials first in environment variables and therefore uses the temporary credentials.

Linux

```
$ export AWS_ACCESS_KEY_ID=ASIAIOSFODNN7EXAMPLE
$ export AWS_SECRET_ACCESS_KEY=wJa1rXUtnFEMI/K7MDENG/bPxrFiCYEXAMPLEKEY
$ export AWS_SESSION_TOKEN=AQoDYXdzEJr...<remainder of session token>
$ aws ec2 describe-instances --region us-west-1
```

Windows

```
C:\> SET AWS_ACCESS_KEY_ID=ASIAIOSFODNN7EXAMPLE
C:\> SET AWS_SECRET_ACCESS_KEY=wJa1rXUtnFEMI/K7MDENG/bPxrFiCYEXAMPLEKEY
```

```
C:\> SET AWS_SESSION_TOKEN=AQoDYXdzEJr...<remainder of token>
C:\> aws ec2 describe-instances --region us-west-1
```

Using temporary security credentials with API operations

If you're making direct HTTPS API requests to AWS, you can sign those requests with the temporary security credentials that you get from the AWS Security Token Service (AWS STS). To do this, you use the access key ID and secret access key that you receive from AWS STS. You use the access key ID and secret access key the same way you would use long-term credentials to sign a request. You also add to your API request the session token that you receive from AWS STS. You add the session token to an HTTP header or to a query string parameter named `X-Amz-Security-Token`. You add the session token to the HTTP header *or* the query string parameter, but not both. For more information about signing HTTPS API requests, see [Signing AWS API Requests](#) in the *AWS General Reference*.

More information

For more information about using AWS STS with other AWS services, see the following links:

- **Amazon S3.** See [Making requests using IAM user temporary credentials](#) or [Making requests using federated user temporary credentials](#) in the *Amazon Simple Storage Service User Guide*.
- **Amazon SNS.** See [Using identity-based policies with Amazon SNS](#) in the *Amazon Simple Notification Service Developer Guide*.
- **Amazon SQS.** See [Identity and access management in Amazon SQS](#) in the *Amazon Simple Queue Service Developer Guide*.
- **Amazon SimpleDB.** See [Using Temporary Security Credentials](#) in the *Amazon SimpleDB Developer Guide*.

Controlling permissions for temporary security credentials

You can use AWS Security Token Service (AWS STS) to create and provide trusted users with temporary security credentials that can control access to your AWS resources. For more information about AWS STS, see [Temporary security credentials in IAM](#). After AWS STS issues temporary security credentials, they are valid through the expiration period and cannot be revoked. However, the permissions assigned to temporary security credentials are evaluated each time a request is made that uses the credentials, so you can achieve the effect of revoking the credentials by changing their access rights after they have been issued.

The following topics assume you have a working knowledge of AWS permissions and policies. For more information on these topics, see [Access management for AWS resources](#).

Topics

- [Permissions for AssumeRole, AssumeRoleWithSAML, and AssumeRoleWithWebIdentity](#)

Permissions for AssumeRole, AssumeRoleWithSAML, and AssumeRoleWithWebIdentity

The permissions policy of the role that is being assumed determines the permissions for the temporary security credentials that are returned by `AssumeRole`, `AssumeRoleWithSAML`, and `AssumeRoleWithWebIdentity`. You define these permissions when you create or update the role.

Optionally, you can pass inline or managed [session policies](#) as parameters of the `AssumeRole`, `AssumeRoleWithSAML`, or `AssumeRoleWithWebIdentity` API operations. Session policies limit the permissions for the role's temporary credential session. The resulting session's permissions are the intersection of the role's identity-based policy and the session policies. You can use the role's temporary credentials in subsequent AWS API calls to access resources in the account that owns the role. You cannot use session policies to grant more permissions than those allowed by the identity-based policy of the role that is being assumed. To learn more about how AWS determines the effective permissions of a role, see [Policy evaluation logic](#).

The policies that are attached to the credentials that made the original call to `AssumeRole` are not evaluated by AWS when making the "allow" or "deny" authorization decision. The user temporarily gives up its original permissions in favor of the permissions assigned by the assumed role. In the case of the `AssumeRoleWithSAML` and `AssumeRoleWithWebIdentity` API operations, there are no policies to evaluate because the caller of the API is not an AWS identity.

Example: Assigning permissions using `AssumeRole`

You can use the `AssumeRole` API operation with different kinds of policies. Here are a few examples.

Role permissions policy

In this example, you call the `AssumeRole` API operation without specifying the session policy in the optional `Policy` parameter. The permissions assigned to the temporary credentials are determined by the permissions policy of the role being assumed. The following example permissions policy grants the role permission to list all objects that are contained in an S3 bucket named `productionapp`. It also allows the role to get, put, and delete objects within that bucket.

Example Example role permissions policy

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": "s3:ListBucket",
      "Resource": "arn:aws:s3:::productionapp"
    },
    {
```

```
    "Effect": "Allow",
    "Action": [
      "s3:GetObject",
      "s3:PutObject",
      "s3:DeleteObject"
    ],
    "Resource": "arn:aws:s3:::productionapp/*"
  }
]
```

Session policy passed as a parameter

Imagine that you want to allow a user to assume the same role as in the previous example. But in this case you want the role session to have permission only to get and put objects in the `productionapp` S3 bucket. You do not want to allow them to delete objects. One way to accomplish this is to create a new role and specify the desired permissions in that role's permissions policy. Another way to accomplish this is to call the `AssumeRole` API and include session policies in the optional `Policy` parameter as part of the API operation. The resulting session's permissions are the intersection of the role's identity-based policies and the session policies. Session policies cannot be used to grant more permissions than those allowed by the identity-based policy of the role that is being assumed. For more information about role session permissions, see [Session policies](#).

After you retrieve the new session's temporary credentials, you can pass them to the user that you want to have those permissions.

For example, imagine that the following policy is passed as a parameter of the API call. The person using the session has permissions to perform only these actions:

- List all objects in the `productionapp` bucket.
- Get and put objects in the `productionapp` bucket.

In the following session policy, the `s3:DeleteObject` permission is filtered out and the assumed session is not granted the `s3:DeleteObject` permission. The policy sets the maximum permissions for the role session so that it overrides any existing permissions policies on the role.

Example Example session policy passed with `AssumeRole` API call

```
{
```

```
"Version": "2012-10-17",
"Statement": [
  {
    "Effect": "Allow",
    "Action": "s3:ListBucket",
    "Resource": "arn:aws:s3:::productionapp"
  },
  {
    "Effect": "Allow",
    "Action": [
      "s3:GetObject",
      "s3:PutObject"
    ],
    "Resource": "arn:aws:s3:::productionapp/*"
  }
]
```

Resource-based policy

Some AWS resources support resource-based policies, and these policies provide another mechanism to define permissions that affect temporary security credentials. Only a few resources, like Amazon S3 buckets, Amazon SNS topics, and Amazon SQS queues support resource-based policies. The following example expands on the previous examples, using an S3 bucket named `productionapp`. The following policy is attached to the bucket.

When you attach the following resource-based policy to the `productionapp` bucket, *all* users are denied permission to delete objects from the bucket. (See the `Principal` element in the policy.) This includes all assumed role users, even though the role permissions policy grants the `DeleteObject` permission. An explicit `Deny` statement always takes precedence over an `Allow` statement.

Example Example bucket policy

```
{
  "Version": "2012-10-17",
  "Statement": {
    "Principal": {"AWS": "*"},
    "Effect": "Deny",
    "Action": "s3:DeleteObject",
    "Resource": "arn:aws:s3:::productionapp/*"
  }
}
```

```
}
```

For more information about how multiple policy types are combined and evaluated by AWS, see [Policy evaluation logic](#).

Monitor and control actions taken with assumed roles

An [IAM role](#) is an object in IAM that is assigned [permissions](#). When you [assume that role](#) using an IAM identity or an identity from outside of AWS, you receive a session with the permissions that are assigned to the role.

When you perform actions in AWS, the information about your session can be logged to AWS CloudTrail for your account administrator to monitor. Administrators can configure roles to require identities to pass a custom string that identifies the person or application that is performing actions in AWS. This identity information is stored as the *source identity* in AWS CloudTrail. When the administrator reviews activity in CloudTrail, they can view the source identity information to determine who or what performed actions with assumed role sessions.

After a source identity is set, it is present in requests for any AWS action taken during the role session. The value that is set persists when a role is used to assume another role through the AWS CLI or AWS API, known as [role chaining](#). The value that is set cannot be changed during the role session. Administrators can configure granular permissions based on the presence or value of the source identity to further control AWS actions that are taken with shared roles. You can decide whether the source identity attribute can be used, whether it is required, and what value can be used.

The way that you use source identity differs from role session name and session tags in an important way. The source identity value can't be changed after it is set, and it persists for any additional actions that are taken with the role session. Here's how you can use session tags and role session name:

- **Session tags** – You can pass session tags when you assume a role or federate a user. Session tags are present when a role is assumed. You can define policies that use tag condition keys to grant permissions to your principals based on their tags. Then you can use CloudTrail to view the requests made to assume roles or federate users. To learn more about session tags, see [Passing session tags in AWS STS](#).
- **Role session name** – You can use the `sts:RoleSessionName` condition key in a role trust policy to require that your users provide a specific session name when they assume a role. Role session

name can be used to differentiate role sessions when a role is used by different principals. To learn more about role session name, see [sts:RoleSessionName](#).

We recommend that you use source identity when you want to control the identity that assumes a role. Source identity is also useful for mining CloudTrail logs to determine who used the role to perform actions.

Setting up to use source identity

The way that you set up to use source identity depends on the method used when your roles are assumed. For example, your IAM users might assume roles directly using the `AssumeRole` operation. If you have enterprise identities, also known as workforce identities, they might access your AWS resources using `AssumeRoleWithSAML`. If end users access your mobile or web applications, they might do so using `AssumeRoleWithWebIdentity`. The following is a high-level workflow overview to help you understand how you can set up to utilize source identity information in your existing environment.

1. **Configure test users and roles** – Using a preproduction environment, configure test users and roles and configure their policies to allow setting a source identity.

If you use an identity provider (IdP) for your federated identities, configure your IdP to pass a user attribute of your choice for source identity in the assertion or token.

2. **Assume the role** – Test assuming roles and passing a source identity with the users and roles that you set up for testing.

3. **Review CloudTrail** – Review the source identity information for your test roles in your CloudTrail logs.
4. **Train your users** – After you've tested in your preproduction environment, ensure that your users know how to pass in the source identity information, if necessary. Set a deadline for when you will require your users to provide a source identity in your production environment.
5. **Configure production policies** – Configure your policies for your production environment, and then add them to your production users and roles.
6. **Monitor activity** – Monitor your production role activity using CloudTrail logs.

Things to know about source identity

Keep the following in mind when working with source identity.

- Trust policies for all roles connected to an identity provider (IdP) must have the `sts:SetSourceIdentity` permission. For roles that don't have this permission in the role trust policy, the `AssumeRole*` operation will fail. If you don't want to update the role trust policy for each role, you can use a separate IdP instance for passing source identity. Then add the `sts:SetSourceIdentity` permission to only the roles that are connected to the separate IdP.
- When an identity sets a source identity, the `sts:SourceIdentity` key is present in the request. For subsequent actions taken during the role session, the `aws:SourceIdentity` key is present in the request. AWS doesn't control the value of the source identity in either the `sts:SourceIdentity` or `aws:SourceIdentity` keys. If you choose to require a source identity, you must choose an attribute that you want your users or IdP to provide. For security purposes, you must ensure that you can control how those values are provided.
- The value of source identity must be between 2 and 64 characters long, can contain only alphanumeric characters, underscores, and the following characters: `. , + = @ -` (hyphen). You cannot use a value that begins with the text `aws:.` This prefix is reserved for AWS internal use.
- The source identity information is not captured by CloudTrail when an AWS service or service-linked role carries out an action on behalf of a federated or workforce identity.

Important

You cannot switch to a role in the AWS Management Console that requires a source identity to be set when the role is assumed. To assume such a role, you can use the AWS CLI or AWS API to call the `AssumeRole` operation and specify the source identity parameter.

Permissions required to set source identity

In addition to the action that matches the API operation, you must have the following permissions-only action in your policy:

```
sts:SetSourceIdentity
```

- To specify a source identity, principals (IAM users and roles) must have permissions to `sts:SetSourceIdentity`. As the administrator, you can configure this in the role trust policy and in the principal's permissions policy.
- When you assume a role with another role, called [role chaining](#), permissions for `sts:SetSourceIdentity` are required in both the permissions policy of the principal who is assuming the role and in the role trust policy of the target role. Otherwise, the assume role operation will fail.
- When using source identity, the role trust policies for all roles connected to an IdP must have the `sts:SetSourceIdentity` permission. The `AssumeRole*` operation will fail for any role connected to an IdP without this permission. If you don't want to update the role trust policy for each role, you can use a separate IdP instance for passing source identity and add the `sts:SetSourceIdentity` permission to only the roles that are connected to the separate IdP.
- To set a source identity across account boundaries, you must include the `sts:SetSourceIdentity` permission in two places. It must be in the permissions policy of the principal in the originating account and in the role trust policy of the role in the target account. You might need to do this, for example, when a role is used to assume a role in another account with [role chaining](#).

As the account administrator, imagine that you want to allow the IAM user `DevUser1` in your account to assume the `Developer_Role` in the same account. But you want to allow this action only if the user has set the source identity to their IAM user name. You can attach the following policy to the IAM user.

Example Example identity-based policy attached to DevUser

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "AssumeRole",
```

```

    "Effect": "Allow",
    "Action": "sts:AssumeRole",
    "Resource": "arn:aws:iam::123456789012:role/Developer_Role"
  },
  {
    "Sid": "SetAwsUserNameAsSourceIdentity",
    "Effect": "Allow",
    "Action": "sts:SetSourceIdentity",
    "Resource": "arn:aws:iam::123456789012:role/Developer_Role",
    "Condition": {
      "StringLike": {
        "sts:SourceIdentity": "${aws:username}"
      }
    }
  }
]
}

```

To enforce the acceptable source identity values, you can configure the following role trust policy. The policy gives the IAM user `DevUser` permissions to assume the role and set a source identity. The `sts:SourceIdentity` condition key defines the acceptable source identity value.

Example Example role trust policy for source identity

```

{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "AllowDevUserAssumeRole",
      "Effect": "Allow",
      "Principal": {
        "AWS": "arn:aws:iam::123456789012:user/DevUser"
      },
      "Action": [
        "sts:AssumeRole",
        "sts:SetSourceIdentity"
      ],
      "Condition": {
        "StringEquals": {
          "sts:SourceIdentity": "DevUser"
        }
      }
    }
  ]
}

```

```
]
}
```

Using the credentials for the IAM user `DevUser`, the user attempts to assume the `DeveloperRole` using the following AWS CLI request.

Example Example AssumeRole CLI request

```
aws sts assume-role \  
--role-arn arn:aws:iam::123456789012:role/Developer_Role \  
--role-session-name Dev-project \  
--source-identity DevUser \  

```

When AWS evaluates the request, the request context contains the `sts:SourceIdentity` of `DevUser`.

Specifying a source identity when assuming a role

You can specify a source identity when you use one of the AWS STS `AssumeRole*` API operations to get temporary security credentials for a role. The API operation that you use differs depending on your use case. For example, if you use IAM roles to give IAM users access to AWS resources that they don't normally have access to, you might use the `AssumeRole` operation. If you use enterprise identity federation to manage your workforce users, you might use the `AssumeRoleWithSAML` operation. If you use web identity federation to allow end users to access your mobile or web applications, you might use the `AssumeRoleWithWebIdentity` operation. The following sections explain how to use source identity with each operation. To learn more about common scenarios for temporary credentials, see [Common scenarios for temporary credentials](#).

Using source identity with AssumeRole

The `AssumeRole` operation returns a set of temporary credentials that you can use to access AWS resources. You can use IAM user or role credentials to call `AssumeRole`. To pass source identity while assuming a role, use the `--source-identity` AWS CLI option or the `SourceIdentity` AWS API parameter. The following example shows how to specify the source identity using the AWS CLI.

Example Example AssumeRole CLI request

```
aws sts assume-role \  

```

```
--role-arn arn:aws:iam::123456789012:role/developer \  
--role-session-name Audit \  
--source-identity Admin \  

```

Using source identity with AssumeRoleWithSAML

The principal calling the `AssumeRoleWithSAML` operation is authenticated using SAML-based federation. This operation returns a set of temporary credentials that you can use to access AWS resources. For more information about using SAML-based federation for AWS Management Console access, see [Enabling SAML 2.0 federated users to access the AWS Management Console](#). For details about AWS CLI or AWS API access, see [About SAML 2.0-based federation](#). For a tutorial of setting up SAML federation for your Active Directory users, see [AWS Federated Authentication with Active Directory Federation Services \(ADFS\)](#) in the AWS Security Blog.

As an administrator, you can allow members of your company directory to federate into AWS using the AWS STS `AssumeRoleWithSAML` operation. To do this, you must complete the following tasks:

1. [Configure a SAML provider in your organization.](#)
2. [Create a SAML provider in IAM.](#)
3. [Configure a role and its permissions in AWS for your federated users.](#)
4. [Finish configuring the SAML IdP and create assertions for the SAML authentication response.](#)

To set a SAML attribute for source identity, include the `Attribute` element with the `Name` attribute set to `https://aws.amazon.com/SAML/Attributes/SourceIdentity`. Use the `AttributeValue` element to specify the value of the source identity. For example, assume that you want to pass the following identity attribute as the source identity.

```
SourceIdentity:DiegoRamirez
```

To pass this attribute, include the following element in your SAML assertion.

Example Example snippet of a SAML assertion

```
<Attribute Name="https://aws.amazon.com/SAML/Attributes/SourceIdentity">  
<AttributeValue>DiegoRamirez</AttributeValue>  
</Attribute>
```

Using source identity with AssumeRoleWithWebIdentity

The principal calling the `AssumeRoleWithWebIdentity` operation is authenticated using OpenID Connect (OIDC)-compliant web identity federation. This operation returns a set of temporary credentials that you can use to access AWS resources. For more information about using web identity federation for AWS Management Console access, see [About web identity federation](#).

To pass source identity from OpenID Connect (OIDC), you must include the source identity in the JSON Web Token (JWT). Include source identity in the <https://aws.amazon.com/> `source_identity` namespace in the token when you submit the `AssumeRoleWithWebIdentity` request. To learn more about OIDC tokens and claims, see [Using Tokens with User Pools](#) in the *Amazon Cognito Developer Guide*.

For example, the following decoded JWT is a token that is used to call `AssumeRoleWithWebIdentity` with the `Admin` source identity.

Example Example decoded JSON Web Token

```
{
  "sub": "johndoe",
  "aud": "ac_oic_client",
  "jti": "ZYUCeRMQVtqHypVPWAN3VB",
  "iss": "https://xyz.com",
  "iat": 1566583294,
  "exp": 1566583354,
  "auth_time": 1566583292,
  "https://aws.amazon.com/source_identity": "Admin"
}
```

Control access using source identity information

When a source identity is initially set, the [sts:SourceIdentity](#) key is present in the request. After a source identity is set, the [aws:SourceIdentity](#) key is present in all subsequent requests made during the role session. As the administrator, you can write policies that grant conditional authorization to perform AWS actions based on the existence or value of the source identity attribute.

Imagine that you want to require your developers to set a source identity to assume a critical role that has permission to write to a production critical AWS resource. Also imagine that you grant AWS access to your workforce identities using `AssumeRoleWithSAML`. You only want senior

developers Saanvi and Diego to have access to the role, so you create the following trust policy for the role.

Example Example role trust policy for source identity (SAML)

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "SAMLProviderAssumeRoleWithSAML",
      "Effect": "Allow",
      "Principal": {
        "Federated": "arn:aws:iam::111122223333:saml-provider/name-of-identity-provider"
      },
      "Action": [
        "sts:AssumeRoleWithSAML"
      ],
      "Condition": {
        "StringEquals": {
          "SAML:aud": "https://signin.aws.amazon.com/saml"
        }
      }
    },
    {
      "Sid": "SetSourceIdentitySrEngs",
      "Effect": "Allow",
      "Principal": {
        "Federated": "arn:aws:iam::111122223333:saml-provider/name-of-identity-provider"
      },
      "Action": [
        "sts:SetSourceIdentity"
      ],
      "Condition": {
        "StringLike": {
          "sts:SourceIdentity": [
            "Saanvi",
            "Diego"
          ]
        }
      }
    }
  ]
}
```

```
]
}
```

The trust policy contains a condition for `sts:SourceIdentity` that requires a source identity of `Saanvi` or `Diego` to assume the critical role.

Alternatively, if you use an OIDC provider for web identity federation and users are authenticated with `AssumeRoleWithWebIdentity`, your role trust policy might look as follows.

Example Example role trust policy for source identity (OIDC provider)

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Principal": {
        "Federated": "arn:aws:iam::111122223333:oidc-provider/server.example.com"
      },
      "Action": [
        "sts:AssumeRoleWithWebIdentity",
        "sts:SetSourceIdentity"
      ],
      "Condition": {
        "StringEquals": {
          "server.example.com:aud": "oidc-audience-id"
        },
        "StringLike": {
          "sts:SourceIdentity": [
            "Saanvi",
            "Diego"
          ]
        }
      }
    }
  ]
}
```

Role chaining and cross-account requirements

Imagine that you want to allow users who have assumed `CriticalRole` to assume a `CriticalRole_2` in another account. The role session credentials that were obtained to assume

`CriticalRole` are used to [role chain](#) to a second role, `CriticalRole_2`, in a different account. The role is being assumed across an account boundary. Therefore, the `sts:SetSourceIdentity` permission must be granted in both the permissions policy on `CriticalRole` and in the role trust policy on `CriticalRole_2`.

Example Example permissions policy on `CriticalRole`

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "AssumeRoleAndSetSourceIdentity",
      "Effect": "Allow",
      "Action": [
        "sts:AssumeRole",
        "sts:SetSourceIdentity"
      ],
      "Resource": "arn:aws:iam::222222222222:role/CriticalRole_2"
    }
  ]
}
```

To secure setting source identity across the account boundary, the following role trust policy trusts only the role principal for `CriticalRole` to set the source identity.

Example Example role trust policy on `CriticalRole_2`

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Principal": {
        "AWS": "arn:aws:iam::111111111111:role/CriticalRole"
      },
      "Action": [
        "sts:AssumeRole",
        "sts:SetSourceIdentity"
      ],
      "Condition": {
        "StringLike": {
          "aws:SourceIdentity": ["Saanvi", "Diego"]
        }
      }
    }
  ]
}
```

```
    }  
  }  
}  
]  
}
```

The user makes the following call using role session credentials obtained from assuming `CriticalRole`. The source identity was set during the assumption of `CriticalRole`, so it does not need to be explicitly set again. If the user attempts to set a source identity that is different from the value set when `CriticalRole` was assumed, the assume role request will be denied.

Example Example AssumeRole CLI request

```
aws sts assume-role \  
--role-arn arn:aws:iam::222222222222:role/CriticalRole_2 \  
--role-session-name Audit \  

```

When the calling principal assumes the role, the source identity in the request persists from the first assumed role session. Therefore, both the `aws:SourceIdentity` and `sts:SourceIdentity` keys are present in the request context.

Viewing source identity in CloudTrail

You can use CloudTrail to view the requests made to assume roles or federate users. You can also view the role or user requests to take actions in AWS. The CloudTrail log file includes information about the source identity set for the assumed-role or federated user session. For more information, see [Logging IAM and AWS STS API calls with AWS CloudTrail](#)

For example, assume that a user makes an AWS STS `AssumeRole` request, and sets a source identity. You can find the `sourceIdentity` information in the `requestParameters` key in your CloudTrail log.

Example Example requestParameters section in an AWS CloudTrail log

```
"eventVersion": "1.05",  
  "userIdentity": {  
    "type": "AWSAccount",  
    "principalId": "AIDAJ45Q7YFFAREXAMPLE",  
    "accountId": "111122223333"
```

```

},
"eventTime": "2020-04-02T18:20:53Z",
"eventSource": "sts.amazonaws.com",
"eventName": "AssumeRole",
"awsRegion": "us-east-1",
"sourceIPAddress": "203.0.113.64",
"userAgent": "aws-cli/1.16.96 Python/3.6.0 Windows/10 botocore/1.12.86",
"requestParameters": {
  "roleArn": "arn:aws:iam::123456789012:role/DevRole",
  "roleSessionName": "Dev1",
  "sourceIdentity": "source-identity-value-set"
}

```

If the user uses the assumed role session to perform an action, the source identity information is present in the `userIdentity` key in the CloudTrail log.

Example Example `userIdentity` key in an AWS CloudTrail log

```

{
  "eventVersion": "1.08",
  "userIdentity": {
    "type": "AssumedRole",
    "principalId": "AROAJ45Q7YFFAREXAMPLE:Dev1",
    "arn": "arn:aws:sts::123456789012:assumed-role/DevRole/Dev1",
    "accountId": "123456789012",
    "accessKeyId": "ASIAIOSFODNN7EXAMPLE",
    "sessionContext": {
      "sessionIssuer": {
        "type": "Role",
        "principalId": "AROAJ45Q7YFFAREXAMPLE",
        "arn": "arn:aws:iam::123456789012:role/DevRole",
        "accountId": "123456789012",
        "userName": "DevRole"
      },
      "webIdFederationData": {},
      "attributes": {
        "mfaAuthenticated": "false",
        "creationDate": "2021-02-21T23:46:28Z"
      }
    },
    "sourceIdentity": "source-identity-value-present"
  }
}

```

To see example AWS STS API events in CloudTrail logs, see [Example IAM API events in CloudTrail log](#). For more details about the information contained in CloudTrail log files, see [CloudTrail Event Reference](#) in the *AWS CloudTrail User Guide*.

Permissions for GetFederationToken

The `GetFederationToken` operation is called by an IAM user and returns temporary credentials for that user. This operation *federates* the user. The permissions assigned a federated user are defined in one of two places:

- The session policies passed as a parameter of the `GetFederationToken` API call. (This is most common.)
- A resource-based policy that explicitly names the federated user in the `Principal` element of the policy. (This is less common.)

Session policies are advanced policies that you pass as parameters when you programmatically create a temporary session. When you create a federated user session and pass session policies, the resulting session's permissions are the intersection of the user's identity-based policy and the session policies. You cannot use the session policy to grant more permissions than those allowed by the identity-based policy of the user that is being federated.

In most cases if you do not pass a policy with the `GetFederationToken` API call, the resulting temporary security credentials have no permissions. However, a resource-based policy can provide additional permissions for the session. You can access a resource with a resource-based policy that specifies your session as the allowed principal.

The following figures show a visual representation of how the policies interact to determine permissions for the temporary security credentials returned by a call to `GetFederationToken`.

Example: Assigning permissions using `GetFederationToken`

You can use the `GetFederationToken` API action with different kinds of policies. Here are a few examples.

Policy attached to the IAM user

In this example, you have a browser-based client application that relies on two backend web services. One backend service is your own authentication server that uses your own identity system to authenticate the client application. The other backend service is an AWS service that provides some of the client application's functionality. The client application is authenticated by your server, and your server creates or retrieves the appropriate permissions policy. Your server then calls the `GetFederationToken` API to obtain temporary security credentials, and returns those credentials to the client application. The client application can then make requests directly to the AWS service with the temporary security credentials. This architecture allows the client application to make AWS requests without embedding long-term AWS credentials.

Your authentication server calls the `GetFederationToken` API with the long-term security credentials of an IAM user named `token-app`. But the long-term IAM user credentials remain on your server and are never distributed to the client. The following example policy is attached to the `token-app` IAM user and defines the broadest set of permissions that your federated users (clients) will need. Note that the `sts:GetFederationToken` permission is required for your authentication service to obtain temporary security credentials for the federated users.

Note

AWS provides a sample Java application to serve this purpose, which you can download here: [Token Vending Machine for Identity Registration - Sample Java Web Application](#).

Example Example policy attached to IAM user `token-app` that calls `GetFederationToken`

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": "sts:GetFederationToken",
      "Resource": "*"
    }
  ]
}
```

```
    },
    {
      "Effect": "Allow",
      "Action": "dynamodb:ListTables",
      "Resource": "*"
    },
    {
      "Effect": "Allow",
      "Action": "sqs:ReceiveMessage",
      "Resource": "*"
    },
    {
      "Effect": "Allow",
      "Action": "s3:ListBucket",
      "Resource": "*"
    },
    {
      "Effect": "Allow",
      "Action": "sns:ListSubscriptions",
      "Resource": "*"
    }
  ]
}
```

The preceding policy grants several permissions to the IAM user. However, this policy alone doesn't grant any permissions to the federated user. If this IAM user calls `GetFederationToken` and does not pass a policy as a parameter of the API call, the resulting federated user has no effective permissions.

Session policy passed as parameter

The most common way to ensure that the federated user is assigned appropriate permission is to pass session policies in the `GetFederationToken` API call. Expanding on the previous example, imagine that `GetFederationToken` is called with the credentials of the IAM user `token-app`. Then imagine that the following session policy is passed as a parameter of the API call. The resulting federated user has permission to list the contents of the Amazon S3 bucket named `productionapp`. The user can't perform the Amazon S3 `GetObject`, `PutObject`, and `DeleteObject` actions on items in the `productionapp` bucket.

The federated user is assigned these permissions because the permissions are the intersection of the IAM user policies and the session policies that you pass.

The federated user could not perform actions in Amazon SNS, Amazon SQS, Amazon DynamoDB, or in any S3 bucket except `productionapp`. These actions are denied even though those permissions are granted to the IAM user that is associated with the `GetFederationToken` call.

Example Example session policy passed as parameter of `GetFederationToken` API call

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": ["s3:ListBucket"],
      "Resource": ["arn:aws:s3:::productionapp"]
    },
    {
      "Effect": "Allow",
      "Action": [
        "s3:GetObject",
        "s3:PutObject",
        "s3:DeleteObject"
      ],
      "Resource": ["arn:aws:s3:::productionapp/*"]
    }
  ]
}
```

Resource-based policies

Some AWS resources support resource-based policies, and these policies provide another mechanism to grant permissions directly to a federated user. Only some AWS services support resource-based policies. For example, Amazon S3 has buckets, Amazon SNS has topics, and Amazon SQS has queues that you can attach policies to. For a list of all services that support resource-based policies, see [AWS services that work with IAM](#) and review the "Resource-based policies" column of the tables. You can use resource-based policies to assign permissions directly to a federated user. Do this by specifying the Amazon Resource Name (ARN) of the federated user in the `Principal` element of the resource-based policy. The following example illustrates this and expands on the previous examples, using an S3 bucket named `productionapp`.

The following resource-based policy is attached to the bucket. This bucket policy allows a federated user named Carol to access the bucket. When the example policy described earlier is attached to the `token-app` IAM user, the federated user named Carol has permission to

perform the `s3:GetObject`, `s3:PutObject`, and `s3:DeleteObject` actions on the bucket named `productionapp`. This is true even when no session policy is passed as a parameter of the `GetFederationToken` API call. That's because in this case the federated user named Carol has been explicitly granted permissions by the following resource-based policy.

Remember, a federated user is granted permissions only when those permissions are explicitly granted to both the IAM user *and* the federated user. They can also be granted (within the account) by a resource-based policy that explicitly names the federated user in the `Principal` element of the policy, as in the following example.

Example Example bucket policy that allows access to federated user

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Principal": {"AWS": "arn:aws:sts::account-id:federated-user/Carol"},
      "Effect": "Allow",
      "Action": [
        "s3:GetObject",
        "s3:PutObject",
        "s3:DeleteObject"
      ],
      "Resource": ["arn:aws:s3:::productionapp/*"]
    }
  ]
}
```

For more information about how policies are evaluated see [Policy evaluation logic](#).

Permissions for GetSessionToken

The primary occasion for calling the `GetSessionToken` API operation or the `get-session-token` CLI command is when a user must be authenticated with multi-factor authentication (MFA). It is possible to write a policy that allows certain actions only when those actions are requested by a user who has been authenticated with MFA. In order to successfully pass the MFA authorization check, a user must first call `GetSessionToken` and include the optional `SerialNumber` and `TokenCode` parameters. If the user is successfully authenticated with an MFA device, the credentials returned by the `GetSessionToken` API operation include the MFA context. This context indicates that the user is authenticated with MFA and is authorized for API operations that require MFA authentication.

Permissions required for GetSessionToken

No permissions are required for a user to get a session token. The purpose of the `GetSessionToken` operation is to authenticate the user using MFA. You cannot use policies to control authentication operations.

To grant permissions to perform most AWS operations, you add the action with the same name to a policy. For example, to create a user, you must use the `CreateUser` API operation, the `create-user` CLI command, or the AWS Management Console. To perform these operations, you must have a policy that allows you to access the `CreateUser` action.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": "iam:CreateUser",
      "Resource": "*"
    }
  ]
}
```

You can include the `GetSessionToken` action in your policies, but it has no effect on a user's ability to perform the `GetSessionToken` operation.

Permissions granted by GetSessionToken

If `GetSessionToken` is called with the credentials of an IAM user, the temporary security credentials have the same permissions as the IAM user. Similarly, if `GetSessionToken` is called with AWS account root user credentials, the temporary security credentials have root user permissions.

Note

We recommend that you do not call `GetSessionToken` with root user credentials. Instead, follow our [best practices](#) and create IAM users with the permissions they need. Then use these IAM users for everyday interaction with AWS.

The temporary credentials that you get when you call `GetSessionToken` have the following capabilities and limitations:

- You can use the credentials to access the AWS Management Console by passing the credentials to the federation single sign-on endpoint at <https://signin.aws.amazon.com/federation>. For more information, see [Enabling custom identity broker access to the AWS console](#).
- You **cannot** use the credentials to call IAM or AWS STS API operations. You **can** use them to call API operations for other AWS services.

Compare this API operation and its limitations and capability with the other API operations that create temporary security credentials at [Comparing the AWS STS API operations](#)

For more information about MFA-protected API access using `GetSessionToken`, see [Configuring MFA-protected API access](#).

Disabling permissions for temporary security credentials

Temporary security credentials are valid until they expire. These credentials are valid for the specified duration, from 900 seconds (15 minutes) up to a maximum of 129,600 seconds (36 hours). The default session duration is 43,200 seconds (12 hours). You can revoke these credentials, but you must also change permissions for the role to stop the use of compromised credentials for malicious account activity. Permissions assigned to temporary security credentials are evaluated each time they are used to make an AWS request. Once you remove all permissions from the credentials, AWS requests that use them fail.

It might take a few minutes for policy updates to take effect. [Revoke the role's temporary security credentials](#) to force all users assuming the role to reauthenticate and request new credentials.

You cannot change the permissions for an AWS account root user. Likewise, you cannot change the permissions for the temporary security credentials that were created by calling `GetFederationToken` or `GetSessionToken` while signed in as the root user. For this reason, we recommend that you do not call `GetFederationToken` or `GetSessionToken` as a root user.

Important

For users in IAM Identity Center, see [Disable user access](#) in the *AWS IAM Identity Center User Guide*. You can also [Remove user access](#) to cloud applications or custom SAML 2.0 applications in the IAM Identity Center console.

Topics

- [Deny access to all sessions associated with a role](#)
- [Deny access to a specific session](#)
- [Deny a user session with condition context keys](#)
- [Deny a session user with resource-based policies](#)

Deny access to all sessions associated with a role

Use this approach when you are concerned about suspicious access by:

- Principals from another account using cross-account access
- External user identities with permissions to access AWS resources in your account
- Users who have been authenticated in a mobile or web application with a web identity provider

This procedure denies permissions to **all** users that have permissions to assume a role.

To change or remove the permissions assigned to the temporary security credentials obtained by calling `AssumeRole`, `AssumeRoleWithSAML`, or `AssumeRoleWithWebIdentity`, `GetFederationToken`, or `GetSessionToken`, you can edit or delete the permissions policy that defines the permissions for the role.

Important

If there's a resource-based policy that allows the principal access, you must also add an explicit deny for that resource. See [Deny a session user with resource-based policies](#) for details.

1. Sign in to the AWS Management Console and open the IAM console.
2. In the navigation pane, choose the name of the role to edit. You can use the search box to filter the list.
3. Select the relevant policy.
4. Choose the **Permissions** tab.
5. Choose the **JSON** tab and update the policy to deny all resources and actions.

```
{
```

```
"Version": "2012-10-17",
"Statement": [
  {
    "Effect": "Deny",
    "Action": "*",
    "Resource": "*"
  }
]
```

6. On the **Review** page, review the policy **Summary** and then choose **Save changes** to save your work.

When you update the policy, the changes affect the permissions of all temporary security credentials associated with the role, including credentials that were issued before you changed the role's permissions policy. After you update the policy, you can [revoke the role's temporary security credentials](#) to immediately revoke all permissions to the role's issued credentials.

Deny access to a specific session

When you update the roles that are assumable from an IdP with a deny-all policy or delete the role entirely, all users that have access to the role are disrupted. You can deny access based on the `Principal` element without impacting the permissions of all other sessions associated with the role.

The `Principal` can be denied permissions using [condition context keys](#) or [resource-based policies](#).

Tip

You can find the ARNs of federated users using AWS CloudTrail logs. For more information, see [How to Easily Identify Your Federated Users by Using AWS CloudTrail](#).

Deny a user session with condition context keys

You can use condition context keys in situations where you want to deny access to specific temporary security credential sessions without affecting the permissions of the IAM user or role that created the credentials.

For more information about condition context keys, see [AWS global condition context keys](#).

Note

If there's a resource-based policy that allows the principal access, you must also add an explicit deny statement on the resource-based policy after you complete these steps.

After you update the policy, you can [revoke the role's temporary security credentials](#) to immediately revoke all issued credentials.

aws:PrincipalArn

You can use condition context key [aws:PrincipalArn](#) to deny access to a specific principal ARN. You do this by specifying the unique identifier (ID) of the IAM user, role, or federated user the temporary security credentials are associated with in the Condition element of a policy.

1. In the IAM console navigation pane, choose the name of the role to edit. You can use the search box to filter the list.
2. Select the relevant policy.
3. Choose the **Permissions** tab.
4. Choose the **JSON** tab and add a deny statement for the principal ARN as shown in the following example.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Deny",
      "Action": "*",
      "Resource": "*",
      "Condition": {
        "ArnEquals": {
          "aws:PrincipalArn": [
            "arn:aws:iam::222222222222:role/ROLENAME",
            "arn:aws:iam::222222222222:user/USERNAME",
            "arn:aws:sts::222222222222:federated-user/USERNAME"
          ]
        }
      }
    }
  ]
}
```

```
}
```

5. On the **Review** page, review the policy **Summary** and then choose **Save changes** to save your work.

aws:userid

You can use condition context key [aws:userid](#) to deny access to all or specific temporary security credential sessions associated with the IAM user or role. You do this by specifying the unique identifier (ID) of the IAM user, role, or federated user the temporary security credentials are associated with in the `Condition` element of a policy.

The following policy shows an example of how you can deny access to temporary security credential sessions using condition context key `aws:userid`.

- `AIDAXUSER1` represents the unique identifier for an IAM user. Specifying the unique identifier of an IAM user as a value for context key `aws:userid` will deny all sessions associated with the IAM user.
- `AROAXROLE1` represents the unique identifier for an IAM role. Specifying the unique identifier of an IAM role as a value for context key `aws:userid` will deny all sessions associated with the role.
- `AROAXROLE2` represents the unique identifier for an assumed-role session. In the `caller-specified-role-session-name` portion of the assumed-role unique identifier you can specify a role session name or a wildcard character if the `StringLike` condition operator is used. If you specify the role session name, it will deny the named role session without affecting the permissions of the role that created the credentials. If you specify a wildcard for the role session name, it will deny all sessions associated with the role.
- `account-id:<federated-user-caller-specified-name>` represents the unique identifier for a federated user session. A federated user is created by an IAM user calling the `GetFederationToken` API. If you specify the unique identifier for a federated user, it will deny the named federated user session without affecting the permissions of the role that created the credentials.

```
{  
  "Version": "2012-10-17",  
  "Statement": [  
    {
```

```
"Effect": "Deny",
"Action": "*",
"Resource": "*",
"Condition": {
  "StringLike": {
    "aws:userId": [
      "AIDAXUSER1",
      "AROAXROLE1",
      "AROAXROLE2:<caller-specified-role-session-name>",
      "account-id:<federated-user-caller-specified-name>"
    ]
  }
}
}
```

For specific examples of principal key values, see [Principal key values](#). For information about IAM unique identifiers, see [Unique identifiers](#).

Deny a session user with resource-based policies

If the principal ARN is also included in any resource-based policies, you must also revoke access based on the specific user's `principalId` or `sourceIdentity` values in the `Principal` element of a resource-based policy. If you only update the permissions policy for the role, the user can still perform actions allowed in the resource-based policy.

1. Refer to [AWS services that work with IAM](#) to see if the service supports resource-based policies.
2. Sign in to the AWS Management Console and open the console for the service. Each service has a different location in the console for attaching policies.
3. Edit the policy statement to specify the identifying information of the credential:
 - a. In `Principal`, enter the ARN of the credential to deny.
 - b. In `Effect`, enter "Deny."
 - c. In `Action`, enter the service namespace and the name of the action to deny. To deny all actions, use the wildcard (*) character. For example: "s3:*."
 - d. In `Resource`, enter the ARN of the target resource. For example: "arn:aws:s3:::EXAMPLE-BUCKET."

```
{
  "Version": "2012-10-17",
  "Statement": {
    "Principal": [
      "arn:aws:iam::222222222222:role/ROLENAME",
      "arn:aws:iam::222222222222:user/USERNAME",
      "arn:aws:sts::222222222222:federated-user/USERNAME"
    ],
    "Effect": "Deny",
    "Action": "s3:*",
    "Resource": "arn:aws:s3:::EXAMPLE-BUCKET"
  }
}
```

4. Save your work.

Granting permissions to create temporary security credentials

By default, IAM users do not have permission to create temporary security credentials for federated users and roles. You must use a policy to provide your users with these permissions. Although you can grant permissions directly to a user, we strongly recommend that you grant permissions to a group. This makes management of the permissions much easier. When someone no longer needs to perform the tasks associated with the permissions, you simply remove them from the group. If someone else needs to perform that task, add them to the group to grant the permissions.

To grant an IAM group permission to create temporary security credentials for federated users or roles, you attach a policy that grants one or both of the following privileges:

- For federated users to access an IAM role, grant access to AWS STS AssumeRole.
- For federated users that don't need a role, grant access to AWS STS GetFederationToken.

For more information about the differences between the AssumeRole and GetFederationToken API operations, see [Requesting temporary security credentials](#).

IAM users can also call [GetSessionToken](#) to create temporary security credentials. No permissions are required for a user to call GetSessionToken. The purpose of this operation is to authenticate the user using MFA. You cannot use policies to control authentication. This means that you cannot prevent IAM users from calling GetSessionToken to create temporary credentials.

Example Example policy that grants permission to assume a role

The following example policy grants permission to call `AssumeRole` for the `UpdateApp` role in AWS account `123123123123`. When `AssumeRole` is used, the user (or application) that creates the security credentials on behalf of a federated user cannot delegate any permissions that are not already specified in the role permission policy.

```
{
  "Version": "2012-10-17",
  "Statement": [{
    "Effect": "Allow",
    "Action": "sts:AssumeRole",
    "Resource": "arn:aws:iam::123123123123:role/UpdateAPP"
  }]
}
```

Example Example policy that grants permission to create temporary security credentials for a federated user

The following example policy grants permission to access `GetFederationToken`.

```
{
  "Version": "2012-10-17",
  "Statement": [{
    "Effect": "Allow",
    "Action": "sts:GetFederationToken",
    "Resource": "*"
  }]
}
```

Important

When you give IAM users permission to create temporary security credentials for federated users with `GetFederationToken`, be aware that this permits those users to delegate their own permissions. For more information about delegating permissions across IAM users and AWS accounts, see [Examples of policies for delegating access](#). For more information about controlling permissions in temporary security credentials, see [Controlling permissions for temporary security credentials](#).

Example Example policy that grants a user limited permission to create temporary security credentials for federated users

When you let an IAM user call `GetFederationToken`, it is a best practice to restrict the permissions that the IAM user can delegate. For example, the following policy shows how to let an IAM user create temporary security credentials only for federated users whose names start with *Manager*.

```
{
  "Version": "2012-10-17",
  "Statement": [{
    "Effect": "Allow",
    "Action": "sts:GetFederationToken",
    "Resource": ["arn:aws:sts::123456789012:federated-user/Manager*"]
  }]
}
```

Managing AWS STS in an AWS Region

By default, the AWS Security Token Service (AWS STS) is available as a global service, and all AWS STS requests go to a single endpoint at `https://sts.amazonaws.com`. AWS recommends using Regional AWS STS endpoints instead of the global endpoint to reduce latency, build in redundancy, and increase session token validity.

- **Reduce latency** – By making your AWS STS calls to an endpoint that is geographically closer to your services and applications, you can access AWS STS services with lower latency and better response times.
- **Build in redundancy** – You can limit the effects of a failure within a workload to a limited number of components with a predictable scope of impact containment. Using regional AWS STS endpoints lets you align the scope of your components with the scope of your session tokens. For more information about this reliability pillar, see [Use fault isolation to protect your workload](#) in the *AWS Well-Architected Framework*.
- **Increase session token validity** – Session tokens from Regional AWS STS endpoints are valid in all AWS Regions. Session tokens from the global STS endpoint are valid only in AWS Regions that are enabled by default. If you intend to enable a new Region for your account, you can use session tokens from Regional AWS STS endpoints. If you choose to use the global endpoint, you must change the Region compatibility of AWS STS session tokens for the global endpoint. Doing so ensures that tokens are valid in all AWS Regions.

Managing global endpoint session tokens

Most AWS Regions are enabled for operations in all AWS services by default. Those Regions are automatically activated for use with AWS STS. Some Regions, such as Asia Pacific (Hong Kong), must be manually enabled. To learn more about enabling and disabling AWS Regions, see [Specify which AWS Regions your account can use](#) in the *AWS Account Management Reference Guide*. When you enable these AWS Regions, they are automatically activated for use with AWS STS. You cannot activate the AWS STS endpoint for a Region that is disabled. Tokens that are valid in all AWS Regions include more characters than tokens that are valid in Regions that are enabled by default. Changing this setting might affect existing systems where you temporarily store tokens.

You can change this setting using the AWS Management Console, AWS CLI, or AWS API.

To change the Region compatibility of session tokens for the global endpoint (console)

1. Sign in as a root user or a user with permissions to perform IAM administration tasks. To change the compatibility of session tokens, you must have a policy that allows the `iam:SetSecurityTokenServicePreferences` action.
2. Open the [IAM console](#). In the navigation pane, choose **Account settings**.
3. Under **Security Token Service (STS)** section **Session Tokens from the STS endpoints**. The **Global endpoint** indicates `Valid only in AWS Regions enabled by default`. Choose **Change**.
4. In the **Change region compatibility** dialog box, select **All AWS Regions**. Then choose **Save changes**.

Note

Tokens that are valid in all AWS Region include more characters than tokens that are valid in Regions that are enabled by default. Changing this setting might affect existing systems where you temporarily store tokens.

To change the Region compatibility of session tokens for the global endpoint (AWS CLI)

Set the session token version. Version 1 tokens are valid only in AWS Regions that are available by default. These tokens do not work in manually enabled Regions, such as Asia Pacific (Hong Kong). Version 2 tokens are valid in all Regions. However, version 2 tokens include more characters and might affect systems where you temporarily store tokens.

- [aws iam set-security-token-service-preferences](#)

To change the Region compatibility of session tokens for the global endpoint (AWS API)

Set the session token version. Version 1 tokens are valid only in AWS Regions that are available by default. These tokens do not work in manually enabled Regions, such as Asia Pacific (Hong Kong). Version 2 tokens are valid in all Regions. However, version 2 tokens include more characters and might affect systems where you temporarily store tokens.

- [SetSecurityTokenServicePreferences](#)

Activating and deactivating AWS STS in an AWS Region

When you activate STS endpoints for a Region, AWS STS can issue temporary credentials to users and roles in your account that make an AWS STS request. Those credentials can then be used in any Region that is enabled by default or is manually enabled. For Regions that are enabled by default, you must activate the Regional STS endpoint in the account where the temporary credentials are generated. It does not matter whether a user is signed into the same account or a different account when they make the request. For Regions that are manually enabled, you must activate the Region in both the account making the request and the account where the temporary credentials are generated.

For example, imagine a user in account A wants to send an `sts:AssumeRole` API request to the AWS STS Regional endpoint `https://sts.us-east-2.amazonaws.com`. The request is for temporary credentials for the role named `Developer` in account B. Because the request is to create credentials for an entity in account B, account B must activate the `us-east-2` Region. Users from account A (or any other account) can call the `us-east-2` endpoint to request credentials for account B whether or not the Region is activated in their accounts.

Note

Active Regions are available to everyone that uses temporary credentials in that account. To control which IAM users or roles can access the Region, use the [aws:RequestedRegion](#) condition key in your permissions policies.

To activate or deactivate AWS STS in a Region that is enabled by default (console)

1. Sign in as a root user or a user with permissions to perform IAM administration tasks.
2. Open the [IAM console](#) and in the navigation pane choose [Account settings](#).
3. In the **Security Token Service (STS)** section **Endpoints**, find the Region that you want to configure, and then choose **Active** or **Inactive** in the **STS status** column.
4. In the dialog box that opens, choose **Activate** or **Deactivate**.

For Regions that must be enabled, we activate AWS STS automatically when you enable the Region. After you enable a Region, AWS STS is always active for the Region and you cannot deactivate it. To learn about enabling Regions that are disabled by default, see [Specifying which AWS Regions your account can use](#) in the *AWS Account Management Reference Guide*.

Writing code to use AWS STS Regions

After you activate a Region, you can direct AWS STS API calls to that Region. The following Java code snippet demonstrates how to configure an `AWSecurityTokenService` object to make requests to the Europe (Ireland) (eu-west-1) Region.

```
EndpointConfiguration regionEndpointConfig = new EndpointConfiguration("https://sts.eu-west-1.amazonaws.com", "eu-west-1");
AWSSecurityTokenService stsRegionalClient =
    AWSSecurityTokenServiceClientBuilder.standard()
        .withCredentials(credentials)
        .withEndpointConfiguration(regionEndpointConfig)
        .build();
```

AWS STS recommends that you make calls to a Regional endpoint. To learn how to manually enable a Region, see [Specify which AWS Regions your account can use](#) in the *AWS Account Management Reference Guide*.

In the example, the first line instantiates an `EndpointConfiguration` object called `regionEndpointConfig`, passing the URL of the endpoint and the AWS Region as the parameters.

To learn how to set AWS STS regional endpoints using an environment variable for AWS SDKs, see [AWS STS Regionalized endpoints](#) in the *AWS SDKs and Tools Reference Guide*.

For all other language and programming environment combinations, refer to the [documentation for the relevant SDK](#).

Regions and endpoints

The following table lists the Regions and their endpoints. It indicates which ones are activated by default and which ones you can activate or deactivate.

Region name	Endpoint	Active by default	Manually activate/deactivate
--Global--	sts.amazonaws.com	 Yes	 No
US East (Ohio)	sts.us-east-2.amazonaws.com	 Yes	 Yes
US East (N. Virginia)	sts.us-east-1.amazonaws.com	 Yes	 No
US West (N. California)	sts.us-west-1.amazonaws.com	 Yes	 Yes
US West (Oregon)	sts.us-west-2.amazonaws.com	 Yes	 Yes

Region name	Endpoint	Active by default	Manually activate/deactivate
Africa (Cape Town)	sts.af-south-1.amazonaws.com	 No ¹	 No
Asia Pacific (Hong Kong)	sts.ap-east-1.amazonaws.com	 No ¹	 No
Asia Pacific (Hyderabad)	sts.ap-south-2.amazonaws.com	 No ¹	 No
Asia Pacific (Jakarta)	sts.ap-southeast-3.amazonaws.com	 No ¹	 No
Asia Pacific (Melbourne)	sts.ap-southeast-4.amazonaws.com	 No ¹	 No
Asia Pacific (Mumbai)	sts.ap-south-1.amazonaws.com	 Yes	 Yes

Region name	Endpoint	Active by default	Manually activate/deactivate
Asia Pacific (Osaka)	sts.ap-northeast-3.amazonaws.com	 Yes	 Yes
Asia Pacific (Seoul)	sts.ap-northeast-2.amazonaws.com	 Yes	 Yes
Asia Pacific (Singapore)	sts.ap-southeast-1.amazonaws.com	 Yes	 Yes
Asia Pacific (Sydney)	sts.ap-southeast-2.amazonaws.com	 Yes	 Yes
Asia Pacific (Tokyo)	sts.ap-northeast-1.amazonaws.com	 Yes	 Yes
Canada (Central)	sts.ca-central-1.amazonaws.com	 Yes	 Yes

Region name	Endpoint	Active by default	Manually activate/deactivate
Canada West (Calgary)	sts.ca-west-1.amazonaws.com	 Yes	 Yes
China (Beijing)	sts.cn-north-1.amazonaws.com.cn	 Yes ²	 No
China (Ningxia)	sts.cn-northwest-1.amazonaws.com.cn	 Yes ²	 Yes
Europe (Frankfurt)	sts.eu-central-1.amazonaws.com	 Yes	 Yes
Europe (Ireland)	sts.eu-west-1.amazonaws.com	 Yes	 Yes
Europe (London)	sts.eu-west-2.amazonaws.com	 Yes	 Yes

Region name	Endpoint	Active by default	Manually activate/deactivate
Europe (Milan)	sts.eu-south-1.amazonaws.com	 No ¹	 No
Europe (Paris)	sts.eu-west-3.amazonaws.com	 Yes	 Yes
Europe (Spain)	sts.eu-south-2.amazonaws.com	 No ¹	 No
Europe (Stockholm)	sts.eu-north-1.amazonaws.com	 Yes	 Yes
Europe (Zurich)	sts.eu-central-2.amazonaws.com	 No ¹	 No
Israel (Tel Aviv)	sts.il-central-1.amazonaws.com	 No ¹	 No

Region name	Endpoint	Active by default	Manually activate/deactivate
Middle East (Bahrain)	sts.me-south-1.amazonaws.com	 No ¹	 No
Middle East (UAE)	sts.me-central-1.amazonaws.com	 No ¹	 No
South America (São Paulo)	sts.sa-east-1.amazonaws.com	 Yes	 Yes

¹You must [enable the Region](#) to use it. This automatically activates AWS STS. You cannot manually activate or deactivate AWS STS in these Regions.

²To use AWS in China, you need an account and credentials specific to AWS in China.

AWS CloudTrail and Regional endpoints

Calls to regional and global endpoints are logged in the `tlsDetails` field in AWS CloudTrail. Calls to regional endpoints, such as `us-east-2.amazonaws.com`, are logged in CloudTrail to their appropriate region. Calls to the global endpoint, `sts.amazonaws.com`, are logged as calls to a global service. Events for global AWS STS endpoints are logged to `us-east-1`.

Note

`tlsDetails` can only be viewed for services that support this field. See [Services that support TLS details in CloudTrail](#) in the *AWS CloudTrail User Guide*

For more information, see [Logging IAM and AWS STS API calls with AWS CloudTrail](#).

Using bearer tokens

Some AWS services require that you have permission to get an AWS STS service bearer token before you can access their resources programmatically. These services support a protocol that requires you to use a bearer token instead of using a traditional [Signature Version 4 signed request](#). When you perform AWS CLI or AWS API operations that require bearer tokens, the AWS service requests a bearer token on your behalf. The service provides you with the token, which you can then use to perform subsequent operations in that service.

AWS STS service bearer tokens include information from your original principal authentication that might affect your permissions. This information can include principal tags, session tags, and session policies. The token's access key ID begins with the ABIA prefix. This helps you to identify operations that were performed using service bearer tokens in your CloudTrail logs.

Important

The bearer token can be used only for calls to the service that generates it and in the Region where it was generated. You can't use the bearer token to perform operations in other services or Regions.

An example of a service that supports bearer tokens is AWS CodeArtifact. Before you can interact with AWS CodeArtifact using a package manager such as NPM, Maven, or PIP, you must call the `aws codeartifact get-authorization-token` operation. This operation returns a bearer token that you can use to perform AWS CodeArtifact operations. Alternatively, you can use the `aws codeartifact login` command that completes the same operation and then configures your client automatically.

If you perform an action in an AWS service that generates a bearer token for you, you must have the following permissions in your IAM policy:

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "AllowServiceBearerToken",
      "Effect": "Allow",
      "Action": "sts:GetServiceBearerToken",
      "Resource": "*"
    }
  ]
}
```

```
    }  
  ]  
}
```

For a service bearer token example, see [Using identity-based policies for AWS CodeArtifact](#) in the *AWS CodeArtifact* user guide.

Sample applications that use temporary credentials

You can use AWS Security Token Service (AWS STS) to create and provide trusted users with temporary security credentials that can control access to your AWS resources. For more information about AWS STS, see [Temporary security credentials in IAM](#). To see how you can use AWS STS to manage temporary security credentials, you can download the following sample applications that implement complete example scenarios:

- [Enabling Federation to AWS Using Windows Active Directory, ADFS, and SAML 2.0](#). Demonstrates how to delegate access using enterprise federation to AWS using Windows Active Directory (AD), Active Directory Federation Services (ADFS) 2.0, and SAML (Security Assertion Markup Language) 2.0.
- [Enabling custom identity broker access to the AWS console](#). Demonstrates how to create a custom federation proxy that enables single sign-on (SSO) so that existing Active Directory users can sign in to the AWS Management Console.
- [How to Use Shibboleth for Single Sign-On to the AWS Management Console](#). Shows how to use [Shibboleth](#) and [SAML](#) to provide users with single sign-on (SSO) access to the AWS Management Console.

Samples for web identity federation

The following sample applications illustrate how to use web identity federation with providers like Login with Amazon, Amazon Cognito, Facebook, or Google. You can trade authentication from these providers for temporary AWS security credentials to access AWS services.

- [Amazon Cognito Tutorials](#) – We recommend that you use Amazon Cognito with the AWS SDKs for mobile development. Amazon Cognito is the simplest way to manage identity for mobile apps, and it provides additional features like synchronization and cross-device identity. For more information about Amazon Cognito, see [Authentication with Amplify](#) in the *Amplify Documentation*.

Additional resources for temporary security credentials

The following scenarios and applications can guide you in using temporary security credentials:

- [How to integrate AWS STS SourceIdentity with your identity provider](#). This post shows you how to set up the AWS STS SourceIdentity attribute when using Okta, Ping, or OneLogin as your IdP.
- [About web identity federation](#). This section discusses how to configure IAM roles when you use web identity federation and the AssumeRoleWithWebIdentity API.
- [Configuring MFA-protected API access](#). This topic explains how to use roles to require multi-factor authentication (MFA) to protect sensitive API actions in your account.

For more information on policies and permissions in AWS see the following topics:

- [Access management for AWS resources](#)
- [Policy evaluation logic](#).
- [Managing Access Permissions to Your Amazon S3 Resources](#) in *Amazon Simple Storage Service User Guide*.
- To learn whether principals in accounts outside of your zone of trust (trusted organization or account) have access to assume your roles, see [What is IAM Access Analyzer?](#).

Logging IAM and AWS STS API calls with AWS CloudTrail

IAM and AWS STS are integrated with AWS CloudTrail, a service that provides a record of actions taken by an IAM user or role. CloudTrail captures all API calls for IAM and AWS STS as events, including calls from the console and from API calls. If you create a trail, you can enable continuous delivery of CloudTrail events to an Amazon S3 bucket. If you don't configure a trail, you can still view the most recent events in the CloudTrail console in **Event history**. You can use CloudTrail to get information about the request that was made to IAM or AWS STS. For example, you can view the IP address from which the request was made, who made the request, when it was made, and additional details.

To learn more about CloudTrail, see the [AWS CloudTrail User Guide](#).

IAM and AWS STS information in CloudTrail

CloudTrail is enabled on your AWS account when you create the account. When activity occurs in IAM or AWS STS, that activity is recorded in a CloudTrail event along with other AWS service events in **Event history**. You can view, search, and download recent events in your AWS account. For more information, see [Viewing Events with CloudTrail Event History](#).

For an ongoing record of events in your AWS account, including events for IAM and AWS STS, create a trail. A trail enables CloudTrail to deliver log files to an Amazon S3 bucket. By default, when you create a trail in the console, the trail applies to all Regions. The trail logs events from all Regions in the AWS partition and delivers the log files to the Amazon S3 bucket that you specify. Additionally, you can configure other AWS services to further analyze and act upon the event data collected in CloudTrail logs. For more information, see:

- [Overview for Creating a Trail](#)
- [CloudTrail Supported Services and Integrations](#)
- [Configuring Amazon SNS Notifications for CloudTrail](#)
- [Receiving CloudTrail Log Files from Multiple Regions](#) and [Receiving CloudTrail Log Files from Multiple Accounts](#)

All IAM and AWS STS actions are logged by CloudTrail and are documented in the [IAM API Reference](#) and the [AWS Security Token Service API Reference](#).

Logging IAM and AWS STS API requests

CloudTrail logs all authenticated API requests (made with credentials) to IAM and AWS STS API operations. CloudTrail also logs non-authenticated requests to the AWS STS actions, `AssumeRoleWithSAML` and `AssumeRoleWithWebIdentity`, and logs information provided by the identity provider. You can use this information to map calls made by a federated user with an assumed role back to the originating external federated caller. In the case of `AssumeRole`, you can map calls back to the originating AWS service or to the account of the originating user. The `userIdentity` section of the JSON data in the CloudTrail log entry contains the information that you need to map the `AssumeRole*` request with a specific federated user. For more information, see [CloudTrail userIdentity Element](#) in the *AWS CloudTrail User Guide*.

For example, calls to the IAM `CreateUser`, `DeleteRole`, `ListGroups`, and other API operations are all logged by CloudTrail.

Examples for this type of log entry are presented later in this topic.

Logging API requests to other AWS services

Authenticated requests to other AWS service API operations are logged by CloudTrail, and these log entries contain information about who generated the request.

For example, assume that you made a request to list Amazon EC2 instances or create an AWS CodeDeploy deployment group. Details about the person or service that made the request are contained in the log entry for that request. This information helps you determine whether the request was made by the AWS account root user, an IAM user, a role, or another AWS service.

For more details about the user identity information in CloudTrail log entries, see [userIdentity Element](#) in the *AWS CloudTrail User Guide*.

Logging user sign-in events

CloudTrail logs sign-in events to the AWS Management Console, the AWS discussion forums, and AWS Marketplace. CloudTrail logs successful and failed sign-in attempts for IAM users and federated users.

To view sample CloudTrail events for successful and unsuccessful root user sign-ins, see [Example event records for root users](#) in the *AWS CloudTrail User Guide*.

As a security best practice, AWS does not log the entered IAM user name text when the sign-in failure is caused by *an incorrect user name*. The user name text is masked by the value `HIDDEN_DUE_TO_SECURITY_REASONS`. For an example of this, see [Example sign-in failure event caused by incorrect user name](#), later in this topic. The user name text is obscured because such failures might be caused by user errors. Logging these errors could expose potentially sensitive information. For example:

- You accidentally type your password in the user name box.
- You choose the link for the sign-in page of one AWS account, but then type the account number for a different AWS account.
- You forget which account you are signing in to and accidentally type the account name of your personal email account, your bank sign-in identifier, or some other private ID.

Logging sign-in events for temporary credentials

When a principal requests temporary credentials, the principal type determines how CloudTrail logs the event. This can be complicated when a principal assumes a role in another account. There are multiple API calls to perform operations related to role cross-account operations. First, the principal calls an AWS STS API to retrieve the temporary credentials. That operation is logged in the calling account and the account where the AWS STS operation is performed. Then the principal then uses the role to perform other API calls in the assumed role's account.

You can use the `sts:SourceIdentity` condition key in the role trust policy to require users to specify an identity when they assume a role. For example, you can require that IAM users specify their own user name as their source identity. This can help you determine which user performed a specific action in AWS. For more information, see [sts:SourceIdentity](#). You can also use [sts:RoleSessionName](#) to require users to specify a session name when they assume a role. This can help you differentiate between role sessions for a role that is used by different principals when you review AWS CloudTrail logs.

The following table shows how CloudTrail logs different user identity information for each of the AWS STS APIs that generate temporary credentials.

Principal type	STS API	User identity in CloudTrail log for caller's account	User identity in CloudTrail log for the assumed role's account	User identity in CloudTrail log for the role's subsequent API calls
AWS account root user credentials	GetSessionToken	Root user identity	Role owner account is same as calling account	Root user identity
IAM user	GetSessionToken	IAM user identity	Role owner account is same as calling account	IAM user identity
IAM user	GetFederationToken	IAM user identity	Role owner account is same as calling account	IAM user identity
IAM user	AssumeRole	IAM user identity	Account number and principal ID (if a user), or AWS service principal	Role identity only (no user)
Externally authenticated user	AssumeRoleWithSAML	n/a	SAML user identity	Role identity only (no user)
Externally authenticated user	AssumeRoleWithWebIdentity	n/a	OIDC/Web user identity	Role identity only (no user)

CloudTrail considers an action read-only if it does not have any mutating effect on a resource. When logging a read-only event, CloudTrail redacts the responseElements information in the

log. When CloudTrail logs an event that is not read-only, the full responseElements is shown in the log entry. However, for the AWS STS APIs AssumeRole, AssumeRoleWithSAML, and AssumeRoleWithWebIdentity, even though they are logged as read-only, CloudTrail will include the full responseElements in the log for these APIs.

The following table shows how CloudTrail logs responseElements and readOnly information for each of the AWS STS APIs that generate temporary credentials.

STS API	Response elements information	Read-only
AssumeRole	Included	true
AssumeRoleWithSAML	Included	true
AssumeRoleWithWebIdentity	Included	true
GetFederationToken	Included	false
GetSessionToken	Included	false

Example IAM API events in CloudTrail log

CloudTrail log files contain events that are formatted using JSON. An API event represents a single API request and includes information about the principal, the requested action, any parameters, and the date and time of the action.

Example IAM API event in CloudTrail log file

The following example shows a CloudTrail log entry for a request made for the IAM GetUserPolicy action.

```
{
  "eventVersion": "1.05",
  "userIdentity": {
    "type": "IAMUser",
    "principalId": "AIDACKCEVSQ6C2EXAMPLE",
    "arn": "arn:aws:iam::444455556666:user/JaneDoe",
    "accountId": "444455556666",
```

```
{
  "accessKeyId": "AKIAI44QH8DHBEXAMPLE",
  "userName": "JaneDoe",
  "sessionContext": {
    "attributes": {
      "mfaAuthenticated": "false",
      "creationDate": "2014-07-15T21:39:40Z"
    }
  },
  "invokedBy": "signin.amazonaws.com"
},
"eventTime": "2014-07-15T21:40:14Z",
"eventSource": "iam.amazonaws.com",
"eventName": "GetUserPolicy",
"awsRegion": "us-east-2",
"sourceIPAddress": "signin.amazonaws.com",
"userAgent": "signin.amazonaws.com",
"requestParameters": {
  "userName": "JaneDoe",
  "policyName": "ReadOnlyAccess-JaneDoe-201407151307"
},
"responseElements": null,
"requestID": "9EXAMPLE-0c68-11e4-a24e-d5e16EXAMPLE",
"eventID": "cEXAMPLE-127e-4632-980d-505a4EXAMPLE"
}
```

From this event information, you can determine that the request was made to get a user policy named `ReadOnlyAccess-JaneDoe-201407151307` for user `JaneDoe`, as specified in the `requestParameters` element. You can also see that the request was made by an IAM user named `JaneDoe` on July 15, 2014 at 9:40 PM (UTC). In this case, the request originated in the AWS Management Console, as you can tell from the `userAgent` element.

Example AWS STS API events in CloudTrail log

CloudTrail log files contain events that are formatted using JSON. An API event represents a single API request and includes information about the principal, the requested action, any parameters, and the date and time of the action.

Example cross-account AWS STS API events in CloudTrail log files

The IAM user named `JohnDoe` in account `777788889999` calls the AWS STS `AssumeRole` action to assume the role `EC2-dev` in account `111122223333`. The account administrator requires users

to set a source identity equal to their user name when assuming the role. The user passes in the source identity value of JohnDoe.

```
{
  "eventVersion": "1.05",
  "userIdentity": {
    "type": "IAMUser",
    "principalId": "AIDAQRSTUVWXYZEXAMPLE",
    "arn": "arn:aws:iam::777788889999:user/JohnDoe",
    "accountId": "777788889999",
    "accessKeyId": "AKIAIOSFODNN7EXAMPLE",
    "userName": "JohnDoe"
  },
  "eventTime": "2014-07-18T15:07:39Z",
  "eventSource": "sts.amazonaws.com",
  "eventName": "AssumeRole",
  "awsRegion": "us-east-2",
  "sourceIPAddress": "192.0.2.101",
  "userAgent": "aws-cli/1.11.10 Python/2.7.8
Linux/3.2.45-0.6.wd.865.49.315.metal1.x86_64 boto3/1.4.67",
  "requestParameters": {
    "roleArn": "arn:aws:iam::111122223333:role/EC2-dev",
    "roleSessionName": "JohnDoe-EC2-dev",
    "sourceIdentity": "JohnDoe",
    "serialNumber": "arn:aws:iam::777788889999:mfa"
  },
  "responseElements": {
    "credentials": {
      "sessionToken": "<encoded session token blob>",
      "accessKeyId": "ASIAI44QH8DHBEXAMPLE",
      "expiration": "Jul 18, 2023, 4:07:39 PM"
    },
    "assumedRoleUser": {
      "assumedRoleId": "AIDAQRSTUVWXYZEXAMPLE:JohnDoe-EC2-dev",
      "arn": "arn:aws:sts::111122223333:assumed-role/EC2-dev/JohnDoe-EC2-dev"
    }
  },
  "sourceIdentity": "JohnDoe"
},
"resources": [
  {
    "ARN": "arn:aws:iam::111122223333:role/EC2-dev",
    "accountId": "111122223333",
    "type": "AWS::IAM::Role"
  }
]
```

```

    }
  ],
  "requestID": "4EXAMPLE-0e8d-11e4-96e4-e55c0EXAMPLE",
  "sharedEventID": "bEXAMPLE-efea-4a70-b951-19a88EXAMPLE",
  "eventID": "dEXAMPLE-ac7f-466c-a608-4ac8dEXAMPLE",
  "eventType": "AwsApiCall",
  "recipientAccountId": "111122223333"
}

```

The second example shows the assumed role account's (111122223333) CloudTrail log entry for the same request.

```

{
  "eventVersion": "1.05",
  "userIdentity": {
    "type": "AWSAccount",
    "principalId": "AIDAQRSTUVWXYZEXAMPLE",
    "accountId": "777788889999"
  },
  "eventTime": "2014-07-18T15:07:39Z",

  "eventID": "dEXAMPLE-ac7f-466c-a608-4ac8dEXAMPLE"
}
```

Example AWS STS role chaining API event in CloudTrail log file

The following example shows a CloudTrail log entry for a request made by John Doe in account 111111111111. John previously used his JohnDoe user to assume the JohnRole1 role. For this request, he uses the credentials from that role to assume the JohnRole2 role. This is known as [role chaining](#). The source identity that he set when he assumed the JohnDoe1 role persists in the request to assume JohnRole2. If John tries to set a different source identity when assuming the role, the request is denied. John passes two [session tags](#) into the request. He sets those two tags as transitive. The request inherits the Department tag as transitive because John set it as transitive when he assumed JohnRole1. For more information about source identity, see [Monitor and control actions taken with assumed roles](#). For more information about transitive keys in role chains, see [Chaining roles with session tags](#).

```
{
  "eventVersion": "1.05",
  "userIdentity": {
    "type": "AssumedRole",
    "principalId": "AROAIN5ATK5U7KEXAMPLE:JohnRole1",
    "arn": "arn:aws:sts::111111111111:assumed-role/JohnDoe/JohnRole1",
    "accountId": "111111111111",
    "accessKeyId": "ASIAIOSFODNN7EXAMPLE",
    "sessionContext": {

Example SAML AWS STS API event in CloudTrail log file

The following example shows a CloudTrail log entry for a request made for the AWS STS `AssumeRoleWithSAML` action. The request includes the SAML attributes `CostCenter` and `Project` that are passed through the SAML assertion as [session tags](#). Those tags are set as transitive so that they [persist in role chaining scenarios](#). The request includes the optional API parameter `DurationSeconds`, represented as `durationSeconds` in the CloudTrail log, and is set to 1800 seconds. The request also includes the SAML attribute `sourceIdentity`, which is passed in the SAML assertion. If someone uses the resulting role session credentials to assume another role, this source identity persists.

```

{

```

Example sign-in events in CloudTrail log

CloudTrail log files contain events that are formatted using JSON. A sign-in event represents a single sign-in request and includes information about the sign-in principal, the Region, and the date and time of the action.

Example sign-in success event in CloudTrail log file

The following example shows a CloudTrail log entry for a successful sign-in event.

```
{
  "eventVersion": "1.05",
  "userIdentity": {
    "type": "IAMUser",
    "principalId": "AIDACKCEVSQ6C2EXAMPLE",
    "arn": "arn:aws:iam::111122223333:user/JohnDoe",
    "accountId": "111122223333",
    "userName": "JohnDoe"
  },
  "eventTime": "2014-07-16T15:49:27Z",
  "eventSource": "signin.amazonaws.com",
  "eventName": "ConsoleLogin",
  "awsRegion": "us-east-2",
  "sourceIPAddress": "192.0.2.110",
  "userAgent": "Mozilla/5.0 (Windows NT 6.1; WOW64; rv:24.0) Gecko/20100101
Firefox/24.0",
  "requestParameters": null,
  "responseElements": {
    "ConsoleLogin": "Success"
  },
  "additionalEventData": {
    "MobileVersion": "No",
    "LoginTo": "https://console.aws.amazon.com/s3/ ",
    "MFAUsed": "No"
  }
}
```

```
},  
  "eventID": "3fcfb182-98f8-4744-bd45-10a395ab61cb"  
}
```

For more details about the information contained in CloudTrail log files, see [CloudTrail Event Reference](#) in the *AWS CloudTrail User Guide*.

Example sign-in failure event in CloudTrail log file

The following example shows a CloudTrail log entry for a failed sign-in event.

```
{  
  "eventVersion": "1.05",  
  "userIdentity": {  
    "type": "IAMUser",  
    "principalId": "AIDACKCEVSQ6C2EXAMPLE",  
    "arn": "arn:aws:iam::111122223333:user/JaneDoe",  
    "accountId": "111122223333",  
    "userName": "JaneDoe"  
  },  
  "eventTime": "2014-07-08T17:35:27Z",  
  "eventSource": "signin.amazonaws.com",  
  "eventName": "ConsoleLogin",  
  "awsRegion": "us-east-2",  
  "sourceIPAddress": "192.0.2.100",  
  "userAgent": "Mozilla/5.0 (Windows NT 6.1; WOW64; rv:24.0) Gecko/20100101  
Firefox/24.0",  
  "errorMessage": "Failed authentication",  
  "requestParameters": null,  
  "responseElements": {  
    "ConsoleLogin": "Failure"  
  },  
  "additionalEventData": {  
    "MobileVersion": "No",  
    "LoginTo": "https://console.aws.amazon.com/sns",  
    "MFAUsed": "No"  
  },  
  "eventID": "11ea990b-4678-4bcd-8fbe-62509088b7cf"  
}
```

From this information, you can determine that the sign-in attempt was made by an IAM user named JaneDoe, as shown in the `userIdentity` element. You can also see that the sign-in

attempt failed, as shown in the responseElements element. You can see that JaneDoe tried to sign in to the Amazon SNS console at 5:35 PM (UTC) on July 8, 2014.

Example sign-in failure event caused by incorrect user name

The following example shows a CloudTrail log entry for an unsuccessful sign-in event caused by the user entering an incorrect user name. AWS masks the userName text with HIDDEN_DUE_TO_SECURITY_REASONS to help prevent exposing potentially sensitive information.

```
{
  "eventVersion": "1.05",
  "userIdentity": {
    "type": "IAMUser",
    "accountId": "123456789012",
    "accessKeyId": "",
    "userName": "HIDDEN_DUE_TO_SECURITY_REASONS"
  },
  "eventTime": "2015-03-31T22:20:42Z",
  "eventSource": "signin.amazonaws.com",
  "eventName": "ConsoleLogin",
  "awsRegion": "us-east-2",
  "sourceIPAddress": "192.0.2.101",
  "userAgent": "Mozilla/5.0 (Windows NT 6.1; WOW64; rv:24.0) Gecko/20100101
Firefox/24.0",
  "errorMessage": "No username found in supplied account",
  "requestParameters": null,
  "responseElements": {
    "ConsoleLogin": "Failure"
  },
  "additionalEventData": {
    "LoginTo": "https://console.aws.amazon.com/console/home?state=hashArgs
%23&isauthcode=true",
    "MobileVersion": "No",
    "MFAUsed": "No"
  },
  "eventID": "a7654656-0417-45c6-9386-ea8231385051",
  "eventType": "AwsConsoleSignin",
  "recipientAccountId": "123456789012"
}
```

IAM role trust policy behavior

On September 21st, 2022, AWS made changes to IAM role trust policy behavior to require explicit allows in a role trust policy when a role assumes itself. IAM roles in the legacy behavior allow list have an additional `EventData` field present for `explicitTrustGrant` for `AssumeRole` events. The value of `explicitTrustGrant` is false when a role on the legacy allow list assumes itself using the legacy behavior. When a role on the legacy allow list assumes itself but the role trust policy behavior has been updated to explicitly allow the role to assume itself, the value of `explicitTrustGrant` is true.

Only a very small number of IAM roles are on the allow list for the legacy behavior, and this field is only present in CloudTrail logs for these roles when they assume themselves. In most cases, it is not necessary for an IAM role to assume itself. AWS recommends updating your processes, code, or configurations to remove this behavior or updating your role trust policies to explicitly allow for this behavior. For more information, see [Announcing an update to IAM role trust policy behavior](#).

Access management for AWS resources

AWS Identity and Access Management (IAM) is a web service that helps you securely control access to AWS resources. When a [principal](#) makes a request in AWS, the AWS enforcement code checks whether the principal is authenticated (signed in) and authorized (has permissions). You manage access in AWS by creating policies and attaching them to IAM identities or AWS resources. Policies are JSON documents in AWS that, when attached to an identity or resource, define their permissions. For more information about policy types and uses, see [Policies and permissions in IAM](#).

For details about the rest of the authentication and authorization process, see [How IAM works](#).

During authorization, the AWS enforcement code uses values from the [request context](#) to check for matching policies and determine whether to allow or deny the request.

AWS checks each policy that applies to the context of the request. If a single policy denies the request, AWS denies the entire request and stops evaluating policies. This is called an *explicit deny*. Because requests are *denied by default*, IAM authorizes your request only if every part of your request is allowed by the applicable policies. The [evaluation logic](#) for a request within a single account follows these rules:

- By default, all requests are implicitly denied. (Alternatively, by default, the AWS account root user has full access.)
- An explicit allow in an identity-based or resource-based policy overrides this default.
- If a permissions boundary, Organizations SCP, or session policy is present, it might override the allow with an implicit deny.
- An explicit deny in any policy overrides any allows.

After your request has been authenticated and authorized, AWS approves the request. If you need to make a request in a different account, a policy in the other account must allow you to access the resource. In addition, the IAM entity that you use to make the request must have an identity-based policy that allows the request.

Access management resources

For more information about permissions and about creating policies, see the following resources:

The following entries in the AWS Security Blog cover common ways to write policies for access to Amazon S3 buckets and objects.

- [Writing IAM Policies: How to Grant Access to an Amazon S3 Bucket](#)
- [Writing IAM policies: Grant Access to User-Specific Folders in an Amazon S3 Bucket](#)
- [IAM Policies and Bucket Policies and ACLs! Oh My! \(Controlling Access to S3 Resources\)](#)
- [A Primer on RDS Resource-Level Permissions](#)
- [Demystifying EC2 Resource-Level Permissions](#)

Policies and permissions in IAM

You manage access in AWS by creating policies and attaching them to IAM identities (users, groups of users, or roles) or AWS resources. A policy is an object in AWS that, when associated with an identity or resource, defines their permissions. AWS evaluates these policies when an IAM principal (user or role) makes a request. Permissions in the policies determine whether the request is allowed or denied. Most policies are stored in AWS as JSON documents. AWS supports six types of policies: identity-based policies, resource-based policies, permissions boundaries, Organizations SCPs, ACLs, and session policies.

IAM policies define permissions for an action regardless of the method that you use to perform the operation. For example, if a policy allows the [GetUser](#) action, then a user with that policy can get user information from the AWS Management Console, the AWS CLI, or the AWS API. When you create an IAM user, you can choose to allow console or programmatic access. If console access is allowed, the IAM user can sign in to the console using their sign-in credentials. If programmatic access is allowed, the user can use access keys to work with the CLI or API.

Policy types

The following policy types, listed in order from most frequently used to less frequently used, are available for use in AWS. For more details, see the sections below for each policy type.

- **[Identity-based policies](#)** – Attach [managed](#) and [inline](#) policies to IAM identities (users, groups to which users belong, or roles). Identity-based policies grant permissions to an identity.
- **[Resource-based policies](#)** – Attach inline policies to resources. The most common examples of resource-based policies are Amazon S3 bucket policies and IAM role trust policies. Resource-based policies grant permissions to the principal that is specified in the policy. Principals can be in the same account as the resource or in other accounts.
- **[Permissions boundaries](#)** – Use a managed policy as the permissions boundary for an IAM entity (user or role). That policy defines the maximum permissions that the identity-based policies can grant to an entity, but does not grant permissions. Permissions boundaries do not define the maximum permissions that a resource-based policy can grant to an entity.
- **[Organizations SCPs](#)** – Use an AWS Organizations service control policy (SCP) to define the maximum permissions for account members of an organization or organizational unit (OU). SCPs limit permissions that identity-based policies or resource-based policies grant to entities (users or roles) within the account, but do not grant permissions.

- **[Access control lists \(ACLs\)](#)** – Use ACLs to control which principals in other accounts can access the resource to which the ACL is attached. ACLs are similar to resource-based policies, although they are the only policy type that does not use the JSON policy document structure. ACLs are cross-account permissions policies that grant permissions to the specified principal. ACLs cannot grant permissions to entities within the same account.
- **[Session policies](#)** – Pass advanced session policies when you use the AWS CLI or AWS API to assume a role or a federated user. Session policies limit the permissions that the role or user's identity-based policies grant to the session. Session policies limit permissions for a created session, but do not grant permissions. For more information, see [Session Policies](#).

Identity-based policies

Identity-based policies are JSON permissions policy documents that control what actions an identity (users, groups of users, and roles) can perform, on which resources, and under what conditions. Identity-based policies can be further categorized:

- **Managed policies** – Standalone identity-based policies that you can attach to multiple users, groups, and roles in your AWS account. There are two types of managed policies:
 - **AWS managed policies** – Managed policies that are created and managed by AWS.
 - **Customer managed policies** – Managed policies that you create and manage in your AWS account. Customer managed policies provide more precise control over your policies than AWS managed policies.
- **Inline policies** – Policies that you add directly to a single user, group, or role. Inline policies maintain a strict one-to-one relationship between a policy and an identity. They are deleted when you delete the identity.

To learn how to choose between managed and inline policies, see [Choosing between managed policies and inline policies](#).

Resource-based policies

Resource-based policies are JSON policy documents that you attach to a resource such as an Amazon S3 bucket. These policies grant the specified principal permission to perform specific actions on that resource and defines under what conditions this applies. Resource-based policies are inline policies. There are no managed resource-based policies.

To enable cross-account access, you can specify an entire account or IAM entities in another account as the principal in a resource-based policy. Adding a cross-account principal to a resource-based policy is only half of establishing the trust relationship. When the principal and the resource are in separate AWS accounts, you must also use an identity-based policy to grant the principal access to the resource. However, if a resource-based policy grants access to a principal in the same account, no additional identity-based policy is required. For step-by-step instructions for granting cross-service access, see [IAM tutorial: Delegate access across AWS accounts using IAM roles](#).

The IAM service supports only one type of resource-based policy called a role *trust policy*, which is attached to an IAM role. An IAM role is both an identity and a resource that supports resource-based policies. For that reason, you must attach both a trust policy and an identity-based policy to an IAM role. Trust policies define which principal entities (accounts, users, roles, and federated users) can assume the role. To learn how IAM roles are different from other resource-based policies, see [Cross account resource access in IAM](#).

To see which other services support resource-based policies, see [AWS services that work with IAM](#). To learn more about resource-based policies, see [Identity-based policies and resource-based policies](#). To learn whether principals in accounts outside of your zone of trust (trusted organization or account) have access to assume your roles, see [What is IAM Access Analyzer?](#).

IAM permissions boundaries

A permissions boundary is an advanced feature in which you set the maximum permissions that an identity-based policy can grant to an IAM entity. When you set a permissions boundary for an entity, the entity can perform only the actions that are allowed by both its identity-based policies and its permissions boundaries. Resource-based policies that specify the user or role as the principal are not limited by the permissions boundary. An explicit deny in any of these policies overrides the allow. For more information about permissions boundaries, see [Permissions boundaries for IAM entities](#).

Service control policies (SCPs)

AWS Organizations is a service for grouping and centrally managing the AWS accounts that your business owns. If you enable all features in an organization, then you can apply service control policies (SCPs) to any or all of your accounts. SCPs are JSON policies that specify the maximum permissions for an organization or organizational unit (OU). The SCP limits permissions for entities in member accounts, including each AWS account root user. An explicit deny in any of these policies overrides the allow.

For more information about Organizations and SCPs, see [How SCPs Work](#) in the *AWS Organizations User Guide*.

Access control lists (ACLs)

Access control lists (ACLs) are service policies that allow you to control which principals in another account can access a resource. ACLs cannot be used to control access for a principal within the same account. ACLs are similar to resource-based policies, although they are the only policy type that does not use the JSON policy document format. Amazon S3, AWS WAF, and Amazon VPC are examples of services that support ACLs. To learn more about ACLs, see [Access Control List \(ACL\) Overview](#) in the *Amazon Simple Storage Service Developer Guide*.

Session policies

Session policies are advanced policies that you pass as a parameter when you programmatically create a temporary session for a role or federated user. The permissions for a session are the intersection of the identity-based policies for the IAM entity (user or role) used to create the session and the session policies. Permissions can also come from a resource-based policy. An explicit deny in any of these policies overrides the allow.

You can create role session and pass session policies programmatically using the `AssumeRole`, `AssumeRoleWithSAML`, or `AssumeRoleWithWebIdentity` API operations. You can pass a single JSON inline session policy document using the `Policy` parameter. You can use the `PolicyArns` parameter to specify up to 10 managed session policies. For more information about creating a role session, see [Requesting temporary security credentials](#).

When you create a federated user session, you use the access keys of the IAM user to programmatically call the `GetFederationToken` API operation. You must also pass session policies. The resulting session's permissions are the intersection of the identity-based policy and the session policy. For more information about creating a federated user session, see [GetFederationToken—federation through a custom identity broker](#).

A resource-based policy can specify the ARN of the user or role as a principal. In that case, the permissions from the resource-based policy are added to the role or user's identity-based policy before the session is created. The session policy limits the total permissions granted by the resource-based policy and the identity-based policy. The resulting session's permissions are the intersection of the session policies and the resource-based policies plus the intersection of the session policies and identity-based policies.

A resource-based policy can specify the ARN of the session as a principal. In that case, the permissions from the resource-based policy are added after the session is created. The resource-based policy permissions are not limited by the session policy. The resulting session has all the permissions of the resource-based policy *plus* the intersection of the identity-based policy and the session policy.

A permissions boundary can set the maximum permissions for a user or role that is used to create a session. In that case, the resulting session's permissions are the intersection of the session policy,

the permissions boundary, and the identity-based policy. However, a permissions boundary does not limit permissions granted by a resource-based policy that specifies the ARN of the resulting session.

Policies and the root user

The AWS account root user is affected by some policy types but not others. You cannot attach identity-based policies to the root user, and you cannot set the permissions boundary for the root user. However, you can specify the root user as the principal in a resource-based policy or an ACL. A root user is still the member of an account. If that account is a member of an organization in AWS Organizations, the root user is affected by any SCPs for the account.

Overview of JSON policies

Most policies are stored in AWS as JSON documents. Identity-based policies and policies used to set permissions boundaries are JSON policy documents that you attach to a user or role. Resource-based policies are JSON policy documents that you attach to a resource. SCPs are JSON policy documents with restricted syntax that you attach to an AWS Organizations organizational unit (OU). ACLs are also attached to a resource, but you must use a different syntax. Session policies are JSON policies that you provide when you assume a role or federated user session.

It is not necessary for you to understand the JSON syntax. You can use the visual editor in the AWS Management Console to create and edit customer managed policies without ever using JSON. However, if you use inline policies for groups or complex policies, you must still create and edit

those policies in the JSON editor using the console. For more information about using the visual editor, see [Creating IAM policies](#) and [Editing IAM policies](#).

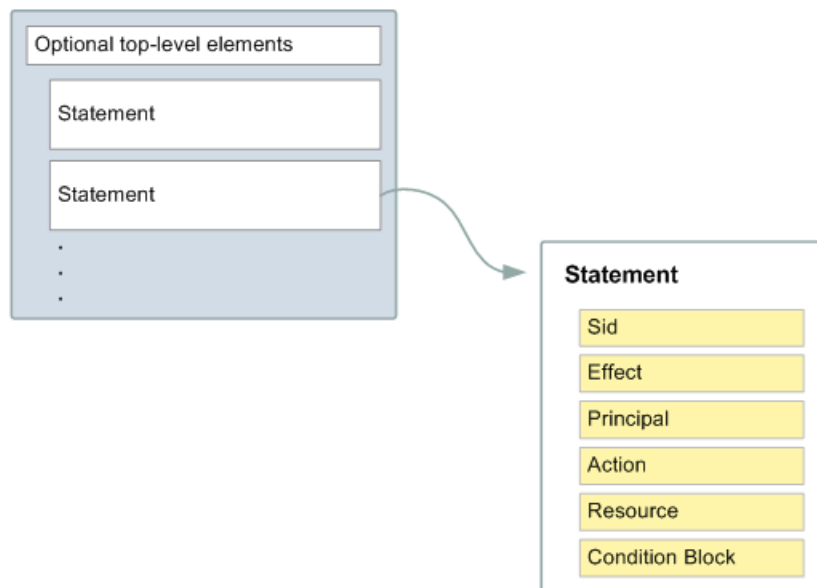

When you create or edit a JSON policy, IAM can perform policy validation to help you create an effective policy. IAM identifies JSON syntax errors, while IAM Access Analyzer provides additional policy checks with recommendations to help you further refine your policies. To learn more about policy validation, see [Validating IAM policies](#). To learn more about IAM Access Analyzer policy checks and actionable recommendations, see [IAM Access Analyzer policy validation](#).

JSON policy document structure

As illustrated in the following figure, a JSON policy document includes these elements:

- Optional policy-wide information at the top of the document
- One or more individual statements

Each statement includes information about a single permission. If a policy includes multiple statements, AWS applies a logical OR across the statements when evaluating them. If multiple policies apply to a request, AWS applies a logical OR across all of those policies when evaluating them.

The information in a statement is contained within a series of elements.

- **Version** – Specify the version of the policy language that you want to use. We recommend that you use the latest 2012-10-17 version. For more information, see [IAM JSON policy elements: Version](#)
- **Statement** – Use this main policy element as a container for the following elements. You can include more than one statement in a policy.
- **Sid (Optional)** – Include an optional statement ID to differentiate between your statements.
- **Effect** – Use Allow or Deny to indicate whether the policy allows or denies access.
- **Principal (Required in only some circumstances)** – If you create a resource-based policy, you must indicate the account, user, role, or federated user to which you would like to allow or deny access. If you are creating an IAM permissions policy to attach to a user or role, you cannot include this element. The principal is implied as that user or role.
- **Action** – Include a list of actions that the policy allows or denies.
- **Resource (Required in only some circumstances)** – If you create an IAM permissions policy, you must specify a list of resources to which the actions apply. If you create a resource-based policy, this element is optional. If you do not include this element, then the resource to which the action applies is the resource to which the policy is attached.
- **Condition (Optional)** – Specify the circumstances under which the policy grants permission.

To learn about these and other more advanced policy elements, see [IAM JSON policy elements reference](#).

Multiple statements and multiple policies

If you want to define more than one permission for an entity (user or role), you can use multiple statements in a single policy. You can also attach multiple policies. If you try to define multiple permissions in a single statement, your policy might not grant the access that you expect. We recommend that you break up policies by resource type.

Because of the [limited size of policies](#), it might be necessary to use multiple policies for more complex permissions. It's also a good idea to create functional groupings of permissions in a separate customer managed policy. For example, Create one policy for IAM user management, one for self-management, and another policy for S3 bucket management. Regardless of the combination of multiple statements and multiple policies, AWS [evaluates](#) your policies the same way.

For example, the following policy has three statements, each of which defines a separate set of permissions within a single account. The statements define the following:

- The first statement, with an Sid (Statement ID) of `FirstStatement`, lets the user with the attached policy change their own password. The `Resource` element in this statement is `"*"` (which means "all resources"). But in practice, the `ChangePassword` API operation (or equivalent `change-password` CLI command) affects only the password for the user who makes the request.
- The second statement lets the user list all the Amazon S3 buckets in their AWS account. The `Resource` element in this statement is `"*"` (which means "all resources"). But because policies don't grant access to resources in other accounts, the user can list only the buckets in their own AWS account.
- The third statement lets the user list and retrieve any object that is in a bucket named `confidential-data`, but only when the user is authenticated with multi-factor authentication (MFA). The `Condition` element in the policy enforces the MFA authentication.

When a policy statement contains a `Condition` element, the statement is only in effect when the `Condition` element evaluates to true. In this case, the `Condition` evaluates to true when the user is MFA-authenticated. If the user is not MFA-authenticated, this `Condition` evaluates to false. In that case, the third statement in this policy does not apply and the user does not have access to the `confidential-data` bucket.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "FirstStatement",
      "Effect": "Allow",
      "Action": ["iam:ChangePassword"],
      "Resource": "*"
    },
    {
      "Sid": "SecondStatement",
      "Effect": "Allow",
      "Action": "s3:ListAllMyBuckets",
      "Resource": "*"
    },
    {
      "Sid": "ThirdStatement",
```

```
    "Effect": "Allow",
    "Action": [
      "s3:List*",
      "s3:Get*"
    ],
    "Resource": [
      "arn:aws:s3:::confidential-data",
      "arn:aws:s3:::confidential-data/*"
    ],
    "Condition": {"Bool": {"aws:MultiFactorAuthPresent": "true"}}
  }
]
```

Examples of JSON policy syntax

The following identity-based policy allows the implied principal to list a single Amazon S3 bucket named `example_bucket`:

```
{
  "Version": "2012-10-17",
  "Statement": {
    "Effect": "Allow",
    "Action": "s3:ListBucket",
    "Resource": "arn:aws:s3:::example_bucket"
  }
}
```

The following resource-based policy can be attached to an Amazon S3 bucket. The policy allows members of a specific AWS account to perform any Amazon S3 actions in the bucket named `mybucket`. It allows any action that can be performed on a bucket or the objects within it. (Because the policy grants trust only to the account, individual users in the account must still be granted permissions for the specified Amazon S3 actions.)

```
{
  "Version": "2012-10-17",
  "Statement": [{
    "Sid": "1",
    "Effect": "Allow",
    "Principal": {"AWS": ["arn:aws:iam::account-id:root"]},
    "Action": "s3:*",
```

```
"Resource": [  
  "arn:aws:s3:::mybucket",  
  "arn:aws:s3:::mybucket/*"  
]  
}]  
}
```

To view example policies for common scenarios, see [Example IAM identity-based policies](#).

Grant least privilege

When you create IAM policies, follow the standard security advice of granting *least privilege*, or granting only the permissions required to perform a task. Determine what users and roles need to do and then craft policies that allow them to perform *only* those tasks.

Start with a minimum set of permissions and grant additional permissions as necessary. Doing so is more secure than starting with permissions that are too lenient and then trying to tighten them later.

As an alternative to least privilege, you can use [AWS managed policies](#) or policies with wildcard * permissions to get started with policies. Consider the security risk of granting your principals more permissions than they need to do their job. Monitor those principals to learn which permissions they are using. Then write least privilege policies.

IAM provides several options to help you refine the permissions that you grant.

- **Understand access level groupings** – You can use access level groupings to understand the level of access that a policy grants. [Policy actions](#) are classified as List, Read, Write, Permissions management, or Tagging. For example, you can choose actions from the List and Read access levels to grant read-only access to your users. To learn how to use policy summaries to understand access level permissions, see [Understanding access level summaries within policy summaries](#).
- **Validate your policies** – You can perform policy validation using IAM Access Analyzer when you create and edit JSON policies. We recommend that you review and validate all of your existing policies. IAM Access Analyzer provides over 100 policy checks to validate your policies. It generates security warnings when a statement in your policy allows access we consider overly permissive. You can use the actionable recommendations that are provided through the security warnings as you work toward granting least privilege. To learn more about policy checks provided by IAM Access Analyzer, see [IAM Access Analyzer policy validation](#).

- **Generate a policy based on access activity** – To help you refine the permissions that you grant, you can generate an IAM policy that is based on the access activity for an IAM entity (user or role). IAM Access Analyzer reviews your AWS CloudTrail logs and generates a policy template that contains the permissions that have been used by the entity in your specified time frame. You can use the template to create a managed policy with fine-grained permissions and then attach it to the IAM entity. That way, you grant only the permissions that the user or role needs to interact with AWS resources for your specific use case. To learn more, see [Generate policies based on access activity](#).
- **Use last accessed information** – Another feature that can help with least privilege is *last accessed information*. View this information on the **Access Advisor** tab on the IAM console details page for an IAM user, group, role, or policy. Last accessed information also includes information about the actions that were last accessed for some services, such as Amazon EC2, IAM, Lambda, and Amazon S3. If you sign in using AWS Organizations management account credentials, you can view service last accessed information in the **AWS Organizations** section of the IAM console. You can also use the AWS CLI or AWS API to retrieve a report for last accessed information for entities or policies in IAM or Organizations. You can use this information to identify unnecessary permissions so that you can refine your IAM or Organizations policies to better adhere to the principle of least privilege. For more information, see [Refining permissions in AWS using last accessed information](#).
- **Review account events in AWS CloudTrail** – To further reduce permissions, you can view your account's events in AWS CloudTrail **Event history**. CloudTrail event logs include detailed event information that you can use to reduce the policy's permissions. The logs include only the actions and resources that your IAM entities need. For more information, see [Viewing CloudTrail Events in the CloudTrail Console](#) in the *AWS CloudTrail User Guide*.

For more information, see the following policy topics for individual services, which provide examples of how to write policies for service-specific resources.

- [Authentication and Access Control for Amazon DynamoDB](#) in the *Amazon DynamoDB Developer Guide*

Managed policies and inline policies

When you set the permissions for an identity in IAM, you must decide whether to use an AWS managed policy, a customer managed policy, or an inline policy. The following topics provide more information about each of the types of identity-based policies and when to use them.

Topics

- [AWS managed policies](#)
- [Customer managed policies](#)
- [Inline policies](#)
- [Choosing between managed policies and inline policies](#)
- [Getting started with managed policies](#)
- [Converting an inline policy to a managed policy](#)
- [Deprecated AWS managed policies](#)

AWS managed policies

An *AWS managed policy* is a standalone policy that is created and administered by AWS. *Standalone policy* means that the policy has its own Amazon Resource Name (ARN) that includes the policy name. For example, `arn:aws:iam::aws:policy/IAMReadOnlyAccess` is an AWS managed policy. For more information about ARNs, see [IAM ARNs](#). For a list of AWS managed policies for AWS services, see [AWS managed policies](#).

AWS managed policies make it convenient for you to assign appropriate permissions to users, groups, and roles. It is faster than writing the policies yourself, and includes permissions for many common use cases.

You cannot change the permissions defined in AWS managed policies. AWS occasionally updates the permissions defined in an AWS managed policy. When AWS does this, the update affects all principal entities (users, groups, and roles) that the policy is attached to. AWS is most likely to update an AWS managed policy when a new AWS service is launched or new API calls become available for existing services. For example, the AWS managed policy called **ReadOnlyAccess** provides read-only access to all AWS services and resources. When AWS launches a new service, AWS updates the **ReadOnlyAccess** policy to add read-only permissions for the new service. The updated permissions are applied to all principal entities that the policy is attached to.

Full access AWS managed policies define permissions for service administrators by granting full access to a service.

- [AmazonDynamoDBFullAccess](#)
- [IAMFullAccess](#)

Power-user AWS managed policies provide full access to AWS services and resources, but do not allow managing users and groups.

- [AWSCodeCommitPowerUser](#)
- [AWSKeyManagementServicePowerUser](#)

Partial-access AWS managed policies provide specific levels of access to AWS services without allowing [permissions management](#) access level permissions.

- [AmazonMobileAnalyticsWriteOnlyAccess](#)
- [AmazonEC2ReadOnlyAccess](#)

One particularly useful category of AWS managed policies are those designed for job functions. These policies align closely with commonly used job functions in the IT industry and facilitate granting permissions for these job functions. One key advantage of using job function policies is that they are maintained and updated by AWS as new services and API operations are introduced. For example, the [AdministratorAccess](#) job function provides full access and permissions delegation to every service and resource in AWS. We recommend that you use this policy only for the account administrator. For power users that require full access to every service except limited access to IAM and Organizations, use the [PowerUserAccess](#) job function. For a list and descriptions of the job function policies, see [AWS managed policies for job functions](#).

The following diagram illustrates AWS managed policies. The diagram shows three AWS managed policies: **AdministratorAccess**, **PowerUserAccess**, and **AWSCloudTrailReadOnlyAccess**. Notice that a single AWS managed policy can be attached to principal entities in different AWS accounts, and to different principal entities in a single AWS account.

Customer managed policies

You can create standalone policies in your own AWS account that you can attach to principal entities (users, groups, and roles). You create these *customer managed policies* for your specific use cases, and you can change and update them as often as you like. Like AWS managed policies, when you attach a policy to a principal entity, you give the entity the permissions that are defined in the policy. When you update permissions in the policy, the changes are applied to all principal entities that the policy is attached to.

A great way to create a customer managed policy is to start by copying an existing AWS managed policy. That way you know that the policy is correct at the beginning and all you need to do is customize it to your environment.

The following diagram illustrates customer managed policies. Each policy is an entity in IAM with its own [Amazon Resource Name \(ARN\)](#) that includes the policy name. Notice that the same policy can be attached to multiple principal entities—for example, the same **DynamoDB-books-app** policy is attached to two different IAM roles.

For more information, see [Creating IAM policies](#)

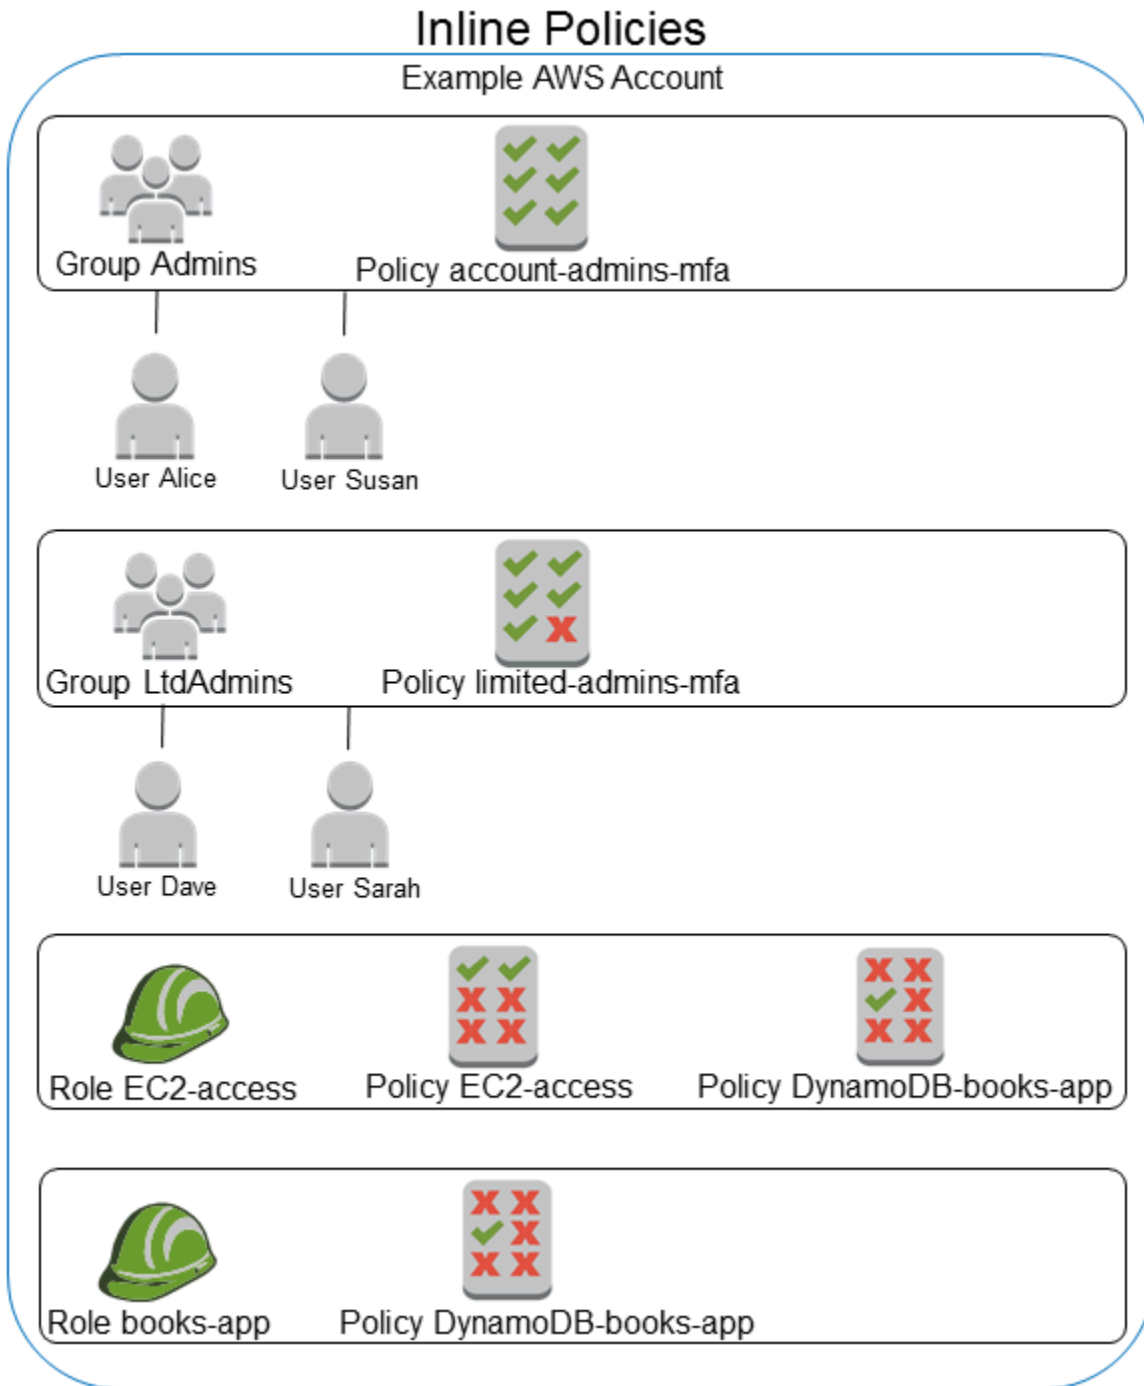

Customer Managed Policies

Inline policies

An inline policy is a policy created for a single IAM identity (a user, group, or role). Inline policies maintain a strict one-to-one relationship between a policy and an identity. They are deleted when you delete the identity. You can create a policy and embed it in an identity, either when you create the identity or later. If a policy could apply to more than one entity, it's better to use a managed policy.

The following diagram illustrates inline policies. Each policy is an inherent part of the user, group, or role. Notice that two roles include the same policy (the **DynamoDB-books-app** policy), but they are not sharing a single policy. Each role has its own copy of the policy.

Choosing between managed policies and inline policies

Consider your use cases when deciding between managed and inline policies. In most cases, we recommend that you use managed policies instead of inline policies.

Note

You can use both managed and inline policies together to define common and unique permissions for a principal entity.

Managed policies provide the following features:

Reusability

A single managed policy can be attached to multiple principal entities (users, groups, and roles). You can create a library of policies that define useful permissions for your AWS account, and then attach these policies to principal entities as needed.

Central change management

When you change a managed policy, the change is applied to all principal entities that the policy is attached to. For example, if you want to add permission for a new AWS API, you can update a customer managed policy or associate an AWS managed policy to add the permission. If you're using an AWS managed policy, AWS updates the policy. When a managed policy is updated, the changes are applied to all principal entities that the managed policy is attached to. In contrast, to change an inline policy, you must individually edit each identity that contains the inline policy. For example, if a group and a role both contain the same inline policy, you must individually edit both principal entities to change that policy.

Versioning and rolling back

When you change a customer managed policy, the changed policy doesn't overwrite the existing policy. Instead, IAM creates a new version of the managed policy. IAM stores up to five versions of your customer managed policies. You can use policy versions to revert a policy to an earlier version as needed.

Note

A policy version is different from a `Version` policy element. The `Version` policy element is used within a policy and defines the version of the policy language. To learn

more about policy versions, see [the section called “Versioning IAM policies”](#). To learn more about the `Version` policy element see [IAM JSON policy elements: Version](#).

Delegating permissions management

You can allow users in your AWS account to attach and detach policies while maintaining control over the permissions defined in those policies. To do this, designate some users as full administrators—that is, administrators that can create, update, and delete policies. You can then designate other users as limited administrators. Those limited administrators can attach policies to other principal entities, but only the policies that you have allowed them to attach.

For more information about delegating permissions management, see [Controlling access to policies](#).

Larger policy character limits

The maximum character size limit for managed policies is greater than the character limit for inline policies. If you reach the inline policy's character size limit, you can create more IAM groups and attach the managed policy to the group.

For more information on quotas and limits, see [IAM and AWS STS quotas](#).

Automatic updates for AWS managed policies

AWS maintains AWS managed policies and updates them when necessary, for example, to add permissions for new AWS services, without you having to make changes. The updates are automatically applied to the principal entities that you have attached the AWS managed policy to.

Using inline policies

Inline policies are useful if you want to maintain a strict one-to-one relationship between a policy and the identity to which it is applied. For example, if you want to be sure that the permissions in a policy are not inadvertently assigned to an identity other than the one they're intended for. When you use an inline policy, the permissions in the policy cannot be inadvertently attached to the wrong identity. In addition, when you use the AWS Management Console to delete that identity, the policies embedded in the identity are deleted as well because they are part of the principal entity.

Getting started with managed policies

We recommend using policies that [grant least privilege](#), or granting only the permissions required to perform a task. The most secure way to grant least privilege is to write a customer managed policy with only the permissions needed by your team. You must create a process to allow your team to request more permissions when necessary. It takes time and expertise to [create IAM customer managed policies](#) that provide your team with only the permissions they need.

To get started adding permissions to your IAM identities (users, groups of users, and roles), you can use [AWS managed policies](#). AWS managed policies don't grant least privilege permissions. You must consider the security risk of granting your principals more permissions than they need to do their job.

You can attach AWS managed policies, including job functions, to any IAM identity. For more information, see [Adding and removing IAM identity permissions](#).

To switch to least privilege permissions, you can run AWS Identity and Access Management Access Analyzer to monitor the principals with AWS managed policies. After learning which permissions they are using, then you can write or generate a customer managed policy with only the required permissions for your team. This is less secure, but provides more flexibility as you learn how your team is using AWS. For more information, see [IAM Access Analyzer policy generation](#).

AWS managed policies are designed to provide permissions for many common use cases. For more information about AWS managed policies that are designed for specific job functions, see [AWS managed policies for job functions](#).

For a list of AWS managed policies, see [AWS Managed Policy Reference Guide](#).

Converting an inline policy to a managed policy

If you have inline policies in your account, you can convert them to managed policies. To do this, copy the policy to a new managed policy. Next, attach the new policy to the identity that has the inline policy. Then delete the inline policy.

To convert an inline policy to a managed policy

1. Sign in to the AWS Management Console and open the IAM console at <https://console.aws.amazon.com/iam/>.
2. In the navigation pane, choose **User groups**, **Users**, or **Roles**.

3. In the list, choose the name of the user group, user, or role that has the policy you want to remove.
4. Choose the **Permissions** tab.
5. For user groups, select the name of the inline policy that you want to remove. For users and roles, choose **Show *n* more**, if necessary, and then expand the inline policy that you want to remove.
6. Choose **Copy** to copy the JSON policy document for the policy.
7. In the navigation pane, choose **Policies**.
8. Choose **Create policy** and then choose the **JSON** option.
9. Replace the existing text with your JSON policy text, and then choose **Next**.
10. Enter a name and optional description for your policy and choose **Create policy**.
11. In the navigation pane, choose **User groups**, **Users**, or **Roles**, and again choose the name of the user group, user, or role that has the policy you want to remove.
12. Choose the **Permissions** tab and then choose **Add permissions**.
13. For user groups, select the check box next to the name of your new policy, choose **Add permissions**, and then choose **Attach policy**. For users or roles, choose **Add permissions**. On the next page, choose **Attach existing policies directly**, select the check box next to the name of your new policy, choose **Next**, and then choose **Add permissions**.

You are returned to the **Summary** page for your user group, user, or role.

14. Select the check box next to the inline policy that you want to remove and choose **Remove**.

Deprecated AWS managed policies

To simplify the assignment of permissions, AWS provides [managed policies](#)—predefined policies that are ready to be attached to your IAM users, groups, and roles.

Sometimes AWS needs to add a new permission to an existing policy, such as when a new service is introduced. Adding a new permission to an existing policy does not disrupt or remove any feature or ability.

However, AWS might choose to create a *new* policy when the needed changes could impact customers if they were applied to an existing policy. For example, removing permissions from an existing policy could break the permissions of any IAM entity or application that depended upon it, potentially disrupting a critical operation.

Therefore, when such a change is required, AWS creates a completely new policy with the required changes and makes it available to customers. The old policy is then marked *deprecated*. A deprecated managed policy appears with a warning icon next to it in the **Policies** list in the IAM console.

A deprecated policy has the following characteristics:

- It continues to work for all *currently* attached users, groups, and roles. Nothing breaks.
- It *cannot* be attached to any new users, groups, or roles. If you detach it from a current entity, you cannot reattach it.
- After you detach it from all current entities, it is no longer visible and can no longer be used in any way.

If any user, group, or role requires the policy, you must instead attach the new policy. When you receive notice that a policy is deprecated, we recommend that you immediately plan to attach all users, groups, and roles to the replacement policy and detach them from the deprecated policy. Continuing to use the deprecated policy can carry risks that are mitigated only by switching to the replacement policy.

Permissions boundaries for IAM entities

AWS supports *permissions boundaries* for IAM entities (users or roles). A permissions boundary is an advanced feature for using a managed policy to set the maximum permissions that an identity-based policy can grant to an IAM entity. An entity's permissions boundary allows it to perform only the actions that are allowed by both its identity-based policies and its permissions boundaries.

For more information about policy types, see [Policy types](#).

Important

Don't use resource-based policy statements that include a `NotPrincipal` policy element with a `Deny` effect for IAM users or roles that have a permissions boundary policy attached. The `NotPrincipal` element with a `Deny` effect will always deny any IAM principal that has a permissions boundary policy attached, regardless of the values specified in the `NotPrincipal` element. This causes some IAM users or roles that would otherwise have access to the resource to lose access. We recommend changing your resource-based policy statements to use the condition operator [ArnNotEquals](#) with the [aws:PrincipalArn](#)

context key to limit access instead of the `NotPrincipal` element. For information about the `NotPrincipal` element, see [AWS JSON policy elements: NotPrincipal](#).

You can use an AWS managed policy or a customer managed policy to set the boundary for an IAM entity (user or role). That policy limits the maximum permissions for the user or role.

For example, assume that the IAM user named `ShirleyRodriguez` should be allowed to manage only Amazon S3, Amazon CloudWatch, and Amazon EC2. To enforce this rule, you can use the following policy to set the permissions boundary for the `ShirleyRodriguez` user:

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "s3:*",
        "cloudwatch:*",
        "ec2:*"
      ],
      "Resource": "*"
    }
  ]
}
```

When you use a policy to set the permissions boundary for a user, it limits the user's permissions but does not provide permissions on its own. In this example, the policy sets the maximum permissions of `ShirleyRodriguez` as all operations in Amazon S3, CloudWatch, and Amazon EC2. Shirley can never perform operations in any other service, including IAM, even if she has a permissions policy that allows it. For example, you can add the following policy to the `ShirleyRodriguez` user:

```
{
  "Version": "2012-10-17",
  "Statement": {
    "Effect": "Allow",
    "Action": "iam:CreateUser",
    "Resource": "*"
  }
}
```

```
}
```

This policy allows creating a user in IAM. If you attach this permissions policy to the ShirleyRodriguez user, and Shirley tries to create a user, the operation fails. It fails because the permissions boundary does not allow the `iam:CreateUser` operation. Given these two policies, Shirley does not have permission to perform any operations in AWS. You must add a different permissions policy to allow actions in other services, such as Amazon S3. Alternatively, you could update the permissions boundary to allow her to create a user in IAM.

Evaluating effective permissions with boundaries

The permissions boundary for an IAM entity (user or role) sets the maximum permissions that the entity can have. This can change the effective permissions for that user or role. The effective permissions for an entity are the permissions that are granted by all the policies that affect the user or role. Within an account, the permissions for an entity can be affected by identity-based policies, resource-based policies, permissions boundaries, Organizations SCPs, or session policies. For more information about the different types of policies, see [Policies and permissions in IAM](#).

If any one of these policy types explicitly denies access for an operation, then the request is denied. The permissions granted to an entity by multiple permissions types are more complex. For more details about how AWS evaluates policies, see [Policy evaluation logic](#).

Identity-based policies with boundaries – Identity-based policies are inline or managed policies that are attached to a user, group of users, or role. Identity-based policies grant permission to the entity, and permissions boundaries limit those permissions. The effective permissions are the intersection of both policy types. An explicit deny in either of these policies overrides the allow.

Resource-based policies – Resource-based policies control how the specified principal can access the resource to which the policy is attached.

Resource-based policies for IAM users

Within the same account, resource-based policies that grant permissions to an IAM user ARN (that is not a federated user session) are not limited by an implicit deny in an identity-based policy or permissions boundary.

Resource-based policies for IAM roles

IAM role – Resource-based policies that grant permissions to an IAM role ARN are limited by an implicit deny in a permissions boundary or session policy.

IAM role session – Within the same account, resource-based policies that grant permissions to an IAM role session ARN grant permissions directly to the assumed role session. Permissions granted directly to a session are not limited by an implicit deny in an identity-based policy, a permissions boundary, or session policy. When you assume a role and make a request, the principal making the request is the IAM role session ARN and not the ARN of the role itself.

Resource-based policies for IAM federated user sessions

IAM federated user sessions – An IAM federated user session is a session created by calling [GetFederationToken](#). When a federated user makes a request, the principal making the request is the federated user ARN and not the ARN of the IAM user who federated. Within the

same account, resource-based policies that grant permissions to a federated user ARN grant permissions directly to the session. Permissions granted directly to a session are not limited by an implicit deny in an identity-based policy, a permissions boundary, or session policy.

However, if a resource-based policy grants permission to the ARN of the IAM user who federated, then requests made by the federated user during the session are limited by an implicit deny in a permission boundary or session policy.

Organizations SCPs – SCPs are applied to an entire AWS account. They limit permissions for every request made by a principal within the account. An IAM entity (user or role) can make a request that is affected by an SCP, a permissions boundary, and an identity-based policy. In this case, the request is allowed only if all three policy types allow it. The effective permissions are the intersection of all three policy types. An explicit deny in any of these policies overrides the allow.

You can learn [whether your account is a member of an organization](#) in AWS Organizations. Organization members might be affected by an SCP. To view this data using the AWS CLI command or AWS API operation, you must have permissions for the `organizations:DescribeOrganization` action for your Organizations entity. You must have additional permissions to perform the operation in the Organizations console. To learn whether an SCP is denying access to a specific request, or to change your effective permissions, contact your AWS Organizations administrator.

Session policies – Session policies are advanced policies that you pass as a parameter when you programmatically create a temporary session for a role or federated user. The permissions for a

session come from the IAM entity (user or role) used to create the session and from the session policy. The entity's identity-based policy permissions are limited by the session policy and the permissions boundary. The effective permissions for this set of policy types are the intersection of all three policy types. An explicit deny in any of these policies overrides the allow. For more information about session policies, see [Session Policies](#).

Delegating responsibility to others using permissions boundaries

You can use permissions boundaries to delegate permissions management tasks, such as user creation, to IAM users in your account. This permits others to perform tasks on your behalf within a specific boundary of permissions.

For example, assume that María is the administrator of the X-Company AWS account. She wants to delegate user creation duties to Zhang. However, she must ensure that Zhang creates users that adhere to the following company rules:

- Users cannot use IAM to create or manage users, groups, roles, or policies.
- Users are denied access to the Amazon S3 logs bucket and cannot access the `i-1234567890abcdef0` Amazon EC2 instance.
- Users cannot remove their own boundary policies.

To enforce these rules, María completes the following tasks, for which details are included below:

1. María creates the `XCompanyBoundaries` managed policy to use as a permissions boundary for all new users in the account.
2. María creates the `DelegatedUserBoundary` managed policy and assigns it as the permissions boundary for Zhang. María makes a note of her admin user's ARN and uses it in the policy to prevent Zhang from accessing it.
3. María creates the `DelegatedUserPermissions` managed policy and attaches it as a permissions policy for Zhang.
4. María tells Zhang about his new responsibilities and limitations.

Task 1: María must first create a managed policy to define the boundary for the new users. María will allow Zhang to give users the permissions policies they need, but she wants those users to be restricted. To do this, she creates the following customer managed policy with the name `XCompanyBoundaries`. This policy does the following:

- Allows users full access to several services
- Allows limited self-managing access in the IAM console. This means they can change their password after signing into the console. They can't set their initial password. To allow this, add the `*LoginProfile` action to the `AllowManageOwnPasswordAndAccessKeys` statement.
- Denies users access to the Amazon S3 logs bucket or the `i-1234567890abcdef0` Amazon EC2 instance

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "ServiceBoundaries",
      "Effect": "Allow",
      "Action": [

    "Resource": "arn:aws:ec2::*:instance/i-1234567890abcdef0"
}
]
}

```

Each statement serves a different purpose:

1. The `ServiceBoundaries` statement of this policy allows full access to the specified AWS services. This means that a new user's actions in these services are limited only by the permissions policies that are attached to the user.

2. The `AllowIAMConsoleForCredentials` statement allows access to list all IAM users. This access is necessary to navigate the **Users** page in the AWS Management Console. It also allows viewing the password requirements for the account, which is necessary when changing your own password.
3. The `AllowManageOwnPasswordAndAccessKeys` statement allows users to manage only their own console password and programmatic access keys. This is important if Zhang or another administrator assigns a new user a permissions policy with full IAM access. In that case, that user could then change their own or other users' permissions. This statement prevents that from happening.
4. The `DenyS3Logs` statement explicitly denies access to the logs bucket.
5. The `DenyEC2Production` statement explicitly denies access to the `i-1234567890abcdef0` instance.

Task 2: María wants to allow Zhang to create all X-Company users, but only with the `XCompanyBoundaries` permissions boundary. She creates the following customer managed policy named `DelegatedUserBoundary`. This policy defines the maximum permissions that Zhang can have.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "CreateOrChangeOnlyWithBoundary",
      "Effect": "Allow",
      "Action": [
        "iam:AttachUserPolicy",
        "iam:CreateUser",
        "iam>DeleteUserPolicy",
        "iam:DetachUserPolicy",
        "iam:PutUserPermissionsBoundary",
        "iam:PutUserPolicy"
      ],
      "Resource": "*",
      "Condition": {
        "StringEquals": {
          "iam:PermissionsBoundary": "arn:aws:iam::123456789012:policy/XCompanyBoundaries"
        }
      }
    }
  ]
}
```

```
},  
{  
  "Sid": "CloudWatchAndOtherIAMTasks",  
  "Effect": "Allow",  
  "Action": [  
    "cloudwatch:*",  
    "iam:CreateAccessKey",

    "iam:SimulateCustomPolicy",  
    "iam:SimulatePrincipalPolicy",  
    "iam:UpdateGroup",  
    "iam:UpdateLoginProfile",  
    "iam:UpdateUser"  
  ],  
}
```

```
    "NotResource": "arn:aws:iam::123456789012:user/Maria"
  },
  {
    "Sid": "NoBoundaryPolicyEdit",
    "Effect": "Deny",
    "Action": [
      "iam:CreatePolicyVersion",
      "iam>DeletePolicy",
      "iam>DeletePolicyVersion",
      "iam:SetDefaultPolicyVersion"
    ],
    "Resource": [
      "arn:aws:iam::123456789012:policy/XCompanyBoundaries",
      "arn:aws:iam::123456789012:policy/DelegatedUserBoundary"
    ]
  },
  {
    "Sid": "NoBoundaryUserDelete",
    "Effect": "Deny",
    "Action": "iam>DeleteUserPermissionsBoundary",
    "Resource": "*"
  }
]
```

Each statement serves a different purpose:

1. The `CreateOrChangeOnlyWithBoundary` statement allows Zhang to create IAM users but only if he uses the `XCompanyBoundaries` policy to set the permissions boundary. This statement also allows him to set the permissions boundary for existing users but only using that same policy. Finally, this statement allows Zhang to manage permissions policies for users with this permissions boundary set.
2. The `CloudWatchAndOtherIAMTasks` statement allows Zhang to complete other user, group, and policy management tasks. He has permissions to reset passwords and create access keys for any IAM user not listed in the `NotResource` policy element. This allows him to help users with sign-in issues.
3. The `NoBoundaryPolicyEdit` statement denies Zhang access to update the `XCompanyBoundaries` policy. He is not allowed to change any policy that is used to set the permissions boundary for himself or other users.

4. The `NoBoundaryUserDelete` statement denies Zhang access to delete the permissions boundary for himself or other users.

María then assigns the `DelegatedUserBoundary` policy [as the permissions boundary](#) for the Zhang user.

Task 3: Because the permissions boundary limits the maximum permissions, but does not grant access on its own, Maria must create a permissions policy for Zhang. She creates the following policy named `DelegatedUserPermissions`. This policy defines the operations that Zhang can perform, within the defined boundary.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "IAM",
      "Effect": "Allow",
      "Action": "iam:*",
      "Resource": "*"
    },
    {
      "Sid": "CloudWatchLimited",
      "Effect": "Allow",
      "Action": [
        "cloudwatch:GetDashboard",
        "cloudwatch:GetMetricData",
        "cloudwatch:ListDashboards",
        "cloudwatch:GetMetricStatistics",
        "cloudwatch:ListMetrics"
      ],
      "Resource": "*"
    },
    {
      "Sid": "S3BucketContents",
      "Effect": "Allow",
      "Action": "s3:ListBucket",
      "Resource": "arn:aws:s3:::ZhangBucket"
    }
  ]
}
```

Each statement serves a different purpose:

1. The `IAM` statement of the policy allows Zhang full access to IAM. However, because his permissions boundary allows only some IAM operations, his effective IAM permissions are limited only by his permissions boundary.
2. The `CloudWatchLimited` statement allows Zhang to perform five actions in CloudWatch. His permissions boundary allows all actions in CloudWatch, so his effective CloudWatch permissions are limited only by his permissions policy.
3. The `S3BucketContents` statement allows Zhang to list the `ZhangBucket` Amazon S3 bucket. However, his permissions boundary does not allow any Amazon S3 action, so he cannot perform any S3 operations, regardless of his permissions policy.

 **Note**

Zhang's policies allow him to create a user that can then access Amazon S3 resources that he can't access. By delegating these administrative actions, Maria effectively trusts Zhang with access to Amazon S3.

María then attaches the `DelegatedUserPermissions` policy as the permissions policy for the Zhang user.

Task 4: She gives Zhang instructions to create a new user. She tells him that he can create new users with any permissions that they need, but he must assign them the `XCompanyBoundaries` policy as a permissions boundary.

Zhang completes the following tasks:

1. Zhang [creates a user](#) with the AWS Management Console. He types the user name `Nikhil` and enables console access for the user. He clears the checkbox next to **Requires password reset**, because the policies above allow users to change their passwords only after they are signed in to the IAM console.
2. On the **Set permissions** page, Zhang chooses the **IAMFullAccess** and **AmazonS3ReadOnlyAccess** permissions policies that allow Nikhil to do his work.
3. Zhang skips the **Set permissions boundary** section, forgetting María's instructions.
4. Zhang reviews the user details and chooses **Create user**.

The operation fails and access is denied. Zhang's `DelegatedUserBoundary` permissions boundary requires that any user he creates have the `XCompanyBoundaries` policy used as a permissions boundary.

5. Zhang returns to the previous page. In the **Set permissions boundary** section, he chooses the `XCompanyBoundaries` policy.
6. Zhang reviews the user details and chooses **Create user**.

The user is created.

When Nikhil signs in, he has access to IAM and Amazon S3, except those operations that are denied by the permissions boundary. For example, he can change his own password in IAM but can't create another user or edit his policies. Nikhil has read-only access to Amazon S3.

If someone adds a resource-based policy to the `logs` bucket that allows Nikhil to put an object in the bucket, he still cannot access the bucket. The reason is that any actions on the `logs` bucket are explicitly denied by his permissions boundary. An explicit deny in any policy type results in a request being denied. However, if a resource-based policy attached to a Secrets Manager secret allows Nikhil to perform the `secretsmanager:GetSecretValue` action, then Nikhil can retrieve and decrypt the secret. The reason is that Secrets Manager operations are not explicitly denied by his permissions boundary, and implicit denies in permissions boundaries do not limit resource-based policies.

Identity-based policies and resource-based policies

A policy is an object in AWS that, when associated with an identity or resource, defines their permissions. When you create a permissions policy to restrict access to a resource, you can choose an *identity-based policy* or a *resource-based policy*.

Identity-based policies are attached to an IAM user, group, or role. These policies let you specify what that identity can do (its permissions). For example, you can attach the policy to the IAM user named John, stating that he is allowed to perform the Amazon EC2 `RunInstances` action. The policy could further state that John is allowed to get items from an Amazon DynamoDB table named `MyCompany`. You can also allow John to manage his own IAM security credentials. Identity-based policies can be [managed or inline](#).

Resource-based policies are attached to a resource. For example, you can attach resource-based policies to Amazon S3 buckets, Amazon SQS queues, VPC endpoints, and AWS Key Management

Service encryption keys. For a list of services that support resource-based policies, see [AWS services that work with IAM](#).

With resource-based policies, you can specify who has access to the resource and what actions they can perform on it. To learn whether principals in accounts outside of your zone of trust (trusted organization or account) have access to assume your roles, see [What is IAM Access Analyzer?](#). Resource-based policies are inline only, not managed.

Note

Resource-based policies differ from *resource-level* permissions. You can attach resource-based policies directly to a resource, as described in this topic. Resource-level permissions refer to the ability to use [ARNs](#) to specify individual resources in a policy. Resource-based policies are supported only by some AWS services. For a list of which services support resource-based policies and resource-level permissions, see [AWS services that work with IAM](#).

To learn how identity-based policies and resource-based policies interact within the same account, see [Evaluating policies within a single account](#).

To learn how the policies interact across accounts, see [Cross-account policy evaluation logic](#).

To better understand these concepts, view the following figure. The administrator of the 123456789012 account attached *identity-based policies* to the JohnSmith, CarlosSalazar, and MaryMajor users. Some of the actions in these policies can be performed on specific resources. For example, the user JohnSmith can perform some actions on Resource X. This is a *resource-level permission* in an identity-based policy. The administrator also added *resource-based policies* to Resource X, Resource Y, and Resource Z. Resource-based policies allow you to specify who can access that resource. For example, the resource-based policy on Resource X allows the JohnSmith and MaryMajor users list and read access to the resource.

The 123456789012 account example allows the following users to perform the listed actions:

- **JohnSmith** – John can perform list and read actions on Resource X. He is granted this permission by the identity-based policy on his user and the resource-based policy on Resource X.
- **CarlosSalazar** – Carlos can perform list, read, and write actions on Resource Y, but is denied access to Resource Z. The identity-based policy on Carlos allows him to perform list and read actions on Resource Y. The Resource Y resource-based policy also allows him write permissions. However, although his identity-based policy allows him access to Resource Z, the Resource Z resource-based policy denies that access. An explicit Deny overrides an Allow and his access to Resource Z is denied. For more information, see [Policy evaluation logic](#).
- **MaryMajor** – Mary can perform list, read, and write operations on Resource X, Resource Y, and Resource Z. Her identity-based policy allows her more actions on more resources than the resource-based policies, but none of them deny access.
- **ZhangWei** – Zhang has full access to Resource Z. Zhang has no identity-based policies, but the Resource Z resource-based policy allows him full access to the resource. Zhang can also perform list and read actions on Resource Y.

Identity-based policies and resource-based policies are both permissions policies and are evaluated together. For a request to which only permissions policies apply, AWS first checks all policies for a Deny. If one exists, then the request is denied. Then AWS checks for each Allow. If at least one policy statement allows the action in the request, the request is allowed. It doesn't matter whether the Allow is in the identity-based policy or the resource-based policy.

Important

This logic applies only when the request is made within a single AWS account. For requests made from one account to another, the requester in Account A must have an identity-based policy that allows them to make a request to the resource in Account B. Also, the resource-based policy in Account B must allow the requester in Account A to access the resource. There must be policies in both accounts that allow the operation, otherwise the request fails. For more information about using resource-based policies for cross-account access, see [Cross account resource access in IAM](#).

A user who has specific permissions might request a resource that also has a permissions policy attached to it. In that case, AWS evaluates both sets of permissions when determining whether to grant access to the resource. For information about how policies are evaluated, see [Policy evaluation logic](#).

Note

Amazon S3 supports identity-based policies and resource-based policies (referred to as *bucket policies*). In addition, Amazon S3 supports a permission mechanism known as an *access control list (ACL)* that is independent of IAM policies and permissions. You can use IAM policies in combination with Amazon S3 ACLs. For more information, see [Access Control](#) in the *Amazon Simple Storage Service User Guide*.

Controlling access to AWS resources using policies

You can use a policy to control access to resources within IAM or all of AWS.

To use a [policy](#) to control access in AWS, you must understand how AWS grants access. AWS is composed of collections of *resources*. An IAM user is a resource. An Amazon S3 bucket is a resource. When you use the AWS API, the AWS CLI, or the AWS Management Console to perform

an operation (such as creating a user), you send a *request* for that operation. Your request specifies an action, a resource, a *principal entity* (user or role), a *principal account*, and any necessary request information. All of this information provides *context*.

AWS then checks that you (the principal) are authenticated (signed in) and authorized (have permission) to perform the specified action on the specified resource. During authorization, AWS checks all the policies that apply to the context of your request. Most policies are stored in AWS as [JSON documents](#) and specify the permissions for principal entities. For more information about policy types and uses, see [Policies and permissions in IAM](#).

AWS authorizes the request only if each part of your request is allowed by the policies. To view a diagram of this process, see [How IAM works](#). For details about how AWS determines whether a request is allowed, see [Policy evaluation logic](#).

When you create an IAM policy, you can control access to the following:

- [Principals](#) – Control what the person making the request (the [principal](#)) is allowed to do.
- [IAM Identities](#) – Control which IAM identities (user groups, users, and roles) can be accessed and how.
- [IAM Policies](#) – Control who can create, edit, and delete customer managed policies, and who can attach and detach all managed policies.
- [AWS Resources](#) – Control who has access to resources using an identity-based policy or a resource-based policy.
- [AWS Accounts](#) – Control whether a request is allowed only for members of a specific account.

Policies let you specify who has access to AWS resources, and what actions they can perform on those resources. Every IAM user starts with no permissions. In other words, by default, users can do nothing, not even view their own access keys. To give a user permission to do something, you can add the permission to the user (that is, attach a policy to the user). Or you can add the user to a user group that has the intended permission.

For example, you might grant a user permission to list his or her own access keys. You might also expand that permission and also let each user create, update, and delete their own keys.

When you give permissions to a user group, all users in that user group get those permissions. For example, you can give the Administrators user group permission to perform any of the IAM actions on any of the AWS account resources. Another example: You can give the Managers user group permission to describe the Amazon EC2 instances of the AWS account.

For information about how to delegate basic permissions to your users, user groups, and roles, see [Permissions required to access IAM resources](#). For additional examples of policies that illustrate basic permissions, see [Example policies for administering IAM resources](#).

Controlling access for principals

You can use policies to control what the person making the request (the principal) is allowed to do. To do this, you must attach an identity-based policy to that person's identity (user, user group, or role). You can also use a [permissions boundary](#) to set the maximum permissions that an entity (user or role) can have.

For example, assume that you want the user Zhang Wei to have full access to CloudWatch, Amazon DynamoDB, Amazon EC2, and Amazon S3. You can create two different policies so that you can later break them up if you need one set of permissions for a different user. Or you can put both the permissions together in a single policy, and then attach that policy to the IAM user that is named Zhang Wei. You could also attach a policy to a user group to which Zhang belongs, or a role that Zhang can assume. As a result, when Zhang views the contents of an S3 bucket, his requests are allowed. If he tries to create a new IAM user, his request is denied because he doesn't have permission.

You can use a permissions boundary on Zhang to make sure that he is never given access to the *DOC-EXAMPLE-BUCKET1* S3 bucket. To do this, determine the *maximum* permissions that you want Zhang to have. In this case, you control what he does using his permissions policies. Here, you only care that he doesn't access the confidential bucket. So you use the following policy to define Zhang's boundary to allow all AWS actions for Amazon S3 and a few other services but deny access to the *DOC-EXAMPLE-BUCKET1* S3 bucket. Because the permissions boundary does not allow any IAM actions, it prevents Zhang from deleting his (or anyone's) boundary.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "PermissionsBoundarySomeServices",
      "Effect": "Allow",
      "Action": [
        "cloudwatch:*",
        "dynamodb:*",
        "ec2:*",
        "s3:*"
      ],
    },
  ],
}
```

```
        "Resource": "*"
    },
    {
        "Sid": "PermissionsBoundaryNoConfidentialBucket",
        "Effect": "Deny",
        "Action": "s3:*",
        "Resource": [
            "arn:aws:s3:::DOC-EXAMPLE-BUCKET1",
            "arn:aws:s3:::DOC-EXAMPLE-BUCKET1/*"
        ]
    }
]
```

When you assign a policy like this as a permissions boundary for a user, remember that it does not grant any permissions. It sets the maximum permissions that an identity-based policy can grant to an IAM entity. For more information about permissions boundaries, see [Permissions boundaries for IAM entities](#).

For detailed information about the procedures mentioned previously, refer to these resources:

- To learn more about creating an IAM policy that you can attach to a principal, see [Creating IAM policies](#).
- To learn how to attach an IAM policy to a principal, see [Adding and removing IAM identity permissions](#).
- To see an example policy for granting full access to EC2, see [Amazon EC2: Allows full EC2 access within a specific Region, programmatically and in the console](#).
- To allow read-only access to an S3 bucket, use the first two statements of the following example policy: [Amazon S3: Allows read and write access to objects in an S3 Bucket, programmatically and in the console](#).
- To see an example policy for allowing users to set their credentials, such as their console password, their programmatic access keys, and their MFA devices, see [AWS: Allows MFA-authenticated IAM users to manage their own credentials on the Security credentials page](#).

Controlling access to identities

You can use IAM policies to control what your users can do to an identity by creating a policy that you attach to all users through a user group. To do this, create a policy that limits what can be done to an identity, or who can access it.

For example, you can create a user group named **AllUsers**, and then attach that user group to all users. When you create the user group, you might give all your users access to set their credentials as described in the previous section. You can then create a policy that denies access to change the user group unless the user name is included in the condition of the policy. But that part of the policy only denies access to anyone except those users listed. You also have to include permissions to allow all the user group management actions for everyone in the user group. Finally, you attach this policy to the user group so that it is applied to all users. As a result, when a user not specified in the policy tries to make changes to the user group, the request is denied.

To create this policy with the visual editor

1. Sign in to the AWS Management Console and open the IAM console at <https://console.aws.amazon.com/iam/>.
2. In the navigation pane on the left, choose **Policies**.

If this is your first time choosing **Policies**, the **Welcome to Managed Policies** page appears. Choose **Get Started**.

3. Choose **Create policy**.
4. On the **Policy editor** section, choose the **Visual** option.
5. In **Select a service** choose **IAM**.
6. In **Actions allowed**, type **group** in the search box. The visual editor shows all the IAM actions that contain the word group. Select all of the check boxes.
7. Choose **Resources** to specify resources for your policy. Based on the actions you chose, you should see **group** and **user** resource types.
 - **group** – Choose **Add ARNs**. For **Resource in**, select the **Any account** option. Select the **Any group name with path** check box and then type the user group name **AllUsers**. Then choose **Add ARNs**.
 - **user** – Select the check box next to **Any in this account**.

One of the actions that you chose, `ListGroups`, does not support using specific resources. You do not have to choose **All resources** for that action. When you save your policy or view the policy in the **JSON** editor, you can see that IAM automatically creates a new permission block granting this action permission on all resources.

8. To add another permission block, choose **Add more permissions**.
9. Choose **Select a service** and then choose **IAM**.

10. Choose **Actions allowed** and then choose **Switch to deny permissions**. When you do that, the entire block is used to deny permissions.
11. Type **group** in the search box. The visual editor shows you all the IAM actions that contain the word group. Select the check boxes next to the following actions:
 - **CreateGroup**
 - **DeleteGroup**
 - **RemoveUserFromGroup**
 - **AttachGroupPolicy**
 - **DeleteGroupPolicy**
 - **DetachGroupPolicy**
 - **PutGroupPolicy**
 - **UpdateGroup**
12. Choose **Resources** to specify the resources for your policy. Based on the actions that you chose, you should see the **group** resource type. Choose **Add ARNs**. For **Resource in**, select the **Any account** option. For **Any group name with path**, type the user group name **AllUsers**. Then choose **Add ARNs**.
13. Choose **Request conditions - optional** and then choose **Add another condition**. Complete the form with the following values:
 - **Condition key** – Choose **aws:username**
 - **Qualifier** – Choose **Default**
 - **Operator** – Choose **StringNotEquals**
 - **Value** – Type **srodriguez** and then choose **Add** to add another value. Type **mjackson** and then choose **Add** to add another value. Type **adesai** and then choose **Add condition**.

This condition ensures that access will be denied to the specified user group management actions when the user making the call is not included in the list. Because this explicitly denies permission, it overrides the previous block that allowed those users to call the actions. Users on the list are not denied access, and they are granted permission in the first permission block, so they can fully manage the user group.

14. When you are finished, choose **Next**.

Note

You can switch between the **Visual** and **JSON** editor options any time. However, if you make changes or choose **Next** in the **Visual** editor option, IAM might restructure your policy to optimize it for the visual editor. For more information, see [Policy restructuring](#).

15. On the **Review and create** page, for the **Policy Name**, type **LimitAllUserGroupManagement**. For the **Description**, type **Allows all users read-only access to a specific user group, and allows only specific users access to make changes to the user group**. Review **Permissions defined in this policy** to make sure that you have granted the intended permissions. Then choose **Create policy** to save your new policy.
16. Attach the policy to your user group. For more information, see [Adding and removing IAM identity permissions](#).

Alternatively, you can create the same policy using this example JSON policy document. To view this JSON policy, see [IAM: Allows specific IAM users to manage a group programmatically and in the console](#). For detailed instructions for creating a policy using a JSON document, see [the section called "Creating policies using the JSON editor"](#).

Controlling access to policies

You can control how your users can apply AWS managed policies. To do this, attach this policy to all your users. Ideally, you can do this using a user group.

For example, you might create a policy that allows users to attach only the [IAMUserChangePassword](#) and [PowerUserAccess](#) AWS managed policies to a new IAM user, user group, or role.

For customer managed policies, you can control who can create, update, and delete these policies. You can control who can attach and detach policies to and from principal entities (user groups, users, and roles). You can also control which policies a user can attach or detach, and to and from which entities.

For example, you can give permissions to an account administrator to create, update, and delete policies. Then you give permissions to a team leader or other limited administrator to attach and detach these policies to and from principal entities that the limited administrator manages.

For more information, refer to these resources:

- To learn more about creating an IAM policy that you can attach to a principal, see [Creating IAM policies](#).
- To learn how to attach an IAM policy to a principal, see [Adding and removing IAM identity permissions](#).
- To see an example policy for limiting the use of managed policies, see [IAM: Limits managed policies that can be applied to an IAM user, group, or role](#).

Controlling permissions for creating, updating, and deleting customer managed policies

You can use [IAM policies](#) to control who is allowed to create, update, and delete customer managed policies in your AWS account. The following list contains API operations that pertain directly to creating, updating, and deleting policies or policy versions:

- [CreatePolicy](#)
- [CreatePolicyVersion](#)
- [DeletePolicy](#)
- [DeletePolicyVersion](#)
- [SetDefaultPolicyVersion](#)

The API operations in the preceding list correspond to actions that you can allow or deny—that is, permissions that you can grant—using an IAM policy.

Consider the following example policy. It allows a user to create, update (that is, create a new policy version), delete, and set a default version for all customer managed policies in the AWS account. The example policy also allows the user to list policies and get policies. To learn how to create a policy using this example JSON policy document, see [the section called "Creating policies using the JSON editor"](#).

Example Example policy that allows creating, updating, deleting, listing, getting, and setting the default version for all policies

```
{
  "Version": "2012-10-17",
  "Statement": {
```

```
"Effect": "Allow",
"Action": [
  "iam:CreatePolicy",
  "iam:CreatePolicyVersion",
  "iam>DeletePolicy",
  "iam>DeletePolicyVersion",
  "iam:GetPolicy",
  "iam:GetPolicyVersion",
  "iam>ListPolicies",
  "iam>ListPolicyVersions",
  "iam:SetDefaultPolicyVersion"
],
"Resource": "*"
}
```

You can create policies that limit the use of these API operations to affect only the managed policies that you specify. For example, you might want to allow a user to set the default version and delete policy versions, but only for specific customer managed policies. You do this by specifying the policy ARN in the `Resource` element of the policy that grants these permissions.

The following example shows a policy that allows a user to delete policy versions and set the default version. But these actions are only allowed for the customer managed policies that include the path `/TEAM-A/`. The customer managed policy ARN is specified in the `Resource` element of the policy. (In this example the ARN includes a path and a wildcard and thus matches all customer managed policies that include the path `/TEAM-A/`). To learn how to create a policy using this example JSON policy document, see [the section called "Creating policies using the JSON editor"](#).

For more information about using paths in the names of customer managed policies, see [Friendly names and paths](#).

Example Example policy that allows deleting policy versions and setting the default version for only specific policies

```
{
  "Version": "2012-10-17",
  "Statement": {
    "Effect": "Allow",
    "Action": [
      "iam>DeletePolicyVersion",
      "iam:SetDefaultPolicyVersion"
    ]
  }
}
```

```
    ],  
    "Resource": "arn:aws:iam::account-id:policy/TEAM-A/*"  
  }  
}
```

Controlling permissions for attaching and detaching managed policies

You can also use IAM policies to allow users to work with only specific managed policies. In effect, you can control which permissions a user is allowed to grant to other principal entities.

The following list shows API operations that pertain directly to attaching and detaching managed policies to and from principal entities:

- [AttachGroupPolicy](#)
- [AttachRolePolicy](#)
- [AttachUserPolicy](#)
- [DetachGroupPolicy](#)
- [DetachRolePolicy](#)
- [DetachUserPolicy](#)

You can create policies that limit the use of these API operations to affect only the specific managed policies and/or principal entities that you specify. For example, you might want to allow a user to attach managed policies, but only the managed policies that you specify. Or, you might want to allow a user to attach managed policies, but only to the principal entities that you specify.

The following example policy allows a user to attach managed policies to only the user groups and roles that include the path /TEAM-A/. The user group and role ARNs are specified in the Resource element of the policy. (In this example the ARNs include a path and a wildcard character and thus match all user groups and roles that include the path /TEAM-A/). To learn how to create a policy using this example JSON policy document, see [the section called "Creating policies using the JSON editor"](#).

Example Example policy that allows attaching managed policies to only specific user groups or roles

```
{  
  "Version": "2012-10-17",
```

```
"Statement": {
  "Effect": "Allow",
  "Action": [
    "iam:AttachGroupPolicy",
    "iam:AttachRolePolicy"
  ],
  "Resource": [
    "arn:aws:iam::account-id:group/TEAM-A/*",
    "arn:aws:iam::account-id:role/TEAM-A/*"
  ]
}
```

You can further limit the actions in the preceding example to affect only specific policies. That is, you can control which permissions a user is allowed to attach to other principal entities—by adding a condition to the policy.

In the following example, the condition ensures that the `AttachGroupPolicy` and `AttachRolePolicy` permissions are allowed only when the policy being attached matches one of the specified policies. The condition uses the `iam:PolicyARN` [condition key](#) to determine which policy or policies are allowed to be attached. The following example policy expands on the previous example. It allows a user to attach only the managed policies that include the path `/TEAM-A/` to only the user groups and roles that include the path `/TEAM-A/`. To learn how to create a policy using this example JSON policy document, see [the section called “Creating policies using the JSON editor”](#).

```
{
  "Version": "2012-10-17",
  "Statement": {
    "Effect": "Allow",
    "Action": [
      "iam:AttachGroupPolicy",
      "iam:AttachRolePolicy"
    ],
    "Resource": [
      "arn:aws:iam::account-id:group/TEAM-A/*",
      "arn:aws:iam::account-id:role/TEAM-A/*"
    ],
    "Condition": {"ArnLike":
      {"iam:PolicyARN": "arn:aws:iam::account-id:policy/TEAM-A/*"}
    }
  }
}
```

```
}
```

This policy uses the `ArnLike` condition operator, but you can also use the `ArnEquals` condition operator because these two condition operators behave identically. For more information about `ArnLike` and `ArnEquals`, see [Amazon Resource Name \(ARN\) condition operators](#) in the *Condition Types* section of the *Policy Element Reference*.

For example, you can limit the use of actions to involve only the managed policies that you specify. You do this by specifying the policy ARN in the `Condition` element of the policy that grants these permissions. For example, to specify the ARN of a customer managed policy:

```
"Condition": {"ArnEquals":  
  {"iam:PolicyARN": "arn:aws:iam::123456789012:policy/POLICY-NAME"}}  
}
```

You can also specify the ARN of an AWS managed policy in a policy's `Condition` element. The ARN of an AWS managed policy uses the special alias `aws` in the policy ARN instead of an account ID, as in this example:

```
"Condition": {"ArnEquals":  
  {"iam:PolicyARN": "arn:aws:iam::aws:policy/AmazonEC2FullAccess"}}  
}
```

Controlling access to resources

You can control access to resources using an identity-based policy or a resource-based policy. In an identity-based policy, you attach the policy to an identity and specify what resources that identity can access. In a resource-based policy, you attach a policy to the resource that you want to control. In the policy, you specify which principals can access that resource. For more information about both types of policies, see [Identity-based policies and resource-based policies](#).

For more information, refer to these resources:

- To learn more about creating an IAM policy that you can attach to a principal, see [Creating IAM policies](#).
- To learn how to attach an IAM policy to a principal, see [Adding and removing IAM identity permissions](#).
- Amazon S3 supports using resource-based policies on their buckets. For more information, see [Bucket Policy Examples](#).

Resource Creators Do Not Automatically Have Permissions

If you sign in using the AWS account root user credentials, you have permission to perform any action on resources that belong to the account. However, this isn't true for IAM users. An IAM user might be granted access to create a resource, but the user's permissions, even for that resource, are limited to what's been explicitly granted. This means that just because you create a resource, such as an IAM role, you do not automatically have permission to edit or delete that role. Additionally, your permission can be revoked at any time by the account owner or by another user who has been granted access to manage your permissions.

Controlling access to principals in a specific account

You can directly grant IAM users in your own account access to your resources. If users from another account need access to your resources, you can create an IAM role. A role is an entity that includes permissions but isn't associated with a specific user. Users from other accounts can then assume the role and access resources according to the permissions you've assigned to the role. For more information, see [Providing access to an IAM user in another AWS account that you own](#).

Note

Some services support resource-based policies as described in [Identity-based policies and resource-based policies](#) (such as Amazon S3, Amazon SNS, and Amazon SQS). For those services, an alternative to using roles is to attach a policy to the resource (bucket, topic, or queue) that you want to share. The resource-based policy can specify the AWS account that has permissions to access the resource.

Controlling access to and for IAM users and roles using tags

Use the information in the following section to control who can access your IAM users and roles and what resources your users and roles can access. For more general information and examples of controlling access to other AWS resources, including other IAM resources, see [Tagging IAM resources](#).

Note

For details about case sensitivity for tag keys and tag key values, see [Case sensitivity](#).

Tags can be attached to the IAM *resource*, passed in the *request*, or attached to the *principal* that is making the request. An IAM user or role can be both a resource and principal. For example, you can write a policy that allows a user to list the groups for a user. This operation is allowed only if the user making the request (the principal) has the same `project=blue` tag as the user they're trying to view. In this example, the user can view the group membership for any user, including themselves, as long as they are working on the same project.

To control access based on tags, you provide tag information in the [condition element](#) of a policy. When you create an IAM policy, you can use IAM tags and the associated tag condition key to control access to any of the following:

- **Resource** – Control access to user or role resources based on their tags. To do this, use the `aws:ResourceTag/key-name` condition key to specify which tag key-value pair must be attached to the resource. For more information, see [Controlling access to AWS resources](#).
- **Request** – Control what tags can be passed in an IAM request. To do this, use the `aws:RequestTag/key-name` condition key to specify what tags can be added, changed, or removed from an IAM user or role. This key is used the same way for IAM resources and other AWS resources. For more information, see [Controlling access during AWS requests](#).
- **Principal** – Control what the person making the request (the principal) is allowed to do based on the tags that are attached to that person's IAM user or role. To do this, use the `aws:PrincipalTag/key-name` condition key to specify what tags must be attached to the IAM user or role before the request is allowed.
- **Any part of the authorization process** – Use the `aws:TagKeys` condition key to control whether specific tag keys can be used in a request or by a principal. In this case, the key value does not matter. This key behaves similarly for IAM and other AWS services. However, when you tag a user in IAM, this also controls whether the principal can make the request to any service. For more information, see [Controlling access based on tag keys](#).

You can create an IAM policy using the visual editor, using JSON, or by importing an existing managed policy. For details, see [Creating IAM policies](#).

Note

You can also pass [session tags](#) when you assume an IAM role or federate a user. These are valid only for the length of the session.

Controlling access for IAM principals

You can control what the principal is allowed to do based on the tags attached to that person's identity.

This example shows how you might create an identity-based policy that allows any user in this account to view the group membership for any user, including themselves, as long as they are working on the same project. This operation is allowed only when the user's resource tag and the principal's tag have the same value for the tag key `project`. To use this policy, replace the *italicized placeholder text* in the example policy with your own information. Then, follow the directions in [create a policy](#) or [edit a policy](#).

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "VisualEditor0",
      "Effect": "Allow",
      "Action": "iam:ListGroupsForUser",
      "Resource": "arn:aws:iam::111222333444:user/*",
      "Condition": {
        "StringEquals": {"aws:ResourceTag/project":
"${aws:PrincipalTag/project"}"}
      }
    }
  ]
}
```

Controlling access based on tag keys

You can use tags in your IAM policies to control whether specific tag keys can be used in a request or by a principal.

This example shows how you might create an identity-based policy that allows removing only the tag with the temporary key from users. To use this policy, replace the *italicized placeholder text* in the example policy with your own information. Then, follow the directions in [create a policy](#) or [edit a policy](#).

```
{
  "Version": "2012-10-17",
  "Statement": [{
```

```
    "Effect": "Allow",
    "Action": "iam:UntagUser",
    "Resource": "*",
    "Condition": {"ForAllValues:StringEquals": {"aws:TagKeys": ["temporary"]}}
  ]
}
```

Controlling access to AWS resources using tags

You can use tags to control access to your AWS resources that support tagging, including IAM resources. You can tag IAM users and roles to control what they can access. To learn how to tag IAM users and roles, see [Tagging IAM resources](#). Additionally, you can control access to the following IAM resources: customer managed policies, IAM identity providers, instance profiles, server certificates, and virtual MFA devices. To view a tutorial for creating and testing a policy that allows IAM roles with principal tags to access resources with matching tags, see [IAM tutorial: Define permissions to access AWS resources based on tags](#). Use the information in the following section to control access to other AWS resources, including IAM resources, without tagging IAM users or roles.

Before you use tags to control access to your AWS resources, you must understand how AWS grants access. AWS is composed of collections of *resources*. An Amazon EC2 instance is a resource. An Amazon S3 bucket is a resource. You can use the AWS API, the AWS CLI, or the AWS Management Console to perform an operation, such as creating a bucket in Amazon S3. When you do, you send a *request* for that operation. Your request specifies an action, a resource, a *principal entity* (user or role), a *principal account*, and any necessary request information. All of this information provides *context*.

AWS then checks that you (the principal entity) are authenticated (signed in) and authorized (have permission) to perform the specified action on the specified resource. During authorization, AWS checks all the policies that apply to the context of your request. Most policies are stored in AWS as [JSON documents](#) and specify the permissions for principal entities. For more information about policy types and uses, see [Policies and permissions in IAM](#).

AWS authorizes the request only if each part of your request is allowed by the policies. To view a diagram and learn more about the IAM infrastructure, see [How IAM works](#). For details about how IAM determines whether a request is allowed, see [Policy evaluation logic](#).

Tags are another consideration in this process because tags can be attached to the *resource* or passed in the *request* to services that support tagging. To control access based on tags, you provide tag information in the [condition element](#) of a policy. To learn whether an AWS service supports

controlling access using tags, see [AWS services that work with IAM](#) and look for the services that have **Yes** in the **Authorization based on tags** column. Choose the name of the service to view the authorization and access control documentation for that service.

You can then create an IAM policy that allows or denies access to a resource based on that resource's tag. In that policy, you can use tag condition keys to control access to any of the following:

- **Resource** – Control access to AWS service resources based on the tags on those resources. To do this, use the **ResourceTag/*key-name*** condition key to determine whether to allow access to the resource based on the tags that are attached to the resource.
- **Request** – Control what tags can be passed in a request. To do this, use the **aws:RequestTag/*key-name*** condition key to specify what tag key-value pairs can be passed in a request to tag an AWS resource.
- **Any part of the authorization process** – Use the **aws:TagKeys** condition key to control whether specific tag keys can be in a request.

You can create an IAM policy visually, using JSON, or by importing an existing managed policy. For details, see [Creating IAM policies](#).

Note

Some services allow users to specify tags when they create the resource if they have permissions to use the action that creates the resource.

Controlling access to AWS resources

You can use conditions in your IAM policies to control access to AWS resources based on the tags on that resource. You can do this using the global **aws:ResourceTag/*tag-key*** condition key, or a service-specific key. Some services support only the service-specific version of this key and not the global version.

Warning

Do not try to control who can pass a role by tagging the role and then using the **ResourceTag** condition key in a policy with the **iam:PassRole** action. This approach

does not have reliable results. For more information about permissions required to pass a role to a service, see [Granting a user permissions to pass a role to an AWS service](#).

This example shows how you might create an identity-based policy that allows starting or stopping Amazon EC2 instances. These operations are allowed only if the instance tag `Owner` has the value of the user name. This policy defines permissions for programmatic and console access.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "ec2:StartInstances",
        "ec2:StopInstances"
      ],
      "Resource": "arn:aws:ec2:*:*:instance/*",
      "Condition": {
        "StringEquals": {"aws:ResourceTag/Owner": "${aws:username}"}
      }
    },
    {
      "Effect": "Allow",
      "Action": "ec2:DescribeInstances",
      "Resource": "*"
    }
  ]
}
```

You can attach this policy to the IAM users in your account. If a user named `richard-roe` attempts to start an Amazon EC2 instance, the instance must be tagged `Owner=richard-roe` or `owner=richard-roe`. Otherwise he will be denied access. The tag key `Owner` matches both `Owner` and `owner` because condition key names are not case-sensitive. For more information, see [IAM JSON policy elements: Condition](#).

This example shows how you might create an identity-based policy that uses the team principal tag in the resource ARN. The policy grants permission to delete Amazon Simple Queue Service queues, but only if the queue name starts with the team name followed by `-queue`. For example, `qa-queue` if `qa` is the team name for the team principal tag.

```
{
  "Version": "2012-10-17",
  "Statement": {
    "Sid": "AllQueueActions",
    "Effect": "Allow",
    "Action": "sqs:DeleteQueue",
    "Resource": "arn:aws:sqs:us-east-2:${aws:PrincipalTag/team}-queue"
  }
}
```

Controlling access during AWS requests

You can use conditions in your IAM policies to control what tag key-value pairs can be passed in a request that applies tags an AWS resource.

This example shows how you might create an identity-based policy that allows using the Amazon EC2 `CreateTags` action to attach tags to an instance. You can attach tags only if the tag contains the `environment` key and the `preprod` or `production` values. If you want, you can use the `ForAllValues` modifier with the `aws:TagKeys` condition key to indicate that only the key `environment` is allowed in the request. This stops users from including other keys, such as accidentally using `Environment` instead of `environment`.

```
{
  "Version": "2012-10-17",
  "Statement": {
    "Effect": "Allow",
    "Action": "ec2:CreateTags",
    "Resource": "arn:aws:ec2:*:*:instance/*",
    "Condition": {
      "StringEquals": {
        "aws:RequestTag/environment": [
          "preprod",
          "production"
        ]
      },
      "ForAllValues:StringEquals": {"aws:TagKeys": "environment"}
    }
  }
}
```

Controlling access based on tag keys

You can use a condition in your IAM policies to control whether specific tag keys can be used in a request.

We recommend that when you use policies to control access using tags, you use the [aws:TagKeys condition key](#). AWS services that support tags might allow you to create multiple tag key names that differ only by case, such as tagging an Amazon EC2 instance with `stack=production` and `Stack=test`. Key names are not case sensitive in policy conditions. This means that if you specify `"aws:ResourceTag/TagKey1": "Value1"` in the condition element of your policy, then the condition matches a resource tag key named either `TagKey1` or `tagkey1`, but not both. To prevent duplicate tags with a key that varies only by case, use the `aws:TagKeys` condition to define the tag keys that your users can apply, or use tag policies, available with AWS Organizations. For more information see [Tag Policies](#) in the *Organizations User Guide*.

This example shows how you might create an identity-based policy that allows creating and tagging a Secrets Manager secret, but only with the tag keys `environment` or `cost-center`. The `Null` condition ensures that the condition evaluates to `false` if there are no tags in the request.

```
{
  "Effect": "Allow",
  "Action": [
    "secretsmanager:CreateSecret",
    "secretsmanager:TagResource"
  ],
  "Resource": "*",
  "Condition": {
    "Null": {
      "aws:TagKeys": "false"
    },
    "ForAllValues:StringEquals": {
      "aws:TagKeys": [
        "environment",
        "cost-center"
      ]
    }
  }
}
```

Cross account resource access in IAM

For some AWS services, you can grant cross-account access to your resources using IAM. To do this, you can attach a resource policy directly to the resource that you want to share, or use a role as a proxy.

To share the resource directly, the resource that you want to share must support [resource-based policies](#). Unlike an identity-based policy for a role, a resource-based policy specifies who (which principal) can access that resource.

Use a role as a proxy when you want to access resources in another account that do not support resource-based policies.

For details about the differences between these policy types, see [Identity-based policies and resource-based policies](#).

Note

IAM roles and resource-based policies delegate access across accounts only within a single partition. For example, you have an account in US West (N. California) in the standard aws partition. You also have an account in China in the aws-cn partition. You can't use a resource-based policy in your account in China to allow access for users in your standard AWS account.

Cross-account access using roles

Not all AWS services support resource-based policies. For these services, you can use cross-account IAM roles to centralize permission management when providing cross-account access to multiple services. A cross-account IAM role is an IAM role that includes a [trust policy](#) that allows IAM principals in another AWS account to assume the role. Put simply, you can create a role in one AWS account that delegates specific permissions to another AWS account.

For information about attaching a policy to an IAM identity, see [Managing IAM policies](#).

Note

When a principal switches to a role to temporarily use the permissions of the role, they give up their original permissions and take on the permissions assigned to the role they've assumed.

Let's take a look at the overall process as it applies to APN Partner software that needs to access a customer account.

1. The customer creates an IAM role in their own account with a policy that allows access the Amazon S3 resources that the APN partner requires. In this example, the role name is APNPartner.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": "s3:*",
      "Resource": [
        "arn:aws:s3:::bucket-name"
      ]
    }
  ]
}
```

2. Then, the customer specifies that the role can be assumed by the partner's AWS account by providing the APN Partner's AWS account ID in the [trust policy](#) for the APNPartner role.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Principal": {
        "AWS": "arn:aws:iam::APN-account-ID:role/APN-user-name"
      },
      "Action": "sts:AssumeRole"
    }
  ]
}
```

```
}
```

3. The customer gives the Amazon Resource Name (ARN) of the role to the APN partner. The ARN is the fully qualified name of the role.

```
arn:aws:iam::APN-ACCOUNT-ID:role/APNPartner
```

Note

We recommend using an external ID in multi-tenant situations. For details, see [How to use an external ID when granting access to your AWS resources to a third party](#).

4. When the APN Partner's software needs to access the customer's account, the software calls the [AssumeRole](#) API in the AWS Security Token Service with the ARN of the role in the customer's account. STS returns a temporary AWS credential that allows the software to do its work.

For another example of granting cross-account access using roles, see [Providing access to an IAM user in another AWS account that you own](#). You can also follow the [IAM tutorial: Delegate access across AWS accounts using IAM roles](#).

Cross-account access using resource-based policies

When an account accesses a resource through another account using a resource-based policy, the principal still works in the trusted account and does not have to give up their permissions to receive the role permissions. In other words, the principal continues to have access to resources in the trusted account while having access to the resource in the trusting account. This is useful for tasks such as copying information to or from the shared resource in the other account.

The principals that you can specify in a resource based policy include accounts, IAM users, federated users, IAM roles, assumed-role sessions, or AWS services. For more information, see [Specifying a principal](#).

To learn whether principals in accounts outside of your zone of trust (trusted organization or account) have access to assume your roles, see [Identifying resources shared with an external entity](#).

The following list includes some of the AWS services that support resource-based policies. For a complete list of the growing number of AWS services that support attaching permission policies to

resources instead of principals, see [AWS services that work with IAM](#) and look for the services that have **Yes** in the **Resource Based** column.

- **Amazon S3 buckets** — The policy is attached to the bucket, but the policy controls access to both the bucket and the objects in it. For more information, see [Access Control](#) in the *Amazon Simple Storage Service User Guide*. In some cases, it may be best to use roles for cross-account access to Amazon S3. For more information, see the [example walkthroughs](#) in the *Amazon Simple Storage Service User Guide*.
- **Amazon Simple Notification Service (Amazon SNS) topics** — For more information, go to [Example cases for Amazon SNS access control](#) in the *Amazon Simple Notification Service Developer Guide*.
- **Amazon Simple Queue Service (Amazon SQS) queues** – For more information, go to [Appendix: The Access Policy Language](#) in the *Amazon Simple Queue Service Developer Guide*.

Delegating AWS permissions in a resource-based policy

If a resource grants permissions to principals in your account, you can then delegate those permissions to specific IAM identities. Identities are users, groups of users, or roles in your account. You delegate permissions by attaching a policy to the identity. You can grant up to the maximum permissions that are allowed by the resource-owning account.

Important

In cross account access, a principal needs an Allow in the identity policy **and** the resource-based policy.

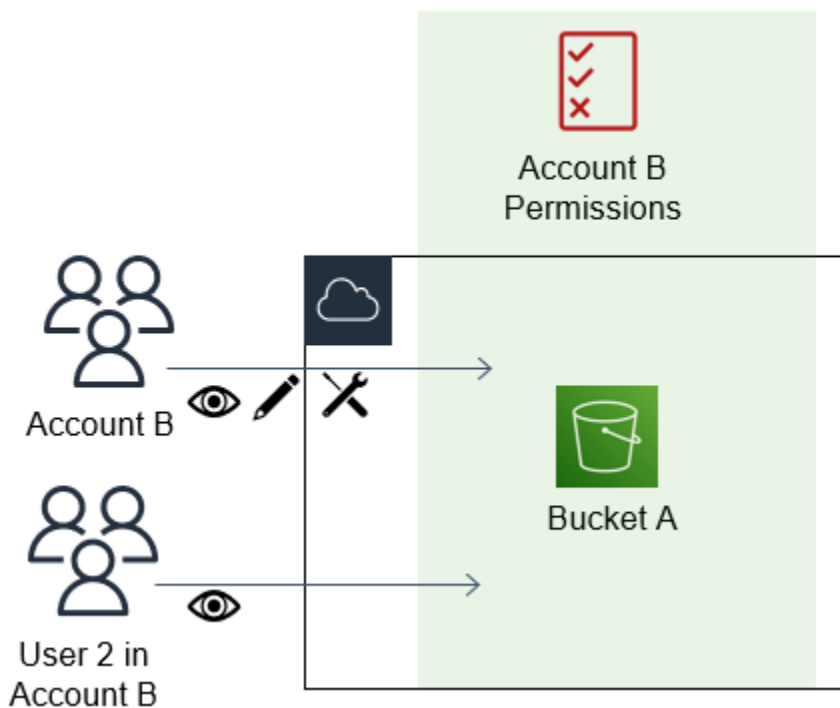

Assume that a resource-based policy allows all principals in your account full administrative access to a resource. Then you can delegate full access, read-only access, or any other partial access to principals in your AWS account. Alternatively, if the resource-based policy allows only list permissions, then you can delegate only list access. If you try to delegate more permissions than your account has, your principals will still have only list access.

For more information about how these decisions are made, see [Determining whether a request is allowed or denied within an account](#).

Note

IAM roles and resource-based policies delegate access across accounts only within a single partition. For example, you can't add cross-account access between an account in the standard aws partition and an account in the aws-cn partition.

For example, assume that you manage AccountA and AccountB. In AccountA, you have an Amazon S3 bucket named BucketA.

1. You attach a resource-based policy to BucketA that allows all principals in AccountB full access to objects in your bucket. They can create, read, or delete any objects in that bucket.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "PrincipalAccess",
      "Effect": "Allow",
      "Principal": {"AWS": "arn:aws:iam::AccountB:root"},
      "Action": "s3:*",
      "Resource": "arn:aws:s3:::BucketA/*"
    }
  ]
}
```

```

    }
  ]
}

```

AccountA gives AccountB full access to BucketA by naming AccountB as a principal in the resource-based policy. As a result, AccountB is authorized to perform any action on BucketA, and the AccountB administrator can delegate access to its users in AccountB.

The AccountB root user has all of the permissions that are granted to the account. Therefore, the root user has full access to BucketA.

2. In AccountB, attach a policy to the IAM user named User2. That policy allows the user read-only access to the objects in BucketA. That means that User2 can view the objects, but not create, edit, or delete them.

```

{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect" : "Allow",
      "Action" : [
        "s3:Get*",
        "s3:List*" ],
      "Resource" : "arn:aws:s3:::BucketA/*"
    }
  ]
}

```

The maximum level of access that AccountB can delegate is the access level that is granted to the account. In this case, the resource-based policy granted full access to AccountB, but User2 is granted only read-only access.

The AccountB administrator does not give access to User1. By default, users do not have any permissions except those that are explicitly granted, so User1 does not have access to BucketA.

IAM evaluates a principal's permissions at the time the principal makes a request. If you use wildcards (*) to give users full access to your resources, principals can access any resources that your AWS account has access to. This is true even for resources you add or gain access to after creating the user's policy.

In the preceding example, if AccountB had attached a policy to User2 that allowed full access to all resources in all accounts, User2 would automatically have access to any resources that AccountB has access to. This includes the BucketA access and access to any other resources granted by resource-based policies in AccountA.

For more information about complex uses of roles, such as granting access to applications and services, see [Common scenarios for roles: Users, applications, and services](#).

Important

Give access only to entities you trust, and give the minimum level of access necessary. Whenever the trusted entity is another AWS account, any IAM principal can be granted access to your resource. The trusted AWS account can delegate access only to the extent that it has been granted access; it cannot delegate more access than the account itself has been granted.

For information about permissions, policies, and the permission policy language that you use to write policies, see [Access management for AWS resources](#).

Forward access sessions

Forward access sessions (FAS) is an IAM technology used by AWS services to pass your identity, permissions, and session attributes when an AWS service makes a request on your behalf. FAS uses the permissions of the identity calling an AWS service, combined with an AWS service's identity to make requests to downstream services. FAS requests are only made to AWS services on behalf of an IAM principal after a service has received a request that requires interactions with other AWS services or resources to complete. When a FAS request is made:

- The service that receives the initial request from an IAM principal checks the permissions of the IAM principal.
- The service that receives a subsequent FAS request also checks the permissions of the same IAM principal.

For example, FAS is used by Amazon S3 to make calls to AWS Key Management Service to decrypt an object when [SSE-KMS](#) was used to encrypt it. When downloading an SSE-KMS encrypted object, a role named **data-reader** calls GetObject on the object against Amazon S3, and does not call AWS

KMS directly. After receiving the GetObject request and authorizing data-reader, Amazon S3 then makes a FAS request to AWS KMS in order to decrypt the Amazon S3 object. When KMS receives the FAS request it checks the permissions of the role and only authorizes the decryption request if data-reader has the correct permissions on the KMS key. The requests to both Amazon S3 and AWS KMS are authorized using the role’s permissions and is only successful if data-reader has permissions to both the Amazon S3 object and the AWS KMS key.

Note

Additional FAS requests can be made by services who have received a FAS request. In such cases, the requesting principal must have permissions for all services called by FAS.

FAS Requests and IAM policy conditions

When FAS requests are made, [aws:CalledVia](#), [aws:CalledViaFirst](#), and [aws:CalledViaLast](#) condition keys are populated with the service principal of the service that initiated the FAS call. The [aws:ViaAWSService](#) condition key value is set to true whenever a FAS request is made. In the following diagram, the request to CloudFormation directly does not have any `aws:CalledVia` or `aws:ViaAWSService` condition keys set. When CloudFormation and DynamoDB make downstream FAS requests on the behalf of the role, the values for these condition keys are populated.

To allow a FAS request to be made when it would otherwise be denied by a Deny policy statement with a condition key testing Source IP addresses or Source VPCs, you must use condition keys to

provide an exception for FAS requests in your Deny policy. This can be done for all FAS requests by using the `aws:ViaAWSService` condition key. To allow only specific AWS services to make FAS requests, use `aws:CalledVia`.

Important

When a FAS request is made after an initial request is made through a VPC endpoint, the condition key values for `aws:SourceVpce`, `aws:SourceVpc`, and `aws:VpcSourceIp` from the initial request are not used in FAS requests. When writing policies using `aws:VPCSourceIP` or `aws:SourceVPCE` to conditionally grant access, you must also use `aws:ViaAWSService` or `aws:CalledVia` to allow FAS requests. When a FAS request is made after an initial request is received by a public AWS service endpoint, subsequent FAS requests will be made with the same `aws:SourceIP` condition key value.

Example: Allow Amazon S3 access from a VPC or with FAS

In the following IAM policy example, Amazon S3 `GetObject` and Athena requests are only allowed if they originate from VPC endpoints attached to `example_vpc`, or if the request is a FAS request made by Athena.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "OnlyAllowMyIPs",
      "Effect": "Allow",
      "Action": [
        "s3:GetObject*",
        "athena:StartQueryExecution",
        "athena:GetQueryResults",
        "athena:GetWorkGroup",
        "athena:StopQueryExecution",
        "athena:GetQueryExecution"
      ],
      "Resource": "*",
      "Condition": {
        "StringEquals": {
          "aws:SourceVPC": [
            "example_vpc"
          ]
        }
      }
    }
  ]
}
```

```
    }
  },
  {
    "Sid": "OnlyAllowFAS",
    "Effect": "Allow",
    "Action": [
      "s3:GetObject*"
    ],
    "Resource": "*",
    "Condition": {
      "ForAnyValue:StringEquals": {
        "aws:CalledVia": "athena.amazonaws.com"
      }
    }
  }
]
```

For additional examples of using condition keys to allow FAS access, see the [data perimeter example policy repo](#).

Example IAM identity-based policies

A [policy](#) is an object in AWS that, when associated with an identity or resource, defines their permissions. AWS evaluates these policies when an IAM principal (user or role) makes a request. Permissions in the policies determine whether the request is allowed or denied. Most policies are stored in AWS as JSON documents that are attached to an IAM identity (user, group of users, or role). Identity-based policies include AWS managed policies, customer managed policies, and inline policies. To learn how to create an IAM policy using these example JSON policy documents, see [the section called "Creating policies using the JSON editor"](#).

By default all requests are denied, so you must provide access to the services, actions, and resources that you intend for the identity to access. If you also want to allow access to complete the specified actions in the IAM console, you need to provide additional permissions.

The following library of policies can help you define permissions for your IAM identities. After you find the policy that you need, choose **view this policy** to view the JSON for the policy. You can use the JSON policy document as a template for your own policies.

Note

If you would like to submit a policy to be included in this reference guide, use the **Feedback** button at the bottom of this page.

Example policies: AWS

- Allows access during a specific range of dates. ([View this policy.](#))
- Allows enabling and disabling AWS Regions. ([View this policy.](#))
- Allows MFA-authenticated users to manage their own credentials on the **Security credentials** page. ([View this policy.](#))
- Allows specific access when using MFA during a specific range of dates. ([View this policy.](#))
- Allows users to manage their own credentials on the **Security credentials** page. ([View this policy.](#))
- Allows users to manage their own MFA device on the **Security credentials** page. ([View this policy.](#))
- Allows users to manage their own password on the **Security credentials** page. ([View this policy.](#))
- Allows users to manage their own password, access keys, and SSH public keys on the **Security credentials** page. ([View this policy.](#))
- Denies access to AWS based on the requested Region. ([View this policy.](#))
- Denies access to AWS based on the source IP address. ([View this policy.](#))

Example policy: AWS Data Exchange

- Deny access to Amazon S3 resources outside of your account except AWS Data Exchange. ([View this policy.](#))

Example policies: AWS Data Pipeline

- Denies access to pipelines that a user did not create ([View this policy.](#))

Example policies: Amazon DynamoDB

- Allows access to a specific Amazon DynamoDB table ([View this policy.](#))
- Allows access to specific Amazon DynamoDB attributes ([View this policy.](#))
- Allows item-level access to Amazon DynamoDB based on an Amazon Cognito ID ([View this policy.](#))

Example policies: Amazon EC2

- Allows attaching or detaching Amazon EBS volumes to Amazon EC2 instances based on tags ([View this policy.](#))
- Allows launching Amazon EC2 instances in a specific subnet, programmatically and in the console ([View this policy.](#))
- Allows managing Amazon EC2 security groups associated with a specific VPC, programmatically and in the console ([View this policy.](#))
- Allows starting or stopping Amazon EC2 instances a user has tagged, programmatically and in the console ([View this policy.](#))
- Allows starting or stopping Amazon EC2 instances based on resource and principal tags, programmatically and in the console ([View this policy.](#))
- Allows starting or stopping Amazon EC2 instances when the resource and principal tags match ([View this policy.](#))
- Allows full Amazon EC2 access within a specific Region, programmatically and in the console. ([View this policy.](#))
- Allows starting or stopping a specific Amazon EC2 instance and modifying a specific security group, programmatically and in the console ([View this policy.](#))
- Denies access to specific Amazon EC2 operations without MFA ([View this policy.](#))
- Limits terminating Amazon EC2 instances to a specific IP address range ([View this policy.](#))

Example policies: AWS Identity and Access Management (IAM)

- Allows access to the policy simulator API ([View this policy.](#))
- Allows access to the policy simulator console ([View this policy.](#))
- Allows assuming any roles that have a specific tag, programmatically and in the console ([View this policy.](#))

- Allows and denies access to multiple services, programmatically and in the console ([View this policy.](#))
- Allows adding a specific tag to an IAM user with a different specific tag, programmatically and in the console ([View this policy.](#))
- Allows adding a specific tag to any IAM user or role, programmatically and in the console ([View this policy.](#))
- Allows creating a new user only with specific tags ([View this policy.](#))
- Allows generating and retrieving IAM credential reports ([View this policy.](#))
- Allows managing a group's membership, programmatically and in the console ([View this policy.](#))
- Allows managing a specific tag ([View this policy.](#))
- Allows passing an IAM role to a specific service ([View this policy.](#))
- Allows read-only access to the IAM console without reporting ([View this policy.](#))
- Allows read-only access to the IAM console ([View this policy.](#))
- Allows specific users to manage a group, programmatically and in the console ([View this policy.](#))
- Allows setting the account password requirements, programmatically and in the console ([View this policy.](#))
- Allows using the policy simulator API for users with a specific path ([View this policy.](#))
- Allows using the policy simulator console for users with a specific path ([View this policy.](#))
- Allows IAM users to self-manage an MFA device. ([View this policy.](#))
- Allows IAM users to set their own credentials, programmatically and in the console. ([View this policy.](#))
- Allows viewing service last accessed information for an AWS Organizations policy in the IAM console. ([View this policy.](#))
- Limits managed policies that can be applied to an IAM user, group, or role ([View this policy.](#))
- Allows access to IAM policies only in your account ([View this policy.](#))

Example policies: AWS Lambda

- Allows an AWS Lambda function to access an Amazon DynamoDB table ([View this policy.](#))

Example policies: Amazon RDS

- Allows full Amazon RDS database access within a specific Region. ([View this policy.](#))

- Allows restoring Amazon RDS databases, programmatically and in the console ([View this policy.](#))
- Allows tag owners full access to Amazon RDS resources that they have tagged ([View this policy.](#))

Example policies: Amazon S3

- Allows an Amazon Cognito user to access objects in their own Amazon S3 bucket ([View this policy.](#))
- Allows federated users to access their own home directory in Amazon S3, programmatically and in the console ([View this policy.](#))
- Allows full S3 access, but explicitly denies access to the Production bucket if the administrator has not signed in using MFA within the last thirty minutes ([View this policy.](#))
- Allows IAM users to access their own home directory in Amazon S3, programmatically and in the console ([View this policy.](#))
- Allows a user to manage a single Amazon S3 bucket and denies every other AWS action and resource ([View this policy.](#))
- Allows Read and Write access to a specific Amazon S3 bucket ([View this policy.](#))
- Allows Read and Write access to a specific Amazon S3 bucket, programmatically and in the console ([View this policy.](#))

AWS: Allows access based on date and time

This example shows how you might create an identity-based policy that allows access to actions based on date and time. This policy restricts access to actions that occur between April 1, 2020 and June 30, 2020 (UTC), inclusive. This policy grants the permissions necessary to complete this action programmatically from the AWS API or AWS CLI. To use this policy, replace the *italicized placeholder text* in the example policy with your own information. Then, follow the directions in [create a policy](#) or [edit a policy](#).

To learn about using multiple conditions within the `Condition` block of an IAM policy, see [Multiple values in a condition](#).

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
```

```

    "Action": "service-prefix:action-name",
    "Resource": "*",
    "Condition": {
      "DateGreaterThan": {"aws:CurrentTime": "2020-04-01T00:00:00Z"},
      "DateLessThan": {"aws:CurrentTime": "2020-06-30T23:59:59Z"}
    }
  }
]
}

```

Note

You cannot use a policy variable with the Date condition operator. To learn more see [Condition element](#)

AWS: Allows enabling and disabling AWS Regions

This example shows how you might create an identity-based policy that allows an administrator to enable and disable the Asia Pacific (Hong Kong) Region (ap-east-1). This policy defines permissions for programmatic and console access. This setting appears in the **Account settings** page in the AWS Management Console. This page includes sensitive account-level information that should be viewed and managed only by account administrators. To use this policy, replace the *italicized placeholder text* in the example policy with your own information. Then, follow the directions in [create a policy](#) or [edit a policy](#).

Important

You cannot enable or disable regions that are enabled by default. You can only include regions that are *disabled* by default. For more information, see [Managing AWS Regions](#) in the *AWS General Reference*.

```

{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "EnableDisableHongKong",
      "Effect": "Allow",

```

```
    "Action": [
      "account:EnableRegion",
      "account:DisableRegion"
    ],
    "Resource": "*",
    "Condition": {
      "StringEquals": {"account:TargetRegion": "ap-east-1"}
    }
  },
  {
    "Sid": "ViewConsole",
    "Effect": "Allow",
    "Action": [
      "account:ListRegions"
    ],
    "Resource": "*"
  }
]
```

AWS: Allows MFA-authenticated IAM users to manage their own credentials on the Security credentials page

This example shows how you might create an identity-based policy that allows IAM users that are authenticated using [multi-factor authentication \(MFA\)](#) to manage their own credentials on the **Security credentials** page. This AWS Management Console page displays account information such as the account ID and canonical user ID. Users can also view and edit their own passwords, access keys, MFA devices, X.509 certificates, and SSH keys and Git credentials. This example policy includes the permissions required to view and edit all of the information on the page. It also requires the user to set up and authenticate using MFA before performing any other operations in AWS. To allow users to manage their own credentials without using MFA, see [AWS: Allows IAM users to manage their own credentials on the Security credentials page](#).

To learn how users can access the **Security credentials** page, see [How IAM users change their own password \(console\)](#).

Note

- This example policy does not allow users to reset a password while signing in to the AWS Management Console for the first time. We recommend that you do not

grant permissions to new users until after they sign in. For more information, see [How do I securely create IAM users?](#). This also prevents users with an expired password from resetting their password during sign in. You can allow this by adding `iam:ChangePassword` and `iam:GetAccountPasswordPolicy` to the statement `DenyAllExceptListedIfNoMFA`. However, we do not recommend this because allowing users to change their password without MFA can be a security risk.

- If you intend to use this policy for programmatic access you must call [GetSessionToken](#) to authenticate with MFA. For more information, see [Configuring MFA-protected API access](#).

What does this policy do?

- The `AllowViewAccountInfo` statement allows the user to view account-level information. These permissions must be in their own statement because they do not support or do not need to specify a resource ARN. Instead the permissions specify "Resource" : "*". This statement includes the following actions that allow the user to view specific information:
 - `GetAccountPasswordPolicy` – View the account password requirements while changing their own IAM user password.
 - `ListVirtualMFADevices` – View details about a virtual MFA device that is enabled for the user.
- The `AllowManageOwnPasswords` statement allows the user to change their own password. This statement also includes the `GetUser` action, which is required to view most of the information on the **My security credentials** page.
- The `AllowManageOwnAccessKeys` statement allows the user to create, update, and delete their own access keys. The user can also retrieve information about when the specified access key was last used.
- The `AllowManageOwnSigningCertificates` statement allows the user to upload, update, and delete their own signing certificates.
- The `AllowManageOwnSSHPublicKeys` statement allows the user to upload, update, and delete their own SSH public keys for CodeCommit.
- The `AllowManageOwnGitCredentials` statement allows the user to create, update, and delete their own Git credentials for CodeCommit.
- The `AllowManageOwnVirtualMFADevice` statement allows the user to create their own virtual MFA device. The resource ARN in this statement allows the user to create an MFA device with

any name, but the other statements in the policy only allow the user to attach the device to the currently signed-in user.

- The `AllowManageOwnUserMFA` statement allows the user to view or manage the virtual, U2F, or hardware MFA device for their own user. The resource ARN in this statement allows access to only the user's own IAM user. Users can't view or manage the MFA device for other users.
- The `DenyAllExceptListedIfNoMFA` statement denies access to every action in all AWS services, except a few listed actions, but **only if** the user is not signed in with MFA. The statement uses a combination of "Deny" and "NotAction" to explicitly deny access to every action that is not listed. The items listed are not denied or allowed by this statement. However, the actions are allowed by other statements in the policy. For more information about the logic for this statement, see [NotAction with Deny](#). If the user is signed in with MFA, then the `Condition` test fails and this statement does not deny any actions. In this case, other policies or statements for the user determine the user's permissions.

This statement ensures that when the user is not signed in with MFA that they can perform only the listed actions. In addition, they can perform the listed actions only if another statement or policy allows access to those actions. This does not allow a user to create a password at sign-in, because `iam:ChangePassword` action should not be allowed without MFA authorization.

The `...IfExists` version of the `Bool` operator ensures that if the [aws:MultiFactorAuthPresent](#) key is missing, the condition returns true. This means that a user accessing an API with long-term credentials, such as an access key, is denied access to the non-IAM API operations.

This policy does not allow users to view the **Users** page in the IAM console or use that page to access their own user information. To allow this, add the `iam:ListUsers` action to the `AllowViewAccountInfo` statement and the `DenyAllExceptListedIfNoMFA` statement. It also does not allow users to change their password on their own user page. To allow this, add the `iam:GetLoginProfile` and `iam:UpdateLoginProfile` actions to the `AllowManageOwnPasswords` statement. To also allow a user to change their password from their own user page without signing in using MFA, add the `iam:UpdateLoginProfile` action to the `DenyAllExceptListedIfNoMFA` statement.

```
{
  "Version": "2012-10-17",

    "NotAction": [
        "iam:CreateVirtualMFADevice",

```

```

        "iam:EnableMFADevice",
        "iam:GetUser",
        "iam:GetMFADevice",
        "iam:ListMFADevices",
        "iam:ListVirtualMFADevices",
        "iam:ResyncMFADevice",
        "sts:GetSessionToken"
    ],
    "Resource": "*",
    "Condition": {
        "BoolIfExists": {
            "aws:MultiFactorAuthPresent": "false"
        }
    }
}
]
}

```

AWS: Allows specific access using MFA within specific dates

This example shows how you might create an identity-based policy that uses multiple conditions, which are evaluated using a logical AND. It allows full access to the service named SERVICE-NAME-1, and access to the ACTION-NAME-A and ACTION-NAME-B actions in the service named SERVICE-NAME-2. These actions are allowed only when the user is authenticated using [multifactor authentication \(MFA\)](#). Access is restricted to actions that occur between July 1, 2017 and December 31, 2017 (UTC), inclusive. This policy grants the permissions necessary to complete this action programmatically from the AWS API or AWS CLI. To use this policy, replace the *italicized placeholder text* in the example policy with your own information. Then, follow the directions in [create a policy](#) or [edit a policy](#).

To learn about using multiple conditions within the Condition block of an IAM policy, see [Multiple values in a condition](#).

```

{
  "Version": "2012-10-17",
  "Statement": {
    "Effect": "Allow",
    "Action": [
      "service-prefix-1:*",
      "service-prefix-2:action-name-a",
      "service-prefix-2:action-name-b"
    ]
  }
}

```

```
    ],
    "Resource": "*",
    "Condition": {
      "Bool": {"aws:MultiFactorAuthPresent": true},
      "DateGreaterThan": {"aws:CurrentTime": "2017-07-01T00:00:00Z"},
      "DateLessThan": {"aws:CurrentTime": "2017-12-31T23:59:59Z"}
    }
  }
}
```

AWS: Allows IAM users to manage their own credentials on the Security credentials page

This example shows how you might create an identity-based policy that allows IAM users to manage all of their own credentials on the **Security credentials** page. This AWS Management Console page displays account information such as the account ID and canonical user ID. Users can also view and edit their own passwords, access keys, X.509 certificates, SSH keys, and Git credentials. This example policy includes the permissions required to view and edit all information on the page *except* the user's MFA device. To allow users to manage their own credentials with MFA, see [AWS: Allows MFA-authenticated IAM users to manage their own credentials on the Security credentials page](#).

To learn how users can access the **Security credentials** page, see [How IAM users change their own password \(console\)](#).

What does this policy do?

- The AllowViewAccountInfo statement allows the user to view account-level information. These permissions must be in their own statement because they do not support or do not need to specify a resource ARN. Instead the permissions specify "Resource" : "*". This statement includes the following actions that allow the user to view specific information:
 - GetAccountPasswordPolicy – View the account password requirements while changing their own IAM user password.
 - GetAccountSummary – View the account ID and the account [canonical user ID](#).
- The AllowManageOwnPasswords statement allows the user to change their own password. This statement also includes the GetUser action, which is required to view most of the information on the **My security credentials** page.

- The `AllowManageOwnAccessKeys` statement allows the user to create, update, and delete their own access keys. The user can also retrieve information about when the specified access key was last used.
- The `AllowManageOwnSigningCertificates` statement allows the user to upload, update, and delete their own signing certificates.
- The `AllowManageOwnSSHPublicKeys` statement allows the user to upload, update, and delete their own SSH public keys for CodeCommit.
- The `AllowManageOwnGitCredentials` statement enables the user to create, update, and delete their own Git credentials for CodeCommit.

This policy does not allow users to view or manage their own MFA devices. They also cannot view the **Users** page in the IAM console or use that page to access their own user information. To allow this, add the `iam:ListUsers` action to the `AllowViewAccountInfo` statement. It also does not allow users to change their password on their own user page. To allow this, add the `iam:CreateLoginProfile`, `iam>DeleteLoginProfile`, `iam:GetLoginProfile`, and `iam:UpdateLoginProfile` actions to the `AllowManageOwnPasswords` statement.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "AllowViewAccountInfo",
      "Effect": "Allow",
      "Action": [
        "iam:GetAccountPasswordPolicy",
        "iam:GetAccountSummary"
      ],
      "Resource": "*"
    },
    {
      "Sid": "AllowManageOwnPasswords",
      "Effect": "Allow",

        "iam>CreateServiceSpecificCredential",
        "iam>DeleteServiceSpecificCredential",
        "iam>ListServiceSpecificCredentials",
        "iam:ResetServiceSpecificCredential",
        "iam:UpdateServiceSpecificCredential"
    ],
}

```

```
        "Resource": "arn:aws:iam::*:user/${aws:username}"
    }
  ]
}
```

AWS: Allows MFA-authenticated IAM users to manage their own MFA device on the Security credentials page

This example shows how you might create an identity-based policy that allows IAM users that are authenticated through [multi-factor authentication \(MFA\)](#) to manage their own MFA device on the **Security credentials** page. This AWS Management Console page displays account and user information, but the user can only view and edit their own MFA device. To allow users to manage all of their own credentials with MFA, see [AWS: Allows MFA-authenticated IAM users to manage their own credentials on the Security credentials page](#).

Note

If an IAM user with this policy is not MFA-authenticated, this policy denies access to all AWS actions except those necessary to authenticate using MFA. To use the AWS CLI and AWS API, IAM users must first retrieve their MFA token using the AWS STS [GetSessionToken](#) operation and then use that token to authenticate the desired operation. Other policies, such as resource-based policies or other identity-based policies can allow actions in other services. This policy will deny that access if the IAM user is not MFA-authenticated.

To learn how users can access the **Security credentials** page, see [How IAM users change their own password \(console\)](#).

What does this policy do?

- The AllowViewAccountInfo statement allows the user to view details about a virtual MFA device that is enabled for the user. This permission must be in its own statement because it does not support specifying a resource ARN. Instead you must specify "Resource" : "*".
- The AllowManageOwnVirtualMFADevice statement allows the user to create their own virtual MFA device. The resource ARN in this statement allows the user to create an MFA device with any name, but the other statements in the policy only allow the user to attach the device to the currently signed-in user.

- The `AllowManageOwnUserMFA` statement allows the user to view or manage their own virtual, U2F, or hardware MFA device. The resource ARN in this statement allows access to only the user's own IAM user. Users can't view or manage the MFA device for other users.
- The `DenyAllExceptListedIfNoMFA` statement denies access to every action in all AWS services, except a few listed actions, but **only if** the user is not signed in with MFA. The statement uses a combination of "Deny" and "NotAction" to explicitly deny access to every action that is not listed. The items listed are not denied or allowed by this statement. However, the actions are allowed by other statements in the policy. For more information about the logic for this statement, see [NotAction with Deny](#). If the user is signed in with MFA, then the `Condition` test fails and this statement does not deny any actions. In this case, other policies or statements for the user determine the user's permissions.

This statement ensures that when the user is not signed in with MFA, they can perform only the listed actions. In addition, they can perform the listed actions only if another statement or policy allows access to those actions.

The `...IfExists` version of the `Bool` operator ensures that if the `aws:MultiFactorAuthPresent` key is missing, the condition returns true. This means that a user accessing an API operation with long-term credentials, such as an access key, is denied access to the non-IAM API operations.

This policy does not allow users to view the **Users** page in the IAM console or use that page to access their own user information. To allow this, add the `iam:ListUsers` action to the `AllowViewAccountInfo` statement and the `DenyAllExceptListedIfNoMFA` statement.

Warning

Do not add permission to delete an MFA device without MFA authentication. Users with this policy might attempt to assign themselves a virtual MFA device and receive an error that they are not authorized to perform `iam:DeleteVirtualMFADevice`. If this happens, **do not** add that permission to the `DenyAllExceptListedIfNoMFA` statement. Users that are not authenticated using MFA should never be allowed to delete their MFA device. Users might see this error if they previously began assigning a virtual MFA device to their user and cancelled the process. To resolve this issue, you or another administrator must delete the user's existing virtual MFA device using the AWS CLI or AWS API. For more information, see [I am not authorized to perform: iam:DeleteVirtualMFADevice](#).

```

AWS: Allows IAM users to change their own console password on the Security credentials page

This example shows how you might create an identity-based policy that allows IAM users to change their own AWS Management Console password on the **Security credentials** page. This AWS Management Console page displays account and user information, but the user can only access their own password. To allow users to manage all of their own credentials with MFA, see [AWS: Allows MFA-authenticated IAM users to manage their own credentials on the Security credentials page](#). To allow users to manage their own credentials without using MFA, see [AWS: Allows IAM users to manage their own credentials on the Security credentials page](#).

To learn how users can access the **Security credentials** page, see [How IAM users change their own password \(console\)](#).

What does this policy do?

- The `ViewAccountPasswordRequirements` statement allows the user to view the account password requirements while changing their own IAM user password.
- The `ChangeOwnPassword` statement allows the user to change their own password. This statement also includes the `GetUser` action, which is required to view most of the information on the **My security credentials** page.

This policy does not allow users to view the **Users** page in the IAM console or use that page to access their own user information. To allow this, add the `iam:ListUsers` action to the `ViewAccountPasswordRequirements` statement. It also does not allow users to change their password on their own user page. To allow this, add the `iam:GetLoginProfile` and `iam:UpdateLoginProfile` actions to the `ChangeOwnPasswords` statement.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
```

```
        "Sid": "ViewAccountPasswordRequirements",
        "Effect": "Allow",
        "Action": "iam:GetAccountPasswordPolicy",
        "Resource": "*"
    },
    {
        "Sid": "ChangeOwnPassword",
        "Effect": "Allow",
        "Action": [
            "iam:GetUser",
            "iam:ChangePassword"
        ],
        "Resource": "arn:aws:iam::*:user/${aws:username}"
    }
]
}
```

AWS: Allows IAM users to manage their own password, access keys, and SSH public keys on the Security credentials page

This example shows how you might create an identity-based policy that allows IAM users to manage their own password, access keys, and X.509 certificates on the **Security credentials** page. This AWS Management Console page displays account information such as the account ID and canonical user ID. Users can also view and edit their own passwords, access keys, MFA devices, X.509 certificates, SSH keys, and Git credentials. This example policy includes the permissions that are required to view and edit only their password, access keys, and X.509 certificate. To allow users to manage all of their own credentials with MFA, see [AWS: Allows MFA-authenticated IAM users to manage their own credentials on the Security credentials page](#). To allow users to manage their own credentials without using MFA, see [AWS: Allows IAM users to manage their own credentials on the Security credentials page](#).

To learn how users can access the **Security credentials** page, see [How IAM users change their own password \(console\)](#).

What does this policy do?

- The AllowViewAccountInfo statement allows the user to view account-level information. These permissions must be in their own statement because they do not support or do not need to specify a resource ARN. Instead the permissions specify "Resource" : "*". This statement includes the following actions that allow the user to view specific information:

- `GetAccountPasswordPolicy` – View the account password requirements while changing their own IAM user password.
- `GetAccountSummary` – View the account ID and the account [canonical user ID](#).
- The `AllowManageOwnPasswords` statement allows the user to change their own password. This statement also includes the `GetUser` action, which is required to view most of the information on the **My security credentials** page.
- The `AllowManageOwnAccessKeys` statement allows the user to create, update, and delete their own access keys. The user can also retrieve information about when the specified access key was last used.
- The `AllowManageOwnSSHPublicKeys` statement allows the user to upload, update, and delete their own SSH public keys for CodeCommit.

This policy does not allow users to view or manage their own MFA devices. They also cannot view the **Users** page in the IAM console or use that page to access their own user information. To allow this, add the `iam:ListUsers` action to the `AllowViewAccountInfo` statement. It also does not allow users to change their password on their own user page. To allow this, add the `iam:GetLoginProfile` and `iam:UpdateLoginProfile` actions to the `AllowManageOwnPasswords` statement.

      "iam:GetSSHPublicKey",
      "iam:ListSSHPublicKeys",
      "iam:UpdateSSHPublicKey",
      "iam:UploadSSHPublicKey"
    ],
    "Resource": "arn:aws:iam::*:user/${aws:username}"
  }
]
}

```

AWS: Denies access to AWS based on the requested Region

This example shows how you might create an identity-based policy that denies access to any actions outside the Regions specified using the [aws:RequestedRegion condition key](#), except for actions in the services specified using `NotAction`. This policy defines permissions for programmatic and console access. To use this policy, replace the *italicized placeholder text* in the example policy with your own information. Then, follow the directions in [create a policy](#) or [edit a policy](#).

This policy uses the `NotAction` element with the `Deny` effect, which explicitly denies access to all of the actions *not* listed in the statement. Actions in the CloudFront, IAM, Route 53, and AWS Support services should not be denied because these are popular AWS global services with a single endpoint that is physically located in the `us-east-1` Region. Because all requests to

these services are made to the us-east-1 Region, the requests would be denied without the NotAction element. Edit this element to include actions for other AWS global services that you use, such as budgets, globalaccelerator, importexport, organizations, or waf. Some other global services, such as AWS Chatbot and AWS Device Farm, are global services with endpoints that are physically located in the us-west-2 region. To learn about all of the services that have a single global endpoint, see [AWS Regions and Endpoints](#) in the *AWS General Reference*. For more information about using the NotAction element with the Deny effect, see [IAM JSON policy elements: NotAction](#).

Important

This policy does not allow any actions. Use this policy in combination with other policies that allow specific actions.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "DenyAllOutsideRequestedRegions",
      "Effect": "Deny",
      "NotAction": [
        "cloudfront:*",
        "iam:*",
        "route53:*",
        "support:*"
      ],
      "Resource": "*",
      "Condition": {
        "StringNotEquals": {
          "aws:RequestedRegion": [
            "eu-central-1",
            "eu-west-1",
            "eu-west-2",
            "eu-west-3"
          ]
        }
      }
    }
  ]
}
```

```
}
```

AWS: Denies access to AWS based on the source IP

This example shows how you might create an identity-based policy that denies access to all AWS actions in the account when the request comes from *principals* outside the specified IP range. The policy is useful when the IP addresses for your company are within the specified ranges. In this example, the request will be denied unless it originates from the CIDR range 192.0.2.0/24 or 203.0.113.0/24. The policy does not deny requests made by AWS services using [Forward access sessions](#) as the original requester's IP address is preserved.

Be careful using negative conditions in the same policy statement as "Effect": "Deny". When you do, the actions specified in the policy statement are explicitly denied in all conditions *except* for the ones specified.

Important

This policy does not allow any actions. Use this policy in combination with other policies that allow specific actions.

When other policies allow actions, principals can make requests from within the IP address range. An AWS service can also make requests using the principal's credentials. When a principal makes a request from outside the IP range, the request is denied.

For more information about using the `aws:SourceIp` condition key, including information about when `aws:SourceIp` may not work in your policy, see [AWS global condition context keys](#).

```
{
  "Version": "2012-10-17",
  "Statement": {
    "Effect": "Deny",
    "Action": "*",
    "Resource": "*",
    "Condition": {
      "NotIpAddress": {
        "aws:SourceIp": [
          "192.0.2.0/24",
          "203.0.113.0/24"
        ]
      }
    }
  }
}
```

```
}  
  }  
}
```

AWS: Deny access to Amazon S3 resources outside your account except AWS Data Exchange

This example shows how you might create an identity-based policy that denies access to all resources in AWS that don't belong to your account, except for the resources that AWS Data Exchange requires for normal operation. To use this policy, replace the *italicized placeholder text* in the example policy with your own information. Then, follow the directions in [create a policy](#) or [edit a policy](#).

You can create a similar policy to restrict access to resources within an organization or an organizational unit, while accounting for AWS Data Exchange owned resources by using the condition keys `aws:ResourceOrgPaths` and `aws:ResourceOrgID`.

If you use AWS Data Exchange in your environment, the service creates and interacts with resources such as Amazon S3 buckets owned by the service account. For example, AWS Data Exchange sends requests to Amazon S3 buckets owned by the AWS Data Exchange service on behalf of the IAM principal (user or role) invoking the AWS Data Exchange APIs. In that case, using `aws:ResourceAccount`, `aws:ResourceOrgPaths`, or `aws:ResourceOrgID` in a policy, without accounting for AWS Data Exchange owned resources, denies access to the buckets owned by the service account.

- The statement, `DenyAllAwsResourcesOutsideAccountExceptS3`, uses the `NotAction` element with the [Deny](#) effect which explicitly denies access to every action not listed in the statement that also do not belong to the listed account. The `NotAction` element indicates the exceptions to this statement. These actions are the exception to this statement because if the actions are performed on resources created by AWS Data Exchange, the policy denies them.
- The statement, `DenyAllS3ResoucesOutsideAccountExceptDataExchange`, uses a combination of the `ResourceAccount` and `CalledVia` conditions to deny access to the three Amazon S3 actions excluded in the previous statement. The statement denies the actions if resources do not belong in the listed account and if the calling service is not AWS Data Exchange. The statement does not deny the actions if either the resource belongs to the listed account or the listed service principal, `dataexchange.amazonaws.com`, performs the operations.

⚠ Important

This policy does not allow any actions. It uses the Deny effect which explicitly denies access to all of the resources listed in the statement that do not belong to the listed account. Use this policy in combination with other policies that allow access to specific resources.

The following example shows how you can configure the policy to allow access to the required Amazon S3 buckets.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "DenyAllAwsReourcesOutsideAccountExceptAmazonS3",
      "Effect": "Deny",
      "NotAction": [
        "s3:GetObject",
        "s3:PutObject",
        "s3:PutObjectAcl"
      ],
      "Resource": "*",
      "Condition": {
        "StringNotEquals": {
          "aws:ResourceAccount": [
            "111122223333"
          ]
        }
      }
    },
    {
      "Sid": "DenyAllS3ResourcesOutsideAccountExceptDataExchange",
      "Effect": "Deny",
      "Action": [
        "s3:GetObject",
        "s3:PutObject",
        "s3:PutObjectAcl"
      ],
      "Resource": "*",
      "Condition": {
        "StringNotEquals": {
          "aws:ResourceAccount": [
```

```

        "datapipeline:PollForTask",
        "datapipeline:PutPipelineDefinition",
        "datapipeline:QueryObjects",
        "datapipeline:RemoveTags",
        "datapipeline:ReportTaskProgress",
        "datapipeline:ReportTaskRunnerHeartbeat",
        "datapipeline:SetStatus",
        "datapipeline:SetTaskStatus",
        "datapipeline:ValidatePipelineDefinition"
    ],
    "Resource": ["*"],
    "Condition": {
        "StringNotEquals": {"datapipeline:PipelineCreator": "${aws:userid}"}
    }
}
]
}

```

Amazon DynamoDB: Allows access to a specific table

This example shows how you might create an identity-based policy that allows full access to the MyTable DynamoDB table. This policy grants the permissions necessary to complete this action programmatically from the AWS API or AWS CLI. To use this policy, replace the *italicized placeholder text* in the example policy with your own information. Then, follow the directions in [create a policy](#) or [edit a policy](#).

Important

This policy allows all actions that can be performed on a DynamoDB table. To review these actions, see [DynamoDB API Permissions: Actions, Resources, and Conditions Reference](#) in the *Amazon DynamoDB Developer Guide*. You could provide the same permissions by listing each individual action. However, if you use the wildcard (*) in the Action element, such as "dynamodb:List*", then you don't have to update your policy if DynamoDB adds a new List action.

This policy allows actions only on DynamoDB tables that exist with the specified name. To allow your users Read access to everything in DynamoDB, you can also attach the [AmazonDynamoDBReadOnlyAccess](#) AWS managed policy.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "ListAndDescribe",
      "Effect": "Allow",
      "Action": [
        "dynamodb:List*",
        "dynamodb:DescribeReservedCapacity*",
        "dynamodb:DescribeLimits",
        "dynamodb:DescribeTimeToLive"
      ],
      "Resource": "*"
    },
    {
      "Sid": "SpecificTable",
      "Effect": "Allow",
      "Action": [
        "dynamodb:BatchGet*",
        "dynamodb:DescribeStream",
        "dynamodb:DescribeTable",
        "dynamodb:Get*",
        "dynamodb:Query",
        "dynamodb:Scan",
        "dynamodb:BatchWrite*",
        "dynamodb:CreateTable",
        "dynamodb>Delete*",
        "dynamodb:Update*",
        "dynamodb:PutItem"
      ],
      "Resource": "arn:aws:dynamodb:*:*:table/MyTable"
    }
  ]
}
```

Amazon DynamoDB: Allows access to specific attributes

This example shows how you might create an identity-based policy that allows access to the specific DynamoDB attributes. This policy grants the permissions necessary to complete this action programmatically from the AWS API or AWS CLI. To use this policy, replace the *italicized placeholder text* in the example policy with your own information. Then, follow the directions in [create a policy](#) or [edit a policy](#).

The `dynamodb:Select` requirement prevents the API action from returning any attributes that aren't allowed, such as from an index projection. To learn more about DynamoDB condition keys, see [Specifying Conditions: Using Condition Keys](#) in the *Amazon DynamoDB Developer Guide*. To learn about using multiple conditions or multiple condition keys within the `Condition` block of an IAM policy, see [Multiple values in a condition](#).

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "dynamodb:GetItem",
        "dynamodb:BatchGetItem",
        "dynamodb:Query",
        "dynamodb:PutItem",
        "dynamodb:UpdateItem",
        "dynamodb>DeleteItem",
        "dynamodb:BatchWriteItem"
      ],
      "Resource": ["arn:aws:dynamodb:*:*:table/table-name"],
      "Condition": {
        "ForAllValues:StringEquals": {
          "dynamodb:Attributes": [
            "column-name-1",
            "column-name-2",
            "column-name-3"
          ]
        },
        "StringEqualsIfExists": {"dynamodb:Select": "SPECIFIC_ATTRIBUTES"}
      }
    }
  ]
}
```

Amazon DynamoDB: Allows item-level access to DynamoDB based on an Amazon Cognito ID

This example shows how you might create an identity-based policy that allows item-level access to the `MyTable` DynamoDB table based on an Amazon Cognito identity pool user ID. This policy grants the permissions necessary to complete this action programmatically from the AWS API or

AWS CLI. To use this policy, replace the *italicized placeholder text* in the example policy with your own information. Then, follow the directions in [create a policy](#) or [edit a policy](#).

To use this policy, you must structure your DynamoDB table so the Amazon Cognito identity pool user ID is the partition key. For more information, see [Creating a Table](#) in the *Amazon DynamoDB Developer Guide*.

To learn more about DynamoDB condition keys, see [Specifying Conditions: Using Condition Keys](#) in the *Amazon DynamoDB Developer Guide*.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "dynamodb:DeleteItem",
        "dynamodb:GetItem",
        "dynamodb:PutItem",
        "dynamodb:Query",
        "dynamodb:UpdateItem"
      ],
      "Resource": ["arn:aws:dynamodb:*:*:table/MyTable"],
      "Condition": {
        "ForAllValues:StringEquals": {
          "dynamodb:LeadingKeys": ["${cognito-identity.amazonaws.com:sub}"]
        }
      }
    }
  ]
}
```

Amazon EC2: Attach or detach Amazon EBS volumes to EC2 instances based on tags

This example shows how you might create an identity-based policy that allows EBS volume owners to attach or detach their EBS volumes defined using the tag `VolumeUser` to EC2 instances that are tagged as development instances (`Department=Development`). This policy grants the permissions necessary to complete this action programmatically from the AWS API or AWS CLI. To use this policy, replace the *italicized placeholder text* in the example policy with your own information. Then, follow the directions in [create a policy](#) or [edit a policy](#).

For more information about creating IAM policies to control access to Amazon EC2 resources, see [Controlling Access to Amazon EC2 Resources](#) in the *Amazon EC2 User Guide for Linux Instances*.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "ec2:AttachVolume",
        "ec2:DetachVolume"
      ],
      "Resource": "arn:aws:ec2:*:*:instance/*",
      "Condition": {
        "StringEquals": {"aws:ResourceTag/Department": "Development"}
      }
    },
    {
      "Effect": "Allow",
      "Action": [
        "ec2:AttachVolume",
        "ec2:DetachVolume"
      ],
      "Resource": "arn:aws:ec2:*:*:volume/*",
      "Condition": {
        "StringEquals": {"aws:ResourceTag/VolumeUser": "${aws:username}"}
      }
    }
  ]
}
```

Amazon EC2: Allows launching EC2 instances in a specific subnet, programmatically and in the console

This example shows how you might create an identity-based policy that allows listing information for all EC2 objects and launching EC2 instances in a specific subnet. This policy defines permissions for programmatic and console access. To use this policy, replace the *italicized placeholder text* in the example policy with your own information. Then, follow the directions in [create a policy](#) or [edit a policy](#).

```
{
  "Version": "2012-10-17",
```

```

"Statement": [
  {
    "Effect": "Allow",
    "Action": [
      "ec2:Describe*",
      "ec2:GetConsole*"
    ],
    "Resource": "*"
  },
  {
    "Effect": "Allow",
    "Action": "ec2:RunInstances",
    "Resource": [
      "arn:aws:ec2:*:*:subnet/subnet-subnet-id",
      "arn:aws:ec2:*:*:network-interface/*",
      "arn:aws:ec2:*:*:instance/*",
      "arn:aws:ec2:*:*:volume/*",
      "arn:aws:ec2:*:*:image/ami-*",
      "arn:aws:ec2:*:*:key-pair/*",
      "arn:aws:ec2:*:*:security-group/*"
    ]
  }
]
}

```

Amazon EC2: Allows managing EC2 security groups with a specific tag key-value pair programmatically and in the console

This example shows how you might create an identity-based policy that grants users permission to take certain actions for security groups that have the same tag. This policy grants permissions to view security groups in the Amazon EC2 console, add and remove inbound and outbound rules, and list and modify rule descriptions for existing security groups with the tag `Department=Test`. This policy defines permissions for programmatic and console access. To use this policy, replace the *italicized placeholder text* in the example policy with your own information. Then, follow the directions in [create a policy](#) or [edit a policy](#).

```

{
  "Version": "2012-10-17",
  "Statement": [{
    "Effect": "Allow",
    "Action": [
      "ec2:DescribeSecurityGroups",

```

```

        "ec2:DescribeSecurityGroupRules",
        "ec2:DescribeTags"
    ],
    "Resource": "*"
  },
  {
    "Effect": "Allow",
    "Action": [
      "ec2:AuthorizeSecurityGroupIngress",
      "ec2:RevokeSecurityGroupIngress",
      "ec2:AuthorizeSecurityGroupEgress",
      "ec2:RevokeSecurityGroupEgress",
      "ec2:ModifySecurityGroupRules",
      "ec2:UpdateSecurityGroupRuleDescriptionsIngress",
      "ec2:UpdateSecurityGroupRuleDescriptionsEgress"
    ],
    "Resource": [
      "arn:aws:ec2:region:111122223333:security-group/*"
    ],
    "Condition": {
      "StringEquals": {
        "aws:ResourceTag/Department": "Test"
      }
    }
  },
  {
    "Effect": "Allow",
    "Action": [
      "ec2:ModifySecurityGroupRules"
    ],
    "Resource": [
      "arn:aws:ec2:region:111122223333:security-group-rule/*"
    ]
  }
]
}

```

Amazon EC2: Allows starting or stopping EC2 instances a user has tagged, programmatically and in the console

This example shows how you might create an identity-based policy that allows an IAM user to start or stop EC2 instances, but only if the instance tag `Owner` has the value of that user's user name. This policy defines permissions for programmatic and console access.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "ec2:StartInstances",
        "ec2:StopInstances"
      ],
      "Resource": "arn:aws:ec2:*:*:instance/*",
      "Condition": {
        "StringEquals": {
          "aws:ResourceTag/Owner": "${aws:username}"
        }
      }
    },
    {
      "Effect": "Allow",
      "Action": "ec2:DescribeInstances",
      "Resource": "*"
    }
  ]
}
```

EC2: Start or stop instances based on tags

This example shows how you might create an identity-based policy that allows starting or stopping instances with the tag key–value pair `Project = DataAnalytics`, but only by principals with the tag key–value pair `Department = Data`. This policy grants the permissions necessary to complete this action programmatically from the AWS API or AWS CLI. To use this policy, replace the *italicized placeholder text* in the example policy with your own information. Then, follow the directions in [create a policy](#) or [edit a policy](#).

The condition in the policy returns true if both parts of the condition are true. The instance must have the `Project=DataAnalytics` tag. In addition, the IAM principal (user or role) making the request must have the `Department=Data` tag.

Note

As a best practice, attach policies with the `aws:PrincipalTag` condition key to IAM groups, for the case where some users might have the specified tag and some might not.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "StartStopIfTags",
      "Effect": "Allow",
      "Action": [
        "ec2:StartInstances",
        "ec2:StopInstances"
      ],
      "Resource": "arn:aws:ec2:region:account-id:instance/*",
      "Condition": {
        "StringEquals": {
          "aws:ResourceTag/Project": "DataAnalytics",
          "aws:PrincipalTag/Department": "Data"
        }
      }
    }
  ]
}
```

EC2: Start or stop instances based on matching principal and resource tags

This example shows how you might create an identity-based policy that allows a principal to start or stop an Amazon EC2 instance when the instance's resource tag and the principal's tag have the same value for the tag key `CostCenter`. This policy grants the permissions necessary to complete this action programmatically from the AWS API or AWS CLI. To use this policy, replace the *italicized placeholder text* in the example policy with your own information. Then, follow the directions in [create a policy](#) or [edit a policy](#).

Note

As a best practice, attach policies with the `aws:PrincipalTag` condition key to IAM groups, for the case where some users might have the specified tag and some might not.

```
{
  "Version": "2012-10-17",
  "Statement": {
    "Effect": "Allow",
    "Action": [
      "ec2:startInstances",
      "ec2:stopInstances"
    ],
    "Resource": "*",
    "Condition": {"StringEquals":
      {"aws:ResourceTag/CostCenter": "${aws:PrincipalTag/CostCenter"}
    }}
  }
}
```

Amazon EC2: Allows full EC2 access within a specific Region, programmatically and in the console

This example shows how you might create an identity-based policy that allows full EC2 access within a specific Region. This policy defines permissions for programmatic and console access. To use this policy, replace the *italicized placeholder text* in the example policy with your own information. Then, follow the directions in [create a policy](#) or [edit a policy](#). For a list of Region codes, see [Available Regions](#) in the *Amazon EC2 User Guide*.

Alternatively, you can use the global condition key [aws:RequestedRegion](#), which is supported by all Amazon EC2 API actions. For more information, see [Example: Restricting access to a specific Region](#) in the *Amazon EC2 User Guide*.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Action": "ec2:*",
      "Resource": "*",
      "Effect": "Allow",
      "Condition": {
        "StringEquals": {
          "ec2:Region": "us-east-2"
        }
      }
    }
  ]
}
```

```
}
```

Amazon EC2: Allows starting or stopping an EC2 instance and modifying a security group, programmatically and in the console

This example shows how you might create an identity-based policy that allows starting or stopping a specific EC2 instance and modifying a specific security group. This policy defines permissions for programmatic and console access. To use this policy, replace the *italicized placeholder text* in the example policy with your own information. Then, follow the directions in [create a policy](#) or [edit a policy](#).

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Action": [
        "ec2:DescribeInstances",
        "ec2:DescribeSecurityGroups",
        "ec2:DescribeSecurityGroupReferences",
        "ec2:DescribeStaleSecurityGroups"
      ],
      "Resource": "*",
      "Effect": "Allow"
    },
    {
      "Action": [
        "ec2:AuthorizeSecurityGroupEgress",
        "ec2:AuthorizeSecurityGroupIngress",
        "ec2:RevokeSecurityGroupEgress",
        "ec2:RevokeSecurityGroupIngress",
        "ec2:StartInstances",
        "ec2:StopInstances"
      ],
      "Resource": [
        "arn:aws:ec2:*:*:instance/i-instance-id",
        "arn:aws:ec2:*:*:security-group/sg-security-group-id"
      ],
      "Effect": "Allow"
    }
  ]
}
```

Amazon EC2: Requires MFA (GetSessionToken) for specific EC2 operations

This example shows how you might create an identity-based policy that allows full access to all AWS API operations in Amazon EC2. However, it explicitly denies access to `StopInstances` and `TerminateInstances` API operations if the user is not authenticated using [multi-factor authentication \(MFA\)](#). To do this programmatically, the user must include optional `SerialNumber` and `TokenCode` values while calling the `GetSessionToken` operation. This operation returns temporary credentials that were authenticated using MFA. To learn more about `GetSessionToken`, see [GetSessionToken—temporary credentials for users in untrusted environments](#).

What does this policy do?

- The `AllowAllActionsForEC2` statement allows all Amazon EC2 actions.
- The `DenyStopAndTerminateWhenMFAIsNotPresent` statement denies the `StopInstances` and `TerminateInstances` actions when the MFA context is missing. This means that the actions are denied when the multi-factor authentication context is missing (meaning MFA was not used). A deny overrides the allow.

Note

The condition check for `MultiFactorAuthPresent` in the Deny statement should not be a `{"Bool": {"aws:MultiFactorAuthPresent": false}}` because that key is not present and cannot be evaluated when MFA is not used. So instead, use the `BoolIfExists` check to see whether the key is present before checking the value. For more information, see [...IfExists condition operators](#).

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "AllowAllActionsForEC2",
      "Effect": "Allow",
      "Action": "ec2:*",
      "Resource": "*"
    },
    {
      "Sid": "DenyStopAndTerminateWhenMFAIsNotPresent",
```

```
    "Effect": "Deny",
    "Action": [
      "ec2:StopInstances",
      "ec2:TerminateInstances"
    ],
    "Resource": "*",
    "Condition": {
      "BoolIfExists": {"aws:MultiFactorAuthPresent": false}
    }
  }
]
```

Amazon EC2: Limits terminating EC2 instances to an IP address range

This example shows how you might create an identity-based policy that limits EC2 instances by allowing the action, but explicitly denying access when the request comes from outside the specified IP range. The policy is useful when the IP addresses for your company are within the specified ranges. This policy grants the permissions necessary to complete this action programmatically from the AWS API or AWS CLI. To use this policy, replace the *italicized placeholder text* in the example policy with your own information. Then, follow the directions in [create a policy](#) or [edit a policy](#).

If this policy is used in combination with other policies that allow the `ec2:TerminateInstances` action (such as the [AmazonEC2FullAccess](#) AWS managed policy), then access is denied. This is because an explicit deny statement takes precedence over allow statements. For more information, see [the section called "Determining whether a request is allowed or denied within an account"](#).

Important

The `aws:SourceIp` condition key denies access to an AWS service, such as AWS CloudFormation, that makes calls on your behalf. For more information about using the `aws:SourceIp` condition key, see [AWS global condition context keys](#).

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
```

```

    "Action": ["ec2:TerminateInstances"],
    "Resource": ["*"]
  },
  {
    "Effect": "Deny",
    "Action": ["ec2:TerminateInstances"],
    "Condition": {
      "NotIpAddress": {
        "aws:SourceIp": [
          "192.0.2.0/24",
          "203.0.113.0/24"
        ]
      }
    },
    "Resource": ["*"]
  }
]
}

```

IAM: Access the policy simulator API

This example shows how you might create an identity-based policy that allows using the policy simulator API for policies attached to a user, group, or role in the current AWS account. This policy also allows access to simulate less sensitive policies passed to the API as strings. This policy grants the permissions necessary to complete this action programmatically from the AWS API or AWS CLI.

```

{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Action": [
        "iam:GetContextKeysForCustomPolicy",
        "iam:GetContextKeysForPrincipalPolicy",
        "iam:SimulateCustomPolicy",
        "iam:SimulatePrincipalPolicy"
      ],
      "Effect": "Allow",
      "Resource": "*"
    }
  ]
}

```

Note

To allow a user to access the policy simulator console to simulate policies attached to a user, group, or role in the current AWS account, see [IAM: Access the policy simulator console](#).

IAM: Access the policy simulator console

This example shows how you might create an identity-based policy that allows using the policy simulator console for policies attached to a user, group, or role in the current AWS account. This policy grants the permissions necessary to complete this action programmatically from the AWS API or AWS CLI.

You can access the IAM Policy Simulator console at: <https://policysim.aws.amazon.com/>

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Action": [
        "iam:GetGroup",
        "iam:GetGroupPolicy",
        "iam:GetPolicy",
        "iam:GetPolicyVersion",
        "iam:GetRole",
        "iam:GetRolePolicy",
        "iam:GetUser",
        "iam:GetUserPolicy",
        "iam:ListAttachedGroupPolicies",
        "iam:ListAttachedRolePolicies",
        "iam:ListAttachedUserPolicies",
        "iam:ListGroups",
        "iam:ListGroupPolicies",
        "iam:ListGroupsForUser",
        "iam:ListRolePolicies",
        "iam:ListRoles",
        "iam:ListUserPolicies",
        "iam:ListUsers"
      ],
      "Effect": "Allow",
      "Resource": "*"
    }
  ]
}
```

```
    }
  ]
}
```

IAM: Assume roles that have a specific tag

This example shows how you might create an identity-based policy that allows an IAM user to assume roles with the tag key-value pair `Project = ExampleCorpABC`. This policy grants the permissions necessary to complete this action programmatically from the AWS API or AWS CLI. To use this policy, replace the *italicized placeholder text* in the example policy with your own information. Then, follow the directions in [create a policy](#) or [edit a policy](#).

If a role with this tag exists in the same account as the user, then the user can assume that role. If a role with this tag exists in an account other than the user's, it requires additional permissions. The cross-account role's trust policy must also allow the user or all members of the user's account to assume the role. For information about using roles for cross-account access, see [Providing access to an IAM user in another AWS account that you own](#).

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "AssumeTaggedRole",
      "Effect": "Allow",
      "Action": "sts:AssumeRole",
      "Resource": "*",
      "Condition": {
        "StringEquals": {"iam:ResourceTag/Project": "ExampleCorpABC"}
      }
    }
  ]
}
```

IAM: Allows and denies access to multiple services programmatically and in the console

This example shows how you might create an identity-based policy that allows full access to several services and limited self-managing access in IAM. It also denies access to the Amazon S3 logs bucket or the Amazon EC2 `i-1234567890abcdef0` instance. This policy defines permissions for programmatic and console access. To use this policy, replace the *italicized placeholder*

text in the example policy with your own information. Then, follow the directions in [create a policy](#) or [edit a policy](#).

⚠ Warning

This policy allows full access to every action and resource in multiple services. This policy should be applied only to trusted administrators.

You can use this policy as a permissions boundary to define the maximum permissions that an identity-based policy can grant to an IAM user. For more information, see [Delegating responsibility to others using permissions boundaries](#). When the policy is used as a permissions boundary for a user, the statements define the following boundaries:

- The `AllowServices` statement allows full access to the specified AWS services. This means that the user's actions in these services are limited only by the permissions policies that are attached to the user.
- The `AllowIAMConsoleForCredentials` statement allows access to list all IAM users. This access is necessary to navigate the **Users** page in the AWS Management Console. It also allows viewing the password requirements for the account, which is necessary for the user to change their own password.
- The `AllowManageOwnPasswordAndAccessKeys` statement allows the users manage only their own console password and programmatic access keys. This is important because if another policy gives a user full IAM access, that user could then change their own or other users' permissions. This statement prevents that from happening.
- The `DenyS3Logs` statement explicitly denies access to the logs bucket. This policy enforces company restrictions on the user.
- The `DenyEC2Production` statement explicitly denies access to the `i-1234567890abcdef0` instance.

This policy does not allow access to other services or actions. When the policy is used as a permissions boundary on a user, even if other policies attached to the user allow those actions, AWS denies the request.

```
{
  "Version": "2012-10-17",
  "Statement": [
```

```

{
  "Sid": "AllowServices",
  "Effect": "Allow",
  "Action": [
    "s3:*",
    "cloudwatch:*",
    "ec2:*"
  ],

IAM: Add a specific tag to a user with a specific tag

This example shows how you might create an identity-based policy that allows adding the tag key `Department` with the tag values `Marketing`, `Development`, or `QualityAssurance` to an IAM user. That user must already include the tag key–value pair `JobFunction = manager`. You can use this policy to require that a manager belong to only one of three departments. This policy defines permissions for programmatic and console access. To use this policy, replace the *italicized placeholder text* in the example policy with your own information. Then, follow the directions in [create a policy](#) or [edit a policy](#).

The `ListTagsForAllUsers` statement allows the viewing of tags for all users in your account.

The first condition in the `TagManagerWithSpecificDepartment` statement uses the `StringEquals` condition operator. The condition returns true if both parts of the condition are true. The user to be tagged must already have the `JobFunction=Manager` tag. The request must include the `Department` tag key with one of the listed tag values.

The second condition uses the `ForAllValues:StringEquals` condition operator. The condition returns true if all of the tag keys in the request match the key in the policy. This means that the only tag key in the request must be `Department`. For more information about using `ForAllValues`, see [Multivalued context keys](#).

```

{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "ListTagsForAllUsers",
      "Effect": "Allow",
      "Action": [
        "iam:ListUserTags",
        "iam:ListUsers"
      ],
      "Resource": "*"
    },
    {
      "Sid": "TagManagerWithSpecificDepartment",
      "Effect": "Allow",

```

```

    "Action": "iam:TagUser",
    "Resource": "*",
    "Condition": {"StringEquals": {
      "iam:ResourceTag/JobFunction": "Manager",
      "aws:RequestTag/Department": [
        "Marketing",
        "Development",
        "QualityAssurance"
      ]
    },
    "ForAllValues:StringEquals": {"aws:TagKeys": "Department"}
  }
}
]
}

```

IAM: Add a specific tag with specific values

This example shows how you might create an identity-based policy that allows adding only the tag key `CostCenter` and either the tag value `A-123` or the tag value `B-456` to any IAM user or role. You can use this policy to limit tagging to a specific tag key and set of tag values. This policy defines permissions for programmatic and console access. To use this policy, replace the *italicized placeholder text* in the example policy with your own information. Then, follow the directions in [create a policy](#) or [edit a policy](#).

The `ConsoleDisplay` statement allows the viewing of tags for all users and roles in your account.

The first condition in the `AddTag` statement uses the `StringEquals` condition operator. The condition returns true if the request includes the `CostCenter` tag key with one of the listed tag values.

The second condition uses the `ForAllValues:StringEquals` condition operator. The condition returns true if all of the tag keys in the request match the key in the policy. This means that the only tag key in the request must be `CostCenter`. For more information about using `ForAllValues`, see [Multivalued context keys](#).

```

{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "ConsoleDisplay",

```

```

    "Effect": "Allow",
    "Action": [
      "iam:GetRole",
      "iam:GetUser",
      "iam:ListRoles",
      "iam:ListRoleTags",
      "iam:ListUsers",
      "iam:ListUserTags"
    ],
    "Resource": "*"
  },
  {
    "Sid": "AddTag",
    "Effect": "Allow",
    "Action": [
      "iam:TagUser",
      "iam:TagRole"
    ],
    "Resource": "*",
    "Condition": {
      "StringEquals": {
        "aws:RequestTag/CostCenter": [
          "A-123",
          "B-456"
        ]
      },
      "ForAllValues:StringEquals": {"aws:TagKeys": "CostCenter"}
    }
  }
]
}

```

IAM: Create new users only with specific tags

This example shows how you might create an identity-based policy that allows the creation of IAM users but only with one or both of the Department and JobFunction tag keys. The Department tag key must have either the Development or QualityAssurance tag value. The JobFunction tag key must have the Employee tag value. You can use this policy to require that new users have a specific job function and department. This policy grants the permissions necessary to complete this action programmatically from the AWS API or AWS CLI. To use this policy, replace the *italicized placeholder text* in the example policy with your own information. Then, follow the directions in [create a policy](#) or [edit a policy](#).

The first condition in the statement uses the `StringEqualsIfExists` condition operator. If a tag with the `Department` or `JobFunction` key is present in the request, then the tag must have the specified value. If neither key is present, then this condition is evaluated as true. The only way that the condition evaluates as false is if one of the specified condition keys is present in the request, but has a different value than those allowed. For more information about using `IfExists`, see [...IfExists condition operators](#).

The second condition uses the `ForAllValues:StringEquals` condition operator. The condition returns true if there's a match between every one of the specified tag keys specified in the request, and at least one value in the policy. This means that all of the tags in the request must be in this list. However, the request can include only one of the tags in the list. For example, you can create an IAM user with only the `Department=QualityAssurance` tag. However, you cannot create an IAM user with the `JobFunction=employee` tag and the `Project=core` tag. For more information about using `ForAllValues`, see [Multivalued context keys](#).

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "TagUsersWithOnlyTheseTags",
      "Effect": "Allow",
      "Action": [
        "iam:CreateUser",
        "iam:TagUser"
      ],
      "Resource": "*",
      "Condition": {
        "StringEqualsIfExists": {
          "aws:RequestTag/Department": [
            "Development",
            "QualityAssurance"
          ],
          "aws:RequestTag/JobFunction": "Employee"
        },
        "ForAllValues:StringEquals": {
          "aws:TagKeys": [
            "Department",
            "JobFunction"
          ]
        }
      }
    }
  ]
}
```

```

    }
  ]
}

```

IAM: Generate and retrieve IAM credential reports

This example shows how you might create an identity-based policy that allows users to generate and download a report that lists all IAM users in their AWS account. The report includes the status of the users' credentials, including passwords, access keys, MFA devices, and signing certificates. This policy grants the permissions necessary to complete this action programmatically from the AWS API or AWS CLI.

For more information about credential reports, see [Getting credential reports for your AWS account](#).

```

{
  "Version": "2012-10-17",
  "Statement": {
    "Effect": "Allow",
    "Action": [
      "iam:GenerateCredentialReport",
      "iam:GetCredentialReport"
    ],
    "Resource": "*"
  }
}

```

IAM: Allows managing a group's membership programmatically and in the console

This example shows how you might create an identity-based policy that allows updating the membership of the group called MarketingTeam. This policy defines permissions for programmatic and console access. To use this policy, replace the *italicized placeholder text* in the example policy with your own information. Then, follow the directions in [create a policy](#) or [edit a policy](#).

What does this policy do?

- The ViewGroups statement allows the user to list all the users and groups in the AWS Management Console. It also allows the user to view basic information about the users in the

account. These permissions must be in their own statement because they do not support or do not need to specify a resource ARN. Instead the permissions specify "Resource" : "*".

- The `ViewEditThisGroup` statement allows the user to view information about the `MarketingTeam` group, and to add and remove users from that group.

This policy does not allow the user to view or edit the permissions of the users or the `MarketingTeam` group.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "ViewGroups",
      "Effect": "Allow",
      "Action": [
        "iam:ListGroups",
        "iam:ListUsers",
        "iam:GetUser",
        "iam:ListGroupsForUser"
      ],
      "Resource": "*"
    },
    {
      "Sid": "ViewEditThisGroup",
      "Effect": "Allow",
      "Action": [
        "iam:AddUserToGroup",
        "iam:RemoveUserFromGroup",
        "iam:GetGroup"
      ],
      "Resource": "arn:aws:iam::*:group/MarketingTeam"
    }
  ]
}
```

IAM: Manage a specific tag

This example shows how you might create an identity-based policy that allows adding and removing the IAM tag with the tag key `Department` from IAM entities (users and roles). This policy does not limit the value of the `Department` tag. This policy grants the permissions necessary to complete this action programmatically from the AWS API or AWS CLI. To use this policy, replace the

italicized placeholder text in the example policy with your own information. Then, follow the directions in [create a policy](#) or [edit a policy](#).

```
{
  "Version": "2012-10-17",
  "Statement": {
    "Effect": "Allow",
    "Action": [
      "iam:TagUser",
      "iam:TagRole",
      "iam:UntagUser",
      "iam:UntagRole"
    ],
    "Resource": "*",
    "Condition": {"ForAllValues:StringEquals": {"aws:TagKeys": "Department"}}
  }
}
```

IAM: Pass an IAM role to a specific AWS service

This example shows how you might create an identity-based policy that allows passing any IAM service role to the Amazon CloudWatch service. This policy grants the permissions necessary to complete this action programmatically from the AWS API or AWS CLI. To use this policy, replace the *italicized placeholder text* in the example policy with your own information. Then, follow the directions in [create a policy](#) or [edit a policy](#).

A service role is an IAM role that specifies an AWS service as the principal that can assume the role. This allows the service to assume the role and access resources in other services on your behalf. To allow Amazon CloudWatch to assume the role that you pass, you must specify the `cloudwatch.amazonaws.com` service principal as the principal in the trust policy of your role. The service principal is defined by the service. To learn the service principal for a service, see the documentation for that service. For some services, see [AWS services that work with IAM](#) and look for the services that have **Yes** in the **Service-Linked Role** column. Choose a **Yes** with a link to view the service-linked role documentation for that service. Search for `amazonaws.com` to view the service principal.

To learn more about passing a service role to a service, see [Granting a user permissions to pass a role to an AWS service](#).

```
{
```

```
"Version": "2012-10-17",
"Statement": [
  {
    "Effect": "Allow",
    "Action": "iam:PassRole",
    "Resource": "*",
    "Condition": {
      "StringEquals": {"iam:PassedToService": "cloudwatch.amazonaws.com"}
    }
  }
]
```

IAM: Allows read-only access to the IAM console without reporting

This example shows how you might create an identity-based policy that allows IAM users to perform any IAM action that begins with the string `Get` or `List`. As users work with the console, the console makes requests to IAM to list groups, users, roles, and policies, and to generate reports about those resources.

The asterisk acts as a wildcard. When you use `iam:Get*` in a policy, the resulting permissions include all IAM actions that begin with `Get`, such as `GetUser` and `GetRole`. Wildcards are useful if new types of entities are added to IAM in the future. In that case, the permissions granted by the policy automatically allow the user to list and get the details about those new entities.

This policy cannot be used to generate reports or service last accessed details. For a different policy that allows this, see [IAM: Allows read-only access to the IAM console](#).

```
{
  "Version": "2012-10-17",
  "Statement": {
    "Effect": "Allow",
    "Action": [
      "iam:Get*",
      "iam>List*"
    ],
    "Resource": "*"
  }
}
```

IAM: Allows read-only access to the IAM console

This example shows how you might create an identity-based policy that allows IAM users to perform any IAM action that begins with the string `Get`, `List`, or `Generate`. As users work with the IAM console, the console makes requests to list groups, users, roles, and policies, and to generate reports about those resources.

The asterisk acts as a wildcard. When you use `iam:Get*` in a policy, the resulting permissions include all IAM actions that begin with `Get`, such as `GetUser` and `GetRole`. Using a wildcard is beneficial, especially if new types of entities are added to IAM in the future. In that case, the permissions granted by the policy automatically allow the user to list and get the details about those new entities.

Use this policy for console access that includes permissions to generate reports or service last accessed details. For a different policy that does not allow generating actions, see [IAM: Allows read-only access to the IAM console without reporting](#).

```
{
  "Version": "2012-10-17",
  "Statement": {
    "Effect": "Allow",
    "Action": [
      "iam:Get*",
      "iam>List*",
      "iam:Generate*"
    ],
    "Resource": "*"
  }
}
```

IAM: Allows specific IAM users to manage a group programmatically and in the console

This example shows how you might create an identity-based policy that allows specific IAM users to manage the `AllUsers` group. This policy defines permissions for programmatic and console access. To use this policy, replace the *italicized placeholder text* in the example policy with your own information. Then, follow the directions in [create a policy](#) or [edit a policy](#).

What does this policy do?

- The `AllowAllUsersToListAllGroups` statement allows listing all groups. This is necessary for console access. This permission must be in its own statement because it does not support a resource ARN. Instead the permissions specify `"Resource" : "*" .`
- The `AllowAllUsersToViewAndManageThisGroup` statement allows all group actions that can be performed on the group resource type. It does not allow the `ListGroupsForUser` action, which can be performed on a user resource type and not a group resource type. For more information about the resource types that you can specify for an IAM action, see [Actions, Resources, and Condition Keys for AWS Identity and Access Management](#).
- The `LimitGroupManagementAccessToSpecificUsers` statement denies users with the specified names access to write and permissions management group actions. When a user specified in the policy attempts to make changes to the group, this statement does not deny the request. That request is allowed by the `AllowAllUsersToViewAndManageThisGroup` statement. If other users attempt to perform these operations, the request is denied. You can view the IAM actions that are defined with the **Write** or **Permissions management** access levels while creating this policy in the IAM console. To do this, switch from the **JSON** tab to the **Visual editor** tab. For more information about access levels. see [Actions, Resources, and Condition Keys for AWS Identity and Access Management](#).

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "AllowAllUsersToListAllGroups",
      "Effect": "Allow",
      "Action": "iam:ListGroups",
      "Resource": "*"
    },
    {
      "Sid": "AllowAllUsersToViewAndManageThisGroup",
      "Effect": "Allow",
      "Action": "iam:*Group*",
      "Resource": "arn:aws:iam::*:group/AllUsers"
    },
    {
      "Sid": "LimitGroupManagementAccessToSpecificUsers",
      "Effect": "Deny",
      "Action": [
        "iam:AddUserToGroup",
        "iam:CreateGroup",

```

```
        "iam:RemoveUserFromGroup",
        "iam>DeleteGroup",
        "iam:AttachGroupPolicy",
        "iam:UpdateGroup",
        "iam:DetachGroupPolicy",
        "iam>DeleteGroupPolicy",
        "iam:PutGroupPolicy"
    ],
    "Resource": "arn:aws:iam::*:group/AllUsers",
    "Condition": {
        "StringNotEquals": {
            "aws:username": [
                "srodriguez",
                "mjackson",
                "adesai"
            ]
        }
    }
}
]
```

IAM: Allows setting the account password requirements programmatically and in the console

This example shows how you might create an identity-based policy that allows a user to view and update their account's password requirements. The password requirements specify the complexity requirements and mandatory rotation periods for the account members' passwords. This policy defines permissions for programmatic and console access.

To learn how to set the account password requirements policy for your account, see [Setting an account password policy for IAM users](#).

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "iam:GetAccountPasswordPolicy",
        "iam:UpdateAccountPasswordPolicy"
      ],
      "Resource": "*"
    }
  ]
}
```

```
}  
}
```

IAM: Access the policy simulator API based on user path

This example shows how you might create an identity-based policy that allows using the policy simulator API only for those users that have the path Department/Development. This policy grants the permissions necessary to complete this action programmatically from the AWS API or AWS CLI. To use this policy, replace the *italicized placeholder text* in the example policy with your own information. Then, follow the directions in [create a policy](#) or [edit a policy](#).

```
{  
  "Version": "2012-10-17",  
  "Statement": [  
    {  
      "Action": [  
        "iam:GetContextKeysForPrincipalPolicy",  
        "iam:SimulatePrincipalPolicy"  
      ],  
      "Effect": "Allow",  
      "Resource": "arn:aws:iam::*:user/Department/Development/*"  
    }  
  ]  
}
```

Note

To create a policy that allows using the policy simulator console for those users that have the path Department/Development, see [IAM: Access the policy simulator console based on user path](#).

IAM: Access the policy simulator console based on user path

This example shows how you might create an identity-based policy that allows using the policy simulator console only for those users that have the path Department/Development. This policy grants the permissions necessary to complete this action programmatically from the AWS API or AWS CLI. To use this policy, replace the *italicized placeholder text* in the example policy with your own information. Then, follow the directions in [create a policy](#) or [edit a policy](#).

You can access the IAM Policy Simulator at: <https://policysim.aws.amazon.com/>

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Action": [
        "iam:GetPolicy",
        "iam:GetUserPolicy"
      ],
      "Effect": "Allow",
      "Resource": "*"
    },
    {
      "Action": [
        "iam:GetUser",
        "iam:ListAttachedUserPolicies",
        "iam:ListGroupsWithUser",
        "iam:ListUserPolicies",
        "iam:ListUsers"
      ],
      "Effect": "Allow",
      "Resource": "arn:aws:iam::*:user/Department/Development/*"
    }
  ]
}
```

IAM: Allows IAM users to self-manage an MFA device

This example shows how you might create an identity-based policy that allows IAM users to self-manage their [multi-factor authentication \(MFA\)](#) device. This policy grants the permissions necessary to complete this action programmatically from the AWS API or AWS CLI.

Note

If an IAM user with this policy is not MFA-authenticated, this policy denies access to all AWS actions except those necessary to authenticate using MFA. If you add these permissions for a user that is signed in to AWS, they might need to sign out and back in to see these changes.

IAM: Allows IAM users to update their own credentials programmatically and in the console

This example shows how you might create an identity-based policy that allows IAM users to update their own access keys, signing certificates, service specific credentials, and passwords. This policy defines permissions for programmatic and console access.

```

{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "iam:ListUsers",
        "iam:GetAccountPasswordPolicy"
      ],
      "Resource": "*"
    },
    {

```

```

    "Effect": "Allow",
    "Action": [
      "iam:*AccessKey*",
      "iam:ChangePassword",
      "iam:GetUser",
      "iam:*ServiceSpecificCredential*",
      "iam:*SigningCertificate*"
    ],
    "Resource": ["arn:aws:iam::*:user/${aws:username}"]
  }
]
}

```

To learn how a user can change their own password in the console, see [the section called “How an IAM user changes their own password”](#).

IAM: View service last accessed information for an Organizations policy

This example shows how you might create an identity-based policy that allows viewing service last accessed information for a specific Organizations policy. This policy allows retrieving data for the service control policy (SCP) with the p-policy123 ID. The person who generates and views the report must be authenticated using AWS Organizations management account credentials. This policy allows the requester to retrieve the data for any Organizations entity in their organization. This policy defines permissions for programmatic and console access. To use this policy, replace the *italicized placeholder text* in the example policy with your own information. Then, follow the directions in [create a policy](#) or [edit a policy](#).

For important information about last accessed information, including permissions required, troubleshooting, and supported Regions, see [Refining permissions in AWS using last accessed information](#).

```

{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "AllowOrgsReadOnlyAndIamGetReport",
      "Effect": "Allow",
      "Action": [
        "iam:GetOrganizationsAccessReport",
        "organizations:Describe*",
        "organizations:List*"

IAM: Limits managed policies that can be applied to an IAM user, group, or role

This example shows how you might create an identity-based policy that limits customer managed and AWS managed policies that can be applied to an IAM user, group, or role. This policy grants the permissions necessary to complete this action programmatically from the AWS API or AWS CLI. To use this policy, replace the *italicized placeholder text* in the example policy with your own information. Then, follow the directions in [create a policy](#) or [edit a policy](#).

```

{
  "Version": "2012-10-17",
  "Statement": {
    "Effect": "Allow",
    "Action": [
      "iam:AttachUserPolicy",
      "iam:DetachUserPolicy"
    ],
    "Resource": "*",
    "Condition": {
      "ArnEquals": {
        "iam:PolicyARN": [
          "arn:aws:iam::*:policy/policy-name-1",
          "arn:aws:iam::*:policy/policy-name-2"
        ]
      }
    }
  }
}

```

AWS: Deny access to resources outside your account except AWS managed IAM policies

Using `aws:ResourceAccount` in your identity-based policies can impact the user or the role's ability to utilize some services that require interaction with resources in accounts owned by a service.

You can create a policy with an exception to allow for AWS managed IAM policies. A service-managed account outside of your AWS Organizations owns Managed IAM Policies. There are four IAM actions that list and retrieve AWS-managed policies. Use these actions in the [NotAction](#) element of the statement. `AllowAccessToS3ResourcesInSpecificAccountsAndSpecificService1` in the policy.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "AllowAccessToResourcesInSpecificAccountsAndSpecificService1",
      "Effect": "Deny",
      "NotAction": [
        "iam:GetPolicy",
        "iam:GetPolicyVersion",
        "iam:ListEntitiesForPolicy",
        "iam:ListPolicies"
      ],
      "Resource": "*",
      "Condition": {
        "StringNotEquals": {
          "aws:ResourceAccount": [
            "111122223333"
          ]
        }
      }
    }
  ]
}
```

AWS Lambda: Allows a Lambda function to access an Amazon DynamoDB table

This example shows how you might create an identity-based policy that allows read and write access to a specific Amazon DynamoDB table. The policy also allows writing log files to CloudWatch

Logs. To use this policy, replace the *italicized placeholder text* in the example policy with your own information. Then, follow the directions in [create a policy](#) or [edit a policy](#).

To use this policy, attach the policy to a Lambda [service role](#). A service role is a role that you create in your account to allow a service to perform actions on your behalf. That service role must include AWS Lambda as the principal in the trust policy. For details about how to use this policy, see [How to Create an AWS IAM Policy to Grant AWS Lambda Access to an Amazon DynamoDB Table](#) in the AWS Security Blog.

```

    ],
    "Effect": "Allow",
    "Resource": "*",
    "Condition": {
        "StringEqualsIgnoreCase": {"rds:es-tag/Owner": "${aws:username}"}
    }
}
]
}

```

Amazon S3: Allows Amazon Cognito users to access objects in their bucket

This example shows how you might create an identity-based policy that allows Amazon Cognito users to access objects in a specific S3 bucket. This policy allows access only to objects with a name that includes `cognito`, the name of the application, and the federated user's ID, represented by the `${cognito-identity.amazonaws.com:sub}` variable. This policy grants the permissions necessary to complete this action programmatically from the AWS API or AWS CLI. To use this policy, replace

the *italicized placeholder text* in the example policy with your own information. Then, follow the directions in [create a policy](#) or [edit a policy](#).

Note

The 'sub' value used in the object key is not the user's sub value in the User Pool, it is the identity id associated with the user in the Identity Pool.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "ListYourObjects",
      "Effect": "Allow",
      "Action": "s3:ListBucket",
      "Resource": [
        "arn:aws:s3:::bucket-name"
      ],
      "Condition": {
        "StringLike": {
          "s3:prefix": [
            "cognito/application-name/${cognito-identity.amazonaws.com:sub}/*"
          ]
        }
      }
    },
    {
      "Sid": "ReadWriteDeleteYourObjects",
      "Effect": "Allow",
      "Action": [
        "s3:DeleteObject",
        "s3:GetObject",
        "s3:PutObject"
      ],
      "Resource": [
        "arn:aws:s3:::bucket-name/cognito/application-name/${cognito-identity.amazonaws.com:sub}/*"
      ]
    }
  ]
}
```

Amazon Cognito provides authentication, authorization, and user management for your web and mobile apps. Your users can sign in directly with a user name and password, or through a third party such as Facebook, Amazon, or Google.

The two main components of Amazon Cognito are user pools and identity pools. User pools are user directories that provide sign-up and sign-in options for your app users. Identity pools enable you to grant your users access to other AWS services. You can use identity pools and user pools separately or together.

For more information about Amazon Cognito, see [Amazon Cognito User Guide](#).

Amazon S3: Allows federated users access to their S3 home directory, programmatically and in the console

This example shows how you might create an identity-based policy that allows federated users to access their own home directory bucket object in S3. The home directory is a bucket that includes a home folder and folders for individual federated users. This policy defines permissions for programmatic and console access. To use this policy, replace the *italicized placeholder text* in the example policy with your own information. Then, follow the directions in [create a policy](#) or [edit a policy](#).

The `${aws:userid}` variable in this policy resolves to `role-id:specified-name`. The `role-id` part of the federated user ID is a unique identifier assigned to the federated user's role during creation. For more information, see [Unique identifiers](#). The `specified-name` is the [RoleSessionName parameter](#) passed to the `AssumeRoleWithWebIdentity` request when the federated user assumed their role.

You can view the role ID using the AWS CLI command `aws iam get-role --role-name specified-name`. For example, imagine that you specify the friendly name John and the CLI returns the role ID `AROAXXT2NJT7D3SIQN7Z6`. In this case, the federated user ID is `AROAXXT2NJT7D3SIQN7Z6:John`. This policy then allows the federated user John to access the Amazon S3 bucket with prefix `AROAXXT2NJT7D3SIQN7Z6:John`.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "S3ConsoleAccess",
      "Effect": "Allow",
```

```

    "Action": [
      "s3:GetAccountPublicAccessBlock",
      "s3:GetBucketAcl",
      "s3:GetBucketLocation",
      "s3:GetBucketPolicyStatus",
      "s3:GetBucketPublicAccessBlock",
      "s3:ListAccessPoints",
      "s3:ListAllMyBuckets"
    ],
    "Resource": "*"
  },
  {
    "Sid": "ListObjectsInBucket",
    "Effect": "Allow",
    "Action": "s3:ListBucket",
    "Resource": "arn:aws:s3:::bucket-name",
    "Condition": {
      "StringLike": {
        "s3:prefix": [
          "",
          "home/",
          "home/${aws:userid}/*"
        ]
      }
    }
  },
  {
    "Effect": "Allow",
    "Action": "s3:*",
    "Resource": [
      "arn:aws:s3:::bucket-name/home/${aws:userid}",
      "arn:aws:s3:::bucket-name/home/${aws:userid}/*"
    ]
  }
]
}

```

Amazon S3: S3 Bucket access, but production bucket denied without recent MFA

This example shows how you might create an identity-based policy that allows an Amazon S3 administrator to access any bucket, including updating, adding, and deleting objects. However, it explicitly denies access to the Production bucket if the user has not signed in using [multi-factor authentication \(MFA\)](#) within the last thirty minutes. This policy grants the permissions necessary

to perform this action in the console or programmatically using the AWS CLI or AWS API. To use this policy, replace the *italicized placeholder text* in the example policy with your own information. Then, follow the directions in [create a policy](#) or [edit a policy](#).

This policy never allows programmatic access to the Production bucket using long-term user access keys. This is accomplished using the `aws:MultiFactorAuthAge` condition key with the `NumericGreaterThanIfExists` condition operator. This policy condition returns `true` if MFA is not present or if the age of the MFA is greater than 30 minutes. In those situations, access is denied. To access the Production bucket programmatically, the S3 administrator must use temporary credentials that were generated in the last 30 minutes using the [GetSessionToken](#) API operation.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "ListAllS3Buckets",

    },
    {
      "Sid": "AllowBucketLevelActions",
      "Effect": "Allow",
      "Action": [
        "s3:ListBucket",
        "s3:GetBucketLocation"
      ],
      "Resource": "arn:aws:s3::*"
    },
    {
      "Sid": "AllowBucketObjectActions",
      "Effect": "Allow",
      "Action": [
        "s3:PutObject",
        "s3:PutObjectAcl",
        "s3:GetObject",
        "s3:GetObjectAcl",
        "s3:DeleteObject"
      ],
      "Resource": "arn:aws:s3::*/*"
    },
  ],
}
```

```
{
  "Sid": "RequireMFAForProductionBucket",
  "Effect": "Deny",
  "Action": "s3:*",
  "Resource": [
    "arn:aws:s3:::Production/*",
    "arn:aws:s3:::Production"
  ],
  "Condition": {
    "NumericGreaterThanIfExists": {"aws:MultiFactorAuthAge": "1800"}
  }
}
```

Amazon S3: Allows IAM users access to their S3 home directory, programmatically and in the console

This example shows how you might create an identity-based policy that allows IAM users to access their own home directory bucket object in S3. The home directory is a bucket that includes a home folder and folders for individual users. This policy defines permissions for programmatic and console access. To use this policy, replace the *italicized placeholder text* in the example policy with your own information. Then, follow the directions in [create a policy](#) or [edit a policy](#).

This policy will not work when using IAM roles because the `aws:username` variable is not available when using IAM roles. For details about principal key values, see [Principal key values](#).

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "S3ConsoleAccess",
      "Effect": "Allow",
      "Action": [
        "s3:GetAccountPublicAccessBlock",
        "s3:GetBucketAcl",
        "s3:GetBucketLocation",
        "s3:GetBucketPolicyStatus",
        "s3:GetBucketPublicAccessBlock",
        "s3:ListAccessPoints",
        "s3:ListAllMyBuckets"
      ],
    }
  ],
}
```

```

    "Resource": "*"
  },
  {
    "Sid": "ListObjectsInBucket",
    "Effect": "Allow",
    "Action": "s3:ListBucket",
    "Resource": "arn:aws:s3:::bucket-name",
    "Condition": {
      "StringLike": {
        "s3:prefix": [
          "",
          "home/",
          "home/${aws:username}/*"
        ]
      }
    }
  },
  {
    "Effect": "Allow",
    "Action": "s3:*",
    "Resource": [
      "arn:aws:s3:::bucket-name/home/${aws:username}",
      "arn:aws:s3:::bucket-name/home/${aws:username}/*"
    ]
  }
]
}

```

Amazon S3: Restrict management to a specific S3 bucket

This example shows how you might create an identity-based policy that restricts management of an Amazon S3 bucket to that specific bucket. This policy grants permission to perform all Amazon S3 actions, but deny access to every AWS service except Amazon S3. See the following example. According to this policy, you can only access Amazon S3 actions that you can perform on an S3 bucket or S3 object resource. This policy grants the permissions necessary to complete this action programmatically from the AWS API or AWS CLI. To use this policy, replace the *italicized placeholder text* in the example policy with your own information. Then, follow the directions in [create a policy](#) or [edit a policy](#).

If this policy is used in combination with other policies (such as the [AmazonS3FullAccess](#) or [AmazonEC2FullAccess](#) AWS managed policies) that allow actions denied by this policy, then access is denied. This is because an explicit deny statement takes precedence over allow statements. For

more information, see [the section called “Determining whether a request is allowed or denied within an account”](#).

Warning

[NotAction](#) and [NotResource](#) are advanced policy elements that must be used with care. This policy denies access to every AWS service except Amazon S3. If you attach this policy to a user, any other policies that grant permissions to other services are ignored and access is denied.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": "s3:*",
      "Resource": [
        "arn:aws:s3:::bucket-name",
        "arn:aws:s3:::bucket-name/*"
      ]
    },
    {
      "Effect": "Deny",
      "NotAction": "s3:*",
      "NotResource": [
        "arn:aws:s3:::bucket-name",
        "arn:aws:s3:::bucket-name/*"
      ]
    }
  ]
}
```

Amazon S3: Allows read and write access to objects in an S3 Bucket

This example shows how you might create an identity-based policy that allows Read and Write access to objects in a specific S3 bucket. This policy grants the permissions necessary to complete this action programmatically from the AWS API or AWS CLI. To use this policy, replace the *italicized placeholder text* in the example policy with your own information. Then, follow the directions in [create a policy](#) or [edit a policy](#).

The `s3:*Object` action uses a wildcard as part of the action name. The `AllObjectActions` statement allows the `GetObject`, `DeleteObject`, `PutObject`, and any other Amazon S3 action that ends with the word "Object".

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "ListObjectsInBucket",
      "Effect": "Allow",
      "Action": ["s3:ListBucket"],
      "Resource": ["arn:aws:s3:::bucket-name"]
    },
    {
      "Sid": "AllObjectActions",
      "Effect": "Allow",
      "Action": "s3:*Object",
      "Resource": ["arn:aws:s3:::bucket-name/*"]
    }
  ]
}
```

Note

To allow Read and Write access to an object in an Amazon S3 bucket and also include additional permissions for console access, see [Amazon S3: Allows read and write access to objects in an S3 Bucket, programmatically and in the console](#).

Amazon S3: Allows read and write access to objects in an S3 Bucket, programmatically and in the console

This example shows how you might create an identity-based policy that allows Read and Write access to objects in a specific S3 bucket. This policy defines permissions for programmatic and console access. To use this policy, replace the *italicized placeholder text* in the example policy with your own information. Then, follow the directions in [create a policy](#) or [edit a policy](#).

The `s3:*Object` action uses a wildcard as part of the action name. The `AllObjectActions` statement allows the `GetObject`, `DeleteObject`, `PutObject`, and any other Amazon S3 action that ends with the word "Object".

      "Resource": ["arn:aws:s3:::bucket-name"]
    },
    {
      "Sid": "AllObjectActions",
      "Effect": "Allow",
      "Action": "s3:*Object",
      "Resource": ["arn:aws:s3:::bucket-name/*"]
    }
  ]
}
```

Managing IAM policies

IAM gives you the tools to create and manage all types of IAM policies (managed policies and inline policies). To add permissions to an IAM identity (IAM user, group, or role), you create a policy, validate the policy, and then attach the policy to the identity. You can attach multiple policies to an identity, and each policy can contain multiple permissions.

Consult these resources for details:

- For more information about the different types of IAM policies, see [Policies and permissions in IAM](#).
- For general information about using policies within IAM, see [Access management for AWS resources](#).
- For information about how permissions are evaluated when multiple policies are in effect for a given IAM identity, see [Policy evaluation logic](#).
- The number and size of IAM resources in an AWS account are limited. For more information, see [IAM and AWS STS quotas](#).

- [Editing IAM policies](#)
- [Deleting IAM policies](#)
- [Refining permissions in AWS using last accessed information](#)

Creating IAM policies

A [policy](#) is an entity that, when attached to an identity or resource, defines their permissions. You can use the AWS Management Console, AWS CLI, or AWS API to create *customer managed policies* in IAM. Customer managed policies are standalone policies that you administer in your own AWS account. You can then attach the policies to identities (users, groups, and roles) in your AWS account.

A policy that is attached to an identity in IAM is known as an *identity-based policy*. Identity-based policies can include AWS managed policies, customer managed policies, and inline policies. AWS managed policies are created and managed by AWS. You can use them, but you can't manage them. An inline policy is one that you create and embed directly to an IAM group, user, or role. Inline policies can't be reused on other identities or managed outside of the identity where it exists. For more information, see [Adding and removing IAM identity permissions](#).

Use customer managed policies instead of inline policies. It's also best to use customer managed policies instead of AWS managed policies. AWS managed policies usually provide broad administrative or read-only permissions. For greatest security, [grant least privilege](#), which is granting only the permissions required to perform specific job tasks.

When you create or edit IAM policies, AWS can automatically perform policy validation to help you create an effective policy with least privilege in mind. In the AWS Management Console, IAM identifies JSON syntax errors, while IAM Access Analyzer provides additional policy checks with recommendations to help you further refine your policies. To learn more about policy validation, see [Validating IAM policies](#). To learn more about IAM Access Analyzer policy checks and actionable recommendations, see [IAM Access Analyzer policy validation](#).

You can use the AWS Management Console, AWS CLI, or AWS API to create customer managed policies in IAM. For more information about using AWS CloudFormation templates to add or update policies, see [AWS Identity and Access Management resource type reference](#) in the *AWS CloudFormation User Guide*.

Topics

- [Creating IAM policies \(console\)](#)
- [Creating IAM policies \(AWS CLI\)](#)
- [Creating IAM policies \(AWS API\)](#)

Creating IAM policies (console)

A [policy](#) is an entity that, when attached to an identity or resource, defines their permissions. You can use the AWS Management Console to create *customer managed policies* in IAM. Customer managed policies are standalone policies that you administer in your own AWS account. You can then attach the policies to identities (users, groups, and roles) in your AWS account.

Topics

- [Creating IAM policies](#)
- [Creating policies using the JSON editor](#)
- [Creating policies with the visual editor](#)
- [Importing existing managed policies](#)

Creating IAM policies

You can create a customer managed policy in the AWS Management Console using one of the following methods:

- **JSON** — Paste and customize a published [example identity-based policy](#).
- **Visual editor** — Construct a new policy from scratch in the visual editor. If you use the visual editor, you do not have to understand JSON syntax.
- **Import** — Import and customize a managed policy from within your account. You can import an AWS managed policy or a customer managed policy that you previously created.

The number and size of IAM resources in an AWS account are limited. For more information, see [IAM and AWS STS quotas](#).

Creating policies using the JSON editor

You can type or paste policies in JSON by choosing the **JSON** option. This method is useful for copying an [example policy](#) to use in your account. Or, you can type your own JSON policy document in the JSON editor. You can also use the **JSON** option to toggle between the visual editor and JSON to compare the views.

When you create or edit a policy in the JSON editor, IAM performs policy validation to help you create an effective policy. IAM identifies JSON syntax errors, while IAM Access Analyzer provides additional policy checks with actionable recommendations to help you further refine the policy.

A JSON [policy](#) document consists of one or more statements. Each statement should contain all the actions that share the same effect (Allow or Deny) and support the same resources and conditions. If one action requires you to specify all resources ("*") and another action supports the Amazon Resource Name (ARN) of a specific resource, they must be in two separate JSON statements. For details about ARN formats, see [Amazon Resource Name \(ARN\)](#) in the *AWS General Reference Guide*. For general information about IAM policies, see [Policies and permissions in IAM](#). For information about the IAM policy language, see [IAM JSON policy reference](#).

To use the JSON policy editor to create a policy

1. Sign in to the AWS Management Console and open the IAM console at <https://console.aws.amazon.com/iam/>.
2. In the navigation pane on the left, choose **Policies**.

3. Choose **Create policy**.
4. In the **Policy editor** section, choose the **JSON** option.
5. Type or paste a JSON policy document. For details about the IAM policy language, see [IAM JSON policy reference](#).
6. Resolve any security warnings, errors, or general warnings generated during [policy validation](#), and then choose **Next**.

 **Note**

You can switch between the **Visual** and **JSON** editor options anytime. However, if you make changes or choose **Next** in the **Visual** editor, IAM might restructure your policy to optimize it for the visual editor. For more information, see [Policy restructuring](#).

7. (Optional) When you create or edit a policy in the AWS Management Console, you can generate a JSON or YAML policy template that you can use in AWS CloudFormation templates.

To do this, in the **Policy editor** choose **Actions**, and then choose **Generate CloudFormation template**. To learn more about AWS CloudFormation see [AWS Identity and Access Management resource type reference](#) in the AWS CloudFormation User Guide.

8. When you are finished adding permissions to the policy, choose **Next**.
9. On the **Review and create** page, type a **Policy Name** and a **Description** (optional) for the policy that you are creating. Review **Permissions defined in this policy** to see the permissions that are granted by your policy.
10. (Optional) Add metadata to the policy by attaching tags as key-value pairs. For more information about using tags in IAM, see [Tagging IAM resources](#).
11. Choose **Create policy** to save your new policy.

After you create a policy, you can attach it to your groups, users, or roles. For more information, see [Adding and removing IAM identity permissions](#).

Creating policies with the visual editor

The visual editor in the IAM console guides you through creating a policy without having to write JSON syntax. To view an example of using the visual editor to create a policy, see [the section called "Controlling access to identities"](#).

To use the visual editor to create a policy

1. Sign in to the AWS Management Console and open the IAM console at <https://console.aws.amazon.com/iam/>.
2. In the navigation pane on the left, choose **Policies**.
3. Choose **Create policy**.
4. In the **Policy editor** section, find the **Select a service** section, and then choose an AWS service. You can use the search box at the top to limit the results in the list of services. You can choose only one service within a visual editor permission block. To grant access to more than one service, add multiple permission blocks by choosing **Add more permissions**.
5. In **Actions allowed**, choose the actions to add to the policy. You can choose actions in the following ways:
 - Select the check box for all actions.
 - Choose **add actions** to type the name of a specific action. You can use wildcards (*) to specify multiple actions.
 - Select one of the **Access level** groups to choose all actions for the access level (for example, **Read, Write, or List**).
 - Expand each of the **Access level** groups to choose individual actions.

By default, the policy that you are creating allows the actions that you choose. To deny the chosen actions instead, choose **Switch to deny permissions**. Because [IAM denies by default](#), we recommend as a security best practice that you allow permissions to only those actions and resources that a user needs. You should create a JSON statement to deny permissions only if you want to override a permission separately allowed by another statement or policy. We recommend that you limit the number of deny permissions to a minimum because they can increase the difficulty of troubleshooting permissions.

6. For **Resources**, if the service and actions that you selected in the previous steps do not support choosing [specific resources](#), all resources are allowed and you cannot edit this section.

If you chose one or more actions that support [resource-level permissions](#), then the visual editor lists those resources. You can then expand **Resources** to specify resources for your policy.

You can specify resources in the following ways:

- Choose **Add ARNs** to specify resources by their Amazon Resource Names (ARN). You can use the visual ARN editor or list ARNs manually. For more information about ARN syntax, see [Amazon Resource Name \(ARN\)](#) in the *AWS General Reference Guide*. For information about using ARNs in the Resource element of a policy, see [IAM JSON policy elements: Resource](#).
 - Choose **Any in this account** next to a resource to grant permissions to any resources of that type.
 - Choose **All** to choose all resources for the service.
7. (Optional) Choose **Request conditions - optional** to add conditions to the policy that you are creating. Conditions limit a JSON policy statement's effect. For example, you can specify that a user is allowed to perform the actions on the resources only when that user's request happens within a certain time range. You can also use commonly used conditions to limit whether a user must be authenticated using a multi-factor authentication (MFA) device. Or you can require that the request originate from within a certain range of IP addresses. For lists of all of the context keys that you can use in a policy condition, see [Actions, resources, and condition keys for AWS services](#) in the *Service Authorization Reference*.

You can choose conditions in the following ways:

- Use check boxes to select commonly used conditions.
- Choose **Add another condition** to specify other conditions. Choose the condition's **Condition Key**, **Qualifier**, and **Operator**, and then type a **Value**. To add more than one value, choose **Add**. You can consider the values as being connected by a logical "OR" operator. When you are finished, choose **Add condition**.

To add more than one condition, choose **Add another condition** again. Repeat as needed. Each condition applies only to this one visual editor permission block. All the conditions must be true for the permission block to be considered a match. In other words, consider the conditions to be connected by a logical "AND" operator.

For more information about the **Condition** element, see [IAM JSON policy elements: Condition](#) in the [IAM JSON policy reference](#).

8. To add more permission blocks, choose **Add more permissions**. For each block, repeat steps 2 through 5.

Note

You can switch between the **Visual** and **JSON** editor options anytime. However, if you make changes or choose **Next** in the **Visual** editor, IAM might restructure your policy to optimize it for the visual editor. For more information, see [Policy restructuring](#).

9. (Optional) When you create or edit a policy in the AWS Management Console, you can generate a JSON or YAML policy template that you can use in AWS CloudFormation templates.

To do this, in the **Policy editor** choose **Actions**, and then choose **Generate CloudFormation template**. To learn more about AWS CloudFormation see [AWS Identity and Access Management resource type reference](#) in the AWS CloudFormation User Guide.

10. When you are finished adding permissions to the policy, choose **Next**.
11. On the **Review and create** page, type a **Policy Name** and a **Description** (optional) for the policy that you are creating. Review the **Permissions defined in this policy** to make sure that you have granted the intended permissions.
12. (Optional) Add metadata to the policy by attaching tags as key-value pairs. For more information about using tags in IAM, see [Tagging IAM resources](#).
13. Choose **Create policy** to save your new policy.

After you create a policy, you can attach it to your groups, users, or roles. For more information, see [Adding and removing IAM identity permissions](#).

Importing existing managed policies

An easy way to create a new policy is to import an existing managed policy within your account that has at least some of the permissions that you need. You can then customize the policy to match it to your new requirements.

You cannot import an inline policy. To learn about the difference between managed and inline policies, see [Managed policies and inline policies](#).

To import an existing managed policy in the visual editor

1. Sign in to the AWS Management Console and open the IAM console at <https://console.aws.amazon.com/iam/>.
2. In the navigation pane on the left, choose **Policies**.

3. Choose **Create policy**.
4. In the **Policy editor**, choose **Visual** and then on the right side of the page, choose **Actions** then choose **Import policy**.
5. In the **Import policy** window, choose the managed policies that most closely match the policy that you want to include in your new policy. You can use the search box at the top to limit the results in the list of policies.
6. Choose **Import policy**.

The imported policies are added in new permission blocks at the bottom of your policy.

7. Use the **Visual** editor or choose **JSON** to customize your policy. Then choose **Next**.

 **Note**

You can switch between the **Visual** and **JSON** editor options anytime. However, if you make changes or choose **Next** in the **Visual** editor, IAM might restructure your policy to optimize it for the visual editor. For more information, see [Policy restructuring](#).

8. On the **Review and create** page, type a **Policy Name** and a **Description** (optional) for the policy that you are creating. You cannot edit these settings later. Review the **Permissions defined in this policy** and then choose **Create policy** to save your work.

To import an existing managed policy in the JSON editor

1. Sign in to the AWS Management Console and open the IAM console at <https://console.aws.amazon.com/iam/>.
2. In the navigation pane on the left, choose **Policies**.
3. Choose **Create policy**.
4. In the **Policy editor** section, choose the **JSON** option, and then on the right side of the page, choose **Actions** then choose **Import policy**.
5. In the **Import policy** window, choose the managed policies that most closely match the policy that you want to include in your new policy. You can use the search box at the top to limit the results in the list of policies.
6. Choose **Import policy**.

Statements from the imported policies are added to the bottom of your JSON policy.

7. Customize your policy in JSON. Resolve any security warnings, errors, or general warnings generated during [policy validation](#), and then choose **Next**. Or, customize your policy in the **Visual** editor. Then choose **Next**.

Note

You can switch between the **Visual** and **JSON** editor options anytime. However, if you make changes or choose **Next** in the **Visual** editor, IAM might restructure your policy to optimize it for the visual editor. For more information, see [Policy restructuring](#).

8. On the **Review and create** page, type a **Policy Name** and a **Description** (optional) for the policy that you are creating. You cannot edit these later. Review the policy **Permissions defined in this policy** and then choose **Create policy** to save your work.

After you create a policy, you can attach it to your groups, users, or roles. For more information, see [Adding and removing IAM identity permissions](#).

Creating IAM policies (AWS CLI)

A [policy](#) is an entity that, when attached to an identity or resource, defines their permissions. You can use the AWS CLI to create *customer managed policies* in IAM. Customer managed policies are standalone policies that you administer in your own AWS account. As a [best practice](#), we recommend that you use IAM Access Analyzer to validate your IAM policies to ensure secure and functional permissions. By [validating your policies](#) you can address any errors or recommendations before you attach the policies to identities (users, groups, and roles) in your AWS account.

The number and size of IAM resources in an AWS account are limited. For more information, see [IAM and AWS STS quotas](#).

Creating IAM policies (AWS CLI)

You can create an IAM customer managed policy or an inline policy using the AWS Command Line Interface (AWS CLI).

To create a customer managed policy (AWS CLI)

Use the following command:

- [create-policy](#)

To create an inline policy for an IAM identity (group, user or role) (AWS CLI)

Use one of the following commands:

- [put-group-policy](#)
- [put-role-policy](#)
- [put-user-policy](#)

Note

You can't use IAM to embed an inline policy for a [service-linked role](#).

To validate a customer managed policy (AWS CLI)

Use the following IAM Access Analyzer command:

- [validate-policy](#)

Creating IAM policies (AWS API)

A [policy](#) is an entity that, when attached to an identity or resource, defines their permissions. You can use the AWS API to create *customer managed policies* in IAM. Customer managed policies are standalone policies that you administer in your own AWS account. As a [best practice](#), we recommend that you use IAM Access Analyzer to validate your IAM policies to ensure secure and functional permissions. By [validating your policies](#) you can address any errors or recommendations before you attach the policies to identities (users, groups, and roles) in your AWS account.

The number and size of IAM resources in an AWS account are limited. For more information, see [IAM and AWS STS quotas](#).

Creating IAM policies (AWS API)

You can create an IAM customer managed policy or an inline policy using the AWS API.

To create a customer managed policy (AWS API)

Call the following operation:

- [CreatePolicy](#)

To create an inline policy for an IAM identity (group, user, or role) (AWS API)

Call one of the following operations:

- [PutGroupPolicy](#)
- [PutRolePolicy](#)
- [PutUserPolicy](#)

Note

You can't use IAM to embed an inline policy for a [service-linked role](#).

To validate a customer managed policy (AWS API)

Call the following IAM Access Analyzer operation:

- [ValidatePolicy](#)

Validating IAM policies

A [policy](#) is a JSON document that uses the [IAM policy grammar](#). When you attach a policy to an IAM entity, such as a user, group, or role, it grants permissions to that entity.

When you create or edit IAM access control policies using the AWS Management Console, AWS automatically examines them to ensure that they comply with the IAM policy grammar. If AWS determines that a policy is not in compliance with the grammar, it prompts you to fix the policy.

IAM Access Analyzer provides additional policy checks with recommendations to help you further refine the policy. To learn more about IAM Access Analyzer policy checks and actionable recommendations, see [IAM Access Analyzer policy validation](#). To view a list of warnings, errors, and suggestions that are returned by IAM Access Analyzer, see [IAM Access Analyzer policy check reference](#).

Validation scope

AWS checks JSON policy syntax and grammar. It also verifies that your ARNs are formatted properly and action names and condition keys are correct.

Accessing policy validation

Policies are validated automatically when you create a JSON policy or edit an existing policy in the AWS Management Console. If the policy syntax is not valid, you receive a notification and must fix the problem before you can continue. The findings from the IAM Access Analyzer policy validation are automatically returned in the AWS Management Console if you have permissions for `access-analyzer:ValidatePolicy`. You can also validate policies using the AWS API or AWS CLI.

Existing policies

You might have existing policies that are not valid because they were created or last saved before the latest updates to the policy engine. As a [best practice](#), we recommend that you use IAM Access Analyzer to validate your IAM policies to ensure secure and functional permissions. We recommend that you open your existing policies and review the policy validation results that are generated. You cannot edit and save existing policies without fixing any policy syntax errors.

Generate policies based on access activity

As an administrator or developer, you might grant permissions to IAM entities (users or roles) beyond what they require. IAM provides several options to help you refine the permissions that you grant. One option is to generate an IAM policy that is based on access activity for an entity. IAM Access Analyzer reviews your AWS CloudTrail logs and generates a policy template that contains the permissions that the entity used in your specified date range. You can use the template to create a policy with fine-grained permissions that grant only the permissions that are required to support your specific use case.

For example, imagine that you are a developer and your engineering team has been working on a project to create a new application. To encourage experimentation and enable your team to move fast, you've configured a role with broad permissions while the application is in development. Now the application is ready for production. Before the application can launch in the production account, you want to identify only the permissions that the role needs for the application to function. This helps you to adhere to the best practice of [granting least privilege](#). You can generate a policy based on the access activity of the role that you have been using for the application in the development account. You can further refine the generated policy and then attach the policy to an entity in your production account.

To learn more about IAM Access Analyzer policy generation, see [IAM Access Analyzer policy generation](#).

Testing IAM policies with the IAM policy simulator

For more information about how and why to use IAM policies, see [Policies and permissions in IAM](#).

You can access the IAM Policy Simulator Console at: <https://policysim.aws.amazon.com/>

Important

The policy simulator results can differ from your live AWS environment. We recommend that you check your policies against your live AWS environment after testing using the policy simulator to confirm that you have the desired results. For more information, see [How the IAM policy simulator works](#).

[Getting Started with the IAM Policy Simulator](#)

With the IAM policy simulator, you can test and troubleshoot identity-based policies and IAM permissions boundaries. Here are some common things you can do with the policy simulator:

- Test identity-based policies that are attached to IAM users, user groups, or roles in your AWS account. If more than one policy is attached to the user, user group, or role, you can test all the policies, or select individual policies to test. You can test which actions are allowed or denied by the selected policies for specific resources.
- Test and troubleshoot the effect of [permissions boundaries](#) on IAM entities. You can only simulate one permissions boundary at a time.
- Test the effects of resource-based policies on IAM users that are attached to AWS resources, such as Amazon S3 buckets, Amazon SQS queues, Amazon SNS topics, or Amazon S3 Glacier vaults. To use a resource-based policy in the policy simulator for IAM users, you must include the resource in the simulation. You must also select the check box to include that resource's policy in the simulation.

Note

Simulation of resource-based policies isn't supported for IAM roles.

- If your AWS account is a member of an organization in [AWS Organizations](#), then you can test the impact of service control policies (SCPs) on your identity-based policies.

Note

The policy simulator doesn't evaluate SCPs that have any conditions.

- Test new identity-based policies that are not yet attached to a user, user group, or role by typing or copying them into the policy simulator. These are used only in the simulation and are not saved. You can't type or copy a resource-based policy in the policy simulator.
- Test identity-based policies with selected services, actions, and resources. For example, you can test to ensure that your policy allows an entity to perform the `ListAllMyBuckets`, `CreateBucket`, and `DeleteBucket` actions in the Amazon S3 service on a specific bucket.
- Simulate real-world scenarios by providing context keys, such as an IP address or date, that are included in `Condition` elements in the policies being tested.

Note

The policy simulator doesn't simulate tags provided as input if the identity-based policy in the simulation doesn't have a `Condition` element that explicitly checks for tags.

- Identify which specific statement in identity-based policy results in allowing or denying access to a particular resource or action.

Topics

- [How the IAM policy simulator works](#)
- [Permissions required for using the IAM policy simulator](#)
- [Using the IAM policy simulator \(console\)](#)
- [Using the IAM policy simulator \(AWS CLI and AWS API\)](#)

How the IAM policy simulator works

The policy simulator evaluates statements in the identity-based policy and the inputs that you provide during simulation. The policy simulator results can differ from your live AWS environment. We recommend that you check your policies against your live AWS environment after testing using the policy simulator to confirm that you have the desired results.

The policy simulator differs from the live AWS environment in the following ways:

- The policy simulator does not make an actual AWS service request, so you can safely test requests that might make unwanted changes to your live AWS environment. The policy simulator doesn't consider real context key values in production.

- Because the policy simulator does not simulate running the selected actions, it cannot report any response to the simulated request. The only result returned is whether the requested action would be allowed or denied.
- If you edit a policy in the policy simulator, these changes affect only the policy simulator. The corresponding policy in your AWS account remains unchanged.
- You can't test service control policies (SCPs) with any conditions.
- The policy simulator doesn't support simulation for IAM roles and users for cross-account access.

Note

The IAM policy simulator doesn't determine which services support [global condition keys](#) for authorization. For example, the policy simulator doesn't identify that a service doesn't support [aws:TagKeys](#).

Permissions required for using the IAM policy simulator

You can use the policy simulator console or the policy simulator API to test policies. By default, console users can test policies that are not yet attached to a user, user group, or role by typing or copying those policies into the policy simulator. These policies are used only in the simulation and do not disclose sensitive information. API users must have permissions to test unattached policies. You can allow console or API users to test policies that are attached to IAM users, user groups, or roles in your AWS account. To do so, you must provide permission to retrieve those policies. In order to test resource-based policies, users must have permission to retrieve the resource's policy.

For examples of console and API policies that allow a user to simulate policies, see [the section called "Example policies: AWS Identity and Access Management \(IAM\)"](#).

Permissions required for using the policy simulator console

You can allow users to test policies that are attached to IAM users, user groups, or roles in your AWS account. To do so, you must provide your users with permissions to retrieve those policies. In order to test resource-based policies, users must have permission to retrieve the resource's policy.

To view an example policy that allows using the policy simulator console for policies that are attached to a user, user group, or role, see [IAM: Access the policy simulator console](#).

To view an example policy that allows using the policy simulator console only for those users with a specific path, see [IAM: Access the policy simulator console based on user path](#).

To create a policy to allow using the policy simulator console for only one type of entity, use the following procedures.

To allow console users to simulate policies for users

Include the following actions in your policy:

- iam:GetGroupPolicy
- iam:GetPolicy
- iam:GetPolicyVersion
- iam:GetUser
- iam:GetUserPolicy
- iam>ListAttachedUserPolicies
- iam>ListGroupsForUser
- iam>ListGroupPolicies
- iam>ListUserPolicies
- iam>ListUsers

To allow console users to simulate policies for user groups

Include the following actions in your policy:

- iam:GetGroup
- iam:GetGroupPolicy
- iam:GetPolicy
- iam:GetPolicyVersion
- iam>ListAttachedGroupPolicies
- iam>ListGroupPolicies
- iam>ListGroups

To allow console users to simulate policies for roles

Include the following actions in your policy:

- `iam:GetPolicy`
- `iam:GetPolicyVersion`
- `iam:GetRole`
- `iam:GetRolePolicy`
- `iam>ListAttachedRolePolicies`
- `iam>ListRolePolicies`
- `iam>ListRoles`

To test resource-based policies, users must have permission to retrieve the resource's policy.

To allow console users to test resource-based policies in an Amazon S3 bucket

Include the following action in your policy:

- `s3:GetBucketPolicy`

For example, the following policy uses this action to allow console users to simulate a resource-based policy in a specific Amazon S3 bucket.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": "s3:GetBucketPolicy",
      "Resource": "arn:aws:s3:::bucket-name/*"
    }
  ]
}
```

Permissions required for using the policy simulator API

The policy simulator API operations [GetContextKeyForCustomPolicy](#) and [SimulateCustomPolicy](#) allow you to test policies that are not yet attached to a user, user group, or role. To test such policies, you pass the policies as strings to the API. These policies are used only in the simulation and do not disclose sensitive information. You can also use the API to test policies that are attached to IAM users, user groups, or roles in your AWS account. To do that, you must provide users with permissions to call [GetContextKeyForPrincipalPolicy](#) and [SimulatePrincipalPolicy](#).

To view an example policy that allows using the policy simulator API for attached and unattached policies in the current AWS account, see [IAM: Access the policy simulator API](#).

To create a policy to allow using the policy simulator API for only one type of policy, use the following procedures.

To allow API users to simulate policies passed directly to the API as strings

Include the following actions in your policy:

- `iam:GetContextKeysForCustomPolicy`
- `iam:SimulateCustomPolicy`

To allow API users to simulate policies attached to IAM users, user groups, roles, or resources

Include the following actions in your policy:

- `iam:GetContextKeysForPrincipalPolicy`
- `iam:SimulatePrincipalPolicy`

For example, to give a user named Bob permission to simulate a policy that is assigned to a user named Alice, give Bob access to the following resource: `arn:aws:iam::777788889999:user/alice`.

To view an example policy that allows using the policy simulator API only for those users with a specific path, see [IAM: Access the policy simulator API based on user path](#).

Using the IAM policy simulator (console)

By default, users can test policies that are not yet attached to a user, user group, or role by typing or copying those policies into the policy simulator console. These policies are used only in the simulation and do not disclose sensitive information.

To test a policy that is not attached to a user, user group, or role (console)

1. Open the IAM policy simulator console at: <https://policysim.aws.amazon.com/>.
2. In the **Mode:** menu at the top of the page, choose **New Policy**.
3. In the **Policy Sandbox**, choose **Create New Policy**.

4. Type or copy a policy into the policy simulator, and use the policy simulator as described in the following steps.

After you have permission to use the IAM Policy Simulator Console, you can use the policy simulator to test an IAM user, user group, role, or resource policy.

To test a policy that is attached to a user, user group, or role (console)

1. Open the IAM policy simulator console at <https://policysim.aws.amazon.com/>.

Note

To sign in to the policy simulator as an IAM user, use your unique sign-in URL to sign in to the AWS Management Console. Then go to <https://policysim.aws.amazon.com/>. For more information about signing in as an IAM user, see [How IAM users sign in to AWS](#).

The policy simulator opens in **Existing Policies** mode and lists the IAM users in your account under **Users, Groups, and Roles**.

2. Choose the option that is appropriate to your task:

To test this:	Do this:
A policy attached to a user	Choose Users in the Users, Groups, and Roles list. Then choose the user.
A policy attached to a user group	Choose Groups in the Users, Groups, and Roles list. Then choose the user group.
A policy attached to a role	Choose Roles in the Users, Groups, and Roles list. Then choose the role.
A policy attached to a resource	See Step 9 .
A custom policy for a user, user group, or role	Choose Create New Policy . In the new Policies pane, type or paste a policy and then choose Apply .

Tip

To test a policy that is attached to user group, you can launch the IAM policy simulator directly from the [IAM console](#): In the navigation pane, choose **User groups**. Choose the name of the group that you want to test a policy on, and then choose the **Permissions** tab. Choose **Simulate**.

To test a customer managed policy that is attached to a user: In the navigation pane, choose **Users**. Choose the name of the user that you want to test a policy on. Then choose the **Permissions** tab and expand the policy that you want to test. On the far right, choose **Simulate policy**. The **IAM Policy Simulator** opens in a new window and displays the selected policy in the **Policies** pane.

3. (Optional) If your account is a member of an organization in [AWS Organizations](#), then select the check box next to **AWS Organizations SCPs** to include SCPs in your simulated evaluation. SCPs are JSON policies that specify the maximum permissions for an organization or organizational unit (OU). The SCP limits permissions for entities in member accounts. If an SCP blocks a service or action, then no entity in that account can access that service nor perform that action. This is true even if an administrator explicitly grants permissions to that service or action through an IAM or resource policy.

If your account is not a member of an organization, then the check box does not appear.

4. (Optional) You can test a policy that is set as a [permissions boundary](#) for an IAM entity (user or role), but not for user groups. If a permissions boundary policy is currently set for the entity, it appears in the **Policies** pane. You can set only one permissions boundary for an entity. To test a different permissions boundary, you can create a custom permissions boundary. To do this, choose **Create New Policy**. A new **Policies** pane opens. In the menu, choose **Custom IAM Permissions Boundary Policy**. Enter a name for the new policy and type or copy a policy into the space below. Choose **Apply** to save the policy. Next, choose **Back** to return to the original **Policies** pane. Then select the check box next to the permissions boundary you want to use for the simulation.
5. (Optional) You can test only a subset of policies attached to a user, user group, or role. To do so, in the **Policies** pane clear the check box next to each policy that you want to exclude.
6. Under **Policy Simulator**, choose **Select service** and then choose the service to test. Then choose **Select actions** and select one or more actions to test. Although the menus show the

available selections for only one service at a time, all the services and actions that you have selected appear in **Action Settings and Results**.

7. (Optional) If any of the policies that you choose in [Step 2](#) and [Step 5](#) include conditions with [AWSglobal condition keys](#), then supply values for those keys. You can do this by expanding the **Global Settings** section and typing values for the key names displayed there.

⚠ Warning

If you leave the value for a condition key empty, then that key is ignored during the simulation. In some cases, this results in an error, and the simulation fails to run. In other cases, the simulation runs, but the results might not be reliable. In those cases, the simulation does not match the real-world conditions that include a value for the condition key or variable.

8. (Optional) Each selected action appears in the **Action Settings and Results** list with **Not simulated** shown in the **Permission** column until you actually run the simulation. Before you run the simulation, you can configure each action with a resource. To configure individual actions for a specific scenario, choose the arrow to expand the action's row. If the action supports resource-level permissions, you can type the [Amazon Resource Name \(ARN\)](#) of the specific resource whose access you want to test. By default, each resource is set to a wildcard (*). You can also specify a value for any [condition context keys](#). As noted previously, keys with empty values are ignored, which can cause simulation failures or unreliable results.
 - a. Choose the arrow next to the action name to expand each row and configure any additional information required to accurately simulate the action in your scenario. If the action requires any resource-level permissions, you can type the [Amazon Resource Name \(ARN\)](#) of the specific resource that you want to simulate access to. By default, each resource is set to a wildcard (*).
 - b. If the action supports resource-level permissions but does not require them, then you can choose **Add Resource** to select the resource type that you want to add to the simulation.
 - c. If any of the selected policies include a **Condition** element that references a context key for this action's service, then that key name is displayed under the action. You can specify the value to be used during the simulation of that action for the specified resource.

Actions that require different groups of resource types

Some actions require different resource types under different circumstances. Each group of resource types is associated with a scenario. If one of these applies to your simulation, select it and the policy simulator requires the resource types appropriate for that scenario. The following list shows each of the supported scenario options and the resources that you must define to run the simulation.

Each of the following Amazon EC2 scenarios requires that you specify `instance`, `image`, and `security-group` resources. If your scenario includes an EBS volume, then you must specify that `volume` as a resource. If the Amazon EC2 scenario includes a virtual private cloud (VPC), then you must supply the `network-interface` resource. If it includes an IP subnet, then you must specify the `subnet` resource. For more information on the Amazon EC2 scenario options, see [Supported Platforms](#) in the *Amazon EC2 User Guide*.

- **EC2-VPC-InstanceStore**

`instance`, `image`, `security-group`, `network-interface`

- **EC2-VPC-InstanceStore-Subnet**

`instance`, `image`, `security-group`, `network-interface`, `subnet`

- **EC2-VPC-EBS**

`instance`, `image`, `security-group`, `network-interface`, `volume`

- **EC2-VPC-EBS-Subnet**

`instance`, `image`, `security-group`, `network-interface`, `subnet`, `volume`

9. (Optional) If you want to include a resource-based policy in your simulation, then you must first select the actions that you want to simulate on that resource in [Step 6](#). Expand the rows for the selected actions, and type the ARN of the resource with a policy that you want to simulate. Then select **Include Resource Policy** next to the **ARN** text box. The IAM policy simulator currently supports resource-based policies from only the following services: Amazon S3 (resource-based policies only; ACLs are not currently supported), Amazon SQS, Amazon SNS, and unlocked S3 Glacier vaults (locked vaults are not currently supported).
10. Choose **Run Simulation** in the upper-right corner.

The **Permission** column in each row of **Action Settings and Results** displays the result of the simulation of that action on the specified resource.

- To see which statement in a policy explicitly allowed or denied an action, choose the **N matching statement(s)** link in the **Permissions** column to expand the row. Then choose the **Show statement** link. The **Policies** pane shows the relevant policy with the statement that affected the simulation result highlighted.

 **Note**

If an action is *implicitly* denied—that is, if the action is denied only because it is not explicitly allowed—the **List** and **Show statement** options are not displayed.

Troubleshooting IAM policy simulator console messages

The following table lists the informational and warning messages you might encounter when using the IAM policy simulator. The table also provides steps you can take to resolve them.

Message	Steps to resolve
This policy has been edited. Changes will not be saved to your account.	<p>No action required.</p> <p>This message is informational. If you edit an existing policy in the IAM policy simulator , your change does not affect your AWS account. The policy simulator allows you to make changes to policies for testing purposes only.</p>
Cannot get the resource policy. Reason: <i>detailed error message</i>	<p>The policy simulator is not able to access a requested resource-based policy. Ensure that the specified resource ARN is correct and that the user running the simulation has permission to read the resource's policy.</p>
One or more policies require values in the simulation settings. The simulation might fail without these values.	<p>This message appears if the policy you are testing contains condition keys or variables but you have not provided any values for these keys or variables in Simulation Settings.</p>

Message	Steps to resolve
	<p>To dismiss this message, choose Simulation Settings, Then enter a value for each condition key or variable.</p>
<p>You have changed policies. These results are no longer valid.</p>	<p>This message appears if you have changed the selected policy while results are displayed in the Results pane. Results shown in the Results pane are not updated dynamically.</p> <p>To dismiss this message, choose Run Simulation again to display new simulation results based on the changes made in the Policies pane.</p>
<p>The resource you typed for this simulation does not match this service.</p>	<p>This message appears if you have typed an Amazon Resource Name (ARN) in the Simulation Settings pane that does not match the service that you chose for the current simulation. For example, this message appears if you specify an ARN for an Amazon DynamoDB resource but you chose Amazon Redshift as the service to simulate.</p> <p>To dismiss this message, do one of the following:</p> <ul style="list-style-type: none">• Remove the ARN from the box in the Simulation Settings pane.• Choose the service that matches the ARN that you specified in Simulation Settings.

Message	Steps to resolve
<p>This action belongs to a service that supports special access control mechanisms in addition to resource-based policies, such as Amazon S3 ACLs or S3 Glacier vault lock policies. The policy simulator does not support these mechanisms, so the results can differ from your production environment.</p>	<p>No action required.</p> <p>This message is informational. In the current version, the policy simulator evaluates policies attached to users and user groups, and can evaluate resource-based policies for Amazon S3, Amazon SQS, Amazon SNS, and S3 Glacier. The policy simulator does not support all access control mechanisms supported by other AWS services.</p>
<p>DynamoDB FGAC is currently not supported.</p>	<p>No action required.</p> <p>This informational message refers to <i>fine-grained access control</i>. Fine-grained access control is the ability to use IAM policy conditions to determine who can access individual data items and attributes in DynamoDB tables and indexes. It also refers to the actions that can be performed on these tables and indexes. The current version of the IAM policy simulator does not support this type of policy condition. For more information on DynamoDB fine-grained access control, see Fine-Grained Access Control for DynamoDB.</p>
<p>You have policies that do not comply with the policy syntax. You can use policy validation to review recommended updates to your policies.</p>	<p>This message appears at the top of the policy list if you have policies that do not comply with the IAM policy grammar. In order to simulate these policies, review the policy validation options at Validating IAM policies to identify and fix these policies.</p>

Message	Steps to resolve
This policy must be updated to comply with the latest policy syntax rules.	This message is displayed if you have policies that do not comply with the IAM policy grammar. In order to simulate these policies, review the policy validation options at Validating IAM policies to identify and fix these policies.

Using the IAM policy simulator (AWS CLI and AWS API)

Policy simulator commands typically require calling API operations to do two things:

1. Evaluate the policies and return the list of context keys that they reference. You need to know what context keys are referenced so that you can supply values for them in the next step.
2. Simulate the policies, providing a list of actions, resources, and context keys that are used during the simulation.

For security reasons, the API operations have been broken into two groups:

- API operations that simulate only policies that are passed directly to the API as strings. This set includes [GetContextKeysForCustomPolicy](#) and [SimulateCustomPolicy](#).
- API operations that simulate the policies that are attached to a specified IAM user, user group, role, or resource. Because these API operations can reveal details of permissions assigned to other IAM entities, you should consider restricting access to these API operations. This set includes [GetContextKeysForPrincipalPolicy](#) and [SimulatePrincipalPolicy](#). For more information about restricting access to API operations, see [Example policies: AWS Identity and Access Management \(IAM\)](#).

In both cases, the API operations simulate the effect of one or more policies on a list of actions and resources. Each action is paired with each resource and the simulation determines whether the policies allow or deny that action for that resource. You can also provide values for any context keys that your policies reference. You can get the list of context keys that the policies reference by first calling [GetContextKeysForCustomPolicy](#) or [GetContextKeysForPrincipalPolicy](#). If you don't provide a value for a context key, the simulation still runs. But the results might not be reliable because the policy simulator cannot include that context key in the evaluation.

To get the list of context keys (AWS CLI, AWS API)

Use the following to evaluate a list of policies and return a list of context keys that are used in the policies.

- AWS CLI: [aws iam get-context-keys-for-custom-policy](#) and [aws iam get-context-keys-for-principal-policy](#)
- AWS API: [GetContextKeysForCustomPolicy](#) and [GetContextKeysForPrincipalPolicy](#)

To simulate IAM policies (AWS CLI, AWS API)

Use the following to simulate IAM policies to determine a user's effective permissions.

- AWS CLI: [aws iam simulate-custom-policy](#) and [aws iam simulate-principal-policy](#)
- AWS API: [SimulateCustomPolicy](#) and [SimulatePrincipalPolicy](#)

Adding and removing IAM identity permissions

You use policies to define the permissions for an identity (user, user group, or role). You can add and remove permissions by attaching and detaching IAM policies for an identity using the AWS Management Console, the AWS Command Line Interface (AWS CLI), or the AWS API. You can also use policies to set [permissions boundaries](#) for only entities (users or roles) that are using the same methods. Permissions boundaries are an advanced AWS feature that control the maximum permissions that an entity can have.

Topics

- [Terminology](#)
- [View identity activity](#)
- [Adding IAM identity permissions \(console\)](#)
- [Removing IAM identity permissions \(console\)](#)
- [Adding IAM policies \(AWS CLI\)](#)
- [Removing IAM policies \(AWS CLI\)](#)
- [Adding IAM policies \(AWS API\)](#)
- [Removing IAM policies \(AWS API\)](#)

Terminology

When you associate permissions policies with identities (users, user groups, and roles), terminology and procedures vary depending on whether you are working with a managed or inline policy:

- **Attach** – Used with managed policies. You attach a managed policy to an identity (a user, user group, or role). Attaching a policy applies the permissions in the policy to the identity.
- **Detach** – Used with managed policies. You detach a managed policy from an IAM identity (a user, user group, or role). Detaching a policy removes its permissions from the identity.
- **Embed** – Used with inline policies. You embed an inline policy in an identity (a user, user group, or role). Embedding a policy applies the permissions in the policy to the identity. Because an inline policy is stored in the identity, it is embedded rather than attached, though the results are similar.

Note

You can embed an inline policy for a [service-linked role](#) only in the service that depends on the role. See the [AWS documentation](#) for your service to see whether it supports this feature.

- **Delete** – Used with inline policies. You delete an inline policy from an IAM identity (a user, user group, or role). Deleting a policy removes its permissions from the identity.

Note

You can delete an inline policy for a [service-linked role](#) only in the service that depends on the role. See the [AWS documentation](#) for your service to see whether it supports this feature.

You can use the console, AWS CLI, or AWS API to perform any of these actions.

More information

- For more information about the difference between managed and inline policies, see [Managed policies and inline policies](#).
- For more information about permissions boundaries, see [Permissions boundaries for IAM entities](#).
- For general information about IAM policies, see [Policies and permissions in IAM](#).

- For information about validating IAM policies, see [Validating IAM policies](#).
- The number and size of IAM resources in an AWS account are limited. For more information, see [IAM and AWS STS quotas](#).

View identity activity

Before you change the permissions for an identity (user, user group, or role), you should review their recent service-level activity. This is important because you don't want to remove access from a principal (person or application) who is using it. For more information about viewing last accessed information, see [Refining permissions in AWS using last accessed information](#).

Adding IAM identity permissions (console)

You can use the AWS Management Console to add permissions to an identity (user, user group, or role). To do this, attach managed policies that control permissions, or specify a policy that serves as a [permissions boundary](#). You can also embed an inline policy.

To use a managed policy as a permissions policy for an identity (console)

1. Sign in to the AWS Management Console and open the IAM console at <https://console.aws.amazon.com/iam/>.
2. In the navigation pane, choose **Policies**.
3. In the list of policies, select the radio button next to the name of the policy to attach. You can use the search box to filter the list of policies.
4. Choose **Actions**, and then choose **Attach**.
5. Select one or more identities to attach the policy to. You can use the search box to filter the list of principal entities. After selecting the identities, choose **Attach policy**.

To use a managed policy to set a permissions boundary (console)

1. Sign in to the AWS Management Console and open the IAM console at <https://console.aws.amazon.com/iam/>.
2. In the navigation pane, choose **Policies**.
3. In the list of policies, choose the name of the policy to set. You can use the search box to filter the list of policies.

4. On the policy details page, choose the **Entities attached** tab, and then, if necessary, open the **Attached as a permissions boundaries** section and choose **Set this policy as a permissions boundary**.
5. Select one or more users or roles on which to use the policy for a permissions boundary. You can use the search box to filter the list of principal entities. After selecting the principals, choose **Set permissions boundary**.

To embed an inline policy for a user or role (console)

1. Sign in to the AWS Management Console and open the IAM console at <https://console.aws.amazon.com/iam/>.
2. In the navigation pane, choose **Users** or **Roles**.
3. In the list, choose the name of the user or role to embed a policy in.
4. Choose the **Permissions** tab.
5. Choose **Add permissions** and then choose **Create inline policy**.

Note

You cannot embed an inline policy in a [service-linked role](#) in IAM. Because the linked service defines whether you can modify the permissions of the role, you might be able to add additional policies from the service console, API, or AWS CLI. To view the service-linked role documentation for a service, see [AWS services that work with IAM](#) and choose **Yes** in the **Service-Linked Role** column for your service.

6. Choose from the following methods to view the steps required to create your policy:
 - [Importing existing managed policies](#) – You can import a managed policy within your account and then edit the policy to customize it to your specific requirements. A managed policy can be an AWS managed policy or a customer managed policy that you created previously.
 - [Creating policies with the visual editor](#) – You can construct a new policy from scratch in the visual editor. If you use the visual editor, you do not have to understand JSON syntax.
 - [Creating policies using the JSON editor](#) – In the **JSON** editor option, you can use JSON syntax to create a policy. You can type a new JSON policy document or paste an [example policy](#).

7. After you create an inline policy, it is automatically embedded in your user or role.

To embed an inline policy for a user group (console)

1. Sign in to the AWS Management Console and open the IAM console at <https://console.aws.amazon.com/iam/>.
2. In the navigation pane, choose **User groups**.
3. In the list, choose the name of the user group to embed a policy in.
4. Choose the **Permissions** tab, choose **Add permissions**, and then choose **Create inline policy**.
5. Do one of the following:
 - Choose the **Visual** option to create the policy. For more information, see [Creating policies with the visual editor](#).
 - Choose the **JSON** option to create the policy. For more information, see [Creating policies using the JSON editor](#).
6. When you are satisfied with the policy, choose **Create policy**.

To change the permissions boundary for one or more entities (console)

1. Sign in to the AWS Management Console and open the IAM console at <https://console.aws.amazon.com/iam/>.
2. In the navigation pane, choose **Policies**.
3. In the list of policies, choose the name of the policy to set. You can use the search box to filter the list of policies.
4. On the policy details page, choose the **Entities attached** tab, and then, if necessary, open the **Attached as a permissions boundary** section. Select the check box next to the users or roles whose boundaries you want to change and then choose **Change**.
5. Select a new policy to use for a permissions boundary. You can use the search box to filter the list of policies. After selecting the policy, choose **Set permissions boundary**.

Removing IAM identity permissions (console)

You can use the AWS Management Console to remove permissions from an identity (user, user group, or role). To do this, detach managed policies that control permissions, or remove a policy that serves as a [permissions boundary](#). You can also delete an inline policy.

To detach a managed policy used as a permissions policy (console)

1. Sign in to the AWS Management Console and open the IAM console at <https://console.aws.amazon.com/iam/>.
2. In the navigation pane, choose **Policies**.
3. In the list of policies, select the radio button next to the name of the policy to detach. You can use the search box to filter the list of policies.
4. Choose **Actions**, and then choose **Detach**.
5. Select the identities to detach the policy from. You can use the search box to filter the list of identities. After selecting the identities, choose **Detach policy**.

To remove a permissions boundary (console)

1. Sign in to the AWS Management Console and open the IAM console at <https://console.aws.amazon.com/iam/>.
2. In the navigation pane, choose **Policies**.
3. In the list of policies, choose the name of the policy to set. You can use the search box to filter the list of policies.
4. On the policy summary page, choose the **Entities attached** tab, and then, if necessary, open the **Attached as a permissions boundary** section and choose the entities to remove the permissions boundary from. Then choose **Remove boundary**.
5. Confirm that you want to remove the boundary and choose **Remove boundary**.

To delete an inline policy (console)

1. Sign in to the AWS Management Console and open the IAM console at <https://console.aws.amazon.com/iam/>.
2. In the navigation pane, choose **User groups**, **Users**, or **Roles**.

3. In the list, choose the name of the user group, user, or role that has the policy you want to remove.
4. Choose the **Permissions** tab.
5. Select the check box next to the policy and choose **Remove**.
6. Choose **Remove** in the confirmation box.

Adding IAM policies (AWS CLI)

You can use the AWS CLI to add permissions to an identity (user, user group, or role). To do this, attach managed policies that control permissions, or specify a policy that serves as a [permissions boundary](#). You can also embed an inline policy.

To use a managed policy as a permissions policy for an entity (AWS CLI)

1. (Optional) To view information about a managed policy, run the following commands:
 - To list managed policies: [aws iam list-policies](#)
 - To retrieve detailed information about a managed policy: [get-policy](#)
2. To attach a managed policy to an identity (user, user group, or role), use one of the following commands:
 - [aws iam attach-user-policy](#)
 - [aws iam attach-group-policy](#)
 - [aws iam attach-role-policy](#)

To use a managed policy to set a permissions boundary (AWS CLI)

1. (Optional) To view information about a managed policy, run the following commands:
 - To list managed policies: [aws iam list-policies](#)
 - To retrieve detailed information about a managed policy: [aws iam get-policy](#)
2. To use a managed policy to set the permissions boundary for an entity (user or role), use one of the following commands:
 - [aws iam put-user-permissions-boundary](#)
 - [aws iam put-role-permissions-boundary](#)

To embed an inline policy (AWS CLI)

To embed an inline policy to an identity (user, user group, or role that is not a [service-linked role](#)), use one of the following commands:

- [aws iam put-user-policy](#)
- [aws iam put-group-policy](#)
- [aws iam put-role-policy](#)

Removing IAM policies (AWS CLI)

You can use the AWS CLI to detach managed policies that control permissions, or remove a policy that serves as a [permissions boundary](#). You can also delete an inline policy.

To detach a managed policy used as a permissions policy (AWS CLI)

1. (Optional) To view information about a policy, run the following commands:
 - To list managed policies: [aws iam list-policies](#)
 - To retrieve detailed information about a managed policy: [aws iam get-policy](#)
2. (Optional) To find out about the relationships between the policies and identities, run the following commands:
 - To list the identities (users, user groups, and roles) to which a managed policy is attached:
 - [aws iam list-entities-for-policy](#)
 - To list the managed policies attached to an identity (a user, user group, or role), use one of the following commands:
 - [aws iam list-attached-user-policies](#)
 - [aws iam list-attached-group-policies](#)
 - [aws iam list-attached-role-policies](#)
3. To detach a managed policy from an identity (user, user group, or role), use one of the following commands:
 - [aws iam detach-user-policy](#)
 - [aws iam detach-group-policy](#)
 - [aws iam detach-role-policy](#)

To remove a permissions boundary (AWS CLI)

1. (Optional) To view which managed policy is currently used to set the permissions boundary for a user or role, run the following commands:
 - [aws iam get-user](#)
 - [aws iam get-role](#)
2. (Optional) To view the users or roles on which a managed policy is used for a permissions boundary, run the following command:
 - [aws iam list-entities-for-policy](#)
3. (Optional) To view information about a managed policy, run the following commands:
 - To list managed policies: [aws iam list-policies](#)
 - To retrieve detailed information about a managed policy: [aws iam get-policy](#)
4. To remove a permissions boundary from a user or role, use one of the following commands:
 - [aws iam delete-user-permissions-boundary](#)
 - [aws iam delete-role-permissions-boundary](#)

To delete an inline policy (AWS CLI)

1. (Optional) To list all inline policies that are attached to an identity (user, user group, role), use one of the following commands:
 - [aws iam list-user-policies](#)
 - [aws iam list-group-policies](#)
 - [aws iam list-role-policies](#)
2. (Optional) To retrieve an inline policy document that is embedded in an identity (user, user group, or role), use one of the following commands:
 - [aws iam get-user-policy](#)
 - [aws iam get-group-policy](#)
 - [aws iam get-role-policy](#)
3. To delete an inline policy from an identity (user, user group, or role that is not a [service-linked role](#)), use one of the following commands:

- [aws iam delete-user-policy](#)
- [aws iam delete-group-policy](#)
- [aws iam delete-role-policy](#)

Adding IAM policies (AWS API)

You can use the AWS API to attach managed policies that control permissions or specify a policy that serves as a [permissions boundary](#). You can also embed an inline policy.

To use a managed policy as a permissions policy for an entity (AWS API)

1. (Optional) To view information about a policy, call the following operations:
 - To list managed policies: [ListPolicies](#)
 - To retrieve detailed information about a managed policy: [GetPolicy](#)
2. To attach a managed policy to an identity (user, user group, or role), call one of the following operations:
 - [AttachUserPolicy](#)
 - [AttachGroupPolicy](#)
 - [AttachRolePolicy](#)

To use a managed policy to set a permissions boundary (AWS API)

1. (Optional) To view information about a managed policy, call the following operations:
 - To list managed policies: [ListPolicies](#)
 - To retrieve detailed information about a managed policy: [GetPolicy](#)
2. To use a managed policy to set the permissions boundary for an entity (user or role), call one of the following operations:
 - [PutUserPermissionsBoundary](#)
 - [PutRolePermissionsBoundary](#)

To embed an inline policy (AWS API)

To embed an inline policy in an identity (user, user group, or role that is not a [service-linked role](#)), call one of the following operations:

- [PutUserPolicy](#)
- [PutGroupPolicy](#)
- [PutRolePolicy](#)

Removing IAM policies (AWS API)

You can use the AWS API to detach managed policies that control permissions or remove a policy that serves as a [permissions boundary](#). You can also delete an inline policy.

To detach a managed policy used as a permissions policy (AWS API)

1. (Optional) To view information about a policy, call the following operations:
 - To list managed policies: [ListPolicies](#)
 - To retrieve detailed information about a managed policy: [GetPolicy](#)
2. (Optional) To find out about the relationships between the policies and identities, call the following operations:
 - To list the identities (users, user groups, and roles) to which a managed policy is attached:
 - [ListEntitiesForPolicy](#)
 - To list the managed policies attached to an identity (a user, user group, or role), call one of the following operations:
 - [ListAttachedUserPolicies](#)
 - [ListAttachedGroupPolicies](#)
 - [ListAttachedRolePolicies](#)
3. To detach a managed policy from an identity (user, user group, or role), call one of the following operations:
 - [DetachUserPolicy](#)
 - [DetachGroupPolicy](#)
 - [DetachRolePolicy](#)

To remove a permissions boundary (AWS API)

1. (Optional) To view which managed policy is currently used to set the permissions boundary for a user or role, call the following operations:
 - [GetUser](#)
 - [GetRole](#)
2. (Optional) To view the users or roles on which a managed policy is used for a permissions boundary, call the following operation:
 - [ListEntitiesForPolicy](#)
3. (Optional) To view information about a managed policy, call the following operations:
 - To list managed policies: [ListPolicies](#)
 - To retrieve detailed information about a managed policy: [GetPolicy](#)
4. To remove a permissions boundary from a user or role, call one of the following operations:
 - [DeleteUserPermissionsBoundary](#)
 - [DeleteRolePermissionsBoundary](#)

To delete an inline policy (AWS API)

1. (Optional) To list all inline policies that are attached to an identity (user, user group, role), call one of the following operations:
 - [ListUserPolicies](#)
 - [ListGroupPolicies](#)
 - [ListRolePolicies](#)
2. (Optional) To retrieve an inline policy document that is embedded in an identity (user, user group, or role), call one of the following operations:
 - [GetUserPolicy](#)
 - [GetGroupPolicy](#)
 - [GetRolePolicy](#)
3. To delete an inline policy from an identity (user, user group, or role that is not a [service-linked role](#)), call one of the following operations:

- [DeleteUserPolicy](#)
- [DeleteGroupPolicy](#)
- [DeleteRolePolicy](#)

Versioning IAM policies

When you make changes to an IAM customer managed policy, and when AWS makes changes to an AWS managed policy, the changed policy doesn't overwrite the existing policy. Instead, IAM creates a new *version* of the managed policy. IAM stores up to five versions of your customer managed policies. IAM does not support versioning for inline policies.

The following diagram illustrates versioning for a customer managed policy. In this example, the versions 1-4 are saved. You can have up to five managed policy versions saved to IAM. When you edit a policy that would create a sixth saved version, you can choose which older version should no longer be saved. You can revert to any of the other four saved versions at any time.

Multiple versions of a single managed policy

A policy version is different from a `Version` policy element. The `Version` policy element is used within a policy and defines the version of the policy language. To learn more about the `Version` policy element see [IAM JSON policy elements: Version](#).

You can use versions to track changes to a managed policy. For example, you might make a change to a managed policy and then discover that the change had unintended effects. In this case, you can roll back to a previous version of the managed policy by setting the previous version as the *default* version.

The following topics explain how you can use versioning for managed policies.

Topics

- [Permissions for setting the default version of a policy](#)

- [Setting the default version of customer managed policies](#)
- [Using versions to roll back changes](#)
- [Version limits](#)

Permissions for setting the default version of a policy

The permissions that are required to set the default version of a policy correspond to the AWS API operations for the task. You can use the `CreatePolicyVersion` or `SetDefaultPolicyVersion` API operations to set the default version of a policy. To allow someone to set the default policy version of an existing policy, you can allow access to either the `iam:CreatePolicyVersion` action or the `iam:SetDefaultPolicyVersion` action. The `iam:CreatePolicyVersion` action allows them to create a new version of the policy and to set that version as the default. The `iam:SetDefaultPolicyVersion` action allows them to set any existing version of the policy as the default.

Important

Denying the `iam:SetDefaultPolicyVersion` action in a user's policy does not stop the user from creating a new policy version and setting it as the default.

You can use the following policy to deny a user access to change an existing customer managed policy:

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Deny",
      "Action": [
        "iam:CreatePolicyVersion",
        "iam:SetDefaultPolicyVersion"
      ],
      "Resource": "arn:aws:iam::*:policy/POLICY-NAME"
    }
  ]
}
```

Setting the default version of customer managed policies

One of the versions of a managed policy is set as the *default* version. The policy's default version is the operative version—that is, it's the version that is in effect for all of the principal entities (users, user groups, and roles) that the managed policy is attached to.

When you create a customer managed policy, the policy begins with a single version identified as v1. For managed policies with only a single version, that version is automatically set as the default. For customer managed policies with more than one version, you choose which version to set as the default. For AWS managed policies, the default version is set by AWS. The following diagrams illustrate this concept.

Managed policy with one version

Managed policy with multiple versions

You can set the default version of a customer managed policy to apply that version to every IAM identity (user, user group, and role) where the policy is attached. You cannot set the default version for an AWS managed policy or an inline policy.

To set the default version of a customer managed policy (console)

1. Sign in to the AWS Management Console and open the IAM console at <https://console.aws.amazon.com/iam/>.
2. In the navigation pane, choose **Policies**.
3. In the list of policies, choose the policy name of the policy to set the default version of. You can use the search box to filter the list of policies.
4. Choose the **Policy versions** tab. Select the check box next to the version that you want to set as the default version, and then choose **Set as default**.

To learn how to set the default version of a customer managed policy from the AWS Command Line Interface or the AWS API, see [Editing customer managed policies \(AWS CLI\)](#).

Using versions to roll back changes

You can set the default version of a customer managed policy to roll back your changes. For example, consider the following scenario:

You create a customer managed policy that allows users to administer a particular Amazon S3 bucket using the AWS Management Console. Upon creation, your customer managed policy has only one version, identified as v1, so that version is automatically set as the default. The policy works as intended.

Later, you update the policy to add permission to administer a second Amazon S3 bucket. IAM creates a new version of the policy, identified as v2, that contains your changes. You set version v2 as the default, and a short time later your users report that they lack permission to use the Amazon S3 console. In this case, you can roll back to version v1 of the policy, which you know works as intended. To do this, you set version v1 as the default version. Your users are now able to use the Amazon S3 console to administer the original bucket.

Later, after you determine the error in version v2 of the policy, you update the policy again to add permission to administer the second Amazon S3 bucket. IAM creates another new version of the policy, identified as v3. You set version v3 as the default, and this version works as intended. At this point, you delete version v2 of the policy.

Version limits

A managed policy can have up to five versions. If you need to make changes to a managed policy beyond five versions from the AWS Command Line Interface, or the AWS API, you must first delete one or more existing versions. If you use the AWS Management Console, you do not have to delete a version before editing your policy. When you save a sixth version, a dialog box appears that prompts you to delete one or more nondefault versions of your policy. You can view the JSON policy document for each version to help you decide. For details about this dialog box, see [the section called “Editing IAM policies”](#).

You can delete any version of the managed policy that you want, except for the default version. When you delete a version, the version identifiers for the remaining versions do not change. As a result, version identifiers might not be sequential. For example, if you delete versions v2 and v4 of a managed policy and add two new versions, the remaining version identifiers might be v1, v3, v5, v6, and v7.

Editing IAM policies

A [policy](#) is an entity that, when attached to an identity or resource, defines their permissions. Policies are stored in AWS as JSON documents and are attached to principals as *identity-based policies* in IAM. You can attach an identity-based policy to a principal (or identity), such as an IAM user group, user, or role. Identity-based policies include AWS managed policies, customer managed policies, and [inline policies](#). You can edit customer managed policies and inline policies in IAM. AWS managed policies cannot be edited. The number and size of IAM resources in an AWS account are limited. For more information, see [IAM and AWS STS quotas](#).

Topics

- [View policy access](#)
- [Editing customer managed policies \(console\)](#)
- [Editing inline policies \(console\)](#)
- [Editing customer managed policies \(AWS CLI\)](#)
- [Editing customer managed policies \(AWS API\)](#)

View policy access

Before you change the permissions for a policy, you should review its recent service-level activity. This is important because you don't want to remove access from a principal (person or application)

who is using it. For more information about viewing last accessed information, see [Refining permissions in AWS using last accessed information](#).

Editing customer managed policies (console)

You can edit customer managed policies to change the permissions that are defined in the policy. A customer managed policy can have up to five versions. This is important because if you make changes to a managed policy beyond five versions, the AWS Management Console prompts you to decide which version to delete. You can also change the default version or delete a version of a policy before you edit it to avoid being prompted. To learn more about versions, see [Versioning IAM policies](#).

To edit a customer managed policy (console)

1. Sign in to the AWS Management Console and open the IAM console at <https://console.aws.amazon.com/iam/>.
2. In the navigation pane, choose **Policies**.
3. In the list of policies, choose the policy name of the policy to edit. You can use the search box to filter the list of policies.
4. Choose the **Permissions** tab, and then choose **Edit**.
5. Do one of the following:
 - Choose the **Visual** option to change your policy without understanding JSON syntax. You can make changes to the service, actions, resources, or optional conditions for each permission block in your policy. You can also import a policy to add additional permissions to the bottom of your policy. When you are finished making changes, choose **Next** to continue.
 - Choose the **JSON** option to modify your policy by typing or pasting text in the JSON text box. You can also import a policy to add additional permissions to the bottom of your policy. Resolve any security warnings, errors, or general warnings generated during [policy validation](#), and then choose **Next**.

Note

You can switch between the **Visual** and **JSON** editor options any time. However, if you make changes or choose **Next** in the **Visual** editor, IAM might restructure

your policy to optimize it for the visual editor. For more information, see [Policy restructuring](#).

6. On the **Review and save** page, review **Permissions defined in this policy** and then choose **Save changes** to save your work.
7. If the managed policy already has the maximum of five versions, choosing **Save changes** displays a dialog box. To save your new version, the oldest non-default version of the policy is removed and replaced with this new version. Optionally, you can set the new version as the default policy version.

Choose **Save changes** to save your new policy version.

To set the default version of a customer managed policy (console)

1. Sign in to the AWS Management Console and open the IAM console at <https://console.aws.amazon.com/iam/>.
2. In the navigation pane, choose **Policies**.
3. In the list of policies, choose the policy name of the policy to set the default version of. You can use the search box to filter the list of policies.
4. Choose the **Policy versions** tab. Select the check box next to the version that you want to set as the default version, and then choose **Set as default**.

To delete a version of a customer managed policy (console)

1. Sign in to the AWS Management Console and open the IAM console at <https://console.aws.amazon.com/iam/>.
2. In the navigation pane, choose **Policies**.
3. Choose the name of the customer managed policy that has a version you want to delete. You can use the search box to filter the list of policies.
4. Choose the **Policy versions** tab. Select the check box next to the version that you want to delete. Then choose **Delete**.
5. Confirm that you want to delete the version, and then choose **Delete**.

Editing inline policies (console)

You can edit an inline policy from the AWS Management Console.

To edit an inline policy for a user, user group, or role (console)

1. In the navigation pane, choose **Users, User groups, or Roles**.
2. Choose the name of the user, user group, or role with the policy that you want to modify. Then choose the **Permissions** tab and expand the policy.
3. To edit an inline policy, choose **Edit Policy**.
4. Do one of the following:
 - Choose the **Visual** option to change your policy without understanding JSON syntax. You can make changes to the service, actions, resources, or optional conditions for each permission block in your policy. You can also import a policy to add additional permissions to the bottom of your policy. When you are finished making changes, choose **Next** to continue.
 - Choose the **JSON** option to modify your policy by typing or pasting text in the JSON text box. You can also import a policy to add additional permissions to the bottom of your policy. Resolve any security warnings, errors, or general warnings generated during [policy validation](#), and then choose **Next**. To save your changes without affecting the currently attached entities, clear the check box for **Save as default version**.
5. On the **Review** page, review the policy summary and then choose **Save changes** to save your work.

Note

You can switch between the **Visual** and **JSON** editor options any time. However, if you make changes or choose **Next** in the **Visual** editor, IAM might restructure your policy to optimize it for the visual editor. For more information, see [Policy restructuring](#).

Editing customer managed policies (AWS CLI)

You can edit a customer managed policy from the AWS Command Line Interface (AWS CLI).

Note

A managed policy can have up to five versions. If you need to make changes to a customer managed policy beyond five versions, you must first delete one or more existing versions.

To edit a customer managed policy (AWS CLI)

1. (Optional) To view information about a policy, run the following commands:
 - To list managed policies: [list-policies](#)
 - To retrieve detailed information about a managed policy: [get-policy](#)
2. (Optional) To find out about the relationships between the policies and identities, run the following commands:
 - To list the identities (users, user groups, and roles) to which a managed policy is attached:
 - [list-entities-for-policy](#)
 - To list the managed policies attached to an identity (a user, user group, or role):
 - [list-attached-user-policies](#)
 - [list-attached-group-policies](#)
 - [list-attached-role-policies](#)
3. To edit a customer managed policy, run the following command:
 - [create-policy-version](#)
4. (Optional) To validate a customer managed policy, run the following IAM Access Analyzer command:
 - [validate-policy](#)

To set the default version of a customer managed policy (AWS CLI)

1. (Optional) To list managed policies, run the following command:
 - [list-policies](#)
2. To set the default version of a customer managed policy, run the following command:
 - [set-default-policy-version](#)

To delete a version of a customer managed policy (AWS CLI)

1. (Optional) To list managed policies, run the following command:
 - [list-policies](#)
2. To delete a customer managed policy, run the following command:
 - [delete-policy-version](#)

Editing customer managed policies (AWS API)

You can edit a customer managed policy using the AWS API.

Note

A managed policy can have up to five versions. If you need to make changes to a customer managed policy beyond five versions, you must first delete one or more existing versions.

To edit a customer managed policy (AWS API)

1. (Optional) To view information about a policy, call the following operations:
 - To list managed policies: [ListPolicies](#)
 - To retrieve detailed information about a managed policy: [GetPolicy](#)
2. (Optional) To find out about the relationships between the policies and identities, call the following operations:
 - To list the identities (users, user groups, and roles) to which a managed policy is attached:
 - [ListEntitiesForPolicy](#)
 - To list the managed policies attached to an identity (a user, user group, or role):
 - [ListAttachedUserPolicies](#)
 - [ListAttachedGroupPolicies](#)
 - [ListAttachedRolePolicies](#)
3. To edit a customer managed policy, call the following operation:
 - [CreatePolicyVersion](#)

4. (Optional) To validate a customer managed policy, call the following IAM Access Analyzer operation:
 - [ValidatePolicy](#)

To set the default version of a customer managed policy (AWS API)

1. (Optional) To list managed policies, call the following operation:
 - [ListPolicies](#)
2. To set the default version of a customer managed policy, call the following operation:
 - [SetDefaultPolicyVersion](#)

To delete a version of a customer managed policy (AWS API)

1. (Optional) To list managed policies, call the following operation:
 - [ListPolicies](#)
2. To delete a customer managed policy, call the following operation:
 - [DeletePolicyVersion](#)

Deleting IAM policies

You can delete IAM policies using the AWS Management Console, the AWS Command Line Interface (AWS CLI), or the IAM API.

Note

Deletion of IAM policies is permanent. After the policy is deleted it cannot be recovered.

For more information about the difference between managed and inline policies, see [Managed policies and inline policies](#).

For general information about IAM policies, see [Policies and permissions in IAM](#).

The number and size of IAM resources in an AWS account are limited. For more information, see [IAM and AWS STS quotas](#).

Topics

- [View policy access](#)
- [Deleting IAM policies \(console\)](#)
- [Deleting IAM policies \(AWS CLI\)](#)
- [Deleting IAM policies \(AWS API\)](#)

View policy access

Before you delete a policy, you should review its recent service-level activity. This is important because you don't want to remove access from a principal (person or application) who is using it. For more information about viewing last accessed information, see [Refining permissions in AWS using last accessed information](#).

Deleting IAM policies (console)

You can delete a customer managed policy to remove it from your AWS account. You cannot delete AWS managed policies.

To delete a customer managed policy (console)

1. Sign in to the AWS Management Console and open the IAM console at <https://console.aws.amazon.com/iam/>.
2. In the navigation pane, choose **Policies**.
3. Select the radio button next to the customer managed policy to delete. You can use the search box to filter the list of policies.
4. Choose **Actions**, and then choose **Delete**.
5. Follow the instructions to confirm that you want to delete the policy, and then choose **Delete**.

To delete an inline policy for a user group, user, or role (console)

1. In the navigation pane, choose **User groups**, **Users**, or **Roles**.
2. Choose the name of the user group, user, or role with the policy that you want to delete. Then choose the **Permissions** tab.

3. Select the check boxes next to the policies to delete and choose **Remove**. To delete an inline policy in **Users** or **Roles**, choose **Remove** to confirm the deletion. If you are deleting a single inline policy in **User groups**, type the name of the policy and choose **Delete**. If you are deleting multiple inline policies in **User groups**, type the number of policies you are deleting followed by **inline policies** and choose **Delete**. For example, if you are deleting three inline policies, type **3 inline policies**.

Deleting IAM policies (AWS CLI)

You can delete a customer managed policy from the AWS Command Line Interface.

To delete a customer managed policy (AWS CLI)

1. (Optional) To view information about a policy, run the following commands:
 - To list managed policies: [list-policies](#)
 - To retrieve detailed information about a managed policy: [get-policy](#)
2. (Optional) To find out about the relationships between the policies and identities, run the following commands:
 - To list the identities (users, user groups, and roles) to which a managed policy is attached, run the following command:
 - [list-entities-for-policy](#)
 - To list the managed policies attached to an identity (a user, user group, or role), run one of the following commands:
 - [list-attached-user-policies](#)
 - [list-attached-group-policies](#)
 - [list-attached-role-policies](#)
3. To delete a customer managed policy, run the following command:
 - [delete-policy](#)

To delete an inline policy (AWS CLI)

1. (Optional) To list all inline policies that are attached to an identity (user, user group, role), use one of the following commands:

- [aws iam list-user-policies](#)
 - [aws iam list-group-policies](#)
 - [aws iam list-role-policies](#)
2. (Optional) To retrieve an inline policy document that is embedded in an identity (user, user group, or role), use one of the following commands:
 - [aws iam get-user-policy](#)
 - [aws iam get-group-policy](#)
 - [aws iam get-role-policy](#)
 3. To delete an inline policy from an identity (user, user group, or role that is not a [service-linked role](#)), use one of the following commands:
 - [aws iam delete-user-policy](#)
 - [aws iam delete-group-policy](#)
 - [aws iam delete-role-policy](#)

Deleting IAM policies (AWS API)

You can delete a customer managed policy using the AWS API.

To delete a customer managed policy (AWS API)

1. (Optional) To view information about a policy, call the following operations:
 - To list managed policies: [ListPolicies](#)
 - To retrieve detailed information about a managed policy: [GetPolicy](#)
2. (Optional) To find out about the relationships between the policies and identities, call the following operations:
 - To list the identities (users, user groups, and roles) to which a managed policy is attached, call the following operation:
 - [ListEntitiesForPolicy](#)
 - To list the managed policies attached to an identity (a user, user group, or role), call one of the following operations:
 - [ListAttachedUserPolicies](#)

- [ListAttachedGroupPolicies](#)
 - [ListAttachedRolePolicies](#)
3. To delete a customer managed policy, call the following operation:
 - [DeletePolicy](#)

To delete an inline policy (AWS API)

1. (Optional) To list all inline policies that are attached to an identity (user, user group, role), call one of the following operations:
 - [ListUserPolicies](#)
 - [ListGroupPolicies](#)
 - [ListRolePolicies](#)
2. (Optional) To retrieve an inline policy document that is embedded in an identity (user, user group, or role), call one of the following operations:
 - [GetUserPolicy](#)
 - [GetGroupPolicy](#)
 - [GetRolePolicy](#)
3. To delete an inline policy from an identity (user, user group, or role that is not a [service-linked role](#)), call one of the following operations:
 - [DeleteUserPolicy](#)
 - [DeleteGroupPolicy](#)
 - [DeleteRolePolicy](#)

Refining permissions in AWS using last accessed information

As an administrator, you might grant permissions to IAM resources (roles, users, user groups, or policies) beyond what they require. IAM provides last accessed information to help you identify unused permissions so that you can remove them. You can use last accessed information to refine your policies and allow access to only the services and actions that your IAM identities and policies use. This helps you to better adhere to the [best practice of least privilege](#). You can view last accessed information for identities or policies that exist in IAM or AWS Organizations.

You can continuously monitor last accessed information with unused access analyzers. For more information, see [Findings for external and unused access](#).

Topics

- [Last accessed information types for IAM](#)
- [Last accessed information for AWS Organizations](#)
- [Things to know about last accessed information](#)
- [Permissions required](#)
- [Troubleshooting activity for IAM and Organizations entities](#)
- [Where AWS tracks last accessed information](#)
- [Viewing last accessed information for IAM](#)
- [Viewing last accessed information for Organizations](#)
- [Example scenarios for using last accessed information](#)
- [IAM action last accessed information services and actions](#)

Last accessed information types for IAM

You can view two types of last accessed information for IAM identities: allowed AWS service information and allowed action information. The information includes the date and time when the attempt to access an AWS API was made. For actions, last accessed information reports service management actions. Management actions include creation, deletion, and modification actions. To learn more about how to view last accessed information for IAM, see [Viewing last accessed information for IAM](#).

For example scenarios for using last accessed information to make decisions about the permissions that you grant to your IAM identities, see [Example scenarios for using last accessed information](#).

To learn more about how the information for management actions is provided, see [Things to know about last accessed information](#).

Last accessed information for AWS Organizations

If you sign in using management account credentials, you can view service last accessed information for an AWS Organizations entity or policy in your organization. AWS Organizations entities include the organization root, organizational units (OUs), or accounts. Last accessed information for AWS Organizations includes information about services that are allowed by a

service control policy (SCP). The information indicates which principals (root user, IAM user, or role) in an organization or account last attempted to access the service and when. To learn more about the report and how to view last accessed information for AWS Organizations, see [Viewing last accessed information for Organizations](#).

For example scenarios for using last accessed information to make decisions about the permissions that you grant to your Organizations entities, see [Example scenarios for using last accessed information](#).

Things to know about last accessed information

Before you use last accessed information from a report to change the permissions for an IAM identity or Organizations entity, review the following details about the information.

- **Tracking period** – Recent activity appears in the IAM console within four hours. The tracking period for service information is at least 400 days depending on when the service started tracking actions information. The tracking period for Amazon S3 actions information began on April, 12, 2020. The tracking period for Amazon EC2, IAM, and Lambda actions began on April 7, 2021. The tracking period for all other services began on May 23, 2023. For a list of services for which action last accessed information is available, see [IAM action last accessed information services and actions](#). For more information on which Regions action last accessed information is available in, see [Where AWS tracks last accessed information](#).
- **Attempts reported** – The service last accessed data includes all attempts to access an AWS API, not just the successful attempts. This includes all attempts that were made using the AWS Management Console, the AWS API through any of the SDKs, or any of the command line tools. An unexpected entry in the service last accessed data does not mean that your account has been compromised, because the request might have been denied. Refer to your CloudTrail logs as the authoritative source for information about all API calls and whether they were successful or denied access.
- **PassRole** – The `iam:PassRole` action is not tracked and is not included in IAM action last accessed information.
- **Action last accessed information** – Action last accessed information is available for service management actions accessed by IAM identities. See the [list of services and their actions](#) for which action last accessed reports information.

Note

Action last accessed information is not available for Amazon S3 data events.

- **Management events** – IAM provides action information for service management events that are logged by CloudTrail. Sometimes, CloudTrail management events are also called control plane operations or control plane events. Management events provide visibility into administrative operations that are performed on resources in your AWS account. To learn more about management events in CloudTrail, see [Logging management events](#) in the *AWS CloudTrail User Guide*.
- **Report owner** – Only the principal that generates a report can view the report details. This means that when you view the information in the AWS Management Console, you might have to wait for it to generate and load. If you use the AWS CLI or AWS API to get report details, your credentials must match the credentials of the principal that generated the report. If you use temporary credentials for a role or federated user, you must generate and retrieve the report during the same session. For more information about assumed-role session principals, see [AWS JSON policy elements: Principal](#).
- **IAM resources** – The last accessed information for IAM includes IAM resources (roles, users, user groups, and policies) in your account. Last accessed information for Organizations includes principals (IAM users, IAM roles, or the AWS account root user) in the specified Organizations entity. The last accessed information does not include unauthenticated attempts.
- **IAM policy types** – The last accessed information for IAM includes services that are allowed by an IAM identity's policies. These are policies attached to a role or attached to a user directly or through a group. Access allowed by other policy types is not included in your report. The excluded policy types include resource-based policies, access control lists, AWS Organizations SCPs, IAM permissions boundaries, and session policies. Permissions that are provided by service-linked roles are defined by the service that they are linked to and can't be modified in IAM. To learn more about service-linked roles, see [Using service-linked roles](#) To learn how the different policy types are evaluated to allow or deny access, see [Policy evaluation logic](#).
- **Organizations policy types** – The information for AWS Organizations includes only services that are allowed by an Organizations entity's inherited service control policies (SCPs). SCPs are policies attached to a root, OU, or account. Access allowed by other policy types is not included in your report. The excluded policy types include identity-based policies, resource-based policies, access control lists, IAM permissions boundaries, and session policies. To learn how the different policy types are evaluated to allow or deny access, see [Policy evaluation logic](#).

- **Specifying a policy ID** – When you use the AWS CLI or AWS API to generate a report for last accessed information in Organizations, you can optionally specify a policy ID. The resulting report includes information for the services that are allowed by only that policy. The information includes the most recent account activity in the specified Organizations entity or the entity's children. For more information, see [aws iam generate-organizations-access-report](#) or [GenerateOrganizationsAccessReport](#).
- **Organizations management account** – You must sign in to your organization's management account to view service last accessed information. You can choose to view information for the management account using the IAM console, the AWS CLI, or the AWS API. The resulting report lists all AWS services, because the management account is not limited by SCPs. If you specify a policy ID in the CLI or API, the policy is ignored. For each service, the report includes information for only the management account. However, reports for other Organizations entities do not return information for activity in the management account.
- **Organizations settings** – An administrator must [enable SCPs in your organization root](#) before you can generate data for Organizations.

Permissions required

To view the last accessed information in the AWS Management Console, you must have a policy that grants the necessary permissions.

Permissions for IAM information

To use the IAM console to view the last accessed information for an IAM user, role, or policy, you must have a policy that includes the following actions:

- `iam:GenerateServiceLastAccessedDetails`
- `iam:Get*`
- `iam:List*`

These permissions allow a user to see the following:

- Which users, groups, or roles are attached to a [managed policy](#)
- Which services a user or role can access
- The last time they accessed the service
- The last time they attempted to use a specific Amazon EC2, IAM, Lambda, or Amazon S3 action

To use the AWS CLI or AWS API to view last accessed information for IAM, you must have permissions that match the operation you want to use:

- `iam:GenerateServiceLastAccessedDetails`
- `iam:GetServiceLastAccessedDetails`
- `iam:GetServiceLastAccessedDetailsWithEntities`
- `iam:ListPoliciesGrantingServiceAccess`

This example shows how you might create an identity-based policy that allows viewing IAM last accessed information. Additionally, it allows read-only access to all of IAM. This policy defines permissions for programmatic and console access.

```
{
  "Version": "2012-10-17",
  "Statement": {
    "Effect": "Allow",
    "Action": [
      "iam:GenerateServiceLastAccessedDetails",
      "iam:Get*",
      "iam:List*"
    ],
    "Resource": "*"
  }
}
```

Permissions for AWS Organizations information

To use the IAM console to view a report for the root, OU, or account entities in Organizations, you must have a policy that includes the following actions:

- `iam:GenerateOrganizationsAccessReport`
- `iam:GetOrganizationsAccessReport`
- `organizations:DescribeAccount`
- `organizations:DescribeOrganization`
- `organizations:DescribeOrganizationalUnit`
- `organizations:DescribePolicy`
- `organizations:ListChildren`
- `organizations:ListParents`

- `organizations:ListPoliciesForTarget`
- `organizations:ListRoots`
- `organizations:ListTargetsForPolicy`

To use the AWS CLI or AWS API to view service last accessed information for Organizations, you must have a policy that includes the following actions:

- `iam:GenerateOrganizationsAccessReport`
- `iam:GetOrganizationsAccessReport`
- `organizations:DescribePolicy`
- `organizations:ListChildren`
- `organizations:ListParents`
- `organizations:ListPoliciesForTarget`
- `organizations:ListRoots`
- `organizations:ListTargetsForPolicy`

This example shows how you might create an identity-based policy that allows viewing service last accessed information for Organizations. Additionally, it allows read-only access to all of Organizations. This policy defines permissions for programmatic and console access.

```
{
  "Version": "2012-10-17",
  "Statement": {
    "Effect": "Allow",
    "Action": [
      "iam:GenerateOrganizationsAccessReport",
      "iam:GetOrganizationsAccessReport",
      "organizations:Describe*",
      "organizations:List*"
    ],
    "Resource": "*"
  }
}
```

You can also use the [iam:OrganizationsPolicyId](#) condition key to allow generating a report only for a specific Organizations policy. For an example policy, see [IAM: View service last accessed information for an Organizations policy](#).

Troubleshooting activity for IAM and Organizations entities

In some cases, your AWS Management Console last accessed information table might be empty. Or perhaps your AWS CLI or AWS API request returns an empty set of information or a null field. In these cases, review the following issues:

- For action last accessed information, an action that you are expecting to see might not be returned in the list. This can happen either because the IAM identity does not have permissions for the action, or AWS does not yet track the action for last accessed information.
- For an IAM user, make sure that the user has at least one inline or managed policy attached, either directly or through group memberships.
- For an IAM group, verify that the group has at least one inline or managed policy attached.
- For an IAM group, the report returns only the service last accessed information for members that used the group's policies to access a service. To learn whether a member used other policies, review the last accessed information for that user.
- For an IAM role, verify that the role has at least one inline or managed policy attached.
- For an IAM entity (user or role), review other policy types that might affect the permissions of that entity. These include resource-based policies, access control lists, AWS Organizations policies, IAM permissions boundaries, or session policies. For more information, see [Policy types](#) or [Evaluating policies within a single account](#).
- For an IAM policy, make sure that the specified managed policy is attached to at least one user, group with members, or role.
- For an Organizations entity (root, OU, or account), make sure that you are signed using Organizations management account credentials.
- Verify that [SCPs are enabled in your organization root](#).
- Action last accessed information is only available for the actions listed in [IAM action last accessed information services and actions](#).

When you make changes, wait at least four hours for activity to appear in your IAM console report. If you use the AWS CLI or AWS API, you must generate a new report to view the updated information.

Where AWS tracks last accessed information

AWS collects last accessed information for the standard AWS Regions. When AWS adds additional Regions, those Regions are added to the following table, including the date that AWS started tracking information in each Region.

- **Service information** – The tracking period for services is at least 400 days, or less if your Region began tracking this feature within the last 400 days.
- **Actions information** – The tracking period for Amazon S3 management actions began on April, 12, 2020. The tracking period for Amazon EC2, IAM, and Lambda management actions began on April 7, 2021. The tracking period for management actions of all other services began on May 23, 2023. If a Region's tracking date is later than May 23, 2023, then action last accessed information from that Region will start at the later date.

Region name	Region	Tracking start date
US East (Ohio)	us-east-2	October 27, 2017
US East (N. Virginia)	us-east-1	October 1, 2015
US West (N. California)	us-west-1	October 1, 2015
US West (Oregon)	us-west-2	October 1, 2015
Africa (Cape Town)	af-south-1	April 22, 2020
Asia Pacific (Hong Kong)	ap-east-1	April 24, 2019
Asia Pacific (Hyderabad)	ap-south-2	November 22, 2022
Asia Pacific (Jakarta)	ap-southeast-3	December 13, 2021
Asia Pacific (Melbourne)	ap-southeast-4	January 23, 2023
Asia Pacific (Mumbai)	ap-south-1	June 27, 2016
Asia Pacific (Osaka)	ap-northeast-3	February 11, 2018
Asia Pacific (Seoul)	ap-northeast-2	January 6, 2016

Region name	Region	Tracking start date
Asia Pacific (Singapore)	ap-southeast-1	October 1, 2015
Asia Pacific (Sydney)	ap-southeast-2	October 1, 2015
Asia Pacific (Tokyo)	ap-northeast-1	October 1, 2015
Canada (Central)	ca-central-1	October 28, 2017
Europe (Frankfurt)	eu-central-1	October 1, 2015
Europe (Ireland)	eu-west-1	October 1, 2015
Europe (London)	eu-west-2	October 28, 2017
Europe (Milan)	eu-south-1	April 28, 2020
Europe (Paris)	eu-west-3	December 18, 2017
Europe (Spain)	eu-south-2	November 15, 2022
Europe (Stockholm)	eu-north-1	December 12, 2018
Europe (Zurich)	eu-central-2	November 8, 2022
Israel (Tel Aviv)	il-central-1	August 1, 2023
Middle East (Bahrain)	me-south-1	July 29, 2019
Middle East (UAE)	me-central-1	August 30, 2022
South America (São Paulo)	sa-east-1	December 11, 2015
AWS GovCloud (US-East)	us-gov-east-1	July 1, 2023
AWS GovCloud (US-West)	us-gov-west-1	July 1, 2023

If a Region is not listed in the previous table, then that Region does not yet provide last accessed information.

An AWS Region is a collection of AWS resources in a geographic area. Regions are grouped into partitions. The standard Regions are the Regions that belong to the `aws` partition. For more information about the different partitions, see [Amazon Resource Names \(ARNs\) Format](#) in the AWS General Reference. For more information about Regions, see [About AWS Regions](#) also in the AWS General Reference.

Viewing last accessed information for IAM

You can view last accessed information for IAM using the AWS Management Console, AWS CLI, or AWS API. See the [list of services and their actions](#) for which last accessed information is displayed. For more information about last accessed information, see [Refining permissions in AWS using last accessed information](#).

You can view information for the following resource types in IAM. In each case, the information includes allowed services for the given reporting period:

- **User** – View the last time that the user attempted to access each allowed service.
- **User group** – View information about the last time that a user group member attempted to access each allowed service. This report also includes the total number of members that attempted access.
- **Role** – View the last time that someone used the role in an attempt to access each allowed service.
- **Policy** – View information about the last time that a user or role attempted to access each allowed service. This report also includes the total number of entities that attempted access.

Note

Before you view the access information for a resource in IAM, make sure you understand the reporting period, reported entities, and the evaluated policy types for your information. For more details, see [the section called “Things to know about last accessed information”](#).

Viewing information for IAM (console)

You can view last accessed information for IAM on the **Access Advisor** tab in the IAM console.

To view information for IAM (console)

1. Sign in to the AWS Management Console and open the IAM console at <https://console.aws.amazon.com/iam/>.
2. In the navigation pane, choose either **User groups**, **Users**, **Roles**, or **Policies**.
3. Choose any user, user group, role, or policy name to open its **Summary** page and choose the **Access Advisor** tab. View the following information, based on the resource that you chose:
 - **User group** – View the list of services that user group members can access. You can also view when a member last accessed the service, what user group policies they used, and which user group member made the request. Choose the name of the policy to learn whether it is a managed policy or an inline user group policy. Choose the name of the user group member to see all of the members of the user group and when they last accessed the service.
 - **User** – View the list of services that the user can access. You can also view when they last accessed the service, and what policies are currently associated with the user. Choose the name of the policy to learn whether it is a managed policy, an inline user policy, or an inline policy for the user group.
 - **Role** – View the list of services that the role can access, when the role last accessed the service, and what policies were used. Choose the name of the policy to learn whether it is a managed policy or an inline role policy.
 - **Policy** – View the list of services with allowed actions in the policy. You can also view when the policy was last used to access the service, and which entity (user or role) used the policy. The **Last accessed** date also includes when access is granted to this policy through another policy. Choose the name of the entity to learn which entities have this policy attached and when they last accessed the service.
4. In the **Service** column of the table, choose the name of [one of the services that includes action last accessed information](#) to view a list of management actions that IAM entities have attempted to access. You can view the AWS Region and a timestamp that shows when someone last attempted to perform the action.
5. The **Last accessed** column is displayed for services and management actions of [the services that include action last accessed information](#). Review the following possible results that are returned in this column. These results vary depending on whether a service or action is allowed, was accessed, and whether it is tracked by AWS for last accessed information.

<number of> days ago

The number of days since the service or action was used in the tracking period. The tracking period for services is for the last 400 days. The tracking period for Amazon S3 actions started on April 12, 2020. The tracking period for Amazon EC2, IAM, and Lambda actions started on April 7, 2021. The tracking period for all other services began on May 23, 2023. To learn more about the tracking start dates for each AWS Region, see [Where AWS tracks last accessed information](#).

Not accessed in the tracking period

The tracked service or action has not been used by an entity in the tracking period.

It is possible for you to have permissions for an action that doesn't appear in the list. This can happen if the tracking information for the action is not currently included by AWS. You should not make permissions decisions based solely on the absence of tracking information. Instead, we recommend that you use this information to inform and support your overall strategy of granting least privilege. Check your policies to confirm that the level of access is appropriate.

Viewing information for IAM (AWS CLI)

You can use the AWS CLI to retrieve information about the last time that an IAM resource was used to attempt to access AWS services and Amazon S3, Amazon EC2, IAM, and Lambda actions. An IAM resource can be a user, user group, role, or policy.

To view information for IAM (AWS CLI)

1. Generate a report. The request must include the ARN of the IAM resource (user, user group, role, or policy) for which you want a report. You can specify the level of granularity that you want to generate in the report to view access details for either services or both services and actions. The request returns a `job-id` that you can then use in the `get-service-last-accessed-details` and `get-service-last-accessed-details-with-entities` operations to monitor the `job-status` until the job is complete.
 - [aws iam generate-service-last-accessed-details](#)
2. Retrieve details about the report using the `job-id` parameter from the previous step.
 - [aws iam get-service-last-accessed-details](#)

This operation returns the following information, based on the type of resource and level of granularity that you requested in the `generate-service-last-accessed-details` operation:

- **User** – Returns a list of services that the specified user can access. For each service, the operation returns the date and time of the user's last attempt and the ARN of the user.
 - **User group** – Returns a list of services that members of the specified user group can access using the policies attached to the user group. For each service, the operation returns the date and time of the last attempt made by any user group member. It also returns the ARN of that user and the total number of user group members that have attempted to access the service. Use the [GetServiceLastAccessedDetailsWithEntities](#) operation to retrieve a list of all of the members.
 - **Role** – Returns a list of services that the specified role can access. For each service, the operation returns the date and time of the role's last attempt and the ARN of the role.
 - **Policy** – Returns a list of services for which the specified policy allows access. For each service, the operation returns the date and time that an entity (user or role) last attempted to access the service using the policy. It also returns the ARN of that entity and the total number of entities that attempted access.
3. Learn more about the entities that used user group or policy permissions in an attempt to access a specific service. This operation returns a list of entities with each entity's ARN, ID, name, path, type (user or role), and when they last attempted to access the service. You can also use this operation for users and roles, but it only returns information about that entity.
 - [aws iam get-service-last-accessed-details-with-entities](#)
 4. Learn more about the identity-based policies that an identity (user, user group, or role) used in an attempt to access a specific service. When you specify an identity and service, this operation returns a list of permissions policies that the identity can use to access the specified service. This operation gives the current state of policies and does not depend on the generated report. It also does not return other policy types, such as resource-based policies, access control lists, AWS Organizations policies, IAM permissions boundaries, or session policies. For more information, see [Policy types](#) or [Evaluating policies within a single account](#).
 - [aws iam list-policies-granting-service-access](#)

Viewing information for IAM (AWS API)

You can use the AWS API to retrieve information about the last time that an IAM resource was used to attempt to access AWS services and Amazon S3, Amazon EC2, IAM, and Lambda actions. An IAM resource can be a user, user group, role, or policy. You can specify the level of granularity to generate in the report to view details for either services or both services and actions.

To view information for IAM (AWS API)

1. Generate a report. The request must include the ARN of the IAM resource (user, user group, role, or policy) for which you want a report. It returns a `JobId` that you can then use in the `GetServiceLastAccessedDetails` and `GetServiceLastAccessedDetailsWithEntities` operations to monitor the `JobStatus` until the job is complete.
 - [GenerateServiceLastAccessedDetails](#)
2. Retrieve details about the report using the `JobId` parameter from the previous step.
 - [GetServiceLastAccessedDetails](#)

This operation returns the following information, based on the type of resource and level of granularity that you requested in the `GenerateServiceLastAccessedDetails` operation:

- **User** – Returns a list of services that the specified user can access. For each service, the operation returns the date and time of the user's last attempt and the ARN of the user.
- **User group** – Returns a list of services that members of the specified user group can access using the policies attached to the user group. For each service, the operation returns the date and time of the last attempt made by any user group member. It also returns the ARN of that user and the total number of user group members that have attempted to access the service. Use the [GetServiceLastAccessedDetailsWithEntities](#) operation to retrieve a list of all of the members.
- **Role** – Returns a list of services that the specified role can access. For each service, the operation returns the date and time of the role's last attempt and the ARN of the role.
- **Policy** – Returns a list of services for which the specified policy allows access. For each service, the operation returns the date and time that an entity (user or role) last attempted to access the service using the policy. It also returns the ARN of that entity and the total number of entities that attempted access.

3. Learn more about the entities that used user group or policy permissions in an attempt to access a specific service. This operation returns a list of entities with each entity's ARN, ID, name, path, type (user or role), and when they last attempted to access the service. You can also use this operation for users and roles, but it only returns information about that entity.
 - [GetServiceLastAccessedDetailsWithEntities](#)
4. Learn more about the identity-based policies that an identity (user, user group, or role) used in an attempt to access a specific service. When you specify an identity and service, this operation returns a list of permissions policies that the identity can use to access the specified service. This operation gives the current state of policies and does not depend on the generated report. It also does not return other policy types, such as resource-based policies, access control lists, AWS Organizations policies, IAM permissions boundaries, or session policies. For more information, see [Policy types](#) or [Evaluating policies within a single account](#).
 - [ListPoliciesGrantingServiceAccess](#)

Viewing last accessed information for Organizations

You can view service last accessed information for AWS Organizations using the IAM console, AWS CLI, or AWS API. For important information about the data, permissions required, troubleshooting, and supported Regions, see [Refining permissions in AWS using last accessed information](#).

When you sign in to the IAM console using AWS Organizations management account credentials, you can view information for any entity in your organization. Organizations entities include the organization root, organizational units (OUs), and accounts. You can also use the IAM console to view information for any service control policies (SCPs) in your organization. IAM shows a list of services that are allowed by any SCPs that apply to the entity. For each service, you can view the most recent account activity information for the chosen Organizations entity or the entity's children.

When you use the AWS CLI or AWS API with management account credentials, you can generate a report for any entities or policies in your organization. A programmatic report for an entity includes a list of services that are allowed by any SCPs that apply to the entity. For each service, the report includes the most recent activity for accounts in the specified Organizations entity or the entity's subtree.

When you generate a programmatic report for a policy, you must specify an Organizations entity. This report includes a list of services that are allowed by the specified SCP. For each service,

it includes the most recent account activity in the entity or entity's children that are granted permission by that policy. For more information, see [aws iam generate-organizations-access-report](#) or [GenerateOrganizationsAccessReport](#).

Before you view the report, make sure that you understand the management account requirements and information, reporting period, reported entities, and the evaluated policy types. For more details, see [the section called "Things to know about last accessed information"](#).

Understand the AWS Organizations entity path

When you use the AWS CLI or AWS API to generate an AWS Organizations access report, you must specify an entity path. A path is a text representation of the structure of an Organizations entity.

You can build an entity path using the known structure of your organization. For example, assume that you have the following organizational structure in AWS Organizations.

The path for the **Dev Managers** OU is built using the IDs of the organization, root, and all OUs in the path down to and including the OU.

```
o-a1b2c3d4e5/r-f6g7h8i9j0example/ou-ghi0-awsccccc/ou-jkl0-awsdddddd/
```

The path for the account in the **Production** OU is built using the IDs of the organization, root, the OU, and the account number.

```
o-a1b2c3d4e5/r-f6g7h8i9j0example/ou-abc0-awsaaaaa/111111111111/
```

Note

Organization IDs are globally unique but OU IDs and root IDs are unique only within an organization. This means that no two organizations share the same organization ID. However, another organization might have an OU or root with the same ID as yours. We recommend that you always include the organization ID when you specify an OU or root.

Viewing information for Organizations (console)

You can use the IAM console to view service last accessed information for your root, OU, account, or policy.

To view information for the root (console)

1. Sign in to the AWS Management Console using Organizations management account credentials, and open the IAM console at <https://console.aws.amazon.com/iam/>.
2. In the navigation pane below the **Access reports** section, choose **Organization activity**.
3. On the **Organization activity** page, choose **Root**.
4. On the **Details and activity** tab, view the **Service access report** section. The information includes a list of services that are allowed by the policies that are attached directly to the root. The information shows you from which account the service was last accessed and when. For more details about which principal accessed the service, sign in as an administrator in that account and [view the IAM service last accessed information](#).
5. Choose the **Attached SCPs** tab to view the list of the service control policies (SCPs) that are attached to the root. IAM shows you the number of target entities to which each policy is attached. You can use this information to decide which SCP to review.
6. Choose the name of an SCP to view all of the services that the policy allows. For each service, view from which account the service was last accessed, and when.
7. Choose **Edit in AWS Organizations** to view additional details and edit the SCP in the Organizations console. For more information, see [Updating an SCP](#) in the *AWS Organizations User Guide*.

To view information for an OU or account (console)

1. Sign in to the AWS Management Console using Organizations management account credentials, and open the IAM console at <https://console.aws.amazon.com/iam/>.
2. In the navigation pane below the **Access reports** section, choose **Organization activity**.
3. On the **Organization activity** page, expand the structure of your organization. Then choose the name of the OU or any account that you want to view except the management account.
4. On the **Details and activity** tab, view the **Service access report** section. The information includes a list of services that are allowed by the SCPs attached to the OU or account *and* all of its parents. The information shows you from which account the service was last accessed and when. For more details about which principal accessed the service, sign in as an administrator in that account and [view the IAM service last accessed information](#).
5. Choose the **Attached SCPs** tab to view the list of the service control policies (SCPs) that are attached directly to the OU or account. IAM shows you the number of target entities to which each policy is attached. You can use this information to decide which SCP to review.
6. Choose the name of an SCP to view all of the services that the policy allows. For each service, view from which account the service was last accessed, and when.
7. Choose **Edit in AWS Organizations** to view additional details and edit the SCP in the Organizations console. For more information, see [Updating an SCP](#) in the *AWS Organizations User Guide*.

To view information for the management account (console)

1. Sign in to the AWS Management Console using Organizations management account credentials, and open the IAM console at <https://console.aws.amazon.com/iam/>.
2. In the navigation pane below the **Access reports** section, choose **Organization activity**.
3. On the **Organization activity** page, expand the structure of your organization and choose the name your management account.
4. On the **Details and activity** tab, view the **Service access report** section. The information includes a list of all AWS services. The management account is not limited by SCPs. The information shows you whether the account last accessed the service and when. For more details about which principal accessed the service, sign in as an administrator in that account and [view the IAM service last accessed information](#).
5. Choose the **Attached SCPs** tab to confirm that there are no attached SCPs because the account is the management account.

To view information for a policy (console)

1. Sign in to the AWS Management Console using Organizations management account credentials, and open the IAM console at <https://console.aws.amazon.com/iam/>.
2. In the navigation pane below the **Access reports** section, choose **Service control policies (SCPs)**.
3. On the **Service control policies (SCPs)** page, view a list of the policies in your organization. You can view the number of target entities to which each policy is attached.
4. Choose the name of an SCP to view all of the services that the policy allows. For each service, view from which account the service was last accessed, and when.
5. Choose **Edit in AWS Organizations** to view additional details and edit the SCP in the Organizations console. For more information, see [Updating an SCP](#) in the *AWS Organizations User Guide*.

Viewing information for Organizations (AWS CLI)

You can use the AWS CLI to retrieve service last accessed information for your Organizations root, OU, account, or policy.

To view Organizations service last accessed information (AWS CLI)

1. Use your Organizations management account credentials with the required IAM and Organizations permissions, and confirm that SCPs are enabled for your root. For more information, see [Things to know about last accessed information](#).
2. Generate a report. The request must include the path of the Organizations entity (root, OU, or account) for which you want a report. You can optionally include an `organization-policy-id` parameter to view a report for a specific policy. The command returns a `job-id` that you can then use in the `get-organizations-access-report` command to monitor the job-status until the job is complete.
 - [aws iam generate-organizations-access-report](#)
3. Retrieve details about the report using the `job-id` parameter from the previous step.
 - [aws iam get-organizations-access-report](#)

This command returns a list of services that entity members can access. For each service, the command returns the date and time of an account member's last attempt and the entity path

of the account. It also returns the total number of services that are available to access and the number of services that were not accessed. If you specified the optional `organizations-policy-id` parameter, then the services that are available to access are those that are allowed by the specified policy.

Viewing information for Organizations (AWS API)

You can use the AWS API to retrieve service last accessed information for your Organizations root, OU, account, or policy.

To view Organizations service last accessed information (AWS API)

1. Use your Organizations management account credentials with the required IAM and Organizations permissions, and confirm that SCPs are enabled for your root. For more information, see [Things to know about last accessed information](#).
2. Generate a report. The request must include the path of the Organizations entity (root, OU, or account) for which you want a report. You can optionally include an `OrganizationsPolicyId` parameter to view a report for a specific policy. The operation returns a `JobId` that you can then use in the `GetOrganizationsAccessReport` operation to monitor the `JobStatus` until the job is complete.
 - [GenerateOrganizationsAccessReport](#)
3. Retrieve details about the report using the `JobId` parameter from the previous step.
 - [GetOrganizationsAccessReport](#)

This operation returns a list of services that entity members can access. For each service, the operation returns the date and time of an account member's last attempt and the entity path of the account. It also returns the total number of services that are available to access, and the number of services that were not accessed. If you specified the optional `OrganizationsPolicyId` parameter, then the services that are available to access are those that are allowed by the specified policy.

Example scenarios for using last accessed information

You can use last accessed information to make decisions about the permissions that you grant to your IAM entities or AWS Organizations entities. For more information, see [Refining permissions in AWS using last accessed information](#).

Note

Before you view the access information for an entity or policy in IAM or AWS Organizations, make sure that you understand the reporting period, reported entities, and the evaluated policy types for your data. For more details, see [the section called “Things to know about last accessed information”](#).

It's up to you as an administrator to balance the accessibility and least privilege that's appropriate for your company.

Using information to reduce permissions for an IAM group

You can use last accessed information to reduce IAM group permissions to include only those services that your users need. This method is an important step in [granting least privilege](#) at a service level.

For example, Paulo Santos is the administrator in charge of defining AWS user permissions for Example Corp. This company just started using AWS, and the software development team has not yet defined what AWS services they will use. Paulo wants to give the team permission to access only the services they need, but since that is not yet defined, he temporarily gives them power-user permissions. Then he uses last accessed information to reduce the group's permissions.

Paulo creates a managed policy named ExampleDevelopment using the following JSON text. He then attaches it to a group named Development and adds all of the developers to the group.

Note

Paulo's power users might need `iam:CreateServiceLinkedRole` permissions to use some services and features. He understands that adding this permission allows the users to create any service-linked role. He accepts this risk for his power users.

```
{
```

```
"Version": "2012-10-17",
"Statement": [
  {
    "Sid": "FullAccessToAllServicesExceptPeopleManagement",
    "Effect": "Allow",
    "NotAction": [
      "iam:*",
      "organizations:*"
    ],
    "Resource": "*"
  },
  {
    "Sid": "RequiredIamAndOrgsActions",
    "Effect": "Allow",
    "Action": [
      "iam:CreateServiceLinkedRole",
      "iam:ListRoles",
      "organizations:DescribeOrganization"
    ],
    "Resource": "*"
  }
]
```

Paulo decides to wait for 90 days before he [views the last accessed information](#) for the Development group using the AWS Management Console. He views the list of services that the group members accessed. He learns that the users accessed five services within the last week: AWS CloudTrail, Amazon CloudWatch Logs, Amazon EC2, AWS KMS, and Amazon S3. They accessed a few other services when they were first evaluating AWS, but not since then.

Paulo decides to reduce the policy permissions to include only those five services and the required IAM and Organizations actions. He edits ExampleDevelopment policy using the following JSON text.

Note

Paulo's power users might need `iam:CreateServiceLinkedRole` permissions to use some services and features. He understands that adding this permission allows the users to create any service-linked role. He accepts this risk for his power users.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "FullAccessToListedServices",
      "Effect": "Allow",
      "Action": [
        "s3:*",
        "kms:*",
        "cloudtrail:*",
        "logs:*",
        "ec2:*"
      ],
      "Resource": "*"
    },
    {
      "Sid": "RequiredIamAndOrgsActions",
      "Effect": "Allow",
      "Action": [
        "iam:CreateServiceLinkedRole",
        "iam:ListRoles",
        "organizations:DescribeOrganization"
      ],
      "Resource": "*"
    }
  ]
}
```

To further reduce permissions, Paulo can view the account's events in AWS CloudTrail **Event history**. There he can view detailed event information that he can use to reduce the policy's permissions to include only the actions and resources that the developers need. For more information, see [Viewing CloudTrail Events in the CloudTrail Console](#) in the *AWS CloudTrail User Guide*.

Using information to reduce permissions for an IAM user

You can use last accessed information to reduce the permissions for an individual IAM user.

For example, Martha Rivera is an IT administrator responsible for ensuring that people in her company do not have excess AWS permissions. As part of a periodic security check, she reviews the permissions of all IAM users. One of these users is an application developer named Nikhil Jayashankar, who previously filled the role of a security engineer. Because of the change in job

requirements, Nikhil is a member of both the `app-dev` group and the `security-team` group. The `app-dev` group for his new job grants permissions to multiple services including Amazon EC2, Amazon EBS, Auto Scaling, Amazon S3, Route 53, and Elastic Transcoder. The `security-team` group for his old job grants permissions to IAM and CloudTrail.

As an administrator, Martha signs into the IAM console and chooses **Users**, chooses the name `nikhilj`, and then chooses the **Access Advisor** tab.

Martha reviews the **Last Accessed** column and notices that Nikhil has not recently accessed IAM, CloudTrail, Route 53, Amazon Elastic Transcoder, and a number of other AWS services. Nikhil has accessed Amazon S3. Martha chooses **S3** from the list of services and learns that Nikhil has performed some S3 `List` actions in the last two weeks. Within her company, Martha confirms that Nikhil has no business need to access IAM and CloudTrail anymore because he is no longer a member of the internal security team.

Martha is now ready to act on the service and action last accessed information. However, unlike the group in the previous example, an IAM user like `nikhilj` might be subject to multiple policies and be a member of multiple groups. Martha must proceed with caution to avoid inadvertently disrupting access for `nikhilj` or other group members. In addition to learning what access Nikhil should have, she must determine *how* he is receiving these permissions.

Martha chooses the **Permissions** tab, where she views which policies are attached directly to `nikhilj` and those attached from a group. She expands each policy and views the policy summary to learn which policy allows access to the services that Nikhil is not using:

- IAM – The `IAMFullAccess` AWS managed policy is attached directly to `nikhilj` and attached to the `security-team` group.
- CloudTrail – The `AWSCloudTrailReadOnlyAccess` AWS managed policy is attached to the `security-team` group.
- Route 53 – The `App-Dev-Route53` customer managed policy is attached to the `app-dev` group.
- Elastic Transcoder – The `App-Dev-ElasticTranscoder` customer managed policy is attached to the `app-dev` group.

Martha decides to remove the `IAMFullAccess` AWS managed policy that is attached directly to `nikhilj`. She also removes Nikhil's membership to the `security-team` group. These two actions remove the unnecessary access to IAM and CloudTrail.

Nikhil's permissions to access to Route 53 and Elastic Transcoder are granted by the app-dev group. Although Nikhil isn't using those services, other members of the group might be. Martha reviews the last accessed information for the app-dev group and learns that several members recently accessed Route 53 and Amazon S3. But no group members have accessed Elastic Transcoder in the last year. She removes the App-Dev-ElasticTranscoder customer managed policy from the group.

Martha then reviews the last accessed information for the App-Dev-ElasticTranscoder customer managed policy. She learns that the policy is not attached to any other IAM identities. She investigates within her company to make sure that the policy will not be needed in the future, and then she deletes it.

Using information before deleting IAM resources

You can use last accessed information before you delete an IAM resource to make sure that a certain amount of time has passed since someone last used the resource. This applies to users, groups, roles, and policies. To learn more about these actions, see the following topics:

- **Users** – [Deleting a user](#)
- **Groups** – [Deleting a group](#)
- **Roles** – [Deleting a role](#)
- **Policies** – [Deleting a managed policy \(this also detaches the policy from identities\)](#)

Using information before editing IAM policies

You can review last accessed information for an IAM identity (user, group, or role), or for an IAM policy before editing a policy that affects that resource. This is important because you don't want to remove access for someone that is using it.

For example, Arnav Desai is a developer and AWS administrator for Example Corp. When his team started using AWS, they gave all developers power-user access that allowed them full access to all services except IAM and Organizations. As a first step towards [granting least privilege](#), Arnav wants to use the AWS CLI to review the managed policies in his account.

To do this, Arnav first lists the customer managed permissions policies in his account that are attached to an identity, using the following command:

```
aws iam list-policies --scope Local --only-attached --policy-usage-filter
PermissionsPolicy
```

From the response, he captures the ARN for each policy. Arnav then generates a report for last accessed information for each policy using the following command.

```
aws iam generate-service-last-accessed-details --arn arn:aws:iam::123456789012:policy/ExamplePolicy1
```

From that response, he captures the ID of the generated report from the JobId field. Arnav then polls the following command until the JobStatus field returns a value of COMPLETED or FAILED. If the job failed, he captures the error.

```
aws iam get-service-last-accessed-details --job-id 98a765b4-3cde-2101-2345-example678f9
```

When the job has a status of COMPLETED, Arnav parses the contents of the JSON-formatted ServicesLastAccessed array.

```
"ServicesLastAccessed": [  
  {  
    "TotalAuthenticatedEntities": 1,  
    "LastAuthenticated": 2018-11-01T21:24:33.222Z,  
    "ServiceNamespace": "dynamodb",  
    "LastAuthenticatedEntity": "arn:aws:iam::123456789012:user/IAMExampleUser",  
    "ServiceName": "Amazon DynamoDB"  
  },  
  {  
    "TotalAuthenticatedEntities": 0,  
    "ServiceNamespace": "ec2",  
    "ServiceName": "Amazon EC2"  
  },  
  {  
    "TotalAuthenticatedEntities": 3,  
    "LastAuthenticated": 2018-08-25T15:29:51.156Z,  
    "ServiceNamespace": "s3",  
    "LastAuthenticatedEntity": "arn:aws:iam::123456789012:role/IAMExampleRole",  
    "ServiceName": "Amazon S3"  
  }  
]
```

From this information, Arnav learns that the ExamplePolicy1 policy allows access to three services, Amazon DynamoDB, Amazon S3, and Amazon EC2. The IAM user named

IAMExampleUser last attempted to access DynamoDB on November 1, and someone used the IAMExampleRole role to attempt to access Amazon S3 on August 25. There are also two more entities that attempted to access Amazon S3 in the last year. However, nobody has attempted to access Amazon EC2 in the last year.

This means that Arnav can safely remove the Amazon EC2 actions from the policy. Arnav wants to review the current JSON document for the policy. First, he must determine the version number of the policy using the following command.

```
aws iam list-policy-versions --policy-arn arn:aws:iam::123456789012:policy/ExamplePolicy1
```

From the response, Arnav collects the current default version number from the Versions array. He then uses that version number (v2) to request the JSON policy document using the following command.

```
aws iam get-policy-version --policy-arn arn:aws:iam::123456789012:policy/ExamplePolicy1 --version-id v2
```

Arnav stores the JSON policy document returned in the Document field of the PolicyVersion array. Within the policy document, Arnav searches for actions with in the ec2 namespace. If there are no actions from other namespaces remaining in the policy, then he detaches the policy from the affected identities (users, groups, and roles). He then deletes the policy. In this case, the policy does include the Amazon DynamoDB and Amazon S3 services. So Arnav removes the Amazon EC2 actions from the document and saves his changes. He then uses the following command to update the policy using the new version of the document and to set that version as the default policy version.

```
aws iam create-policy-version --policy-arn arn:aws:iam::123456789012:policy/ExamplePolicy1 --policy-document file://UpdatedPolicy.json --set-as-default
```

The ExamplePolicy1 policy is now updated to remove access to the unnecessary Amazon EC2 service.

Other IAM scenarios

Information about when an IAM resource (user, group, role, or policy) last attempted to access a service can help you when you complete any of the following tasks:

- **Policies** – [Editing an existing customer-managed or inline policy to remove permissions](#)
- **Policies** – [Converting an inline policy to a managed policy and then deleting it](#)
- **Policies** – [Adding an explicit deny to an existing policy](#)
- **Policies** – [Detaching a managed policy from an identity \(user, group, or role\)](#)
- **Entities** – [Set a permissions boundary to control the maximum permissions that an entity \(user or role\) can have](#)
- **Groups** – [Removing users from a group](#)

Using information to refine permissions for an organizational unit

You can use last accessed information to refine the permissions for an organizational unit (OU) in AWS Organizations.

For example, John Stiles is an AWS Organizations administrator. He is responsible for ensuring that people in company AWS accounts do not have excess permissions. As part of a periodic security audit, he reviews the permissions of his organization. His Development OU contains accounts that are often used to test new AWS services. John decides to periodically review the report for services that have not been accessed in more than 180 days. He then removes permissions for the OU members to access those services.

John signs into the IAM console using his management account credentials. In the IAM console, he locates the Organizations data for the Development OU. He reviews the **Service access report** table and sees two AWS services that have not been accessed in more than his preferred period of 180 days. He remembers adding permissions for the development teams to access Amazon Lex and AWS Database Migration Service. John contacts the development teams and confirms that they no longer have a business need to test these services.

John is now ready to act on the last accessed information. He chooses **Edit in AWS Organizations** and is reminded that the SCP is attached to multiple entities. He chooses **Continue**. In AWS Organizations, he reviews the targets to learn to which Organizations entities that the SCP is attached. All of entities are within the Development OU.

John decides to deny access to the Amazon Lex and AWS Database Migration Service actions in the NewServiceTest SCP. This action removes the unnecessary access to the services.

IAM action last accessed information services and actions

The following table lists the AWS services for which [IAM action last accessed information](#) is displayed. For a list of actions in each service, see [Actions, resources, and condition keys for AWS services](#) in the Service Authorization Reference.

Service	Service prefix
AWS Identity and Access Management Access Analyzer	access-analyzer
AWS Account Management	account
AWS Certificate Manager	acm
